ISSN 2158-107X(Print)

# Editorial Preface

## *From the Desk of Managing Editor...*

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

**Thank you for Sharing Wisdom!**

# Editorial Board

## Editor-in-Chief

### **Dr. Kohei Arai - Saga University**

*Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation*

---

## Associate Editors

### **Alaa Sheta**

#### **Southern Connecticut State University**

*Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems*

### **Domenico Ciuonzo**

#### **University of Naples, Federico II, Italy**

*Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things*

### **Doroła Kaminska**

#### **Lodz University of Technology**

*Domain of Research: Artificial Intelligence, Virtual Reality*

### **Elena Scutelnicu**

#### **"Dunarea de Jos" University of Galati**

*Domain of Research: e-Learning, e-Learning Tools, Simulation*

### **In Soo Lee**

#### **Kyungpook National University**

*Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning*

### **Krassen Stefanov**

#### **Professor at Sofia University St. Kliment Ohridski**

*Domain of Research: e-Learning, Agents and Multi-agent Systems, Artificial Intelligence, e-Learning Tools, Educational Systems Design*

### **Renato De Leone**

#### **Università di Camerino**

*Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming*

### **Xiao-Zhi Gao**

#### **University of Eastern Finland**

*Domain of Research: Artificial Intelligence, Genetic Algorithms*

# CONTENTS

Paper 1: Performance Impact of Type-I Virtualization on a NewSQL Relational Database Management System

*Authors: J. Bryan Osborne*

PAGE 1 – 8

Paper 2: Knock Knock, Who's There: Facial Recognition using CNN-based Classifiers

*Authors: Qiyu Sun, Alexander Redej*

PAGE 9 – 16

Paper 3: Design of Smart IoT Device for Monitoring Short-term Exposure to Air Pollution Peaks

*Authors: Eric Nizeyimana, Jimmy Nsenga, Ryosuke Shibasaki, Damien Hanyurwimfura, JunSeok Hwang*

PAGE 17 – 24

Paper 4: Robust Facial Recognition System using One Shot Multispectral Filter Array Acquisition System

*Authors: M. Eléonore Elvire HOUSSOU, A. Tidjani SANDA MAHAMA, Pierre GOUTON, Guy DEGLA*

PAGE 25 – 33

Paper 5: Detecting Distributed Denial of Service in Network Traffic with Deep Learning

*Authors: Muhammad Rusyaidi, Sardar Jaf, Zunaidi Ibrahim*

PAGE 34 – 41

Paper 6: Proficient Networking Protocol for BPLC Network Built on Adaptive Multicast, PNP-BPLC

*Authors: Ali Md Liton, Zhi Ren, Dong Ren, Xin Su*

PAGE 42 – 48

Paper 7: Method for Improvement of Ocean Wind Speed Estimation Accuracy by Taking into Account the Relation between Wind Speed and Wind Direction

*Authors: Kohei Arai, Kenta Azuma*

PAGE 49 – 57

Paper 8: A Study of Security Impacts and Cryptographic Techniques in Cloud-based e-Learning Technologies

*Authors: Lavanya-Nehan Degambur, Sheeba Armoogum, Sameerchand Pudaruth*

PAGE 58 – 66

Paper 9: Various Antenna Structures Performance Analysis based Fuzzy Logic Functions

*Authors: Chafaa Hamrouni, Aarif Alutaybi, Slim Chaoui*

PAGE 67 – 71

Paper 10: Empirical Analysis Measuring the Performance of Multi-threading in Parallel Merge Sort

*Authors: Muhyidean Altarawneh, Umur Inan, Basima Elshqeirah*

PAGE 72 – 78

Paper 11: Special Negative Database (SNDB) for Protecting Privacy in Big Data

*Authors: Tamer Abdel Latif Ali, Mohamed Helmy Khafagy, Mohamed Hassan Farrag*

PAGE 79 – 91

Paper 12: Drug Sentiment Analysis using Machine Learning Classifiers

*Authors: Mohammed Nazim Uddin, Md. Ferdous Bin Hafiz, Sohrab Hossain, Shah Mohammad Mominul Islam*

PAGE 92 – 100

**Paper 13: Effective Malware Detection using Shapely Boosting Algorithm**

*Authors: Rajesh Kumar, Geetha S*

**PAGE 101 – 111**

**Paper 14: Using a Rule-based Model to Detect Arabic Fake News Propagation during Covid-19**

*Authors: Fatimah L. Alotaibi, Muna M. Alhammad*

**PAGE 112 – 119**

**Paper 15: Hybrid Deep Neural Network Model for Detection of Security Attacks in IoT Enabled Environment**

*Authors: Amit Sagu, Nasib Singh Gill, Preeti Gulia*

**PAGE 120 – 127**

**Paper 16: A Node Monitoring Agent based Handover Mechanism for Effective Communication in Cloud-Assisted MANETs in 5G**

*Authors: B.V.S Uma Prathyusha, K.Ramesh Babu*

**PAGE 128 – 136**

**Paper 17: Design of an Intelligent Hydroponics System to Identify Macronutrient Deficiencies in Chili**

*Authors: Deffa Rahadiyan, Sri Hartati, Wahyono, Andri Prima Nugroho*

**PAGE 137 – 145**

**Paper 18: Automatic Fake News Detection based on Deep Learning, FastText and News Title**

*Authors: Youssef Taher, Adelmoutalib Moussaoui, Fouad Moussaoui*

**PAGE 146 – 158**

**Paper 19: Determine the Level of Concentration of Students in Real Time from their Facial Expressions**

*Authors: Bouhlal Meriem, Habib Benlahmar, Mohamed Amine Naji, Elfilali Sanaa, Kaiss Wijdane*

**PAGE 159 – 166**

**Paper 20: Medical Image Cryptanalysis using Adaptive, Lightweight Neural Network based Algorithm for IoT based Secured Cloud Storage**

*Authors: M V Narayana, Ch Subba Lakshmi, Rishi Sayal*

**PAGE 167 – 173**

**Paper 21: Analysis of Logistics Service Quality and Customer Satisfaction during COVID-19 Pandemic in Saudi Arabia**

*Authors: Amjaad Bahamdain, Zahyah H. Alharbi, Muna M. Alhammad, Tahani Alqurashi*

**PAGE 174 – 180**

**Paper 22: Investigate the Ensemble Model by Intelligence Analysis to Improve the Accuracy of the Classification Data in the Diagnostic and Treatment Interventions for Prostate Cancer**

*Authors: Abdelrahman Elsharif Karrar*

**PAGE 181 – 188**

**Paper 23: Dynamic Deployment of Road Side Units for Reliable Connectivity in Internet of Vehicles**

*Authors: Abdulwahab Ali Almazroi, Muhammad Ahsan Qureshi*

**PAGE 189 – 194**

**Paper 24: Customer Satisfaction with Digital Wallet Services: An Analysis of Security Factors**

*Authors: Dewan Ahmed Muhtasim, Siok Yee Tan, Md Arif Hassan, Monirul Islam Pavel, Samiha Susmit*

**PAGE 195 – 206**

**Paper 25: Towards a Strategic IT GRC Framework for Healthcare Organizations**

*Authors: Fawaz Alharbi, Mohammed Nour A. Sabra, Nawaf Alharbe, Abdulrahman A. Almajed*

**PAGE 207 – 213**

**Paper 26: Ambulatory Monitoring of Maternal and Fetal using Deep Convolution Generative Adversarial Network for Smart Health Care IoT System**

*Authors: S. Venkatasubramanian*

**PAGE 214 – 222**

**Paper 27: Periapical Radiograph Texture Features for Osteoporosis Detection using Deep Convolutional Neural Network**

*Authors: Khasnur Hidjah, Agus Harjoko, Moh. Edi Wibowo, Rurie Ratna Shantiningasih*

**PAGE 223 – 232**

**Paper 28: Prediction of Diabetic Obese Patients using Fuzzy KNN Classifier based on Expectation Maximization, PCA and SMOTE Algorithms**

*Authors: Ibrahim Eldesouky Fattoh, Soha Safwat*

**PAGE 233 – 238**

**Paper 29: Evaluation Optimal Prediction Performance of MLMs on High-volatile Financial Market Data**

*Authors: Yao HongXing, Hafiz Muhammad Naveed, Muhammad Usman Answer, Bilal Ahmed Memon, Muhammad Akhtar*

**PAGE 239 – 246**

**Paper 30: Optimize and Secure Routing Protocol for Multi-hop Wireless Network**

*Authors: Salwa Othmen, Wahida Mansouri, Somia Asklany, Wided Ben Daoud*

**PAGE 247 – 253**

**Paper 31: A Machine Learning Approach to Weather Prediction in Wireless Sensor Networks**

*Authors: Suvarna S Patil, B.M.Vidyavathi*

**PAGE 254 – 259**

**Paper 32: Detecting Diabetic Retinopathy in Fundus Images using Combined Enhanced Green and Value Planes (CEGVP) with k-NN**

*Authors: Minal Hardas, Sumit Mathur, Anand Bhaskar*

**PAGE 260 – 268**

**Paper 33: A Novel Secure Transposition Cipher Technique using Arbitrary Zigzag Patterns**

*Authors: Basil Al-Kasasbeh*

**PAGE 269 – 276**

**Paper 34: Feature Concatenation based Multilayered Sparse Tensor for Debond Detection Optical Thermography**

*Authors: Junaid Ahmed, Abdul Baseer, Guiyun Tian, Gulsher Baloch, Ahmed Ali Shah*

**PAGE 277 – 282**

**Paper 35: Unmoderated Remote Usability Testing: An Approach during Covid-19 Pandemic**

*Authors: Ambar Relawati, Guntur Maulana Zamroni, Yanuar Primanda*

**PAGE 283 – 289**

**Paper 36: 4PCDT: A Quantifiable Parameter-based Framework for Academic Software Project Management**

*Authors: Vikas S. Chomal, Jatinderkumar R. Saini, Hema Gaikwad, Ketan Kotecha*

**PAGE 290 – 297**

**Paper 37: Neuromarketing Solutions based on EEG Signal Analysis using Machine Learning**

*Authors: Asad Ullah, Gulsher Baloch, Ahmed Ali, Abdul Baseer Buriro, Junaid Ahmed, Bilal Ahmed, Saba Akhtar*

**PAGE 298 – 304**

**Paper 38: Tomato Leaf Disease Detection using Deep Learning Techniques**

*Authors: Nagamani H S, Sarojadevi H*

**PAGE 305 – 311**

**Paper 39: Feature Selection Pipeline based on Hybrid Optimization Approach with Aggregated Medical Data**

*Authors: Palwinder Kaur, Rajesh Kumar Singh*

**PAGE 312 – 320**

**Paper 40: Educational Data Mining to Identify the Patterns of Use made by the University Professors of the Moodle Platform**

*Authors: Johan Calderon-Valenzuela, Keisi Payihuanca-Mamani, Norka Bedregal-Alpaca*

**PAGE 321 – 328**

**Paper 41: Assessing the Quality of Educational Websites in Sudan using Quality Model Criteria through an Electronic Tool**

*Authors: Asim Seedahmed Ali Osman*

**PAGE 329 – 334**

**Paper 42: Secure Inter-Domain Routing for Resisting Unknown Attacker in Internet-of-Things**

*Authors: Bhavana A, Nanda Kumar A N*

**PAGE 335 – 342**

**Paper 43: Snowball Framework for Web Service Composition in SOA Applications**

*Authors: Mohamed Elkholly, Youcef Bagdadi, Marwa Marzouk*

**PAGE 343 – 350**

**Paper 44: Selection of Requirement Elicitation Techniques: A Neural Network based Approach**

*Authors: Mohd Muqem, Sultan Ahmad, Jabeen Nazeer, Md. Faizan Farooqui, Afroj Alam*

**PAGE 351 – 359**

**Paper 45: The Performance of Personality-based Recommender System for Fashion with Demographic Data-based Personality Prediction**

*Authors: Iman Paryudi, Ahmad Ashari, Khabib Mustofa*

**PAGE 360 – 368**

**Paper 46: A Greedy-based Algorithm in Optimizing Student's Recommended Timetable Generator with Semester Planner**

*Authors: Khyrina Airin Fariza Abu Samah, Siti Qamalia Thusree, Ahmad Firdaus Ahmad Fadzil, Lala Septem Riza, Shafaf Ibrahim, Noraini Hasan*

**PAGE 369 – 375**

**Paper 47: Development of an Efficient Electricity Consumption Prediction Model using Machine Learning Techniques**

*Authors: Ghaidaa Hamad Alraddadi, Mohamed Tahar Ben Othman*

**PAGE 376 – 384**

**Paper 48: Critical Review of Technology-Enhanced Learning using Automatic Content Analysis**

*Authors: Amalia Rahmah, Harry B. Santoso, Zainal A. Hasibuan*

**PAGE 385 – 394**

**Paper 49: A Knowledge-based Expert System for Supporting Security in Software Engineering Projects**

*Authors: Ahmad Azzazi, Mohammad Shkoukani*

**PAGE 395 – 400**

**Paper 50: Performance Comparison between Lab-VIEW and MATLAB on Feature Matching-based Speech Recognition System**

*Authors: Edita Rosana Widasari, Barlian Henryranu Prasefio, Dian Eka Ratnawati*

**PAGE 401 – 407**

**Paper 51: A New Priority Rule for Initial Ordering of Jobs in Permutation Flowshop Scheduling Problems**

*Authors: B. Dhanasakkaravarthi, A. Krishnamoorthy*

**PAGE 408 – 415**

**Paper 52: Preserving Location Privacy in the IoT against Advanced Attacks using Deep Learning**

*Authors: Abdullah S. Alyousef, Karthik Srinivasan, Mohamad Shady Alrahal, Majdah Alshammari, Mousa Al-Akhras*

**PAGE 416 – 427**

**Paper 53: A Conceptual User Experience Evaluation Model on Online Systems**

*Authors: Norhanisha Yusof, Nor Laily Hashim, Azham Hussain*

**PAGE 428 – 438**

**Paper 54: Applying Artificial Intelligence in Retrieving Design Solution**

*Authors: Y. Moubachir, B. Hamri, S. Taibi*

**PAGE 439 – 444**

**Paper 55: State-of-the-Art Approach to e-Learning with Cutting Edge NLP Transformers: Implementing Text Summarization, Question and Distractor Generation, Question Answering**

*Authors: Spandan Patil, Lokshana Chavan, Janhvi Mukane, Deepali Vora, Vidya Chitre*

**PAGE 445 – 453**

**Paper 56: A Regression Model to Predict Key Performance Indicators in Higher Education Enrollments**

*Authors: Ashraf Abdelhadi, Suhaila Zainudin, Nor Samsiah Sani*

**PAGE 454 – 460**

**Paper 57: A Novel Stance based Sampling for Imbalanced Data**

*Authors: Isha Agarwal, Dipti Rana, Aemie Jariwala, Sahil Bondre*

**PAGE 461 – 467**

**Paper 58: Energy Efficient and Quality-of-Service Aware Routing using Underwater Wireless Sensor Networks**

*Authors: P. Sathya, P. Sengottuvelan*

**PAGE 468 – 474**

**Paper 59: The Trend of Segmentation for Arabic Handwritten Touching Characters**

*Authors: Ahmed Mansoor Mohsen Algaradi, Mohd Sanusi Azmi, Intan Ermahani A. Jalil, Abdulwahab Fuad Ayyash Hashim, Afrah Abdullah Muhammad Al-Malki*

**PAGE 475 – 479**

**Paper 60: What Influences Customer's Trust on Online Social Network Sites (SNSs) Sellers?**

*Authors: Ramona Ramli, Asmidar Abu Bakar, Fiza Abdul Rahim*

**PAGE 480 – 489**

**Paper 61: New Textual Authentication Method to Resistant Shoulder-Surfing Attack**

*Authors: Islam Abdalla Mohamed Abass, Loay F.Hussein, Tarak kallel, Anis Ben Aissa*

**PAGE 490 – 496**

**Paper 62: CovSeg-Unet: End-to-End Method-based Computer-Aided Decision Support System in Lung COVID-19 Detection on CT Images**

*Authors: Fatima Zahra EL BIACH, Imad IALA, Hicham LAANAYA, Khalid MINAOUI*

**PAGE 497 – 504**

**Paper 63: Elevint: A Cloud-based Internet of Elevators**

*Authors: Sarah Mohammed Aljadani, Shahd Mohammed Almutairi, Saja Saeed Ghaleb, Lama Al Khuzayem*

# Performance Impact of Type-I Virtualization on a NewSQL Relational Database Management System

J. Bryan Osborne

Computing & Mathematics  
Oral Roberts University, Tulsa, OK, USA

**Abstract**—For more than 40 years, the relational database management system (RDBMS) and the atomicity, consistency, isolation, durability (ACID) transaction guarantees provided through its use have been the standard for data storage. The advent of Big Data created a need for new storage approaches that led to NoSQL technologies, which rely on basic availability, soft-state, eventual consistency (BASE) transactions. Over the last decade, NewSQL RDBMS technology has emerged, providing the benefits of RDBMS ACID transaction guarantees and the performance and scalability of NoSQL databases. The reliance on virtualization in IT has continued to grow, but an investigation of current academic literature identified a void regarding the performance impact of virtualization of NewSQL databases. To help address the lack of research in this area, a quantitative experimental study was designed and carried out to answer the central research question, "What is the performance impact of Type-I virtualization on a NewSQL RDBMS?" VMware ESXi virtualization software, NuoDB RDBMS, and OLTP-Bench software were used to execute a mixed-load benchmark. Performance metrics were collected comparing bare metal and virtualized environments, and the data analyzed statistically to evaluate five hypotheses related to CPU utilization, memory utilization, disk and network input-output (I/O) rates, and database transactions per second. Findings indicated a negative performance impact on CPU and memory utilization, as well as network I/O rates. Performance improvements were noted in disk I/O rates and database transactions-per-second.

**Keywords**—Database benchmarking; NewSQL; relational database; virtualization

## I. INTRODUCTION

Drastically changing paradigms of data management and storage, Big Data continues to be a disruptive technology in the world of computing [1]. To provide acceptable performance, databases required new architectures and a built-from-scratch approach to overcome performance limitations inherent to traditional relational database management systems [RDBMSs; 2]. The newest of these databases are referred to as NewSQL and have been gaining traction with their ability to support massively large datasets, provide atomicity, consistency, isolation, durability (ACID) transaction guarantees, support for structured query language (SQL) queries, and do so with the performance provided by NoSQL solutions [3].

The use of virtualization in the modern era provides information technology (IT) management the ability to more efficiently manage resources through improved utilization rates and allows for greater flexibility of existing equipment and increased scalability of physical servers [4]. Pogarcic, Krnjak and Ozanic [5] demonstrated that virtualization could provide

decreased capital and operation costs for businesses in areas of actual and procurement costs for server hardware, utility, and administration costs. Virtualization technology provides the foundation for cloud computing, which continues to shape the world of modern IT [6]. Cloud computing providers regularly utilize virtualization's flexibility and scalability to maximize revenue and meet the increasing demands for their services [7]. Cloud computing relies heavily on virtualization to provide server and database services to customers [8].

NewSQL databases have demonstrated superiority in performance testing against NoSQL databases involving Internet of Things (IoT) applications [9] and as a solution for Big Data OLTP applications [10]. Performance comparisons of NewSQL offerings appear in the literature but are limited to comparisons of NewSQL databases against each other in bare metal [9, 11], virtualized [12], and cloud [13] environments. There is a lack of published research on the performance implications of the virtualization of NewSQL systems. The continued increase in the use of virtualization technology in data centers and the increase in the implementation of NewSQL database systems in cloud computing indicated a need for this research effort.

The strong presence of virtualization as a technology in IT services including the cloud [4], the continued growth in the use of NewSQL databases [3], and the simultaneous use of both, presented a need to understand the impact of one on the other. A review of extant literature indicated a void with respect to the examination and quantification of the impact of virtualization on NewSQL RDBMS. Therefore, the research effort posed a central question of "What is the performance impact of Type-I virtualization on a NewSQL RDBMS?" NewSQL databases are relational by nature and therefore the measures related to RDBMS are relevant, as is the impact of virtualization on relevant system metrics. The use of throughput of RDBMS software, measured by transactions-per-second (TPS) as suggested by Bitton, et al. [14], remains a prevalent and accepted metric for performance along with the use of benchmarking software to perform testing [15]. Therefore, performance measures of system CPU, memory, disk and network I/O, and NewSQL database throughput were utilized as the dependent variables in this research. The impact on these dependent variables due to changes in the independent variable, stated as the condition of the system being bare metal or Type-I virtualized, led to the central question being operationalized into five null (and corresponding alternative) hypotheses, one for each of the five performance measures to be tested. The research quantified the level of impact virtualization caused to a system running a NewSQL database

via an experimental design constructed to measure and analyze variables relevant to system performance in both bare metal and virtualized environments. The investigation contributes to the body of knowledge by filling a void in the academic literature regarding the performance impact of virtualization of NewSQL databases. Further, it provides information relevant to potentially needed modifications to a system to more efficiently host a NewSQL RDBMS.

The rest of the paper is organized as follows. Section II briefly discusses virtualization, NewSQL database management systems, and research relevant to the project. Section III describes the experimental methodology, hardware and software configuration, benchmarking software used in the test environment and statistical methods utilized. Section IV contains the results of the statistical analysis of the data collected and a discussion of the results of the analysis. Finally, Section V presents conclusions reached.

## II. BACKGROUND AND RELATED WORK

### A. Virtualization

Type I hypervisors interface directly with the computer's underlying hardware on which they run and map the physical resources of a computer to the VM being hosted, as shown in Fig. 1. This architectural approach has led to these types of hypervisors being referred to as native [16] or bare metal [17] hypervisors as they execute directly on the host computer and serve as a link between the virtual machines and the host computer.

The goal of virtualization is to use a layer of software to abstract the specific hardware of a computing machine from operating systems executing on the machine [18]. Thus, virtualization creates both an abstraction and encapsulation of the various components of the underlying hardware [19], and it is the role of the hypervisor to provide this abstraction as well as provide the virtual machine's integrity and isolation from other VMs on the same hardware [20]. Three major virtualization approaches, full virtualization, paravirtualization, and hardware-assisted virtualization, have been used to overcome the shortcomings of the x86 architecture [20].

The impact of virtualization caused by the insertion of a layer of processing between the guest OS and hardware has been demonstrated by extant research. In a review of 112 publications produced prior to 2016, Kao [21] found that the majority of evaluations of virtualized environments utilized benchmarks to measure performance. The specific benchmarks used by studies reviewed as part of this literature review mirrored those found by Kao [21] and reflected the emphasis found in the literature on using measurements of CPU, memory, disk, and network utilization as a basis for performance analysis. While it can be argued that differences exist between benchmarks and real-world workloads [22], benchmarking has a long history and provides for the gathering of metrics using a well-defined, universally accepted set of tests that can be compared across applications, operating systems, and hardware platforms [15]. Based on the review of all articles, the research focused on these metrics to assist in the evaluation of the impact of virtualization on NewSQL databases.

Fig. 1. Comparison of Non-virtualized and Type-1 Virtualized Systems.

### B. NewSQL

The term "NewSQL" is generally attributed to a report issued by the 451 Group analysts Matthew Aslett, who is referring to what was at the time new vendor offerings of databases that supported SQL, ACID transactions, and the high performance and scalability of NoSQL databases [23]. A short time later, in a blog post on Communications of the ACM website, Michael Stonebraker argued that instead of continuing the "gold standard in enterprise computing" of multiple relational databases connected by extract-load-transform (ETL) processes, NewSQL database systems, with the characteristics listed above, address consistency issues and preserve SQL language capabilities [24]. In a blog posting, Stonebraker outlined five specific characteristics of NewSQL as having ACID transactional ability, concurrency control that was non-locking, high performance, possessed a distributed, horizontally scalable, shared-nothing architecture, and SQL as application language. Although these characteristics were not presented in the format of an academic paper, the qualifications listed are present in academic works discussing NewSQL systems [2, 10, 12, 25-27].

NewSQL systems can be categorized into three types, novel systems built from scratch utilizing a new architecture, middleware approaches, and Database-as-a-Service (DBaaS) offerings [2]. The research in this paper focuses on an example of the first category, which includes the characteristics outlined by Stonebraker [24] for NewSQL systems and is created through the writing of completely new code, thereby being free from architectural choices of existing systems [28]. The development of the system as a new application provides the ability to manage best the disk and memory storage, replication approaches, query optimization, and node communication, allowing better performance than systems built through the layering of existing technologies [2].

Research by Hrubaru and Fotache [29] evaluated the performance of RDBMS and NewSQL using the TPC-H benchmark, capturing and analyzing loading and query times, which are essentially throughput measures, as well as the amount of memory used by the DBMSs. Not surprisingly, the in-memory NewSQL instance used more memory than the two RDBMS but performed better in most cases in terms of loading and query times. Similarly, Oliveira and Bernardino [11] compared two NewSQL RDBMSs using TPC-H, comparing loading and query execution times, but an evaluation of memory utilization was not performed. In both of these

articles, as with Fatima and Wasnik [9], the experimental setup only used a single server to perform tests. Two studies involving performance measures of virtualized NewSQL environments were identified. Both focused on comparing RDBMS performances when running in virtual machines, but no evaluation was made comparing bare metal and virtual environments. Kaur and Sachdeva [12] compared throughput performance measures of four popular NewSQL databases but did not specify the exact tests performed, only providing latency times captured for read, write, and update operations and total execution time. Tests were performed using a single instance RDBMS running in a single Type II hypervisor. While relative performance measures provide some helpful information, it is limited due to the use of single-instance NewSQL servers and a Type II hypervisor, neither of which would be common in a larger scale production system. Borisenko and Badalyan [30] utilized a Type I hypervisor with individual cluster nodes running in separate VMs to evaluate two NewSQL RDBMSs. One of the NewSQL RDBMSs evaluated, Apache Ignite [31], would be considered by the definitions provided by Pavlo and Aslett [2] as a middleware approach. The other, VoltDB [32], is a new architecture, thereby providing a performance comparison between the two approaches. The workload utilized was described as "TPC-H like," and metrics gathered and analyzed consisted only of query execution times [30]. Although both investigations utilized virtualized environments, Borisenko and Badalyan [30] and Kaur and Sachdeva [12] treated the performance testing as if performed on bare metal and did not provide any insights into the performance impact of virtualization.

Given the relevance of cloud computing today and the importance of virtualization to cloud computing, the implementation of NewSQL databases in the cloud is very probable [25]. Previous research has identified comparative performance studies of NewSQL databases, but none that reflected the impact of Type-I virtualization on NewSQL databases. Further, the studies examined reflected the use of single-node systems, not reflecting the true distributed nature of NewSQL databases [2, 27, 28]. This paper fills the gap in the literature by providing a quantification of performance impacts to distributed NewSQL systems due to Type-I virtualization.

### III. METHODOLOGY

The quantitative experimental research embodied in this study provides insight into the impact of Type-I virtualization on a NewSQL database, as well as a foundation for further exploration of potential mechanisms to best leverage virtualization in this new and important realm of computing. The research quantified the level of impact virtualization causes to a system running a NewSQL database via an experimental design constructed to measure and analyze variables relevant to system performance in both bare metal and virtualized environments. The central research question, "What is the performance impact of Type-I virtualization on NewSQL relational databases?" operationalized into five null hypotheses, each stating there was no difference in recorded values of the respective dependent variables during database benchmarking for a system hosting a NewSQL database

instance when comparing bare metal and Type-I virtualized environments.

The configuration of the system, bare metal or virtualized, reflects the independent variable in the experimental design. Metrics of CPU and memory utilization, disk and network I/O measurements, and the number of transactions-per-second executed by the databases represent dependent variables. These values were captured and recorded during benchmark tests executed on bare metal and virtualized systems built on identical servers. The values captured were then analyzed to quantify differences in performance between bare metal and virtualized systems.

The computer hardware used consisted of a Hewlett Packard Enterprise (HPE) Apollo r2600 chassis with 3 HPE dual-processor nodes. Each processor node was comprised of two Intel Xeon Broadwell E5-2698v4 2.4GHz CPUs, each with 14 cores and 50MB cache, 128GB of DDR4-2400 memory, and a single 480MB SATA solid-state drive (SSD). Internode communications are performed through 1 GbE Ethernet ports connected via an Omnipath 100Gb port. The computing nodes resided on an isolated network, ensuring only intended access to the machines.

The software configuration of each node varied based upon its functionality in the test. Each node ran the same operating system, CentOS 7.7.1908, an open source version of the Red Hat Enterprise Linux operating system [33]. Two of the three hardware nodes were designated as database cluster nodes using the recommended CentOS infrastructure server template, NuoDB NewSQL RDBMS, and performance metric collection software. The third node, configured to execute benchmark and load generation software, was configured as a developer's workstation to allow for the compiling of software with the GNU compiler.

In a recent study by Almassabi, Bawazeer [27], 13 of the top NewSQL databases were identified. From this group, NuoDB CE 4.0.4.2 [34] was selected for the current research effort as it meets the requirements defined by Stonebraker [24]. NuoDB is a distributed, peer-to-peer, ACID-compliant, elastic, and highly scalable relational database management system that falls into the "new architecture" class, elastic and highly scalable [35], and offers a fully functional, community edition version available at no cost.

NuoDB is designed to operate in bare metal, virtualized, and cloud environments [36]. The database management system has a two-tier, distributed architecture separating transactional and storage tiers. The transactional tier is an in-memory tier responsible for atomicity, consistency, and isolation aspects of the ACID transactional model and is designed to ensure fast access to data by applications. The storage management tier is responsible for the durability aspect, ensuring data is safely stored when committed, and providing data in case of a cache miss. Although all nodes are peers in a cluster, NuoDB nodes execute as either a Transaction Engine (TE) or a Storage Manager (SM). SMs maintain complete, consistent, independent copies of the entire database. TEs cache database tables in memory, accept database requests and execute SQL queries. For purposes of

this research, one of the two nodes functioned as an SM and the other database node as a TE. Installation of the NuoDB software was performed per the manufacturer's instructions [37]. Also installed on each of the database nodes was the performance metric gathering tool, "nmon" [38], a software tool written in the C programming language, demonstrated to be effective in capturing metrics in performance testing research [39, 40]. The nmon application captured data on database nodes for CPU utilization measured as a percent of total available, total system memory utilization measured in MB allocated, disk I/O measured in KB/s, and network I/O measured in KB/s, each of which represents a dependent variable in the experiment.

The third node ran the load-generating, benchmarking software, OLTP-Bench [41]. OLTP-Bench is an open-source, extensible, flexible benchmarking testbed capable of executing a number of existing benchmarks on both on-premise and cloud databases [42]. The Java source code for the OLTP-Bench software is open-source and available on GitHub and was downloaded and compiled for the CentOS platform on the benchmark node. The software was utilized to exercise the NewSQL database and system and provided the transactions-per-second measurement, a dependent variable, for all tests. Due to the different nature of online transaction processing (OLTP) and online analytical processing (OLAP), separate databases with different designs have typically been implemented [43]. A growing need for real-time analytics has generated a change in this paradigm, and new databases, like NewSQL, have been developed to provide support for these needs [44]. Subsequently, benchmarking tests to evaluate the performance of databases designed to handle mixed workloads are needed [45].

One such benchmark, currently supported by OLTP-Bench, is CH-benCHmark [46]. CH-benCHmark is a hybrid/mixed-workload benchmark designed to execute TPC-C (OLTP) and TPC-H-equivalent (OLAP) queries concurrently against a common set of database tables. The entities and relationships of the TPC-C model are implemented without modification, and only a slight modification to the TPC-H schema is made to ensure the integration into the TPC-C schema is non-intrusive. Previous work by Oliveira and Bernardino [11] and Hrubaru and Fotache [29] revealed issues running all 22 of the TPC-H queries against new architecture NewSQL databases due to lack of support for the SQL HAVING clause, view creation capabilities, and excessively long-running query conditions. Initial tests performed as part of this research revealed similar incompatibility issues as well as hang-ups in benchmark execution with the CH-benCHmark TPC-H comparable queries. The subset consisting of seven of the CH-benCHmark TPC-H comparable queries, which ran without issue, was placed in the OLTP-Bench configuration file to be used for testing.

Based on the assumption that a One-Way ANOVA would be utilized for statistical analysis, a sample size based upon a power analysis using the G\*Power application [47] indicated a need for 21 bare metal and 21 virtualized runs of the benchmark test against the NewSQL databases. The first set of tests in the experiment in this research effort was the execution of the CH-benCHmark using the OLTP-Bench testbed against

the NuoDB database in a bare metal environment. The creation and loading of the test databases were performed in separate, sequential steps from the execution of the benchmark test to delineate the response of the system under test to these operations, as part of an effort to ensure "cold" runs of the benchmark workload [48]. The stopping and restarting of the database after loading causes a flushing of the database server buffer pool, eliminating data caching between runs and enhancing consistency in values of performance metrics. Preliminary benchmark runs revealed that system performance metrics stayed in a consistent range in benchmark runs lasting as long as one hour. It was also determined that the entire set of TPC-H like queries was completed in approximately five minutes, even in the presence of concurrent OLTP transactions. Therefore, benchmark runs of fifteen minutes were used for data collection runs to allow three sets of the TPC-H queries.

Once all experiments had been run under bare metal conditions, the "treatment" (virtualization software) was installed on the same hardware used for the first set of experiments. VMware 6.5 [49] served as the virtualization software utilized in the experiment. VMware is a major player in the virtualization space, garnering an 80.7 % share of the 2017 virtualization market [50]. A single virtual machine closely matching the specifications of the physical machine on which it resides was created on the nodes of the database cluster. Each database node used a thin-provisioned, 400GB disk configured using a SCSI-controller in dependent mode and located in a VMware datastore. The VMware Paravirtual SCSI controller was used following Dakic [51], Goldsand and Brown [52], and VMware [53]. The VMware VM Network was configured with the physical NIC connected to a vSwitch, which was connected to the virtual machine.

Each virtual machine was installed with the identical software configuration, i.e., operating system, NewSQL database, and performance metric gathering software, as was installed on the machine in its bare metal state. The same type and number of benchmark runs were performed, and performance data was collected. Once data collection was completed under virtualized conditions, the two sets of data required for the independent variable, bare metal versus virtualized environment, were made available for analysis.

#### IV. RESULTS AND DISCUSSION

Care was taken to ensure the appropriate statistical approach was taken in the comparison of data collected in bare metal and virtualized environments. Using SPSS, an evaluation to determine the normality of the individual datasets was completed via a Shapiro Wilk test, followed by either an ANOVA or Kruskal-Wallis H (K-W) test depending on whether a parametric or non-parametric test was needed to determine statistical significance. A summary of the inferential statistical tests and changes due to virtualization is provided in Table I, and a detailed description of the statistical results follows.

The results of the ANOVA analyzing CPU utilization for the SM node indicated that the difference in the means was statistically significant,  $F(1,40)=3083.879$ ,  $p<0.001$ , and the null hypothesis was rejected. The rejection of the null hypothesis led to the acceptance of the alternative hypothesis

that there was a difference in CPU use when virtualization is implemented. A comparison of the mean values of CPU utilization between bare metal (M=1.492, SD=0.052) and virtualized (M=2.26, SD=0.057) environments for the SM node indicated an increase of 62.5%. In the case of the TE node, the ANOVA also demonstrated that the difference in the means is statistically significant,  $F(1,40)=5027.822$ ,  $p<0.001$ , and the null hypothesis can be rejected. A comparison of the mean values of CPU utilization between bare metal (M=2.684, SD=0.049) and virtualized environments (M=4.546, SD=0.110) indicated an increase of 69.4 %.

TABLE I. RESULTS

Perf Measure	SM Virtualized vs. Bare Metal			TE Virtualized vs. Bare Metal		
	Test	p-value	Chg	Test	p-value	Chg
CPU Util	ANOVA	$p < 0.001$	62.5%	ANOVA	$p < 0.001$	69.4%
Memory Util	ANOVA	$p < 0.001$	1.4%	K-W	$p < 0.001$	2.7%
Disk I/O	K-W	$p < 0.001$	37.3%	K-W	$p < 0.001$	N/A
Network I/O	ANOVA	$p < 0.001$	-12.4%	ANOVA	$p < 0.001$	-8.6%
TPS	ANOVA	$p < 0.001$	66.1%			

The SE experienced a 62.5% increase, and the TE, a 69.4% increase in CPU utilization with the additional layer of virtualization software in place. The amount of overhead caused by virtualization can vary based on the VM's workload capable of running directly on a physical processor and the amount requiring virtualization [54]. Tudor [55] found increases in CPU utilization ranging from 38% to 45% with open source RDBMS, attributing the increase to increased I/O wait times. The current research found increases occurring in user and system CPU utilization. A comparison of bare metal and virtualized NoSQL environments found that CPU utilization increased by roughly 29% under mixed (read/write) loads [56]. In experiments using CPU-intensive benchmark applications, Pousa and Rufino [57] found decreases in CPU efficiency due to the existence of an ESXi 6.0 virtualization layer in areas of process creation, disk to RAM transfers, context switching, and system call overhead. The current research indicates that the impact of virtualization on CPU utilization on the NewSQL RDBMS was greater than levels found in open source RDBMSs and NoSQL database testing in the studies referenced. The increased CPU utilization should be strongly considered in the migration or implementation of NewSQL on virtualized systems.

The results of the ANOVA for memory utilization for the SM node indicated that the difference in the means was statistically significant,  $F(1,40)=25.746$ ,  $p<0.001$ , leading to the acceptance of the alternative hypothesis that there was a difference in memory use when virtualization is implemented. A comparison of the mean values of memory utilization between bare metal (M=4702.894, SD=56.362) and virtualized (M=4766.631, SD=11.696) environments indicated only a

slight increase of 1.4% in the SM node. In the case of the TE node, the assumptions necessary to use ANOVA were not met, and a Kruskal Wallis H test was used. The results of the Kruskal Wallis H indicated that the difference in the means was statistically significant,  $\chi^2(1)=23.694$ ,  $p<0.001$ , and the null hypothesis could be rejected. A comparison of the mean values of memory utilization between bare metal (M=3163.598, SD=37.606) and virtualized (M=3249.873, SD=38.754) environments indicated an increase of 2.7% in the TE node.

Concerning memory utilization, the difference between the two environments, bare metal and virtualized, indicated an increase in memory utilization in the virtualized environment of 1.4% for the SM and 2.7% for the TE. The additional overhead is present and can be attributed to the addition of the virtualization layer, but given the low percentage increases, adjustments in memory size are not warranted.

In the analysis of disk I/O, the assumptions to use an ANOVA were not met in either the case of the SM or the TE, so a Kruskal Wallis H test was used. The results of the Kruskal Wallis H indicated that the means for the SM node were significantly different,  $\chi^2(1)=30.767$ ,  $p<0.001$ , and the null hypothesis was rejected. A comparison of the mean values of disk I/O utilization between bare metal (M=3574.681, SD=358.112) and virtualized (M=4907.644, SD=60.220) environments for the SM indicated an increase of 37.3%. In the case of the TE node, the Kruskal Wallis H test yielded  $\chi^2(1)=1.339$ ,  $p=0.247$ . The data failed to provide the evidence needed to reject the null hypothesis, and it was therefore retained as  $p>0.05$ .

A statistically significant difference in the disk I/O measurement was reflected in increased disk I/O in the virtualized SM node. Using system benchmark performance tools, Pousa and Rufino [57] found disk performance under ESXi virtualized conditions to be very similar to bare metal. Shirinbab, Lundberg [56] found disk I/O write rates to be the same or higher with virtualized NoSQL databases. Tudor [55] found that disk I/O was higher in virtualized open source RDBMS through the collection of values of OS disk I/O as percentages. The faster data can be moved from disk to RAM, the greater availability of data for the RDBMS. The disk-intensive nature of RDBMSs depends on I/O bandwidth to function properly [58]. Lee and Fox [59] suggested that greater IOPS are good for database systems. The existence of statistical significance in datasets collected on the SM node allowed for the comparison of bare metal and virtualized NewSQL environments and a 37.3% increase in the disk I/O rate was observed in the virtualized environment. The increase in disk I/O can be attributed to the VMware Paravirtualized SCSI controller as noted by Dakic [51], although the increase in disk I/O in this research exceeded the 12% found in that research effort which used vSphere 6.0. Additional statistical analysis on data collected as part of the current research effort found that along with increased disk I/O rate as measured in KB/s, the virtualized SM node had increased I/O operations per second (IOPS). The virtualized SM IOPS (M=175.78, SD=2.12) exceeded bare metal SM IOPS (M=132.36, SD=10.88) by 32.8%, and the difference in the means of the two datasets was shown to be statistically significant via a

Kruskal Wallis H test,  $\chi^2(1)=30.767$ ,  $p<0.001$ . The data indicates an increase in disk I/O rate under virtualized conditions for the SM node, whose role is to manage and maintain complete, consistent, independent copies of the entire database. In a discussion with a VMware engineer, he stated that the improvements emphasize the importance of disk I/O drivers in the software and that VMware drivers will coalesce disk I/O reads and writes, but the proprietary nature of the software prevented extensive discussion (D. Robertson, personal communication, May 6, 2020). Given disk I/O is often a bottleneck for increased system performance, the increases found is positive. The disk I/O data collected on the TE would not allow the rejection of the null hypothesis that stated there was no effect due to virtualization. It is worth noting that given that the role of the TE is to cache database tables in memory, accept database requests and execute SQL queries, the values of disk I/O KB/s recorded were in the single digits, which would decrease the potential impact on the system overall.

The results of the ANOVA performed on data collected for network I/O measurements indicated the difference in the means were statistically significant both for the SM,  $F(1,40)=238.429$ ,  $p<0.001$ , and the TE,  $F(1,40)=113.81$ ,  $p<0.001$ , and the null hypothesis was rejected for both nodes. A comparison of the mean values of network I/O between bare metal ( $M=14270.151$ ,  $SD=396.245$ ) and virtualized ( $M=12502.987$ ,  $SD=343.571$ ) environments indicated a decrease of 12.4% for the SM node. The TE node saw a difference between bare metal ( $M=14491.517$ ,  $SD=404.175$ ) and virtualized ( $M=13243.229$ ,  $SD=352.401$ ) environments corresponding with a decrease of 8.6%.

Both the virtualization of CPU resources and virtualized network adaptors will increase the time to transmit data packets [54]. The components required in the processing of virtualized network I/O are virtual network drivers, known as the vNIC, the vSwitch, the VMkernel, and the physical NIC driver [60]. This results in virtualization overhead impacting three of the four networking-specific components involved. The benchmarking server remained in a bare metal state for all experiments to ensure that virtualization effects were confined to the database nodes. The SM and the TE experienced a decrease in the network I/O (KB/s) of 12.4% and 8.6%, respectively. The statistical analysis of the data collected allowed for the acceptance of the alternate hypothesis that the additional overhead imposed is due to the virtualization of the NewSQL RDBMS. Direct-path I/O was not supported by the NIC used in the systems tested, but if available, would provide a means to minimize these performance decreases.

The fifth and final hypothesis sought to provide focus on the transactional volume of the NewSQL database. Since the necessary assumptions were met, a One-Way ANOVA was performed on the datasets using SPSS. The results of the ANOVA indicated that there was a statistically significant difference in the means,  $F(1,40) = 683.821$ ,  $p < 0.001$ , indicating the null hypothesis could be rejected and the alternative hypothesis accepted. A comparison of the mean values of TPS between bare metal ( $M=16.474$ ,  $SD=1.189$ ) and virtualized ( $M=27.821$ ,  $SD=1.534$ ) environments indicated an increase of 66.1%.

A relevant, overall throughput metric for an RDBMS is the rate of database transactions, TPS. The TPS values, as reported by the benchmarking software, increased 66.1% in the virtualized environment as compared to bare metal. The improvement in TPS found in this research contradicts the results of Tudor [55], but it must be pointed out that the virtualization software was VMware ESXi 5.0 as compared to version 6.5 used in the current research. Essential to the performance of an RDBMS is the ability to quickly and efficiently read data from disk into memory when needed and to write new or updated data from memory to disk [61]. The 37.3% increase in the disk I/O and the ample CPU cycles present on the SM node provided an environment with increased processing potential. Such conditions could give the system an increased ability for transaction throughput, but additional research will be required for this to be definitively demonstrated.

## V. CONCLUSION

Virtualization continues to play an important role in the delivery of IT Services in on-premise data centers and via the cloud [4]. With the virtualizing of computing resources, organizations have been able to enhance and improve the management and utilization of IT resources. New architectural approaches found in NewSQL allow for the use of SQL and adherence to relational database standards, characteristics, and guarantees in the context of the immense volumes of data present in Big Data applications [2]. Just as the use of traditional relational databases and NoSQL technologies in virtualized environments occurred, the use of NewSQL in a virtualized environment is to be expected [25]. The absence of literature reflecting research to quantify the performance impact of virtualization on NewSQL RDBMS served as a motivation for this effort. The work presented allows for a better understanding and quantification of this impact of virtualization, providing benefits to organizations seeking to virtualize NewSQL servers, and represents an effort to fill the gap in the literature on this specific topic.

The evidence of the virtualization penalty in RDBMSs [55] and NoSQL database systems [56] is present in the literature. However, with the advent of NewSQL technology and continuous improvement in virtualization software, existing paradigms should be revisited. In this research, non-trivial virtualization penalties were identified in CPU utilization and network I/O, but memory utilization was only nominally impacted, and both disk I/O and TPS values were improved in the virtualized environment. The performance improvements would indicate that the new architecture NewSQL solutions may involve dynamics different than those present in traditional and NoSQL database solutions. The architecture of the Nuodb NewSQL RDBMS creates a dependency on disk I/O for the SM, but not the TE, which is memory-dependent. Given the virtualization goal of sharing underutilized hardware resources between virtual machines, existing paradigms must be reconsidered in light of ideas such as the complementary nature of the needs of the SM and TE, which might be amendable to separate VMs on the same physical machine. Additional research surrounding such synergies should be explored.

# Knock Knock, Who's There: Facial Recognition using CNN-based Classifiers

Qiyu Sun, Alexander Redei  
Department of Computer Science  
Central Michigan University  
Mount Pleasant, MI

**Abstract**—Artificial intelligence (AI) has captured the public's imagination. Performance gains in computing hardware, and the ubiquity of data have enabled new innovations in the field. In 2014, Facebook's DeepFace AI took the facial recognition industry by storm with its splendid performance on image recognition. While newer models exist, DeepFace was the first to achieve near-human level performance. To better understand how this breakthrough performance was achieved, we developed our own facial image detection models. In this paper, we developed and evaluated six Convolutional Neural Net (CNN) models inspired by the DeepFace architecture to explore facial feature identification. This research made use of the You Tube Faces (YTF) dataset which included 621,126 images consisting of 1,595 identities. Three models leveraged pretrained layers from VGG16 and InceptionResNetV2, whereas the other three did not. Our best model achieved a 84.6% accuracy on the test dataset.

**Keywords**—Face recognition; deep learning; convolutional neural networks; DeepFace

## I. INTRODUCTION

Facial recognition is a method of identifying an individual using his or her face from a digital image or a video clip. Such methods could be used for facial authentication by pinpointing and determining facial features from a given image, uniquely identifying the person. Initially this was limited to desktop computers due to demanding computational power constraints. Recently however it has seen wider usage, such as on mobile devices, robotics, finding missing people, and diagnosing diseases. Facial recognition is also applied in diagnosing diseases. 22q11.2 deletion syndrome (22q11.2 DS) is the most common micro-deletion syndrome and was underdiagnosed in a variety of populations in the past. Because the disease results in multiple defects throughout the body, including cleft palate, heart defects, a characteristic facial appearance, and learning problems, healthcare providers often can't pinpoint the disease, especially in diverse populations. After analyzing the disease with facial analysis technology, researchers found that sensitivity and specificity were greater than 96% for all populations, which demonstrated how facial analysis technology can assist clinicians in making accurate 22q11.2 DS diagnoses [1]. Researchers with the National Human Genome Research Institute (NHGRI), part of the National Institutes of Health, and their collaborators, have successfully used facial recognition software to diagnose a rare, genetic disease in Africans, Asians, and Latin Americans [2].

Facial recognition technology has a wide range of applications and profound social and cultural impacts and has been introduced across various aspects of public life. For

example, facial recognition payment services are now possible. Nowadays, in China people can purchase food at the grocery store and can even complete their payment directly by scanning their face at a register without needing a credit card or mobile application [3]. In terms of the design and implementation of security systems, facial recognition technology also has a wide range of applications including web and mobile authentication [4], airport check-in [5], and smart medicine cabinets [6]. In the education industry, facial recognition has been applied to compulsory schooling to address issues such as campus security, automated registration, and student emotion detection and has largely been seen as routine additions to school systems with already extensive cultures of monitoring and surveillance [7]. While facially driven learning has been widely used, critical commentators are beginning to question the pedagogical limitations of it. They purposed multiple questions about facial recognition technology including the likelihood of it altering the nature of schools and schooling along divisive, authoritarian and oppressive lines, and what kind of law and regulatory mechanisms can help for eliminating the potential risks to consumers when they are making use of it [7]. Due to the relatively limited technology, the current ability to detect human faces in this field provides a buffer from coping with the potential consequences including a serious threat to online identities being misused by hackers for illegal activities.

An overview of the rest of the paper is as follows: in Section 2 we reviewed some of the related work in the same research field with DeepFace; in Section 3, we introduce core techniques related to DeepFace: Deep Learning and Convolutional Neural Networks; Section 4 describes the 3D model-based face alignment method applied and the model architecture used; Section 5 talks about our deep learning model that follows the architecture of DeepFace's and was trained on YouTube Faces (YTF) video data set. In Section 6 we present some quantitative results of our models and the last section is the conclusion.

## II. RELATED WORK

Biometric facial recognition, also known as automatic face recognition, is a particularly attractive method of biometric recognition because it focuses on "faces," the same identifiers that humans primarily use to distinguish people. One of its main goals is the understanding of the complex human visual system and the knowledge of how humans represent faces in order to discriminate different identities with high accuracy. Facial recognition consists of three basic processes: detection, capture, and face match. The detection process is to determine

if there is a target face in the source. The capture process transforms the targeted face into a set of digital data based on the facial features. The face match process verifies if the two faces are of the same person. This process is shown in Fig. 1 below.

Fig. 1. Facial Recognition Processing Flow.

A large number of approaches have emerged in the field of facial recognition, including a hand-crafted features based method [8] and a widely applied metric learning methods with task-specific objectives [9]. These approaches were never quite able to reach human-level performance in identifying faces. Although progress in facial recognition was encouraging, the task has also turned out to be a difficult endeavor.

#### A. DeepFace

DeepFace is a deep learning face recognition technology developed by a research group at Facebook. It identifies human faces in digital images with human-level performance. In DeepFace, researcher revisited both the alignment step and the representation step of the face recognition process and proposed a new approach of deriving a face representation by employing explicit 3D face modeling. It employed a nine-layer neural net with over 120 million connection weights and was trained on four million images uploaded by Facebook users [10] [11]. DeepFace demonstrates that a 3D model-based alignment method can effectively help in face recognition and closes the gap to human-level accuracy. Next Generation Identification (NGI) is another application developed by Federal Bureau of Intelligence (FBI) of the same year. According to one report the NGI's performance is non-satisfactory. It returns a ranked list of 50 possibilities and only promises an 85% chance of returning the suspect's name in the list [12]. The DeepFace system (stated by the Facebook Research team) reaches an accuracy of  $97.35 \pm 0.25\%$  on labeled faces in the wild (LFW) data set whereas human beings have 97.53% [13]. Google FaceNet later achieved a 99.65% accuracy on the same data set [14].

#### B. Local Binary Patterns (LBP)

Local binary patterns (LBP) is a type of visual descriptor used for classification in computer vision and it is the particular case of the Texture Spectrum model proposed in 1990 [15]. LBP was first described in 1994 [16] and it is a simple yet very efficient texture operator which labels the pixels of an image by thresholding the neighborhood of each pixel and considers the result as a binary number [17]. Using the LBP combined with histograms we can represent the face images with a simple data vector [18]. In the LBP approach for texture classification, the occurrences of the LBP codes in an image are collected into a

histogram. The classification is then performed by computing simple histogram similarities. However, considering a similar approach for facial image representation results in a loss of spatial information and therefore one should codify the texture information while retaining also their locations. One way to achieve this goal is to use the LBP texture descriptors to build several local descriptions of the face and combine them into a global description. The basic methodology for LBP based face description proposed by Ahonen et al. [19] is as follows: The facial image is divided into local regions and LBP texture descriptors are extracted from each region independently. The descriptors are then concatenated to form a global description of the face, as shown in Fig. 2.

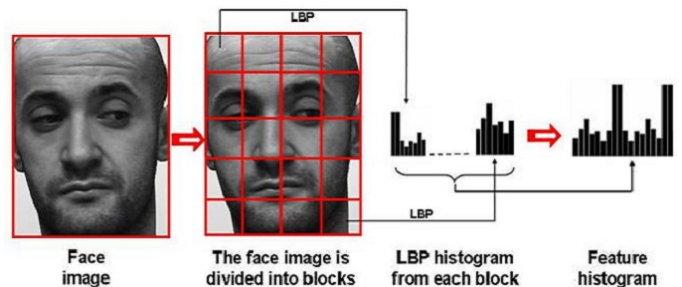

Fig. 2. Face Description with Local Binary Patterns.

#### C. DeepID-Net

A pre-trained model is a model that was trained on a large benchmark dataset to solve a problem similar to the one that we want to solve. As for most image detection problems, the main features of the objects to be detected are often similar, so a pre-trained model can be leveraged to typically get improved performance. But researchers found a gap between the pre-training task and the fine-tuning task that makes pre-training less effective [20]. Inspired by the need to adopt more targeted optimization solutions for specific objects, researchers propose the DeepID-Net model. DeepID-Net is an image detection model developed by the Multimedia Laboratory of the Chinese University of Hong Kong. Its full name is DeepID-Net: Deformable Deep Convolutional Neural Networks for Object Detection [20]. They added more steps on the region-based convolutional neural networks on the region-based convolutional neural networks (R-CNN) processing, including bounding box rejection, deep model training, def pooling layer, SVM-net(replace softmax with hinge loss to accelerate learning), multi-stage training, etc, as shown in Fig. 3. The model yields a 99.8% accuracy, while the state-of-the-art method achieves a 97% accuracy when testing multi-view facial images [20]. This paper was published on CVPR2014. After that, the team focused on applying the model to the specific application of facial recognition, and correspondingly made some changes and optimizations to the DeepID model. The updated two versions of the model are called DeepID2 and DeepID3.

#### D. FaceNet

FaceNet is a universal system that can be used for face verification (is it the same person?), recognition (who is this person?) and clustering (looking for similar people?) [22]. The

Fig. 3. Overview of DeepID-Net Process (Texts in Red Highlight the Steps that are Not Present in RCNN.) [21]

method adopted by FaceNet is to map images into Euclidean space through a convolutional neural network. Different from the application of other deep learning methods on human faces, FaceNet did not use the traditional softmax method to classify and learn, and then extract a certain layer as a feature. It directly used triplets-based LMNN (Maximum Boundary Neighbor Classification) loss function to train the neural network, and the network directly outputs a 128-dimensional vector space [22]. FaceNet has achieved an accuracy of  $99.63 \pm 0.09\%$  on the LFW dataset and an accuracy of  $95.12 \pm 0.39\%$  on the YTF dataset [22]. The advantage of this model is that the target image can be used with very little processing. It also provides future research directions, such as analyzing wrong samples to improve accuracy, reducing model size to speed up training, etc.

### III. METHODOLOGY

Deep learning is a specific subfield of machine learning [23]. It represents learning process from data, emphasizing on learning successive "layers" of increasingly meaningful representations. The word "deep" in "deep learning" is not referring to deeper understanding achieved through the approach but stands for the idea of successive layers of representations. The number of layers that contribute to the model is called the depth of the model. These layered representations are learned through models called neural networks and they are structured in layers stacked one after the other. Deep learning is technically a mathematical framework for learning representations from data with a multi-stage way. A large deep network has multiple layers with many more nodes in each layer, which leads to many more parameters to tune. It would be too slow and insufficient to train a deep learning model without a large dataset and powerful computers. Compared to the traditional learning algorithms (Regression, Random Forest, Support Vector Machine, etc.), deep learning may not necessarily outperforms when given data of small scale. But once the data scale goes up exponentially, deep learning outperforms others because more parameters provide the capability to learn complicated nonlinear patterns [24]. Generally, we expect the model to capture the most helpful features by itself without too much expert-involved manual intervening on features learning.

Machine learning is about mapping inputs to target outputs. The specification of what each layer does to their input data is stored in a bunch of parameters called "weight". The learning process refers to finding a set of values of the weights of all layers in a network so that the network will correctly map

inputs to their associated targets. But here comes the issue: to find the correct value for all of the weights can be a daunting task, especially when modifying the value of one parameter will affect the performance of the whole model. To control the output of a neural network, the loss function plays an important role in making the prediction of the network and the target. It computes a distance score measuring how well the network performs. The job of the "optimizer" is to use this score as a feedback signal to adjust the value of the weights, successively trying to lower the loss score. Implementing "back-propagation" is the central algorithm used for this in deep learning architectures. In recent years, deep learning has achieved a revolution with tremendous achievements on many types of difficult problems, especially perceptual problems, which have long been historically difficult for machine learning.

Convolutional neural networks are a type of feed-forward artificial neural networks, most commonly applied to analyzing visual imagery [25]. They are also known as shift invariant or space invariant artificial neural networks (SIANN), based on their shared-weights architecture and translation invariance characteristics [26] [27]. They have applications in image classification, Image segmentation, character recognition [28], medical image analysis [29], natural language processing [30].

A convolutional neural network consists of an input layer, multiple hidden layers and an output layer. In any feed-forward neural network, all middle layers are called hidden layers due to their inputs and outputs are sealed by the activation function and final convolution [31]. Convolution refers to a mathematical operation between two matrices, it is defined as the integral of the product of the two functions after one is reversed and shifted. It then evaluates the integral over all values of the shift to produce a convolutional function. Convolutional networks are a specialized type of neural networks that use convolution in place of general matrix multiplication in at least one of their layers [32]. The convolutional layer has a defined fixed small matrix, also called a kernel or filter. It computes the element-wise multiplication of the values in the kernel matrix and the original image values as the kernel is sliding, or convolving, across the matrix representation of the input image as shown in Fig. 4. Specially designed kernels can fast and efficiently process images for common purposes like edge detection and many others. Convolutional and pooling layers respond to feature extraction. The fundamental difference between a densely connected layer and a convolution layer is that dense layers learn global patterns in their input feature space, while convolution layers learn local patterns [33].

Fig. 4. The LeNet Architecture Consists of Two Sets of Convolutional, Activation, and Pooling Layers, Followed by a Fully-connected Layer, Activation, Another Fully-Connected Layer, and Finally a Softmax Classifier [34].

We used the development environment provided by Google Colab with the TensorFlow and Keras stacks. All the models

were trained using NVIDIA Tesla T4 graphical processing units (GPU) hardware equipped with 16 GB of memory and 12.7 GB RAM. This allowed us to create and simulate a deepface-esq model architecture.

For the interested reader, a link to our source code repository can be found here: <https://github.com/QiyuSun/Facial-Recognition-using-CNN-classifier>. This repository includes our Jupiter notebook python files as well as a readme file with links to the YTF dataset. The full dataset is not included in our repo due to space constraints, we only link to it.

#### IV. DEEPFACE ARCHITECTURE

Before the deepface architecture came about, one of the challenges to facial recognition was the reduced accuracy caused by face images collected from different perspectives. In fact, facial alignment is still considered a difficult issue, especially in an unsupervised environment. The task of face alignment is to automatically locate key facial feature points, such as eyes, nose tip, mouth corners, eyebrows, and contour points of various parts of the facial contour according to the input face image. The process of face alignment can be divided into three sub-problems: 1) How to model the apparent image (input) of a human face? 2) How to model the face shape (output)? 3) How to establish the association between the apparent image (model) of the face and the shape (model) of the face? In terms of the DeepFace method, Facebook researchers have made a great contribution in the development of an effective deep neural network architecture with a very large, labeled dataset of faces, an effective facial alignment system based on explicit 3D modeling of faces, and results that reach near real time human-level performance [13].

##### A. Alignment Pipeline

The alignment pipeline of DeepFace is as follows:

- (a) Detect face with 6 initial points.
- (b) Crop out the face with 2D-aligned inducing.
- (c) Apply Delaunay triangulation by 67 fiducial points on the 2D-aligned crop, adding triangles on the contour to avoid discontinuities.
- (d) Transform triangulated face into 3D shape.
- (e) The face becomes a deep 3D triangle net.
- (f) Delect the triangulation.
- (g) The final frontalized crop.
- (h) A new view generated by the 3D model (not used in paper).

The function of these steps uses the 3D model to align the face, so that the CNN can exert its maximum effect. This is shown in Fig. 5.

##### B. Representation

After 3D alignment, the images formed are all shrunk into 152x152 pixel inputs into the network structure shown in Fig. 6, the parameters of the structure are as follows:

- (a) The 3D aligned 152x152 pixel 3-channel RGB face image is sent to the convolutional layer (C1) with 32x11x11x3 filters.

Fig. 5. DeepFace Alignment Pipeline.

- (b) Then the obtained 32 feature maps are fed to the maximum pooling layer (M2), and the 3x3 spatial neighborhood is maximum pooled with a stride of 2. Each channel is executed separately.
- (c) After M2 is a convolutional layer with 16x9x9x16 filters (C3).
- (d) Locally connected 1 [35], but each position in the feature map learns a different filter bank. Local means the parameters of the convolution kernel do not share. Locally connected layer is different from the convolutional layer in its kernel.
- (e) F7 and F8 are fully connected layers and they can capture the correlation between the features of the face image, such as the position and shape of the eyes and mouth. The output of F7 will be used as the original face representation feature vector with 4096 dimensions. The face representation on F8 is sent to K-way Softmax to generate the probability distribution on the category label for classification. The 4030 dimension is respective to the number of identities in the SFC training data set, and each identity has 800 to 1200 face pictures.
- (f) Normalization of face representation: Normalize the face representation feature to be between zero and one to reduce the sensitivity to changes in illumination.

Fig. 6. Outline of the DeepFace Architecture.

##### C. Datasets

In DeepFace, researchers trained their model on the Social Face Classification (SFC) dataset and evaluated the model

on the Labeled Faces in the Wild database (LFW) and the YouTube Faces (YTF) dataset. In this work, our model is built on the YTF dataset. The YTF Database is a face video database, which aims to study the problem of unconstrained face recognition in videos. It contains 3,425 videos of 1,595 different identities. All the videos were downloaded from YouTube. It provides an average of 2.15 videos available for each subject with clips duration varying from 48 frames to 6,070 frames, and 181.3 frames of average length. It initially performs automatic screening to ensure that the videos are long enough to capture useful information for the various recognition algorithms with stable detection. The remaining videos were manually verified to ensure that the videos would be correctly labeled corresponding to the subjects, not static images or slides, and no duplicated videos were included [36].

In terms of designing the data set structure and benchmarks, the YTF dataset follows the principal of the Labeled Faces in the Wild (LFW) collection. All video frames are encoded with well-built descriptors with the face detector output considered in each frame. The face images are bounded and cropped from the frame, 2.2 times of their original sizes. Additionally, the images are resized to 200x200 pixels then cropped into 100x100 pixels in central area. The images are aligned by fixing the coordinates of facial feature points following a conversion to grayscale. The image is divided to a fixed grid of blocks with the descriptions of each block normalized to a unit Euclidean length [36]. For the benchmark tests of the YTF dataset, the YTF dataset follows the example of the LFW benchmark various tests like standard test and ten-fold test. It is divided into 5,000 video pairs and 10 groups, for evaluating video-level face verification [36].

## V. MODEL TRAINING AND EVALUATION PROTOCOL

Six models were built and trained. First we built a baseline model, next a frame base model, aligned base model, VGG16 base model, InceptionResNetV2 base model, and finally InceptionResNetV2 model. The training and validation distribution for all models followed the same split.

### A. Dataset

Twenty images were extracted for the train set of each identity. The remaining images in folders of each identity are divided into training set and validation set with ratio of 8:2. All base models were built on a subset of YTF frame\_images\_DB and aligned\_image\_DB with 160 classes, which consisted of the first 10 percent of videos ordered by name. It is of note that in practical face recognition applications today, the images processed by the model are often already aligned. For example in our dataset, each image is assigned a unique floating point number corresponding to its identity. For example Figure 7 corresponds to the unique identifier '0.614', where the '0' indicates the folder with the identity of a known actor — Aaron Eckhart — and '614' indicates the particular frame sequence in the dataset. Because pre-aligned images were already available, we did not implement an alignment subsystem. Instead after implementing a model architecture, we trained and validated that model on the aligned\_image\_DB dataset.

Fig. 7. '0.614' Images of Aaron Eckhart in Frame\_Image\_DB (left) and Aligned\_Image\_DB (Right).

### B. Baseline Model

Our first approach initially applied a CNN-based model with a single Conv2D layer to train a baseline model on frame\_image\_DB subset for developing a better performing model. The baseline model consisted only one Conv2D layer with 32 nodes, input shape of (152, 152, 3) and activation function relu. The output layers consisted of 160 nodes and the pooling window sizes were 3 by 3 and 2 by 2 for Conv2D and MaxPooling2D, respectively. After converting the pooled feature map to a single column, only one Dense layer was defined and which also served as output layer using softmax for multi-class classification. Categorical\_crossentropy, Adam, and accuracy were defined in compiling for loss, optimizer and metrics. After training, the accuracy of training and validation reached 99.84% and 97.64% within 20 epochs Fig. 8.

Fig. 8. Baseline Model Performance.

### C. Frame and Aligned Base Model

After the baseline model was developed, we added one more Conv2D layer with 16 nodes and relu as activation function, one more dense layer with 1024 nodes to train the Frame Base Model and Aligned Base Model, essentially structuring our model to the model architecture of DeepFace. Since the data set is relatively large, and there was no obvious overfitting observed during the training process, Regularization methods were not added. The learning rate of optimizer Adam was 0.00002. Both Frame Base Model and Aligned Base Model were trained to 20 epochs. The frame base model reached 97.23% and 95.15% accuracy of training and validation Fig. 9. The Aligned Base Model reached 86.51% and 80.65% accuracy of training and validation Fig. 10.

### D. VGG16 and InceptionResNetV2 Base Model

The next iteration constructed utilized the VGG16 Base Model and InceptionResNetV2 Base Model following a similar architecture. The Conv2D layers and MaxPooling layers of both two models were replaced with pre-trained conv\_base.

Fig. 9. Frame Base Model Performance.

Fig. 10. Aligned Base Model Performance.

We froze the top layers of conv\_base so that weights of those layers would keep unchanged during training process. The first dense layer was set 4096 nodes. After training, the VGG16 Base Model reached 98.76% and 97.03% accuracy of training and validation Fig. 11. The InceptionResNetV2 Base Model reached 99.75% and 97.23% accuracy of training and validation Fig. 12.

Fig. 11. VGG16 Base Model Performance.

Fig. 12. InceptionResNetV2 Base Model Performance.

### E. InceptionResNetV2 Model

The final InceptionResNetV2 Model shared the same model architecture with the InceptionResNetV2 Base Model. It was trained on the entire aligned\_image\_DB dataset (621,126 images of 1,595 identities) with same dataset distribution as

the base dataset. After training with 200 epochs, the InceptionResNetV2 model reached 91.12% and 90.79% accuracy of training and validation as shown in Fig. 13.

Fig. 13. InceptionResNetV2 Model Performance.

## VI. RESULTS

The basic baseline model showed great performance in accuracy (99.84% on train set, 97.64% on validation set, 98.60% on test set) but it was just a simple classifier that allowed us to explore what parameters needed to be tweaked to obtain even better results. We can use the performance of other models as a baseline to evaluate the performance of the all models trained on the specific dataset. Based on the baseline models, we developed the Frame Base Model and Aligned Base Model. The Frame Base Model reached 97.23%, 95.15% and 90.78% accuracy on train set, validation set and test set. The Aligned Base Model reached 86.51%, 80.65% and 64.92% accuracy on train set, validation set and test set (Table I, Table II). The Frame Base Model considerably outperformed but the result was not that convincing. It was built on different datasets with the same architecture, which implied that the difference in performance could be caused by the specific dataset used for validation. At this point, we believe the Base Model learned little from facial features and instead was emphasizing on other factors too much. It was those no-facial related features that helped it reached greater performance than the Aligned Base Model, meaning it could be objects like chairs, studio backgrounds, etc.

The VGG16 Base Model and the InceptionResNetV2 Base Model were trained on subset of aligned image subset with more neurons added in dense layers and more training epochs compared to previous two models. The VGG16 Base Model reached 94.98% and 93.47% of train and validation accuracy at the 20th epoch, and the InceptionResNetV2 Base Model reached 99.63% and 96.58% of accuracy, respectively. After 30 epochs of training, the VGG16 Base Model reached 98.76%, 97.03% and 89.60% on train set, validation set and test set (Table I, Table II), and the InceptionResNetV2 Base Model reached 99.75%, 97.23% and 93.96% of accuracy on train set, validation set and test set (Table I, Table II). The accuracy curves of the two models were both smooth, which indicated that no apparent overfitting was observed in training. On the ground, we can see the great performance of pre-trained model layers in image classification.

The finalized InceptionResNetV2 Model was built with the same structure as the InceptionResNetV2 Base Model. It had 1,595 neurons in the final output layer corresponding to the number of identities in the completed aligned image dataset (621,126 images of 1,595 identities) and was trained

with 50 epochs. It took 0.033s for each image during the training process. The model reached accuracy of 92.75% and 91.46% at the 198th epochs then it performed increasingly higher loss and relatively lower accuracy afterwards (Table III). The decline in performance may be caused by a variety of factors, including poor architecture of model and overfitting. Considering that no explicit overfitting was found in previous models, it would be of help to promote the model performance with a better networks architecture rather than with additional regularization methods added. In the DeepFace architecture, researchers added three locally-connected layers after 3D convolutional layers and maxpooling layers, which might be one of the solutions for structural optimization of the model. In the final evaluation on test set, the InceptionResNetV2 Model performed 84.60% of accuracy and 1.2582 of loss, which demonstrated that more tuning on the model were required, as well as some pre-operations on images before being fed into model.

TABLE I. PERFORMANCE OF TRAINING & VALIDATION ACCURACY

Model	Train-Acc	Val-Acc
Baseline Model	99.84%	97.64%
Frame Base Model	97.23%	95.15%
Aligned Base Model	86.51%	80.65%
VGG16 Base Model	98.76%	97.63%
InceptionResNetV2 Base Model	99.75%	97.23%
InceptionResNetV2	91.12%	90.79%

TABLE II. PERFORMANCE ON TEST DATA

Model	Test-Loss	Test-Accuracy
Baseline Model	0.0866	98.60%
Frame Base Model	0.6357	90.78%
Aligned Base Model	1.8023	64.92%
VGG16 Base Model	0.9026	89.60%
InceptionResNetV2 Base Model	0.2992	93.96%
InceptionResNetV2	1.258	84.60%

TABLE III. INCEPTIONRESNETV2 MODEL PERFORMANCE IN FINAL EPOCHS

Epoch	Loss	Accuracy	Val_loss	Val_Accuracy
195	0.7641	0.9294	0.9466	0.9062
196	0.7965	0.9156	0.9768	0.8975
197	0.8055	0.9131	0.9380	0.9082
198	0.7046	0.9275	0.9005	0.9146
199	0.7391	0.9231	0.9204	0.9106
200	0.7834	0.9112	0.9276	0.9079

We were not able to best DeepFace's 96% accuracy. However, our top model achieved a respectable 84.6%. Considering the constrained resources we had (this was developed entirely on a single laptop and Google Colab compared to the massive resources available at Facebook), the mission of this project was achieved.

We directly used the aligned dataset published in YouTube Face dataset rather than implementing a specific face alignment method. In DeepFace, the method developed to map 2D human facial features to 3D models and use them as 3D input to train models was key to making DeepFace achieve its breakthrough outstanding performance. In addition, unlike our training and verification based entirely on the YouTube Face (YTF) dataset, DeepFace's training set and verification set involved a total of three different data sets (Social Face Classification dataset,

Labeled Faces in the Wild dataset, and YTF dataset). Training on one dataset and using the different datasets for validation reduces its accuracy deviation when facing images of different sizes and types. When looking only at the YTF dataset making full use of these factors, DeepFace achieved the test accuracy of  $91.4 \pm 1.1\%$ . This number is a more accurate threshold to compare our model against as it's an apples-to-apples comparison leveraging the same dataset. Taking into account the limitations of so many conditions mentioned above, the result we obtained, when compared to DeepFace, seems to be rewarding.

Although we were inspired by the architecture of DeepFace, as described in detail above we did not fully copy the DeepFace model. We were limited by the computational power available to us. Just the memory required to fully reproduce the DeepFace model is massive and greatly exceeds that which we had access to. Instead, we demonstrated that the simpler and more accessible models we built have promise in recreating DeepFace-style breakthrough performance, utilizing a fraction of the resources.

## VII. CONCLUSION

DeepFace revolutionized the facial image recognition industry. In this paper, we demonstrated the power of learned features through six convolutional neural networks (CNNs). Inspired by the DeepFace architecture, but in making our own tweaks, the models we constructed were trained on the YouTube Faces (YTF) dataset to be multi-class classifiers. The Base Models showed satisfactory performance, which indicated that a CNN-based architecture could manifest remarkable performance in image classification if given a large dataset. Compared to the DeepFace model architecture, the model was less complex, which potentially would bring difficulties in capturing essential facial features effectively in other datasets. Based on the first experiment, it was obvious that there are multiple factors that needed to be taken into consideration when constructing an image classifier for a face recognition system. When dealing with exponentially massive amounts of data, the architecture and depth of the model will play a crucial role in performance. The success of DeepFace showed that remarkable results could be achieved with the right architecture combined with face alignment and frontalization. We demonstrated that our models could obtain good results at much lower computational cost.

The first few models we built showed us many factors that need to be considered when building a large CNN classifier, such as: how to make full use of the structure and characteristics of CNN itself, the suitable combination of hyperparameters for training, and how to adjust particular parts of model architecture when working with datasets at large scales. This paper is a valuable contribution to the field of image classification and facial recognition.

In future work, we wish to further improve the model. First, we would explore adding some preprocessing methods for face images, such as image sharpening, extended face alignment, and frontalization. Second, in terms of the model architecture, we may consider trying to combine layer functionalities such as with locally-connected layers or pooling layers.

**Abstract**—Air pollution spikes have been causing harm to human beings and the environment. Most exposure to Air pollution spikes has demonstrated a significant impact on mental health, especially children at an early age. That lead to suicide or depression. Previous research concentrated on air pollution in general. Existing monitoring systems do not consider Short-term air pollution peaks. This paper presents the co-design of the hardware and software for IoT to monitor air pollution spikes for a short duration in real-time monitoring. The system comprises two technologies like edge computing to capture short-term exposure and a mathematical model for distribution in analyzing the captured data. This system ensures the presence of the spikes start and end for each pollutant. Monte Carlo simulation has been used in this research to predict the next spike of each pollutant. Artificial Intelligent is used to analyze immutable data for a short term prediction. After the analysis, legislators based on intelligent contracts created using blockchain to reduce pollution based on its source.

**Keywords**—Short-duration air pollution peak/spike; real-time monitoring; short-term prediction; immutable data; blockchain; AI

## I. INTRODUCTION

Air pollution is the silent, prolific and invisible killer from previous years [1]. Most existing systems for monitoring air pollution are measuring the long-term peaks. Instead, the research shows that the short-term peaks are perilous [2] and can lead to different diseases such as eye and adnexa [3], brain volume, cognitive decrements, dementia development [4], heart, chronic obstructive pulmonary disease (COPD), lung cancer, migraine, acute lower respiratory infections and stroke [5]. Air pollution is exposed to more than nine to ten children and is stunting their brains, affecting their health [6]. That leads to the problem of mental health, especially in children (brain cell inflammation). Short-term spikes of air pollution are the source of increased hospital visits for childhood psychiatric. And the research shows that children from low-income families are more affected, leading to an increase of 44% of those who visited the hospital with suicidal thoughts due to the spikes in the air pollution [7] [8].

The spikes of air pollution have more severe effects on the brain of children. The research shows that air pollution spikes can cause mental health, depression, and anxiety. It can lead to the children having a lower intelligence quotient (IQ), poorer memory, delaying their development, leaving women infertile earlier, ..... Spikes affect brain chemistry differently; for example, industries and traffics may carry toxins using tiny

passageways and then enter directly into the brain [7]. In 2020, spikes increased higher than five years [9]. But until now, minor effects of short-term exposure to air pollution are known.

Spikes of air pollution are damaging the future generation of humans, and emitters do not condemn the creation of that harm. Governments have tried to prevent air pollution in general, but the research shows that none of them has been viewing the spikes as a dangerous and long-lasting killer of children. The research suggested that legislators should protect children's' exposure to air pollution to advance the initiative for their public health [10].

This research paper is composed of the following section: The section of background covers all literature reviews related to the monitoring system of Air Pollution. The following section is about the co-design of hardware and software for the prototype monitoring of the spikes. The following section is about performance analysis and simulation, where the analysis made for some data and tools used to do simulation and the results shown in that section. The last section is the conclusion, which summarizes the paper and the proposal for future research.

## II. BACKGROUND

This section highlights the background of the existing systems in monitoring Air Pollution. The section deeply explains the previous research and enumerates some challenges that are still in this area that can be solved using this research.

WHO has put the Global Air quality guidelines in different years to prevent air pollution in general, but there are no measures taken for spikes [11]. Many people are victims of air pollution, and emitters of pollutants are not charged for anything because none knows the air pollution they produce. Some measures have been taken [11], but they do not regularize the correspondence of emitters and victims of spikes. When these spikes continue to be repetitive, they cause more problems of health [12].

Many people are living in big and small cities. Developing countries used to have high populations exposed to air pollution. It is also where most sources of pollutants are found [13]. Once the spikes appear in the cities, it affects a large population [14]. Spikes can appear anytime, so this may come from different sources. If the spikes are not monitored, they can affect the living of human beings, as explained above. Spikes

Partnership for Skills in Applied Sciences, Engineering and Technology (PASET) under the Regional Scholarship and Innovation Fund (RSIF).

occur in a short time, and most existing monitoring systems for air pollution cannot recognize their appearance. Children are the most affected, primarily their mental, leading to their future loss [7]. Emitters of spikes may not even know how they affect human beings' health because there are no systems to monitor these spikes [15].

Authorities are oriented toward monitoring air pollution in general [16] [17]. Instead, spikes are affecting the future generation and the population as well. The source of spikes allows the identification of emitters, and then authorities may take advanced majors accordingly. Victims of these spikes are more in danger once they are repetitive. That may lead to many unexpected severe health problems.

The author of [18], proposed a system that can monitor the spikes from air pollution and predict the next spike using road management data.

Air pollution spikes have a short lifetime, requiring monitoring in a smaller time resolution [19]. These spikes need to be monitored at each appearance not to affect the living. Spikes need particular ways of monitoring them that differ from the existing methods. They appear in a short time, and then they disappear. If they do not monitor their appearance, they mix with other collected results of pollution and then may result in the average instead of the over-level for pollutants. Spikes monitoring can enable counting all spikes passed, predicting the following occurring spikes in the system. Once they occur from their sources, these unexpected pollutants may damage many things because they do not prepare before. They do not last for an extended period, leading to the big mess of not monitoring them. Spikes generated due to some occurred events planned before, but no analysis of the effect may cause. Also, spikes may occur due to unexpected events from the environment or any other source without any prior planning of the event. Spikes need a real-time and a low-time resolution to react to the effects that may occur due to its presence [20] [21], sometimes to the loss of life [22].

Most existing systems for monitoring air pollution are based on cloud-centric architecture [23] [24]. These systems measure air pollution with long term exposure. The average of peaks for air pollution in a specific time is considered the result of a monitored place. That is because of allowing sensors to capture information during a specific time and wake up to send the data on the cloud, known as duty cycle mode (taking a long sleep period to save the battery energy). That is for saving battery life during the wireless communication mode of sending data to the cloud. In the design of the sensor node of IoT applications, battery life is one of the critical parameters to consider. The reporting of collected data to the remote centric-cloud architecture of air pollution has a low frequency for at least 1hour to extend the battery lifetime.

The centric-cloud architecture uses wireless communication for transferring data from sensors to the remote. That leads to high energy consumption, and the sensors are sleeping within a certain period of collecting data and storing them locally. That makes sensors monitor long-term average peaks instead of capturing all peaks [25]. That leads to the miss of monitoring short duration peaks. These spikes may

appear periodically or not. The air pollution peak average threshold may exceed for specific pollutants, and the system may not be aware of that unexpected change. No system can capture spikes for a short duration from the existing cloud-based systems.

Cloud-centric has failed to monitor spikes because of transferring data by waking up the sensor. The cloud-centric architecture collects data of air pollution using sensors at data gathering. It uses wireless communication to send the data to the cloud [26, 27]. Then, the system does the data management for the given application in the cloud. At the first phase of data gathering, sensors collect information related to air pollution. This information is transferred to the cloud through the wireless communication channel. This communication channel consumes high energy [28]. The last phase is data management, which analyses, processes, and stores data in the cloud. These data can be used to predict air quality [29].

The cloud-centric architecture also has a latency problem due to transferring the data after a specific time. These systems also take time to react to the processed data [30]. Predicting the possible air pollution event may take longer as data processing is based on the cloud, not on edge. There is a need for data transparency and trust, and this may be difficult for the data passing in the network without additional security measures.

Therefore, there is a need for an edge-centric system to monitor short-term peaks for air pollution. This paper helps to understand the design of the edge-centric smart sensor to monitor air pollution by waking up the sensor once the air pollution variation attained the given threshold.

There are not many several systems developed to monitor and predict air pollution spikes. Artificial Intelligence technology is the predictor developed by a new wireless company, and that system can predict the following levels of air pollution within an hour. This system uses AI for analyzing weather measurements, images of CCTV cameras, air pollution sensing devices, Bluetooth, and history readings. The system links the existing real-time data to predict the next coming hour for traffic jams and air pollution. This predictor is accurate at 97%. It has been tested for implementation in some cities like Wolverhampton [18]. It is excellent and friendly to the existing technologies, but it doesn't take pollutant data on the roads or nearby since it is linked to the load management system. And this leads to the lack of identifying the source of each pollutant and the quantity. The predictor predicts air pollution in general but doesn't identify spikes that come and may arrive.

Following the previous works that researchers have done, the existing systems only measure a few pollutants. Most monitor air pollution at the cloud-centric, leading to latency, security, cost, and control problems. The existing system woke up sensors periodically, leading to the danger of an unexpected increase of pollutants. Existing systems haven't mentioned the identification of spikes and the time stay based on their appearance level.

This research takes all six primary pollutants as explained by WHO in [11], and it can be installed and not based on historical readings.

### III. HARDWARE AND SOFTWARE CO-DESIGN

#### A. Improve IoT Energy Management

In designing the embedded system for performing a real-time environment, there is the issue of the increase of power dissipation. IoT hardware design increases power dissipation from the real-time application and the device for the best performance. The problem was created during the deployment of the number of transistors comparable with the power consumption. There are two causes of power dissipation in designing lower-power IoT systems. The first one is when the power dissipation for each transistor increases with impact to the increase of density gate, which implies the increase of power density for the whole system. The second is the increase of the frequency of IoT systems for better performance.

The power dissipation problem is improving IoT energy management by waking up the device using analogue interrupts.

Energy management is still a crucial problem in today's sensors [31]. There is a need to continuously allow the sensor to stay in energy-saving deep sleep mode to solve that issue. The system needs to wake up on measurement appearance with low energy consumption. Since the energy consumption implies a decrease in battery life, the system should monitor sensors connected to use little energy.

The system stays asleep most of the time and only wakes up for the threshold's quick and effective measurement. The CPU of the system uses much energy by comparison to the rest of the other parts. That means that reducing the CPU system's busy time is the best way to reduce consumption energy.

Fig. 1, the system wakes up periodically to detect events, making the CPU continuously active. The sensors capture data from the environment and send these data for processing. The analogue event creates a signal which is transformed directly to a digital signal.

Fig. 2 gives the intention to look at the signal after using analogue interrupts. The sensors can record all analogue events, and once the threshold passes, the system wakes up for recording and processing.

There are two options for using analogue interrupts: The first is ADC wake up and the second is an external op-amp-based voltage comparator.

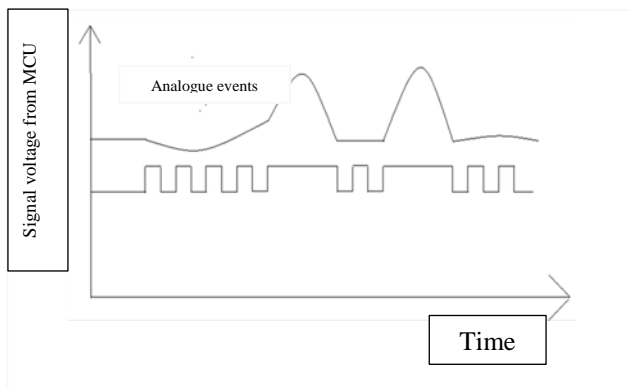

Fig. 1. System Wakes up Periodically to Detect Events.

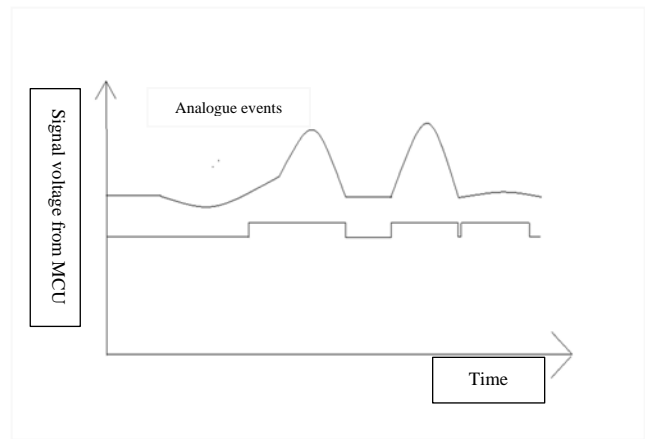

Fig. 2. System Wakes up on the Threshold.

1) *ADC Wake up:* Sensors convert analogue measurements into electronic signals. The ADC (Analog to Digital Converter) converts the produced analogue signal to a digital signal using the frequency sampling mode based on the Nyquist theorem. Interrupts that are alerting electronic signals are sent to the Microcontroller Unit (MCU) processor, which may come as an external part of the internal peripheral or external one.

The below is an ADC component designed using the Proteus simulator. The ADC is composed of one ADC0804 Integrated Circuit, eight LEDs, one resistor of 1k, one variable resistor or potentiometer, one push button, one wero board, one nonpolar capacitor with 150pf and some jumper wires. This proteus simulation designs system that switches ON and OFF based on the voltage once the input exceeds the threshold. Then, it helps to monitor all events that come and exceed the threshold. That is useful in air pollution monitoring based on spikes only.

Fig. 3 uses the button to switch off the ADC. The button is activated by the measurement to the node sensor for air pollution. The input signal is an analogue signal generating the output that can switch on LEDs.

Fig. 4 shows that the data are generated from the physical environment, and then the sensor accepts these analogue measurements in the form of analogue signals. The analogue signal transforms into a digital signal and is then sent to the processor. At the input, the environment creates a signal using physical quantity. Then sensor takes that signal and makes it in the presence of an electrical signal. The signal is in analogue form and needs to transform into digital form, and then using the ADC tool; it generates the digital signal used to monitor air pollution using the given threshold.

This paper applies the sampling of analogue signals, and the system acts based on the threshold. That should be done using ADC to trigger timers precisely. That uses many MCU resources, which leads to high-power consumption since timers must be active to perform ADC. Another methodology is not to use timers and allow signals to be monitored continuously by the ADC, which consumes a high-power consumption.

Fig. 3. ADC Circuit from Proteus Simulation.

Fig. 4. Measurement to Signal Processing.

The solution to be adapted that may not consume huge amounts of power is to integrate ADC in the MCU without dependency on the CPU (Central Processing Unit). That allows the CPU to disable all clocks except the one of ADC. Then the ADC wakes up the CPU and other parts of the MCU by using the logical conditions. The ADC creates interrupts to wake up the rest of the system by referencing the configured threshold.

The ADC wake up uses the voltage comparator to activate the CPU and the system. The reference voltage  $V_{ref}$  is compared to the input voltage  $V_{in}$  for deciding to wake up the system or not. The  $V_{out}$  is in digital mode, and from there, the decision to wake up the system is taken. Since that is on the sensor by detecting the measurement of the event to wake up the system, there is the optimality of this strategy because no loss of data appears and the optimization of the sleeping time.

2) *External op-amp based voltage comparator:* The other way to wake up the system is to use an external operational amplifier based on the voltage comparator. This way requires extra resources to add to the system. And adding this wake-up circuit to the sensor node decreases the average power consumption, but also it may create the loss of information since the original signal was amplified.

The external op-amp compares one analogue voltage level to another and generates output based on the comparison. It

detects the voltage from measurements and then switches from the sleeping mode of the system to an active mode. The switching time of the op-amp voltage comparator slows the system even though it operates on analogue voltage.

The op-amp voltage comparator uses input, amplification, and output terminals. It uses negative feedback voltage, which leads to compensation capacitance to prevent oscillation in that integrated circuit. That creates an inside power dissipation, which may increase the temperature for the chip and the self-heating.

The operational amplifier voltage comparator may present an error voltage called the input offset voltage caused by the characteristics of transistors of each terminal or by the input bias current.

Fig. 5 shows the graph of the op-amp voltage comparator with its five terminals.

Therefore, based on the above comparison of ADC wake up and external op-amp voltage comparator wake up, this paper suggests using ADC wake up to activate the system from the sleeping mode to active mode. The measurements are taken from the environment and create analogue input to the sensor node, and that analogue input changes to an analogue signal with a certain amount of voltage. Then the analogue signal needs to transform into a digital signal using an ADC converter, and during that conversation, the ADC decides if it wakes up the whole system based on the comparison of the input voltage and the reference voltage. The system needs to identify the starting voltage above the threshold voltage and record these values. The following subsection explained how the system used to pick these signals that attained the threshold.

### B. Peak Digital Signal Processing

Measurements captured from the environment need to be processed and analyzed. Once the ADC wakes up, it gets an analogue signal and converts it to a digital signal, quickly processing scientifically. The system is woken up based on the data that exceed the predefined threshold, allowing the system to record that event.

This research is working on air pollution spikes. These spikes are identified based on the minimum predetermined value of pollutants. WHO has defined each pollutant's threshold as shown in Table 1. These values are measured in micrograms per cubic meter.

Fig. 5. Op-amp Voltage Comparator.

TABLE I. AIR POLLUTANTS

Pollutant name	Minimum Concentration ( $\mu\text{g}/\text{m}^3$ )
Particulate Matter $\text{PM}_{2.5}$	35
Particulate Matter $\text{PM}_{10}$	70
Carbone monoxide/ Carbone dioxide (CO/ $\text{CO}_2$ )	1000
Nitrate Oxide ( $\text{NO}_x$ )	80
Sulfur of Oxide ( $\text{SO}_x$ )	50
Ozone ( $\text{O}_3$ )	120

This research detects a peak in a signal and measures its position, height, width, and/or area. When the sensor node identifies the signal that exceeds a threshold value of any type of pollutant, the system starts to record the event, and when it attains the peak, it starts to decrease, going to the value which should always be less than the threshold. The first derivative of the peak is applied to downward-going zero-crossing (threshold) at the maximum of the peak. Since the signal may have noise from measurement due to the environment, this can lead to false zero-crossing. Therefore, the smooth technique can detect only the desired peaks and ignore peaks that are too small, too wide, or too narrow.

Once they become high frequency, air pollution spikes (peaks) cause mental health problems that can lead to hypertension, suicide, and heart diseases. These peaks imply the concentration of pollutants in respect of the given time. If not reduced, that concentration cause health problems compared to normal pollutants that don't pass the threshold.

The input signal is taken in the window size measured based on the length of the signal above the threshold. The height of that signal is also identified.

The digital signal processing from ADC is set low or high. We examine all signals with high since they are above the threshold. Signals which are less than the threshold are identified as low. Then finding the peaks in the given signal that we can call X describes all points above the threshold. Each peak has its amplitude or the height of the signal.

Fig. 6 is for peak detection of digital signals with a height of 1 and the length of the period of 500 microseconds.

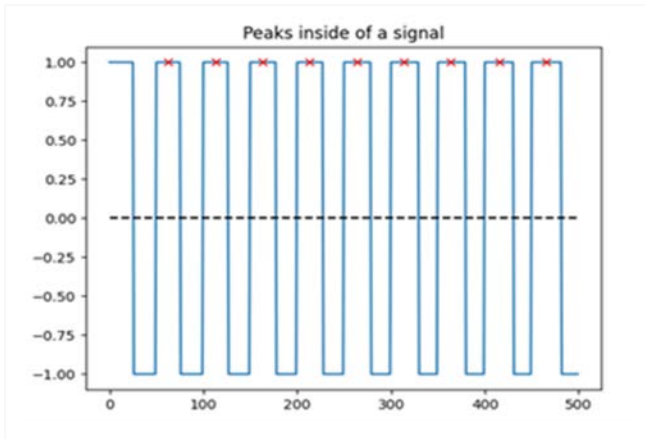

Fig. 6. Peaks Detection.

From the input signal of the sensor node, ADC wakes up activates the system once the peak has appeared. The probability of obtaining a peak at a particular point  $t_i$  of the input signal from the environment depends on its incoming voltage and the given standard threshold voltage  $t_v$ .

$$P(\text{Spike at } t_i | \text{Spike at } t_v) = \int_{v \in C_i} G[V(t)]$$

With  $C_i$ , the set of possible voltages can rise in the interval  $i$ .  $V$  presents the voltage signal. And  $G[V(t)]$  is the Gaussian distribution.

Once peaks are detected from the given interval time and their location, the system is applied to collect these peaks. These peaks are stored in the array of integers for future analysis using Machine Learning. The system can analyze the collected peaks for notifying the appearance of pollutants and the expectation of the next peak.

#### IV. PERFORMANCE ANALYSIS / SIMULATION

##### A. Distribution Patterns of Air Pollution Spikes

Air pollution spikes are coming from the increase of unexpected pollution generated by emitters. All these spikes are from the environment and can be distributed in the atmosphere. The system for monitoring spikes can capture distributed pollutants either directly or indirectly from the source.

Direct spikes are captured by the system and then analyzed without adding the environment to it and for example, having the sensor node connected to the place generates pollutants. The indirect spikes are those that pass in the environment and meet with other pollutants before being measured by the system.

The system accepts measurement in any of three patterns or their combination. Spikes can be presented to the system either: uniform random and/or clumped.

Uniform spikes are these spikes that come within a given period. They occur periodically in the system. These spikes are easy to predict the next peak. These peaks can appear in different sizes and densities.

Random spikes are these peaks that are entered into the system randomly. These peaks can be very harmful since they are not easily predictable. This research suggests using a certain period to analyze all peaks appearing, and then using Machine learning, and it can predict the next peak.

Clumped spikes are predicted or unpredicted peaks with a heavy density. These peaks are perilous, and they need profound observations to analyze their prediction.

The nature of the air pollution environment can have all these above patterns of distribution of spikes. All these spikes are based on the period to predict the next appearance of the peak.

The distribution model has been used to predict the next within a specific period. Since the generated signal from the ADC wakes up converter is a digital signal, it has discrete values. The Poisson distribution is used in this paper to model the arrival rate of spikes in a specific fixed interval of time.

The performance parameters are based on the mean of signals in a period  $\lambda$  and the number of spikes  $k$ .

Let  $\lambda$  be the parameter greater than 0 and let distribution  $k = 1, 2, 3, \dots, n$  be the appearance of spikes in the input signal to the sensor node; in other words,  $k$  is presenting a discrete random variable counted. The probability density function (*pdf*) is used to specify the random variable's probability being in the range of the values.

Then the *pdf* that a Poisson random variable  $X$  with the mean  $\lambda$  is equal to a given by the formula.

$$pdf = P(X = a) = \frac{\lambda k e^{-\lambda}}{k!}$$

Where  $e$  is a constant approximately to 2.71828.

The *pdf* gives the probability of getting spikes each time by using the mean of the spikes and the number of spikes counted.

The system can identify spikes and predict finding peaks in the given time. Most existing systems for monitoring air pollution are using cloud-centric duty cycle mode. The sensor collects data related to air pollution while it is in sleeping mode to save the battery's lifetime or the harvested power for energy conservation. The sensor only wakes up after a specific period to transmit collected data to the cloud-centric for the analysis.

The duty cycle  $D$  can be defined as a ratio of pulse width ( $PW$ ), a busy time and the total period of  $T$  of the signal and then expressed in percentage.

$$D = \frac{PW}{T} \times 100$$

Therefore the 60% duty cycle means that the signal is on 60% of the time but off 40%. That implies the power consumption in recording data. There is a need for much energy during the transmission of the data to the cloud-centric server. This energy consumption reduces the sensor battery lifetime or the harvest power storage of energy.

The solution of optimizing the use of sensor energy or harvest power is edge centric HW/SW Codesign smart sensor. That allows the analogue interrupt to wake up the sensor once the coming signal voltage is higher than the threshold voltage. Only the system is active in collecting spikes for quick analysis of data. Once the spikes are over, the intelligent sensor goes back to sleep mode.

The above Fig. 7 describes the edge centric HW/SW co-design system. The measurement from the environment is those pollutants CO, CO<sub>2</sub>, PM<sub>2.5</sub>, PM<sub>10</sub>, SO<sub>x</sub> and NO<sub>x</sub>. Once one of these pollutants sends the value more significant than the threshold defined in the table [1], the sensor node will send all signals to ADC, which wakes up the processor, memory, protocol for analyzing the coming signal since it is a spike. The power unit is there to empower each device. That reduces the power consumption since it is waking up for recording spikes.

In edge centric HW/SW co-design, data analysis is performed locally, and there is no transmission energy of short periodical time. Only transmission can be once in a while for further analysis. The edge-centric smart sensor is a real-time monitoring system for air pollution spikes and can react to its

appearance. From those spikes, it does analysis locally, and the decision is taken quickly.

The cloud-centric is still needed to analyze big data collected by sensors, while edge centric can be considered an operator of instant data. At the edge, centric analytical tools and AI tools are nearest the system, implying operational efficiency. The security and privacy are strong at the edge centric smart sensor. This system is reliable. Since one node can go down and is unreachable, the other system parts continue to operate. The speed of data at edge computing implies analytical, computational resources to the end-users, bringing quick responses and applications.

### B. Performance Metrics

The energy consumption at the edge centric HW/SW co-design smart sensor and cloud-centric can be distinguished in the below metrics:

- Throughput: output at the edge is generated in real-time while data is transmitted in the cloud, which consumes much energy.
- Collecting data: at this stage, edge computing uses to wake up only during the collection of spikes while the cloud uses a duty cycle which implies power consumption.
- Processing: at computing only, the system wakes up on the threshold, while the CPU and other parts of the system operate periodically for cloud-centric—the probability of identifying the subsequent spikes at edge computing within the length of the interval of spikes.

From Table 2, the designed system performs better in all performing metrics. The designed system can save energy consumption at 40% on the throughput metric since the existing systems (mostly cloud computing systems) are using a duty cycle. On the second metric of data collection, the designed system woke up on the appearance of spikes, and that can lead to quickly identifying the spike while the existing systems wake up periodically and can miss some spikes, which may be dangerous. Lastly, the processing metric is so quick at the designed system while existing systems take enough time to process and predict the next appearance of the spike for air pollution.

Fig. 7. Edge-Centric HW/SW Codesign System.

TABLE II. COMPARISON OF THE EXISTING SYSTEM AND OUR DESIRED SYSTEM

	Throughput	Data collection	Processing / Performance
Designed system	Save energy consumption at 40%	Spikes to wake up the system	Quick processing and prediction
Existing systems [32, 33]	Energy consumption	Periodically wake up	It takes periodically time to predict the next spike.

Peaks can be harmful to human beings, and there is a need to monitor them. For cloud computing, some peaks may be lost during the sleep mode of the sensor at the sleeping mode of the sensor. At the sleeping mode of the sensor, all peaks arrive and can be combined with the whole signal for presenting the mean of the whole period. On edge centric, the system is woken up by spikes in the input signal.

### C. Monte - Carlo Simulation

This research uses Monte-Carlo simulation as a mathematical technique used to estimate the probability of possible outcomes in a process that cannot be predicted due to its uncertain appearance.

It is based on making a computational algorithm to find the numerical results of repeated random sampling. These uncertainty events can be predicted and forecasted using the Monte-Carlo technique to model them.

This research uses Monte-Carlo simulation to predict the subsequent spikes using their probabilities of occurring. As our data are stored discretely after the ADC converter, we estimate the probability of occurring in a specific period.

Let's use the same example of PM2.5 for its Poisson distribution, which was 7.1%. Then that means in the interval of a period there is a 7.1% probability to find the spikes of PM2.5. The figure below is for particulate matter data; and it uses the synthetic data generated mostly.generate. The mean  $\lambda$  of the data is 29, and the appearance of spikes is 27. Then the probability of getting the spikes is 0.071.

The performance of the proposed system has good accuracy since it can identify each appearance of the spike of each pollutant. Most other existing systems measure air pollution in general and are not specific on spikes prediction of each pollutant.

The signal length is sampled at 30 samples for the whole period, and the probability of finding the next peak of PM2.5 is 7.1%, as shown in Fig. 8.

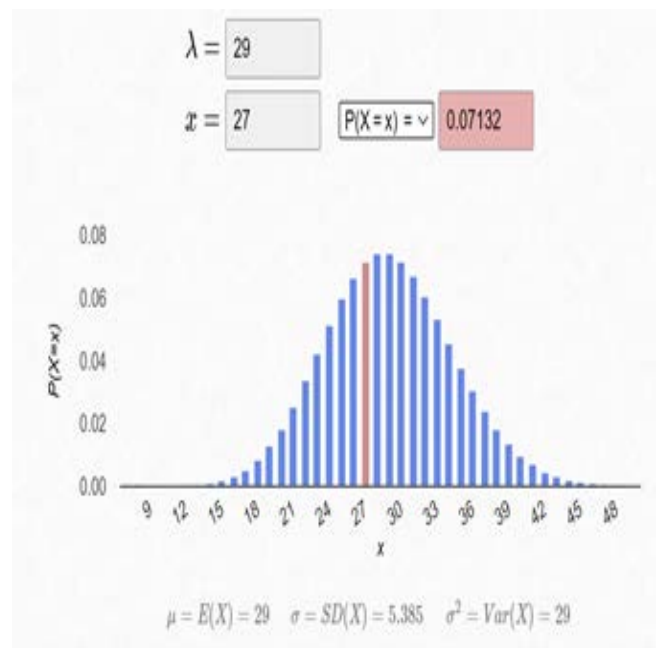

Fig. 8. Probability of following Peaks for PM2.5.

### V. CONCLUSION

This research designs a hardware-software smart IoT device to monitor short-term exposure to air pollution peaks. Spikes are causing significant health problems, especially children, leading to mental problems, suicide, stroke, heart diseases, lung, etc. This research improves the IoT energy by waking up the system through the appearance of digital signals using ADC wake up. The designed system performs better than the existing system through the performance metrics, as explained in Table 2. The paper explained the finding of peaks that are stored in the array. The mathematical model was generated using Poisson distribution to find the appearance of peaks. Monte-Carlo has been introduced to predict the next coming peak. The prediction showed that PM2.5 could be predicted at a 7.1% probability of the spikes to appear. This probability is high since it showed that in the appearance of spikes, there should be a 7.1% of PM2.5.

The system and authorities analyze the collected peaks to compensate for the peak emitters. As peaks are dangerous to health, there should be a proposal of fining people accordingly if they exceed the threshold. The hardware-software co-design generates a dataset of spikes signature that will be used by machine learning for future research. In future works, this research will be oriented on the security of the data transmitted across the network using blockchain.

**Abstract**—Face recognition in the visible and Near Infrared range has received a lot of attention in recent years. The current Multispectral (MS) imaging systems used for facial recognition are based on multiple cameras having multiple sensors. These acquisition systems are normally slow because they take one MS image in several shots, which makes them unable to acquire images in real time and to capture moving scenes. On the other hand, currently there are snapshot multispectral imaging systems which integrate a single sensor with Multispectral Filter Arrays (MSFA) allow having at each acquisition an image on several spectra. These systems drastically reduce image acquisition time and are able to capture moving scenes in real time. This paper proposes a study of robust facial recognition using Multispectral Filter Array acquisition system. For this goal, a MSFA one-shot camera was used to collect the images and a robust facial recognition method based on Fast Discrete Curvelet Transform and Convolutional Neural Network is proposed. This camera covers the spectral range from 650 nm to 950 nm. A comparison of the facial recognition system using Multispectral Filter Arrays camera is made with those that using multiple cameras. Experimental results proved that face recognition systems whose acquisition systems are designed using MSFA perform more efficiently with an accuracy of 100%.

**Keywords**—Multispectral image database; multispectral imaging; multispectral filter array (MSFA); one-shot camera; facial recognition system

## I. INTRODUCTION

The Biometric system is defined as an automatic measurement system based on the recognition of physiological and / or behavioral characteristics specific to a person. It is characterized by its uniqueness, its public nature, and its performance. There are several biometric modalities namely fingerprint, palm sign, face, iris, retina, DNA, voice etc.

Facial recognition is one of the widely used biometric identification methods because face is easy to capture in a controlled or not controlled environment, and in a cooperative or non-cooperative manner [1] [2]. Facial recognition systems performance depends on the electromagnetic spectra in which face images have been acquired. Facial recognition based on the visible spectrum generally use texture characteristics. Its performance is affected by light, occlusions, and pose variations. Infrared spectrum has several advantages over the visible spectrum; it is not perceptible to the human eye and at the same time, less sensitive to variations in light[3] [4]. The infrared spectrum is subdivided into near infrared spectrum (770-1400 nm), Short Wavelength Infrared (1,4–3  $\mu\text{m}$ ), mid-

wave infrared spectrum (3 – 8  $\mu\text{m}$ ) and thermal infrared spectrum (8 - 15  $\mu\text{m}$ ). There have been reported some research showing that in environments with uncontrolled illumination the NIR approach remarkably has higher performance in comparison to VIS approach in the extraction of information in different aspects such as appearance and structure [5]. The use of visible and near infrared spectra in facial recognition combines the benefits of both spectra and improves the performance of facial identification systems. Face recognition in the visible and infrared range has received a lot of attention in recent years. A multispectral recognition system is a system using images acquired on 3 to 10 spectral bands. Each of the images acquired in a given band contains specific information that is very important and useful in facial recognition.

MS imaging [6] systems can be broadly grouped into three categories: multi-cameras systems, single-camera and multi-shot systems, and single-camera one-shot. The multispectral systems based on the first category consist of several cameras, at least one per inference filter (or spectral band filter), multispectral systems using a single camera and several shots are made up of several image sensors each equipped with a narrow bandwidth wavelength filter, which makes them heavy, bulky, energy-intensive and very expensive. The last category that of single camera one shot, uses a single sensor with Spectral Filter Array (SFA) or Multispectral Filter Array (MSFA) to acquire a single image on multiple spectral band simultaneously. These imaging systems are very fast and operate in real time.

Most current MS imaging facial recognition systems use acquisition systems consisting of multiple cameras or a single camera with multiple sensors. Considering the real time operations and benefits of these one-shot multispectral cameras, the research has been oriented towards facial recognition using multispectral images acquired with Multispectral Filter Array camera. This paper proposes a robust facial recognition system using MS image dataset collected with MSFA one shot camera that covers the visible and near infrared spectrum. Fast Discrete Curvelet Transform(FDCT)[7], VGG19 [8] and ResNet 101[9] convolutional neural networks have been used to develop recognition end.

This paper is organized as follows: Section 2 focuses on different MS facial recognition systems used in the literature. Section 3 describes our Multispectral Filter Array one shot acquisition system and the method. The experimental results are reported in Section 4. Section 5 is dedicated to the discussion and the conclusion is presented in the last section.

## II. RELATED WORK

The use of multiple spectral bands improves the performance of facial recognition system, this explains the interest of researchers on MS facial recognition in recent years [5] [10] [11]. A face recognition system can be represented by four main modules: capture, feature extraction, matching and decision. The capture module is mainly based on image acquisition system that enables the acquisition of images. The acquisition system consists of one or several cameras. The feature extraction module takes the acquired images and extracts only the relevant information in order to build a new data representation. The matching module compares the set of extracted features with the features of those images stored by the system in the database during enrollment. The decision module verifies the identity asserted by a user based on the degree of similarity between the extracted features and the ones from the database. The following figure (Fig. 1) illustrates the architecture of a face recognition system.

Fig. 1. Architecture of a Facial Recognition System.

There are several facial recognition systems operating in the visible and Near InfraRed range, but in the most of the cases images were not acquired in real time.

Aboud et al. [12] proposed a face recognition system using Fusion of Multispectral Imaging to overcome the limitations of visible facial recognition. This recognition system merges features from visible, near infrared and thermal infrared images. This system did not acquire images in the capture module but used images from the Carl database for the other modules. Carl Face images Database contains visible, NIR and thermal images of 41 persons. This database had been collected with two cameras: customized Logitech Quickcam messenger E2500 with a Silicon based CMOS image sensor for near infrared image and thermal camera TESTO 880-3 (incorporating an uncooled detector with a spectral sensitivity range from 8 to 14  $\mu\text{m}$  and provided with a germanium optical lens) for visible and thermal images. Auteurs used Gabor wavelet transform for feature extraction and Support Vector Machine (SVM) for classification. Experimental results achieve a recognition rate of 96, 4%.

Y.Jin et al. [13] have developed a Coupled Discriminative Feature Learning for Heterogeneous Face Recognition. They implement a method that represents the discriminative features of the face by building an optimal filter eigenvector with the raw pixels of the image. The developed approach uses Local Ternary Patterns for encoding local patterns and cosine metrics to estimate the similarities between images. The performance of this method was tested on CASIA 2.0 NIR-VIS database.

This database is widely used in publications. CASIA NIR-VIS 2.0 was collected from 2007 to 2010 by Stan Z. Li et al.[5], it contains visible and near infrared frontal images of 735 subjects. Two cameras were used to acquire the visible and near infrared images. The visual color face images are captured using Canon A640 Camera and home-brew device were used for near infrared image acquisition. The NIR imaging device used to capture NIR image is a standard version for indoor use and under fluorescent lighting. A long pass optical filter is integrated in this camera and allows capturing images in wavelengths 720, 800, 850 and 880 nm. The spatial resolution of acquired images is  $640 \times 480$  images. Experimental results indicated that the accurate recognition rate is less than 90%.

In 2021 R. He et al. [14] have proposed a Coupled Adversarial Learning (CAL) system for semi-supervised heterogeneous face recognition. This approach has used the VIS-NIR face matching by performing adversarial learning on both image and feature levels. VIS images had been generated from the unmatched VIS-NIR images. This system did not acquire images in the capture module but used images from CASIA NIR-VIS 2.0 database for the other modules. A series of end-to-end neural network composed with 29 convolution layers with residual blocks (LightCNN-29) have been used to extract and learn features. The experimental results indicated a rank 1 accuracy from 98.6% to 99.6%.

A. Yu et al [15] have implemented face recognition system that used Generative Adversarial Networks(GANs) in the VIS and NIR. The VIS images have been generated from the NIR images. In order to reduce the domain gap between the NIR and VIS data, an attention module has been developed by the authors. This system has acquired images for visible and NIR range with two camera. A Large-Scale Multi-pose High-Quality Database of NIR-VIS images called LAMP-HQ was collected. A LightCNN-29 has been used as classifier. The performance achieved with this system has showed a rank 1 accuracy from 94.94% to 97.91%.

Song et al. [16] have implemented an adversarial discriminative feature learning framework for VIS and NIR face recognition. In order to compensate the detection gap the authors have applied the methods based on adversarial learning on both the raw pixel space and the compact feature space. This approach combines ResNet and Light CNN. The experiment has been performed on three databases: CASIA NIR-VIS 2.0 database, BUAA-VisNir [5] face database and Oulu-CASIA NIR-VIS facial expression database. Experimental results achieved give respectively for the tree databases a rank 1 accuracy of 98,15%, 95.2% and 95.5%. The BUAA-VisNir face database has been created by D. Huang et al. It contains 162 images/person of 150 persons. The images were acquired in visible and NIR range with 9 different facial expressions.

Oulu-CASIA NIR&VIS facial expressions database was set up by Chinese Academy of Sciences. It contains videos with six typical expressions i.e. happiness, sadness, surprise, anger, fear and disgust from 80 subjects captured with two imaging systems (SN9C201 & 202) which combines a NIR camera and a visible camera. This imaging system captures NIR and visible images under three different illumination conditions

normal indoor illumination, weak illumination and dark illumination. The imaging hardware works at the rate of 25 frames per second and the image resolution is  $320 \times 240$  pixels.

In order to correct misalignment problems between visible and NIR matched images P. Zao et al. [17] have developed a Self-Aligned Dual NIR-VIS Generation for Heterogeneous Face Recognition. The architecture proposed by the authors is based on GANS and allows generating semantically aligned dual NIR-VIS images with the same identity. This system has not acquired images in the capture module but has used images from CASIA NIR-VIS 2.0, Oulu-CASIA NIR-VIS and BUAA VIS-NIR. The features have been extracted with lighCNN and two encoder networks for generation tasks. A rank 1 accuracy close to 99.9% has been performed for each datasets.

M. Diarra et al. [18] have proposed the MS-FRHF (Multispectral Face Recognition using Hybrid Feature) approach for visible and thermal. They used Robotics Intelligent System (IRIS) database for feature extraction. The points of interest and the texture have been extracted respectively with the Maximally Stable Extremal Region (MSER) keys points extractor and Gray Level Co-Occurrence Matrix (GLCM). Principal Component analysis (PCA) was used to fuse the feature. Authors have concluded this approach gives the best recognition rates than those obtained in the visible and thermal infrared.

In 2020, Zhihua Xie et al. [19] have developed the fusion methods based on the local binary model and the discrete cosine transform for face recognition in the infrared and visible range. For this purpose, the low frequency information is first extracted from the near-infrared images with the discrete cosine transform and the LBP is applied to represent the discriminative features. Then the features of the visible images have been extracted with the LBP and finally a fusion has been done. Experimental results have shown that the recognition rate has been improved with this approach.

Guo et al. [20] have proposed Face recognition system using both visible light image and near-infrared image and a deep network. This system uses two different cameras, one in the visible and the other in the near infrared. The visible and near infrared features have been first extracted with the neural network. Then the authors have used the cosine distance to determine the classification score. Finally, a fusion of the classification scores has been performed. They have used HIT LAB2 and SunWin Face database to test the performance of their model. Accuracy of 99.89% and 99.56% has been achieved on the two databases respectively in weak light change.

Hu et al. [21] have presented a Discriminant Deep Feature Learning based on joint supervision Loss and Multi-layer Feature Fusion for heterogeneous face recognition. This approach implements Convolutional Neural Networks by integrating a loss function called scatter loss in order to improve the discriminating power of the learned features in depth. The features extracted by the CNNs in the different visible and near infrared bands have then been merged. The performance of the system has been tested on CASIA NIR-VIS 2.0 and Oulu-CASIA NIR-VI databases. The experimental

results have given a rank 1 accuracy of 98.5% to 98.8% on the CASIA NIR-VIS 2.0 dataset, and of 98.5% to 99.3% on Oulu-CASIA NIR-VIS database.

F. Wei et al. [22] have developed an intraspectrum discrimination and interspectrum correlation analysis deep network (IDICN) approach for facial recognition. This system has improved the performance of multispectral face recognition by including inter- and intra-spectral information. Authors didn't acquire images but have used three databases: Hong Kong Polytechnic University (HK PolyU) dataset, Carnegie Mellon University (CMU) dataset and the University of Australia (UWA) dataset. This approach consists of a set of spectrum-set-specific deep convolutional neural networks with a spectrum pooling layer. The convolutional neural networks extract features related to a set of spectra, and the spectrum pooling layer selects a group of spectra with discriminative capabilities.

The HK PolyU dataset consists of 48-subject hyper-spectral image cubes, which are acquired using CRIs VariSpec liquid crystal tunable filter (LCTF) under halogen light. The spectral range extends from 400 to 720 nm with a step size of 10 nm.

CMU database is collected with a prototype spectropolarimetric camera developed by CMU. It contains the images of 54 subjects. The hyper-spectral range is between 450 and 1090 nm with a step length of 10 nm.

The UWA dataset consists of 120 hyper-spectral image cubes of 70 subjects acquired with the VariSpec LCTF CRIs integrated with a photonic focusing camera. Each hyperspectral image cube contains 33 bands covering the spectral range from 400 to 720 nm with a 10 nm step size.

Experimental results have achieved average recognition rates of 99.76%, 100% and 99.85 respectively on the three bases.

### III. MATERIALS AND METHODS

#### A. Our One-shot Multispectral Filter Array Acquisition System

This section describes the Multispectral Filter Array one shot camera used for image database collection.

In recent years, sustained research efforts have been carried in the field of multispectral imaging systems incorporating MSFA. Multi-spectral imaging using a single camera with MSFA is an efficient way to acquire spectral data. It has the potential to promote a fast and real time multispectral imaging system. The concept of Spectral (or Multispectral) Filter Arrays has been developed recently and enables one shot multispectral acquisition with a compact camera design. Generally, Multi-Spectral filter array (MSFA) is made up recurrent patterns of filtering elements. Multi-Spectral filter array (MSFA) cameras are a new single-shot spectral imaging technology that is defined by a basic repetitive pattern composed of filter elements. Each filtering element is sensitive to a specific spectral band. Multi-spectral Filters Array are filter matrix in which each filter corresponds to a spectral band. During the technical design of the cameras the filters are carefully selected. MSFA one-shot camera architecture shows

that the MSFA overlap the camera sensor so as to cover it. The light entering the camera is filtered with a band pass spectral filters on each pixel. A MSFA aims at object property estimation and/or objective color measurement. A MSFA might be defined by its moxel, mosaic element, which corresponds to the occurrence of a pre-defined pattern that consist of a set of filters arranged geometrically in a relative manner [23]. The moxels or multispectral pixels are the smallest patterns in the MSFA. An overview of the global approach is shown in following figure (Fig. 2).

Fig. 2. Global Scheme of MS Imaging System with MSFA.

Multispectral Filter Array Camera was used to create the multispectral images database. The oneshot acquisition system has been designed in the Electronics, Computer and Image (LE2I) Laboratory which is now ImViA (Imaging and Artificial Vision) during UE H2020 project called EXIST (EXtended Image Sensing Technologies). It is a compact and lightweight acquisition system that integrates a single Viimagic 9220H sensor, MSFA for one-shot imaging system, Optic lenses, Electronic board for driving the sensor and Camera board for image acquisition. In order to correct the linearity of the sensor and also to measure the spectral sensitivity, a characterization of the CMOS sensor has been made before mounting the Multi-Spectral filter Arrays. The MSFA has been selected carefully considering a regular distribution of pixels in the moxel. Our personalized filter matrix was built using SILIOS technologies. SILIOS Technologies has developed the COLOR SHADES® technology, which use Fabry-Perot interferometer to manufacture multispectral transmittance filters. This technology is based on the combination of thin film deposition and micro- / nano-etching processes on a fused silica substrate. Standard micro-photolithography steps are used to define the cell geometry of the multispectral filter. COLOR SHADES® provides band pass filters originally in the visible range from 400 nm to 700 nm. SILIOS has developed filters in the NIR range in collaboration with LE2I (ImViA) laboratory, combining their technology with a classical thin film interference technology to realize our filters. The MSFA system, integrated into a camera with dedicated hardware and software computations, allows operating in real-time application with 30 fps. The filters used overcome the problems caused by lighting variation, motion blur noise and SNR noise which severely affect the performance of facial recognition systems using CMOS. These are 8 optimal filters selected in the wavelengths {685, 720, 770, 810, 835, 870, 895, 930} (in nm) thanks to a technical study carried out at LE2I laboratory. Fig. 3 illustrates the spatial distribution of moxel.

Fig. 3. Final Moxel of MSFA.

This acquisition system is a light robust, broadband multispectral system which tends to measure the physical properties of the object. It is also a real time system which covers visible and near infrared spectra (650 to 950 nm). The MSFA integrated in our acquisition system has a small moxel 4x4 with 2 pixels per band and the size of filter pitch is 5x5  $\mu\text{m}^2$ . At each acquisition, the MSFA one shot camera provides a best resolution of raw or mosaic image of size 2072 x 1104 pixels in which the values of every channel are accessible at each pixel according to the MSFA. The missing channel values are there after estimated by demosaicking process. In order to provide an optimal solution for the loss of spatial resolution inherent to MSFA, specific algorithms have been developed for multispectral demosaicking. Indeed, the demosaicking process must be associated with the design of the MSFAs otherwise the loss of image resolution could be critical. As the acquisition system is an MSFA one shot camera, it privileges spectral resolution. The Fig. 4 presents the MSFA camera.

Fig. 4. MSFA One-Shot Camera.

### B. Data Collection

Multispectral face images were collected over two years in Imaging and Artificial Vision (ImViA) Laboratory in Faculty of Science and Technology of Burgundy University in France. The acquisition room is a black room, dedicated to MS imaging. The photos were taken with an illuminant light with different orientations. This light illuminates the subject's face to be photographed. The light is oriented from left to right and vice versa during the acquisition. The distance between the camera and the subject to be acquired is 1 meter. The relative position of camera is shown in Fig. 5.

The MS images database have been acquired in winter 2020, winter 2021 and spring 2021. Participants were made up of residents and international students, and 75% of subjects agreed to have their photo posted. They are men and women of all ages, black and white. Participants are from different continents namely Europe, Asia, Africa, Arabic and African. The multi-spectral image database named EXIST MS database contains faces images of 103 subjects. Face images MS database is structured as follows:

- All images are tiff format and size 2072 x 1104;

- Our database contains 20 different mosaic faces images per subject;
- 20x8 demosaic faces images per subject.

In total our MS images database contains 103x20x8 (16 480) MS images.

The following figure (Fig. 6) shows some mosaic face images of a subject in the database.

Fig. 5. Acquisition Set-up in the Black Room.

Fig. 6. Sample Images from our MS Database.

### C. Image Demosaicking Algorithm

Having used a multispectral acquisition system which provides a mosaic image, a demosaicking is necessary to

generate multi-band images. In fact, a mosaic or raw image is of size  $(X \times Y)$  pixels, in which a single band  $k \in \{1, \dots, K\}$  is refers to the value of each pixel  $p$  depending on the MSFA structure. Image demosaicking is a process that separates mosaic or raw images into multispectral images according to filter number in the MSFA. Before the demosaicking, a strip extraction was done. It consists of multiplying the mosaic image by different binary masks  $M^k(x,y)$ ,  $k \in \{1,2, \dots, K\}$  [24](pp. 31-34).

These masks have the value 1 at the positions where the component is available, and 0 at the other positions. Each plane component is obtained after multiplying the mosaic image by the corresponding mask  $M^k$ .

$$M^k_{(x,y)} = \begin{cases} 1 & \text{si } (x \bmod \sqrt{K}) + (y \bmod \sqrt{K}) \times \sqrt{K} = k \\ 0 & \text{sinon} \end{cases} \quad (1)$$

In this case, the multiplication of the mosaic image by each mask allows us to obtain 8 planes of shifted images in which only one component is available at each pixel. Each mask corresponds to an image plane  $I'^k$ .

$$I'^k = I \odot M^k \quad (2)$$

Where  $\odot$  denotes the element-wise product and  $M^k$  is a binary mask defined at each pixel  $p$ .

Bilinear interpolation method is used for multispectral demosaicking. This method enables to estimate the missing in each pixel. Bilinear interpolation can be expressed as a resampling technique based on distance weighted average of the four nearest pixel values to evaluate each missing pixel value. Bilinear interpolation is a succession of two linear interpolations, each in one direction. The linear interpolations can be performed in multiple directions. For a missing pixel  $P(i,j)$  at position  $(i,j)$ , the linear interpolation is defined as follows:

- Diagonally

$$P(i,j) = \frac{1}{4} \sum_{(m,n) \in \{(-1,-1), (-1,1), (1,-1), (1,1)\}} p(i+m, j+n) \quad (3)$$

- Vertically

$$P(i,j) = \frac{1}{2} \sum_{(m,n) \in \{(-1,0), (1,0)\}} p(i+m, j+n), \quad (4)$$

- Horizontally

$$P(i,j) = \frac{1}{2} \sum_{(m,n) \in \{(0,-1), (0,1)\}} p(i+m, j+n) \quad (5)$$

The multispectral image demosaicking using bilinear interpolation also consists in convolving each component plane obtained by an H filter. This filter is determined as a function of the spatial distance between the neighbors from the central pixel.

Two filters H1 and H2 (Fig. 7) were used to do the convolution. The interpolated image band is defined by

$$I^k = I'^k \odot H \quad (6)$$

With  $H=H1$  or  $H=H2$

1/9	2/9	1/3	2/9	1/9
2/9	4/9	2/3	4/9	2/9
1/3	2/3	1	2/3	1/3
2/9	4/9	2/3	4/9	2/9
1/9	2/9	1/3	2/9	1/9

1/5	1/4	1/5	1/3	0
0	1/3	1/5	1/4	1/5
1/5	1/3	1	1/3	1/5
1/5	1/4	1/5	1/3	0
0	1/3	1/5	1/4	1/5

Fig. 7. Filter H1 and H2.

To estimate the missing pixel value  $P(i,j)$ , the image  $I^k$  is convolved with each of the H1 and H2 filters. If V1 and V2 are convolution results then the missing pixel value is defined by average of V1 and V2. This process is used to estimate each missing pixel in  $I^k$ . The figure (Fig. 8) shows the missing pixel value estimation in demosaicing process.

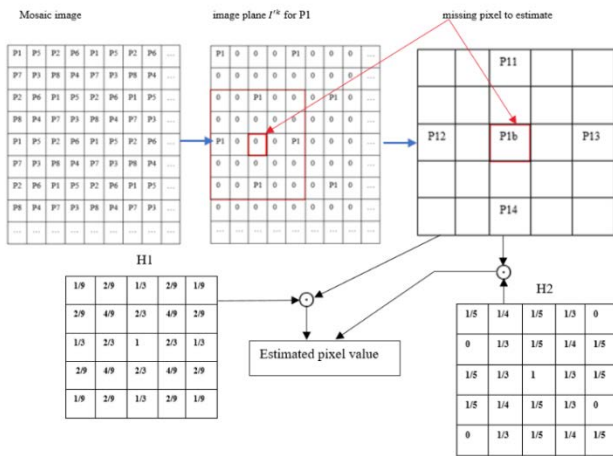

Fig. 8. Missing Pixel Estimation for Demosaicing Process.

The image demosaicing generates 8 images belonging to the wavelengths {685, 720,770, 810, 835, 870, 895, and 930} (in nm). The figure (Fig. 9) illustrates the demosaicking images process.

Fig. 9. The Process of Multispectral Images Demosaicking.

#### D. Methodology

This section describes the algorithms used for facial recognition with the Multi-Spectral Filters Array camera described above. Fast Discrete Curvelet Transform (FDCT) and Convolutional Neural Networks are used to implement the facial recognition system. In order to exploit the important information contained in each spectral band we first use a

fusion at the image level with the FDCT. First, the image-level fusion method is implemented with FDCT. Then, VGG19 and ResNet 101 neural networks are used to perform the recognition. The following figure (Fig. 10) illustrates the proposed method:

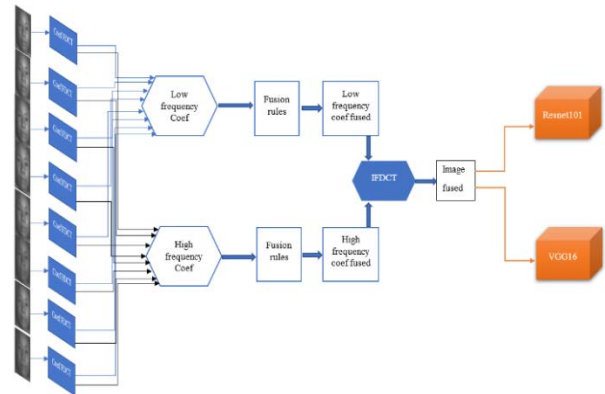

Fig. 10. Bloc Diagram of the Proposed Face Recognition Method using MSFA One-shot Camera.

The Fast Discrete Curvelet Transform (FDCT) is a wavelet transform that decomposes an image in low and high frequency. FDCT adopts local Fourier transform for the frequency domain decomposition. First, each of the eight demosaic image was decomposed with the FDCT. Then the low frequency coefficients are merged together and so for the high frequency coefficients. Inverse Fast Discrete Curvelet Transform was applied to obtain a merged image containing the information of all bands. Finally transfer learning for VGG19 and ResNet 101 are used to classify the images fused with FDCT method.

#### IV. EXPERIMENTS AND RESULTS

EXIST is the image database acquired with the described acquisition system and the one used evaluation purpose.

All the images are acquired from 20 different positions per person; in total 2000 images in the multi-spectral images database are taken.

Experimentations are carried out on Microsoft System windows, version 2010, with two computers. The first one was equipped with an Intel (R) Core (TM) i7-8565U CPU, 8 GB of RAM memory. The second has a graphical processing unit (GPU) NVIDIA Quadro P400 with 32GB of Random Access Memory (RAM). All the code are developed in the programming language of Matlab 2020 and Python 3.7.

Table I describes the training parameters for VGG19 and ResNet101.

To analyse the results, the following performance evaluation metrics have been calculated: accuracy, precision, recall, F1 score, Matthews Correlation Coefficient (MCC) and Means Square Error (MSE).

An accuracy indicates the percentage of correct predictions.

$$accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (7)$$

TABLE I. PARAMETERS USED IN THE TRAINING PROCEDURE

Parameters	CNN	
	VGG19	ResNet101
Batch size	32	16
Optimization algorithm	SGD <sup>a</sup>	ADAM
Learning rate	0.0001	0.0001
Epoch number	20	20

<sup>a</sup>. Stochastic Gradient Descent

Where  $TP$  (True Positive),  $TN$  (True Negative),  $FP$  (False Positive),  $FN$  (False Negative).

The precision is the proportion of true positives out of all detected positives.

$$precision = \frac{TP}{TP+FP} \quad (8)$$

The recall is the number of true positives that are correctly classified.

$$recall = \frac{TP}{TP+FN} \quad (9)$$

Component F1 score includes recall and precision and is calculated as

$$F1_{score} = \frac{2*precision*recall}{precision+recall} \quad (10)$$

The Matthews Correlation Coefficient (MCC) is the method of calculating correlation coefficient between real and predicted values. MCC is more informative score and give best result in binary classification assessment [25]. The range of values of MCC is between -1 and 1. A model with a score of 1 is a perfect model and -1 is a poor model.

$$MCC = \frac{(TP*TN)-(FP*FN)}{\sqrt{(TP+FP)*(TP+FN)*(TN+FP)*(TN+FN)}} \quad (11)$$

The Mean Squared Error (MSE) allows to calculate error between predict values  $\hat{y}$  and reals value  $y$ .

$$MSE = \frac{1}{N} \sum_{i=1}^N (y_i - \hat{y}_i)^2 \quad (12)$$

Where N is the number of samples we are testing against.

The different metrics calculated allow for a better interpretation of the results. The accuracy of a model predicts the percentage of all persons that can be recognized by the model. The recall indicates the number of correct predictions that were actually recognized.

The fusion rules such as min, max and average are used to obtain the images. Three types of experiments were done: a first one with the images obtained with FDCT and the min fusion rule, a second one with the images obtained with FDCT and the max fusion rule and a third one with the average fusion rule.

In Table II and Table III, the performance of the VGG19 and ResNet101 model for min, max and average fusion are listed respectively.

TABLE II. VGG19 RESULTS

Fusion	Metrics				
	Precision	MSE	F-score	Recall	MCC
average	1.0	2.80e-07	1.0	1.0	1.0
min	0.9849	7.96e-07	0.98	0.98	0.98
max	0.9870	6.76e-07	0.98	0.98	0.98

TABLE III. RESNET101 RESULTS

Database	Metrics				
	Precision	MSE	F-score	Recall	MCC
average	0.99	4.91e-10	0.99	0.99	0.99
min	0.97	7.98e-10	0.97	0.97	0.97
max	0,96	91e-10	0,96	0,96	0,96

Note that the two models VGG19 and ResNet101 have been trained with the images of the databases, taking into account different batches size 8, 16 and 32.

By comparing the different metrics calculated on the two neural networks, the results show that the performance of average fusion rule method are superior to those of min and max fusion rule.

Table IV describes the recognition rate of stat of art recognition and the proposed system.

TABLE IV. THE RECOGNITION RATES

Acquisition system	Recognition methods	Recognition Rate
Visible camera + NIR camera + thermal camera	Gabor wavelet transform and Support Vector Machine (SVM) [12]	96.4%
Visible camera and NIR camera	Local Ternary Patterns and cosine metrics [13]	90%
Visible camera and NIR camera	LightCNN-29 [14]	98.6% to 99.6% <sup>a</sup>
Visible camera and NIR camera	LightCNN-29 [15]	94.94% to 97.91%.
Visible camera and NIR camera	ResNet and LightCNN-29[16]	98.15%, 95.2% and 95.5% <sup>b</sup>
Visible camera and NIR camera	lighCNN and two encoder networks[17]	99.9%
Visible camera and NIR camera	Neural Network and cosine distance[20]	99.89% and 99.56%
Visible camera and NIR camera	CNN[21]	98.5% to 98.8% and 98.5% to 99.3%
Hyper-spectral camera	deep convolutional neural networks[22]	99.76%, 100% and 99.85
EXIST camera	FDCT and VGG19	100%
EXIST camera	FDCT and ResNet 101	99%

<sup>a</sup> Results achieved between two values

<sup>b</sup> Results achieved on different databases

Table IV indicates that most facial recognition systems in the visible and NIR range use multiple cameras. Depending to the image database used, the recognition rate range 95.3% to 100%. The rate of 100% was reached with the deep convolutional neural network algorithm. In general systems using neural networks algorithm have a rate close to 100%. In this case, depending to the recognition algorithm, the rate is range 90% to 100%. The face recognition systems that use an acquisition system integrating Multispectral Filters Arrays (MSFA) achieve perform as well as those using several cameras.

## V. DISCUSSION

In this article, face recognition based on MSFA oneshot camera were demonstrated. Most previous studies in the literature used multiple cameras and Convolutional neural to extract features for face identification. Y.Jin et al. in [13] used multiple cameras with Local Ternary patterns, cosine metrics and achieve recognition rate of 90%. The recognition systems presented in the literature that are based on Gabor wavelet Transform and Support Machine Vector (SVM) achieve a recognition rate of 96.4% [12]. The recognition systems based on Convolutional Neural Network [14],[15],[16],[18],[22] achieve respectively accuracy in [98.6% - 99.6%], [94.94% - 97.91%] and [98.15%, 95.2%,95.5%], [99.89%, 99.56%],[98.5%-98.8%, 98.5%-99.3%] depending on database. Also [23] used hyperspectral camera with neural networks and get [99.76%, 100%, 99.6%] accuracies on three different databases. Results and experiments of the facial recognition using MSFA oneshot camera achieve accuracies of 99% and 100% with respectively Resnet101 and VGG19.

The comparison of the results shows that the different facial recognition algorithms implemented give good performance depending on the images and methods used. The proposed system reaches one of the best performances. But also because of its camera and its algorithms, it is the only system which proposes a real time acquisition of images.

## VI. CONCLUSION

This paper presents a new multispectral facial recognition system using one shot multispectral imaging systems integrated Multispectral Filters Array for acquisition. It is a one-shot acquisition system that operates in real time on the visible and NIR spectra. A multispectral database containing images with spectral information has been created for this end. This recognition system is based on the Fast Discrete Curvelet Transform, ResNet 101 and VGG19 Convolutional Neural Network. Experimental results show that face recognition systems using MSFA cameras perform as well as those using multiple cameras. This system is however more interesting as it is more economical, technically reliable and especially equipped with a real time acquisition system.

In future work, the image database will be extended; other multispectral demosaicing and recognition algorithms will be implemented.

**Abstract**—COVID-19 has altered the way businesses throughout the world perceive cyber security. It resulted in a series of unique cyber-crime-related conditions that impacted society and business. Distributed Denial of Service (DDoS) has dramatically increased in recent year. Automated detection of this type of attack is essential to protect business assets. In this research, we demonstrate the use of different deep learning algorithms to accurately detect DDoS attacks. We show the effectiveness of Long Short-Term Memory (LSTM) algorithms to detect DDoS attacks in computer networks with high accuracy. The LSTM algorithms have been trained and tested on the widely used NSL-KDD dataset. We empirically demonstrate our proposed model achieving high accuracy (~97.37%). We also show the effectiveness of our model in detecting 22 different types of attacks.

**Keywords**—Cybersecurity; Cyber-attack; DDoS attack; machine learning; deep learning; recurrent neural networks; long short-term memory

## I. INTRODUCTION

COVID-19 pandemic has caused a great deal of fear, worry, and a significant shift in our way of life. Organizations have had to adapt to the requirement for remote working on a large scale and rapidly. Because COVID19 has produced or expanded applications and use cases of digital technologies, this pandemic is proven to be a motivator for digital transformation. Despite the pandemic, the world can still interconnect with each other through a network with rapid development in IoT4.0 technologies. This involves millions of data bytes being produced, processed, converted, exchanged, or shared and utilized to produce an outcome in specific applications. This involves the security elements to protect sensitive data and the privacy of each individual user of cyberspace or network. Distributed Denial of service (DDoS) is a type of attack in which the victim's resources are depleted, rendering them unable to handle valid requests. Nonetheless, the number of DDoS attacks and the amount of DDoS traffic are increasing, requiring more research into the detection of such security risks. Therefore, the use of machine learning to ensure the intensity of this data is very important. In this study, we examine network traffic behaviors for cyber detection by the application of various machine learning algorithms to improve the accuracy of DDoS attack detection.

DDoS attacks are common network exploitation type of cyber-attack. The attacker creates network exhaustion to legitimate users by causing a computer or network system to

crash, stopping them from accessing server or the Internet, either temporarily or continuously. According to Singh et al. [1], the DDoS attack is one of the most common and major cyber-attacks. Ray et al. [2] also states that more advanced technology is needed to improve DDoS attack detection in computer networks. Since detecting DDoS attacks is a difficult task before any mitigation measures can be performed, cybersecurity fundamentals are required to design a system that can detect threats. DDoS attacks were initially detected by traffic engineers using rule-based approach. This strategy have fallen behind the dynamic and evolving nature of DDoS attacks. Academics and industry are researching the prospect of integrating machine learning into DDoS detection process because of their immense potential and success in various Computing domains. Threats can be recorded more rapidly and correctly with machine learning algorithms, such as Naïve Baysian, K-Nearest Neighbor, Random Forest and Recurrent Neural Network.

In this study, we focus on exploring the effectiveness of deep learning algorithms to improve the accuracy of DDoS attack detection in order to better analyze network traffic activities for cyber threat detection.; Also, we aim to discover a feature selection strategy that, when combined with a machine learning system, can improve DDoS detection accuracy rates. Our selected deep learning algorithm is based on a Recurrent Neural Network (RNN) classifier to distinguish between normal and attack traffic.

The remaining of this paper is organized as follow: Section II describes the literature review; Section III describes our methodology. The results from our experiments are presented in Section IV and we discuss our finding in Section V. We compare our results with previous research in Section VI. In Sections VII and VIII we conclude the paper and outline our future work, respectively.

## II. LITERATURE REVIEW

Recent research has demonstrated the effectiveness of machine learning application in detecting DDoS attacks. In this section, Sambangi et al. [3] developed a machine learning model to predict DDoS and botnet attacks by using machine learning algorithm with multiple linear regression. They used the most widely used CICIDS 2017 benchmark dataset with entire packet payloads in pcap format, which is extensively used in labeled network flows. They also demonstrated that their machine learning model could detect DDoS attacks using

the regression analysis technique. Yuan et al. [4] showed that Recurrent Neural Network surpasses Random Forest in terms of generalization. the effectiveness of deep learning, where reduced the error rate from 7.517% to 2.103% using an ISCX2012 dataset, compared to traditional machine learning methods. They experiment uses the ISCX2012 dataset, made available by the University of New Brunswick in 2012. Guerre- Manzanares et al. [5] proposed the concept of employing hybrid feature selection models to lower the size of the feature to achieve more accurate results. The dataset contained 115 features. To limit the number of features, the filter; wrapper; and hybrid models were used for choosing the potential feature. These features were then loaded into a K-Nearest Neighbor (KNN) and Random Forest model, both of which had a high accuracy of 99%.

Sabeel et al. [6] presented the idea of using two deep learning models (deep neural network and long short-term memory) for binary prediction of unknown Denial of Service (DoS) and DDoS attacks. The models were evaluated on the benchmark CICIDS2017 dataset. According to Sabeel et al. [6], the models fail to detect unknown threats accurately. However, after retraining the deep learning models by merging newly synthesized datasets with the old ones, the True Positive Rate (TPR) achieved was 99.8% and 99.9% for DNN and LSTM, respectively. Rusyaidi et al. [7] demonstrated deep learning effectiveness in DDoS detection. Elsayed et al. [8] demonstrate that combining RNN with an autoencoder allows input traffic to be classified into two categories: normal and malicious. Elsayed et al. [8] and Catak et al. [9] have used Deep learning to deal with a high degree of complex nonlinear interactions. They were making it a possible tool for identifying network attacks. By using 70% of the input data for training, Elsayed et al [8]. model showed the best results when compared to existing traditional machine learning techniques, resulting in 99% accuracy in their proposed method.

The experiment conducted by Gadze et al. [10], they used RNN and LSTM in the software-defined networking (SDN) controller to identify and mitigate DDoS attacks. It was gathering certain network parameters when operating in a normal and also when subjected to DDoS attack. The number of packets received and transferred at each switch, the packet count (number of packets per flow), the protocol type (TCP, UDP, or ICMP), the Source IP, and the Destination IP were some of the main features. They looked at three different possibilities. In the first case, 80% of the data was used for training, while 20% was used for testing. In the second instance, 70% of the data was used for training and 30% for testing. In the third situation, 60% of the data was used for training and 40% for testing. RNN and were used for detecting and mitigating DDoS attacks. The 70/30 (train-test ratio) split yields improved model accuracy compared to the 80/20 and 60/40 split ratios.

Ugwu et. al. [11] compared the results of traditional machine learning algorithms such as Naive Bayes (NB), Decision Tree (DT), and Support Vector Machine (SVM). The suggested LSTM and Singular Value Decomposition (SVD): deep learning algorithms demonstrate a significant improvement. Data pre- processing is performed on the network data, which includes data normalization and feature

conversion methods. The normalization method requires limiting network feature values to a narrow range of values and feature conversion method requires transforming non-numeric feature values to numeric. Kasim [12] used dimensional reduction features in the autoencoder (AE) model and Support Vector Machine (SVM) classifier to classify encoded data as DDoS or normal. AE-SVM successfully distinguishes between normal and DDoS attack traffic. The min-max method was used to normalize their data between 0 and 1, and the training vectors for the AE model were created. With the encoding process, the trained model delivered feature learning and feature reduction. The results showed that the AE-SVM method performed well in terms of low false-positive DDoS detection rates and fast anomaly detection.

Gormez et al. [13] demonstrate that by using traditional machine learning algorithms, ensemble, and deep feature extraction methods, Bayesian optimization is faster than traditional grid search optimization. However, it requires more computing resources than the train-test step. The scikit-library of Python is used to implement the experiment classification methods. Network traffic packet data was captured and converted into connection records. They used three types of features: basic features, time-based features, and connection-based features. Basic features are characteristics that can be easily derived from packet headers by counting specific packet properties for the connection. Before evaluating a model's performance, hyper-parameter optimization allows researchers to fine-tune its hyper-parameters. The Bayesian optimization process is used to create samples of hyper-parameter values to locate the optimums.

Hossain et al. [14] highlighted that one of the most important criteria in evaluating the performance of network attack detection systems is the availability of labeled dataset. According to their experimental data, the optimal hyper-parameter combinations were used for constructing their robust intrusion detection system. LSTM multiclass classification was used in the experiment, with 80% of the dataset used for training and 20% for testing. Hyper-parameter adjustment was also used to investigate the performance. The experiment results demonstrated that deep learning models (LSTM) have become emerging technology for network attack detection systems.

### III. METHODOLOGY

#### A. Dataset Preparation and Pre-Processing

The NSL-KDD dataset from the University of New Brunswick Lab, which includes 125,973 network packets with 22 different types of attacks, as shown in Table I.

According to Tang et al. [15], one of the most up-to-date datasets for Intrusion Detection System (IDS) evaluation is the NSL-KDD dataset. There are 41 features in this dataset, divided into three categories: fundamental, content-based, and traffic-based features. DoS, probe, U2R, and R2L are the four types of attacks. We use the NSL-KDDTrain+ dataset train our DDoS detection system, while the NSL-KDDTest+ dataset is used to test it. As a result, the NSL-KDDTest+ dataset is a useful indicator of a model's zero-day attack resistance. To distinguish between genuine and malicious traffic, the use of

DoS as a basis is utilized. Table II summarizes the dataset's features. These features are not ordered on a scale. These attributes are further passing to the next phase for normalization.

A dataset may have missing values, irrelevant features, categorical data, or other flaws that prevent a machine learning algorithm from analyzing it. In some cases, standardization, data normalization, and other issues might prevail in some circumstances. The NSL-KDDTrain+ customized datasets have missing values, irrelevant features, and an issue with the categorical column. The following data cleaning and preparation processes were included in this project and will be discussed in the paragraph below. The selected dataset contains 4,898,431 data records.

There are a few rows/columns in the customized dataset that do not have a number (NaN) or have infinite values. In the NSL-KDD dataset, not all values are filled, and some have strings. Research made by Nimbalkar et al. [17] shows that the captured network traffic is unsuitable for machine learning models due to noise, which includes NaN and missing data. These settings must be fixed before any further operations can be performed. To address the problem of NaN values, a variety of approaches can be used, as stated in Nimbalkar et al. [17]. One method involves removing rows or columns with a particular number of NaN values, while the other approaches involve replacing a missing value with another value, such as the mean, median, mode, or other statistical measures of a column, a row, or a group of data. The selection must be made wisely based on the information available about the dataset. We are replacing the NaN values with mean and median at the features in this project since there are some features that have missing values. Some columns do not include the information needed to classify traffic as normal or malicious. As a result, constant columns are useless for any detection process. In the dataset, there is one attribute, num\_outbound\_cmds, which is always 0 for all rows in the training and test data. We remove this attribute because it could otherwise result in performance degradation and unnecessary complications. Therefore, for algorithms that demand numerous samples of one or more-time steps and features, we reshaped two-dimensional data where each row represents a sequence of three-dimensional array.

TABLE I. 22 DIFFERENT TYPES OF ATTACKS ALZHRANI ET AL. [16]

Attack Categories	Training Set Attack Names	Test Set Attack Names
DoS	Back, land, Neptune, pod, smurf, teardrop	Back, land, Neptune, pod, smurf, teardrop, (mailbomb), process table, udpstorm, apache2, worm

Each sequence has several time steps, each with one observation which is a feature. There are enough data records in the NSL-KDD dataset for training and testing. The availability of data records and the lack of redundant records, which can prevent false detection of DDoS attack, help in improved learning accuracy. After the dataset had been cleaned and pre-processed, we trained and tested LSTM and RNN algorithms. The dataset is split to train and test sets. These sets are necessary for training the estimator and subsequently evaluating the performance of the associated model. In this project, we use NSL-KDDTrain+ for training and NLS-KDDTest+ for testing. However, a common practice is to split for training and testing machine learning algorithms, as has been done by Rusyaidi et al. [7] and Gadze et al. [10].

Creating a model for classification or other similar tasks is at the basis of machine learning-based work. This is what the training phase accomplishes. The training dataset, produced before in the data split phase, is used to train a machine learning algorithm on a section of the whole dataset. An algorithm that has been trained produces a model that has learned from the data. There are a variety of classification estimators available. In this work, RNN and LSTM algorithms were used. These estimators were chosen for their ease of use, widespread use in the literature, and solid performance in related work by Yuan et al. [4], Elsayed et al. [8] and Gadze et al. [10].

### B. Deep Learning Model Development

Traditional feedforward neural networks have the problem of assuming data to be unrelated. The feedback loops of the hidden units are the major difference between a RNN and a feedforward neural network. RNNs can process a sequence of inputs and save their state while processing the next sequence of inputs in deep learning. The essential information is stored in the node's memory and will be used for learning in future time steps as shown in Nazih et al. [18]. However, RNN has some issues remembering long-term memories as stated in Staudemeyer et al. [19]. Thus, it does not work well with long sequences. As a result, problems with RNNs such as vanishing gradient and short-term memory, can be solved using a type of RNN known as Long Short-Term Memory Networks (LSTM).

According to Laghrissi et al. [20], LSTM is a Recurrent Neural Network that can recall more context information than RNN and select what information is significant and not important by using distinct cell states. Different gates and a cell state are included in the LSTM. Althubiti et al. [21] explain that LSTM has a sigmoid function that produces numbers between 0 and 1. If the activation function's value is 0, the information is lost; if the value is 1, the information is saved. The input gate changes the state of the cell. The previous hidden state and the current input are sent into the input gate. The tan and sigmoid activation functions are included, as well as their multiplied values. The cell state is now computed by adding the output of the input gate point by point. Finally, the output gates determine the value of the next concealed state.

The LSTM algorithm overcomes the limitation of RNNs by learning long-term dependencies. Another distinction is that, whereas RNNs have only one neural network layer.

LSTM has four neural network layers that interact with each other. In this project, the input and embedding layers are used first, followed by one LSTM layer with dense layers as depicted in Fig. 1. Note that mean absolute error is used as loss function, Adam as optimizer function, Accuracy as performance metrics.

LSTM is particularly suited for data sequence applications because of its unique design. Fig. 1 shows the model looks up the embedding for each character, converts two-dimensional data into a three-dimensional array, executes the LSTM batch size, timestep, and LSTM units with the embedding as input, then applies the dense layer to generate result accuracy prediction results. Many previous research Laghrissi et al. [20], Althubiti et al. [21], Gadze et al. [10], and Sabeel et al. [6]

indicated that LSTM is an effective approach for learning long-term dependencies and efficiently representing the relationship between current occurrences and historical events. In this paper, we adopted LSTM for the design of our deep learning architecture.

### C. Training and Testing Proposed LSTM – RNN Model

Feature selection is a key issue in machine learning projects. Guerra-Manzanares et al. [5] highlighted that one aspect of dimensionality reduction is feature selection. Not all the features in a dataset are equally essential for detecting the attack. In many cases, increasing the number of characteristics above a particular threshold has no discernible effect on classification performance. It simply adds to the complexity and delays in performance. Not only that, but it may also lead to overfitting and a decline in classification performance. As a result, we look for a minimal number of features that can appropriately identify the traffic in a dataset wherever possible. For this, we use the wrapper technique, namely correlation feature selection, which is supported in Scikit-learn.

The easiest strategy to train a model is to train the specific attack types to avoid being attacked by the same sort of attack. The 22 various forms of attacks (as shown in Table I) were utilized for training the model to reinforce it. The attributes of each attack have distinct values. These features and attack types were part of the training set, which was 80% of the full NSL-KDDTrain+ dataset. We use 20% of the NSL-KDDTest+ database for testing our model. The test set is separate from the training set.

### D. Proposed Model Architecture

Fig. 2 shows the main components of the proposed system: the pre-processing, adaptive attribute selection, and classification of DDoS attack type. The procedure of subsystems is divided into three stages:

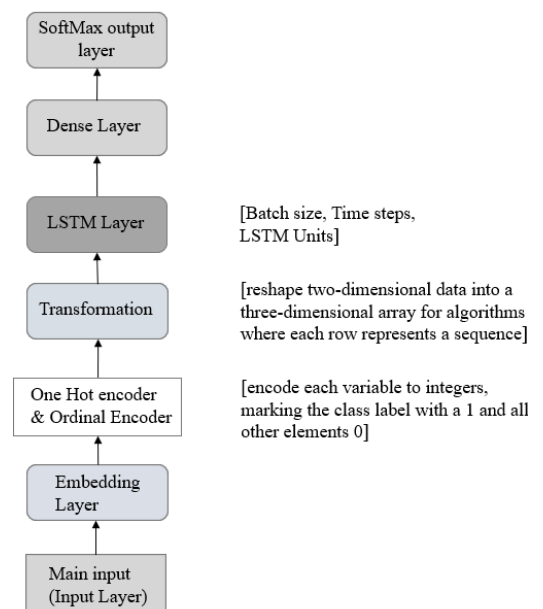

Fig. 1. The Proposed System Architecture representing each Layer.

Fig. 2. The Main Components of the Proposed System Architecture with Representing the Processing Stage.

Stage 1: The Pre-processing stage involves collecting and normalizing attributes from network traffic. Data is separated into subgroups for training and testing. 80% of the data in NSL-KDDTrain+ is set as a training dataset for use in attribute selector (Stages 2), while the remaining 20% of the data in NSL-KDDTest+ is set to test dataset for use in Stage 3.

Stage 2: Various automatic threshold procedures are used in the Attribute Selection Subsystem to determine the minimum number of attributes.

Stage 3: classification and detection of DDoS attacks.

In order to have a more practical structure of the results, all of the experiments were organized into three stages, as shown in Fig. 2. Two experiments were carried out in Stage 1. These tests were conducted using estimators set to their default settings. No extra parameter tuning or feature selection work was done here; instead, a basic percent split technique was applied. A series of feature selection experiments were carried out in Stage 2. Once again, a percent split technique was applied without taking cross-validation into account. In Stage 2, multiple experiments comprising a feature selection operation were carried out.

Finally, the classification is in charge of detecting traffic data as DDoS in Stage 3. The results of stages 1, 2, and 3 were successfully achieved. The proposed machine learning model improved the DDOS attack detection approaches and increased the DDOS detection accuracy with a combination of features selection, adam optimizer, mean absolute error, oneHotEncoder strategy. Hence, there are test accuracy results after being implemented in the module. In the sections below, discussions are included that go along with it.

#### IV. EXPERIMENTAL RESULTS

We have implemented our deep learning architecture in TensorFlow with Keras backend. We used the mean absolute error approach to verify the model's loss while learning the deep neural network, which comprises two hidden layers. The "Adam" optimization function was used. "one-hot encoder" and "Ordinal Encoder" libraries from the "Sklearn" library also have been used to convert order-like values to numeric numbers. We trained the model with 150 epochs with a batch size of 44.

The training accuracy of the model used the sample loss and accuracy using a batch size of 44, as shown in Fig. 5. We have experimented with varying learning rates, but the selective learning rate of 0.013 produced the best result in our experiment. After 150 epochs, where the training and validation performance converged, the model achieved the highest training accuracy of 98.21% and 0.0211 error rate. Fig. 3 shows the training and validation loss, and Fig. 4 shows the training validation accuracy.

Fig. 5 illustrates training accuracy and loss value of the model during train phrase. We have tested the model on test data, the model performance tested on the test set produced 97.37% accuracy as shown in Fig. 6.

## V. RESULT

The NSL-KDD dataset, on the other hand, was utilized to test this approach. The proposed machine learning-based categorization solution for DDoS attacks has high accuracy in testing. From the results of the trained model, it was observed the proposed model's accuracy is 98.21%, which is almost a perfect method to prevent and protect the 22 different types of attacks, including DDoS attacks. Moreover, the LSTM evaluation model generates a 97.37% accuracy in the test set, the algorithm fits the patterns of the dataset with a 97.37% accuracy.

## VI. COMPARISON OF RELATED WORK

Table III illustrates the comparison results of the accuracy between the proposed LSTM model with various deep learning methods using the same NSL-KDD dataset. Alkahtani et al. [22] conducted an experiment in which they chose the essential network features. To detect the anomaly in cybersecurity threats, these features were analyzed by classifying algorithms. SVM and KNN algorithms and deep learning based on the LSTM-RNN model were used to develop machine learning models. When compared to the KNN and LSTM, the SVM method produces better results. In the KDD Cup '99 and NSL-KDD datasets, the SVM method performed better than the LSTM-RNN and KNN methods. Their deep learning technique, based on the LSTM-RNN algorithm, had a high accuracy of 93.55%, but it couldn't surpass SVM's performance. Furthermore, they split the data into 70/30 train-test ratios in their experiment, while the proposed model utilized an 80/20 train-test ratio. As a result, the 80/20 split ratio produces better model accuracy than the 70/30 split ratio used in the LSTM-RNN algorithms.

TABLE III. ACCURACY COMPARISON FOR VARIOUS DEEP LEARNING TECHNIQUE WITH PROPOSED MODEL USING NSL-KDD DATASET

Authors	Technique	Accuracy testing model (%)
Alkahtani et al. [22]	LSTM-RNN. Support Vector Machine (SVM). K-Nearest Neighbor (K-NN).	93.55 (LSTM RNN) 96.53 (SVM) 87.65 (KNN)
Tang et al. [15]	Gated Recurrent Unit Recurrent Neural Network (GRU-RNN)	89.00
Niyaz et al. [23]	Self-taught Learning (STL), a deep learning-based technique	88.39
Ugwu et al. [11]	LSTM + SVD	90.59
Proposed model	LSTM-RNN	97.37

The "Adam" optimizer for DNN optimization was utilized in our study, which reduces the loss and optimizes the model. To transform order-like values to numeric numbers, the researcher uses the "OneHotEncoder" and "OrdinalEncoder" libraries. Despite their excellent performance, our proposed model has achieved better outcomes with a testing accuracy model of 97.37% and a loss value of 0.0287 from 52977 sample test packets. This evaluation reveals that the LSTM is

an effective solution for preventing and protecting against 22 different sorts of attacks.

The accuracy of our proposed method against the other approaches is significantly different in these comparisons. In the NSL-KDD dataset, our LSTM-RNN beats models that utilize all 41 features for training and testing. When compared to previously implemented deep learning methods in Alkahtani et al. [22], Tang et al. [15], Niyaz et al. [23], Ugwu et al. [11], the proposed model of LSTM-RNN did very well on the evaluation of the test data. This comparison demonstrates how our method's clear phases are predictable, accurate, effective, and authoritative.

Tang et al. [15] claim that when using a GRU-RNN method, their Deep Recurrent Neural Network (DNN) methodology obtained an accuracy of 88.39%. They use a Nadam optimizer and a mean squared error (MSE) model in their experiment. Our proposed model was developed using the Adam optimizer, which is the best optimizer. According to Kandel et al. [24], each optimizer is compared differently depending on the architecture, and the Adam optimizer has the best performance on the dataset in evaluation. They also used the mean square error (MSE) method to remove and appreciate the average error. Mean absolute error (MAE) was utilized in the proposed model. As a consequence, MSE outperformed the MSE technique in terms of interpretation.

Niyaz et al. [23] use NIDS based on sparse autoencoder and soft-max regression. As a result, they claim that the NSL-KDD dataset's Normal and anomaly (2-class) classification yielded an accuracy of 88.39%. By monitoring their method, autoencoder trains to effectively represent a manifold on which the training data resides. It was done by utilizing the mean square error (MSE) approach, which does not show an average error.

Ugwu et al. [11] designed the LSTM and SVD deep learning methods to show considerable improvement. They pre-processed the network data by converting features and normalizing the data. Non-numeric feature values were converted to numeric values using the feature conversion method. Their feature conversion method is nearly identical to the feature selection technique employed in our proposed model. However, our proposed model outperformed theirs.

## VII. DISCUSSION

The machine learning detection approach was proposed and addressed in identifying a DDoS attack in this research study. This research has led to the understanding that many traditional machines learning, and deep learning methods can be used to detect a DDoS attack. However, when deciding whether to use traditional machine learning or deep learning with a large dataset, deep learning was considered due to its ability to solve difficult issues involving finding hidden patterns in data. It has a deep understanding of the complex relationships among a huge number of interdependent variables. Deep learning algorithms can create far more efficient decision rules. Deep learning is particularly effective in this study because the NSL-KDD dataset frequently requires dealing with unstructured data. Our findings reveal that LSTM is a nearly ideal strategy for preventing and protecting against 22 different types of

attacks. Classical machine learning, on the other hand, can be a preferable solution for smaller jobs that require less complex feature engineering and do not require the analysis of unstructured data.

### VIII. CONCLUSION

The study has focused on presenting and demonstrating the design, implementation, and testing of a Detecting DDoS by Machine Learning solution to provide end-users with machine learning-based detection of DDoS attacks. End-users can re-route all traffic to an external server with DDoS mitigation capabilities hosted. The designed model solution allows researchers to build network-based detection models for network attacks using multiple machine learning methods, primarily classification. This result concludes that the objective to explore the type and study the characteristics of a DDoS attack from the viewpoint of machine learning was successfully achieved.

From the observation of the results for the proposed machine learning method, the LSTM RNN-based classification algorithm enhanced the detection of DDoS attacks. Pre-processing, attribute selection, and a detection and prevention system are the three components that the researcher proposes. The LSTM evaluation model fitting with the LSTM algorithm is demonstrated in the final phase. Significant testing was carried out, and the findings reveal that LSTM-RNN greatly surpasses existing DDoS attack detection systems. The algorithm learns the dataset's patterns with a 97.37% accuracy with a 0.0309 value loss. It was considerably easier to train numerous models in a short amount of time with TensorFlow, Google's second-generation machine learning framework. The LSTM recurrent neural network algorithm has been shown to have higher accuracy in detecting DDoS attacks in this study. These results covered achieving the objectives to improve DDoS attack detection approaches using a machine learning model to analyze network traffic activities for cyber threat detection; and to discover a feature selection strategy that, when combined with a machine learning system, can improve DDoS detection rates.

In a comparison of related work, the accuracy of our proposed method against all the other methods is significantly different. Our LSTM-RNN outperforms models that use all 41 features for training and testing in the NSL-KDD dataset. The proposed LSTM-RNN performed very well on the evaluation of the test data when compared to previously applied deep learning methods in Alkahtani et al. [22], Tang et al. [15], Niyaz et al. [23], Ugwu et al. [11]. This demonstrates how our method's phases are predictable, accurate, effective, and authoritative.

### IX. FUTURE WORK

Even though DDoS packets or attacking packets are known, DDoS detection is not perfect. In the future, there will always be diverse approaches. However, this scope is not defined as one of the projects' objectives that should be achieved. A solution for improvement could be to add more datasets to the proposed system; another feature Selection technique that can be used; And other classifiers could be added to improve attack detection; Use of confusion matrix to show the mistaken type of attacks. In the future direction of this research, I suggest using advanced deep learning algorithms to build a predictive analytics model to

develop an automated system that can react based on current situations to analyze incoming data in networks. It could decide on defense mechanisms, evaluation and provide safety data on what is going on in a network.

# Proficient Networking Protocol for BPLC Network Built on Adaptive Multicast, PNP-BPLC

Ali Md Liton, Zhi Ren, Dong Ren, Xin Su

School of Information and Communication Engineering Chongqing  
University of Posts and Telecommunications, Chongqing, China

**Abstract**—In order to solve the problems of the existing broadband power line carrier communication standard IEEE1901.1 data link layer protocol network, multiple primary nodes receiving the beacon will send connotation entreaty message, and CCO will send an association sanction message proximately after receiving the message to confirm their character the central coordinator CCO association confirmation message reply is not timely to reduce the success rate of network access, high network access delay and control overhead. Based on the characteristics of BPLC carrier network, Proficient networking instrument of broadband PLC built on adaptive multicast PNP-BPLC is proposed in this paper. The simulation results show that adaptive multicast is used when CCO replies to the primary station, which can excellently recover the success rate of low-voltage PLB carrier communication nodes, decrease the network access delay and cut the network control overhead. Finally we used to OPNET simulation software to prove simulation result.

**Keywords**—Powerline communication; network delay; control overhead; central coordinator

## I. INTRODUCTION

Low voltage broadband powerline carrier communication (BPLC) [1, 2, 3] is a communication mode that uses low-voltage power distribution line (380/220V subscriber line) as information transmission medium for voice or data transmission. It has the natural advantage that there is no need to reset up the network. The BPL carrier communication has wide bandwidth, and the basic frequency band is 1MHz ~ 20MHz Compared with the traditional NBPLC carrier communication, Broadband PLC has higher transmission rate, stronger anti-interference performance and better performance. At present, the international standard for broadband power line carrier communication is IEEE 1901.1 [4-5]. This standard is created on Q/GDW 11612 technical description for interconnection and interworking of low voltage PLB carrier communication [5] of the state grid corporation of china, and grasps the operative tender of internet of things expertise based on power line carrier communication in energy internet [6]. BPLC has been widely used in automatic meter reading [7 8 9], intelligent power consumption system [8], street lamp control [8], charging pile construction [10 11], etc. At present, there are a lot of research in the field of BPLC technology. For example, literature [10, 11, 12] explores the features of low-voltage BPL carrier communication channel. For the input impedance features, signal noise and interloping characteristics, phase shift characteristics, the actual communication area of PLC is hundreds of meters. In order to

confirm link stability and long distance transmission, literature [13-14] offers that tree networking and multi hop transmission similar to wireless sensor networks are assumed in the network management sublayer. Many people have planned the BPLC networking algorithm Literature [14-15] proposed an improved Q-learning algorithm suitable for multi restraints of PLC, LAN through incessant collaboration with the unknown situation. Although this kind of ant colony algorithm has certain adaptive ability, it needs to send a large number of control messages to interact with neighbor nodes, which has the problems of excessive control overhead and waste of resources. Reference [16-17] provides a tree based networking method for low voltage BPL carrier communication network, which uses topology assessment frame to travel the network topology, upholds and updates the sub node set according to the lowest energy value required for normal [18,19,20] communication, picks candidate routing nodes in turn according to the energy value, and then assigns [24-25] network address to each sub node in the sub node set, Although this technique is simple and easy, it does not give the vigorous rebuilding and optimization manner of routing, and the network constancy is poor. IEEE1901.1 [21, 22, 23,] standard also espouses impart networking. The CCO elicits the network access appeal of STA level by level by sending the central beacon, placing the sending of discovery beacon and sending of proxy beacon to ample the entire networking procedure.

Rest of the paper we have described simulation results of the paper. In the Section of III(B)(1) we described, Network Access success rate, in Section III(B)(2) Average network access delay and in Section III(B)(3) Network control overhead, proposed PNP-BPLC Protocol is better than the other two protocols.

## II. SYSTEM MODEL AND PROBLEM DESCRIPTIONS

### A. Network Scenario

The broadband carrier communication network will normally form a multi-layer tree network with the central coordinator CCO as the center and the proxy coordinator PCO as the relay agent to connect all stations STA. As shown in Fig. 1, the topology of a typical BPL carrier communication network is shown.

### B. Protocol Stack Structure of BPLC

Based on the standard open system interconnection (OSI) seven layer model, the Broadband carrier communication network protocol stack defines three layers, physical layer, data link layer and application layer.

Fig. 1. Topology of BPL Carrier Communication Network.

Fig. 2. BPLC Communication Network Protocol Stack.

The basic structure is shown in Fig. 2. The data link layer is divided into network management sublayer and media access control sublayer. The data link layer directly provides transmission services for the application layer and can also be prolonged to edge with standard TCP / IP to grasp standard IP network communication.

### C. The BPLC Networking

In order to certify the consistency of BPLC network routing and data spread, BPLC network will be networked. The procedure is as follows.

- 1) After CCO is powered on, coordinate the time slot and network documentation among networks. After effective organization, demeanor solitary network networking.
- 2) CCO starts to send the central beacon in the beacon slot, and the station receiving the central beacon wants to enter by sending the association appeal message in the CSMA slot access.
- 3) CCO verifies the site requesting network access through the white list. After positive confirmation, CCO sends the dispensation result to the STA site requesting network entree through the connotation sanction message, expressive the effective network access of the node.
- 4) After the primary node effectively arrives the network, CCO will arrange beacon time slot for it to send discovery beacon. The sending of discovery beacon can elicit the secondary site around the new site to recruit the request for related network access.

- 5) This rotation allows the main level STA site utmost from CCO to connection the network.

### D. Problem Description

It is found that there are two problems in the BPLC networking progression.

1) In BPLC networking, after CCO sends the central beacon in the beacon slot, multiple primary nodes receiving the beacon will send connotation entreaty message, and CCO will send an association sanction message proximately after receiving the message to confirm their character. With the STA node layer by layer forwarding the association request message network entire tender through PCO, the number of STA nodes increases, and the association authorization message is likely to be hugged in the CCO queue, ensuing in the CCO inept to apportion TEI, time slot and other evidence to the nodes to be edited in time, and the network access solicitation node cannot access the network normally, resulting in the reduction of the network access attainment rate of BPLC network nodes.

2) STA sends a huge number of connotation entreaty messages, and CCO needs to send Association validation messages of the similar scale for retort. However, distinct beacon time slots, CSMA time slots assign superior time slots for separately node, so encounters must be dodged, ensuing in CCO's fiasco to reply relationship validation messages to overtone request messages sent by some nodes smearing for network access in time, then these STA,s will prompt the instrument of resending connotation request message because they cannot collect overtone sanction message within the waiting time edge  $T_{max}$ , consequent in the rise of control overhead and network access delay.

### E. PNP-BPLC Mechanism

In order to solve the problems described in the previous section, this paper offers a BPLC proficient Networking (PNP) mechanism built on adaptive multicast, including two new mechanisms adaptive multicast reply Association confirmation message and association reply based on retransmission message. The specific ideas are as follows.

### F. Adaptive Multicast Reply Connotation Confirmation Message Mechanism

For the problem a) declared in the previous section, seeing that the BPLC is a tree topology, some STA sub sites will be equestrian under PCO, which means that the higher the level is, the more stations are likely to be. Then it is likely that the association confirmation messages sent by multiple websites to be accessed will be put into the cache queue by CCO and not replied in time. Therefore, this paper propositions CCO adaptive multicast replies Association sanction message apparatus.

The core idea is CCO queries the number of association confirmation messages in its queue. When the number is 1, unicast Association confirmation messages. When the number is greater than 1, multicast association instant warning messages are sent to send association reply messages more

rationality, which increases the network access success rate of nodes and condenses the network access delay and control overhead. Since multilevel nodes will also forward the association request message to the prime node, which is principally the same as that of the prime node, this paper mainly discusses the association retort of CCO to the principal node. The basic process is as follows.

Step 1: Start the neighbor network observing timer when CCO is drove on. If the inter network direction frame is received within the listening time  $t$ , coordinate the inter network identification NID and time slot. If the inter network direction frame is not received within the listening time  $t$ , single network networking is carried out. CCO recordings the central beacon in the beacon slot.

Step 2: The neighbor node receives the central beacon, forms whether the "start association flag bit" of the beacon is 1, and is ready to send the association entreaty message, before the station is ready to send, listen for data being transmitted on the bus whether the line is busy or not. If the line is found to be busy during listening, wait for a delay and listen again. If it is still busy, continue to delay the wait. If the waiting times  $n$  exceed the threshold 16, STA retransmits the association entreaty message and marks the message. If the time of each delay is erratic, it is resolute by the reduced two the M-ray exponential bakeoff algorithm fixes the delay value.

Step 3: CCO receives the association request message sent by the node relating for network access, inquiries the STA site information consistent to the association request message, and completes white list confirmation. CCO queries the number of layers of the site and regulates the terminal address of the next hop. If it is a first class site, the destination address is the node. If it is a multi-layer site, the destination address is the PCO of the lowest level agreeing to the inviting site. CCO allocates TEI and time slot to the node and keeps them in the reminder reply message. CCO makes association reply to the principal site. If the channel is busy when sending Association reply, CCO will put the association reply message into a distinct association reply backlog.

Step 4: Check the number of association retorts in the queue. If it is 1, wait for the channel idle unicast to send the association sanction message. If it is greater than 1, all overtone messages in the queue are taken out, the address evidence of each node is found, and the association rapid hint message is formed. When the channel is idle, multicast is sent to the crucial node.

Step 5: The primary node limits whether it is the node applying for network access. If so, the network entree is effective. If not, the node is the lowest level PCO of the node applying for network access. The node forms an association endorsement message through the association reply message sent by CCO to itself and sends it to the next level node. The next level node also benches whether it is the node applying for network access first. If not, the node is the lowest level PCO of the node applying for network entree.

Then the node is the secondary PCO of the network access node. The node installs the address evidence and remains to send the association sanction message to its subsidiary nodes,

and so on until the association request node is found and the network entrée is effective.

### G. Association Reply Apparatus Based on Retransmission Message

In order to solve the problem b), this paper propositions an association reply apparatus based on retransmission message. Its core idea is perceptive.

CCO adaptively sends the first level reply message by arbitrating whether the retransmitted association request message has been received around. If CCO receives the association request message retransmitted from STA node, it specifies that the association request message formerly sent by STA node has not received Association confirmation, which tortuously indicates that the BPLC network channel is busy.

If CCO remains to unicast Association credit messages in CSMA time slots, the channel cramming will be impaired. CCO stops generating association confirmation message unicast transmission and selects to verify the received association request message, and generates association rapid hint message, so that there is no large number of association confirmation messages competing with association request messages in CSMA time slot, so as to slow down the message load of the channel and reduce the control overhead.

Fig. 4 is 1 graphic diagram of association reply apparatus built on retransmission message. Fig. 4(1) shows the uplink association request message sent by STA and the association sanction message sent by CCO under normal conditions. Fig. 4(2) shows the graphic diagram of more network access nodes. As can be seen from the figure, due to the large number of nodes, both uplink and downlink messages need to compete for channels, resulting in the STA sending the uplink Association reply message represented by the blue arrow not receiving the agreeing association confirmation message and not being able to access the network normally. After a waiting time, the association request message with the green arrow is sent again. Fig. 3 is the graphic diagram of the new apparatus, and the red arrow represents the association instant indication message sent by CCO multicast. In Fig. 3, after CCO senses that some STA resend association request messages, it uses the method of ending sending Overtone sanction messages and multicast Overtone instant indication messages, which almost reduces the control overhead by 50% and importantly cuts the drain of the channel.

Fig. 3. Message Interaction of Associated Network for BPLC.

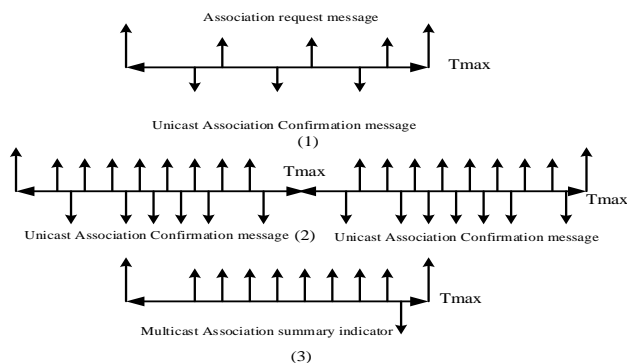

Fig. 4. Association Reply Apparatus based on Retransmission Message.

The Basic Operation Process is as follows:

Step 1: CCO performs network organization, which is reliable with CCO in the adaptive multicast reply association confirmation message device.

Step 2: STA makes association request, which is consistent with the association request made by STA in the adaptive multicast reply Connotation confirmation message apparatus.

Step 3: CCO receives the association request message sent by STA and benches whether there is a retransmission flag. If so, it stops sending the connotation confirmation message. In this time slot, it only accepts the association request message, takes out the node ID, original address and other information, and forms an association instant hint message. Multicast sends Association instant indication message at  $T_{max}$  time. The algorithm of multicast sending association rapid hint message is consistent with that of adaptive multicast reply connotation confirmation message apparatus.

Step 4: The main node regulates whether it is the node smearing for network access. If so, the network access is effective. If not, the node is the lowest level PCO of the node smearing for network access, forming an association confirmation message. This procedure is constant with the progression in which the node judges whether it is the node smearing for network access in the adaptive multicast reply association confirmation message apparatus.

#### H. PNP-BPLC Apparatus Progression

The flow chart of BPLC proficient networking apparatus based on adaptive multicast is shown in Fig. 5, which includes two new mechanisms adaptive multicast reply association confirmation message and association reply built on retransmission message.

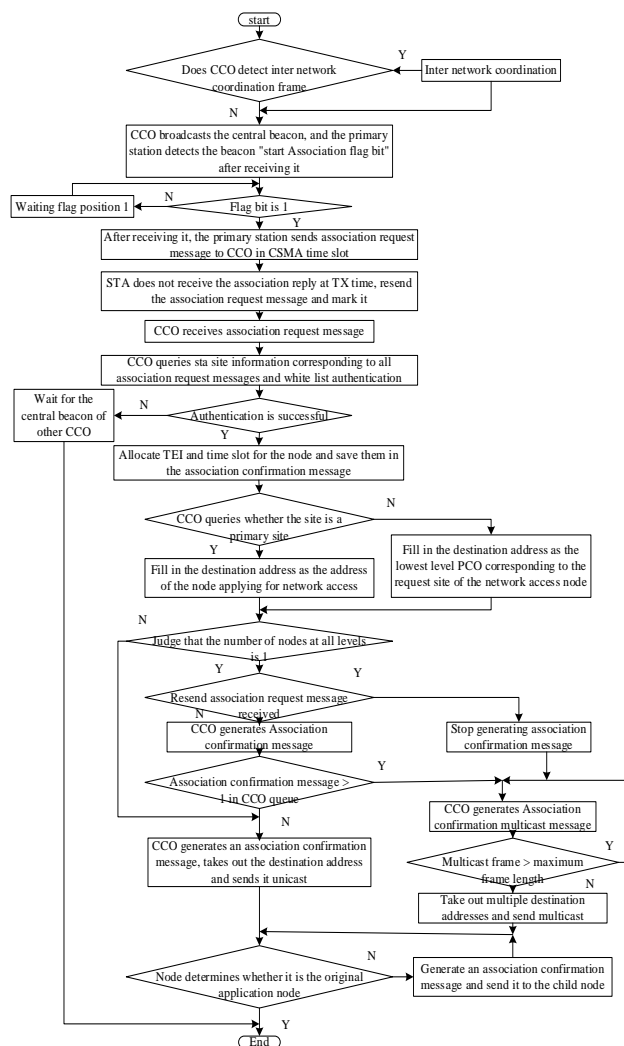

Fig. 5. Adaptive Multicast Access Protocol Process.

### III. SIMULATION ANALYSIS

#### A. Simulation Parameter Setting

This paper uses OPNET 14.5 simulation tools to simulate IEEE1901.1 technical standard and Literature [15], PNP-BPLC apparatus are used to simulate the network access success rate, average network access delay and control overhead. The main simulation parameters are shown in Table I.

TABLE I. MAIN PARAMETER SETTING

Simulation Parameter	Value
Simulation scene /m*m	3000*1000
Simulation running times/s	100
Number of nodes/Pc	[4,9,14,19,24]
Transmission rate /Mbps	10
Single level network access time/s	20
Single hope effective transmission distance /M	500
Number of CCO	1
Maximum hops/hop	3

**B. Performance Index**

1) *Network access success rate*: Indicates the network access success rate of each STA site of BPL carrier communication network. The network access success rate P is calculated as Formula 1.

$$P = \sum_{i=1}^{i=n} Xi \div \sum_{i=1}^{i=n} Yi \times 100\% \tag{1}$$

Where n represents the simulation scenario with n nodes, Xi represents the number of association request messages sent by the *i*th node, and Yi represents the number of association confirmation messages received by the *i*th node.

2) *Average network access delay*: The average network access delay represents the generation time T<sub>pk</sub> from the creation of the central beacon frame the average time of T<sub>sim</sub> when the association reply message sent by the create to the CCO is received by the node applying for network access. With transmission delay, spread delay, inter layer processing delay and MAC layer queuing delay. The average network access delay is calculated according to formula 2.

$$\bar{T} = \frac{1}{n} \sum_{i=1}^{i=n} (T_{sim}(i) - T_{pk\_creat}(i)) \tag{2}$$

3) *Network control overhead*: Network Control overhead refers to the sum of bits of control message required in the whole networking process of BPLC network. In BPLC network, there are four types of control messages inter network coordination message, beacon message, association request message and association reply message. Because the simulation is in a single network environment, the overhead message in this paper does not include inter network coordination message. Among them, the beacon message is divided into central beacon, proxy beacon and discovery beacon. The association reply message also includes association validation message and association summary indication message. The calculation of BPLC control cost C is shown in Formula 3.

$$C = 8 * (M * (c_{11} + c_{12} + c_{13}) + N * c_2 + O * (c_{31}) + P(c_{32})) \tag{3}$$

Among them, C11, C12, C13, C2, C31 and C32 are the number of central beacon, proxy beacon, discovery beacon, overtone request message, association confirmation message and association rapid indication message singly, which can be counted by simulation. M, N, O and P, are beacon frames, association request message, association validation message and association instant indication message, respectively. According to IEEE 1901.1 standard, MAC frame is the basic transmission unit for transmission between MAC layers of different stations. A MAC frame consists of MAC frame header, MAC service data unit MSDU and integrity check value. In this paper, the size of long frame header is h = 26 bytes and the size of integrity check value is w = 4 bytes.

The beacon frame size M is calculated according to formula 4.

$$M = h + m + w \tag{4}$$

M is beacon frame MSDU size = MPDU frame control size 16 bytes + frame load 520 bytes = 536 bytes. Thus, M = 576 bytes can be obtained.

The calculation of association request message n is shown in formula 5.

$$N = h + n + w \tag{5}$$

N is the MSDU size of association request message = 4 bytes of Association message header + 64 bytes of association request message format = 68 bytes. It can be concluded that n = 98 bytes.

The calculation of association confirmation message O is shown in formula 6.

$$O = h + o + w \tag{6}$$

O is the MSDU size of association confirmation message = 4 bytes of association message header + 64 bytes of association confirmation message format = 68 bytes. It can be concluded that o = 98 bytes.

The calculation of association request message P is shown in formula 7.

$$P = h + p + w \tag{7}$$

P is the size of MSDU of association instant hint message = 4 bytes of header of association message + format of association summary indication message q, q = basic length of association instant indication message + extended variable length.

It is assumed that the maximum threshold of association confirmation messages queued in CCO queue at the same time is 10. Therefore, q is the maximum number of fills 10 \* each site information field, as shown in Table II, the size is 8 bytes = 80 bytes. Therefore, P = 84 + 30 = 114 bytes.

TABLE II. SITE INFORMATION FIELD

Field	Byte number	Bits	Field size	Definition
Site address 1	0-5	0-7	6 bytes	MAC address
Site ETI 1	6	0-7	12 bits	TEI assigned to site
Site ETI 1	7	0-3	Site TEI 1	TEI assigned to site
Retain	7	4-7	4bits	Retain
.....	.....	.....	.....	.....
Site n address	.....	.....	.....	Site n address
Site TEI n	.....	.....	.....	TEI n=Total number of stations

It can be proved theoretically that the message overhead using PNP apparatus is less than that of the original BPLC network access apparatus.

Condition (1): Except for the associated reply message, the overhead of other control messages is equal and is not counted

Condition (2): Number of messages in CCO Association confirmation queue  $m > 1$ .

Prove: The message overhead of PNP apparatus is less than that of the original BPLC network access apparatus.

Multicast association summary indication message overhead  $C2 = 8 * (H + 8 * m + W) = (84m + 240)$  bit using the PNP mechanism; because  $m > 1$ ; Therefore,  $C1 - C2 = 784m - (84m + 240) = 700m - 240 > = 460\text{bit} > 0$ ; Get a certificate.

Using the original PLC networking apparatus, unicast association confirmation message overhead  $C1 = 8 * (m * (H + O + W)) = 784m\text{bit}$ ;

### C. Analysis of Simulation Results

1) *Network access success rate*: As shown in Fig. 6, the PNP-BPLC contrivance and IEEE1901.1, Literature [15] simulation comparison diagram of data link layer protocol data network access success rate. It can be seen that with the increase of the number of stations and network level, the network access success rate of the two mechanisms gradually decreases, which is due to the increase of channel load and the repeated retransmission of association request message through the comparison of the two figures.

It can be seen that when there are few nodes, the network access success rates of the two mechanisms are basically the same. With the increase of the number of nodes, the network access success rate of PNP device is higher than that of IEEE190.11 and Literature [15] network access appliance of 1 MAC protocol. Because the BPLC network is a multi-level and multisite network, the two improved methods proposed by PNP-BPLC contrivance successfully improve the network access success rate of BPLC network.

2) *Average network access delay*: As shown in Fig. 7, the PNP-BPLC device and IEEE1901.1, Literature [15] comparison diagram of network access delay of different node scenarios in 100s simulation time of 1 MAC layer protocol network access mechanism. Through comparison, it can be seen that with the increase of the number of nodes, the amount of data in the network gradually increases, resulting in the gradual increase of the average network access delay of nodes. The network access delay of PNP-BPLC appliance is lower than IEEE1901.1, Literature [15] the network access delay of 1 MAC layer protocol network access mechanism, and the advantages become more obvious with the number of nodes. Description in IEEE1901.1, Literature [15] under the standard, with the increase of the number of nodes, many association confirmation messages are not sent in time in the CCO queue. It increases the network access delay. The PNP-BPLC

contrivance reduces the transmission of control messages, reduces the congestion of the channel almost.

3) *Network control overhead*: As shown in Fig. 8, control overhead comparison diagram shows the PNP-BPLC and the original PLC network access mechanism IEEE1901.1, Literature [15] the comparison diagram of the control overhead of the standard network access mechanism can clearly see that the control overhead of the two apparatuses increases steadily when the BPLC enters the network step by step, because with the increase of nodes, more nodes need to send control messages, which upsurges the control overhead. Through comparison, it is obvious that the control overhead of PNP-BPLC appliance is basically the same as that of the original PLC network access mechanism when the number of nodes is small. This shows that when the number of nodes is small and the channel is idle, the reply of CCO to the network access node is mainly association confirmation message. However, in the multi-layer PLC network environment with a large number of nodes, the control overhead of the original PLC network access mechanism increases almost exponentially, while the control overhead of PNP-BPLC mechanism increases only linearly.

Depiction in IEEE 901.1, Literature [15] standard, with the growth of the number of nodes, many association confirmation messages are not sent in time in the CCO queue, resulting in retransmitted association request messages, which greatly increases the control overhead of the network. The PNP-BPLC mechanism can adaptively send the association reply message, which greatly reduces the overhead of the association confirmation message sent by the original CCO. At the same time, it also reduces the retransmission of the association request message by the network access application node, and reduces a large number of message overhead.

Fig. 6. Comparison of Success Rate of Network Access.

Fig. 7. Comparison of Average Network Access Delay.

Fig. 8. Comparison of Network Control Overhead.

#### IV. CONCLUSION

The low voltage PLC communication network is affected by robust interference, which requires the networking process to have high adaptive ability. Aiming at the two problems of BPLC data link layer networking, combined with the BPLC network scenario, this paper propositions proficient BPLC networking apparatus built on adaptive multicast. It includes two new mechanisms adaptive multicast reply association confirmation message and association reply based on retransmission message. By sending the primary association reply message more reasonably, the channel resources are more reasonably utilized, and the BPLC networking efficiency is higher. The experimental results show that the above mechanism can improve the data access success rate of BPLC network, reduce the access delay, and greatly reduce the control overhead of multi-layer BPLC network, which verifies the effectiveness of PNP-BPLC mechanism.

# Method for Improvement of Ocean Wind Speed Estimation Accuracy by Taking into Account the Relation between Wind Speed and Wind Direction

Kohei Arai<sup>1</sup>, Kenta Azuma<sup>2</sup>

Science and Engineering Faculty, Saga University, Saga City, Japan<sup>1</sup>  
Former Student, Saga University, Saga City, Japan<sup>2</sup>

**Abstract**—A method for improvement of ocean wind speed estimation accuracy by taking into account the relation between wind speed and wind direction is proposed. Brightness temperature observed with microwave radiometer onboard satellite is modified with microwave radiometer derived wind direction proposed by Frank Wentz. Using the modified brightness temperature, more precise wind speed is estimated. Experiments with AMSR-E and NCEP GDAS data show improvements of wind speed estimation in comparison to the existing method based on the geophysical model of Frank Wentz together with the retrieval algorithm of Akira Shibata.

**Keywords**—Sea surface wind speed (WS); advanced microwave scanning radiometer for earth observing system (AMSR-E); NCEP Global Data Assimilation System (GDAS); relative wind direction (RWD)

## I. INTRODUCTION

The physical quantity can be estimated. This is called remote sensing. Remote sensing generally has visible, near-infrared, thermal-infrared, and microwave observation wavelengths, and sensors are used [1]. Compared to other wavelengths, remote sensing that measures microwaves has poor resolution and can only make rough measurements [2]. However, it has the advantage of being observable even if it is affected by clouds, regardless of day or night. Furthermore, at present, the wind speed on the ocean surface can be remotely sensed only by sensors in the microwave wavelength range [3].

However, it is known that the estimation accuracy of the wind speed changes due to the influence of the relative wind direction in the marine physical quantity cage determination using microwaves. Frank. Wentz (2002) [4] describes the microwave radiation transfer equation and the marine physical quantity using the microwave radiation transfer equation when using the Top of Atmosphere (TOA) obtained from the microwave radiometer AMSR. We created an equation to estimate. Observation of atmosphere, ocean, and land with multi-wavelength microwave radiometer is introduced [5]. At this time, the influence of the relative wind direction was also taken into consideration. However, this effect was used in the microwave radiometer SSM / I and cannot be expected in AMSR. This is because AMSR and ASMR / I have different observation frequency bands.

Arai and Sakakibara proposed a method using the Wentz algorithm using improved simulated annealing for the radiometer ASMR-E [6]. This made it possible to simultaneously estimate various marine physical quantities, which led to an improvement in the estimation structure. On the other hand, Konda, Shibata, Ebuchi, and Arai (2006) used the estimated wind speed obtained from the AMSR product mounted on the observation satellite ADEOS-II and the wind direction obtained from the microwave scatterometer, SeaWinds onboard on the satellite [7].

One of the important issues of the improvement of ocean wind speed estimation accuracy is how to take into account the influence due to wind direction dependency from the wind speed estimation. This is the issue of this paper. The influence of the relative wind direction on the wind speed estimation was investigated, and the index of the influence of the relative wind direction under various situations was derived. They confirmed that the estimation accuracy was improved by performing the estimation using the derived index in the wind speed cage determination of ASMR and ASMR-E. However, in the case of simultaneous estimation of physical quantities, a method of modifying only the wind speed after estimation causes a contradiction in terms of estimation means. Therefore, it is desirable to influence the relative wind direction on the brightness temperature for simultaneous estimation. Therefore, in this study, the effect of relative wind direction is used using the global meteorological data (GDAS) obtained from the US National Environmental Forecast Center NCEP and the observed brightness temperature of the microwave radiometer AMSR-E mounted on the meteorological satellite aqua [8]. By analyzing the above, we analyzed how the relative wind direction affects the brightness temperature. Furthermore, by approximating the influence of the relative wind direction with several equations, we created a model that can derive the influence due to wind direction by linear calculation. By modifying Wentz's algorithm for estimating marine physical quantities with the model, the accuracy of marine wind speed estimation was improved. Experiments with AMSR-E and NCEP GDAS data show improvements of wind speed estimation in comparison to the existing method based on the geophysical model of Frank Wentz together with the retrieval algorithm of Akira Shibata.

The following section describes related research works followed by theoretical background. Some experiments are described. After that conclusion is described together with some discussions.

## II. RELATED RESEARCH WORK

Simplified expression of the radiative transfer equation in thermal infrared window spectrum is proposed [9]. Evaluation of vector winds observed by NSCAT in the seas around Japan is conducted [10]. Polarization sensitivity of the ocean surface together with wind vector derived from POLDER and NSCAT on ADEOS is also evaluated [11].

Estimation of SST, wind speed and water vapor with microwave radiometer data based on simulated annealing is conducted and validated with the truth data [12] together with simultaneous estimation of sea surface temperature, wind speed and water vapor with AMSR-E data based on improved simulated annealing [13].

Space and time retrieval of tide wind speed and wave height with altimeters onboard satellites based on PostGIS system is conducted [14]. Estimation of SST, wind speed and water vapor with microwave radiometer data based on simulated annealing is also conducted [15].

Correction of the effect of relative wind direction on wind speed derived by AMSR is conducted [16]. Data fusion between microwave and thermal infrared radiometer data and its application to skin sea surface temperature, wind speed and salinity retrievals are proposed [17].

Comparative study of optimization methods for estimation of Sea Surface Temperature: SST and Ocean Wind: OW with microwave radiometer data is conducted [18].

## III. THEORETICAL BACKGROUND

Effect of relative wind direction is considered based on the physical background. It is known that the brightness temperature of the upper atmosphere of microwaves largely depends on the gradient distribution of the sea surface and the state of the sea surface.

When the wind blows on the sea surface, the gradient distribution of the sea surface changes, and the brightness temperature at the upper end of the atmosphere fluctuates greatly. By utilizing this action, the sea wind speed can be estimated from the observed brightness temperature of a microwave radiometer or a microwave scatterometer. It is also known that the gradient distribution is distorted in the wind direction due to the wind.

It is considered that the upper-atmospheric brightness temperature changes further due to the distortion of the gradient distribution, that is, the upper-atmospheric brightness temperature also depends on the difference between the wind direction and the observation direction. The difference between the azimuth of the wind and the azimuth of the observation is called "Relative Wind Direction (RWD)". In other words, the upper atmosphere brightness temperature is considered to depend on the relative wind direction. The microwaves observed by the microwave radiometer mounted

on the satellite can be roughly divided into three elements as shown in Fig. 1.

$TB_{air\ emission}$  is microwaves emitted by the atmosphere, and  $TB_{ref}$  is microwaves emitted by the atmosphere scattered on the surface of the sea.  $TB_{sea\ emission}$  is a microwave emitted from the sea surface.

The sum of each is the observed brightness temperature of the radiometer, which can be expressed by Eq. (1).

$$TB = TB_{air\ emission} + TB_{ref} + TB_{sea\ emission} \quad (1)$$

First, consider  $T$ . If the sea level is a calm mirror surface,  $T$  is expressed by Eq. (2).

$$TB_{0ref} = R_{0p} TB_{air} \quad (2)$$

$R_{0p}$  is the reflectance, the subscript 0 is the mirror surface, and the subscript  $p$  is the polarization. Also,  $TB_{air}$  means downward atmospheric radiation.  $R_{0p}$  is expressed by Eq. (3) from Fresnel's reflection law.

$$R_{0p} = |\rho_p|^2, \quad \rho_p = \sqrt{\rho_v^2 + \rho_h^2} \quad (3)$$

$$\rho_v = \frac{\varepsilon \cos \theta_i - \sqrt{\varepsilon - \sin^2 \theta_i}}{\varepsilon \cos \theta_i + \sqrt{\varepsilon - \sin^2 \theta_i}} \quad (4)$$

$$\rho_h = \frac{\varepsilon \cos \theta_i - \sqrt{\varepsilon - \sin^2 \theta_i}}{\varepsilon \cos \theta_i + \sqrt{\varepsilon - \sin^2 \theta_i}} \quad (5)$$

where  $\rho$  is the reflectance coefficient of Fresnel, the subscripts  $v$  and  $h$  are vertically polarized waves and horizontally polarized waves, and  $\varepsilon$  is the complex permittivity, and  $\theta_i$  is the angle of incidence. Also, as shown in Fig. 2, the angle of incidence and the angle of reflection are equal. Furthermore, since the emissivity of the sea surface is obtained by subtracting the reflectance from 1,  $TB_{sea\ emission}$  can be formulated in the same manner.

The sum of these and the radiation from the atmosphere is the brightness temperature of the satellite-mounted microwave radiometer. Assuming that the observation dip of the microwave radiometer is the observation azimuth, this microwave radiometer can detect microwave radiation traveling in the direction of the zenith and azimuth. Although it is necessary to consider the beam width when actually calculating, the beam width is not considered because this chapter only explains the concept.

Fig. 1. Observed Brightness Temperature.

Fig. 2. Relative Wind Direction.

The observed brightness temperature  $TB_{ref}$  value of the microwave radiometer is the component of the zenith angle that scatters on the sea surface at the azimuth angle. Therefore, only the components of the zenith angle scattered in the azimuth angle are considered. In this paper, the angle of incidence in this case is called the observed angle of incidence. The actual sea level creates a complex gradient distribution due to various causes such as wind waves and swells.

Due to such sea level gradients, downward atmospheric radiation is scattered in all directions. It is said that the gradient distribution of the sea surface can be approximated by the Gaussian distribution, but strictly speaking, it is considered that the gradient distribution is distorted in the wind direction by the wind. That is, the wave created by the wind becomes a wave that travels in parallel with the wind direction, and the gradient distribution is biased. Although it is difficult to know the specific degree of bias, it is easy to imagine that winds and wind waves have characteristics that depend on the observation azimuth and the angle of the wind direction, as shown in Fig. 2. That is, the variance of the gradient distribution parallel to the wind direction is large, and the variance of the gradient distribution perpendicular to the wind direction is small. Therefore, the average observer firing angle differs between the case where the observation azimuth is parallel to the wind direction and the case where the observation azimuth is perpendicular to the wind direction.

When considering the local wave gradient, it is common to divide the wave into the smallest surfaces. By doing so, the reflection of the rough sea surface can be thought of as a specular reflection as shown in Fig. 3. In this paper, the average observation angle of the observation area at this time is set to the wind direction with the azimuth angle (RWD=0 deg. and / or 180 deg.), as shown in Fig. 4.

Temporarily,  $\theta_{i1}=x^\circ$ , then,  $\theta_{i2}>x^\circ$ ,  $\theta_{i3}<x^\circ$ ,  $\theta_{i4}=x^\circ$ . That is,  $\theta_m=x^\circ$ . In this case, there is also the influence of the rotation of the plane of polarization. Therefore, the following discussion advances to the front bank that the influence of the

rotation of the plane of polarization is small. Next, when the observation azimuth is perpendicular to the wind direction (RWD = 90 deg.), the observation incident angle changes as shown in Fig. 5.

Therefore, it is considered that the average incident angle increases as the relative wind direction approaches the vertical. As can be seen from equations (3) to (5), the reflectance changes as the incident angle changes. In addition, the state of change in reflectance differs between vertically polarized waves and horizontally polarized waves. Fig. 6 shows an example of the change in reflectance when the angle of incidence changes.

Fig. 3. Specular Reflection.

Fig. 4. Incidence Angle when Microwave Radiometer Observes in Parallel with Wind Direction.

Fig. 5. Incidence Angle when Microwave Radiometer Observes in Perpendicular with Wind Direction.

Fig. 6. Relation between Reflectivity and Relative Wind Direction.

First, in the case of horizontally polarized waves, the incident angle of ASMR-E is 55 deg. In the vicinity, the reflectance increases as the incident angle increases. On the contrary, reflectance becomes greater in accordance with the incident angle becomes smaller.

A similar relationship can be seen at 10GHz, 18GHz and 23GHz. Therefore,  $RWD = 90$  deg., which increases the average observation angle of incidence. Then, the horizontal polarization component of the upper atmosphere brightness temperature becomes large, and the vertical polarization becomes small. In addition,  $RWD \approx 0^\circ$  and/or  $180^\circ$ , which has a relatively small average observation angle. Then, it can be expected that the horizontal polarization of the upper atmosphere brightness temperature becomes smaller, and the vertical polarization becomes larger. However, since the exact gradient distribution is unknown, it is not known how much the relative wind direction affects the brightness temperature. In this study, the effect was analytically derived.

#### IV. PROPOSED METHOD

In this study, the effect of the relative wind direction on the brightness temperature was analyzed by comparing the brightness temperature affected by the relative wind direction with the brightness temperature not affected. In this case, the brightness temperature includes not only the downward component of atmospheric radiation, but also the upward component of atmospheric radiation and radiation from the sea surface.

As the brightness temperature affected by the relative wind direction, the brightness temperature data (TB: Brightness Temperature) of Level 1B of the microwave radiometer AMSR-E mounted on the AQUA was used. AMSR-E Level 1B products have polarization types of horizontal polarization and vertical polarization, and the center frequencies of the frequency bands are 6.9, 10.7, 18.7, 23.8, 36.5, 89.0GHz, respectively. In this study, we used horizontal and vertical polarization in the frequency band below 23.8 GHz and used winter data that can be expected to have relatively strong winds and summer data that can be expected to have relatively weak winds.

Table I shows the time zones of the observation data. In the table, start time and end time indicate the observation start and end times in GMT, respectively. The observation positions are shown in Fig. 7. ASMR-E data for half a lap is 196 columns x about 2000 rows. It is the brightness temperature data of about 3920 opening points. Furthermore, the latitude range is relatively strong at latitude 60 north, from latitude 60 south. Therefore, we targeted about 261333 predictable data. Estimates at all points are shown in Table I.

TABLE I. TIME ZONES OF THE OBSERVATION DATA

No	Date	Start	End
1	Aug.11	23:21	00:11
2	Aug.12	11:43	12:33
3	Dec.8	23:27	00:18
4	Dec.9	11:49	12:39

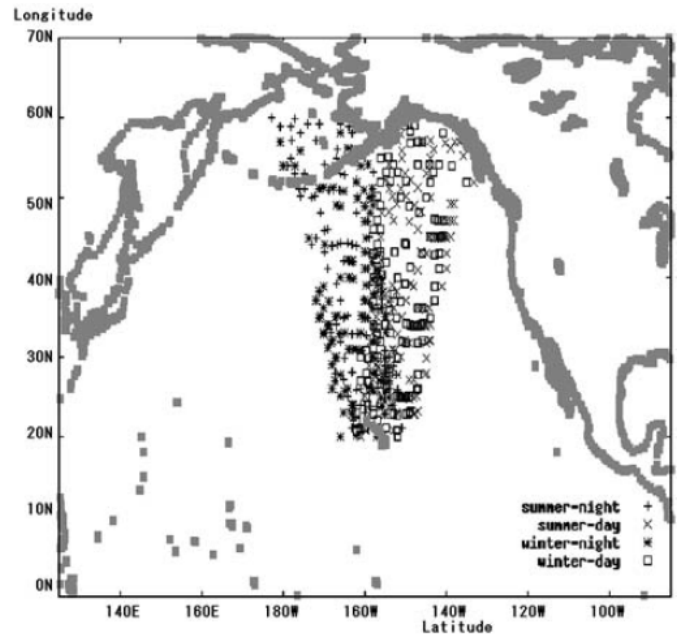

Fig. 7. Observation Positions.

Since it takes too much time, we used one-thousandth of the data and the data for GMT at random sampling. Therefore, the amount of data of the observed positions used is 261. We prepared representative summer / winter and day / night datasets and used them for the experiment. Wentz's microwave radiation transfer model based on global meteorological data (GTAD83.2: Global Tropospheric Analyses dS083.2) provided by the National Centers for Environmental Prediction (NCEP) as a brightness temperature that is not affected by the wind direction.

The brightness temperature derived using the above was used. The global meteorological data used at this time is the data at the same position and time as the ASMR-E data to be compared. The variables given as the input value of the microwave radiation transmission model are the absolute azimuth of the wind (WD: Wind Direction), the sea surface temperature (SST: Sea Surface Temperature), Precipitable water (PW), cloud water amount (CW: Cloud Liquid water). The output value is represented by the brightness temperature TB of the microwave. All these variables are obtained from GTAD83.2. GTAD83.2 has a mesh size of 1 by 1 degrees and is updated every 6 hours for ASMR-E data and GTAD.

Since the data of GTAD83.2 has a difference in the observation position, the data of GTAD83.2 was linearly interpolated to correspond to the data position of ASMR-E. The relative wind direction was defined by equations (6) to (8).

$$\theta_{amsr} = \begin{bmatrix} \cos(\theta_{amsr}) \\ \sin(\theta_{amsr}) \end{bmatrix} \quad (6)$$

$$\theta_{wind} = \begin{bmatrix} \cos(\theta_{wind}) \\ \sin(\theta_{wind}) \end{bmatrix} \quad (7)$$

$$RWD = \cos^{-1} \left( \frac{\theta_{amsr} \theta_{wind}}{|\theta_{amsr}| |\theta_{wind}|} \right) \quad (8)$$

RWD represents the relative wind direction,  $\theta_{amsr}$  is the ASMR-E observation azimuth, and  $\theta_{wind}$  is the wind azimuth.

The calculation result of the radiation transfer model is used as the data that is not affected by the relative wind direction, and it is defined by the following formula.

$$TB_{simu} = SIMU(sst, ws, pw, cw) \quad (9)$$

where  $TB$  is the brightness temperature that is not affected by the relative wind direction,  $SIMU()$  is the microwave radiation transmission model, and the arguments are the sea surface temperature, sea wind speed, precipitable water, and cloud water obtained from GTAD083.2, respectively. Furthermore, the brightness temperature affected by the relative wind direction is represented by  $TB_{amsr}$ , and the relative influence of the wind direction is defined by the following formula.

$$\Delta TB = TB_{amsr} - TB_{simu} \quad (10)$$

Furthermore, since it is considered that the influence of the wind direction depends on the wind speed, the  $\Delta TB$  call at a certain wind speed is represented by  $\Delta TB/ws$ . This relationship was approximated by Eq. (11).

$$\Delta TB|_{ws} \cong A RWD^2 + B RWD + C \quad (11)$$

Fig. 8 to 11 show examples of horizontal polarization in the 10 GHz band. Examples of band vertical polarization are shown in Fig. 12 to 13. From Fig. 8 to Fig. 13, it can be seen that the coefficients  $a_1$  and  $c_3$  in Eq. (11) change depending on the wind speed. The relationship was approximated by equations (12), (13), and (14).

$$A \cong a_1 WS^2 + a_2 WS + a_3 \quad (12)$$

$$B \cong b_1 WS^2 + b_2 WS + b_3 \quad (13)$$

$$C \cong c_1 WS^2 + c_2 WS + c_3 \quad (14)$$

Equations (11) to (14) and nine approximation coefficients from  $a_1$  to  $c_3$  can be used to add the RWD effect to the physical model. As a result, the coefficients in Table II were derived.

Examples of horizontal polarization in the 10 GHz band are shown in Fig. 14, 15, and 16.

From Fig. 8 to Fig. 10, the characteristics of the relative wind direction dependence become clear as the wind speed increases. That is, the observed brightness temperature increases as the relative wind direction approaches 90 degrees. This feature is prominent in horizontal polarization.

Fig. 10. Relation between Relative Wind Direction and Delta Brightness Temperature (10GHz H-pol 12.93 m/s).

Fig. 13. Relation between Relative Wind Direction and Delta Brightness Temperature (10GHz V-pol 19.09 m/s).

Fig. 11. Relation between Relative Wind Direction and Delta Brightness Temperature (10GHz H-pol 19.09 m/s).

Fig. 14. Relation between Coefficient A and Wind Speed (10GHz H-pol).

Fig. 12. Relation between Relative Wind Direction and Delta Brightness Temperature (10GHz V-pol 12/93 m/s).

Fig. 15. Relation between Coefficient B and Wind Speed (10GHz H-pol).

Fig. 16. Relation between Coefficient C and Wind Speed (10GHz H-pol).

As shown in Fig. 14 to Fig. 16, the change in  $\Delta TB$  when the wind speed exceeds about 15 m/s is clearly different from that when the wind speed is below 15 m/s. It is known that wind waves grow when the wind speed increases and collapse when the wind speed exceeds a certain level. From this, it is considered that the feature of about 15 m/s is due to the collapsing waves. Another possible cause is the white waves that occur when the wind speed is strong. In addition, Fig. 12 and Fig. 14 clearly show the difference of  $\Delta TB$  when observed from the front and the rear of the collapsing wave.

When the RWD is 90 degrees, that is, when observing from behind the collapsing wave, the observed  $TB$  becomes large; when  $RWD > 90$  degrees, that is, when observing from the front of the collapsing wave, the observation becomes small.

## V. EXPERIMENT

Sea wind direction, wind speed, sea surface temperature, precipitable water, cloud water estimations are conducted. Using Equations (11) to (14) and Table II described in the previous chapter, the effect of the relative wind direction on the brightness temperature can be understood. Therefore, by adding the brightness temperature derived using this equation and the coefficient to the microwave radiation transfer equation of Wentz, the radiation transfer equation considering the relative wind direction can be obtained.

This function is non-linear. Therefore, to determine the physical quantity at sea from the brightness temperature at the upper end of the atmosphere, the inverse problem must be solved. To solve this reverse problem, we used Simulated Annealing, which was proposed by Arai. The luminance temperature used for the estimation was ASMR-E Level 1B (horizontal and vertical polarization 6,10,18,23 GHz band), which was the same as the data used in the previous chapter. The estimated physical quantities are sea surface temperature SST, sea surface temperature WS, relative wind direction RWD, precipitable water PW, and cloud water volume CW, and the estimated location is over the Pacific Ocean (20-60 north latitude, 180-230 east longitude).

The correct answer data used to compare the estimation results is the global meteorological data GTAD83.2 provided by UCEP, which is also the same as the one used in the previous chapter. As in the previous chapter, linear interpolation was performed to positionally correspond to the ASMR-E data. The standard deviation between the value estimated from the luminance temperature of ASMR-E and the correct answer value obtained from GTAD83.2 was used as the standard deviation. The standard difference was derived by Equation 15.

$$Acu = \sqrt{\frac{\sum_{i=1}^n (Ans_i - X_i)^2}{n}} \quad (15)$$

where  $Acu$  is the estimation accuracy,  $Ans_i$  is the correct value obtained from GTAD83.2,  $X_i$  is the estimated physical quantity,  $n$  is the data number, and  $d$  is the total number of estimated data. In addition, when calculating this estimation accuracy, the estimation point where the error (energy  $E$ ) due to simulated annealing was clearly large was rejected because the estimation result is clearly wrong. Table III summarizes the estimation accuracy of each estimated physical quantity. In addition, Table III also summarizes the estimation accuracy when estimating with the conventional model as a target for comparison. The data numbers are shown in Table I.

The conventional model is a method using Wentz's microwave radiation transfer equation and improved simulated annealing by Arai and Sakakibara. Hereafter, the algorithm when considering the influence of the relative wind direction derived in this study is called the modified model and is distinguished from the conventional model. The modified model is Wentz's microwave radiation transfer equation modified by the influence of the relative wind direction shown in the previous chapter. Regarding the wind speed, the estimation accuracy improved except for data 1. The reason why the estimation accuracy of data 1 deteriorated is that it is estimated at the same time.

It is probable that the estimation accuracy of the relative wind direction was poor. On the contrary, the data 3 in which the estimation accuracy of the relative wind direction is greatly improved also greatly improves the estimation accuracy of the wind speed. It can be seen that to improve the accuracy of wind speed estimation in consideration of the relative wind direction, it is necessary to improve the estimation accuracy of the relative wind direction. However, the effect of the relative wind direction on the observed luminance temperature is small compared to other physical quantities estimated at the same time. Therefore, in the estimation method used in this study, it is considered that the estimation accuracy of the relative wind direction deteriorated due to the error that occurred when calculating other physical quantities.

Compared to data 1 and data 2 observed in summer, the estimation accuracy of wind speeds in data 3 and data 4 observed in winter has improved significantly. This is thought to be because the relative wind direction has a stronger effect in winter when the wind is strong than in summer when the wind is weak.

TABLE III. SUMMARY OF THE ESTIMATION ACCURACY WHEN ESTIMATING WITH THE CONVENTIONAL MODEL AS A TARGET FOR COMPARISON

Model	No.	SST[K]	WS[m/s]	RWD[deg]	PW[kg/m <sup>2</sup> ]	CW[kg/m <sup>2</sup> ]
Existing	1	2.63	2.13	86.92	2.45	0.004
	2	1.26	2.39	67.69	1.28	0.08
	3	1.53	2.01	62.65	2.92	0.08
	4	1.32	2.52	52.64	2.75	0.07
Proposed	1	0.96	2.15	99.76	2.25	0.04
	2	1.19	1.91	56.53	1.83	0.1
	3	1.71	0.78	18.12	1.3	0.01
	4	1.37	1.76	68.02	1.29	0.05

Since the estimation method used in this study is a method of estimating physical quantities at the same time, the estimation accuracy of other physical quantities is affected as well as the change in the estimation accuracy of the wind speed, as shown in Table III. The accuracy of sea surface temperature estimation has improved in summer, and the accuracy of precipitable water estimation has improved in winter.

#### VI. CONCLUSION

By comparing the observed brightness temperature affected by the relative wind direction with the observed brightness temperature not affected, the effect of the relative wind direction on the observed brightness temperature was found. In particular, we were able to extract clear features in horizontally polarized waves. In addition, these features could be expressed by equations and coefficients. In the case of the data used in this study, it was found that the estimation accuracy of the wind speed changed by using the model in which the proposed relative winds direction affects the luminance temperature.

When the estimation accuracy of the relative wind direction estimated at the same time was relatively good, the estimation accuracy of the wind speed was also improved. However, if the estimation accuracy of the relative wind direction estimated at the same time is poor, the estimation accuracy of the wind speed may also deteriorate. Therefore, it was also found that it is necessary to improve the estimation accuracy of the relative wind direction in order to improve the estimation accuracy of the wind speed by the proposed model. In addition, the proposed model is a symmetric function with the observed brightness temperature deviation as the peak when the relative wind direction is 90 degrees, and it is considered that the deviation becomes smaller when the relative wind direction is smaller or larger than this.

Considering that the quadratic function approximation is the first-order approximation, the relationship between the relative wind direction and the observed brightness temperature was approximated by a quadratic equation. However, it is necessary to consider a more appropriate approximation function in consideration of physical grounds.

In this study, the effect of the relative wind direction on the luminance temperature was attributed to changes in reflectance. Especially when the wind speed exceeds about 15 m, the optimum approximation formula can be obtained by understanding the physical phenomena related to the relative wind direction, such as the change in brightness temperature due to the collapsing waves that occur when the wind speed is strong, it is conceivable then.

In this study, the proposed method was evaluated by comparing it with the conventional method using NCEP GDAS as the correct answer, but the errors included in NCEP GDAS will be examined in the future. The error analysis and sensitivity solution in the simultaneous estimation of multiple physical parameters and the simultaneous estimation for improving the accuracy of wind direction determination are left to the references.

#### VII. FUTURE RESEARCH WORK

In this paper, we have shown a method for classifying each pixel for a certain image, but the proposed method can be applied not only to images but also to various sets with values for each element, such as remote sensing, GIS, and it is considered that it can be widely applied to other data mining. Further research works are required for the other applications not only rice paddy field detection with SAR imagery data.

#### ACKNOWLEDGMENT

The authors have received regular discussions, useful opinions and suggestions. Remote Sensing Systems Co., Ltd., Dr. Frank J. Wentz, Professor Masanori Neda of Kyoto University, Professor Naoto Ebuchi of Hokkaido University, JAXA Akira Shibata I am deeply grateful to the doctor. In addition, the master's degree of our graduate school that cooperated with the data collection experiment and analysis.

We would like to thank Mr. Atsushi Sakakibara of former student of Saga University and Prof. Dr. Hiroshi Okumura and Prof. Dr. Osamu Fukuda of Saga University for his valuable comments and suggestions.

Kohei Arai, He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January, 1979 to March, 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science on April 1990. He was a councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA since 1998. He also is Vice Chairman of the Science Commission "A" of ICSU/COSPAR since 2008 then he is now award committee member of ICSU/COSPAR. He wrote 55 books and published 620 journal papers as well as 450 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Mister of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. <http://teagis.ip.is.saga-u.ac.jp/index.html>

# A Study of Security Impacts and Cryptographic Techniques in Cloud-based e-Learning Technologies

Lavanya-Nehan Degambur, Sheeba Armoogum, Sameerchand Pudaruth  
ICT Department, University of Mauritius, Moka, Mauritius

**Abstract**—e-Learning has transposed the perception of teaching and learning considering knowledge delivery and knowledge acquirement. Today, e-learning participants access and upload their materials at any time and at any place since e-learning technologies are typically hosted on the cloud. Cloud computing has embellished the base platform for the future of e-learning, however, security and privacy remains a major concern. Cloud-hosted e-learning technologies as they are accessed over the internet suffer from the same risks to information security aspects namely availability, confidentiality, and integrity. In such a context, data authenticity, privacy, access rights and digital footprints are vulnerable in the cloud. Research in this domain focuses on specific components of cloud and e-learning without covering a holistic view of applied cryptographic techniques and practical implementation. Hence, aiming at the various security aspects and impacts of cloud-based e-learning technologies, this paper puts forward reviewing the various cryptographic techniques used to secure data across the whole end-to-end cloud-based e-learning service spectrum using systematic review and exploratory method. The results obtained define several sets of criteria to evaluate the requirements of cryptographic techniques and propose an implementation framework across an end-to-end cloud-based e-learning architecture using multi-agent software.

**Keywords**—e-Learning; cloud computing; data management; pseudonymization; data deduplication

## I. INTRODUCTION

In a world where the internet is the most potent communications enabler, humanity has transcended orthodox teaching and learning ways and made them global with e-learning where information, communication and digital technologies are utilized to ease the learning process. The e-learning concept has offered an effective educational tool that is accessible from anywhere to anyone encompassing professionals, scholars, teachers, and students by combining the virtues of the internet and the wisdom of knowledge. The efficacy of e-learning is improvised by enhancing the training of teachers, curriculum developments, assessments reforms and infrastructure optimization in a holistic manner. e-Learning has enriched the economic growth in various countries and has reduced the digital divide between countries, societies, and communities. The introduction of e-learning technologies in patriarchal or male-supremacist communities allows the emancipation of girls without bypassing societal norms. Underserved students can make use of this method to study at their own pace and improve their participation abilities and cognitive growth. Hence, through the dissemination of programs, gender gaps can be narrowed across the whole human diaspora. The recent COVID-19 pandemic has

increased the demand for e-learning platforms since traveling has been inhibited owing to recurrent lockdowns. Thus, to be fully transformative, e-learning should be integrated formally into curriculum creation and teacher training and informally into the habits of students [1]. Cloud computing platforms have diversified the conceptualisation of delivering education using modern e-learning methods. However, this base platform for the future of e-learning is vulnerable to security threats and privacy issues.

### A. Modern e-Learning Technologies

Modern e-learning involves the delivery of courses to people in an automated or virtualized form such as videos and interactive methods or via formal teaching from teachers in a personal form via the internet using digital technologies [1, 2]. Virtual learning leans on the visual acumen of protagonists to help the users present and understand topics, study at any time anywhere without teacher intervention, the ability to edit, update and share materials without prior notification and synchronization between teachers and students. Moreover, it can provide an increased number of courses without logistical investment; increase the number of students owing to the flexibility, and cost-effectiveness of such learning. Using the virtualized form, or virtual learning, students and teachers can share a variety of resources, topics and materials and present them in a customizable and personalized format to ease teaching and comprehension. Whereas in a personal form or personal learning, students and teachers have a personal space on a single-use instance or continuous use instance and use their materials to learn and improve skills and teach respectively. Features of personal learning are the ability of users to manage teaching sessions and learning materials in learning platforms, multi-user interaction during e-learning sessions and performance and goal setting per user profile.

Modern e-learning is cloud-based whereby the e-learning platforms are hosted on the cloud instead of hardware and software being installed, run, and administered on the learning provider's premises. The educational materials in today's e-learning are virtualized in cloud infrastructures and it is up to the cloud service providers to guarantee the uptime of the services available to e-learning protagonists. Cloud-based e-learning platform has triumphed due to the abilities of remote access, cost efficiency, open research-oriented environments, ability to analyze and provide insights about the behaviors of protagonists, the disintegration of geographical barriers and time constraints.

However, where information is present, dangers to information are omnipresent and information traveling on the

internet is constantly exposed to security threats. Since e-learning systems are diversified, there is a variety of resources and consumers of those online resources. Collaboration, interconnectivity, and information sharing are the pillars of e-learning systems so that data and the information it induces must be protected to maintain confidentiality, integrity, and availability. Information security issues in e-learning include data manipulation, confidentiality compromises and fraudulent authentications as e-learning developments always lean towards interoperability between learning environments, heterogeneous devices, multi-technology applications, and academic discoveries. Cloud computing readily provides this unified interconnected requirement for successful e-learning technologies.

### B. Cloud-Computing and e-Learning

One exclusively pays the cloud services to fit and enhance business needs, administer infrastructure optimally and reduce operational costs. A wide-scale pooling of computing and networking resources such as processing, memory, storage, and bandwidth, all available on-demand, achieves this. Accessing those resources requires flexibility because resource distribution needs to be precise and fast to cater to rapid fluctuations in demand without service disruption or quality deterioration [2, 3]. Cloud-based e-learning platforms use cloud computing service models such as Infrastructure as a Service (IaaS), Platform as a Service (PaaS) and Software as a Service (SaaS) that are deployed in three deployment models named public cloud, private cloud and hybrid cloud. IaaS provides the physical IT infrastructure and architecture of the system that the clients will use and allows the clients to control only the infrastructure resources provided to them, not the underlying cloud infrastructure hosting the IaaS.

PaaS provides services in terms of the operating system, hosting software and application development lifecycle-software using which the customers can develop their applications that are run on virtual machines, which abstracts the platform from the underlying physical infrastructure. SaaS offers software applications as services over the internet as compared to usual software packages bought by individual clients [4]. The end-user can hence use the cloud service provider's applications hosted on the cloud from anywhere at any time without catering for the management and control on the underlying platform or infrastructure. The public cloud deployment model delivers the cloud services readily available to the public while private cloud services by an organization are made available only to that organization and selected protagonists. Hybrid cloud computing is a mix of public and private cloud deployments to create an automated, unified, and fault-tolerant environment that offers modulated services based on user usage and requirements.

Accordingly, cloud-hosted e-learning technologies depend on the internet-connected cloud resources to function. However, both the cloud-based e-learning technology and e-learner are under constant threats by being connected with the internet. The COVID-19 pandemic has induced a rapid growth in cloud-based e-learning usage but this has also amplified attacks on such technologies. The main security concerns to cloud computing are browser security, authentication, privacy, duplication, and availability while those of e-learning are user

authentication and authorization, data confidentiality and blocking, denial of service and flooding attacks. Thus, the similitude between security concerns of cloud computing and e-learning can be easily observed [2, 3].

This study aims to conceptualize how e-learning services are provided by cloud technologies, discover the various cyber security issues that impact cloud-based e-learning technologies, study the state of art cryptographic techniques used to address the issues in several aspects of cloud-based e-learning technologies, find discrepancies in application and implementation of such cryptographic techniques and finally propose solutions to those problems. The proposed approach will be beneficial for the research community to identify the set of criterias to evaluate different cryptographic techniques.

This paper is structured as follows: Section 2 relates the literature review on the security impacts upon the usage of e-learning and cloud computing technologies. Section 3 describes the research methodology used to perform the study. Section 4 analyses the findings and provides results and Section 5 concludes the paper.

## II. LITERATURE REVIEW

In this section, a detailed review is provided on the security impacts on the usage of e-learning and cloud computing technologies and the different cryptographic techniques applied along with the entire end-to-end cloud-based e-learning service architecture.

### A. e-Learning Technologies Security Aspects, Impacts and Threats

Security threats on e-learning are the problems that can adversely influence the safety of e-learning end users and their data and also apply to user authentication, authorization, and confidentiality. If the usernames and passwords given to users to log onto the e-learning platforms are compromised, users may lose the ability to use the e-learning platforms and may risk their personal, professional, and confidential transaction information being accessed and misused by unauthorized parties. Compromised systems may be vulnerable to blocking attacks whereby an attacker attacks a user's e-learning content and access e-learning material and flooding attacks whereby an attacker bombards the e-learning platform with bogus requests using an account so that the user loses access time [2]. In addition to user authentication, concerns are raised for user operation process tampering to damage data patterns and social behavior deduction through patterns to impede user privacy.

According to the study in [2, 5], Short Message Service texts (SMS) can be used as two-factor authentication to complement usernames and passwords and prevent unauthorized access; biometrics such as fingerprints, iris recognition, or voice recognition can be used with attribute-based cryptography; digital signatures can be used to authenticate identity and integrity of data and also non-repudiation of transactions; access control lists and processes can be applied to the server and user resources access to customize access mechanisms. SaaS security by default is used to secure e-learning applications. Hence, the whole system infrastructure of servers and storage must be considered in terms of security impacts. To reduce threats, the authors

recommended including server, disaster recovery, and safety and management aspects.

Aside from user authentication and authorization, private information protection, and data integrity protection; raising awareness, learning resources authenticity, seamless access, location privacy, digital rights, and usage anonymity should also be catered for e-learning security. Doing so will fulfill basic security criteria such as availability, integrity, confidentiality, authenticity, non-repudiation, and accuracy. Maitra and Bhatia [6] used vulnerability scanners such as Netsparker and N-Stalker to test e-learning platform vulnerabilities and proposed methodologies to ensure security. Both scanners identified the following vulnerabilities: SQL injection, cross-site scripting, directory traversal, BREACH attack, JavaScript library vulnerabilities, CRIME SSL/TLS attack, HTTP response splitting/CRLF injection, file inclusion, HTTP parameter pollution, HTTP authentication, and insecure cookies. According to Maitra and Bhatia [6], e-learning platform security can be accomplished in two proposed approaches: hierarchical and distributed. The hierarchical approach involves applying security in a top-down centralized manner across components while distributed approach applies different security models for every different component in the e-learning system while allowing interaction.

Although e-assessment, the use of integrated information technologies to support assessment processes across all stages in its life cycle in e-learning [7] has proliferated, it has faced three main threats: identity misuse, disclosure of information, and fraudulent alteration. During an e-assessment session, identity misuse may happen if an attacker uses the identity of the real e-learning user being assessed; sensitive and private data transmitted may lead to the disclosure of confidential information. Since e-assessment and e-learning data are stored in databases, they can be subject to alteration which is problematic to students and teachers in terms of data integrity. Those issues can be analyzed and tackled in two perspectives namely the educational perspective by considering learners and teachers scenarios and problems and using the technical architectural perspective to secure the information system running the e-assessment solutions [7]. According to [8], the e-learning system, as well as the underlying infrastructure, should be evaluated for threats and risks to secure the subsequent technological solutions analysis and security policy audits by financial institutions and payments.

Cloud-based m-learning extends the e-learning by expediting the delivery of educational activities, materials, and contents that can be readily performed and accessed at any time at any place via the internet using mobile devices. Since mobile devices are exposed to operating system vulnerabilities, mobile web browser vulnerabilities, untrusted applications, application collusion, spyware, malware attacks, data leaks, jailbreaks, and personal user malpractices; cloud-based m-learning is posed to vulnerabilities. These vulnerabilities can be analyzed in a three-tiered architecture comprising of mobile device tier, network platform/provider tier, and cloud tier. Malicious push advertisements and SMS's can be sent using mobile devices to perform distributed attacks. Vulnerabilities due to network tier threats are inherent to the service provider such as internet protocol vulnerabilities, Man-In-The-Middle

(MITM) attacks, and malicious server agents. Generally, the cloud platforms are vulnerable to DNS/web spoofing, in-house unauthorized access, malware injection attack, authentication, and MITM attack, side-channel attack, virtual machine escape, and Denial of Service (DoS) attacks [9]. Conventionally, cloud-hosted applications are affected via attacks like cross-site forgeries and SQL injections; viruses and e-learning modules from session hijackings and riding affect Learning Management Systems (LMS). Besides, cloud data storage is susceptible to obsolete and insecure cryptographic storage and data duplication.

### *B. Cloud Computing Security Aspects, Impacts and Threat*

Security concerns related to cloud computing are associated with basic security on aspects of data such as transmission, storage, and recovery, availability of applications, services, and data authentication demands, and browser security [2]. From a customer perspective and owing to the abstract nature of cloud and lost physical control, the following five main security threats have been obtained: data exposure to unauthorized antagonists, unauthorized access, data loss, manipulation and induction, Service Level Agreement (SLA) violation and privacy breaches. Data exposure and unauthorized access affect the data confidentiality requirement; data loss and data manipulation breaches data integrity requirement; privacy breaches antagonizes privacy preservation requirement while SLA violation goes against both data confidentiality and integrity.

Threats faced by e-learning users and providers are mostly internet-based where the Denial-of-Service (DoS) and Distributed DoS (DDoS) are omnipresent threats to the availability of such services. Rahman et al. [5] subsequently explored the different attacks on cloud-based e-learning platforms. Firstly, the web browser, which is the user's gateway to the e-learning platform exposed an ideal target for an attack. Phishing attacks eventuate when during the authentication process the user access has not been verified and certified. However, backdoor channel attacks negate authentication to prevent trusted users from accessing their confidential data, and virtual machine attacks involve seizing vulnerabilities in virtualization platforms to detach the physical resources to the virtual resources and reroute data access towards hackers. Nevertheless, insider attacks involve people familiar with the e-learning service provider getting access to the system through knowledge of system policies and architectures. Third-party cloud providers outsource cloud resources among themselves to provide high availability; however, this can be detrimental to user data privacy if policies, procedures, and contracts are not clearly defined. To prevent theft, unauthorized induction, and dissemination, they suggest disposing of the imperfect and redundant data from the cloud and physically.

Since cloud computing is provided in three distinctively different service models, each of them has its own security requirements which should be analyzed. In SaaS, security impacts are about data security, network security, data integrity, data segregation, and data breaches. Security issues regarding PaaS affect data location, and privileged access while those in IaaS are web service attacks, SLA attacks, DDoS, MITM attacks, and DNS security. Data location

vulnerabilities arise because it is unknown where data is stored and processed physically when users are accessing the applications on the platform [10]. Whereas privileged access vulnerabilities occur as a consequence of cloud providers potentially having all possible access rights to data residing on their platforms and any breach on the cloud provider side cascades onto the data.

To use a cloud service over the internet, the cloud provider runs web service protocols that are exposed to attack using XML signatures breaking security between a user's browser and the cloud service. Since SLAs are the legal bindings to service delivery between providers and users, attacks are possible against SLAs to exploit undefined metrics and hence defy quality, availability, performance, and reliability of resources. DDoS attacks deny important services from running by unleashing a tremendous number of requests, which are difficult to be handled by the attacked service. Usually, a Master controls several Slave bots to launch a DDoS on the Target cloud IaaS server. MITM attacks, a subcomponent of eavesdropping, happen when the attacker positions itself between the cloud user and the cloud IaaS server to hear and retrieve communication and even falsify the connection [10]. Besides, DNS attacks occur when vulnerabilities in domain name services are exploited to prevent the resolution of the IaaS cloud environment's domain names to the correct IP addresses. Both the cloud users' and the providers' packets can then get rerouted to prevent access, provoke a DoS, compromise credentials, falsify connections or clone queries and requests.

### C. Cryptographic Techniques in e-Learning Technologies

To secure e-assessment in terms of personal data protection and hosts and network protection, the TeSLA system proposed transport layer security (TLS) using authorization certificates, public key infrastructure, and pseudonymization. TLS allows every entity to mutually authenticate with its peers and create tunnels secured with data encryption and integrity checks using X.509 certificates instead of passwords. TeSLA's PKI manages certificates employing different certificate authorities (CA), revocation lists, three-layered security procedures, and 4096 bits RSA (Rivest-Shamir-Adleman) keys for Certification Authority (CA) certificates [7]. Identity management and data protection are achieved with pseudonymous credentials adapted from attribute-based signatures utilizing randomized TeSLA IDs generated per user so that the full identity of a user remains anonymous.

In contemplation of securing cloud-based m-learning architecture, each tier is secured in a top-down hierarchical manner starting with mobile devices with multi-client authentication, multiple firewalls, and network and exchange servers. Authentication and authorization protection, identity and key management, backup and disaster recovery, anti-replay techniques, state-of-the-art encryption, and protection as a service are solutions to protect the cloud infrastructure tier. Lastly, the network tier is protected using next-generation firewalls and application access authorization [9].

To secure and authenticate data storage in e-learning systems, hash tables and hash trees have been proposed to ensure data integrity for the transmission, storage, and

processing of authentication data between a user and the e-learning system. Encryption is performed on authentication information before transmission and a linear dimensional reduction transformation projects user data and verification data into lower dimensions to preserve relative vector distances and authentication correctness. To secure authentication data integrity, InterPlanetary File System (IPFS) is proposed to store data on a Merkle Directed Acyclic Graph (DAG) file structure, which combines a Merkle tree and a Guided Ring graph. IPFS uses SHA-1, SHA-256, and BLAKE2 cryptographic hash functions to guarantee immutability and immunity to DDoS attacks on the authentication process [11].

To protect multi-agent e-learning platforms' access control and ensure trust and reputation, a combination of Role-Based Access Control (RBAC) inspired models called Trust-Based Access Control (TrustBAC) and Trust Satisfaction and Reputation (T-SR) have been proposed by Asmaa and Najib [12]. Trust levels between users/actors/agents can usually be generated by using user credentials, results of past user interactions, user characteristics, and the context in which those actions occurred [12]. This allows conditions to be created to define safety rules to be applied in access control processes, simplify the generation of trust value, and trust establishment.

Cyber-trust provides legal significance to a public exchange of documents over the network in e-learning environments and hence helps counteract cyber-attacks and cyber-espionage. Network Time Synchronization (NTS) provides standardized cyber-trust assurance for e-learning systems by using three layers of trust criteria expanded to the public internet cyberspace together with an independent Network Time Synchronization source. The three layers of trust criteria are the basic factors that combine to granularly model what a legal user should be and are based on five trust characteristics targeted, subjective, measurable, dynamics, and conditionally passed [13]. Independent Network Time Synchronization source is used because in-built time synchronization modules and synchronization subnets based on network time protocol can be compromised which can threaten end-user and e-learning platform private keys and digital signatures while also endangering the whole public key infrastructure used to secure the communication.

Ali and Zafar [14] recommended that, for e-learning security, DoS attacks and unauthorized logins can be handled by single sign-on authentication. Data evaluation issues at login and on course contents are solved using trust certificates and biometrics. Architecture challenges concerning data transmission channels and access controls are catered for using virtualization technologies and encrypted SSL/TLS channels via the web administration console.

### D. Cryptographic Techniques in Cloud Computing

Challenges to data exposure are intercepted with the use of convergent encryption, homomorphic encryption, and proxy-re-encryption. Identity-Based Cryptography (IBC) and Attribute-Based Cryptography (ABC) serve as potential cryptographic solutions for unauthorized access [3]. However, data loss and manipulation are mitigated using Proof of Data Possession (PDP) and Proof of Retrievability (POR) while Privacy breaches' cryptographic solutions are searchable

encryption and are achieved using Private Information Retrieval (PIR). PDP checks if remote cloud servers have outsourced data using a challenge-response protocol. A client using PDP can check if a file is stored and is available on a cloud server in its original form using a four-step procedure: pre-process, challenge, proof, and verification. POR verifies data integrity and data recoverability in case of failure by adding sentinels in data. The data owner can send a challenge to the cloud server using randomly selected sentinel positions in the data and as a response, the corresponding sentinels must be sent back. If it is not the case, the data are suspected to be modified or deleted.

Searchable Encryption allows a cloud server to search encrypted data using information that the data owner or client has previously provided. This is called a trapdoor [3]. The cloud host hence does not know the exact query nor the data that matches the query thus providing confidentiality with searching ability. The data owner or a cloud client can receive the data locally and decrypt it while saving bandwidth. There are two types of searchable encryptions: symmetric and public keys. PIR schemes provide clients with the ability to request data from cloud servers without revealing which item is being retrieved to the storage itself hence protecting curious cloud providers. PIR is available in two schemes: computation PIR (cPIR) which provides privacy from computationally linked servers and information theoretic PIR (itPIR) which provides privacy for computationally independent servers.

Convergent encryption, a content hash keying cryptosystem, both protects data outsourced to the cloud and ensures client-side data duplication so that the storage can host only one copy of a file regardless of the number of users accessing it. In client-side deduplication, convergent encryption provides two levels of encryption, symmetric data encryption level, and asymmetric key encryption level. At the data encryption level, an enciphering key,  $K$ , is derived from the data itself using a one-way hash function and used to encrypt the data so that the same data encrypted by several users will produce the same encrypted data, which will be stored only once [3]. At the asymmetric key encryption level, the depositor uses the recipient's public key and asymmetric encryption to encrypt the key  $K$ , to be shared alongside user metadata.

Homomorphic encryption algorithms allow third parties to perform deterministic computations on encrypted data to ensure privacy preservation [3]. Homomorphic mechanisms also allow private queries whereby the client sends an encrypted query and the cloud server replies with an encrypted response without looking at the query itself. A user can also save encrypted data on the cloud and then have the cloud server retrieve only some files that when decrypted satisfy some conditions without the server having decrypted the data. To provide data secrecy against cloud providers, proxy re-encryption algorithms usage has officiated the cloud storage outsourcing storage clouds use proxy re-encryption algorithms to provide data secrecy against cloud providers [3]. If a cloud entity wants to access cloud data from a depositor, the cloud server must first re-encrypt the data using the cloud entity's public key and the server's public master key while considering privileges granted.

To secure user data storage and access on the cloud, Pavani et al. [15] performed a comprehensive review of several types of Attribute-Based Encryption (ABE) where each user is identified by a set of attributes. For key policing, by assigning a range of attributes to each user within a control tree, Encryption Key Policing attributes (KP-ABE) are used in general. En route towards the use of non-monotonic access structures, that used control doors such as NOT operations in the control framework, the Expressive Main Regulation ABE (EKP-ABE) which is an expanded version of Key-Policy ABE (KP-ABE) has been proposed. To protect the user's privacy, Ciphertext-Policy ABE (CP-ABE), an inverse iteration of KP-ABE uses a series of attributes for the user's private key to feed the ciphertext to an access framework. To integrate multiple data domains and associated processes, Hierarchical Attribute Dependent Encryption (HABE) ensured data consistency and accuracy throughout the system.

To protect user revocation, Multi-Authority ABE (MA-ABE) uses secured encryption that processes encryption using global public parameters. Additionally, for file protection, File Hierarchy ABE (FH-ABE) encryption scheme is used where files are protected based on the layered entry layout. Pertaining to encryption where users encrypt data based on attributes induced by measuring user's characteristics and corresponding assigned weights, Ciphertext-Policy Weighted ABE (CPW-ABE) was suggested as an efficient ABE. Moreover, to prevent the disclosure of data owners' and data users' sensitive data, Policy Hidden ABE (PH-ABE) has been used [16]. Multi-level ABE (ML-ABE) allows data to be encrypted through multi-level access control schemes whereby users can access only parts of data. Partially hidden access policies are maneuvered to hide the private information attributes and fully hidden ABE policies are used to hide private information and their values.

Policy Hidden Outsourced ABE (PHO-ABE) allows a user to delegate the decryption process execution to a semi-trusted server but keeps the ability to verify decrypted data correctness. To perform user authentication, Attribute-Based Signatures (ABS) have been proposed whereby the user must hold a set of attributes satisfying an access policy to sign a message. An attribute authority generates user attributes and private keys, and a verification entity verifies generated signatures [16]. Multiple Authority ABS (MA-ABS) allows multiple authorities to manage attributes and private keys. Attribute-Based SignCryption (ABSC) logically combines ABE and ABS in one-step to provide fine-grained and granular access control, authentication of data origin, and data confidentiality.

There is a certain cryptographic method, the location-based encryption method, which allows encryption and decryption to be possible only at a specific location using location details to generate cryptographic keys. Relatively, a hybrid algorithm, comprising of both the symmetric Advanced Encryption Standard (AES) algorithm to encrypt data and the asymmetric Rivest-Shamir-Adleman (RSA) algorithm to encrypt the AES private key for key exchange are used to protect data [17]. The fast computation of symmetric algorithms and the high security of asymmetric key pairs prevent HTTP-centric brute force attacks while guaranteeing secure key exchange.

Cognitive cryptography is used for intelligent data management which involves managing strategic, confidential, and secret data, following protocols to verify every information holder, managing semantic information that data contains, and managing data at all the operational levels of the organization entity. In cognitive cryptography, data are secured using unique personal information from biometrics and using semantic information that distinctly identifies individual features of a participant [18]. The cognitive cryptographic protocol involves concealing and encrypting data by splitting and distributing it among a selected group of secret and trusted entities that are identified and verified using their biometric characteristic information and their selected personal features' semantic description.

The review indicates that there are significant research gaps given the security impacts and issues on cloud-based e-learning platforms. e-Learning technologies deal with end-user data such as personal information, location, behavioral patterns, digital footprints, and intellectual properties such as applications, notes, videos, and research. Since cloud computing deals with the transmission, storage, processing, and access of this e-learning data, the analysis and recommendations cover a broad view and multiple aspects of the entire cloud-based e-learning service.

### III. METHODOLOGY

This section demonstrates the methodology used for reviewing the literature of e-learning and cloud computing security and also on the analysis of the identified concerns. An empirical study was performed using qualitative techniques and systematic review as the research instruments for the technical analysis of documents. A systematic review was employed in selecting and critically appraising research relevant to the domain. The documents focus on e-learning technologies, cloud computing, information security, security impacts, and cryptographic techniques on e-learning and cloud computing. These technical documents have been reviewed to learn about how cloud-based e-learning technologies work and about the latest advancements in security aspects and cryptographic techniques in cloud computing and e-learning. The development of cryptography in the recent years related to the theme of cloud-based e-learning is evaluated from the literature using chronological and thematic methods. The results are categorised thematically based on functionalities, security aspects and different cryptographic techniques. Based on the evaluation, several criterias have been thematised to propose an implementation framework in which a critical appraisal has been performed on these findings in order to formulate recommendations based on different scenarios.

### IV. RESULTS AND DISCUSSION

Following the study of the state of art in cryptographic techniques applied to cloud-based e-learning systems, the following observations have been made:

1) The entire end-to-end high-level architecture of the cloud-based e-learning service that includes the end-user, the administrators, the internetwork, and the cloud service including servers and storage must be considered when

analyzing the cyber security threats faced and the cryptographic techniques used to protect the various aspects of information.

2) The aspects that require protection are Confidentiality, Integrity, Availability, Authenticity, Accuracy, and Non-Repudiation.

3) We propose to use a hybrid form of hierarchical and distributed approaches to break down each component of the end-to-end cloud-based e-learning system in a top-down manner and analyze each component separately.

4) The end-to-end cloud-based e-learning system can be broken down into three tiers, namely, User Tier, Network Tier, and Cloud Tier.

5) The user tier consists of the end-user devices and services accessed by a web browser or an e-learning application. End users can be students, teachers, or administrators.

6) The network tier consists of the internetwork services provided by a network provider or an internet service provider. Usually, TLS/SSL and IPSec VPN technologies are used to secure the connection.

7) The Cloud tier embodies the server and storage infrastructure that is broken down based on IaaS, PaaS, and SaaS service models. The cryptographic techniques specifically used in the Storage component of the Cloud Tier are also analyzed as an independent entity aside from service models.

8) Each tier has its functionality and security aspect requirements, which are fulfilled by cryptographic techniques.

9) Several criteria have been extrapolated from information gathered and are considered when using cryptographic techniques to fulfill the requirements.

10) While the use of cryptographic techniques has been theorized and implemented in some capacity, no explicit method or framework has been defined for their implementation across the whole cloud-based e-learning spectrum.

#### A. Cryptographic Techniques Tabulation

These ten observations exhibit several inferred criteria, and the different cryptographic techniques used in the User Tier and the Cloud Tier as tabularized below. The Cloud Tier includes the Storage, IaaS, PaaS, and SaaS cloud computing services. Table I depicts the functionality of end-user devices and security aspect requirements when accessing a web browser or an e-learning platform that uses cryptographic techniques.

Table II represents the Storage Cloud Tier to analyze the storage component of cloud-based services to protect the various aspects of information.

Table III depicts the IaaS Cloud Tier that explores the security aspects of the running applications and different workloads in the cloud.

Table IV illustrates the PaaS Cloud Tier to analyze the security aspects of developing and managing application functionalities and the corresponding cryptographic techniques.

## B. Criteria Definition

The criteria below define what cryptographic techniques need to provide and what can be used to measure and evaluate the application of cryptography in fulfilling the requirements previously mentioned. The criteria consider the security needs of end-users of cloud-based e-learning technologies while entirely leaving the implementation specifics upon the cloud-based e-learning provider.

1) Authentication Criteria: The authentication mechanism should use cryptographic personalized based on the attributes of the users so that third-party attributes do not define the key generated per user.

2) Access Control Criteria: Access control and trust establishment cryptographic techniques should be used granularly based on user identity and attributes following the principles of least privilege and separation of privileges principle.

3) Pseudonymisation Criteria: Cryptographic techniques should ensure that a user's e-learning activity and data cannot be used for traceability and inference basis.

4) Anonymous Searching Criteria: Cryptographic techniques should ensure that any e-learning user can perform searches on encrypted data stored on the cloud without revealing what the original data is, to protect intellectual property and integrity.

5) Anonymous Retrieval Criteria: Cryptographic techniques should ensure that any e-learning user can retrieve encrypted data and part of encrypted data on the cloud without revealing what the original data is, to protect intellectual property and integrity.

6) Anonymous Storage Criteria: Cryptographic techniques should ensure that any e-learning user can store encrypted data stored on the cloud without revealing what the original data is.

7) Deduplication Criteria: Cryptographic techniques should ensure that data is not duplicated when stored on the cloud, whether at the source client-side or the destination cloud side.

8) Replication Criteria: Cryptographic techniques should ensure the high availability of data stored on the cloud through replication without revealing what the original data is.

## C. Proposed Implementation Framework

The application and implementation of the above cryptographic techniques along the end-to-end cloud-based e-learning architecture can be done in a holistic and guided software framework as follows:

1) A multi-agent system consisting of software agents could be installed on all users' devices including computers, smartphones, and tablets to perform various activities based on each user's roles and attributes.

2) Administrators could manage cryptography applied to cloud storage and each of the cloud service models of IaaS, PaaS, and SaaS.

3) Students could encrypt, decrypt, sign, authenticate, manage keys, choose ciphers, verify certificates and signatures and check e-assessment cryptography features based on the roles, privileges, and attributes they have been assigned.

4) Since high-end and computationally intensive cryptographic techniques have been proposed, the underlying cloud infrastructure could be provisioned with adequate resources such as Graphical Processing Units (GPU), virtual GPUs (vGPU), and memory, to handle both Cloud Tier cryptographic processes and to sustain client-side ones that could be outsourced to them via the agents.

5) The locally installed software agents could use the available end-user device resources to perform calculations if the device can support such activities using inbuilt technology such as trusted platform modules in the case of computers and laptops or encryption chips for smartphones.

6) The local agents could interface with web browsers installed on the end-user devices and provide access to the e-learning services through a web portal without affecting user experience or adding ambiguity.

7) If the e-learning platform being accessed provides a VPN to the end-user to access its services, the software agent could be the local endpoint of the VPN to the user, providing both token generation and authentication interface and web access to the service via web browser integration.

8) The software agent could also automatically or interactively install security certificates in the web browsers to which it is integrated.

9) The software agent could be integrated into the cloud service management console provided to the administrators by cloud providers via their application programming interfaces.

10) Finally, the administrators could implement and administer the PKI that governs the certificates being used using the software agent.

## V. CONCLUSION

The use of cloud computing and its service models to deliver e-learning technologies, followed by the impact on cyber security aspects and threats was reviewed systematically. The innovative cryptographic techniques used in cloud computing and e-learning have been presented in terms of authentication, access control, pseudonymization, data storage, and access. It was observed that instead of a holistic approach to cryptography, only specific aspects of cloud-based e-learning were focused on and that no explicit implementation guidelines nor framework currently exist. As a result, this comprehensive review provides a holistic tabulation of cryptographic techniques for cloud-based e-learning. It also defines a set of criteria that can be used to evaluate whether the existing cryptographic techniques are fulfilling the requirements as needed. Finally, a framework is proposed to implement cryptographic techniques in a unified way across an end-to-end cloud-based e-learning architecture using multi-agent software. The empirical results are considered in the light of some limitations to the existing literature in cryptography

for cloud-based e-learning technologies. For future work, a theoretical framework will be implemented via a holistic approach using different cryptographic techniques. This will lead the pathway to practical implementations of the framework.

**Abstract**—The antenna is a critical component of the communication system. The antenna is used in wireless communication for signal transmission and reception over long distances. There are numerous sorts of antennas, such as wire antennas, traveling wave antennas, reflector antennas, microstrip antennas, and so on. The application of antennas is determined by the antenna's attributes as well as the frequency range of operation. As a result, it is vital to understand the behavior of antennas over a wide range of operations and select the optimum antenna for the application. The performance parameters of the antenna determines its efficiency. VSWR, Return Loss, Directivity, Bandwidth, and more parameters are available. As a result, one of the primary areas of focus is antenna analysis. In this study, we simulate various antenna types and derive performance parameters such as return loss, directivity, and so on. MATLAB will be used to simulate the antenna at various frequencies. When all of the parameters are taken into account, the analysis becomes quite tough. In this case of ambiguity, we use fuzzy logic to calculate the antenna's performance index. A variety of antenna parameters will be fed into the fuzzy inference system, which will make a judgment based on a set of rules. The crisp numbers are turned into fuzzy values using the fuzzification process, then evaluated and defuzzified to obtain the antenna's performance index. The fuzzy inference system will be developed in MATLAB, and the overall system will be modeled in Simulink.

**Keywords**—Antenna; antenna element; function; fuzzy logic function; fuzzy inference system; Matlab; Simulink

### I. INTRODUCTION

A radiated element is a type of electrical equipment that converts electric power into radio waves, allowing the signal to be transmitted over open space. It also converts incoming radio signals to electrical impulses. As a result, in the field of wireless communication systems, the antenna is extremely significant. Several things influence antenna selection. The frequency of operation [1], as well as the application, are two of these criteria. The antenna's performance is determined by numerous criteria such as return loss, reflection coefficient, and voltage standing wave ratio. In this research, multiple antenna topologies are modeled for performance characteristics for different frequencies using MATLAB's antenna [2] toolbox. These parameters are fed into the fuzzy inference system, which analyzes the antenna's performance while taking all of the parameters into account. The fuzzy inference system is created using a rule set drawn from antenna experts'

knowledge. Using fuzzy rules, the crisp values are fuzzified [3] and assessed for performance, while the linguistic values are defuzzified to crisp values. The proposed fuzzy inference method is used to analyze the antenna's performance. Simulink is used to model the system, and the performance of the antennas at various frequencies is assessed, as well as the performance variation of the antennas regarding frequency, is plotted. This study addresses the construction of a system that uses fuzzy logic to examine the performance of antenna configurations. The antenna structures are simulated in this step using the MATLAB antenna design toolkit, and the performance parameters are extracted. These collected parameters are fed into the analyzer, which determines the antenna's performance. Lotfi A. Zadeh published a study on fuzzy logic in 1964. Zadeh continued to develop the fuzzy set theory between 1965 and 1975. Fuzzy logic arose as a result of the challenges experienced by standard mathematical techniques in constructing and evaluating complicated systems. The performance study of the antenna structure is particularly complex because the parameters that determine performance must be considered and studied at the same time. The fuzzy inference system described in this paper was designed to avoid this complexity [4]. The first research team considers the use of fuzzy logic in educational institutions. It discusses how fuzzy logic can be used to analyze student performance. The marks earned by pupils are fed into the fuzzy inference system, which evaluates the student's performance. The rectangular microstrip antenna [5] was modeled and simulated. It also provided a method for integrating Matlab into Visual Basic. Matlab is a great tool for designing and simulating antenna structures of all types. The tool provides a detailed explanation of the performance parameters of the designed antenna. [6] Proposes utilizing Matlab to construct and analyze a parabolic reflector. [7] examines the analysis of E-plane and H-plane normalized patterns. Analysis of the parabolic reflector, such as f/D, gain, and radiation patterns, was performed, and the appropriate results were provided. A second study team considers faculty performance evaluation in educational institutions. In this research, we propose the creation of a fuzzy inference system to evaluate the antenna's performance. MATLAB is used to simulate the many types of antennas [8] describes the modeling of a rectangular microstrip antenna using Matlab and Visual Basic. [9]. Shows a Matlab simulation of an NxN antenna array, with the antenna array factor indicated for each person. It demonstrates the effect of increasing the directivity of the

DOI: 10.14569/IJACSA.2022.0130109

beam array factor of the antenna array with an increase in antenna elements, as well as analyzing the effect of increasing the antenna elements on the array factor.[10]-[11]-[12]-[13] cover the design and improvement of antenna element performance. The design of many antennas is known in the literature. [14] describes the design of a square patch antenna. A stacked square patch slotted broadband microstrip antenna is described in another paper [15].

## II. FUZZY LOGIC

Nowadays, fuzzy control is considered an important tool for control, in addition, it is used for helping developers to solve several problems such as designing switched dynamic output for continuous-time. A new type of dynamic output feedback controllers, namely, switched dynamic parallel distributed compensation controllers, is proposed, which are switched by basing on the values of membership functions. For guaranteeing stabilities, and maintaining parameters values, we propose, for the various antenna structures, abased fuzzy logic functions solution to be used for performance analysis. In practice, type-2 fuzzy logic was initially introduced by Zadeh [16]. The presented technique has been proved to be very interesting especially in complex problems which are treating real-world noisy applications [17]. We know that during system development steps, Type-2 Fuzzy Logic (T2FL) defines the same lexicon of the classical type-1 FL as membership functions, rules, norms operations, fuzzification, inference, and defuzzification [18], but those terms have unlike definitions to picture them. The big differentiation between Type-1 and Type-2 FL consists essentially in kind of fuzzy sets and in the output processor step which precedes the defuzzification bloc; the type-1 MFs are certain and crisp, whereas these type-2 are themselves fuzzy; they are represented by a bounded region limited by two MFs, were corresponding to each primary MF (which is in  $[0, 1]$ ), a secondary MF is used to the primary one. With regard to the output processor, in type1 FLSs it is represented just by the known defuzzification process (center of sets...), however, in type-2 FLSs it consists of two components: Type reduction and defuzzification; type reduction makes a reduction from a type-2 fuzzy output sets to type-1 sets and then these reduced sets will be defuzzified to obtain the final crisp outputs. Zadeh pioneered fuzzy logic in the 1960s and 1970s. Fuzzy logic incorporates human knowledge with operational algorithms. The computer may be programmed to work in the same way that the human mind does. Traditional logic and set theory are all about whether something is true or false, white or black, zero or one. Fuzzy logic, on the other hand, accepts all conceivable values.

### A. Fuzzy Sets

The fuzzy set notion is simply an extension of the classical set concept. When compared to the classical set, the fuzzy set is substantially larger. The classical set has only a few membership options, such as true or false, '0' or '1'.

### B. Fuzzification and Defuzzification

The values must be linguistic in order to be applied to the fuzzy inference system. The degree of membership in the fuzzy set is used to represent these linguistic values. Fuzzification refers to the process of transforming these crisp linguistic values into fuzzy linguistic values. The technique of producing

quantitative outcomes is known as defuzzification. The fuzzy inference system will generate a fuzzy result that will be represented in terms of the degree of membership of fuzzy sets. Defuzzification assigns explicit real values to the membership degrees of fuzzy sets.

## III. IMPLEMENTATION

In this article, several antenna topologies are simulated for different frequency ranges using the MATLAB antenna processing tool. With this collection of characteristics, analyzing the performance of the antenna becomes a tiresome task. At this point of uncertainty, the fuzzy logic idea [19] is used to examine the performance of the antennas while taking into account all of the characteristics. The antennas [20] are simulated for frequency ranges ranging from 1MHz to 10MHz, and the performance characteristics are assessed with a fuzzy inference algorithm to provide a performance index. The derived performance index is displayed versus frequency

## IV. SIMULATION RESULTS AND DISCUSSIONS

### A. Antenna Design and Simulation

Antennas are constructed and simulated in Matlab using the antenna design toolbox. We primarily built and simulated five antenna structures: a bow-tie antenna, a monopole antenna, a dipole antenna, an inverted f antenna, and a helix antenna. The simulation yields parameters such as directivity, VSWR, and reflection coefficients, which determine the antenna's performance. The concentration of radiation in a specific direction is measured by directivity. It specifies the antenna's directionality. Efficiency affects both directivity and gain. Patterns can be used to simply determine directivity. The ratio of maximal radiation intensity to average radiation intensity is defined as directivity. The return loss is another key aspect that influences performance. It is a parameter that reflects how much power is lost. As a result, it is a critical element in determining antenna performance. The simulation's VSWR and reflection coefficients are retrieved and used for further processing.

### B. Development of Fuzzy Inference System

- The If and Then set of rules is used to create a fuzzy inference system. The regulations are determined based on professional guidance, taking into account all factors of antenna performance.
- The fuzzy system's output is the linguistic value, which must be translated back to crisp value. Defuzzification is the name given to this type of conversion. Defuzzification strategies include the max membership concept, the centroid method, the weighted average method, the mean max method, the center of sum, the center of the biggest area, and the first (or last) of maxima. The centroid approach is utilized for defuzzification in this article. The centroid approach is also known as the center of gravity method.
- The fuzzy logic toolbox is used to create the fuzzy decision system. Performance characteristics such as VSWR, reflection coefficient, return loss, and directivity is fed into the system. Fuzzification is a

process that converts crisp input values to fuzzy language variables.

- The core of the membership function for the given fuzzy set A is defined as that region of the universe characterized by complete and full membership in A. This means that the core consists of those universe elements x such that  $A(x) = 1$ . The set of fuzzy linguistic variables is referred to as the fuzzy set A. Triangular membership functions are studied in this study.

### C. Parameters of Performance

During the simulation step performance parameters of the antenna are determined and the performance variation value parameters are presented in Table (I) to the Table (V), for bow-tie antenna, a dipole antenna Table (II), inverted f antenna Table (III), a monopole antenna Table (IV), and helix antenna respectively. We simulated the antennas in the frequencies range from 1 Mhz to 10 Mhz.

We presented values in Table (I). In practice, the obtained performance index parameters are optimized due to the fuzzy inference system, we analyze d using the fuzzy rules and the performance index is obtained. Table VI gives the variation of the performance index of various antennas at different frequencies.

These performance parameters are input to the fuzzy inference system and analyzed efficiently by using the fuzzy rules. We storage, at a different frequency, performance index variation of various antennas in the Table (VI). We present a plot of performance index variation in Fig. 7. We need a reasonable separation range than a semantic obfuscation technique. At level 3, semantic obfuscation technique separation range came to 40.6 km, which is a high accomplishment regarding area protection, yet utility of administration is debased, while at that level enhanced semantic obfuscation technique accomplished balance between area protection and administration utility, see Table I.

## V. CONCLUSION

In this research, various antenna topologies are simulated using Matlab, and performance characteristics are retrieved from the simulation results. The antennas are simulated for frequency ranges ranging from 1MHz to 10MHz. Based on fuzzy logic, this research provides a new method for evaluating the performance of an antenna. The traditional mathematical paradigm for decision making cannot be applied to complicated systems such as antenna performance. As a result of this paper, this problem is alleviated, and an exact evaluation of the antenna's performance is possible. The fuzzy system is created, and the proposed system is modeled with Simulink. The constructed system is fed inputs, and the output is observed. The obtained performance index of the antennas is plotted. According to the results of the analysis, the inverted f antenna outperforms the other antennas studied in the frequency range 1MHz to 10MHz.

## ACKNOWLEDGMENT

The Author would like to acknowledge the Dean of the Khurma University College and the Taif University Department of Scientific Research in the Kingdom of Saudi Arabia, for motivation to accomplish the research work.

**Abstract**—Sorting is one of the most frequent concerns in Computer Science, various sorting algorithms were invented for specific requirements. As these requirements and capabilities grow, sequential processing becomes inefficient. Therefore, algorithms are being enhanced to run in parallel to achieve better performance. Performing algorithms in parallel differ depending on the degree of multi-threading. This study determines the optimal number of threads to use in parallel merge sort. Furthermore, it provides a comparative analysis of various degrees of multithreading. The implementation in this empirical experiment takes a group of devices with various specifications. For each device, it takes fixed-sized data set and executes merge sort for sequential and parallel algorithms. For each device, the lowest average runtime is used to measure the efficiency of the experiment. In all experiments, single-threaded is more efficient when the data size is less than  $10^5$  since it claimed 53% of the lowest runtime than the multithreaded executions. The overall average of the experiments shows either four or eight threads, with 72% and 28%, respectively, are most efficient when data sizes exceed  $10^5$ .

**Keywords**—Parallel merge sort; sort; multithread; degree of multithreading

## I. INTRODUCTION

Merge sort is a divide and conquer algorithm that was invented by John von Neumann in 1945, it is an efficient, general-purpose, comparison-based sorting algorithm [1]. Most implementations produce a stable sort, which means that the implementation preserves the input order of equal elements in the sorted output. A detailed description and analysis of bottom-up merge sort appeared in a report by Goldstine and Neumann as early as 1948 [2]. Such divide and conquer algorithm recursively break down a problem into sub-problems, making it simple to be solved easily, then combine the solutions of the sub-problems until the original problem is solved. In sorting  $n$  objects (list of array elements), merge sort is an efficient algorithm that has an average and worst-case performance of  $O(n \log n)$  [2].

If the running time of merge sort for a list of length  $n$  is  $T(n)$ , then the recurrence  $T(n) = 2T(n/2) + n$  follows from the definition of the algorithm (apply the algorithm to two lists of half the size of the original list and add the  $n$  steps taken to merge the resulting two lists). In the worst case, the number of comparisons merge sort makes is equal to or slightly smaller than  $(n \log n - 2 \log n + 1)$ , which is between  $(n \log n - n + 1)$  and  $(n \log n + n + O(\log n))$  [3]. In the section below, a pseudo-

code of merge sort is illustrated, followed by an example in Fig. 1, using a simple data set of  $\{38,27,43,3,9,82,10\}$  [4].

Fig. 1 illustrates how the algorithm divides all items one by one then combines them recursively. This approach indicates the possibility of applying the algorithm in parallel. Hence, parallel merge sort reduces the complexity to  $O(n \log n/t)$ , where  $t$  is the number of threads, by using multi-threaded operations where the data is divided into equal portions and each portion is assigned to a specific thread. The complexity is reduced to  $O(n)$  but could vary according to the number of threads used [5].

Merge sort is suitable when the data structure is a linked list because it is a sequential access structure. Implementing a linked list hinders the performance of other algorithms such as quicksort and heapsort [6,7]. Moreover, parallel merge sort is frequently used in various domains, including; sorting NoSql databases [8], high-performance computing environments [9], and massively parallel architectures [10,11].

### Algorithm 1 Merge Sort

---

```
1: procedure Mergesort
2:   var list left ,right , result
3:   if length(m) ≤ 1 then return m
4:   else
5:     var middle = length(m) / 2
6:     for each x in m up to middle do
7:       add x to left
8:     end for
9:     for each x in m after middle do
10:      add x to right
11:    end for
12:    left ← mergesort(left)
13:    right ← mergesort(right)
14:    result ← merge(left, right) return result
15:
```

---

When it comes to executing algorithms in parallel, most studies show results of the performance on several processors [12-15]. These results will mainly rely on the specifications of the device and the behavior of the execution in terms of multithreading. The question that led to this research is, what is the suitable degree of multi-threading required for parallel merge sort? This study conducts an empirical experiment and highlights several factors that influence multithreading performance. First, the number of cores that affect multithreading performance and second, the given data size that demands multithreading when a single-threaded performance degrades.

Fig. 1. Merge Sort Algorithm.

The contribution of this paper is to determine the optimal number of threads to use in parallel merge sort. Furthermore, it provides a comparative analysis of various degrees of multithreading. Each data size is examined among a determined number of threads, starting from one thread (sequential), two, four, eight, and sixteen threads (parallel).

In Section 2, related studies were taken to see how parallel merge sort was implemented and what the results were. Section 3 explains and walks through how the experiment was conducted. The results are illustrated in Section 4 and elucidated in the discussion. Finally, Section 5 presents the conclusion of this study.

## II. RELATED WORK

There have been several papers that conducted various researches on parallel merge sort, and they have come up with the following.

Jeon [13] improved parallel merge sort by distributing and computing the approximately equal number of keys in all processors throughout the merging phases. Using the histogram information, keys can be divided equally regardless of their distribution, which evaluated the speedup showing a better performance by applying parallel merge sort on two different parallel machines: a Cray T3E and a Pentium III PC cluster on maximum data size of  $10^6 \times 4$ .

The tested algorithm on loosely coupled parallel machines and the performance of the algorithm has been observed. It has been found that the computational time of the algorithm varies logarithmically for a varying number of processors scenario [14].

Uyar [5] experimented with applying parallel merge sort using multi-threads similar to this experiment. It stated that two threads could perform one merge operation simultaneously. One thread generates the first half of the sorted values that start from the minimums of the two sorted subsets. The other thread generates the second half of the sorted values starting from the maximums of the two sorted subsets. It also compared it with double merging by using four threads implementing it on Java. The comparison focused on array sizes from 10 million up to

50 million. In this study, the array size starts from 5000 up to 50 million to detect when executing in parallel is more efficient than sequential.

A study was conducted on three parallel sorting algorithms (Odd-even transposition sort, Parallel rank sort, and Parallel merge sort) on a number of processors 2, 4, 6, 8, 10, and 12 on 10000 integers [15]. The results proved that parallel merge sort was the fastest, yet the study was comparing only one input size and may differ when the data size increases.

These previous studies show that merge sort could be conducted in parallel in several ways, giving better results than sequential as the array size increases [5,13-15]. Yet, these studies were concerned with enhancing the performance of merge sort without comparing the degree of multi-threading. Only [5] compared different array sizes that were only applied up to four threads on a specific range of sizes, from  $10^6$  to  $10^6 \times 5$ . This study experiments parallel merge sort on four different degrees of multi-threading in a broader range of array sizes from  $10^5$  to  $10^7$ , which is explained in Section 3 maintaining the integrity of the specifications.

## III. EXPERIMENT

### A. Requirements

This experiment was implemented on Java SE8. It was conducted on five devices to ensure diversity in the environment of implementation. Moreover, to verify the results are not dependent on the specifications of a particular device. The specifications of the devices used in this experiment are shown in Table I.

### B. Implementation

This experiment takes a specific data set and executes it in two approaches: 1) Sequential (one thread), 2) Parallel (two, four, eight, and sixteen threads). The source code is available on <https://github.com/muhyidean/ParallelMergeSort.git>.

The implementation in this experiment takes a data set and applies merge sort for sequential and parallel algorithms. For sequential, it executes Algorithm 1. As for parallel, it executes Algorithm 2 based on the following:

1) *Data formation:* The array sizes for the data sets begin from  $10^3 \times 5$ ,  $10^4$ ,  $10^4 \times 5$ ,  $10^5$ , ... up to  $10^7$ . Based on the array size, ten different random data sets are initiated to be implemented in both execution approaches. Each data set will be placed in a separate array and executed in each approach. The average runtime of ten executions for each array size is taken in milliseconds.

TABLE I. DEVICE SPECIFICATIONS

	OS	Processor	# Cores	RAM
Device 1	Windows	Intel i5	4	16
Device 2	Windows	Intel i7	8	16
Device 3	macOS	Intel i5	4	8
Device 4	macOS	Intel i7	8	16
Device 5	Ubuntu	Intel i5	4	4

2) *Partition process*: The partitioning will be in five categories, one in sequential and four degrees of multi-threading 2, 4, 8, 16. The original data set is considered the first partition, so it will be directly executed (sequentially). Then the same data set is taken and split in half making two data sets, each partition is assigned to a thread to run parallel. The process goes on for the other partitions with respect to the number of threads to be implemented which are two, four, eight, and sixteen.

3) *Thread management*: The implementation for the parallel merge sort divides the array into sub-arrays to be sorted by the number of threads. The threads sort their assigned sub-arrays independently. Two consecutive sorted sub-arrays are combined by one thread. Each merging thread merges two sorted arrays. The merge operation follows this approach. Whenever the arrays are sorted, the number of arrays is decreased by half. During the last iteration, two sorted arrays are merged to produce a sorted array. This implementation did not use any third-party libraries/frameworks, it was implemented with the java thread package in JDK (Java Development Kit).

Fig. 2 illustrates the partitioning process and the merging mechanism. Each elliptical shape is considered a thread; the shapes labeled with D represent the partition of the original array sorted by merge sort. The shapes labeled with M merge the results from the previous threads until it merges the whole array. To be better illustrated, sixteen threads are not shown Fig. 2 because it follows similar partitioning.

### C. Data Analysis

Tables III to VII shows the average runtime for different array sizes on each. Furthermore, they also show how each device performs on different execution approaches (sequential and parallel). For example, the average execution time is calculated by running the algorithm ten times, then the average of times is taken. Table II is one of the execution results for device 4 on array size  $10^5$ . For instance, the result shows that (Th-4) was the most efficient for this case. However, it may differ as the size increases and is subject to the device specifications. For each device, on each data size, it will have a table like Table II.

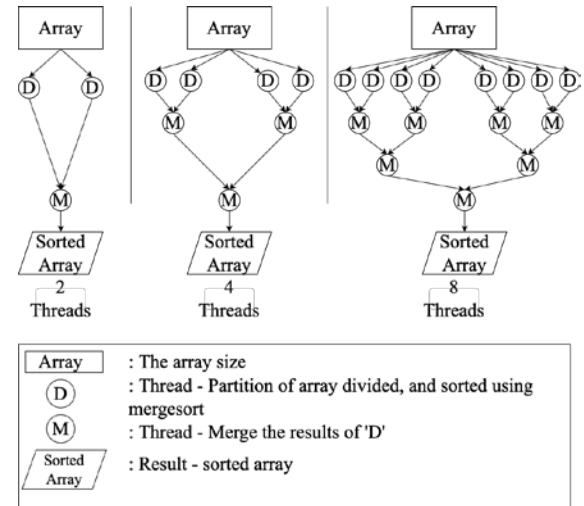

Fig. 2. Parallel Merge Sort using Three Degrees of Multi-threading (2,4,8).

### Algorithm 2 Parallel Merge Sort

```

1: procedure PMergesort
2: var val ← (v) // v: the number of values here
3: // x: the number of threads
4: var list arr test _1[ ], arr test 2[ ], ...arr test x[ ] // Defining main arrays
5: var list arr 2[ ] ... arr x[ ] // Defining sub arrays
6: // Defining threads to execute merge sort for each array
7: threads t1(mergesort(arr 1)), t2(mergesort(arr 2))... t_x(mergesort(arr x))
8: // Assign random integers to main arrays, to give each same set of random values
9: for i ← 0 to val do
10: n ← random value in range of (1 - x)
11: arr test1[ ], arr test 2[ ], ...arr _test x[ ] ← n
12: end for
13: // Partition data set and add into x sub arrays for each set of threads
14: var mid ← (length of arr test x/x) // Get mid points for each partition
15: * repeat code in line 14 for x partitions
16: // Calculate the time taken for each set of threads
17: var ts ← take current time
18: execute t1 , t2 ... tx // Execute threads
19: var te ← take current time
20: * repeat codes in lines (17 - 19) for each set of threads (2,4, 8 ... x)
21: var tr ← ts - te // to calculate the time taken in parallel mergesort (x threads)
22: file ← export results(tr1,tr2...trx) // to take results (time taken in milliseconds)
23: end procedure=0

```

#### IV. RESULTS AND DISCUSSION

This section highlights and points out the main findings of the empirical experiment. To measure the efficiency of the experiment, the lowest average execution time (ms) is taken for each data size on each device.

##### A. Results

In Tables III to VII, it shows the average of 10 executions for each degree of multi-threading. Each column is a different size starting from  $10^3 \times 5$  up to  $10^7$ . The rows show the performance of each thread for a specific data size. For example, (Th-1) is one thread, (Th-2) is two threads and goes on. As shown in Tables III to VII, for data size  $10^3 \times 5$ , all devices perform efficiently in terms of runtime in a single-threaded execution. As for the sizes  $10^4$  and  $10^4 \times 5$ , it varies from one to eight threads depending on the number of cores in the device. With data sizes of  $10^5$  and larger, each device performs better with a certain number of threads, depending on the number of cores. All results are illustrated in Fig. 3 to 7.

Fig. 3 to 7 illustrates the performance graphs according to different data sizes and the number of threads used. Multithreading is clearly more efficient when the data size increases. The appropriate number of threads will generally be visible when the data size exceeds  $10^5$ .

##### B. Findings

There were two main findings from these results. First, multithreading does not always have the most efficient runtime as it depends on the data size. Second, even when the data size increases, a specific number of threads will determine the optimized performance based on the device specifications. In other words, implementing as many threads as possible will not lead to higher runtime performance.

Tables VIII and IX were presented to highlight the findings of the results, one below  $10^5$  and the other greater  $10^5$ . Table VIII shows the overall average for each device with data sizes below  $10^5$ . For example, in Device 1, the sequential runtime performance was most efficient. By taking the overall average,

single-threaded was more efficient since it claimed 53% of the lowest runtime than the multithreaded executions. Table IX shows the overall average for each device with data sizes above  $10^5$ . As shown in Table IX, multi-threaded implementation with either four or eight threads provided better performance with 72% and 28%. Fig. 8 and 9 visualize which threads performed better in the overall average for different data sizes. A higher percentage indicates that using a specific number of threads is more efficient on a particular data size.

Based on the experiment results, all devices that have four cores achieved efficient runtime performance with four threads. Moreover, all devices with eight cores achieved efficient runtime performance with eight threads. Evidently, the selection of the number of threads is mainly determined by the number of the cores.

##### C. Discussion

The main question of this study is, what is the optimal number of threads for parallel merge sort considering two main factors: data size and number of cores?

TABLE III. DEVICE 1 - RESULTS - AVERAGE RUNTIME (MS)

Fig. 3. Device 1 - Results - Average Runtime (MS).

The results of this study had shown that having as many threads as possible will not lead to the best runtime performance. To achieve the best runtime performance, the number of cores present is crucial in determining the optimal number of threads. The cruciality is due to how multiple threads are executed by the operating system. Correspondingly, the data size determines whether multiple threads are required. In small data sets, the use of multiple threads is unnecessary since one thread can perform more efficiently.

The conclusion is that if the data size is under 10<sup>5</sup>, single-threaded will be more efficient. In contrast, having multiple threads will perform better for data sizes that exceed 10<sup>5</sup>. In addition, it should not spawn threads more than the number of cores (excluding merging threads).

## V. CONCLUSION

This study conducts an empirical experiment to determine the optimal number of threads to use in parallel merge sort. Several factors are discussed in this study to answer this question. First is the number of cores that impact multithreading performance. Second is the given data size that requires the use of multiple cores.

The implementation in this experiment takes a group of devices with various specifications. For each device, it takes fixed-sized data set and applies merge sort for sequential and parallel algorithms. For each device, the lowest average execution time (ms) is used to measure the efficiency of the experiment. Taking the average for all experiments, single-threaded is more efficient when the data size is less than  $10^5$  since it claimed 53%. Whereas, for data sizes exceeding  $10^5$ , multi-threaded implementation has better performance. The overall average of the experiments shows either four or eight threads are most efficient, with 72% and 28% respectively.

There were two main findings from these results. First, multithreading does not always have the most efficient runtime as it depends on the data size. Second, even when the data size increases, a specific number of threads will determine the optimized performance based on the device specifications. In other words, implementing as many threads as possible will not lead to higher runtime performance.

The conclusion is that if the data size is under  $10^5$ , single-threaded will be more efficient. In contrast, having multiple threads will perform better for data sizes that exceed  $10^5$ . In addition, the number of threads spawned should not exceed the number of cores (excluding merging threads).

**Abstract**—Despite the importance of big data, it faces many challenges. The most important big data challenges are data storage, heterogeneity, inconsistency, timeliness, security, scalability, visualization, fault tolerance, and privacy. This paper concentrates on privacy which is one of the most pressing issues with big data. As mentioned in the Literature Review below there are numerous methods for safeguarding privacy with big data. This paper introduces an efficient technique called Specialized Negative Database (SNDB) for protecting privacy in big data. SNDB is proposed to avoid the drawbacks of all previous techniques. SNDB is based on deceiving bad users and hackers by replacing only sensitive attribute with its complement. Bad user cannot differentiate between the original data and the data after applying this technique.

**Keywords**—Big data; big data challenges; privacy violations; privacy-preserving techniques; special negative database; data integrity

## I. INTRODUCTION

One of the most pressing challenges in big data is data privacy. Patients' data must be kept private since there is a risk of improper use of personal information being exposed when data from multiple sources is combined. In Privacy, every person has the right to select the extent of his or her interaction with the environment, as well as the amount of data that can be accessible by a third party. While it is sufficient to detect information as a "password" in security issues, since security is between two trusted parties, the server provider (SP) may be an adversary in privacy difficulties. We classified likely privacy violations in big data systems into four categories based on a literature review: data breaches, re-identification attacks, information gathering by service providers, and government tracking. The motivation of this manuscript is the importance of preserving privacy for everyone specially when dealing with big data. Also, the drawbacks of previous techniques like time consuming, losing data integrity, increasing size of data, low level of privacy and high complexity are one of the motivation factors for the author to propose a new technique called SNDB that will avoid drawbacks of other techniques. The next section will introduce literature review of previous techniques and their drawbacks. While in the third section, proposed technique and the manuscript contribution will be introduced. In fourth section, the author will introduce datasets used in proposed technique. Fifth section will discuss results and evaluation of the proposed technique when comparing with other

techniques. Finally, conclusion and future work will be introduced [1], [2], [3], [4].

## II. LITERATURE REVIEW

### A. Privacy Preserving by Slicing

Slicing is a method of dividing a dataset in vertical and horizontal manner. The process of dividing attributes into columns based on their correlations means vertical partitioning. Slicing can handle data with high dimensions according to attribute splitting. However, horizontal partitioning happens when records are combined into various buckets, and values in each column are permuted within each bucket randomly to disrupt the relationship between columns. The links between columns are broken by slicing, but the associations within each column are preserved [5].

### B. Privacy in Big Data Generation Phase

1) *Access restriction*: Advertisement blockers, encryption methods, anti-tracking extensions, anti-virus software and anti-Malware are used to limit the access to sensitive data [6].

#### 2) *Falsifying data*

- Socketpuppet is a deception-based method of masking an individual's internet identity [6].
- Users can use MaskMe to establish aliases for personal information such as their credit card number or email address [6].

### C. Privacy in Big Data Storage Phase

1) *Attribute based encryption (ABE)*: ABE is a cloud storage encryption technique that assures big data privacy. The data owner defines the access policies in ABE, and data is encrypted according to those policies. Users whose features match with the data owner's access requirements can decrypt the encrypted data [6].

2) *Identity based encryption (IBE)*: IBE is used to simplify key management in a certificate-based public key infrastructure (PKI) by employing personal identities as public keys, such as an IP address or an email address, to maintain sender and receiver anonymity [6].

3) *Homomorphic encryption*: By calculating directly on the encryption of a message, it is possible to obtain the encryption of a function of that message [6].

4) *Storage path encryption*: The huge amount of data is first divided into numerous sequential parts, and each component is then saved on a distinct storage media controlled by several cloud storage providers [6].

5) *Usage of hybrid clouds*: The inherent qualities of public clouds, such as scalability and processing capacity, are combined with the inherent features of private clouds, such as security, to open up possible research opportunities in the processing and storage of enormous amounts of data [6].

#### D. Privacy in Big Data Processing Phase using Anonymization Techniques

1) *Generalization*: In the taxonomy of an attribute, a parent value is used to replace some values. An artist, rather than a singer or actor, might be used to symbolise a job attribute [6].

2) *Suppression*: A special character (e.g., \*) is replaced for some values to declare that the modified value is not exposed in suppression. Value suppression, record suppression and cell suppression are examples of suppression schemes [6].

3) *Anatomization*: Rather of changing the quasi-identifier or sensitive features, anatomization separates the connection between the two [6].

4) *Permutation*: By dividing a set of data into groups and rearranging the sensitive values within each group, the connection between the quasi-identifier and the numerically sensitive feature is de-associated in permutation [6].

5) *Perturbation*: The actual data values are replaced with generated data values in perturbation, resulting in statistical information acquired from modified data that is statistically similar to that computed from the original data [6].

#### E. Privacy Protection Using Laws and Cyber Security

1) *Privacy laws and regulations*: Regulations and Laws have helped to protect privacy by limiting government tracking and limiting the reading, analysing, and publishing of users' personal information. Laws can also compel service providers to put in place necessary safeguards to protect data confidentiality and prevent data theft. This can enhance protecting privacy by avoiding privacy violations [7].

2) *Cyber security measures to prevent data breaches and cyber attacks* [7], [8].

- Honeypots and other espionage devices.
- Firewalls and other preventative measures.
- Malicious behavior is also detected via access logs and alert systems.
- Mechanisms for encrypting data.

#### F. Foggy Dummies

This approach is utilized in fog computing, and the fundamental idea is to create extremely intelligent dummies to preserve the user's privacy. This technique is used by the researcher to swap requests between fogs before sending them to server provider and then swapping the responses. This will be accomplished by fogs cooperating to exchange data before

sending it to the server provider [9].

#### G. Blind Third Party (BTP)

The essential point is why we must rely on a third party (TP) to keep the user safe from SP. That is, we are transferring the problem from one server to another. This strategy is dependent on fog's role as a middleman between the user and the SP in each location [9].

#### H. Double Foggy Cache

The primary idea behind this method is to use traditional cooperation to tackle the problem of peer trust. Furthermore, use SP to preserve your privacy. This strategy, in particular, can be seen as a significant advancement in the field. To accomplish this, we propose placing two caches in the Fog that will operate as intermediaries between peers. The first is for questions, while the second is for responses [9].

#### I. Secured Map Reduce Model (SMR)

As the data passes through the map-reduce phase, this new layer applies the security techniques to each individual piece of data. This security technique should be a simple encryption scheme, so that the complexity of new technique does not interfere with the big data's fundamental functioning. When data is processed using this suggested Secured Map Reduce (SMR) layer of big data, it can also be stored and secured. It begins with the collecting of data from social media, weblogs, and streaming data which is then delivered to Hadoop Distributed File System (HDFS). SMR is a suggested paradigm that adds a privacy layer between HDFS and the Map Reduce Layer (MR). Randomized procedures and perturbation were employed to strengthen the data's privacy [10].

#### J. Blind Peer Approach

This technique fixes the fundamental flaw in the prior technique, in which blind third party may collude with server provider to infringe on consumers' privacy. The new notion in the BLP strategy is to rely on collaboration with a large number of peers rather than dealing with a single TP. As a result of user's request would be sent to another peer in the same area, then encrypted by SPPK, giving the other peer no choice but to pass the question on to the SP, who would decrypt and resolve it [11].

#### K. Integrated Blind Parties (IBPs)

By integrating the BTP and BLP, This IBPs strategy raises the level of privacy while removing the disadvantages of the other seven options. When a peer isn't active in the area, the user can only rely on the BLP in this case. Furthermore, in the event of a resource shortage, without encrypting the query, the user might exchange it with another peer. In that circumstance, the peer can perform the BTP strategy rather than the user. This strategy can be used in any of the seven techniques [11].

#### L. Negative Database Conversion Algorithm

Instead of a single tuple, a negative database conversion technique is utilised to generate a big set of values. The data sets that have been generated are inserted into the database. In contrast to normal database applications, a harmful request in our negative database will be unable to access the database's

data. Because of the fabrication of fake sets of data in comparison to the premier data, the term negative is utilized. Both database encryption algorithms and virtual database encryption are used to encrypt the actual data [12].

#### M. Negative Database and Generic Database

The Entity, Attributes, and Values model of the general database design (EAV) was evaluated using the blob data storage type. The data collected, such as exam results, will be organized into three columns Entity, Attributes and Values as the name implies, the EAV is made up of three parts: entities, attributes, and values. The most straightforward approach to apply this principle is to create three tables for each data input (entity). There are two ways to implement the Negative database concept: one that statically generates negative data, i.e. the System Administrator defines the Negative data. Another that both statically and dynamically generates negative data. The user i.e. generates the dynamic negative data [13].

#### N. Enhanced BTP

In this enhanced approach, there is a new factor added to the old BTP, which is a unique token. This new technique consists of seven factors. A unique token is defined when the user sends a hidden code within a query to the service provider (SP) while SP returns the previous query token. Then SP will store the token for each ID generated by the third party, so the previous one cannot be used in a later query. When the third party inquiries from SP, a change will occur on the user's token, and the user will discover unauthorized access to his data by third party, so the proposed technique will be a powerful guarantee that there is no breakthrough [14].

#### O. Light Weight Cryptography Techniques(LWCT)

Based on an oil spill detection application, LWCT is utilized to secure a data transmission framework for the internet of things. Through locative and boundary value aggregation, this strategy eliminates duplicate data transmission. The suggested method protects data transfer by combining known lightweight cryptographic techniques with simple ID-based authentication [15], [16].

#### P. Block Nested Loop (BNL) Skyline Algorithms

This method is used to determine which encryption algorithm is best for ensuring data protection and privacy issue. The author of the Skyline algorithm considers two primary parameters: the rate of variation and the number of dimensions [17].

The author summaries all important drawbacks of previous techniques in the following factors:

- Time consuming
- High complexity
- Losing data integrity
- Low privacy protection
- Increasing size of data

The next section will introduce the major contribution of this manuscript. The author will propose a new technique based on negative database and the deception of bad users or hackers. The proposed technique is special negative database. This manuscript contribution can be summarized to enhance preserving privacy in big data and avoid time consuming, losing data integrity, complexity and violating any other big data challenges like its size, fault tolerance, timeliness and scalability.

### III. PROPOSED TECHNIQUE

In this section, the authors introduce a new technique to protect privacy in big data in a new manner that deceives bad users or hackers.

Bad user cannot differentiate between the original data and the data after applying this technique. This technique is called Special Negative Database (SNDB). SNDB is based on deceiving bad users and hackers by replacing only sensitive attribute with its complement. SNDB takes into consideration all attribute types such as binomial, numeric, polynomial as mentioned in Fig. 1. The authors divided the technique into different cases as we will see in the following subsections.

#### A. Binomial

Binomial attribute means having only two values. Binomial consists of two categories one of them is binary and the other is Boolean. Binary consists of two values 0 or 1 but Boolean is like True or False values or other two values that are vice versa. SNDB deals with binomial attribute by replacing the value with its complement.

#### B. Numeric

The numeric attribute can be either integer or real numbers. SNDB deals with the numeric value in a different manner. It computes the complement of the digit into 9 individually with a maximum of 4 digits from right taking into consideration the national ID.

For example, if the numeric value is 2896547, the value after complement will be 2893452. While in real numbers, SNDB computes the complement of the digit into 9 individually with a maximum of 4 digits from left.

#### C. Date and Time

In the case of the date attribute, the date is divided into the year, month, and day. If the value represents a year, SNDB complement each value as a whole to current year when values are less than current year. If some values are equal to current year, the complement of each value will be a whole to Current year+1. If the value represents a month, SNDB will compute the complement of the value into 13. If the value represents a day, SNDB will compute the complement of the digit into 31.

In the case of time attribute. The time is divided into hours, minutes, and seconds. If the value represents hours, SNDB will compute the complement of the value into 24. If the value represents minutes or seconds, SNDB will compute the complement of the value into 9 for the right digit and into 6 for the left digit.

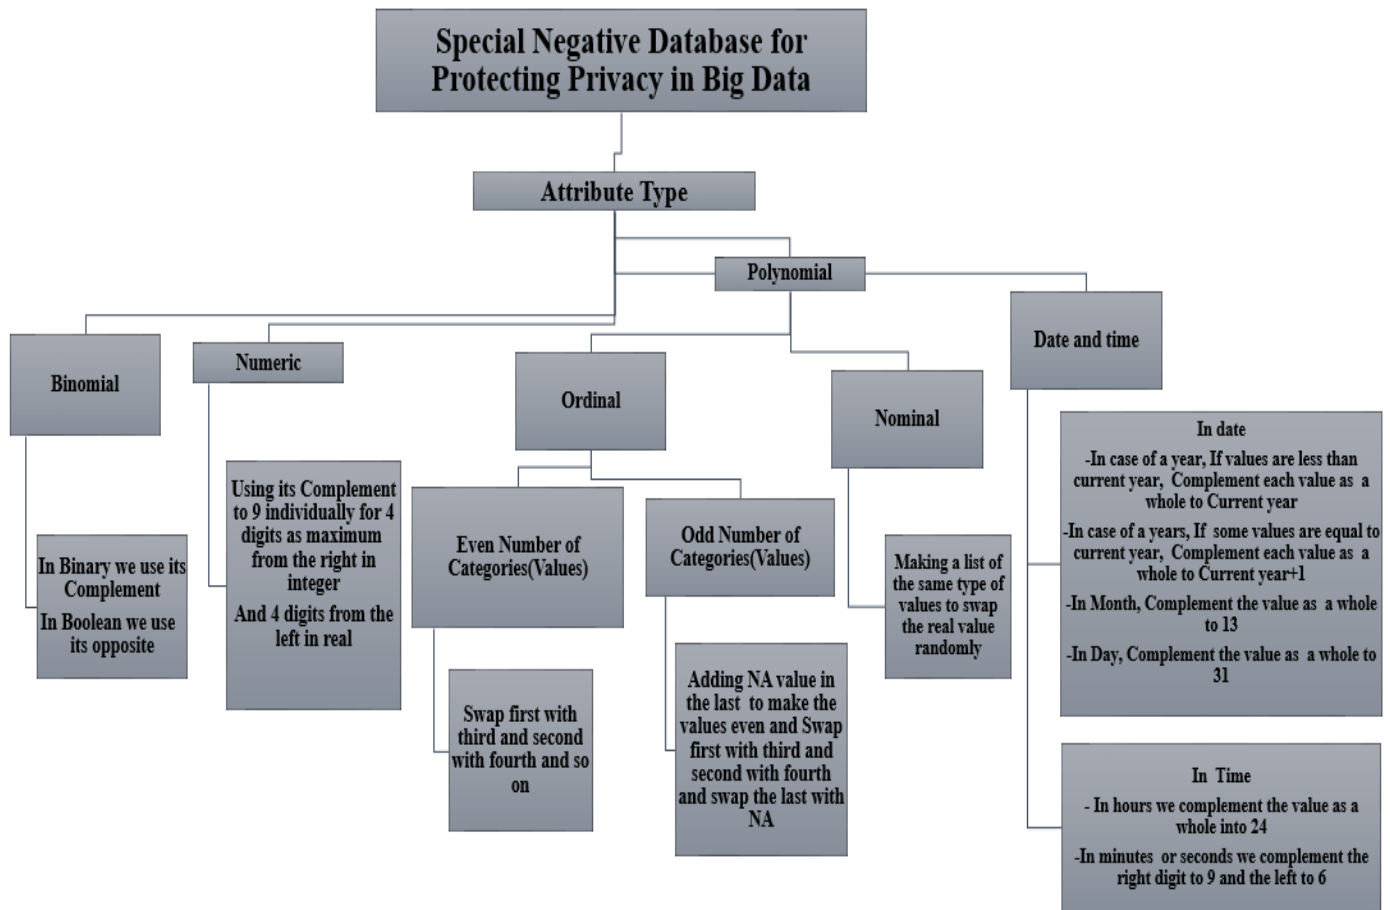

Fig. 1. Architecture of Special Negative Database (SNDB).

#### D. Polynomial

Polynomial means that the attribute has more than two text values. Polynomial is divided into two main types. The first is called ordinal and the second is called nominal.

1) *Ordinal*: Ordinal means that the values can be categorized, classified, ranked, and ordered. Drink size, for example, is an ordinal feature that correlates to the sizes of drinks available at fast-food restaurants. Small, medium, and large are the three possible values for this nominal attribute. These values have a logical order (which correlates to increasing drink size), but the values do not indicate how much larger a medium is than a large. Grade (e.g., A+, A, A-, B+, and so on) and professional rank are two further examples of ordinal characteristics [18].

In ordinal, the number of categories is very important in dealing with the swapping technique. Swapping is used to deceive the bad user that the data is real. In the case of an even number of categories, swapping is very easy to be implemented. SNDB will swap the first value with the third and the second with the fourth and so on. But in case of the odd number of categories, first, we will add the not allowed value (NA) at the last then swapping will be applied as an even manner.

2) *Nominal*: A nominal attribute's values are names of things or symbols. Nominal implies "related to names." Because each value reflects a state, code or category, nominal characteristics are also known as categorical. There is no discernible order to the values.

Enumerations are another term for values in computer science. Hair color and marital status are two attributes are examples of nominal. Black, blond, red, brown, auburn, grey, and white are all conceivable hair color values in our system. The value of single, married, divorced, or widowed can be assigned to the characteristic of marital status. Both marital status and hair color are also examples of nominal attributes. An occupation is another example of a nominal attribute, having values such as teacher, programmer, farmer dentist, and so on [18].

In the Nominal case, it's important to make a list of values to swap between the real value and one from this list randomly. If the values are names of persons, a list of names will be created. Then one value from this list will be selected and replaced randomly with the original one saving its index in the list. This operation will be repeated again and so on. Using the index, we can get the original data.

#### IV. DATASETS

In this paper, we apply our model on different datasets according to sensitive attributes taking into consideration all data types.

##### A. Pollution Dataset

This dataset is about pollution in the United States. The EPA has well-documented pollution in the United States, but downloading all of the data and arranging it in a format that data scientists are interested in is a nuisance. As a result, I gathered data for four key pollutants (nitrogen dioxide, carbon monoxide, ozone, and Sulphur dioxide) for every day between 2000 and 2016 and organized them in a CSV file. There are a total of twenty-eight fields. Each of the four pollutants (NO<sub>2</sub>, CO, O<sub>3</sub>, and SO<sub>2</sub>) has its own set of five columns. 1746661 observations were made. The city, date local, and CO mean are all sensitive parameters.

##### B. Prouni

This dataset is about Brazil student's scholarship given by Brazilian government on the Prouni program. It contains data from 2005 to 2019 and each line of it corresponds to a student who benefits or has benefited from the Prouni program along with details about them. This dataset consists of 2692540 records.

#### V. RESULTS AND EVALUATIONS

This section will list the results and the evaluation of

applying SNDB technique on the datasets for privacy preserving. The author of this paper introduces results for applying SNDB on sensitive attributes in case of binomial, year date and full date and the rest of attribute types will be introduced in the next paper.

##### A. Binomial Results

Assuming that the sensitive attribute is BENEFICIARIO\_DEFICIENTE\_FISICO that means does student have special needs. SNDB swap the value nao that means no with the value sim that means yes and vice versa. Fig. 2 and Fig. 3 illustrate one sample of Prouni dataset before applying SNDB technique and another sample after applying it.

Fig. 4 shows computing some statistical operations on Prouni dataset before applying SNDB technique to get the type of scholarship according to special need. The results show that the number of students who have a special need and have got BOLSA PARCIAL 50% scholarship is 4,947 while the number of who do not have a special need with the same scholarship is 808,557. But students with special needs who have got BOLSA INTEGRAL scholarship is 14,222 while the number of the students who do not have special needs with the same scholarship is 1,862,484. On the other hand, the number of the students with special needs who have got BOLSA COMPLEMENTAR 25% scholarship is 4. While the number of who do not have special needs with the same scholarship is 2,326.

Fig. 3. Sample of Prouni Dataset after Applying SNDB.

Fig. 4. Type of Scholarship with respect to Special need before Applying SNDB.

Fig. 5 shows computing some statistical operations on Prouni dataset after applying SNDB technique to get the type of scholarship according to special needs. The results show that the number of students who have a special need and have got BOLSA PARCIAL 50% scholarship is 808,557 while the number of who do not have special needs with the same scholarship is 4,947. But students with special needs who have got BOLSA INTEGRAL scholarship is 1,862,484 while the number of who do not have special needs with the same

scholarship is 14,222. On the other hand, the number of the students with special needs who have got BOLSA COMPLEMENTAR 25% scholarship is 2,326. While the number of students who do not have special needs with the same scholarship is 4. Fig. 4 and Fig. 5 show that the results have a big difference before applying SNDB and after applying SNDB on the same dataset which mean the success of the algorithm when applying on binomial sensitive attribute.

Fig. 5. Type of Scholarship with respect to Special Need after Applying SNDB.

### B. Date Results

1) *Year date*: SNDB technique deals with sensitive attribute with the type date in a special manner. Assuming the sensitive attribute is ANO\_CONCESSAO\_BOLSA that means the year of the scholarship. It consists of a year only. SNDB applies the complement of a year to the current year (2021). Fig. 6 and Fig. 7 illustrate one sample of Prouni dataset before applying SNDB technique and another sample after applying SNDB on ANO\_CONCESSAO\_BOLSA.

Fig. 8 and Fig. 9 illustrate the difference between gender of the student who has got the scholarship before applying SNDB and after applying it. If we check out Fig. 8 and Fig. 9, we will say that the years of scholarship in the original data are from 2005 to 2019 while years from 2002 to 2016 are the years of scholarship after applying SNDB technique. When taking 2005 as an example, we will see the number of male students is 36,097 and the number of female students is 39,532 in the original data. While in the data after applying SNDB, the number of male students is 108,057 and the number of female students is 131,205 in original data. Fig. 8 and Fig. 9 show that the results have a big difference before applying SNDB and after applying SNDB on ANO\_CONCESSAO\_BOLSA in the same dataset which

means the success of the algorithm when applying on date sensitive attribute of year value only. In the next section the paper will show the result of applying SNDB on different date value.

Full date: Assuming the sensitive attribute is date local. SNDB deals with date local in a different manner, SNDB changes the month only because changing the month is sufficient to change the original data. SNDB swaps January with December and vice versa, February with November and vice versa, March with October and vice versa, April with September and vice versa, May with August and vice versa and Jun with July and vice versa. Fig. 10 and Fig. 11 illustrate one sample of pollution dataset before applying SNDB technique and another sample after applying SNDB on date local attribute. Fig. 12 and Fig. 13 below illustrate the difference between the maximum value of (Sulphur Dioxide and Nitrogen Dioxide) mean before and after applying SNDB on date local. This paper takes the first five days of December,2000 as an example to show the difference between the original dataset and the dataset after applying SNDB technique. When checking out Fig. 12 and 13, we will see the big difference between the values of original and SNDB dataset.

Fig. 11. Sample of Pollution Dataset after Applying SNDB on Date Local.

As seen from results figures above, SNDB is valid for big data since the size of data does not change before and after applying SNDB. Processing time is fast when comparing to traditional negative database. The deception of SNDB technique is big and this makes privacy level is stronger. Bad users or hackers cannot differentiate between the original data and the data after applying SNDB technique. This makes the

decryption very hard for bad users while it is very easy for data owner to decrypt the SNDB data. Table I below shows the comparison between SNDB and traditional negative database. There are comparative results on different datasets because SNDB technique is applied according to sensitive attributes covering all data types of each dataset.

Fig. 12. Maximum Value of (Sulphur Dioxide and Nitrogen Dioxide) mean before Applying SNDB on Date Local.

Fig. 13. Maximum Value of (Sulphur Dioxide and Nitrogen Dioxide) mean after Applying SNDB on Date Local.

TABLE I. COMPARISON BETWEEN TRADITIONAL NEGATIVE DATABASE AND SNDB

Technique	Records in the original pollution dataset	Records in the pollution dataset after applying the algorithm	Records in the original Prouni dataset	Records in the Prouni dataset after applying the algorithm	Processing Time	Deception level	Privacy level	Decryption for users and hackers	Decryption for data owner	Validity for Big data
<b>Traditional Negative Database</b>	1,746,661	3,493,322 In case of full date attribute	2,692,540	5,385,080 In case of binomial and year date attributes	Slow 32 seconds in case of Pollution dataset and 47 seconds in case of Prouni dataset	There is a little deception for bad users and hackers	Strong	Hard	Easy	Not valid because the size of data increases and doubles
<b>SNDB</b>	1,746,661	1,746,661 In case of full date attribute	2,692,540	2,692,540 In case of binomial and year date attributes	Fast 9 seconds in case of Pollution dataset and 12 seconds in case of Prouni dataset	There is a big deception for bad users and hackers	More stronger	Harder	Easier	Valid because the size of data does not change

## VI. CONCLUSION

This paper lists the most important big data challenges and focuses on privacy challenge; it summaries privacy violation situations. The author also provides a list of the most efficient and popular techniques used to protect data privacy with their advantages and drawbacks. The proposed technique in this paper is SNDB based on negative database in different manner. SNDB is based on deceiving bad users and hackers by replacing only sensitive attribute with its complement. SNDB takes into consideration all attribute types such as binomial, numeric, polynomial. SNDB technique is applied on different datasets according to the type of the sensitive attributes of each dataset. In this technique, bad user cannot differentiate between the original data and the data after applying this technique which enhances the level of privacy.

As seen from results, SNDB can avoid drawbacks of previous techniques since it has the advantage of high privacy protection in big data. SNDB has no time consuming since it deals with sensitive attribute only. It also keeps track of data integrity and data size since there is no decreasing or increasing for any record of data and this advantage makes SNDB very suitable for big data. It also has low complexity since it only replaces sensitive attribute value with its complement. After applying SNDB, we can easily get the original data by applying the complement another time according to the rules of the data owner.

## VII. FUTURE WORK

Finally, the author provides the results of applying SNDB on big dataset with binomial, year date and full date sensitive attribute. In the future work, the author will introduce the results of applying SNDB on numeric, ordinal and nominal sensitive attributes. Also, the author tends to take into consideration transposition techniques instead of replacing values with each other's.

**Abstract**—In recent times, one of the most emerging sub-dimensions of natural language processing is sentiment analysis which refers to analyzing opinion on a particular subject from plain text. Drug sentiment analysis has become very significant in present times as classifying medicines based on their effectiveness through analyzing reviews from users can assist potential future consumers in gaining knowledge and making better decisions about a particular drug. The objective of this proposed research is to measure the effectiveness level of a particular drug. Currently most of the text mining researches are based on unsupervised machine learning methods to cluster data. When supervised learning methods are used for text mining, the usual primary concern is to classify the data into two classes. Lack of technical terms in similar datasets make the categorization even more challenging. The proposed research focuses on finding out the keywords through tokenization and lemmatization so that better accuracy can be achieved for categorizing the drugs based on their effectiveness using different algorithms. Such categorization can be instrumental for treating illness as well as improve one's health and well-being. Four machine learning algorithms have been applied for binary classification and one for multiclass classification on the drug review dataset acquired from the UCI machine learning repository. The machine learning algorithms used for binary classification are naive Bayes classifier, random forest, support vector classifier (SVC), and multilayer perceptron; among these machine learning algorithms, linear SVC was used for multiclass classification. Results obtained from these four classifier algorithms have been analyzed to evaluate their performances. The random forest has been proven to have the best performance among these four algorithms. However, multiclass classification was found to have low performance when applied to natural language processing. On the contrary, the applied linear SVC algorithm performed better for class 2 with AUC 0.82 in this research.

**Keywords**—Machine Learning Algorithms; natural language processing; drugs sentiment analysis; text mining

## I. INTRODUCTION

Among many research dimensions in Natural Language Processing (NLP), sentiment analysis has become one of the promising fields of research in the recent century [1] [2]. A wide range of research domains has been covered by sentiment analysis, i.e. economy, polity, and medicine. In the pharmaceutical industry, large volumes of online user's views are evaluated automatically in order to obtain useful information about the efficacy and side effects of

pharmaceuticals that could be utilized to enhance pharmacovigilance systems. Throughout the years, Sentiment analysis techniques have grown significantly in the last decade, evolving from basic rules to advanced machine learning techniques like deep learning, which has become a prominent technology in many NLP tasks. This triumph is not lost on sentiment analysis. Besides, several machine learning systems have recently been shown to be better than previous methods. These methods have achieved impactful results on standard sentiment analysis datasets [3] [4].

Various aspects such as 'medical condition', 'treatment procedure', etc., use the medical sentiment as a research study that directly impacts the users' health conditions. Any sort of progress or deterioration can be identified by analyzing patient status periodically. The medical condition can be expressed implicitly or explicitly. Mentioning the symptoms is a part of the implicit sentiment in the medical context. For example, consider the statement: 'I recently started Lexapro 3 days, I'm on extreme weight losses'. The term "weight losses here do not reflect a negative sense; however, it implies the negative medication side effect, where sentiment is defined as negative in the preceding statement. Hence, for making correct interpretations, additional information is required.

On the contrary, analyzing the health conditions is relatively much easier in the case of explicit sentiment. For instance, considering the statement, "I recently started Lexapro 3 days, I'm absolutely lost I feel weak and shaky every day". The words absolutely 'lost', 'weak', and 'shaky' are used to describe symptoms in this statement. Deciding about patients' medical issues is an important aspect, specifically when they learn from other patients' experiences, i.e., choosing a hospital, clinic, and medication [5]. Hospitals gain from this information since it allows them to understand better and address the interests and concerns of their patients. The experience covered with sentiment analysis and passions are being shared by the patients; sentiment analysis is being taught by the power of this type of experiment since this type of study identifies people's sentiment about a topic as well as its characteristics. The medical material available on the internet is completely free. Manually analyzing such a large volume of data is ineffective because of its existence in large volumes. Assessed examinations are denoted as positive or negative, for the most part, based on the pre-programmed acceptance of extreme suppositions. The online and traditional

\*Corresponding Author.

review methods are supplanted by notion investigation nowadays, which is led by organizations for finding a broad conclusion regarding their products and service. As a result, their marketing approach and product awareness increase, and user management improve. It is quite imperative to be broken down since a tremendous amount of content is available online. That includes deep comprehensions of standard dialects are included in the programmed examination of this data. In our everyday life, thoughts and sentiments play an essential role. Basic leadership, learning, correspondence, and mindfulness in human circumstances are assisted. Socially produced regional substances are becoming prevalent in online life; hence the importance of dealing with and comprehending vernacular content is growing. Existing materials notwithstanding, such as nearby sayings, Myths, and fables are unearthed, widely disseminated on the internet.

Compared to reviews of other products, drug reviews are investigated less. When analyzed, drug reviews are primarily utilized to categorize a particular drug as a positive or a negative one as multi-class classification from text mining can be unyielding. The proposed research facilitates the categorization of drugs not into two categories rather into five classes based on their effectiveness. Such an outcome can be beneficial for both consumers and manufacturers to understand the effectiveness of drugs as well as whether a particular drug has any significant side-effect.

This paper is organized as follows: Section II illustrates literature review for sentiment analysis, Section III explains the algorithms those classify the sentiment of the drugs, Section IV portrays the findings of the study, and Section V demonstrates the contributions of the proposed research.

## II. LITERATURE REVIEW

Supervised machine learning methods used by Twitter datasets, such as support bigram, vector machines and unigram, were analyzed by a research study led by Balahur (2013) [6]. Following the applications of these approaches to Twitter data, the results indicated that methods of unigram and bigram support vector machines are outshined. Emotive words, modifiers and unique tags were included in these results, enhancing the performance rating of emotions. Another study conducted by Jianqiang et al. [7] (2018) presented an approach that is word embedded using unsupervised learning as a base. This suggested technique makes use of hidden contextual semantic connections and characterization between words and tweets. The

characteristics of mood polarity and n-gram are combined with the score of the embedded word to structure. A deep convolutional neural network was used to include a collection of emotional characteristics. Facebook, Instagram, and Twitter are a few examples of social media platform that helps to generate data and circulate content quickly. The amount of hate utterances has risen significantly while circulating content related to a particular topic. To filter these sorts of utterances, a research study presented by Schmidt and Wiegand [8] suggested a filtering tool for natural language processing. According to the results, character-level strategies are superior to token-level ones. The authors' methodology demonstrated that using a lexical list of resources to rank them might be beneficial when utilized with others. Based on K-means and cuckoo searching methods, Pandey et al. [9] suggested a unique metaheuristic approach. The best feasible cluster heads are found using this method based on the Twitter dataset's emotional subject material. Wang and Li [10] categorized the changed text algorithms to anticipate motions in image data for the sentiment analysis. Textual and visual features for labelling emotions inside an image are unsuitable for the forecast, according to their technique. The authors conducted experiments on two datasets and found that the recommended technique outperforms current methods in terms of accuracy. Unique research on Hierarchical Deep Fusion (HDF) emotional analysis methodology was studied by Xu et al. [11]. The relationship between the properties of text, images and sentimental content has been analyzed in the proposed model. The authors combined visual content with textual content using three-level Hierarchical Long Short Term Memory (H-LSTM) to investigate the inter-modal association of text and image at various levels. Some of the most widely applied machine learning and deep learning algorithms have been described in Table I.

Most of the above-mentioned researches primarily focus on unsupervised learning method. Compared to other product reviews, number of researches conducted on drug reviews is significantly low. One of the key challenges with dataset similar to the one used in this research is the lack of technical terms. A few researches that utilize supervised learning methods, perform binary classification as multi-class classification using the existing machine learning algorithms have been proven to be challenging. In this research, tokenization and lemmatization identify the key words. Also multi-class classification has been performed unlike the researches mentioned in this section.

TABLE I. EXITING ALGORITHMS ACCURACIES

Algorithm	Description
Neural Network	The neural network approach technique has a very high performance. It is a widely used technique for sentiment analysis and is capable of detecting all possible interactions between attributes. It is effective for dealing with a nonlinear connection between variables that is complex. The main disadvantage is that it takes longer to compute than other algorithms [12].
Naive Bayes	It is a Bayes' theorem based probabilistic classifier. Researchers use this method less commonly to make a prediction. The primary advantage is that it is scalable in comparison to other algorithms [13].
Support Vector machine	It is also a way of supervised machine learning for classification and regression analysis. When dealing with small datasets, the Support Vector Machine is very effective. It is more efficient than other approaches of classification and regression [14].
Decision Tree	Decision trees are simple but extensively used tools for prediction. IF-THEN rules can be simply converted from a decision tree. According to a previous study, prediction and forecast can be done using a decision tree. It can predict drug sentiment with low accuracy [15].
K-Nearest Neighbor	It is a popular pattern recognition method that is less non-parametric. It has the ability to utilize both regression and classification. It provides the finest performance and precision. It is the most basic machine learning algorithm [16].
AdaBoost	AdaBoost combines a number of poor classifiers to create a powerful one by iteratively retraining and weighing the classifiers depending on their accuracy [17].
Logistic regression	The log odds of the dichotomous result can be modelled as a linear combination of the predictor factors using this method [18].
Convolutional neural network	A feed-forward neural network that has been trained to extract key characteristics for the prediction job at hand. Nonlinear functions are used to filter features via convolutions. The dimensionality can then be reduced via pooling [19].
Maximum entropy	The greatest entropy concept is used to create a probabilistic classifier [20].
Conditional random fields	Given an observation series based on a conditional probability distribution across label sequences, this approach for segmenting and labelling structured data can be used [21].

### III. METHODOLOGY

The dataset that used in this experiment has been collected from the UCI repository [22]. Tokenization and lemmatization were performed on the data after collecting the dataset. Four machine learning algorithms have been applied to the dataset for binary classification. The classes for binary classification are class 0, and class 1, where class 0 represents the effective drugs and class 1 indicates the ineffective drugs. The algorithms used for binary classification are naïve Bayes classifier, random forest (RF), support vector classifier (SVC) and multilayer perceptron (MLP). Linear SVC has also been applied to the dataset for multiclass classification.

Table II represents the classes for multiclass classification along with counts for each class. Class 0 represents highly effective drugs with a count of 1741, whereas class 1 represents considerably effective drugs with a count of 1238. Class 2 represents moderately effective drugs with a count of 529. In addition, class 3 represents marginally effective drugs with a count of 329. Besides, class 4 represents ineffective drugs with a count of 263.

#### A. Tokenization

In the case of natural language processing, a series of well-defined processes need to be carried out for analyzing the text. One of the primary processes is known as tokenization which plays a crucial role in the efficiency and correctness of the entire analysis. Tokenization refers to splitting the text into meaningful smaller units known as tokens. In most cases, tokens are identified as words or word sequences. Tokens are usually recognized when a white space character is encountered just after scanning a token. Preprocessing of text for punctuation removal and uppercase to lowercase conversion are often involved with the tokenization process [23].

#### B. Lemmatization

One of the most essential and elementary processes associated with natural language processing (NLP) is lemmatization. The base or dictionary form of a word is called a lemma. The term lemmatization refers to the morphological conversion of a word that exists in the textual form of the dataset to its lemma. The basic idea for this conversion is the removal of the declension from the end part of the word. In the case of a verb, lemma represents the infinitive form; in the case of a noun, lemma represents the singular form, and in the case of adjective or adverb, lemma represents the positive form. For example, the lemma for the word 'better' is 'good'. The lemma for the word 'brought' is 'bring'. Lemmatization can be perceived as a normalization method in which various morphological variants of a word are analyzed as a single item by mapping them into the same underlying lemma. As the aggregate number of specific terms are reduced, the complexity for analyzing the text is significantly decreased and thus, the overall time and resource utilization is improved. Lemmatization is widely applied for preprocessing the text in information retrieval, document clustering, sentiment analysis, etc. [24].

Table III shows tokenization and lemmatization of the feature benefitsReview.

TABLE II. DATA STATISTICS FOR CLASSIFICATION

Class	Effectiveness	Count
0	Highly Effective	1741
1	Considerably Effective	1238
2	Moderately Effective	572
3	Marginally Effective	329
4	Ineffective	263

After simplifying equation 3, we get the following probabilistic model:

$$P(X|Y_1, Y_2, \dots, Y_n) \propto P(X) * \prod_{i=1}^n P(Y_i|X) \quad (4)$$

Equation 4 exhibits the probabilistic model, which is obtained after simplifying equation 3.

From this probabilistic model, a classifier model is generated by calculating the probability of all given inputs for the possible values of the class variable, and the maximum value is identified to determine the specific value of the class. It can be expressed as follows:

$$X = \text{argmax} P(X) * \prod_{i=1}^n P(Y_i|X) \quad (5)$$

2) *Random forest*: The high variance problem of the decision tree classifier, where a minor change in the training data set can produce a very different tree, makes the decision tree classifier unstable. To eradicate this issue, the concept of the random forest was proposed which is an ensemble of decision trees. Random forest is a classifier with various classification methods or a single method with various parameters from the dataset. Assume a learning data set  $D = ((x_1, y_1), (x_2, y_2), \dots, (x_n, y_n))$  that consists of  $n$  vectors, where  $x \in X$  ( $X$  is a set of numerical observations) and  $y \in Y$  ( $Y$  is a set of class labels). For a classification instance, a classifier maps  $X \rightarrow Y$ . Each tree of the forest is responsible for classifying a new input vector. Random forest combines the idea of bootstrapping data from a learning dataset to form training data set and selecting parameters randomly to construct decision trees. Bootstrap refers to selecting three-fourths of the learning dataset (sometimes two-thirds of the learning dataset) and replacing the rest of the data with some of the selected samples. While constructing a decision tree, features and their positions as nodes in a particular tree are chosen randomly. Thus random forest classifier,  $h$ , can be defined as:

$$h = \{h_1(X), h_2(X), \dots, h_n(X)\} \quad (6)$$

In equation 6,  $h_k$  is a decision tree having parameters  $\theta_k$ , which is a subset of features chosen randomly [27].

3) *Support vector classifier*: Support Vector Classifier is a supervised learning algorithm to analyze data for classification. One of the distinctive properties of this algorithm is the ability to reduce empirical classification error and expand the geometric margin simultaneously. SVC provides high accuracy in text categorization, image classification, hand-written digits recognition, data classification, sentiment analysis, etc. SVC constructs a maximal separating hyperplane. Two parallel hyperplanes, which represent two different classes, are built on both sides of this separating hyperplane. By using SVC, an input vector is mapped to any of these two parallel hyperplanes. The purpose of the separating hyperplane is to maximize the space between the two parallel hyperplanes. It is assumed that less classification error can be achieved with a higher distance or margin between the parallel hyperplanes.

Consider a training dataset  $((x_1, y_1), (x_2, y_2), \dots, (x_n, y_n))$  where each  $x_n$  is a  $p$  dimensional vector that maps to corresponding  $y_n$ , which specifies the class. The value of  $y_n$  can be either  $-1$  or  $+1$ . The equation of the separating hyperplane can be written as:

$$w \cdot x - b = 0 \quad (7)$$

In equation 7,  $w$  is a one-dimensional vector and  $b$  is a scalar. The equations for the two parallel hyperplanes can be written in equation 8 and equation 9 as follows:

$$w \cdot x + b = 1 \quad (8)$$

$$w \cdot x + b = -1 \quad (9)$$

The distance between these two hyperplanes is  $\frac{b}{|w|}$  which implies that by minimizing  $|w|$ , we can maximize the distance between the two hyperplanes and thus achieve high performance.

In the case of hard margin where no misclassification is allowed from the training dataset, the problem can be stated as:

Minimize  $|w|$  for

$$y_i(w^T x_i - b) \geq 1 \text{ for } i = 1, 2, \dots, n \quad (10)$$

In equation 10, the classifier is determined by solving  $w$  and  $b$  for the above problem statement.

In the case of soft margin where a few misclassifications are allowed from the training data set to achieve better accuracy for testing dataset, the problem can be stated as:

Minimize  $|w|$  for

$$\left[ \frac{1}{n} \sum_{i=1}^n \max(0, 1 - y_i(w^T x_i - b)) \right] + \lambda |w|^2 \quad (11)$$

In equation 11, the trade-off between putting  $x_i$  in the right hyperplane and maximizing the distance between the parallel hyperplanes is determined by  $\lambda$  [28].

4) *Multilayer perceptron*: Inspired by the functioning procedure of human nervous systems, the concept of artificial neural networks has been developed and applied to design mathematical models to solve complex classification or regression problems. The building blocks of the artificial neural network are 'artificial neurons' or 'neurons'. Frequently these neurons are referred to as nodes. In a multilayer perceptron, which is a feedforward artificial neural network, these neurons are organized in layers and completely interconnected with each other via edges to construct a directed graph. The term 'feedforward' refers that this graph as acyclic. Each of these edges is associated with a real number which is called the weight of the edge. The layers of multilayer perceptron neural networks are the input layer, a number of hidden layers, and the output layer. For each neuron, there exists a summation function and an activation function. The summation function can be written as:

$$S_j = \sum_{i=1}^n w_{ij} I_i + \beta_j \quad (12)$$

In equation 12,

$w_{ij}$  = The connection weight from neuron  $I_i$  to  $I_j$

$\beta_j$  = Bias weight

$n$  = The total number of neuron inputs

The output of this summation function becomes an input of the activation function. There are various types of activation functions. One of the most applied activation functions is a nonlinear 'S' shaped curved sigmoid activation that can be expressed as:

$$f(x) = \frac{1}{1+e^{-x}} \quad (13)$$

Applying this activation function from equation 13, the output of the neuron  $I_j$  can be expressed as equation 14, which is shown below:

$$y_j = f_j(\sum_{i=1}^n w_{ij} I_i + \beta_j) \quad (14)$$

Once the neural network is constructed, the set of weights are tuned to estimate the required result [29].

#### IV. RESULTS

A confusion matrix has been developed as a binary prediction for each algorithm utilized to evaluate the performance system. One of the widely utilized methods for calculating predictions is a binary prediction which consists of the most significant building blocks of a ROC curve [30]. Each classification problem contains two classes. There exist two sets of positive and negative ((P) and (N)) labels of class for every instance. There are four possible categories for a classifier instance. True positive (TP) refers to the number of positive instances being classified appropriately. Similarly, true negative (TN) represents the number of negative instances being classified without any error. Opposite to that, if a positive instance is classified as a negative instance, it is considered as false positive (FP). Likewise, if a negative example is classified as a positive example, it is labelled as a false negative. While applying the algorithms to the dataset, in each instance, 80 percent of the dataset has been utilized as training data and the rest 20 percent has been used for testing.

We found accuracy, precision (P), recall (R), and F1 score by using the following equations:

$$\text{Accuracy} = (TP + TN)/(TP + TN + FP + FN) \quad (15)$$

In equation 15, accuracy is measured as the total number of correctly identified cases divided by the total number of test cases.

$$\text{Precision (P)} = TP / (TP + FP) \quad (16)$$

In equation 16, precision is measured as number of true positive cases divided by number of all predicted positive cases.

$$\text{Recall (R)} = TP / (TP + FN) \quad (17)$$

In equation 16, recall is measured as the number of true positive cases divided by all actual positive cases.

$$\text{F1 Score} = 2 * (R * P) / (R + P) \quad (18)$$

In equation 18, F-1 score is measured from the calculated precision and recall values.

Table IV shows the confusion matrix for the proposed machine learning classifiers for all features. Random forest works as the best classifier with 94% accuracy among the four algorithms. The accuracies for MLP, SVC, and NB are almost the same. Later we calculate the accuracy by changing the number of features ranging from 5000 to 9000.

Table V shows the accuracy for the proposed machine learning classifiers for features ranging from 5000 to 9000. The proposed model provides consistent results for different features ranging from 5000 to 9000.

Fig. 3 shows ROC curves for individual classes and all classes for linear SVC. Fig. 3(a) shows that the area under the ROC curve is 0.56, which indicates that linear SVC is not very efficient in the case of identifying class 0 (highly effective drugs). Fig. 3(b) shows that the area under the ROC curve is 0.64, which indicates that linear SVC is slightly more efficient in the case of identifying class 1 (considerably effective drugs) than class 0. Fig. 3(c) shows that the area under the ROC curve is 0.82, which indicates that linear SVC is very efficient in the case of identifying class 2 (moderately effective drugs). Fig. 3(d) shows that the area under the ROC curve is 0.65, which indicates that linear SVC is approximately as efficient in the case of identifying class 3 (marginally effective) as class 1. Fig. 3(e) shows that the area under the ROC curve is 0.59, which indicates that linear SVC is slightly less efficient in the case of identifying class 4 (ineffective) than class 3. Fig. 3(f) plots precision against recall for all the classes. After analyzing the ROC curve, it is conspicuous that linear SVC has a significant positive performance in identifying class 2 drugs.

weighted avg	0.93	0.94	0.93	1036

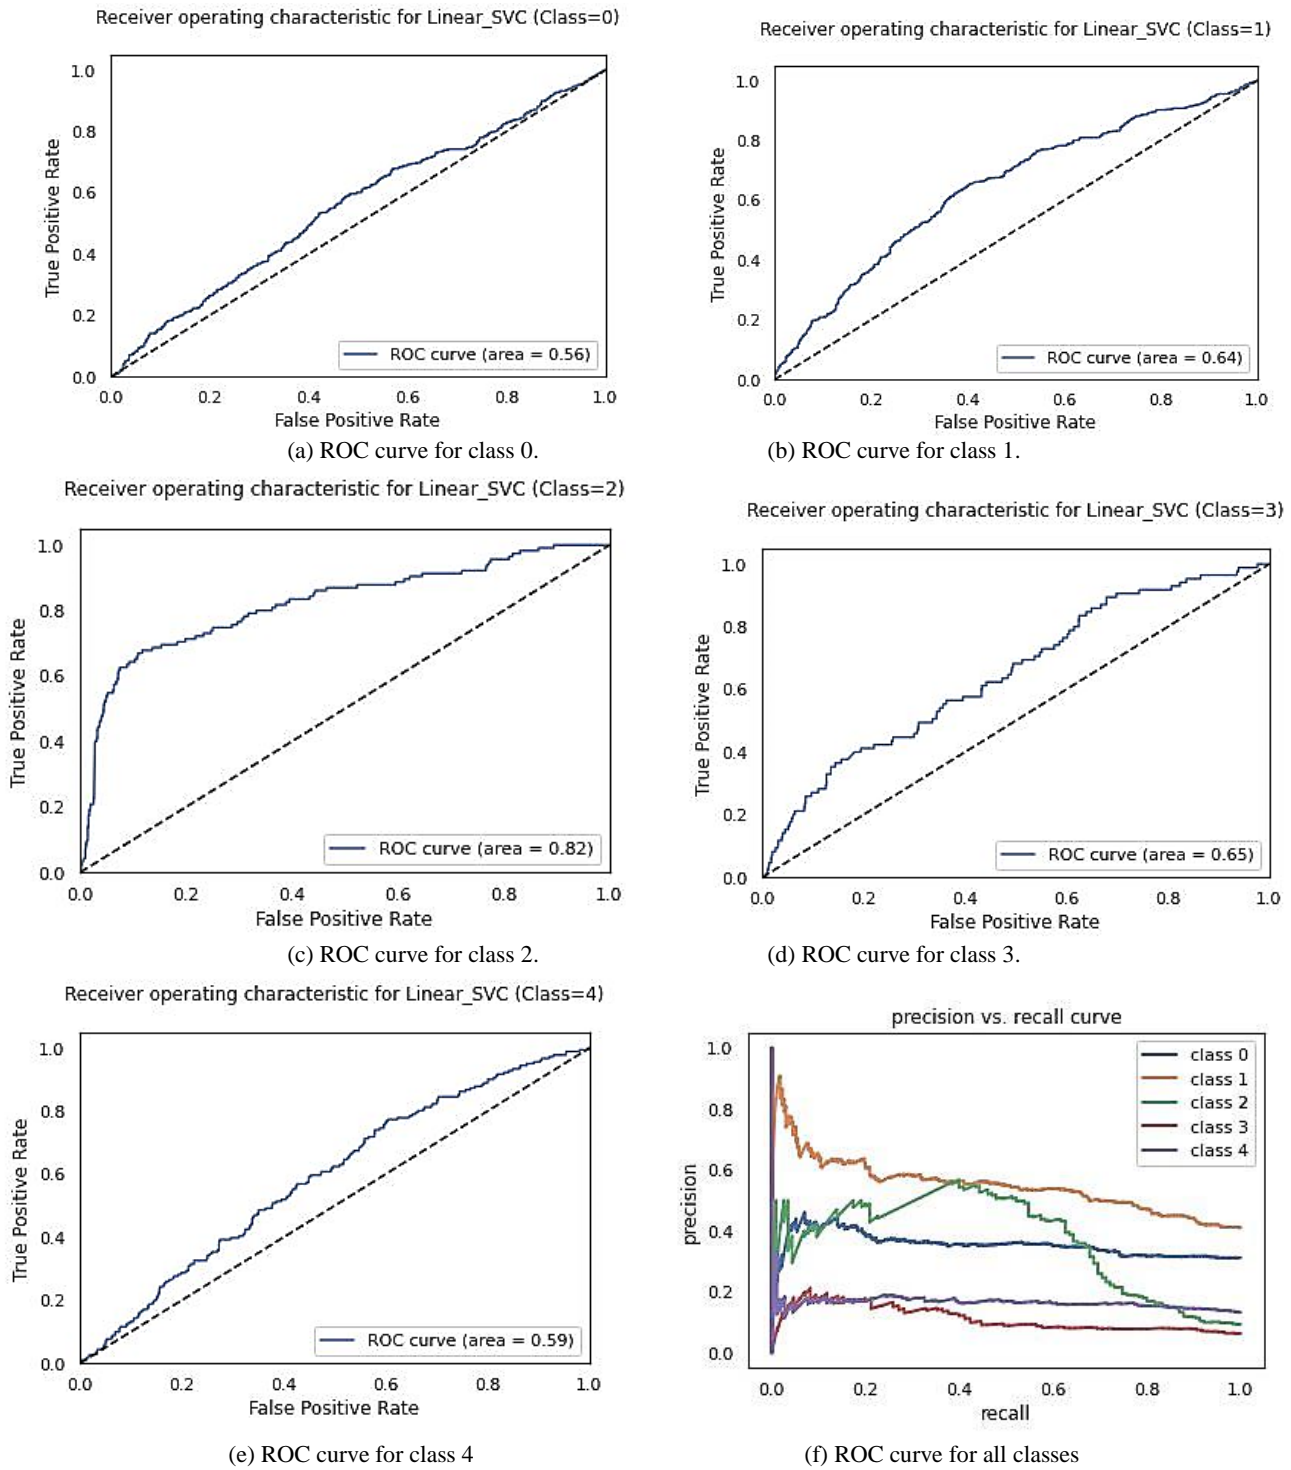

Fig. 3. ROC Curve for Linear SVC.

The evaluation metric used to represent the multiple class classification is the ROC curve which plots True Positive Rate (TPR) against False Positive Rate (FPR) at different threshold settings. Though the ROC curve is applicable for binary classification, there is an alternative way to integrate it for multiple-class classification. This approach is known as 'one vs rest' where a multiple-class problem is treated as a binary classification problem. In a ROC curve, a higher value in the

X-axis indicates a greater false positive rate than the true negative rate. A higher value in the Y-axis indicates a greater false-negative rate than the true positive rate. The efficient way to discriminate between accurate and inaccurate classification is to measure the area under the ROC curve (AUC). This area accepts values between 0 and 1, where 0 indicates the completely inaccurate classification of the class and 1 indicates perfectly accurate classification. Although

multiclass sentiment classification is extremely challenging for textual data, but Fig. 3(c) shows very promising accuracy in this research.

## V. CONCLUSION

From the experimental result, the calculated average accuracy for Radom Forest, Multilayer Perceptron, Support Vector Classifier and Naïve Bayes Classifier is 94.06%, 86.82%, 88.63% and 88.57%, respectively. It is found that the Random Forest algorithm has generated the best accuracy among the four algorithms. In the case of Random Forest, higher precision, recall, and f1-score have been achieved for effective drugs compared to those measurements of ineffective drugs. The reason behind calculating the f-1 score is to get accuracy measurement from a different perspective as the f-1 score delivers the balance between precision and recall. Although multiclass classification is a challenging task for sentiment analysis, linear SVC shows the promising result for class 2 (moderately effective drugs). In this research, we have applied five machine learning algorithms. Unlike most of the similar researches in NLP when text mining is used for clustering the data, supervised learning methods have been implemented in this research to gain a better understanding of a drug by measuring its level of effectiveness. It can play an important role for curing diseases. In future, we intend to apply deep learning algorithms like Long Short Term Memory Networks (LSTMs), Generative Adversarial Networks (GANs), Recurrent Neural Networks (RNNs), Convolutional Neural Networks (CNNs). In addition to that, we would like to implement multi-language sentiment analysis using data-driven approaches.

# Effective Malware Detection using Shapely Boosting Algorithm

Rajesh Kumar, Geetha S  
School of Computer Science and Engineering  
Vellore Institute of Technology  
Chennai, India

**Abstract**—Malware constitutes a prime exploitation tool to attack the vulnerabilities in software that lead to a threat to security. The number of malware gets generated as exploitation tools need effective methods to detect them. Machine learning methods are effective in detecting malware. The effectiveness of machine learning models can be increased by analyzing how the features that build the model contribute to the detection of malware. The model can be made robust by getting insight into how features contribute to each sample that is fed to a trained model. In this paper, the boosting machine learning model based on LightGBM is enhanced with Shapely value to detect the contribution of the top nine features for classification such as true positive or true negative and for misclassification such as false positive or false negative. This insight in the model can be used for effective and robust malware detection and to avoid wrong detections such as false positive and false negative. The comparison of the top features and their contribution in shapely value for each category of the sample gives insight and inductive learning into the model to know the reasons for misclassification. Inductive learning can be transformed into rules. The prediction by the trained model can be re-evaluated with such inductive learning and rules to ensure effective and robust prediction and avoid misclassification. The performance of models gives 98.48 at maximum and 97.45 at a minimum by 10 fold cross-validation.

**Keywords**—Artificial intelligence; machine learning; malware detection; shapely value; decision plot; waterfall plot

## I. INTRODUCTION

At the current time, the malware is generated in large numbers. Open Threat Exchange [1] is a platform for the exchange of information related to computer security. The reason for the high volume generation of malware is both from the generation side, and end-use of it. Malware authors use tools such as polymorphic and metamorphic engines. Metamorphic engines can generate malware with minor modification of code. It uses techniques such as register reassignment, NOP instruction insertion, code transposition, the substitution of machine-level opcode/instructions, dead code insertion, and combinations of these techniques. Polymorphic engines can generate malware with encryption, prepend data, append data, and combinations of these techniques. The generated malware exhibits the same behavior as old malware. However, this generated malware can evade detection by antivirus software based on the signature. The detection engine of many antiviruses is based on the signature. Hence, databases of signatures need a constant update for upcoming malware. On the use side of malware, the number of software products has

increased over time. Ten top software products with vulnerabilities are listed in Table I [2]. Software products with vulnerabilities from the top ten vendors are listed in Table II [3]. These vulnerabilities are exploited for an attack using existing or new malware. The software products are not limited to but include Operating Systems (OS), Driver for hardware devices, software applications, etc. The more a software product is used and popular, the more attacks it may have. Hence, hackers need more malware to attack the vulnerabilities. The vulnerabilities in hardware, OS, application, firewalls, anti-virus products, etc. may be by accident. The author [4] identifies three phases of the life cycle of vulnerabilities. In the first phase, a product is released in the market. The second phase starts when a vulnerability is found in the software product. In the third phase, the vulnerability has to be fixed by the developer and released for the user of the software. The vulnerabilities can be systematically discovered with needful tools. Knowing vulnerabilities is not enough, the vulnerabilities have to be proven by exploits, and attack software (malware). Machine learning and deep learning methods are used for malware detection and classification in research work these days.

TABLE I. TOP SOFTWARE VENDORS WITH VULNERABILITIES

SL No	Vendor Name	Number of Products	Number of Vulnerabilities	#Vulnerabilities/#Products

The objective of this paper is to further improve the effectiveness of the machine learning (ML) model based on boosting algorithms such as LightGBM by overcoming the wrong prediction, misclassification the ML model may have. Good ML models are made general with feature engineering and learning from a large dataset, to detect unknown malware. There are many algorithms for ML models and many feature engineering techniques to make the models effective that resulting in increasing the accuracy of models. Misclassification in the machine learning model is wrong identification. For malware, the ML model may not identify them and they are termed as a false negative. A false negative detection can be very dangerous for any organization. As the malware is not detected, it will be able to meet the objective of the attacker despite all the security solutions applied. ML model may also declare benign software as malware. Such occurrences are termed false positives. A false positive detection causes issues such as panic among users of the software, inconveniences, non-use of software until a confirmed source declares the software as benign. All machine learning models have misclassification without exception.

Machine learning models to detect malware are many and they also use feature importance as part of an algorithm to identify top features. There are other methods for feature importance using feature engineering such as Principal Component Analysis (PCA), Redundant Feature Removal (RFR), and Haar Wavelet Transform (HWT) [6] and Leave One Feature Out importance (LOFO) method [7].

In this paper, a novel method is proposed to identify the change in top features that contribute to the misdetection of malware or future input sample that may be malware or benign software to a trained ML model. In addition, to identify the amount of contribution the top features are having for misclassification of a future sample in consideration as input to the ML model. Shapely values and visualization techniques are used to achieve these objectives. Shapely values are from classic game theory. Shapely values are used to find feature importance in an ML model. Lundberg et al. [5] have used Shapley value for explainable artificial intelligence. Hence, Shapley values can identify the top features in an ML model. The top features in an ML model based on LightGBM have

shapely values associated with them. These top features along with their contribution to Shapley values are visualized using decision plot, waterfall plot, and force plots. Further, this work proposes to identify the false positive and false negative from the test dataset part. Further, the work also associates visualization with change in top features and amount of contribution of top features. Having identified top features and the amount of contribution of the top features for misclassification, this work proposes the use of inductive learning techniques to overcome the misclassification of future samples. The present work aims to improve the effectiveness of the ML model based on the LightGBM model. It can be used for zero-day malware detection as well.

The gaps that this work addresses are highlighted as follows.

- These feature importance from algorithms and feature engineering methods cannot associate the top features for a new sample used for prediction by a trained machine learning model.
- They cannot determine the amount of contribution of a feature for a sample used for prediction by a trained machine learning model. Hence, they cannot associate the visualizations with the amount of contribution of a feature for a new sample to be predicted by the machine learning model.
- There remains always a doubt if the new sample under test is part of high accuracy as published for the model or part of misclassification as false negative or false positive.
- The inductive method proposed in this work improves the probability of prediction to a higher level.
- A novel approach as proposed in this work is not available in the literature survey. Hence, this paper opens new dimensions for increasing the probability of effective detection of a new sample by a trained model.

Specific contributions in this study are:

- Use of Shapley values and visualization for identification of top features for false negative (FN), false positive (FP), true positive (TP), and true negative (TN) categories of samples for LightGBM machine learning models.
- Amount of contribution by top features for each predicted category in Shapley values are identified. So that the comparison for inductive learning is effective.
- Comparison of the features and amount of contributions of features for samples with the test dataset part that may be FP, FN, TP, and TN. Using the comparison to identify the top features and their contribution for misclassified FP and FN samples.
- Use of LightGBM, boosting algorithms, for effective prediction of a future sample that may be malware or benign software. The proposed inductive method will avoid misclassification and improve the effectiveness of the ML model.

This paper is organized with a literature survey in Section II, followed by the methodology of malware detection and the use of shapely values for visualization in Section III. The Dataset, experimental setup, and results are outlined in Section IV. The paper concludes in Section V with a conclusion and an Appendix in Section VI.

## II. LITERATURE SURVEY

Malware is like any software product. It has to be distinguished from a benign software product. The methods available to distinguish and detect the malware are broadly categorized into static analysis, dynamic analysis, and hybrid analysis.

### A. Static Analysis

In static analysis, the malware is not executed. Features for machine learning are extracted from the software without running the software, the sample under consideration. It has the advantage that the sample cannot infect the system used for extraction of features. All the software, malware, shared libraries required, and dynamic link libraries (DLL) have a header. For windows, the header of the executable is termed Portable Executable (PE) header. The features from the PE header of windows executables can be extracted as explained in [6][8]. In addition, features can be extracted using properties of the executable file as an object and are termed file-related features. File related features are not limited to but include a histogram of bytes in executable, the entropy of complete file entropy of various parts of files, strings embedded in the executable, N-grams [9] from byte code, N-grams from assembly code, N-grams from API calls, images of hex bytecode of a file [10][11], images of hex bytecode of different part of a file, etc. Many machine learning models and deep learning models use features with different combinations derived from static analysis[12]. However, malware authors use methods such as obfuscation [13], encryption of various types to evade feature extraction methods. The obfuscation and encryption methods are many and may be categorized into standard and non-standard (private). These shortcomings of static analysis may be overcome by dynamic analysis [14].

Authors in [15] convert the sample file to images and extract features using the trained CNN model. The extracted features are plotted using t-Distributed Stochastic Neighbor to identify the cluster of malware. Subsequently, they make N-grams with n values 1 to 5 using the API call sequence for six types of malware actions. The malware actions are creating or modifying files, hooking on to system services, getting information for loading the DLL, etc. The N-grams are used with eight types of distance measurement to make a similarity matrix using four types of kernel functions with the Support Vector Method (SVM). Distance measurements used in this work are Cosine, Bray-Curtis, Canberra, Manhattan, Chebyshev, Euclidean, Hamming distance, and Correlation for feature extraction. This technique may handle malware with a known packing method, as they can be unpacked to process and get features but will have a deficiency in handling packed malware with unknown packing methods.

Yousefi-Azar et al in [15] extract static features of a sample, malware, or benign software, using term frequency based on

natural language processing. Extracted features are used with the deep learning model and Extreme Learning Machine (ETM) for malware detection. Backpropagation results in large feature space which increases computation complexity. The authors multiply term frequency with a random projection matrix to reduce the computation complexity. Balanced android dataset Drebin and Dexshare and windows executables from 2016 are used as a dataset. Windows executables from 2017 are tested as zero-day malware to achieve an accuracy of 95.5%.

The authors [16] collect malware samples that are used for attacks in financial institutions in Brazil, affecting cyber users for over 6 years. They use static analysis to extract features from PE header of collected samples and use Multilayer Layer Perceptron, K-nearest neighbor (KNN), Random Forest (RF), and Support Vector Machine (SVM) classifiers to detect malware. Further, they identify the family of malware using the t-Distributed Stochastic Neighbor Embedding (SNE) method. Concept drift of ML model is detected using Drift Detection Method (DDM) and Early Drift Detection Method (EDDM) to detect drift in the malware samples over time. The authors visualize and relate the new malware families coming over time using confirmation and warning indicated by the drift methods. They conclude that a warning indication by drift methods implies a degradation of ML models and a confirmation indication by drift method implies that the ML model needs to be updated.

### B. Dynamic Analysis

In dynamic analysis, the malware is executed in a protected environment, and the behaviors, actions of malware are observed. In a normal environment, the sample will infect the system and will affect the future normal use of the system. Hence, a protected environment is used to avoid infection of the system conducting the malware test. The actions and behaviors of malware are not limited to but include adding, deleting, and modifying related changes in the file name, registry, processes, communication in the network, system configuration, etc. Features are derived with these changes and used in machine learning models with various algorithms. The dynamic analysis method is very expensive in terms of time to execute malware, computing resources, and trained manpower required. Besides, the malware authors employ techniques to avoid malware detection. One of the techniques employed by the malware author is to detect the virtual environment required for running the malware. If the virtual environment is detected, they switch off the behavior of malware and act as benign software. Another technique used by malware authors is to connect to the command and control center owned by them and download the malware at a later time to take control of the target machine. If the network is not available in virtual environment, the sample acts as benign software. Hence, trained persons are required to note this behavior of malware. The hybrid analysis is used to overcome these shortcomings of dynamic analysis.

Robert et al. [17] use a large dataset of malware with a Malheur tool to know the behavior of samples. Malheur tool executes the samples and generates a report. Useful information such as DLLs imported, API used as the callback are extracted from the report to understand the actions, behavior of malware with help of domain experts. Domain experts make rules and rules are externalized to the malware detection

module. Authors believe malware will exhibit its behavior as per framed rule and that can be detected. However, new types of malware may not exhibit behavior as per rules framed, because that malware was not part of the dataset used. Hence, this unknown malware will not be detected.

Binayak et al. [18] create a knowledge database of In-memory processes based on the use of Dynamic Link Library (DLL) sequences using TF-IDF (Term Frequency-Inverse Document Frequency) and multinomial logistic regression based learning approach. The suspected process from malware uses a different DLL than of system DLL. This knowledge database is compared with DLL sequences used by In-memory processes to identify suspected, unwanted processes and malware.

### C. Hybrid Analysis

Hybrid analysis combines static and dynamic analysis to overcome their shortcoming. Lifan Xu et al. [19] extract both static and dynamic features from android malware dataset and represent the features as vector. Advance features are derived using deep learning, a Deep Neural Network (DNN) using both the original static and dynamic feature vector sets. The advanced and original features are concatenated as new vectors as input to the DNN that modifies with multiple different kernel to detect malware. The combined hybrid analysis has shortcomings as in dynamic analysis or static analysis.

Sethi et al. [20] use feature from both static analysis and dynamic analysis on PHP, pdf, exe files. For dynamic analysis, the authors use a Cuckoo sandbox. Cuckoo sandbox is a virtual environment to run executable. It gives an analysis report of actions and behavior of the file executed. J48, SMO, and Random Forest machine learning algorithms are applied in the WEKA tool with the combined feature extracted using static and dynamic analysis. They achieved 100% accuracy with J48.

The literature survey gives different methods of improving the accuracy and other performance parameters of the machine learning model by feature engineering for malware detection. However, they do not give insight into the top features and contribution of each feature for a new sample by a trained machine learning model. Hence, there is a gap in research that can give insight into the top features and their contribution in the prediction of an unseen sample by machine learning model. This work is an effort to fill the gap.

## III. METHODOLOGY

### A. Shapley Value and Feature Importance

The machine learning model should be both interpretable and accurate. Interpretation of ML model based on decision tree may be based on decision path, heuristic value to features, and model-agnostic. In this work, Shapley value is used for making the ML model interpretable. A local explanation is assigning a numeric measure, credit, to each input feature that constitutes a machine learning model based on a decision tree. These local explanations are combined to represent a global structure that represents an ML model based on a decision tree or an ensemble of decision trees. The ensemble of decision trees may be based on a bagging algorithm such as Random Forest or boosting algorithm such as LightGBM. The global explanation

of the ML model continues to retain the local faithfulness as in local explanation. Shapely values from game theory satisfy simultaneously local accuracy, consistency, and missingness three properties required for credit score to a feature in an ML model. The credit score, Shapley values, are computed by one feature at a time into the output function of the model with some condition as in Eq. (1). Lundberg et al. [5] follow the causal do-notation formulation. It justifies use of the Shapley additive explanation (SHAP) interaction values as a richer type of local explanation and feature perturbation formulation.

$$f_x(S) = E[f(X)|do(X_s = x_s)] \quad (1)$$

S = Set of features to condition on

X = A random variable from M input features of model

x = input vector for the current prediction for the model

Lundberg et al. [5] give TreeExplainer, an explanation method for ML models based on tree, that enables optimal local explanations based on shapley values from classic game theory. Classic Shapley values are ways to measure feature importance. It is optimal and maintains natural properties from cooperative game theory. Exact computation of these values is NP-hard problem. Hence, they have approximate computation. Authors have developed an algorithm for decision tree categories of algorithms that computes local explanations with theoretical guarantees of local accuracy and consistency in polynomial time with Shapley values. Local explanations are also used to capture feature interactions in a theoretically grounded way. S is the set of features in Eq. (1) to condition on and refers to features of a specific tree in the ensemble of trees in the boosting LightGBM machine learning model. We can find the SHAP value for each feature, x in Eq. (1), in a tree using the TreeExplainer and add for all the features, X in Eq. (1), in the tree under consideration to match with the tree. This can be applied to all the trees in the model one by one. Finally, we find the contribution of a feature for the ensemble of trees by the TreeExplainer. By knowing the contribution of all features in an ML model, it provides valuable insight into top features for each prediction.

### B. Malware Detection Model

All samples in the dataset are from windows executable. The features are derived from the PE header of the samples and as properties of a file. Each window executable contains a PE header that is explained in [6] [8] [21]. The PE header can be extracted using a python program using "Library for Instrumenting Executable Files" (LIEF) a library in python. The extracted features are listed in detail in Appendix A. PE header consists of DOS header, file header, NT header, section header, optional header, and many directories such as Import directories, Resource directory, Export directory, and Exception directory. Import directories list Dynamic Link Libraries (DLL) loaded by the executable and Application Program Interfaces (APIs) used by executables. Resource directory lists the information required by executable such as icons, bitmaps, strings, menus, dialogs, configuration files, version information, etc. Exception directory lists exception handling information. Features extracted are listed in Appendix A. Some of the features are described here. File header of PE header gives features such as timestamp, vsize, has\_debug, has\_relocations,

has\_signature, has\_tls, has\_symbol, imports, Machine1-Machine10 listed in Appendix A. Machine representing, type of processor required, in the file header part of PE header is hashed and put into one of ten bins and named as Machine1 - Machine10. Features that are hashed and put in several bins are named like this. Section header and optional header give section name, section size, section characteristics, and start and end byte contents of each section. The section name is a string. It is hashed and put into 1 of 50 bins. This gives us feature entry\_name1 - entry\_name50 listed in Appendix A. Section size, section virtual size, and section characteristics values are hashed and put into 1 of 50 bins. These operations give us features Sec\_size\_1 - sec\_size\_50, sec\_vsize1 - sec\_vsize50, sec\_char1 - sec\_char50 listed in Appendix A. Entropy of content of each section in the sample is hashed and put in to 1 of 50 bins. This gives us features sec\_entropy\_1 - sec\_entropy\_50 listed in Appendix A.

DLL in an import directory and the name of an API in the DLL are concatenated to make a string. The string is hashed and put into one of 1280 bins. This gives us the feature Imp1-Imp1280 listed in Appendix A. Function name in the export directory is hashes and out into one of 128 bins. This gives us feature exp1-exp128 listed in Appendix A. File-related information used to derive features are histogram of bytes, strings, and entropy of hex values in each sample. The byte value in the sample can be 0-255. A histogram is count of value of the byte in each sample. The count of the value of a byte is put into the respective bin H1-H256 to represent the feature listed in Appendix A. Strings in a sample give very important, insightful information used by malware. Strings reveal created and modified filenames and registry related information. Strings may also reveal IP addresses used by malware authors for communication, command and control center URLs, signature of malware authors and groups. All strings of size five-character or more are extracted, hashed, and put in one of 104 bins. This gives us features Str1 - Str104 listed in Appendix A. The encryption and packing methods increase the entropy, disorder of bytes in samples. Entropy is computed as the method described by [8]. In this method, a block size of 2048 bytes is extracted and counts of bytes are put in 16x16 bins. These operations of making a block of 2048 bytes with windows of 1024 bytes and putting in 16x16 bins are repeated for the entire content of a sample. This gives us features Ben1-Ben256 listed in Appendix A. Both the PE header and file-related information give 2351 features. Dataset consists of malware and benign samples and belongs to January 2017 time period.

Gradient Boosting Decision Tree (GBDT) LightGBM ML algorithms are selected for experiments in this work. The ML algorithm is selected for the following advantages.

- Feature importance of the ML model can be extracted after training of the model.
- Faster training and prediction
- Ease of computation

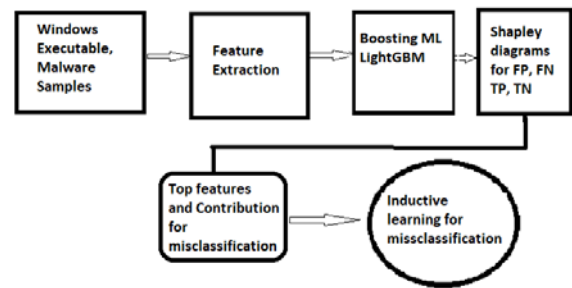

Fig. 1. System Block Diagram for Top Feature and their Contribution from Shapley Diagrams for Misclassification and Inductive Learning.

The system block diagram for this work is shown in Fig. 1. LightGBM boosting machine learning algorithm in the sklearn library is used to train the ML model. A trained model can predict the samples in the test dataset and correct detection of samples in true positive (TP), malware, and true negative (TN) benign software categories. Misclassified samples such as false positive (FP), benign software detected as malware, and false negative (FN), malware detected as benign software categories can also be identified. Nine to twenty five top features among the 2351 features can be identified for samples in TP, TN, FP, FN categories using diagrams such as waterfall plots, decision plots, and force plots. These diagrams show the amount of contribution by each top feature in Shapley values. Shapley values give a local explanation of top features with global structure as per ML model prediction for a sample. Changes in the top few features and their contribution to Shapley value for TP, TN, FP, and FN is compared. The comparison identifies a change in top features and their contribution for FP, FN also. This insight can be used as inductive learning to identify other samples which may have been misclassified and for future unknown samples without labels. Having found the misclassified samples by trained ML classifier, correct classification or malware detection can be performed. This leads to an increase in the performance of the trained ML model. One has to be very careful in this comparison and inductive learning with an unknown sample that does not have a label. Top features and their contribution in Shapley value for the unknown sample should match top features and their contribution in Shapley value for with known TP and TN samples also.

#### IV. EXPERIMENTAL RESULTS AND ANALYSIS

##### A. Dataset

The dataset in the proposed system is derived from [21]. It has Malware data from December-2006 to December 2017. The dataset from December 2006 to December 2016 contains only the malware and no benign entries and the reason for exclusion. Fig. 2 shows the exclusions, filter and pre-process used on the dataset to get the sub dataset used in this experiment. Dataset part from January 2017 is used in this proposed system. The unidentified entries are without labels in the dataset and are excluded for malware detection and analysis. The unidentified entries in the dataset may be malware or cleanware. The dataset consists of 32761 malware and 17186 benign software that appeared in January-2017. The details of the derived dataset are in Table III.

Fig. 2. Filter and Process the Database for the Experiments.

TABLE III. DATASET USED IN THIS WORK

SL No.	Samples	label	appeared
1	28606	Unidentified	2017-01
2	17180	Benign	2017-01
3	32761	Malware	2017-01

Each entry in the dataset has 2351 features. These features are from PE headers, sections of windows executable, systems APIs used in the executable, exported API from the executable, and file related properties. File related properties include Histogram of the complete executable in 256 bins, Byte entropy of executable file hashed into 256 bins and strings in 104 bins. The executable here means both the malware and cleanware. These features are defined in Appendix A and are used in the various diagrams in this paper. These features' names help identify exact features that are contributing to the detection of malware and the amount of contribution in the detection of malware or cleanware.

**B. Experimental Setup**

Intel(R) Core(TM) i5-7200U CPU @ 2.50 GHz, 2701 MHz, 2 Core(s), and 4 Logical Processor(s) with 8 GB Ram is used as computing resource in this work.

**C. Malware Detection with LightGBM**

Dataset is divided into a training set and testing set in the ratio of 70% and 30%. The model is trained with the training set and tested with the testing set. The results of this are in row 1 of Table IV. It has performance data for Accuracy, Precision, Recall, F1-score, and confusion matrix parameters in terms of false negative (FN), false positive (FP), true positive (TP), and true negative (TN).

30% of the dataset is separated for the testing of the LightGBM model. The samples in the test dataset are identified in false negative (FN), false positive (FP), true positive (TP), and true negative (TN) categories. It is interesting to explore how the top features and other features contribute to FP, FN, TP, and TN samples by the LightGBM algorithm. Waterfall plot, decision plot, and force plot are drawn with Shapley values.

TABLE IV. PERFORMANCE OF LIGHTGBM MODEL WITH ZERO-DAY MALWARE

	Accur acy	TP	F P	F N	TN	precis ion	rec all	f1- score	supp ort
D1- Test	98.483	552 0	15 0	10 0	107 11	0.99	0.9 9	0.99	1081 1
D1	99.389	169 98	18 2	12 3	326 38	0.99	1	1	3276 1

Fig. 3. Waterfall Plot of True Positive Sample in a Dataset with Shapley Values for each Feature.

Fig. 3 shows the waterfall plot for a true positive in the dataset. The Shapley value sum features to 5.378. The waterfall plot adds the contribution of each feature and also shows the top features with their contribution leading to the decision. Although the total contribution of 2342 features; lowest bar, in figure is significant compared to any top feature. In additional analysis, the feature importance of LightGBM showed only 588 features contributed to the model. Other 1763 features do not have any contribution to malware detection. Hence, many features in 2342 features have zero contribution. Kumar et al. [22] identified that 276 features among 2351 only contributed to prediction in the XGBoost model with 600k samples of training dataset from [21]. The remaining 2075 features have zero contribution to the model.

These figures help us to identify top features contributing to decision at leaf node with LightGBM algorithm.

Fig. 4 displays the decision plot for a true positive entry in the dataset and shows how the top features contribute to make the decision. The decision plot adds the contribution of each feature and draws the line that takes it to make a decision. It has the same TOP features as in Fig. 3. The waterfall plot adds the contribution of all the features but does not show the graph that leads to a decision as in the decision plot.

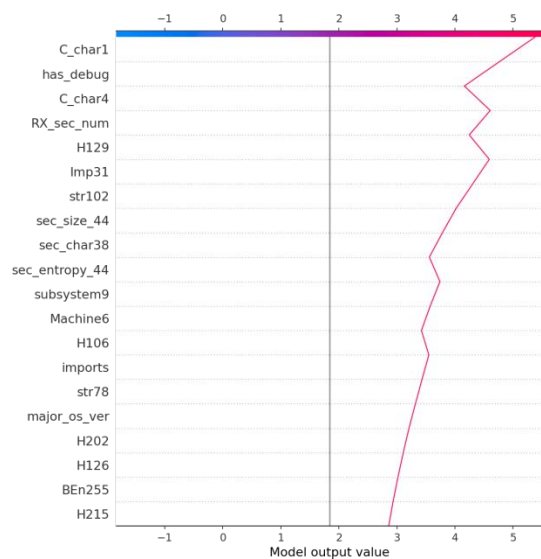

Fig. 4. Decision Plot of True Positive Sample in Dataset with Shapley Values for each Feature.

The decision plot can be for more number of samples. Fig. 5 shows the decision plot for the first ten samples in the dataset. The value that shows negative from zero in blue color are benign and the values that are on the right side of two, the purple color vertical line, in the graph are malware. The seven samples, pink color, with the specific features as shown are the malware and three samples are benign. The objective of these figures is to display how the features are contributing to decision with use of the LightGBM model. The label of samples is verified with the prediction of each sample with the LightGBM GBDT algorithm for all the 10 samples. It matches as given in the decision plot.

Fig. 6 shows the force plot for a true positive sample in the dataset in the Shapley values. The force plot shows how each of the feature is contributing in the positive direction from the left side with red color and other features that contribute negatively to scale value down and finally the value set near 5.38 for Shapley values. The top three features that contribute to the decision are named. The meaning of these features can be referred at Appendix A. The force plot cannot display the name of many features as in the decision plot. The top three features are the same as in Fig. 3 and Fig. 4.

Fig. 7 shows the force plot for the first 10 samples of the dataset in Shapley values. This figure is like rotating Fig. 6 clockwise and stacking the ten force plot of the figure in the x-axis. The count of the sample is seen at the top with numbers 0, 1, 9. The Y-axis displays the Shapley value for samples. The Shapley values for sample 2 are different from another sample. This change in Shapley value for each sample in the dataset is visible. It is possible to change the parameters in x-axis and y-axis from a drop down menu and analyze the top features for a sample. Amount of contribution top features make to the decision using the LightGBM algorithm can be observed.

Fig. 5. Decision Plot of First 10 Samples in Dataset with Shapley Values for each Feature.

Fig. 6. Force Plot of True Positive in Dataset with Shapley Values for each Feature.

Fig. 7. Force Plot of First 10 Samples in Dataset with Shapley Value for each Feature.

Fig. 8 displays a waterfall plot for a false positive sample from the test dataset part of the dataset. The advantages of waterfall plots are:

- Top 9 features contributing to predicting the sample as a false positive.
- In the Shapley scale, it starts at 2.0 and adds up to 3.589 with the top 9 features contributing in both positive and negative directions.
- The contribution of the remaining 2342 features for the sample is +0.2, much less than the top five features.

Fig. 8. Waterfall Plot of a False Positive Sample in Dataset in Shapley Value for each Feature.

Fig. 9 reveals the force plot for a false positive sample in the test dataset from dataset. The top features are RX\_sec\_num, C\_char1, and has\_debug from the PE header. The contribution of RX\_sec\_num is the highest among all the features. The top features for false positive in Fig. 9 are very different from the top features of malware (true positive) in Fig. 3. In addition, the final Shapley value for the sample is down to -0.09 in Fig. 9 compared to 5.38 in Fig. 3 for malware. The start point is very low at less than -6 in Fig. 9 compared to the start point at -1 in Fig. 3.

Fig. 10 presents a waterfall plot for a False Negative sample in the test dataset from the dataset in the Shapley value. All the advantages as explained for a false positive sample can be observed. In addition, features that are making the sample false positive and false negative can be compared. There is no contribution of the RX\_sec\_num, H129 feature in the false negative sample as in the false positive sample. The contribution of feature C\_char4 is there in false negative but not in false positive.

Fig. 11 shows the force plot for a False Negative (FN) sample in the test dataset in Shapley values.

Fig. 9. Force Plot of a False Positive Sample in Dataset in Shapley Value for each Feature.

Fig. 10. Waterfall Plot of a False Negative Sample in Dataset in Shapley Value for each Feature.

Fig. 11. Force Plot of a False Negative Sample in Dataset in Shapley Value for each Feature.

Fig. 12 shows the waterfall plot for the True negative sample in test dataset in Shapley value. Fig. 13 gives the force plot for the True negative (TN) sample in the test dataset in Shapley value.

The top features of waterfall plots in Shapley value from Fig. 3, Fig. 8, Fig. 10, Fig. 12 for in FP, FN, TP, and TN samples respectively in test dataset of the dataset are compared in Table V. Top features are listed in the features column. For a sample in each category in false positive, false negative, true positive and true negative, it identifies the presence of a feature as “Y” and no presence as “N”. Further, it identifies the topmost feature, with the value among the top feature with a “T” in each category. The probability value contributed by each feature is identified in respective columns. This table helps to conclude that there is disjoint set of features for each category samples in FP, FN, TP, and TN. The topmost feature for the FN sample is has\_debug and is present in FP and TP. The topmost feature for FP is Rx\_sec\_num and contributes very low value in other categories of samples.

The contribution of the remaining 2342 features is lowered significantly for FP and FN. For TP the value is +ve .42, for TN the value is negative -.03.

These comparisons can identify the misclassified FP and FN samples and improve the efficiency of the ML model by correct classification for an unknown sample. Few insightful rules that can be formed are as follows:

- The malware sample with a high contribution of Imp321, H33, C\_char1, and str43 may be a FP sample.
- The Malware sample with the highest contribution by Rx\_sec\_num among all the features will be a FN sample.

Fig. 12. Waterfall Plot of a True Negative Sample in dataset in Shapley Value for each Feature.

Fig. 13. Force Plot of a True Negative Sample in the Dataset in Shapley Value for each Feature.

TABLE V. FEATURES AND THEIR CONTRIBUTION IN FALSE POSITIVE, FALSE NEGATIVE, TRUE POSITIVE, TRUE NEGATIVE PREDICTION BY LIGHTGBM MODEL

Sl no	Features	False Positive	False Negative	True Positive	True Negative
1	C_char1	Y,+0.81	Y, 0.73	Y, <b>0.61</b>	Y, <b>-2.25</b>
2	C_char4	N	Y, -0.65	Y, -0.45	Y, - 1.08
3	Machine6	N	N	N	Y, -1.27
4	Subsystem9	0.18	N	N	Y, -1.0
5	Rx_sec_num	Y, <b>+0.95</b>	N	Y, 0.36	0.24
6	has_debug	Y, +0.48	Y, <b>-0.88</b>	Y, 0.61	-0.5
7	sec_size43	Sec_size44 = -0.17	Y, 0.31	0.24, sec_char38	N
8	H129	Y, -0.37	Y, H33 = -0.28 H67=0.26	Y, -0.35	-0.28
9	Imp370	Y, -0.32 imp857=0.16	N	Imp31=0.29	N
10	sec_char38	N	N	0.23	N
11	Str43	N	-0.25	N	str104=0.18
12	imports	N	N	N	-0.48
13	Ben255	N	-0.26, BEn253=-0.24	N	N
14	Other 2342 features	0.2	Y,-0.67	Y, 1.72	Y, -2.04

D. k-Fold Cross-Validation

Cross-validation with k=10 is performed for less biased and less optimistic accuracy value for the LightGBM model. The test dataset is used for this 10-fold cross-validation test. The results of cross-validation are tabulated in Table VI.

TABLE VI. TEN K FOLD CROSS-VALIDATION FOR THE TEST DATASET

Sl. no	Accuracy
1	0.97938144
2	0.9836165
3	0.97936893
4	0.9848301
5	0.97451456
6	0.97815534
7	0.97512136
8	0.97936893
9	0.9836165
10	0.97815534

E. Comparison with other Malware Detection Works

This work is compared with other malware detection works in Table VII. This work achieves higher accuracy with datasets compared to Yousefi-Azar et al. and comparable accuracy with Venkatraman et al. and Alazab et al. Jung et al [24] take 333 malware files with .swf extension into the test dataset from 2007-2015 for zero-day malware to get 51–100 % accuracy. Alazab et al. [25] get marginal higher accuracy of 98.6 compared to 98.49%. Shafiq et al. have a small size dataset and give the model performance at 99.2 Area under curve (AUC) that cannot be compared with accuracy.

They use more than three times malware compared to benign software for training and testing. They do not define ways to determine unknown malware. [6] Use only one tenth of benign software compared to malware. This highly unbalanced dataset lowers the probability of false positives. They consider zero-day malware as one which does not match known signature or unknown malware.

TABLE VII. COMPARISON WITH OTHER ZERO-DAY MALWARE WORKS

Paper	Method	Sample/Dataset	Result/Accuracy
This work	Boosting algorithms: LightGBM	Dataset Details in Table III	98.49
Yousefi-Azar et al. [15]	NLP and the term frequency tf-simhasing: term frequency of sample multiple with rand projection matrix	Android:Drebin, DexShare Windows PE files: Training:11983 Malware, 8912 Benign (2016) Testing: 12127 Malware, 11983	97.33
Venkatraman et al. [23]	Malware files to image as input to pre-trained CNN to get features, Apply SVM with SMO-Normalized Polynomial	52k samples	98.6%
Jung et al. [24]	API call sequence features Use Deep Feed-forward NN, RNN	Malicious .swf files 333 Benign .swf files 333	51% to 100%
Alazab et al. [25]	NB, kNN, 4 kernels with SMO. SMO–PolyKernel, SMO –Puk, SMO-Normalized, and SMO- RBF Backpropagation J48 and Neural Networks Algorithm	66703 samples with 51223 Malware and 15480 Benign software	98.6
Shafiq et al. [6]	Ripper, Ibk and SVM-SMO classifier	1447 Benign software 8892 + 5586 = 14478 malware	99.2% g AUC

## V. CONCLUSION

In this work, a boosting machine model based on LightGBM is enhanced using Shapely value to build an effective and robust machine learning model. Features derived by static analysis of malware and benign samples in the dataset are used to build the LightGBM boosting machine learning model. Datasets from Jan 2017 for malware is used for training and prediction. Waterfall plots, Decision plots and Force plots based on Shapely value helped identify the top few features. The Waterfall plots demonstrated a change in features and their contribution for a sample from different categories of samples as insight into the ML model. Table V compared the top features contributed to misclassified samples. The top feature for samples that is detected as false positive, false negative samples by trained models is analyzed and inductive learning rules are made. The inductive learning rules can be applied to unknown, unlabeled samples to avoid misclassification into FP and FN and to ensure correct detection. These top features and their contribution may be used to overcome the misclassification of malware. The cross-validation with the test dataset is 98.48 at maximum and 97.45 at minimum.

The work can be further extended to analyze change in features and to derive inductive learning rules for misclassification by other ML models for false positive and false negative cases to ensure correct prediction. The Shapely values for a feature may be mapped to the probability score of the ML model. This will help to correlate the Shapely value to probability value for a feature as local explanation and as a whole for a sample at global explanation (structure). Large datasets may be used to make a robust ML model and analyze reasons for misclassification for various families of malware such as ransomware, rootkit, Trojan horse, etc.

## APPENDIX A

Bn1-Bn256: The entropy of executable for a window size of 2048 bytes is computed for the joint distribution of byte value and put into 16x16 bins. This is repeated for a step size of 1024 for the full file.

C\_char1 - C\_char10: Characteristics of the sample from PE file header to indicate if the file is DLL, Executable, systems file, etc. The value is hashed and put into one of the ten bins.

dll\_c1 – dll\_c10: The DLL characteristics value from the optional header of PE for the sample is hashed put into one of the ten bins.

entry\_name1 - entry\_name50: The name of each section in the PE header of the sample is hashed and put into one of the fifty bins.

exp1 – esp128: The exported APIs in the sample are hashed and put into one of the 128 bins.

Exports: Flag interpreted by LIEF, a python package, indicating the executable exports API in the data directory of PE header.

Imp1 – Imp1280: The DLL names and imported APIs in the DLL are hashed and put into one of the 1280 bins.

H1-H256: Byte count of hex value 0x00 to 0xFF of benign software, malware is put their respective bin. These counts are further normalized with the file size.\

has\_debug: A flag in the characteristics field of file header in PE header of the sample, indicating debug information for the sample.

has\_relocations: A flag in the characteristics field to indicate relocation sections, relocation directory.

has\_resources: A flag in the characteristics field to indicate a resource section, a resource data directory.

has\_signature: A flag in the characteristics field to indicate digital signature related information.

has\_tls: A flag in the characteristics field to indicate tls section, tls data directory.

has\_symbol: A flag in the characteristics field to indicate debug section with symbols.

Imports: Flag interpreted by LIEF, a python package, indicating the executable has imports of API from DLL.

Machine1-Machine10: It indicates hardware architecture 32/64 bit, processor for executable. The values are hashed and put in to one of the ten bins.

Magic1 – Magic10: Magic value from optional header of PE for the sample is hashed and put in to one of the ten bins.

num\_of\_sec\_morethan0: Number of sections in section part of PE header which has content and size greater than 0 size.

Num\_sec\_noname: Number of sections in section part of PE header which are without a name. Generally, the name of a section is .text, .rdata, .data etc.

RX\_sec\_num: Number of sections in section part of PE header which has read and execute permission.

Sec\_size\_1 – sec\_size\_50: The size of each section in the PE header of the sample is hash and put in to one of the fifty bins.

sec\_entropy\_1 -- sec\_entropy\_50: The entropy of each section in the PE header of the sample is computed, hashed, and put into one of the fifty bins.

sec\_vsize1 -- sec\_vsize50: The memory size of each section in the PE header of the sample is hashed and put in to one of the fifty bins.

sec\_char1 - sec\_char50: The characteristics of each section in the PE header of the sample is hashed and put in to one of the fifty bins.

Size: Size of executable.

Str1-Str104: Five or more printable characters in the samples are hashed in to 104 bins. These strings include URLs starting with HTTP: HTTPS: registry keys starting with HKEYS, paths in systems such as c: /, file name, malware author's messages, etc.

Subsystem1 – Subsystem10: Subsystem value from optional header of PE header of the sample. The values are hashed and put in to one of the ten bins.

timestamp: Date, the timestamp of a sample.

Vsize: virtual size of executable in memory.

W\_sec\_num: Number of section in section part of PE header which has write permission.

# Using a Rule-based Model to Detect Arabic Fake News Propagation during Covid-19

Fatimah L. Alotaibi, Muna M. Alhammad  
Collage of Business Administration  
King Saud University  
Riyadh, Saudi Arabia

**Abstract**—Since the emergence of the Covid-19, both factual and false information about the new virus has been disseminated. Fake news harms societies and must be combated. This research aims to identify Arabic fake news tweets and classify them into six categories: entertainment, health, politics, religious, social, and sports. The study also aims to uncover patterns in the spread of Arabic fake news associated with the Covid-19 pandemic. The researchers created an Arabic dictionary and used text classification based on a rule-based system to detect and categorize fake news. A dataset consisting of 5 million tweets was analyzed. The developed model achieves an overall accuracy of 78.1% with 70% precision and 98% recall. The model detected more than 26006 fake news tweets. Interestingly we found an association between the number of fake news tweets and dates. The result demonstrates that as more information and knowledge about Covid-19 become available over time, people's awareness increase, while the number of fake news tweets decreases. The categorization of false news indicates that the social category was highest in all Arab countries except Palestine, Qatar, Yemen, and Algeria. Conversely, fake news related to the entertainment category was the weakest dissemination in most Arab countries.

**Keywords**—Fake news; Covid-19; text classification; rule-based system; trends

## I. INTRODUCTION

Social media networks are increasingly being used as a source of information. Its low cost, easy access, and speed of information delivery encourage people to use it as a searching tool to obtain information. The widespread use of social media around the world provides a perfect setting for the dissemination of fake news. Fake news is described as low-quality news [1] or false news purposely broadcast to divert people away from true news and facts [2]. It is considered to be one of the most dangerous weapons capable of bringing harm to both society and people [3]. Its prevalence increases during crises as crises represent a perfect time for spreading fake news and rumors, especially when knowledge of a problem is limited and ambiguous.

Due to the breakout of the novel coronavirus "Covid-19" in 2020, the world faced health and economic concerns. The virus was first discovered in China in November of 2019 then formally declared a pandemic by WHO [4] on the 11th of March 2020, making it the worst global crisis of the 21st century. Many people are afraid and anxious because of the virus's secrecy and uncertainty. Therefore, both true and false news began to spread about this virus. Social network websites have become essential for obtaining news and information

about Covid-19 [5]. With curfew and lockdown being implemented in many countries, social network websites were full of endless discussion about the Covid-19, with much fake news being exchanged. Many individuals intentionally propagated social media with fake news to gain personal benefits, such as having a lot of likes and followers. In addition, some companies and organizations have benefited from the spread of false and misleading information on social media to promote and advertise products or services to increase their sales profit [6]. The propagation of fake news had a negative influence on public health throughout this crisis, increasing tension, rage, anxiety, panic, and depression [2]. It has been documented, for example, that some consumers in the United Kingdom and Australia experienced panic-buying while purchasing a specific product, such as toilet paper [7]. As a result, the negative impact of the propagation of fake news may lead to more severe problems within society as well as the Covid-19 problem.

As a response to control the spread of fake news during the pandemic, many countries and governments have taken the issue seriously and introduced new laws to prevent the spread of such information. For example, Twitter announced that it would remove any misleading and unspecified content about Covid-19. Moreover, social network websites, such as Facebook, Google, WhatsApp, and Microsoft, have pledged to work with governments to fight the spread of fake news. In the middle east, Saudi Arabia is one of the countries that is seriously fighting the spread of misleading information about the Covid-19 pandemic. The Public Prosecution in Saudi Arabia applied high penalties against fake news propagators with fines of up to 3 million SAR and imprisonment of up to 5 years.

Although the media paid considerable attention to studying the spread of fake news [8], most of these studies were conducted in western countries, with the English being the primary language of the studied samples. There are few empirical investigations of the diffusion of fake news in the Arab region. Cultural disparities are evident, highlighting the importance of researching the dissemination of fake news in many cultural contexts. In addition, studies of the diffusion of fake news during the time of pandemics and crises are currently limited. Therefore, this research aims to answer the following two questions: how to detect Arabic fake news about Covid-19 on Twitter through the use of rule-based systems, and what are the current trends of fake news diffusion during the pandemic in the Arab region?

This paper starts with reviewing the literature, followed by introducing the methodology used in this research. Data analysis results and discussion will then be presented. Finally, the conclusion, limitations, and future work will be presented.

## II. LITERATURE REVIEW

### A. Fake News

Since the inception of fake news, there has been no single definition of fake news [3]. According to [9], fake news is also defined as a news article intentionally written to deliver false information for a different purpose. Therefore, fake news is described in this study as manipulated false or misleading information to appear like real news for several purposes.

Several researchers were interested in studying the spread of fake news. For example, Allcott et al.[10] did a study to measure trends in the diffusion of misinformation circulating on social media from January 2015 to July 2018. The result from their research shows users' interactions with incorrect information rose steadily on both Facebook and Twitter up to the end of 2016. However, after one month, the interactions with false information dropped sharply on Facebook while rising on Twitter. This may result from a change in the Facebook platform after the 2016 elections to combat fake news. Another study was conducted by [2] to develop a method to overcome the spread of fake news in health during the current outbreak. The study focused on determining the type of false health information and used social impact in social media (SISM) methodology to analyze data. In addition, they selected Facebook, Twitter, and Reddit as social media channels for analysis. The study found that posts focused on fake health information are most aggressive. The spread of fake news during the current pandemic, i.e., Covid-19, made many individuals fearful and panicked. According to [2], psychological and neurological problems increased during the current pandemic, with fake news playing a significant role. In a recent study, researchers designed a dashboard to track misinformation on popular social media news sharing platforms (i.e., Twitter). To do so, they collected data from the platform beginning on March 1, 2020, and up to date [5]. This dashboard aims to fight false information and increase awareness about Covid-19.

Fake news can be detected by using three main methods. The first method relies on analyzing the news context where linguistic features are extracted and analyzed to identify fake news based on the writing styles that are commonly used in fake news [11, 12]. In addition, visual features can be used and analyzed to identify fake images [3]. The second method relies on analyzing social context where user-based, post-based, and networks-based segments are analyzed to determine fake news. User-based features such as users' profiles and characteristics can be analyzed to detect fake news through identifying the source of the fake news [12]. Post-based features mainly identify fake news by extracting and analyzing people's responses toward fake news [3]. Networks-based featured can remove by building specific networks among the users who published related posts [3]. The third and most recent one is using a knowledge-based context model, which aims to use external sources to check facts and identify fake news [13]. This last method is currently widely used because of its

accurate results and the increasing number of available high-quality fact-checking websites.

### B. Text Mining and Text Classification

With the massive volume of data, companies and organizations started to use text mining techniques to improve their services, monitor brand reputation, gain a competitive advantage, and understand customers' behavior [14]. Text mining is used to extract hidden meaningful information from text [15, 16]. Moreover, text mining deals with unstructured data, while data mining deals with structured data [15, 17]. The process of mining text includes several stages: data gathering, data preparation, text transformation, feature selection, pattern selection, and evaluation [17]. Text mining involves a large set of algorithms and techniques for analyzing text, such as information retrieval, natural language processing, text summarization, classification (supervised learning), and clustering (unsupervised learning) [15]. These algorithms and techniques are being used in several contexts such as Business Intelligence, Customer care services, Knowledge management, Bioinformatics, Web Search Enhancement, and Risk Management [17].

In detecting fake news, the study [18] used semantic features and text mining to detect the spread of fake news in online articles. The used dataset was obtained from Kaggle about real-or-fake news. They applied five semantic features, including term frequency (TF), term frequency-inverse document frequency (TFIDF), bigrams, trigrams, quad-grams, and glove word embeddings along with Naive Bayes, random forest, and recurrent neural networks (RNN) classifiers. The study points out the bigram features with the random forest classifier achieved the best accuracy of 95.66%. So, text mining techniques are beneficial for finding misinformation. Another study was conducted by [19] to understand the impact of Covid-19 in Mexican society by using the text mining approach. The study extracted Twitter tweets about Covid-19 from the 13th to the 20th of March 2020, and the geo-localization of the retrieved tweets was Mexico City. The study found a positive correlation between the number of these tweets each day and the number of positive Covid-10 cases reported by the government on the same day. In addition, the people were fearful of health risks and economic crises that Covid-19 may cause. This required developing strategies to comfort the fear and panic associated with Covid-19.

Text classification is one of the essential methods in supervised learning [17]. It aims to assign classes or labels to texts, and it is used in many applications like image processing, document organization, etc. [15]. There are many learning algorithms used for text classification, such as Naïve Bayes Classifier, decision trees, Neural networks, and rule-based classifier. A team of researchers has developed a text-based algorithm, i.e., a supervised decision tree model, for analyzing customers' comments about a famous food brand on Twitter. The developed model predicted about 85% negative comments and 15% positive comments after analyzing 500 tweets [14]. A recent study applied text classification on Twitter data to analyze public fear sentiment during the Covid-19 pandemic [20]. Two machine learning (ML) classification methods were used, i.e., Naïve Bayes and logistic regression. Over nine hundred thousand tweets from February to March of 2020 were

analyzed using R software. The Naïve Bayes was able to classify public fear sentiment with a 91% accuracy rate, while the logistic regression was able to classify public fear sentiment with only a 74% accuracy rate. It is noted that the text classification helped in understanding the feeling of the public. Hence, it can be used to study social phenomena such as the spread of fake news.

1) *Rule-based classifier*: The rule-based classifier is one approach to text classification which uses a set of rules to separate the text into distinct groups [21]. Each of these rules contains an antecedent part, and a consequent part uses a series of "if-then" to represent them [22]. In [23] used a rule-based classifier with supervised learning to perform a Twitter sentiment analysis. Rules were built based on the occurrences of words related to emotion and opinion within the text. The study found that a rule-based classifier can improve the support vector machine SVM's predictions.

In summary, studies concerned with detecting fake news used either rule-based models or machine learning techniques to detect fake news. In this research, a rule-based classifier with a developed dictionary will be used to classify and detect fake news.

### III. RESEARCH METHODOLOGY

Twitter data analysis has occupied a large volume of research in recent years, with many researchers relying on text mining techniques such as classification and clustering [16]. This study will develop an Arabic dictionary to detect fake news on social media (i.e., Twitter) and study the propagation of fake news in the Arab region. For our Arabic dictionary, we gathered fake news about the Covid-19 pandemic from various fact-checking websites, then built our dictionary around it. Our detection model is based on text classification that depends on rule-based systems to classify the tweets as fake or not fake news. The method of this study was divided into three steps: data collection, data preparation, and model building. Besides, we used python language (Jupyter notebook) to preprocess and analyze the dataset, Microsoft Excel to build the dictionary, and Power BI for data visualization.

#### A. Data Collection

We used a dataset of Arabic tweets on Covid-19 released on GitHub by Dr. Sultan Almujaivel<sup>1</sup> after getting his consent to use the data. The data were gathered between March 1, 2020, and April 30, 2020. To retrieve the dataset from Twitter, he used Arabic hashtags related to coronavirus disease to retrieve relevant tweets. Those hashtags are "#كورونا", "#covid-19", "#فيروس كورونا", "#coronaviruse", "#منع التجول", "#curfew", "#حظر التجول", "#curfew", "#كورونا\_المستجد", "#novel\_coronaviruse", "#العالم\_في\_مواجهة\_كورونا", and "#world\_facing\_covid-19". The number of tweets in this dataset was 5015111 tweets.

#### B. Data Preparation

To clean and prepare the dataset for analysis, a series of processes were conducted. Noised tweets containing ads, coupons, and other irrelevant tweets were removed, as were old

tweets tweeted on a date other than the study's covered period. Arabic and English punctuation, numbers, hashtags, emoji, and empty tweets were removed too. Additionally, English letters, @username, and website links were replaced with an empty string. We also normalized the tweets in Arabic. Furthermore, missing values in the Location and Username columns were replaced with "undefine" values. As the data preparation finishes, the total number of tweets eligible for analysis was lowered to 4643425.

#### C. Model Building

To analyze the data, we performed two steps to building the model:

1) *The development of fake news dictionary*: The main goal of this study's dictionary development is to categorize Arabic tweets that contain fake news. Tweets that have spread in Arab communities are included in the dictionary. Initially, fake news was gathered from fact-checking websites as well as the fake news set published by [24] in GitLab<sup>2</sup>. The fact-checking websites that were used in this study are Misbar<sup>3</sup>, Norumors<sup>4</sup>, AFPfact check<sup>5</sup>, Fatabyano<sup>6</sup>, Google fact check tools<sup>7</sup>. Duplicate news was checked and removed as it was gathered from various websites. A total of 212 pieces of fake news were discovered. Each piece of news was then tokenized, and the seven most important words were taken into account. One of these words has been identified as the primary key to fake news, with the remaining words serving as secondary keys. Table I shows two examples of fake news and how to extract the crucial words, where the "Fake" column represents the fake news, the "Key" column represents the fake news's primary key, and the reminder columns represent the fake news's secondary keys<sup>8</sup>. Following that, the fake news in the dictionary was classified into six categories, which corresponded to the categories identified by [24]. Table II. represents the categories and the number of relevant fake news categorized under each category in our dictionary. An example for each of the categories is presented in Table III.

2) *Rule-based model development*: The rule-based model was performed using two steps. First, the rule-based model will determine whether the primary key in the dictionary of fake news can be found in the text of the tweet. If the first condition is met, the model will check to see if at least two words from the dictionary's secondary words are found in the tweet's text. As a result, if the two conditions are met, the model will verify that the text does not contain any vocabularies that reject fake news, such as: ('false claim- ادعاء المعلومات- 'misinformation- ' لا صحه لذلك- ' زائف المغلوطة'). This is significant because some accounts on Twitter

<sup>1</sup> <https://github.com/salmujaivel>

fight and reject fake news. Therefore, by checking the existence of these vocabularies, one can verify that the tweet categorization as fake news is accurate. If the preceding conditions are met, the fake news category will be retrieved from a dictionary and assigned to the relevant tweet. Otherwise, the tweet will be categorized as not-fake news. Fig. 1 depicts the code used to determine whether a tweet contains fake news and to assign tweets to the appropriate category. The second step aims to label tweets based on the category, with label =1 indicating that the tweet contains fake news and label =0 indicating that the tweet does not contain fake news. To do so, we look to see if the category contains a "not" value, which indicates that the label is equal to zero; otherwise, the label is equal to one. Fig. 2 depicts the code that was used to assign the tweets to the label.

TABLE I. EXAMPLES OF FAKE NEWS IN THE DICTIONARY

Fake	Key	S1	S2	S3	S4	S5	S6

#### IV. RULE-BASED MODEL EVALUATION

To evaluate and confirm the proposed model, a balanced sample of 2000 tweets was extracted at random. The tweets in the sample were labeled manually, with label=1 indicating fake news and label=0 indicating not-fake news (i.e., real news or others). In this sample, there were 997 tweets labeled as fake news and 1003 tweets labeled as not fake news. The sample was then divided into 70 percent (1400 tweets) for training our model and the remaining 30 percent (600 tweets) for testing. The performance of the proposed model was assessed using accuracy, precision, and recall. These three metrics are measured by calculating the number of correct positive predictions (TP), the number of correct negative predictions (TN), the number of incorrect positive predictions (FP), and the number of incorrect negative predictions (FN) [9], as shown respectively in equations 1, 2, and 3.

$$\text{Accuracy} = \left( \frac{(|TP|+|TN|)}{(|TP|+|TN|+|FP|+|FN|)} \right) \quad (1)$$

$$\text{Precision} = \left( \frac{(|TP|)}{(|TP|+|FP|)} \right) \quad (2)$$

$$\text{Recall} = \left( \frac{(|TP|)}{(|TP|+|FN|)} \right) \quad (3)$$

Table IV displays the precision, recall, and accuracy of our model when applied to training and testing data in this sample. Our model's prediction level is adequate based on these results. As a result, we may use the model to examine our data.

TABLE IV. ACCURACY, PRECISION, AND RECALL FOR VALIDATING THE RULE-BASED MODEL

	Training Data	Testing Data
<b>Accuracy</b>	79.7%	78.1%
<b>Precision</b>	71.2%	70%
<b>Recall</b>	99%	98%

#### V. MODEL EVALUATION USING FUTURE DATASET

To validate the proposed model, the researchers obtained 545 tweets at random as future data. The tweets were then manually labeled. When the model was applied to these data, the accuracy was 95.9 percent, indicating that the model was acceptable and applicable.

#### VI. RESULTS AND DISCUSSION

##### A. Fake news Propagation Trends across the Arab Region

After ensuring that our model had an acceptable level of accuracy, it was applied to the dataset. 26006 tweets were

labeled as fake news by the model. According to an analysis of the source of these tweets, only 13491 fake news tweets have location details. This is because location data on Twitter is provided only if the user has a geo-enabled feature or mentions a valid location in his public profile [5]. The analysis of the location of fake news tweets reveals that the majority of fake news tweets originated in Saudi Arabia, Egypt, Kuwait, Qatar, Yemen, United Arab Emirates, Iraq, Palestine, Lebanon, Jordan, Oman, Algeria, Morocco, Libya, Sudan, Syria, Bahrain, and Tunisia respectively (see Fig. 3). Given that the majority of the analyzed tweets originated from Saudi Arabia and Egypt, it was expected that a high number of fake news tweets are being exchanged in these countries. This is also consistent with recent statistics showing that Saudi Arabia and Egypt are ranked 8th and 18th in the world in terms of the number of Twitter users, respectively<sup>9</sup>. However, the high number of fake news tweets from Kuwait, which is so close to Egypt, is surprising. Kuwait is a small country with a population of only 4.4 million<sup>10</sup> people. Nevertheless, about 99.5%<sup>11</sup> of its population are current Internet users, and more than half of them are Twitter users. Therefore, this may have affected the spread of fake news in Kuwait.

As previously stated, the model was trained to categorize fake news tweets into six categories based on the general theme of the tweet. Table V shows the number of tweets in each category of fake news.

##### B. Fake News Word Cloud

After extracting the fake news tweets from the dataset, we used a word cloud to analyze the frequency of the words in these tweets. However, it was decided to exclude two words (corona "كورونا"; and virus "فيروس") because they were found to harm the word cloud's results. Fig. 4 depicts the word cloud results for the most common words found in fake news tweets. The most frequent tweeted fake news was related to the daily use of hot steam inhalation to 'kill' the Covid-19 coronavirus.

Total	26006

Fig. 4. Word Cloud for Fake News.

C. Analysis of the Fake News across the Dates

The dataset for our study was obtained from Twitter between March and April. After analyzing the data, we discovered that the spread of fake news tweets was much higher in March than in April. Fig. 5 shows that approximately 63.06% of fake news tweets were posted in March, while only 36.94% were posted in April indicating a decrease in the number of fake news tweets in April. These findings show that ambiguity surrounding the coronavirus and people's feeling of fear may have increased fake news propagation at the beginning of this crisis. Therefore, as users' awareness and knowledge of Covid-19 increases, the spread of fake news tweets decreases.

Fig. 5. Distribution of Fake News Tweets across Categories.

Because the number of fake news tweets in March is higher than in April, we attempted to improve our understanding of the spread of fake news tweets in March by analyzing the distribution of fake news during the month's days. Fig. 6 shows that the 14<sup>th</sup>, 15<sup>th</sup>, 16<sup>th</sup>, and 25<sup>th</sup> of March saw the most incredible spread of fake news tweets in the Arab region. On or around March 15th, most Arab countries suspended in-class study and switched to online study for both schools and universities. Egypt, for example, temporarily suspended traditional education on March 15<sup>th</sup>, which explains why the 14th, 15th, and 16th of March have the highest number of fake news tweets. Furthermore, the partial curfew in Saudi Arabia began on March 23<sup>rd</sup> and in Egypt on March 25<sup>th</sup>, which could explain the rise in fake news on March 25<sup>th</sup>. This demonstrates that as more information and knowledge about Covid-19 become available over time, user awareness of the current pandemic grows, while the number of spread fake news tweets decreases.

As previously observed, Saudi Arabia, Egypt, and Kuwait had the highest number of fake news tweets. As a result, we attempted to comprehend the distribution of fake news during March and April. Fig. 7 shows that the number of fake news tweets in Egypt and Kuwait decreased by roughly half between March and April, but not significantly in Saudi Arabia. It is plausible that the total curfew imposed by Saudi Arabia in major cities on April 6th contributed to the continuation of fake news.

Fig. 6. Spread Fake News Tweets during March.

Fig. 7. Spread of Fake News Tweets by Months in the Top Three Arabic Countries

Fig. 8. Categories of Fake News across Arab Countries.

#### D. Distribution of Fake News Categories across Arab Countries

Fig. 8 depicts the various categories of fake news tweets in Arab countries. Fake news tweets about social issues are the most prevalent in all Arab countries except Palestine, Qatar, Yemen, and Algeria. In Palestine, fake news tweets were mostly about religion, whereas in Qatar and Yemen, fake news tweets were mainly about politics. In Algeria, fake news tweets were mostly about religious or political issues. Fake news related to entertainment, on the other hand, was the lowest across all Arab countries, except Morocco, which has a deficient number of fake news tweets related to health topics.

### VII. CONCLUSION

This study was carried out to understand better the spread of the fake news phenomenon in the Arab region during Covid-19. We created an Arabic dictionary and used text classification, i.e., a rule-based system, to analyze the spread of fake news in the Arab region using a secondary dataset to detect fake news. We discovered that the number of fake news spreads on Twitter was much higher in March than in April and that dates with significant response measures taken to control the spread of Covid-19 had the highest number of fake news spreads. This figure usually falls a few days after the measurement is taken. This demonstrates that at the start of new changes, people panic, mainly due to a lack of information about what will happen next, and that as more information becomes available, users adapt to the new norms and stop spreading such fake news.

### VIII. LIMITATION AND FUTURE RESEARCH

This study has some limitations. The primary limitation is the difficulty of processing Arabic. The Arabic language, unlike other languages, has distinct writing principles such as writing from the right to the left side, the absence of capital letters, and distinct grammatical rules for detecting entities, acronyms, and abbreviations. The presence of many dialects in the Arab region, the use of slang words and colloquial terms, and many spelling errors are also significant challenges when analyzing the Arabic language. The tweets dataset used in this

study came from various Arabic countries, and the tweets were written in a variety of Arabic dialects, making it difficult to process and analyze texts using stemming. To improve the efficiency of the analysis, future work should focus on developing the stemming process for the Arabic language. Additionally, because new fake news is created periodically, the developed fake news dictionary must be updated regularly. In addition, the result of the proposed model in this study will be compared in the future with the results of the machine learning models to extra validate and assess the performance of the proposed model. Also, an additional dataset from other social media platforms, such as Facebook, will be used in the future to see if the same trends of fake news dissemination are observed across platforms.

### ACKNOWLEDGMENT

The authors would like to thank Dr. Sultan Almujaivel, who works at King Saud University, for providing them with the dataset of Covid-19 Arabic tweets used in this study.

# Hybrid Deep Neural Network Model for Detection of Security Attacks in IoT Enabled Environment

Amit Sagu, Nasib Singh Gill, Preeti Gulia  
Department of Computer Science and Applications  
Maharshi Dayanand University  
Rohtak, Haryana, India

**Abstract**—The extensive use of Internet of Things (IoT) appliances has greatly contributed in the growth of smart cities. Moreover, the smart city deploys IoT-enabled applications, communications, and technologies to improve the quality of life, people's wellbeing, quality of services for the service providers and increase the operational efficiency. Nevertheless, the expansion of smart city network has become the utmost hazard due to increased cyber security attacks and threats. Consequently, it is more significant to develop the system models for preventing the attacks and also to protect the IoT devices from hazards. This paper aims to present a novel deep hybrid attack detection method. The input data is subjected for preprocessing phase. Here, data normalization process is carried out. From the preprocessed data, the statistical and higher order statistical features are extracted. Finally, the extracted features are subjected to hybrid deep learning model for detecting the presence of attack. The proposed hybrid classifier combines the models like Convolution Neural Network (CNN) and Deep Belief Network (DBN). To make the detection more precise and accurate, the training of CNN and DBN is carried out by using Seagull Adopted Elephant Herding optimization (SAEHO) model by tuning the optimal weights.

**Keywords**—Internet of things; deep learning; optimization; convolutional neural network; security attack detection

## I. INTRODUCTION

IoT is an integration of services, people, interconnected entities, and physical infrastructure that process the information [1]. Moreover, the IoT systems are dynamically distribute, edge based computational resources and allocations of information. IoT devices communicate with one another by wireless communication systems and transfer the information to a centralized model [2][3]. IoT is one of the interrelated models that supports seamless information among the devices (e.g.), automotive sensors, environmental sensor, industrial robots, road-side sensors, surveillance devices, medical devices and smart home sensors. The sum figure of the linked IoT devices has touched the usage of 27 billion in 2017. IoT devices used various technologies, service types, and protocols [4]. Consequently, it seems more complex to maintain the upcoming IoT framework as it leads to unwanted vulnerability in the environment. The cyber-attack could access the details in an illegal manner regarding each activity of citizens without the user's knowledge or can reconfigure the devices with the unsecured settings [5][6].

The risk rendering through these attacks may affect the protection of IoT networks and the entire eco-system such as

applications, web-sites, servers and social networks, through malicious smart device known as botnet (i.e.), robot networks. Also, a communication channels or single component in IoT-based systems can be compromised by paralyzing the complete or part of Internet network [7][8][9]. Hence, the standard attack detection model is required, which could analyze the behavior of attacks in network. The rising of deep learning (DL) has alleviated the limitations of the conventional machine learning (ML) schemes due to the combined implementation of classifier and feature extraction, and its strong representative ability [10] [11][12] Further, DL model is used for avoiding the overhead of manual selection of features, and that is an essential section for traditional classification systems [13][14].

Several researchers have used the DL tools for solving the problems related to the communication which is progressively being carried out [15] [16]. Particularly, DBN is implemented based on the AMC scheme through SCF feature; however, it attains the restricted classification outcomes due to inadequate ability. Furthermore, an unsorted DNN is used for identifying the signal modulation systems with less computational complication [17] [18] [19] [20][21]. Still, the deficiencies of the convolutional operation make it more complex for extracting the high-dimensional features. The IoT devices creates large amount of data. Moreover, the ML [22][23] pipelines has performed the process of data collection, feature extraction, and binary classification in many systems or models for the detection of IoT traffic. Several ML algorithms [24][25] [26][27] including NNs[28][29][30], BNs, EL, clustering, FS, SVMs, and DTs are used for IoT attack detection with great impact. Recently, DL model is used for detecting the anomalous behavior in the IoT field [31][32][33].

The key contributions of the proposed model are given below:

- Introduces the Hybrid model for detection of attack in IoT.
- Proposed the Seagull Adopted Elephant Herding Optimization (SAEHO) algorithm for training the hybrid system through tuning the optimal weights.

In this paper, the literature review on attack detection in IoT is given in Section II. Overall description of the adopted attack detection model is determined in Section III. Pre-processing and feature extraction phase are described in

Section IV. Section V describes attack detection by proposed hybrid deep learning model. Section VI depicts the proposed seagull adopted elephant herding optimization algorithm for optimal training of hybrid model via tuning the weights. Section VII specifies the result and discussion. At the end, the conclusion of this paper is depicted in Section VIII.

## II. LITERATURE REVIEW

### A. Related Works

In [34] Li, et al., (2019) has introduced the information security approach of block chain on the basis of intrusion detection technique in the IoT. Moreover, the intrusion detection technology was used for analyzing the recognition technology on the basics of dissimilar systems, and the security of block chain information. From hacker attack, the intrusion detection model was one of the security technologies for protecting the network resources. IDS were more beneficial enhancement to the firewall that would assist the network approach for enhancing the integrity of the information security framework and detecting the attacks quickly. Finally, the proposed intrusion detection technique was used for the block chain information security system, and the experimental outcomes have shown better fault tolerance and higher detection efficiency.

In [35] Boubeta, et al., (2020) has proposed an intelligent architecture which combined ML paradigm and the CEP technology for detecting various categories of security attacks in real time IoT. Additionally, the proposed architecture was accomplished for managing the event patterns easily and the conditions depend on values attained via ML models. Moreover, an automatic code generation and a model-driven graphical device were provided for pattern definition in security attack and it hides all the complication attained from execution information of domain experts. The simulation outcome of the adopted model has demonstrated better performance than other schemes.

In [36] Marcos, et al., (2020) have adopted a near real-time SDN security model in which it secures the basis of SDN controller besides the traffic destruction and avoids the DDoS attacks in the source-end network. Further, the CNN for DDoS detection was tested and applied, and determined the system alleviate the identified attacks. A GT based technique was used to mitigate the attack in which it optimized the packet discard rate and concern within the SDN's central controller. At the end, the experimental results of the presented SDN security scheme have shown better outcomes against next-generation DDoS attacks.

In [37] Mabodi, et al., (2020) have determined a hybrid system based on the cryptographic authentication. In addition, the adopted model includes four stages like gray hole attack discovery, testing the routes, the malicious attack removal procedure in MTISS-IoT, and the IoT identifying node trust. The adopted system was assessed via extensive simulations that were done in the NS-3 tool. At the end, the experimental results of four circumstances have determined that the MTISS-IoT model has shown better FPR, FNR, and detection rate than other models.

In [38] Chunsheng, et al., (2020) have implemented a MMFN for identifying the signal modulations via a new feature known as PCCs. Furthermore, a PCCP was implemented for converting the raw modulated signals into PCCs, and it was the inputs given to MMFN. The multi-module fusion model was proposed in MMFN for acquiring the higher representation capability. Moreover, the characterization module was implemented for balancing the tradeoff among the dimensions of the extracted features and the number of parameters. At the end, the experimental results of the presented MMFN approach have achieved 90% accuracy at 1 dB SNR and superior classification performance.

In [39] Mohammed, et al., (2020) has discussed the IoT-ED possibility with implanted HT which provides serious privacy, security, and available issues to the IoT based HAN. Moreover, the traditional network attack detection models have worked the network protocol layers, while the IoT-ED with HT leads to the demonstration of attack at the firmware or/and physical level. The adopted model was used for identifying the multiple attacks and differentiated the various attack types. Further, the IoT-ED behaviors have been studied for 5 various random attacks that includes the DoS, impersonation attacks, power depletion, ARQ, and covert channel. The adopted method could distinguish with 92% accuracy for all the attacks simultaneously.

In [40] Sahay, et al., (2020) have determined a layered scheme of IoT routing security for analyzing the susceptibility linked with every phase of the routing method. The adopted system has explored the leverage of inherent features in blockchain for enhancing the security in IoT-LLNs. Moreover, the blockchain network operated as a protected data link among the attack detection mechanism and the IoT-LLN to enhance the outcomes of XGBoost algorithm. Finally, the blockchain-based model was implemented with elegant contract to generate the real-time alerts for identifying the sensor nodes.

In [41] Alabady, et al., (2020) have introduced a novel security system in the IoT era for cooperative virtual networks. The proposed model has determined the attacks and risks in switches, network security vulnerabilities, threats, routers and firewalls, along with a policy for mitigating those risks. The adopted method has offered the basics of secure networking scheme that includes router, firewall, VLAN technology and AAA server. At last, the simulation results of the adopted approach have demonstrated an effective security execution with excellent network services and speed.

### B. Review

Table I shows the review on attack detection system in IoT. Originally, the Mapping UML model was determined in [41] that presents higher detection efficiency, fault tolerance and better accuracy; however, the data selection sensor technique was not incorporated into the computer environment. Moreover, the CEP and ML models were deployed in [24] that provide better precision, higher recall, and maximum F1 score. Nevertheless, more event patterns were not defined in the proposed model for detecting other types of attacks. CNN model was exploited in [42] that offer

higher accuracy, improved precision rate, and maximum recall, but need to maximize the host count in the simulated SDN environment. Likewise, MTISS-IoT model was exploited in [23], which offers better FPR, low FNR and maximum detection rate. However, the firefly optimization was not used in the proposed work to lower consumption energy and malicious attacks on the IoT. MMFN method was exploited in [29] that have robustness, higher classification accuracy, and strong characterization ability; however, the small-scale data-driven DL- AMC model with less training time was needed for training the neural network (NN). In addition, an IoT-based HAN model was determined in [28], which offers better accuracy, reduced false positives, and high precision. However, the proposed work needs to suggest the moving data process nearer to the network edge. XGBoost Classifier was suggested in [33] that offers secured network, maximum accuracy, higher recall and improved operational efficiency. However, need to investigate an efficient mechanism to address and analyze the challenges. Finally, the VLAN was introduced in [35], that offers effective security execution, best network speed and services, but the VLAN technology were not utilized in the LAN environment. Thus, the challenges have to be taken into account based on attack detection method in IoT in the present work efficiently.

### III. SYSTEM MODEL OF INTRUSION DETECTION ON IOT FRAMEWORK

The IoT plays significant role in the information age, and it is a significant component of the novel information technology. Moreover, the IoT server is the functional core of the entire IoT business scheme. The essential functions of terminal sensor processing, data collection and return the processing outcomes are all designed through the server. Further, the security vital in cyber life as it relies with great advancement of IoT techniques. In addition, the IDS are the protector for the Internet servers. Fig. 1 indicates the circumstances in which the IDS are concerned in the IoT network. Many of the IoT devices and IoT servers are exposed directly to the public Internet due to the feature of remote control. In addition, the attackers would capture the vulnerabilities for intruding the IoT servers. However, the IDS are extremely needed for protecting and detecting the IoT servers from the attackers. The IDS usage would protect the terminal users and also protect the service providers from the hazards on the Internet. The security protections are not fully achieved in the IoT application as it reduces the attack plane. The lowering of the attack plane is limited extremely, and intruders may find the path to crack the assured node in the network. This work seeks the strategy of deep learning concept in the intrusion detection system. Fig. 1 illustrates the IoT framework.

TABLE I. REVIEW ON TRADITIONAL ATTACK DETECTION MODEL IN IOT: FEATURES AND CHALLENGE

Author [citation]	Adopted scheme	Features	Challenges
Li <i>et al.</i> [34]	Mapping UML model	✓ Higher detection efficiency ✓ Fault tolerance ✓ Better accuracy	➤ The data selection sensor technique was not incorporated into the computer environment.
Boubeta, <i>et al.</i> [35]	CEP and ML models	✓ Better precision ✓ Higher recall ✓ Maximum F1 score	➤ More event patterns were not defined in the proposed model for detecting other types of attacks.
Marcos <i>et al.</i> [36]	CNN model	✓ Higher accuracy ✓ Improved precision rate ✓ Maximum recall	➤ Need to maximize the host count in the simulated SDN environment.
Mabodi <i>et al.</i> [37]	MTISS-IoT model	✓ Better FPR ✓ Low FNR ✓ Maximum detection rate	➤ The firefly optimization was not used in the proposed work to lower consumption energy and malicious attacks on the IoT.
Sai <i>et al.</i> [38]	MMFN method	✓ Robustness, ✓ Higher classification accuracy ✓ Strong characterization ability.	➤ The small-scale data-driven DL- AMC model with less training time was needed for training the NN.
Mohammed <i>et al.</i> [39]	IoT-based HAN model	✓ Better accuracy ✓ Reduced false positives ✓ High precision	➤ The proposed work needs to suggest the moving data process close to the network edge
Sahay <i>et al.</i> [40]	XGBoost Classifier	✓ Secured network ✓ Maximum accuracy ✓ Higher recall ✓ Improved operational efficiency	➤ Need to investigate an efficient mechanism to address and analyze the challenges.
Alabady <i>et al.</i> [41]	VLAN	✓ Effective security execution ✓ Best network speed and services	➤ The VLAN technology were not utilized in the LAN environment.

#### IV. OVERALL DESCRIPTION OF THE ADOPTED ATTACK DETECTION MODEL IN IoT

This proposal intends to introduce a novel deep hybrid attack detection system that consists of three phases: “(i) preprocessing (ii) Feature extraction (iii) Classification”. Originally, the input data is preprocessed under data normalization process. Subsequently, the preprocessed data is subjected to the feature extraction stage, where the higher order statistical features and statistical features are extracted. Moreover, the statistical features include mean, median, SD, mode, HM, RMS, peak amplitude and pitch angle; and the higher order statistical features include kurtosis, skewness,

energy, entropy, mean frequency, and percentile are extracted. Moreover, the extracted features are provided as the input to the detection phase with hybrid model that combines the models like CNN and DBN. It is obvious that the detection model must be trained in a proper manner, such that the detection accuracy increases in this way. To make this possible, this work adhere the utilization of optimization logic that could make the training process more optimal. Thereby, the weights of both the CNN and DBN are optimally tuned by a new SAEHO algorithm. This is the proposed hybrid algorithm, which combine the logic of both the EHO and SOA algorithm. Fig. 2 illustrates the architecture of proposed detection system.

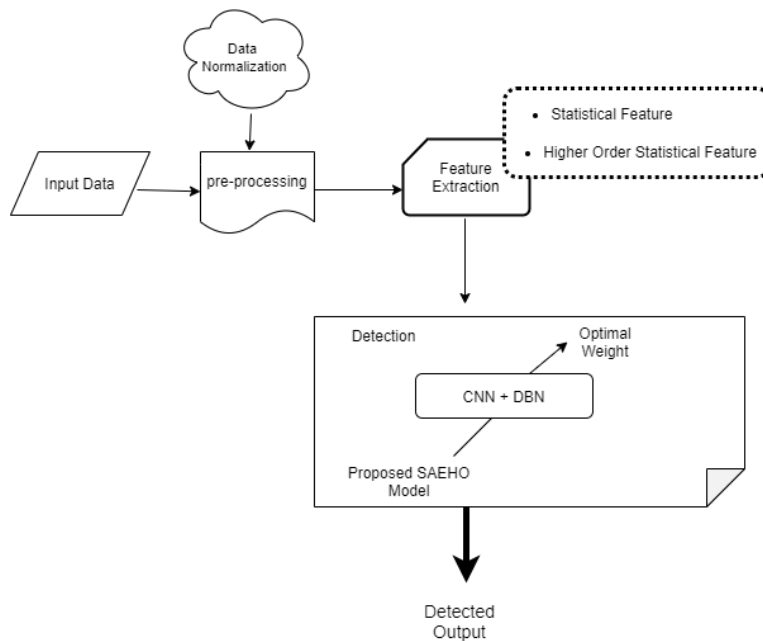

Fig. 2. Overall Framework of the Proposed Model.

## V. ATTACK DETECTION BY PROPOSED HYBRID DEEP LEARNING MODEL

The proposed hybrid model follows the parallel execution of both the models with the extracted feature set, and finally averages the outcomes obtained from each model, which is considered as the final detection results.

### A. Optimized CNN Model

The extracted features  $FE$  are provided as input to optimized CNN [43]. Convolutional Networks are the trainable multistage framework that includes numerous stages. The input and output of every stage are group of arrays recognized as feature maps. In addition, the well-recognized classifier is CNN that consists of 3 layers like “fully connected layer, pooling layer, and convolution layers”. Furthermore, the convolution layer contains of several convolution kernels. The entire feature map was determined by the numerous kernels. Moreover, the  $s^{th}$  layers matched to  $x^{th}$  feature map and feature values in the place  $(e, g)$  is denoted as  $H_{e,g,x}^s$ , and it is given in Eq. (1). Similarly, the  $x^{th}$  filter value is provided in the  $s^{th}$  layer. Consequently, the optimal tuning of the weight is performed using the adopted SAEHO scheme. The linked input patches in the  $x^{th}$  layer at location  $(e, g)$  are determined using  $L_{e,g}^s$ . The non-linearity is attained through the activation function which predicts the nonlinear features of multi-layer networks. Moreover,  $(A_{e,g,x}^s)$  and  $A(\bullet)$  are defined in Eq. (2). Even though, the shift-variance in the pooling layer is deployed through minimizing the resolution of feature maps as given in Eq. (3).  $pool(\ )$  and Local neighbourhood for every feature map  $(A_{e,g,x}^s)$  at  $(e, g)$  is portrayed as  $I_{e,g}$ .

$$H_{e,g,x}^s = W_l^{sT} L_{e,g}^s + B_l^s \quad (1)$$

$$A_{e,g,x}^s = A(H_{e,g,x}^s) \quad (2)$$

$$O_{e,g,x}^s = pool(A_{e,g,x}^s), \forall (\hat{e}, \hat{r}) \in I_{e,g} \quad (3)$$

Eq. (4) determines the loss function in CNN. The constraints  $(\zeta)$  of CNN are associated to the required  $IO$  input-output relation, and it is given as  $\{(V^{(t)}, U^{(t)}); t \in [1, \dots, IO]\}$ .

$$Loss = \frac{1}{Num} \sum_{t=1}^{ms} \hat{P}(\zeta; U^{(t)}, OUT^{(t)}) \quad (4)$$

Pooling layer: “In CNN, the pooling layer has performed the processes of down sampling with the resultant attained from the convolutional layers. Further, the 2 renowned pooling types such as max pooling and average pooling are used. The max pooling has attained the higher value; but the average value is observed in the average pooling”.

Fully connected layer: It works within the flattened inputs. In general, the results attained from the pooling layer are given as the input of fully connected layer and thus the inputs are connected to all layers. In the CNN structure, the fully connected layer occurs at its edges. The output of CNN is denoted as  $CL_{CNN}$ .

### B. DBN based Attack Detection

In 1986, Smolensky implemented DBN [44] with multiple layers, and there is a visible and hidden neuron in each of the layer. The visible neurons are fully interconnected with the

hidden neurons. Naturally, the stochastic neuron’s outcome is probabilistic in the Boltzmann networks. The DBN is fully trained to distinguish the occurrence of attackers within the network grounded on the extracted features. DBN framework is an intellectual model that includes of hidden neurons, visible neurons and layers form output layer. Furthermore, there found connotation exists via hidden and input neurons; yet, no relation in visible neurons, the association rule is not existing among hidden neurons. The link existing among visible and hidden neurons is symmetric and exclusive.

The output of the neurons is probabilistic in the Boltzmann network. The output  $\hat{o}$  is grounded on the probability function  $S(\psi)$  in Eq. (5). The probability function has used the sigmoid-shaped function.

$$\hat{o} = \begin{cases} 1 & \text{with } S(\psi) \\ 0 & \text{with } 1 - S(\psi) \end{cases} \quad (5)$$

$$S(\psi) = \frac{1}{1 + e^{-\frac{\psi}{p}}} \quad (6)$$

Eq. (7) define the DBN model, where,  $p$  signifies the pseudo-temperature.

$$\lim_{p \rightarrow 0^+} S(\psi) = \lim_{p \rightarrow 0^+} \frac{1}{1 + e^{-\frac{\psi}{p}}} = \begin{cases} 0 & \text{for } \psi < 0 \\ \frac{1}{2} & \text{for } \psi = 0 \\ 1 & \text{for } \psi > 0 \end{cases} \quad (7)$$

In DBN architecture, the path of the feature processing is shown by a collection of RBM layers, and the classification procedure shown by MLP. The mathematical model depict Boltzmann machine energy in the method of neuron or binary state as portrayed in Eq. (8) and Eq. (9). Where,  $w_{c,r}$  indicates the weights amid neurons, which is optimally adjusted or tuned by a new proposed SAEHO model and  $\gamma_c$  specifies the biases.

$$F(\hat{b}) = -\sum_{c < r} \hat{b}_c w_{c,r} - \sum_c \gamma_c \hat{b}_c \quad (8)$$

$$\Delta F(\hat{b}_c) = \sum_r \hat{b}_c w_{c,r} + \gamma_c \quad (9)$$

The growth of energy grounded on combined conformation in visible or hidden neurons  $(a, f)$  is described in Eq. (10), Eq. (11) and Eq. (12), where,  $f_c$  and  $a_c$  portrays the binary state of hidden unit  $r$  and  $c$  visible unit.  $X_c$  and  $Y_r$  indicates the biases and  $w_{c,r}$  signifies the weight among them.

$$F(\vec{a}, \vec{f}) = -\sum_{(c,r)} w_{c,r} a_c f_r - \sum_c X_c a_c - \sum_r Y_r f_r \quad (10)$$

$$\Delta F(a_c, \vec{f}) = \sum_r w_{c,r} f_r + X_c \quad (11)$$

$$\Delta F(\vec{a}, f_r) = \sum_c w_{c,r} a_c + Y_r \quad (12)$$

RBM training achieves the resultant weight allocation and the distributed probabilities are stated as in Eq. (13). The probability distribution in RBM method for the visible and hidden vectors pair  $(\vec{a}, \vec{f})$  is given in Eq. (14). The partition function  $Z$  is specified in Eq. (15).

$$\hat{w}_{(c)} = \max_{\hat{w}} \prod_{\vec{a} \in I} D(\vec{a}) \quad (13)$$

$$D(\vec{a}, \vec{f}) = \frac{1}{Z} e^{-F(\vec{a}, \vec{f})} \quad (14)$$

$$Z = \sum_{\vec{a}, \vec{f}} e^{-F(\vec{a}, \vec{f})} \quad (15)$$

DBN scheme utilize the CD learning approach and the output of DBN is denoted as  $CL_{DBN}$ . The final classification output is denoted as  $CL$ , and it is expressed in Eq. (16).

$$CL = \frac{CL_{CNN} + CL_{DBN}}{2} \quad (16)$$

## VI. PROPOSED SEAGULL ADOPTED ELEPHANT HERDING OPTIMIZATION ALGORITHM FOR OPTIMAL TRAINING OF HYBRID MODEL VIA TUNING THE WEIGHTS

### A. Solution Encoding and Fitness Evaluation

The weight of both DBN and CNN are optimally adjusted or tuned via the adopted SAEHO. The input solution subjected to the adopted SAEHO scheme is demonstrated in Fig. 3, where,  $W_1, W_2, \dots, W_N$  shows the weights of CNN,  $w_1, w_2, \dots, w_{mn}$  shows the weights of DBN,  $N$  indicates the total counts of weight in CNN, and  $mn$  denotes the total number of weights in DBN. The fitness objective of adopted detection model is stated in Eq. (17). Here,  $Loss$  indicates the detection error.

$$Obj = Min(Loss) \quad (17)$$

Fig. 3. Solution Encoding.

### B. Proposed SAEHO Model

This paper implements a new hybrid SAEHO scheme which combines the logic of EHO [45] and SOA [46], respectively. While the traditional EHO gives better performance; the disadvantage is that it will not use the required data to identify the present and future searches. The existing SOA model has solved the challenging large-scale constrained issues and hence solve 7 constrained real-life industrial applications; still, the constraints are very tedious and computational complexity. This becomes the issue while solving optimization problems. This makes us to combine the logics of both the algorithm since the Hybrid models are reported to be promising for certain search problems with better convergence speed [23]. Here, the logic of SOA is integrated with EHO, and thereby named as SAEHO.

Naturally, the elephants live in social groups called clans and each clan stay with Matriarch, the female elephant leader. The grown male elephant lives separately from their groups. The elephant population is produced randomly and it splits into a number of clans according to their fitness value. EHO algorithm having three major rules to follows.

- The elephant population consists of number of clans with fixed number of female and male elephants in every clan.
- Some of male elephants live far from the clans individually.
- The elephant lives together with the leader of all clans, matriarch (i.e.,) female elephant in each clan.

1) *Clan updating*: In this operator, each clan updating is done individually. Conventionally, the subsequent position is influenced by matriarch  $h$  and for each elephant in clan  $h$  for the clan updating operators. However, as per the proposed SAEHO method, the SOA updation function is used for clan updation as given in Eq. (18).

$$R_b(\vec{t}) = \hat{B} \times (R_{best}(\vec{t}) - R_l(\vec{t})) + Levy(\zeta) \quad (18)$$

In Eq. (18),  $R_b$  indicates the locations of seagull search agent  $R_l$  towards the best fit search agent  $PR_{best}$  (i.e., fittest seagull),  $R_l$  denotes the search agent's current position,  $\vec{t}$  refers to the current iteration, and the behavior  $\hat{B}$  is randomized used for proper balancing among exploitation and exploration.

Moreover, for the best fit elephant, the updation is achieved by Eq. (19).

$$R_{n,h,k} = \eta \times R_{cen,h} \quad (19)$$

In Eq. (19),  $\eta[0,1]$  is the center of clan  $h$ . The new individual  $R_{n,h,k}$  is expressed from the information obtained by all elephants in clan  $h$ .  $R_{cen,h}$  represent the centre of clan  $h$ , and it is given in Eq. (20).

$$R_{cen,h} = \frac{1}{G_h} \times \sum_{k=1}^{G_h} R_{h,k,\vec{d}} \quad (20)$$

In Eq. (21),  $1 \leq \vec{d} \leq \vec{d}$  denotes the  $\vec{d}^{th}$  dimension and  $\vec{d}$  indicates the total dimensions.  $G_h$  specify the number of elephants in clan  $h$ .  $R_{h,k,\vec{d}}$  refers to the  $\vec{d}$  dimensions of the elephant individual  $R_{h,k}$ .

2) *Separating operator*: The grown male elephants in clan starts live separately. The separating operator is determined after the separating process while solving the optimization problem. As per the proposed SAEHO logic, for enhancing the search ability, the worst fitness of elephant at each generation in the separating operator is defined as per the proposed evaluation given in Eq. (21).

$$R_{worst,h} = R(R_{best} - R_{worst})_{min} \quad (21)$$

Here,  $R_{min}$  indicates the minimum bounds in the positions of single elephant.  $R_{worst,h}$  indicates the worst elephant individuals of clan  $ci$  and  $rand$  value is calculated using Chebyshev chaotic map. The value ranges from 0 to 1.

$$R_{\vec{q}+1} = \cos(\vec{q} \cos^{-1}(R_{\vec{q}})) \quad (22)$$

The pseudo code of adopted approach is given in Algorithm 1.

---

**Algorithm 1: Pseudo code of proposed SAEHO method**

---

**Initialization**

Compute the elephant fitness

**Repeat**

Arrange all the elephants based on its fitness

**Clan updating**

For  $h = 1$  to  $n_{clan}$  do

For  $k = 1$  to  $n_{ci}$  do

If  $R_{h,k} = R_{best,ci}$  then

Clan updation is done by the elephant position using Eq. (20).

Else

Proposed clan updation is done by the seagull position using Eq. (19)

End if

End for  $k$

## VI. CONCLUSION

This paper has introduced a novel deep hybrid attack detection method. The input data subjected for preprocessing phase and data normalization process was carried out. From the preprocessed data, the statistical and higher order statistical features were extracted. Finally, the extracted features were given to hybrid deep learning model for detecting the presence of attack. The proposed hybrid classifier combines the models like DBN and CNN. To make the detection more precise and accurate algorithm named SAEHO proposed which used for tuning the optimal weights. SAEHO combines the logic of EHO and SOA. In the algorithm, two kinds of operator used i.e., clan updating and separating. Clan updating is done by EHO providing it able to find the best position else SOA is used to find the solution. As our next task, the performance of the proposed model will be computed over the present methods in terms of various metrics like FNR, MCC, Rand index, sensitivity, FPR, specificity, FDR, precision, NPV, accuracy, and FMS, correspondingly.

**Abstract**—As nodes often join or leave the network, the communication between the cloud and the MANET remains unreliable in Cloud-Assisted MANET. The event of connection failure in MANET presents several challenges to the network, in particular, the handover issue and high energy consumption during route re-establishment if a connection fails in D2D (device-to-device) communication networks. To address this problem of D2D mobile communication in 5G, we propose a Node Monitoring Agent Based Handover Mechanism (NMABHM). To improve the network's efficiency, we use the K-means algorithm for clustering and cluster head selection in Hybrid MANET and maintain a backup routing table based on a Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS) to quickly recover the route. Additionally, a Node Monitoring Agent (NMA) is introduced to handle the handover issue if a node comes out of range during the communication phase. The NMABHM-based handover mechanism is proposed with group mobility over a cluster-based architecture involving agents. The results of the simulation indicate that, in terms of lower energy consumption and higher throughput, our proposed mechanism is more effective than the current routing mechanisms.

**Keywords**—MANET; clustering; cloud computing; 5G Wireless networks; cloud-assisted MANET

## I. INTRODUCTION

Wireless technology, the most important communication medium for information between different devices, has witnessed rapid growth over the subsequent years. The future wireless technology, i.e. 5G, which is a new global standard of communication, is especially designed for the purpose of forward compatibility and to flexibly support services like mission-critical communication, mobile broadband, IOT, cloud-based services, and D2D communication [1]. With the increasing demand for QoS and the data transfer speed for mobile networks, there is still a requirement for new communication technologies [2,3]. Due to the compatibility features, Cloud Assisted MANET, which is the combination of Cloud and Mobile Ad-Hoc Network, has received a lot of interest from researchers today.

### A. MANET

MANET is one of the most widely used Ad-Hoc wireless networks [4]. Routing in MANET is multi-hop and each node

in the network is a transceiver with bidirectional links. MANET's distinguishing feature, in addition to its unique features and advantages like dynamic topology, mobility, multi-hop, and decentralised administration, is its ease of connection with other networks. With this superiority in communication, MANET has made significant contributions to the growth of the Internet industry [3].

### B. Cloud Computing

Cloud Computing has been observed exponential growth in recent developments and the potential has been developed to limit energy consumption and to enhance the usefulness of mobile nodes in MANET [5]. Cloud storage platforms are used by the three administrative models, like IaaS (Infrastructure as a Service), SaaS (Software as a Service), and PaaS (Platform as a Service), which are delivered to users through Internet-connected systems [6]. In addition to the benefits of Cloud Computing like scalability, affordability, and security, the 5G and D2D connectivity specifications require the use of CA-MANETs, resulting in various research gaps in this area.

### C. CA-MANET

The convergence of MANET and Cloud Computing has become more popular in recent years. MANETs are widely used in emergency situations because they don't adhere to a predetermined topology. When disasters like earthquakes or other natural calamities strike, smart devices in MANET will need to access the data on health care services and other essentials stored on site maps via the Cloud. The requirement for mobile devices in MANET to access cloud services, as well as D2D communication and 5G wireless networks, necessitated the CA-MANET architecture, where multiple devices may be simply connected. CA-MANET unquestionably constructs robust 5G networks [7]. An overlay of peers, i.e. mobile devices and cloud data servers, is formed in CA-MANET, as shown in Fig. 1, when the cloud server joins the MANET [8,9]. The overlay in CA-MANET is self-organizing, i.e. any Peer can join or leave the network anytime. In CA-MANET, Super Peers are the cloud data servers interconnected logically to the Peers. In order to route, search, and send messages, each Peer keeps the information necessary to do so and may be linked to the Super Peer either directly or indirectly. If a Peer and a Super Peer have an indirect link, intermediate Peers operate as routers and help forward the requested services.

\*Corresponding Author.

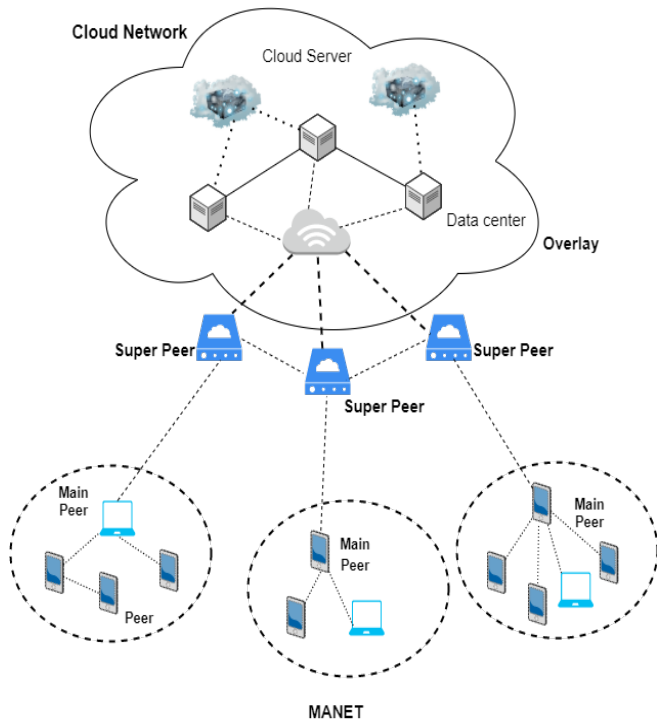

Fig. 1. An Overlay of Data Centers and Cloud Servers with D2D Communication.

The role of cloud servers in the overlay is to provide the required data and services for MANET communication. When MANET requests a particular cloud service, the cloud server performs operations like searching, routing, and updating its database in order to provide future service requests [10]. Due to frequent link breakages in MANET, there is a chance for communication loss between the cloud and MANET. This creates several of the issues like handover, link failures, an increase in overhead and energy consumption in route re-discovery, which indeed effects the cloud servers' service delivery efficiency [11,12]. The cost of processing power and energy consumption grows as network resources are depleted, affecting D2D network performance in 5G networks, which is the main challenge. In addition to that, link failures, effective handover, bandwidth utilization, and route selection are also other challenges to consider. Analyzing the above concerns in detail indicates that energy consumption is the key concern, which is dependent on MANET routing protocols [31]. If energy degradation is handled by selecting the most robust and optimal MANET routing approach, most CA-MANET problems will be solved. For this, we propose a Node Monitoring Agent-Based Handover Mechanism (NMABHM) that focuses on the minimization of energy consumption by effectively handling link failure and service handover.

The significant contributions of the proposed work include:

- Organizing the MANET into Clusters and electing the Cluster Head (CH) based on the K-means algorithm that benefit in bandwidth reusability.

- Introducing a Node Monitoring Agent (NMA) that can perform the ease of handover process without failure by supervising the link failures and node movement.
- Effective Route establishment and maintenance by introducing TOPSIS [13,14] procedure in the AODV algorithm that benefits in maintaining backup route table for selecting optimal alternate paths during link failure.

The rest of the paper is structured in the following manner: Section 2 describes existing works related to minimizing energy consumption in CA-MANET. Section 3 describes the problem description and scenario. Section 4 describes our proposed NMABHM. Section 5 provides performance evaluation and results, followed by Section 6 of Conclusion and Future Work.

## II. LITERATURE SURVEY

Due to the growing popularity and increasing demand of mobile devices in wireless communication, 5G networks have evolved. Because of the limited resources available, 5G network components must be able to efficiently use energy and power [15]. To increase overall network performance, it is necessary to study the energy consumption of network nodes [16]. This can be accomplished by the deployment of intelligent approaches to make optimal routing decisions in communication.

In [17,18] the authors suggested a new protocol with a sophisticated costing function that uses residual battery capacity and hop count as parameters to determine high throughput, low energy and long-lasting data transmission routes on the basis of mobile agent technology. In [19] the authors proposed a new strategy called SBR-Stable Backup Routing, which includes techniques for the design and management of backup routes. The SBR greatly reduces packet loss and increases delivery ratio by overhearing MAC signals and the bit error rate of networks. In order to improve the efficiency of the OLSR routing protocol, the authors in [20] developed a method, termed AIS-OLSR, that uses an artificial immune system. Negative selection and ClonalG algorithms are used to calculate hop count, residual energy in relay nodes, and distance between nodes.

In [21] the authors presented ELBRP, which focuses on the problem of energy-awareness by analysing the nodes' amounts of energy and various forwarding strategies that decrease the energy utilization, optimize the delay, and enhance the network usage. In the survey on mobile device energy usage [22], the authors concentrated on various offloading mechanisms that are responsible for the low battery life of mobile phones due to their unique components. In [23] the authors conducted a detailed assessment of the MANET network challenges and discussed the prospect of resolving them using neural network-based clustering by using a multi-criteria decision of network characteristics, specific cluster algorithm implementations for routing applications. To optimize energy consumption of wireless sensor networks, the authors in [24] suggested an effective cluster head selection approach utilising the K-means algorithm. In this method, the cluster head is identified by

reducing the sum of Euclidean distances amongst the head and its members.

In [8] the authors proposed a novel collaboration paradigm between cloudlets and MANETs, in which the objective is to conserve energy and benefit from green computing by developing DCRM. In [9,18] the authors proposed an overlay architecture, in which a viable energy saving strategy is used to reduce searching and routing activities in cloud data servers.

Due to the high degree of node mobility in MANET, handover happens when a node in communication moves out of the coverage ratio. The functionality of the handover requires a time delay. The difficult part is to identify the appropriate handover and execute it well. In [29] the authors proposed a Vertical handover using MIH/SDN to optimise handover in the future generation of mobile networks. In [25] the authors proposed the IMMH mobility handover strategy for IPv6-based MANETs. In IMMH, a user always communicates with a node via its home address, and both the node's mobility handover and care-of address updating processes eliminate the cost and latency associated with duplicate address detection. In [26] the authors address the handover problem for a fixed path by introducing a cloud-assisted ant colony-based solution termed CAFP. This solution leverages Cloud Computing to significantly reduce the time required for handover, notably during handover judgment.

The energy issue is among the most difficult issues to deal with when using cloud networks and MANETs together. When there is a disconnect between a MANET and the cloud, it might result in a cost issue. Many studies have offered routing options for MANETs that save energy and increase performance. EERR is an energy-efficient and effective routing method that has been developed by the authors in [27] for mobility prediction-based MANET systems. EERR uses location information to determine the best transmission power for delivering packets successfully. In [10,18] the authors

proposed CEPRM method, in which service requests can be directed directly to the destination cloud server by preserving a content map on the Super Peer nodes. It decreases the cost of searching time and so minimises the amount of energy consumed by the cloud server's search operation. To help CA-MANETs recover quickly when a connection fails, the authors in [28] developed an EECRM -Energy Efficient Cloud-Assisted Routing Mechanism. In this mechanism, the Bellman-Ford algorithm is altered with parameters such as residual and total energy of the nodes in the network. Backup nodes discovered via nearby nodes during the route maintenance stage aid quick route restoration by presenting alternate paths that are discovered, which reduces energy exhaustion. According to existing research, it is clear that high energy consumption and connection handover issues in CA-MANET's are still unsolved [30]. Also, most of the currently available techniques, such as CEPRM and EEPRM, are proposed for optimal route recovery and maintenance in the event of a link failure between the Main Peer and the Super Peer. However, none of these approaches took into account the scenario of establishing and maintaining an effective route for the Indirect Peer when it moves out of range during the on-going communication process. This contributes to the motivation for the proposed NMABHM, which successfully establishes a path between the Indirect Peer and the Main Peer, by utilising residual energy and handover procedures effectively.

### III. PROBLEM DESCRIPTION

Fig. 2 describes the problem scenario in CA-MANET that has been considered for the proposed work. Here, Peer A is the Main Peer as it connects directly to the Super Peer S1. The services provided by Super Peer S1 can be accessed by the Indirect Peers via Main Peer A. Now the Indirect Peer C requests service from S1 through A. If the service requested by Peer C is in the cache of S1, then S1 can respond to the service through Main Peer A.

Fig. 2. Link Failure in CA-MANET during Ongoing Communication Process.

Assume that the requested service is in the cache of S1 and the communication is initiated between the Super Peer S1 and the Indirect Peer C through Main Peer A, as shown in Fig. 2(a). During the ongoing communication process between Super Peer S1 and indirect Peer C through Main Peer A and relay Peer B, imagine that Indirect Peer C begins to move away from Main Peer A. As shown in Fig. 2(b), when the indirect Peer C comes out of range from Main Peer A, a link failure occurs, resulting in communication loss between Super Peer S1 and the indirect Peer C. This interrupts the ongoing service communication between Super Peer S1 and Indirect Peer C, as the Indirect Peer C is now out of range from the Main Peer A to access the service. This is due to loss of connectivity and it results in a problem of incomplete service requests. This problem can be resolved by the effective handover of the requested service when the Indirect Peer moves out of range of its service resource.

#### A. Approach

To address this problem, we propose a Node Monitoring Agent-Based Handover Mechanism (NMABHM), in which the main idea is to implement a mechanism that allows the Indirect Peer to have access to the requested service from the cloud, in the case when it moves out of range from the Super Peer. For the proposed work, we follow an approach based on the following assumptions in CA-MANET:

- A Hybrid MANET scenario is implemented using a cluster-based architecture and the Cluster Head (CH) is considered the Main Peer.
- CH maintains a direct link to the Super Peer to communicate with the cloud services.
- CHs are all static in nature.
- Using the CEPRM algorithm, the Super Peers can share service information with one another and with additional Super Peers when they enter an overlay [10].

### IV. PROPOSED MECHANISM

#### A. NMABHM Algorithm

Fig. 3 represents the CA-MANET considered for the proposed work, in which the NAMBHM operates in three phases as follows:

1) *Step 1*: Using a K-means algorithm to group the mobile nodes for reliable and successful data transmission and Optimal Cluster Head Selection by following K-means algorithm based on the Euclidean distance and residual energy.

2) *Step 2*: Implementing a Node Monitoring Agent (NMA) to perform effective handover in the event of a link failure.

3) *Step 3*: Introducing the TOPSIS technique into the AODV algorithm for Effective Route establishment and Maintenance.

Fig. 3. Indirect Peer Movement from Cluster 1 to Cluster 2 during Ongoing Communication Process.

#### B. Clustering and CH Selection using K-Means Algorithm

1) *Clustering*: Clustering is still the most extensively utilised performance optimization technique for MANETs, enabling them to expand to a large number of mobile nodes. In order to perform the clustering in the network, a K-means algorithm is applied to group the mobile nodes, which creates clusters of nodes based on their Euclidean distances from one another [28]. This technique is used to generate clusters, so that the distance between nodes and the CH is as short as possible. For this, we suppose that most nodes have understood their particular location information by using either a GPS unit or a network localization technique.

2) *Cluster head selection*: The CH selection procedure is divided into three steps, which are as follows:

a) *Step 1*: The First step is initial clustering.

The K-means technique is used to form clusters among the nodes within the network [24]. Assume that the n-node network is partitioned into k-clusters. Then, k nodes out of n are chosen at random to be the CHs. Based on the Euclidean distance, each of the available node chooses the CH nearest to it.

b) *Step 2*: The next step is to re-cluster.

The centroid of each cluster with an “s” number of nodes is computed after assigning each node to one of the network’s k-clusters.

$$\text{Centroid}(X, Y) = \left( \frac{1}{s} \sum_{i=1}^s x_i, \frac{1}{s} \sum_{i=1}^s y_i \right) \quad (1)$$

c) *Step 3*: The third step is to choose a Cluster Head.

After generating the clusters, each node is assigned an ID number in the cluster based on its centroid distance, such that the closer nodes receive smallest ID number. A node's ID number determines the sequence in which it shall be elected as the Cluster Head. As a result, the ID number is critical in determining which node is designated as CH.

In each round, the CHs residual energy is verified to maintain the networks connectivity link. If the energy of the CH is less than the predefined threshold, the next order node is chosen as the new CH. The newly elected CH communicates the change in the CH to other nodes. This approach employs a routing mechanism that enables CHs to communicate directly with the Super Peer through a single-hop connection. The Super Peer then processes the collected information.

### C. Node Monitoring Agent based Handover Mechanism

Once the Cluster Heads (CHs) are selected, Node Monitoring Agent Based Handover Mechanism (NMABHM) is incorporated with group mobility over cluster-based architecture involving agents in the CA-MANET for effective handover of service during the link breakage. This mechanism comprises all the correspondent properties for making handover decision. The various properties considered by the NMA are described as follows:

1) *Capacity of cluster*: This property ensures that the number of nodes available in a cluster is always lower than the original capacity of nodes that could be serviced by the CH in the corresponding cluster. Failure of this property results in handover.

2) *Cloud Services*: If the cloud service demanded by the mobile host is the same as that supplied by CH, the Peer must be present in the cluster, otherwise, according to the application specifications, it must scan for another network.

3) *Received signal strength indication (RSSI)*: If the mobile host has same RSSI values from two different CHs it is then important to search the next near-hop and decide which cluster it will have to communicate with.

4) *NMA*: NMA is a handover issue detection agent that supervises various network events and updates the collection of CHs and is ultimately responsible for property-based handover decisions. It is responsible for interacting with CHs and Super Peers with various parameter-based decisions to choose the appropriate policy and providing CHs with suggestions. If anyone of the following properties fails, then handover occurs.

5) *Property 1*: Capacity of cluster

If the nodes count in a cluster is greater than the capacity, then

Set value for the parameter as:

$pr_{var1}$ : No. of nodes to make handover

$pr_{var2}$ : D is distance in terms of hop count to new cluster head.

$pr_{var3}$ : Handover latency ( $H_{lay}$ )

6) *Property 2*: Cloud Services

When looking for specified services on mobile hosts, the parameter values are

$pr_{var1}$ : Offered Service list

$pr_{var2}$ : Offered service plans

$pr_{var3}$ : Security features provided

7) *Property 3*: Next Hop Specification

If two mobile hosts receive same RSSI from two or more different cluster heads, then

Set parameter Value as:

$pr_{var1}$ : Min  $P_{Consumed}$  (MN)

$pr_{var2}$ : RSSI value

$pr_{var3}$ : Weight variable value

To perform these steps, dynamic packets are created. Those packets are known as Request Packets of Handover (RPH). Then handoff is predicted via Handoff Label Packet (HLP) as shown in Table I.

TABLE I. PACKET INFORMATION

Request Packet of Handover (RPH)		
$pr_{var1}$	$pr_{var2}$	$pr_{var3}$
Handoff Label Packet (HLP)		
RSSI value	$H_{lay}$	Min $P_{Consumed}$ (MN)

### D. Optimal Route Selection using TOPSIS Algorithm

In the proposed work, nodes can communicate with each other by using the AODV routing protocol and a backup routing table is maintained based on two parameters such as the hop count and the available energy. In case of an ongoing communication process, when the communicating Indirect Peer moves out of range from the Main Peer (CH), communication loss occurs between the Main Peer and the communicating Indirect Peer which results in a connectivity issue between the Super Peer and the communicating Indirect Peer. Now, to utilize the requested service, the Indirect Peer must be connected to the Main Peer (CH) of that particular region in which the Indirect Peer is present i.e. a route must be established between the Cluster Head and the Indirect Peer.

1) Route establishment and maintenance:

- The node movement information is shared by the NMA with all the Cluster Heads in the CA-MANET.
- On receiving the node movement information, the CH broadcasts the HELLO messages to all of the neighbouring nodes in the cluster.
- The Indirect Peer broadcasts RREQ and route establishment is done between the CH (Main Peer) and the Indirect Peer as shown in Fig. 4.

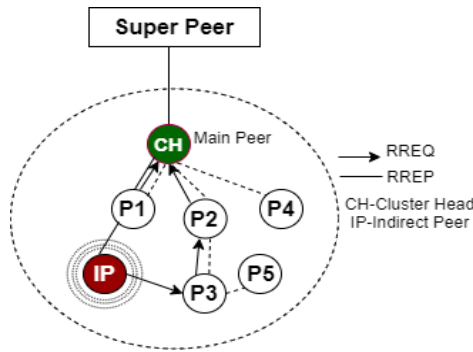

Fig. 4. Route Establishment and Maintenance when Indirect Peer Enters into Another Cluster.

## 2) TOPSIS process:

The following measures include the TOPSIS process:

a) Step 1: To define the Decision Matrix (DM)

$$DM = \begin{matrix} & T_1 & T_2 & \dots & T_n \\ \begin{matrix} AP_1 \\ AP_2 \\ \vdots \\ AP_m \end{matrix} & \begin{bmatrix} t_{11} & t_{12} & \dots & t_{1n} \\ t_{21} & t_{22} & \dots & t_{2n} \\ \vdots & \vdots & \dots & \vdots \\ t_{m1} & t_{m2} & \dots & t_{mn} \end{bmatrix} \end{matrix} \quad (2)$$

In this case,  $i = 1..m$  represents the criterion index,  $m$  represents the number of possible connections, and  $j = 1..n$  represents the alternative index [13,14]. The criteria are  $T_1, T_2, \dots, T_n$ , and the alternate positions are  $AP_1, AP_2, \dots, AP_m$ . The matrix components in alternative  $j$  are linked to the set of parameters  $i$ .

b) Step 2: Create a Normalized Decision Matrix (NDM) that accurately represents the output of design alternatives.

$$NDM = R_{ij} = \frac{x_{ij}}{\sqrt{\sum_{i=1}^m x_{ij}^2}} \quad (3)$$

c) Step 3: Evaluate the weight decision Matrix by considering the random weight as  $W_j$ .

$$V = V_{ij} = W_j \times R_{ij} \quad (4)$$

d) Step 4: Using the weighted decision matrix the Ideal solutions are generated.

$$I^+ = \{v_1^+, v_2^+, v_3^+, \dots, v_n^+\} \quad (5)$$

in which  $V_j^+ = \{(max_i(v_{ij}) \text{ if } j \in J); (min_i v_{ij} \text{ if } j \in J')\}$

$$I^- = \{v_1^-, v_2^-, v_3^-, \dots, v_n^-\} \quad (6)$$

in which  $V_j^- = \{(min_i(v_{ij}) \text{ if } j \in J); (max_i v_{ij} \text{ if } j \in J')\}$

where,  $I^+$  is the Positive Ideal Solution and  $I^-$  is the Negative Ideal Solution [14]. The beneficial attributes are given with  $J$  and non-beneficial attributes with  $J'$ .

e) Step 5: Using the above Ideal solution i.e.,  $I^+$  and  $I^-$ , compute each competitive alternative's separation distance (SD) with the criteria index 'i' and the alternative index 'j'.

$$SD^+ = \sqrt{\sum_{j=1}^n (V_j^+ - V_{ij})^2} \text{ for } i = 1, \dots, m \quad (7)$$

$$SD^- = \sqrt{\sum_{j=1}^n (V_j^- - V_{ij})^2} \text{ for } i = 1, \dots, m \quad (8)$$

f) Step 6: Calculate the optimal solution for all the locations depending on their proximity.

The relative closeness (RC) of each possible position within the optimal solution is determined for each competitive alternative.

$$RC_i = \frac{SD_i^-}{(SD_i^+ + SD_i^-)}, 0 \leq RC_i \leq 1 \quad (9)$$

g) Step 7: Prioritize the alternatives in order of preference.

The greater the value for relative proximity, the better the order of rating, and thus, dependent on the value of  $C_i$ , the greater the alternative output. In descending order, the rating of preference thus makes it possible to equate comparatively better results.

## V. PERFORMANCE EVALUATION

### A. Simulation Setup

To evaluate the simulation findings with other research work, the standard simulation environment for the NS2 simulator has been implemented using this mechanism. Table II presents the simulation parameters considered for the network.

### B. Result and Analysis

By assuring effective handover, the proposed NMABHM addresses the issue of energy consumption in CA-MANETs. For this purpose, the execution process period and energy consumption are chosen as the parameters for performance evaluation. Energy consumption is calculated based on execution time, and a comparison is made between our Node Monitoring Agent-based Handover Mechanism-(NMABHM) and the existing Energy-Efficient Cloud-Assisted Routing Mechanism-(EECRM).

TABLE II. SIMULATION PARAMETERS: NS2 SIMULATOR

Parameter	Value
Area	1000*500
No of nodes	40
Queue Length	50
Protocol	NMABHM (modifying AODV)
Model	Energy Model
Initial Energy	100 J
Topology	Flat Grid
Simulation time	400 sec

The other parameters considered are:

1) *Distance between node measurements in NS2:* A Dynamic topology (coordinates x and y) is created. The distance between the nodes is calculated by applying the coordinates of the node (x, y) in the Pythagorean theorem.

2) *Available energy in NS2:* The level of energy in the network is described by utilizing the energy model. In this energy model, the initial value, called "initial energy," is the energy level that the node has at the starting point of simulation. At any given time, the variable "energy" indicates the amount of energy in a node. The original energy value is passed on as an input argument. For each packet transmission, a node loses a particular amount of energy. As a result, the value of a node's initial energy is reduced and is known as the "Residual Energy". This residual energy is evaluated at different times by accessing the built-in variable "energy" in the find Energy method.

By considering the above parameters, we simulated 40 nodes with a total simulation time of 400 sec with the EECRM and our proposed NMABHM. The results obtained for the metrics are as follows:

a) *Average End-to-End delay:* Fig. 5 depicts the average end-to-end delay in milliseconds (m/s) experienced while transmitting data from mobile nodes to the Main Peer within 400 units of time. For simulation times up to 200 seconds, the EECRM and the NMABHM both produce outputs that are delayed by a similar amount. The delay in EECRM begins to increase after 200 units of time, but our NMABHM achieves respectable results in terms of delay.

Fig. 5. Average End-to-End Delay in 400 Units of Time.

b) *Throughput:* It is defined as the number of successfully received packets in a unit time and is shown in Fig. 6. While the results of both approaches are identical at the beginning of the simulation, our proposed NMABHM strategy achieves a maximum throughput of 180 kbps (approximately) towards the end of the simulation.

c) *Average Energy consumption in NMABHM:* Fig. 7 depicts the average amount of energy spent by the MANET nodes during the communication process during a period of 400 units of time. This energy consumption is measured based

on the Optimal Route Selection using the TOPSIS Algorithm and the shortest Euclidean distance from the Super Peer to the Main Peer. During the simulation, it can be observed that the energy requirements of the existing EECRM approach is high than our suggested NMABHM approach. The energy consumption is reasonable in the midst of the execution, but at the end of the process, NMABHM has demonstrated reasonable energy usage.

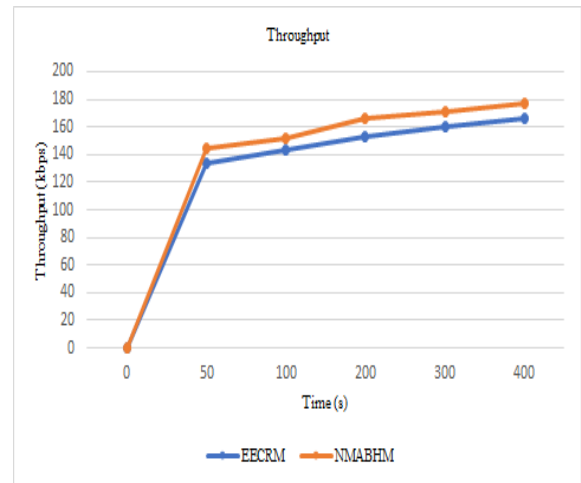

Fig. 6. Throughput in 400 Units of Time.

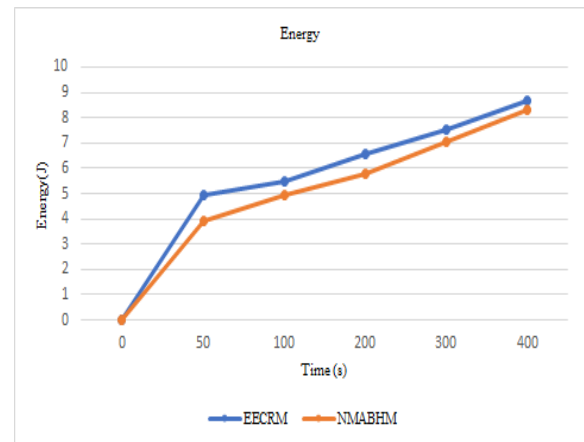

Fig. 7. Average Energy Consumption in 400 Units of Time.

Fig. 8. Routing Overhead (RO) in 400 Units of Time.

d) *Routing Overhead*: The total number of routing packets needed for network communication is "Routing Overhead". Fig. 8 represents the routing overhead caused due to the route failure and route establishment of nodes in MANET. It is clear from the graph that there is a significant variation in the routing overhead results. The packet dropping rate is identical at the beginning of the simulation, but as the simulation progresses, the EECRM causes considerably more packet losses when compared to the NMABHM, resulting in a higher routing overhead when compared to our proposed work.

The experimental results show that the End-to-End delay in our proposed work has shown approximately 25% improvement than the compared EECRM. Also, there is 25-30% of energy gains, the Overhead is improved by approximately 10-15% and the throughput is achieved almost by 80-90%. The experimental results indicate that our suggested work can significantly minimize energy consumption in the event of a network link failure.

## VI. CONCLUSION AND FUTURE WORK

In this work, we proposed a Node Monitoring Agent-based Handover Mechanism (NMABHM) in CA-MANET that helps in reducing the high energy consumption which occurs due to connectivity loss between the Super Peer and Indirect Peer. A Cluster-based CA-MANET architecture is suggested for effective use of bandwidth and energy in the network. We employ a Node Monitoring Agent (NMA) that acts as a Supervising node in the network to indicate the handover issue which can be effectively solved by adapting a multi-attribute decision-making technique called TOPSIS for Optimal route selection in MANET. The Simulation is done using an NS-2 simulator and the experimental results prove that the NMABHM mechanism helps in handling the Handover situation and lowering the energy consumption in the CA-MANET efficiently when compared to the existing EECRM mechanism. Simulations of our proposed work have been done with fewer nodes and with the assumption that cluster heads are static. By considering the cluster head's dynamic nature and scaling the simulation to include a larger number of nodes, we may expect our suggested technique to find many more practical applications in future work.

**Abstract**—Nutrient contents are important for plants. Lack of macronutrients causes plant damage. Several macronutrient deficiencies exhibit similar visual characteristics that are difficult for ordinary farmers to identify. Collaboration between Computer Vision technology and IoT has become a non-destructive method for nutrient monitoring and control, included in the hydroponic system. Computer vision plays a role in processing plant image data based on specific characteristics. However, the analysis of one characteristic cannot represent plant health. In addition, knowing the percentage of macronutrient deficiencies is also needed to support precision agriculture systems. Therefore, we propose a Multi Layer Perceptron architecture that can perform multi-tasks, namely, identification and estimation. In addition, the optimal architecture will also be sought based on the characteristics of the combination of three features in the form of texture, color, and leaf shape. Based on analysis and design, our proposed model has a high potential for identifying and estimating macronutrient deficiency at the same time as well and can be applied to support precision agriculture in Indonesia.

**Keywords**—Multi Layer perceptron; internet of things; feature combination; leaf image; nutrient deficiency

## I. INTRODUCTION

The chili plant is a high economic value of the horticultural plant in Indonesia. However, the production level is lower than the consumption level, with inflation of 0.20% to 0.55% in 2019 [1]. The thing that causes low production is limited land due to the transition of the farming areas to settlements. Another thing is crop failure due to erratic weather changes, pest attacks, and plant diseases[2]. A System that can be applied to limited land in uncertain weather is hydroponics [3].

Hydroponics is a farming system that emphasizes the fulfillment of plant nutrients [4]. A plant needs macro and micronutrients to grow and develop [5]. Macronutrients include N, P, K, Ca, Mg, S (> 1000 mg/kg dry matter) and micronutrients include Iron, Mn, Zn, Cu, Cl, B, and Mo (<100 mg/kg dry matter)[6]. Inappropriate nutrient content causes plants to have macronutrient deficiency. Nutrient deficiency is more easily observed in the leaves [7], [8]. The symptoms in leaves include marginal, interveinal, and uniform chlorosis, distorted edges, reduction in the size of the leaf, necrosis, etc. [9]. However, identifying macronutrient deficiency is difficult for ordinary farmers because several nutrients show similar characteristics [10].

Technology in agriculture is an important part of supporting the application of industry 4.0 in Indonesia [11]. One of its applications is a monitoring and control system in intelligent hydroponics using the Internet of Things (IoT) [12]. One thing that needs to be monitored is the plant's health condition. Computer Vision is one of the technologies that can help the farmer to check the condition of plants [13], [14]. Collaboration between IoT technology and computer vision produces an automatic hydroponic system that can find out the condition of the plant and the solution.

Computer vision technology utilizes image data for analysis. Several images color model have been used, one of them is an RGB image that works like the human eye which is sensitive to the red, green, and blue light bands [15], [16]. Identification of macronutrient deficiencies using RGB leaves images has been carried out. Coffee, tomato, chili, cucumber, etc. have been analyzed using texture and color using K-Nearest Neighbors (KNN), Artificial Neural Network (ANN), Naïve Bayes [17], Multi Layer Perceptron (MLP), and Convolutional Neural Network (CNN) with various architecture [18], [19]. MLP gives a promising result. However, most of these studies only determined the type of nutrient deficiency [20]. To support a precise agricultural system, the percentage of deficiency is important so nutrient solutions accordance with plant needs [21], [22].

The percentage of macronutrient deficiency estimation using plant RGB images has been carried out [16], [23]. Color characteristics in plants have been used as in wheat using Multivariate Linear Regression, Genetic Algorithm, Back Propagation-ANN, and KNN [23], [24]. Texture features have also been developed using the Support Vector Machine (SVM) algorithm[25]. Several studies have also utilized deep learning such as in chili plants using Recurrent Convolution Neural Network (RCNN) [1]. Most of them only use one feature for estimation, so the resulting model is not robust for all types of macronutrients [26]. It because of each macronutrient shows different visual characteristics.

The proposed study is image-processing-based to identify and estimate the percentage of macronutrient deficiencies in a hydroponics environment. There are several phases to determine the lack of macronutrients such as image acquisition, preprocessing, segmentation, feature extraction, identification, and estimation task. The smart hydroponic system is assisted by IoT so that the process of image data acquisition is carried out automatically. Image data is crop

\*Corresponding Author.

data in real conditions so, preprocessing such as histogram equalization is required. Then, the chili plant objects are separated from a complex background using a segmentation technique. One of the challenges faced at the segmentation stage is separating overlapping leaves images. A combination of three features in the form of color, texture, and leaf shape is proposed to support precision agriculture. Careful selection of features must be conducted to obtain accurate models. The main contribution in this paper is identification and estimation in a multi-layer perceptron architecture based on combination features. The study aims to identify and estimates five types of plant conditions such as healthy, potassium deficiency, calcium deficiency, magnesium deficiency, and Sulphur deficiency.

## II. RELATED WORK

The study of macronutrient identification and estimation has been done from destructive to non-destructive methods [5], [16]. The destructive method is tested in the laboratory but it is costly and time-consuming[27]. Then, a monotonous and long duration of work would raise a human error [28]. Therefore, non-destructive is needed.

Internet of Thing is one of the non-destructive methods that have been used [29]. IoT can be used to monitor and control physical phenomena around agricultural environments such as temperature, light intensity, pH, and others [30], [31], [33]. Not only observing, but IoT also helps to determines the health condition of plants based on the image data [38]. However, the visual condition of the plant is not considered, even though the condition of the plant is important. Table I shows visual characteristics of several macronutrient deficiencies. A sensor that can perform visual plant condition is camera sensors that usually used for monitoring the agricultural environment [39].

The camera is useful for capturing plant images in a hydroponic environment [34]. Some of the plants that have been observed are tomato, chili, tobacco, spinach, okra, and others [28], [35], [36]. Digital image processing is used to analyze the captured images to obtain plant conditions. Plant conditions that will be analyzed are the type of macronutrient deficiency and the percentage. These stages are preprocessing and augmentation, segmentation, feature extraction, to identification and estimation tasks [22], [37].

Preprocessing uses to improve image quality[48]. Several preprocessing types are an enhancement, resizing, histogram equalization, and others[7]. Histogram equalization has been used to cope with different exposures on captured images [39], [40]. Then, data augmentation is a process for data enrichment. One example of data augmentation is processing rotation and blurring [41]. The study [42], [43] has proven that image augmentation so that each class has the same amount of data increases the accuracy of the model.

Segmentation is process to separate objects from the background, even a complex background [9], [16]. Several methods have been applied for segmentation, from K-Means Clustering, Genetic Algorithm with DSELM, Otsu, masking

green, Fuzzy C-Means (FCM) method to thresholding [21], [22], [44]. However, thresholding and green masking methods cannot overcome overlapping leaves. FCM is a clustering method that can group data. In [45], it is proven that FCM can overcome overlapping objects.

Feature extraction can be done using several methods based on the information characteristics. Statistical features in the RGB, HSV, and YUV color models represent color information from objects [24], [32]. While some methods, such as GLCM, Sobel, etc., can represent texture and shape information on leaf objects [17]. Feature combination is important because each deficiency shows a different visual features[9]. There is a nutrient that shows color characteristics, and some do not. Therefore, a combination of 3 features such as color, shape, and leaf texture is needed. A combination GLCM, hue, and color histogram has been used to analyze maize plants [46]. Then, a combination of RGB and Sobel edge improves the accuracy [21], [35].

Several methods have been used to identify and estimate macronutrient deficiencies in plants, such as Rule-based method to deep learning in the different models [47], [48]. The rule-based, histogram, and RGB-based method were used to identify leaf deficiency [48], [49]. However, those methods cannot handle data with high variance. Learning methods such as supervised learning have also been used, such as MLP, ANN, KNN, SVM, and others [24], [50], [51]. MLP shows promising results for data in different lighting conditions [52]. It can be concluded that MLP is a method that can be used to process hydroponic data in a natural environment. Each method is only robust on certain macronutrients. It is proven in [26] study using the derivative function method. The first derivative obtains more accurate results for predicting N, P, and S. Nutrient such as Mg, and K in plants uses logarithmic transformation while Ir uses smoothed reflectance. Br and Mn use the first derivative, while Zn uses the second derivative. In addition, CNN with various architectures has been used. However, it is a black box method [2], [8], [53] so it can be challenging to analyze the effect of feature combinations on the resulting model. Table II shows a summary of some of the studies that have been mentioned.

TABLE I. KEY SYMPTOMS OF NUTRIENT DEFICIENCIES [19]

Type of Deficiencies	Characteristics of leaves plant			
	Colour	Shape	Texture	Part of Plant
(-Ca)	Healthy Green	Misshapen	curling leaf tip	Top
(-N)	Turning yellow	Ellipse	Smooth	Bottom
(-Mg)	Necrosis (cell injury), interveinal chlorosis	Ellipse/ Misshapen	Smooth	Bottom
(-K)	Brown in the edge	Misshapen	Curling	Top
Health	Green	Ellipse	Smooth	overall

TABLE II. RESEARCH ON IDENTIFICATION MACRONUTRIENT DEFICIENCY

Plant	Dataset	Preprocessing	Feature Extraction	Classifier	Result	Reference
Paddy	500 images for 5 categories	resize to 256x256 and Median Filter	RGB feature (0-255)	Rule based	improving the database and refining the rules can improve the accuracy.	[54]
Paddy	400 images for 5 categories	RGB to HSV	HSV color model	Rule based	86% of accuracy	[48]
Coffee	269 images for 4 categories	Segmentation using Otsu method	BSM and GLCM to extract Shape and Texture	KNN, Naïve bayes, NN	the best results associated with the GLCM for Iron	[17]
Wheat	360 images	Segmentation using DSELM and GA	Color	a number of DSELMs and committee with GA	single color features and their combinations are not suitable to estimate nitrogen	[22]
Okra Plant	231 images for 4 categories	Resizing image to 299 x 299 and data augmentation using ImageDataGenerator by Keras	Automated FE	Inception ResNet-v2 CNN	the amount of data for several deficiency only produces 2 classes	[35]
Banana	540 images for 4 categories	Data augmentation, RGB convert to YUV, HE, CIELAB, YCbCr and HSV.	Automated FE	Neural Network. VGG16 model.	The model has very high accuracy and minimal error by data augmentation	[42]
Tobacco	204 tobacco leaves for tested	RGB to HSV color space, image thresholding, morphological operation, and crop leaf image	Color analysis	Voting from each patch based on a set of thresholds	The proposed method was able to detect the defect and classify tobacco leaf with 91.667% accuracy	[28]
Eucalyptus	100 leaves	First and second Derivative, Leaf reflectance logarithmic transformation	Color feature	PLSR	each nutrient has high performance in different methods	[26]
Tomato	596 images	596 images of 3024 x 4032 px size were stored in the dataset	a set of convolutional layers as the feature extraction part,	CNN+AHN	CNN+AHN is able to estimate with an accuracy of 95.57% outperforming the literature	[8]
Olive tree	4000 images for 2 categories	RGB to HSV color space, masking	YGB, percentage of RGB value	ML, decision tree and Naïve Bayes models	machine learning model showed the best results with 97% accuracy.	[55]
Multi Plant	484 for training and 13 for testing	There is no pre-processing	Automated FE	CNN	the model only search for colors in the leaf images	[56]
Multi Plant	5000 images of different plants	preprocessing task using SMOTE	CNN is used to extract the patterns of leaf images	the use of an EM classifier to supplement the ELM-based classifier.	proposed modified CNN model obtains improved training and testing classification accuracy than other methods.	[29]
Rice	8911 images for 5 categories	Segmentation using Mean Shift image. Then, RGB image is convert to grayscale for other color model such as YCbCr and HSI	Color using Ybr and HSI value, shape using traditional shape feature such as area, roundness, shape complexity	CNN, Deep learning CNN + SVM, AlexNet, VGG	CNN with image segmentation shows better result than without segmentation. But, CNN +SVM best result.	[57]
Vigna Mungo	4088 images for 7 categories	Flipping and resizing of the image,	taking the advantages of the deep pre-trained model using ResNet50	CNN, SVM, and MLP	MLP achieved superior performance than SVM and logistic regression by the accuracy of 88.33 %.	[14]

Based on some of the literature reviews above, it can be concluded that IoT and Computer Vision-based in smart hydroponic farming can help farmers find outcrop conditions

quickly. In addition, methods for analyzing image data are essential, such as MLP, which can process image data with different lighting. Then, MLP performs the best result with 88,33 accuracy than logistic regression and SVM in [14].

Several features can be used to analyze, such as histogram value, HSV statistic value, texture using GLCM, and others. But, several researches above shows that the types of features analyzed from the image data need to be combined to improve the quality of the model so that the model can be robust across various types of macronutrients.

### III. PROPOSED SYSTEM

This section discusses intelligent hydroponics system workflow and Computer Vision in Hydroponics systems. The discussion of the two parts of this model answers the research question.

#### A. Smart Hydroponics System Workflow

Overall, there are three steps in a hydroponics system such as data acquisition, data analysis, and user area. Fig. 1 presents a schematic of the proposed model. Based on Fig. 1 below, Part A is the data acquisition stage. Part B contains a process to identify and estimate macronutrient deficiency in the plant. Then, part C is an interface that connects farmers with hydroponic systems so plants and agricultural environments can be observed and controlled well. The hydroponic system runs automatically. The detail of each part is discussed below:

- **Data Acquisition:** There are two types of data in the hydroponic system: agricultural environmental and plant conditions data. The environment data includes light intensity, humidity, temperature, and water levels. While plant conditions are plant image data. Each sensor acquires different data. Then via Raspberry Pi, data is sent to the server using Wi-Fi and other protocol.

Image plant data is taken in the morning and afternoon to avoid distraction by lighting conditions. Image data is taken using a camera sensor with a certain distance.

- **Data Analysis:** Data is grouped into a database according to their needs. Plant image is used to test the identification and estimation model that has been built using digital image processing and machine learning. The result is plant condition and their percentages. These results are used as input on the Nutrient Control to give nutrient solutions according to plant needs.
- **Web Development:** Hydroponic runs automatically, but each process can be observed on the web development interface that can be accessed through computers or smartphones. So, users can observe the ongoing process and control the agricultural environment.

#### B. Identification and Estimation Process

Image data are analyzed using digital image processing. Fig. 2 shows a flowchart of identification and estimation of macronutrient deficiency. The stages of digital image processing are divided into five stages. The first stage is preprocessing using histogram equalization and extraction of three types of features. Features are selected and combined with high considerations so that the analyzed features can represent the condition of the plant, then, training to determine the percentage of visual characteristics match. The percentage of visual characteristics becomes the input for the MLP training stage. The output is an appropriate identification and estimation model.

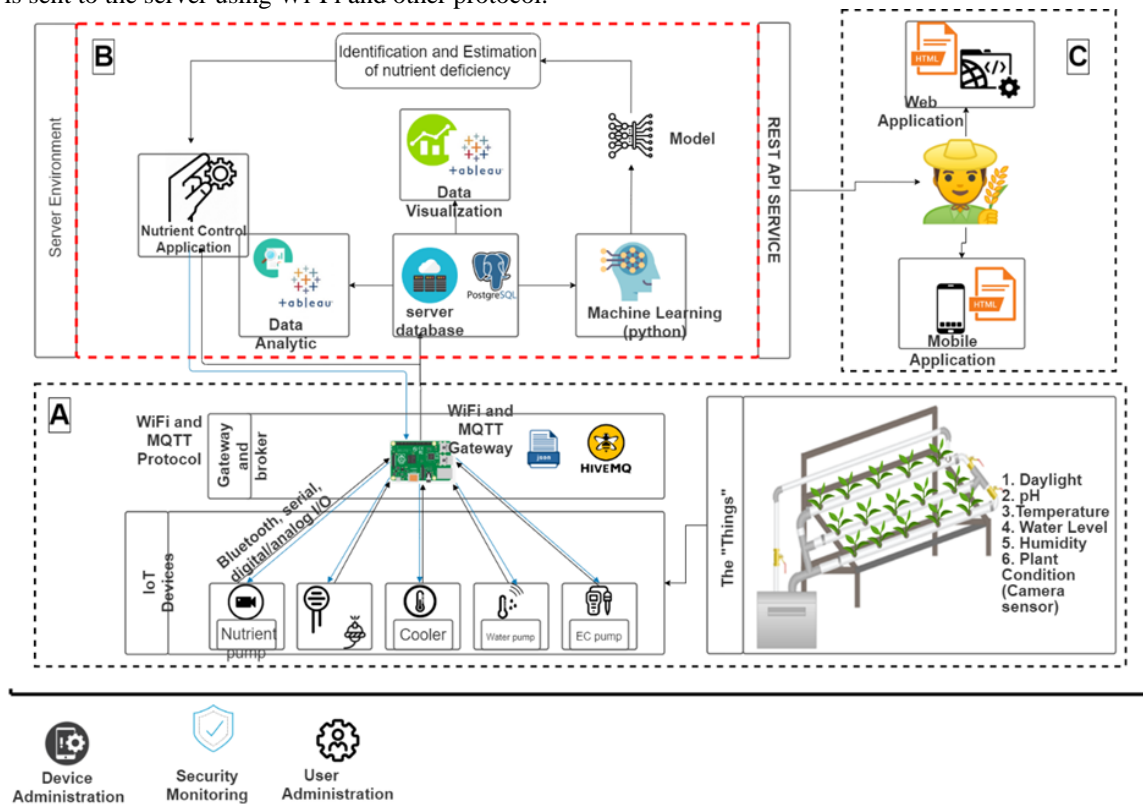

Fig. 1. Smart Hydroponics Design System.

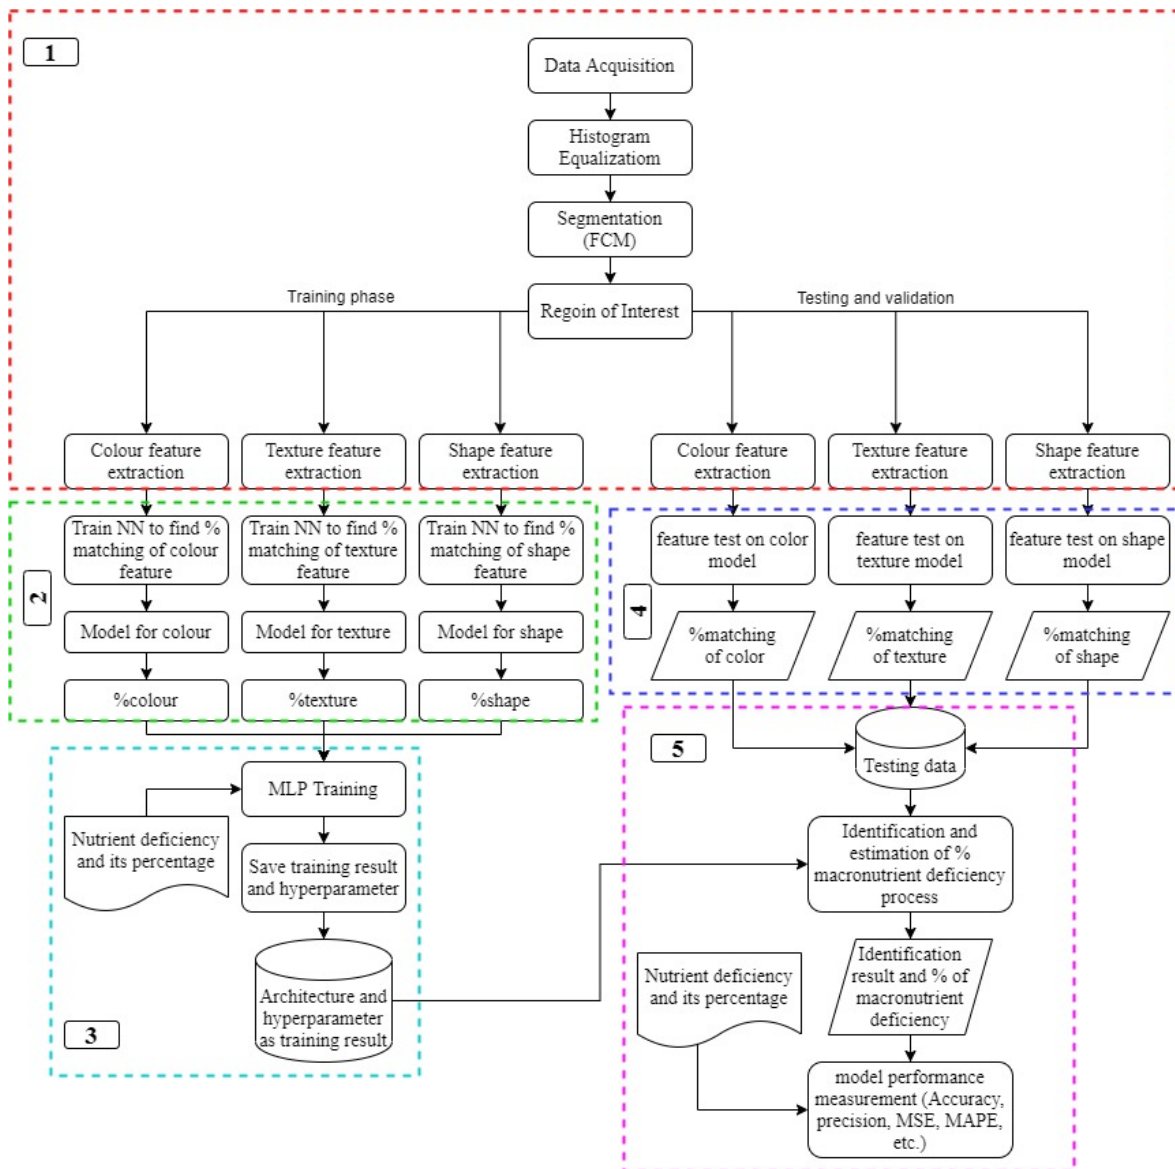

Fig. 2. Identification and Estimation Macronutrient Deficiency Steps.

In this proposed method, there are two types of training data. The first train is to determine the percentage of matches based on visual characteristics. Then, the second train uses the percentage of matching data obtained from the first training for identification and estimation tasks. Our model develops a system that can identify macronutrient deficiencies and estimate the percentage of deficiency at one time. In addition, we are also looking for the suitable MLP architecture based on the combination of three features used, namely color, shape, and leaf texture. The model is evaluated using two different types of evaluators based on their tasks. The last is the resulting model will test in a natural hydroponic system environment that has been build. Each stage is described in detail in the next section.

#### IV. EXPERIMENTAL RESULT AND DISCUSSION

This section discusses the detail process of image processing in hydroponic systems. The camera acquires the

image data in natural environment. Fig. 3 shows some results of image acquisition of chili plants. Healthy plants are given different treatments by reducing certain macronutrients. After 1 week, the plants will show visual characteristics. The planned amount of data taken is 500 for each class. The data includes data with a percentage label of the deficiency.

Fig. 3. Image Plant Data in Real Condition.

1) *Preprocessing and feature extraction*: Each training and testing data are treated the same at this stage. The result of the acquisition is an RGB image with different lighting. Histogram equalization is applied to equalize the different exposures in the image. Where the results of the conversion of RGB to HSV images are transformed into histograms so that they can be normalized using the Cumulative Distribution Function (CDF) as shown in (1) where  $n_{r_j}$  is the histogram value and  $n$  is the total [51]. Then the intensity transformation is carried out from the input image  $r_k$  to  $s_k$  as shown in (2) with a pixel of level  $L$ .

$$cdf(j) = \sum_{j=0}^k \frac{n_{r_j}}{n} \quad (1)$$

$$s_k = T(r_k) = \text{round}(cdf(r_k) \times (L - 1)) \quad (2)$$

The result of Histogram equalization shown on Fig. 4 It will be segmented to separate objects from complex backgrounds using FCM. FCM is a clustering method that can be used for abstract data. In this case, FCM is used to overcome overlapping leaves. The basic idea of FCM is to divide  $n$  pieces of data into non-unique sets to improve cluster data based on membership degrees, where the membership degrees are real numbers in the range [0,1] [52]. To select the leaves that are not overlapping ROI is applied. Segmentation and ROI result are several single leaf images whose leaves do not overlap as shown on Fig. 5.

Feature extraction is performed for each single leaf image. In this study, three features used are: shape, texture, and leaf color. These traits were chosen based on the leaves visual characteristics. Each feature is processed using a different method. Color feature extraction using HSV values, texture feature extraction using Gray Level Co-occurrence Matrix (GLCM), and shape feature extraction using Canny edge detection with Freeman Chain code. The output of color feature extraction is Mean value in (3), Standard deviation in (4), and skewness in (5) for each H, S, and V [48]. Where  $\mu$  is Mean,  $\sigma$  is Standard Deviation,  $M$  is image dimension based  $i$ -th pixel,  $N$  is the total number of  $j$ -th, and  $I_{ij}$  is value of the  $j$ -th pixel of the image at the  $i$ -th color channel.

$$\mu = \frac{1}{MN} \sum_{i=1}^M \sum_{j=1}^N I_{ij} \quad (3)$$

$$\sigma = \sqrt{\frac{1}{MN} \sum_{i=1}^M \sum_{j=1}^N (I_{ij} - \text{Mean})^2} \quad (4)$$

$$\text{Skewness} = \sqrt[3]{\frac{1}{MN} \sum_{i=1}^M \sum_{j=1}^N (I_{ij} - \text{Mean})^3} \quad (5)$$

While the GLCM output is two parameters, such as Angular second moment (ASM) in (6) and Inverse Difference Moment (IDM) in (7) [17]. In shape feature extraction, it is still a chain code. Chain code can be converted into 15 normalized Elliptic Fourier Descriptors based on the Chain code result.

$$\text{Kontras} = \sum_{n=1}^L n^2 \{ \sum_{|i-j|=n} \text{GLCM}(i, j) \} \quad (6)$$

$$\text{IDM} = \sum_{i=1}^L \sum_{j=1}^L \frac{(\text{GLCM}(i, j))^2}{1+(i-j)^2} \quad (7)$$

2) *Training to get matching percentage of visual characteristics*: The results of each feature extraction are trained using NN-Backpropagation to check the matching percentage of characteristics. The output of NN-Backprop is the percentage matching characteristics which grouped into specific types, as shown in Table III. For example, for Nitrogen, The possible matching percentage is shown in Table III. The output of NN-Backprop is input into the MLP architecture, so the type of nutrient deficiency and its percentage are known.

3) *Training to get identification and estimation model using mlp*: The model proposed in this study is an MLP architecture that can perform estimation and identification simultaneously. The model has two output types. They are numerical predictions and class predictions. Fig. 6 shows the proposed MLP architecture.

The type of MLP developed is fully connected. Each neuron is accumulated using a certain activation function where  $W_i$  is the weight of the  $i$ -th data,  $X_i$  is the  $i$ -th data, the value of  $b$  is the bias, and  $y$  is the output. Neuron input consists of nine values of chili plant matching percentage normalized with a range of [0-1]. After normalization, initialized weights and biases are given for each input neuron to the hidden layer with values  $w_{11}, w_{12}, \dots, w_{xx}$ , and  $b_{11}, b_{12}, \dots, b_{xx}$  [19]. The decision layer has three neurons, where two neurons are for identification and one neuron is for estimation. The MLP output representation uses a binary output with the number of classes is  $2^n$  where  $n$  is the number of neurons.

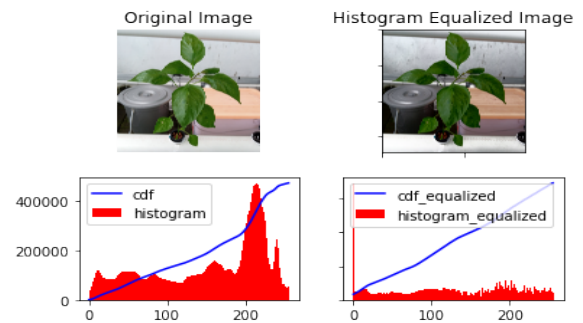

Fig. 4. Histogram Equalization Result.

Fig. 5. Segmentation and ROI Result.

TABLE III. TYPE OF VISUAL CHARACTERISTICS

Colour				Texture			Shape	
Dark green	Yellow	Brown	Green	smooth	wavy	hole	Normal	Mishapen
10%	75%	5%	10%	80%	15%	5%	90%	10%

Fig. 6. Multi Layer Perceptron Architecture Design.

The activation function in the hidden layer is different from the output layer. Each neuron in the hidden layer uses the Rectified Linear Unit (ReLU). ReLU makes a limit on the number zero, if  $x \leq 0$  then  $x = 0$  and if  $x > 0$  then  $x = x$  as shown in (8)[14]. Meanwhile, in the decision layer, two different activation functions are used. A numerical prediction has single node and SoftMax activation function[5]. SoftMax not only maps the outputs to the range [0,1] but also maps each output with the total sum is 1. Therefore, SoftMax's output is suitable for the binary classification problem [0,1] as shown in (9). The Sigmoid activation function as shown in (10) is used for the estimation[58]. The sigmoid output normalized to obtain the percentage of macronutrient deficiency in the range 0%–100%.

$$f(x) = \max(0, x) \quad (8)$$

$$Softmax = \frac{e^{z_i}}{\sum_{j=1}^K e^{z_j}} \quad (9)$$

$$\phi = \frac{1}{1+e^{-y}}, \text{ where } y = (\sum_{i=1}^n W_i X_i + b) \quad (10)$$

In the machine learning method, the loss function is used to optimize the model during training so that the error is minimum. In identification task, the loss function that will be used is Categorical Cross Entropy that can be shown in (11) where  $L_{CE}$  is the loss category entropy,  $T_i$  is the target value and  $S_i$  is the result of the Softmax. A good model has  $L_{CE}$  close to 0. However, estimation task uses Mean Square Error (MSE) [59].

$$L_{CE} = -\sum_{i=1} T_i \log(S_i) \quad (11)$$

The number of hidden layers used affects the learning process. More hidden layers are used, the deeper features are studied. In the proposed model, the exact number of hidden layers and nodes of MLP is sought so that the optimal architecture is produced based on the three features combination. The effect of the number of epochs, learning rate, and others are considered.

4) *Find match percentage of testing data:* The test data that has been through the preprocessing process is searched for the matching percentage of the visual characteristics using

the NN-Backprop model from the previous stage. The expected output is to know each matching percentage of the visual characteristics.

5) *Identification and estimation macronutrient deficiency:* The matching percentage of its characteristics data is tested on the MLP model to know plant condition and its percentage. An evaluation is carried out to find out the model's performance against the test data. The identification task is evaluated using the confusion matrix to get the accuracy and precision based in (12) and (13) [9,14]. The rule of a confusion matrix is shown in Table IV.

TABLE IV. CONFUSION MATRIX REPRESENTATION [60]

		Prediction Class	
		Positive	Negative
Actual Class	Positive	TP	FN
	Negative	FP	TN

While the estimation task is evaluated by calculating the error using Mean Square Error (MSE) and Mean Absolute Percentage Error (MAPE). Predictive result are good if the MAPE value is less than 10% [58]. Meanwhile, for MSE using a gradient-based method, a lower value makes a better prediction. The formula for calculating MAPE and MSE can be observed in (14) and (15) where  $Y_t$  is the actual value of period  $t$ ,  $Y'_t$  is the forecast value of period  $t$ , and  $n$  is the number of periods.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \times 100\% \quad (12)$$

$$Precision = \frac{TP}{TP+FP} \times 100\% \quad (13)$$

$$MSE = \frac{1}{n} (\sum_{i=1}^n (Y_t - Y'_t)^2) \quad (14)$$

$$MAPE = \frac{1}{n} \sum_{t=1}^n \frac{|Y_t - Y'_t|}{Y_t} \quad (15)$$

The intelligent hydroponic system can identify nutrient deficiencies and provide solutions automatically. Based on the analysis and literature study that has been done, the proposed

model potential is to be applied. The MLP architecture performs two different tasks, namely, classification and regression. In addition to developing a multi-task architecture, the number of hidden layers and nodes will find based on the combination of the three features used.

#### V. CONCLUSION

This research is in the stage of data collection and software development. Intelligent hydroponics hardware has been built and is still being evaluated based on system requirements. This proposed model answers research questions about identifying and estimating macronutrient deficiency in intelligent hydroponics systems. First, identification and estimation are faster and more precise so that the provision of plant considers the needs of plants. Second, three features combination such as color, shape, and leaf texture is applied to increase information so that the system can identify the right type of nutrient. Third, build a model that can perform both identification and estimation tasks. Fourth, it analyzes more than one type of nutrients to be applied in the real environment. In the future, this model can be implemented in the natural environment of intelligent hydroponics systems in Indonesia. Limitations still exist because the model is only implemented in chili hydroponics plants.

#### ACKNOWLEDGMENT

This work is funded by the Ministry of Research and Technology of the Republic of Indonesia in the PMDSU program. The authors also gratefully acknowledge the helpful comments and suggestions of the reviewers, which have improved the presentation.

**Abstract**—As a range of daily phenomena, Fake News is quickly becoming a longstanding issue affecting individuals, public and private sectors. This major challenge of the connected and modern world can cause many severe and real damages such as manipulating public opinion, damaging reputations, contributing to the loss in stock market value and representing many risks to the global health. With the fast spreading of online misinformation, checking manually Fake News becomes ineffective solution (not obvious, difficult and takes a long time). The improvement of Deep Learning Networks (DLN) can support with high degree of accuracy and efficiency the classical processes of Fake News spotting. One of the keys improvement strategies are optimizing the Word Embedding Layer (WEL) and finding relevant Fake News predicting features. In this context, and based on six DLN architectures, FastText process as WEL and Inverted Pyramid as News Articles Pattern (IPP), the present paper focuses on the assessment of the first news article feature that is hypothesized as affecting the performances of fake news predicting: News Title. By assessing the impact that the Embedding Vector Size (EVS), Window Size (WS) and Minimum Frequency of Words (MFW) in News Titles corpus can have on DLN, the experiments carried out in this paper showed that the News Title feature and FastText process can have a significant improvement on DLN fake news detection with accuracy rates exceeding 98%.

**Keywords**—Fake news; automatic detection; deep learning; FastText; news title

## I. INTRODUCTION

Nowadays, fake news and sophisticated disinformation can have serious real world negative effects [1]. Often the main objectives of these false information is to intentionally deceive, gain attention, manipulate public opinion or to damage reputations.

During a time of uncertainty or crisis (ex. Covid-19), people are more likely to believe the false rumour they find on web, social media as well as online newspapers if it appeals to their emotions. As shown in Table I, this phenomenon of fake news can fall into different categories and take on different faces.

Deciphering these massive, instantaneous and heterogeneous daily news categories are valid or not becomes a serious challenge. In the era of social media, these false information and hoaxes spread freely, wider and more faster than ever before. These digital platforms enable novel forms

of communication, affect and accelerate the way individuals interpret daily developments.

Recently, in many democratic systems fake news distort and change how the electoral campaigns of candidates and political parties [2]. In the post-election period, significant number of websites and social media publish and share falsified or heavily biased information and stories, which calls into question the legitimacy of the elections.

In business and economics systems fake news and sophisticated disinformation are currently a hot topics. On the world economy, disinformation and hoaxes have direct and greater impacts. As example of consequences, every year fake news contribute to the loss in stock market value and investors can lose money due this problem [3].

In health systems, false information can spread easily and widely than pandemics, and can become accepted as true [4]. False information about virus can do real harm with often dangerous consequences. As examples, misleading information about medical services, medical products, treatments, official sources and guidelines can directly endangering the public health.

To develop the ability to decipher these fake news categories, various techniques and approaches have been developed. These solutions can be classified into two classes of methods (Fig. 1).

The first class is manual. This class is mainly based on comparing real news with unverified news by visiting fact checking sites.

TABLE I. FAKE NEWS CATEGORIES

Fake news categories	
▪	Blatantly false articles
▪	True articles with some false interpretations
▪	Pseudoscientific articles
▪	Opinion articles disguised as news
▪	Satirical articles
▪	Articles comprised of mostly text, tweets and quotes from other people

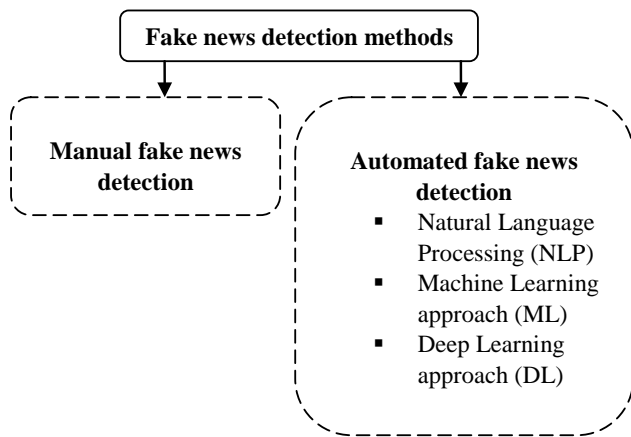

Fig. 1. Fake News Detection Approaches.

The second class is based on automated systems. To detect and predict misinformation, these recent systems exploit many important benefits of Natural Language Processing (NLP) and Artificial Intelligence (AI) [5] such as Machine Learning (ML) algorithms and Deep Learning (DL) networks (Singh et al., 2021)[6].

Recently, the improvement of these automated models can support with high degree of accuracy and efficiency the classical process of Fake News spotting. One of the key improvement strategies is optimizing the main Fake News predicting features and Word Embedding Layer (WEL).

In this context, and based on many DLN architectures and the news articles pattern IPP (Inverted Pyramid Pattern), the present paper focuses on the assessment of the first news feature that is hypothesized as affecting the performances of automatic Fake News spotting: News articles title.

The experiments carried out in this paper assess the impact of this key feature on Fake News DLN predicting performances by using six Deep Learning models: Simple LSTM, Stacked LSTM with two layers, Bidirectional LSTM, Simple GRU, Stacked GRU with two layers and Bidirectional GRU. These DLN models are feed by several rows of real and Fake News titles. Each title is a collection of English language words. To improve the embedding process of this corpus, the FastText process is used as a first embedding layer.

For each used model, the experiments assess the impact that Embedding Vector Size (EVS), Window Size (WS) and Minimum Frequency of Words (MFW) in the used corpus can have on Fake News spotting performances (execution time, loss and accuracy). To illustrate the diagnostic ability of each used model as its discrimination threshold is varied, the Receiver Operating Characteristics Curve (ROC) are plotted and the AUC values (Area Under the ROC Curve) are calculated by testing several values of EVS, WS and MFW.

Compared to many recent relevant studies on automatic fake detection based on the DLN architectures (summarized in paragraph III-B), the main objective of these experiments is to improve the performance of the execution time, loss and accuracy by testing a new embedding process (FastText), and reducing the dimensionality of the used articles news data by assessing the impact of the first news title feature that is

hypothesized as affecting the performances of automatic Fake News spotting.

This paper is organized as follows. Section 2 presents a brief overview of the used deep learning architectures. Section 3 provides a review of recent relevant studies on Fake Detection based on DLN and we summarize our findings. The contribution of this paper is presented in Section 4. This section presents the used architecture, embedding layer, used dataset, summarizes the five main features of the Inverted Pyramid Pattern (IPP), and discuss the impact of news title feature and FastText on fake news spotting performances. Finally, Section 5 presents our conclusions.

## II. FUNDAMENTALS OF THE USED DEEP LEARNING ARCHITECTURES

In Deep Learning, Recurrent Neural Networks (RNN) are a family of Neural Networks [7]. These networks excels in learning by processing sequential data (one input follows another in time). RNN models use the current input and remember the preceding elements. The output at the current time step becomes the input to the next time step (Fig. 2).

Through its effectiveness, this kind of neural network is often used to handle text as news articles, tweets, comments, and have shown an important success in many Natural Language Processing (NLP) projects (Machine Translation, Speech Recognition, Generating Image Descriptions).

The basic architecture of RNN networks is Vanilla RNN (RNN network with single hidden layer). To deal with many limits of this RNN class, researchers have invented more advanced types of RNNs [8] such as Stacked RNNs, Bidirectional RNNs, Deep Bidirectional RNNs, Long Short Term Memory Networks (LSTM) [9], and Gated Recurrent Unit Networks (GRU).

The Stacked (Deep) RNN networks use multiple hidden RNN layers (Fig. 3). This architecture stacks multiple layers on top of each other. Each layer contains multiple cells, processes some part of the project tasks and passes it on to the next layer. The last layer provides the output. This approach (processing pipeline) has many potential benefits: exponentially more efficient to represent some functions and can for example extract more abstract features of news titles. However, these networks suffer from the vanishing gradient problem in the vertical direction.

Fig. 2. Vanilla RNN.

Fig. 3. Stacked RNN.

Bidirectional Recurrent Neural Networks (BRNNs) (Fig. 4) put two independent RNNs together without interacting with one another [10]. The first RNN network feeds the input sequence in normal time order (positive time direction). The second one feeds the input in reverse time order (negative time direction). Therefore, the model receives information from both past and future states. At each time, the output of BRNNs is computed after passing the merged results (by concatenating, adding, multiplying) of the forward and backward layers into the sigmoid function. Applied to fake news spotting process, this approach can improve the model performance and accuracy by obtaining the context in two directions compared to unidirectional RNN.

The Recurrent Neural Networks presented above suffer from vanishing and exploding gradient problems [11]. One of the important approaches to deal with these problems is Long Short Term Memory Networks (LSTM) [12]. To learn, remember and store relevant information for learning, these networks use a memory unit. By using a gating mechanism, LSTM architecture decides to pass the information to the next layer or forget the information it has. Fig. 5 summarizes the basic cell of LSTM network.

Fig. 4. Bidirectional RNN.

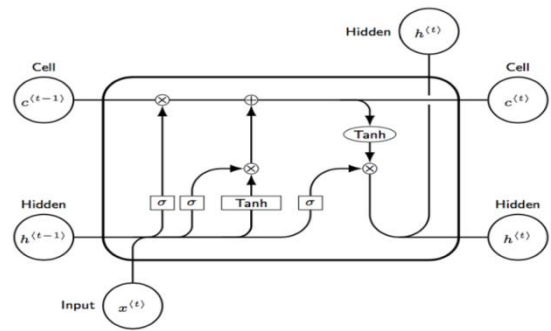

Fig. 5. Basic Cell of LSTM Network.

Each LSTM cell has three inputs ( $h(t-1)$ ,  $c(t-1)$ ,  $x(t)$ ) and two outputs ( $h(t)$ ,  $c(t)$ ).

$x(t)$  : the input at time  $t$ .

$h(t-1)$  : the previous hidden state.

$h(t)$  : the current hidden state.

$c(t-1)$  : the previous cell state (the explicit memory unit).

$c(t)$  : the current cell state.

The forget gate (first sigmoid layer with the inputs  $x(t)$  and  $h(t-1)$ ) selects the amount of information of the previous cell to be included. The input gate (second sigmoid layer with the inputs  $x(t)$  and  $h(t-1)$ ) decides what new information is to be added to the cell. These sigmoid layers determine the information to be stored in the cell state. By calculating the point-wise multiplication of the result of the tanh layer and the result of the input gate (Fig. 5), LSTM cell decides the amount of information to be added to the cell state. To produce  $c(t)$ , the result of this point-wise multiplication is added with the result of the first sigmoid layer multiplied by  $c(t-1)$ . By using a sigmoid and a tanh layer, the LSTM cell calculates the output. The sigmoid layer decides which part of  $c(t)$  will be present in the output. The tanh layer shifts the output in the range of  $[-1,1]$ .

To simplify the internal design and to improve the design complexity, Cho proposed the Gated Recurrent Unit Network (GRU). This variant of the LSTM is based on two gates illustrated in Fig. 6: update gate ( $z$ ) and a reset gate ( $r$ ). To keep around how much previous memory, the GRU cell uses the update gate. To define how much information needs to be forgotten this cell uses the reset gate.

$z$  : update gate

$r$  : reset gate

Instead of the input, forget, and output gates in LSTM cell, GRU architecture uses this gated mechanism to capture dependencies of different time scales effectively, and retains LSTM's resistance to the vanishing gradient problem. The internal structure of GRU needs few computations to make updates to its hidden state.

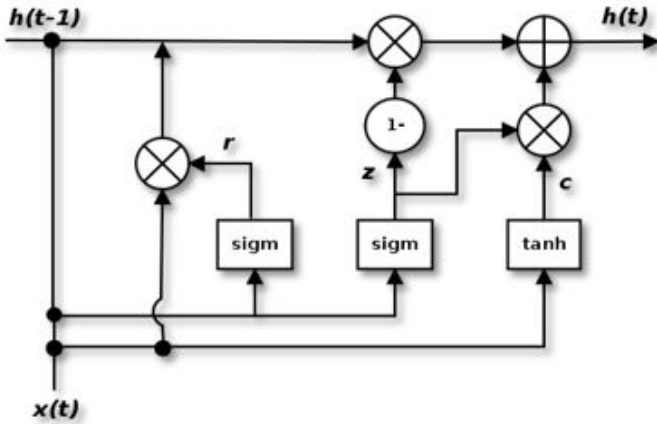

Fig. 6. Basic Cell of GRU Network.

### III. RELATED WORK

#### A. Study Objective

This study investigates the impact of news articles titles on Fake News DLN spotting performances by using six DLN models: Simple LSTM (SI\_LSTM), Stacked LSTM (ST\_LSTM), Bidirectional LSTM (BI\_LSTM), Simple GRU (SI\_GRU), Stacked GRU (ST\_GRU) and Bidirectional GRU (BI\_GRU). To improve vectors representation of news titles corpus, the FastText library is used as first embedding layer.

By feeding these six models by several values of Embedding Vector Size (EVS), Window Size (WS) and Minimum Frequency of a Word in news titles corpus (MFW), an empirical study is performed on how does news titles impact Fake News prediction performances based on DLN.

To check and visualize these performances, the assessment process is based on the time execution, loss and accuracy. To illustrate the diagnostic ability of each used model as its discrimination threshold is varied, the Receiver Operating Characteristics curves (ROC) are plotted [13] and the Area under the ROC Curve values (AUC) are calculated [14].

The ROC curves are plotted with the rate TFNR (True Fake News Rate) on the y-axis against the rate FFNR (False Fake News Rate) on the x-axis. These rates are defined as follows:

$$TFNR = \frac{\text{True Fake News}}{\text{True Fake News} + \text{False Real News}} \quad (1)$$

$$FNR = \frac{\text{False Fake News}}{\text{True Real News} + \text{False Fake News}} \quad (2)$$

#### B. Automatic Fake News Detection based on Deep Neural Networks (DLN)

In the paragraph below, a summary of recent relevant studies on automatic fake detection based on the DLN architectures is provided above.

Recently, detecting fake news and sophisticated disinformation has become an important need and challenge for citizens and governments. This phenomena is turbo-charged by digital technology, and can have significant negative effects on individuals, social, political and economic environments.

Across the world, people need to be well-equipped to separate false information from real information. Using classical solutions (manual processes) to meet this need has many drawbacks. Indeed, with the fast spreading of online information, checking manually Fake News becomes an ineffective approach (not obvious, difficult, takes a long time). Therefore, automated Fake News detection based on Natural Language Processing (NLP), Machine Learning (ML) and Deep Learning (DL) present an efficient, accurate and fast solution to support and improve manual methods [15].

In the era of artificial intelligence, Deep Learning models can be trained through the use of large amounts of real / fake articles news and accomplishing complex news tasks. One of these important tasks is Fake News prediction.

Lastly, Deep Learning architectures such as Recurrent Neural Networks (RNN), Short Term Memory Networks (LSTM) and Gated Recurrent Unit Network (GRU) offer a lot of promise for spotting Fake News. Indeed, various recent research projects have been used these architectures to detect Fake News by taking advantages of these networks.

Among these recent investigations, we can cite the important recent study of S. R. Sahoo and B. B. Gupta [16]. In this investigation, the authors introduce automatic Fake News detection approach in chrome environment on which it can detect Fake News on Facebook. They use multiple features associated with Facebook account with some news content features to analyze the behavior of the account through deep learning. This Fake News detection approach has achieved higher accuracy than the existing state of art techniques.

Other recent important deep learning model is proposed by R. K. Kaliyar et al. [17]. To extract several features at each layer, the authors propose a Deep Convolutional Neural Network (FNDNet) for Fake News detection. The proposed model achieved state-of-the-art results with an accuracy of 98.36% on the test data.

To address the shortcoming caused by Deep Learning model entirely based on Natural Language Processing (NLP), D. S and B. Chitturi [18] propose a new Deep Neural approach to Fake News identification. This system includes a live data stage mining which provides secondary features (source domains of the article, author names, etc.). By exploring LSTM and FF Neural Networks, the authors seek to compare the results from models with and without these secondary mined features.

By using different embedding models for news items of different lengths, M. H. Goldani et al [19] propose the use of capsule neural networks in the fake news detection task. The authors use two recent well-known datasets in the field, namely ISOT and LIAR. They apply different levels of n-grams for feature extraction. The results show encouraging performance.

Based on Bi-directional LSTM-recurrent neural network, Bahad et al. [10] propose a deep leaning model for a fake news detection. This study uses two publicly available unstructured news articles datasets are used to assess the performance of the model. This model shows an important

accuracy over other methods namely CNN, vanilla RNN and unidirectional LSTM.

C. Used Embedding Process

Producing efficiently numerical dense vector (word embedding) is a key process for many news articles processing tasks such as articles news classification, fake news predicting, etc.

The optimized numerical vectors can encode efficiently the semantic information, measure the semantic similarity between two words in news articles, and use these numerical vectors as news articles features [20].

One of the most popular techniques used to create and to learn these vectors is Word2Vec [21]. This model developed by Google supports supervised learning and unsupervised learning. It based on two methods involving simple Neural Networks with one hidden layer: the Skip-Gram model and the Continuous Bag-of-Words model (CBOW). The word vectors are learned via backpropagation and stochastic gradient descent. The Skip-Gram model can use the target word to predict the context. The CBOW method takes the context of each word as the input and tries to predict the word corresponding to the context.

As a modified version (extension) of Word2Vec (Skip-Gram and CBOW) presented above, the FastText process [22] is used as embedding layer in the proposed architecture.

FastText is a library for efficient word embeddings and text classification. This library is developed by the Facebook research team has shown excellent results on many Natural Language Processing (NLP) projects (faster with superior performance).

To improve the used vector representations, FastText process treats each word in news titles corpus as composed of character n-grams (split each word in multiple n parts). It may be bigram, trigram, etc. (Table II). The character n-grams of length n can be generated by sliding a window of n-characters from the start till the end.

By providing Skip-Gram and CBOW models, FastText process computes News words representations. Each word of the used dictionary is represented by the sum of the vector representations of its n-gram. Consequently, and by averaging the vectorized representation of all its constituent n-grams, the embedding process can generate News Titles word vectors for the words that does not appear in the training corpus.

In addition to this last benefit, this used embedding layer is significantly better than the original Word2Vec on syntactic tasks, especially in the case of training corpus with small sizes (case of the present study).

The pooling strategy of FastText can generate a huge number N of unique n-grams. To bind the memory requirements, a hashing process is used. Each character n-gram is hashed to an integer between 1 to H (bucket size). Therefore, FastText learns a total H embeddings instead of learning a total N embedding (Fig. 7).

TABLE II. EXAMPLES OF DIFFERENT LENGTH CHARACTER N-GRAMS

Word	Length(n)	Character n-grams
author	3	<au, aut, uth, tho, hor, or>
author	4	<aut, auth, utho, thor, hor>
author	5	<auth, autho, uthor, thor>
author	6	<autho, author, uthor>

Fig. 7. Hashed Dictionary.

D. Used News Article Pattern

Usually, news articles describe events, persons, occurrences, experiences, places and other topics by following a particular pattern (how information should be prioritised and structured) [23].

One of the most common used patterns is the Inverted Pyramid (IP) which often composed of five important news features (Fig. 8).

News information in the IP pattern is presented in descending order of importance. The first part (feature) is the title (headline). This feature tells what the news is about. The second feature shows who wrote the news (byline). The third feature is the lead (first paragraph). This paragraph summarizes the main and important facts of the news, and based on 5 W's (who, what, when, where, and why) and how. The fourth feature is the body. This part is the core information and details about the news, which supports and amplifies the lead. The fifth feature is the ending which usually gives something to think about.

Often the order of IP pattern allows reading quickly the most crucial information, and estimating an initial manual spotting of Real or Fake News.

Based on IP order of importance, this paper assesses the impact of news title feature (first feature) that is hypothesized as affecting the performances of fake news spotting.

Fig. 8. Used Article News Pattern IP.

E. Used Dataset

The present study uses two Fake and Real News datasets from Kaggle source [24]. This news dataset is based on two 2 files (two lists of news articles): Fake News and True News files. Each file has four features: News Title, News Lead, News Subject and News Date (Table III).

TABLE III. FEATURES OF THE USED DATASET

News title	News lead	News subject	News date
The title of the article	The lead of the article	The subject of the article	The date at which the article was posted

After downloading, these two files are merged into a single dataset. This news dataset is labelled by adding a new feature called News Label. "0" value is assigned to Fake News (FN) and "1" value is assigned to True News (TN).

Fig. 9 summarizes the number of each label value. News Title data are extracted to fed FastText embedding layer and building the used six DLN models.

Fig. 9. Number of used Fake and True News Articles.

The encoded news data are tokenized, created and padded by using TensorFlow [25] and Keras [26] preprocessing tools (Fig. 10).

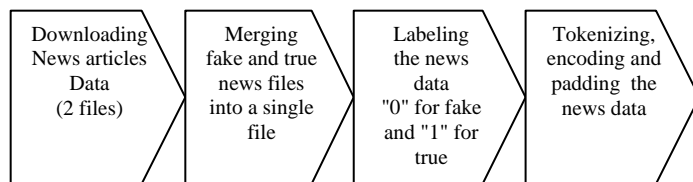

Fig. 10. Articles News Data Pre-Processing Process.

F. Automatic Fake News Detection based on DLN, FastText and News Titles

1) Assessment of execution time performance: Usually fake news predicting projects focus on the accuracy of Deep Learning (DL) or Machine Learning (ML) models that they are using. However, optimizing DLN execution time is one of the important processes that can improve the performances of Fake News detection software. Particularly, when DL model is used as a specific service or part of service installed on personal computers or other devices with limited resources [27]. In this context, the first experiments of this study assess

the time performances of the used embedding layer (FastText process) based on news title feature.

Generally, the duration of the embedding process can be due to the hardware platform architecture (Central Processing Unit (CPU), Graphics Processing Unit (GPU), Random Access Memory (RAM)), internal or external interruptions during the computation and the used libraries if are optimized or not.

The first experiments used the hardware configuration summarized in the following Table IV:

TABLE IV. USED HARDWARE CONFIGURATION

Processor	Intel (R) Core (TM) i7- 4610 M
Processor's speed	CPU@3.00 GHz
Memory size	8.00 Go

The main objective of these first experiments is estimating and assessing the impact that the main parameters of the embedding layer (Embedding Vector size (EVS), Window Size (WS), Minimum Frequency of Words (MFW)) can have on time performance. These experiments start by feeding the embedding layer by several EVS values and setting the used maximum dimension to 140 (≈ half of the maximum length of News Titles). As shown in Fig. 11, the execution time of the embedding layer increases with important rate by increasing EVS values. The average execution time obtained by smaller sizes (less than 40) is relatively small compared to longer embedding vectors (greater than 100). If the embedding size go from 10 to 100, the execution time will double its value.

The second experiment assesses the effect of WS parameter (window of surrounding context words) on the execution time. We fed the embedding layer by several WS sizes on a scale of 1 to 10. As shown in Fig. 12, as WS values increase, the execution time increases. When WS changes from WS =1 to WS = 10, the approximate change in the execution time is around 67 percent (67, 01%). Large values of WS (greater than WS = 5) increase slightly the execution time (≈3 seconds of difference from WS = 6 to WS = 10).

Fig. 11. Variation of the Execution Time Values with Different Embedding Vector Sizes. WS =2, MFW=2.

Fig. 12. Variation of the Execution Time Values with Different Window Sizes. EVS=50, MFW=2.

In contrast with the impact of the parameters EVS and WS discussed above, the execution time of the embedding layer decreases by increasing the MFW values in the used corpus. As shown in Fig. 13, the execution time can be reduced to half ( $\approx 55,96\%$ ) of its initial value when MFW changes from MFW =1 to MFW = 10.

Fig. 13. Variation of the Execution Time Values with Different MFW Values. EVS=50, WS=2.

As a main result of these first experiments, the execution time of the used embedding layer can be improved if the set of parameters (WS, MFW, EVS) is optimized. Consequently,

TABLE V. VARIATION OF LOSS VALUES WITH DIFFERENT DEEP LEARNING MODELS AND EVS VALUES. WS =2, MFW=2

Models	Embedding Vector Size (EVS)				
	10	50	80	100	140
Simple GRU	1,16%	0,62%	0,53%	0,52%	0,49%
Bidirectional GRU	1,12%	0,46%	0,31%	0,27%	0,26%
Stacked GRU	1,11%	0,55%	0,55%	0,55%	0,48%
Simple LSTM	1,09%	0,63%	0,59%	0,55%	0,55%
Stacked LSTM	1,05%	0,57%	0,54%	0,53%	0,51%
Bidirectional LSTM	0,96%	0,44%	0,30%	0,27%	0,25%

this optimized execution time can positively impact the total duration of DLN computation process (embedding layer and DLN models execution times).

2) *The impact of embedding vector size (EVS) on fake news detection performances:* This experiment assesses the effects of FastText process and News title feature on Fake News detection performances by building the used six DLN architectures with less EVS sizes and then more EVS sizes. The used EVS ranges from 10 to 140 (140  $\approx$  half of the maximum length of news titles). As shown in Table V, as EVS values increase, the loss values decrease slightly for all the used six DLN architectures. When EVS changes from EVS =10 (small size) to EVS = 140 (high-dimensionality), the approximate decreases in the loss are around 0.67% for simple GRU, 0.86% for bidirectional GRU, 0.63% for stacked GRU, 0.54% for simple LSTM, 0.54% for stacked LSTM, and 0.71% for bidirectional LSTM. According to the Table VI, the News Title feature has a significant influence on the accuracy for all used detection models. These six architectures can achieve an accuracy that exceeds 98% for small and high values of EVS. The accuracy value increases slightly by increasing EVS. If EVS go from 10 to 140, the approximate increases in accuracy are around 0.83% for simple GRU, 1,06% for bidirectional GRU, 0,76% for stacked GRU, 0,72% for simple LSTM, 0,71% for stacked LSTM, and 0,99% for bidirectional LSTM. Compared to the other used models, the bidirectional LSTM network achieved the best accuracy for all used EVS values.

The ROC curves plotted with different models and EVS values show that News Title feature and the six used architectures provide a high fake news detection accuracy (Fig. 14). These curves show that there is significant improvement in News classification accuracy with lower decision thresholds, in particular with the bidirectional LSTM network. The AUC (Area Under ROC Curve) ranges in value from 0.95 to 0.97 when the used EVS values range from 10 to 140.

As a main result of this experiment, it's possible to achieve better Fake News detection performance by choosing a low Embedding Vector Sizes (EVS).

TABLE VI. VARIATION OF ACCURACY VALUES WITH DIFFERENT DEEP LEARNING MODELS AND EVS VALUES. WS =2, MFW=2

Models	Embedding Vector Size (EVS)				
	10	50	80	100	140
Simple GRU	98,63%	99,30%	99,45%	99,45%	99,46%
Bidirectional GRU	98,68%	99,50%	99,69%	99,74%	99,74%
Simple LSTM	98,68%	99,31%	99,37%	99,40%	99,40%
Stacked GRU	98,74%	99,29%	99,33%	99,42%	99,50%
Stacked LSTM	98,75%	99,38%	99,44%	99,44%	99,46%
Bidirectional LSTM	98,82%	99,61%	99,73%	99,79%	99,81%

Window Size (WS)						
	1	3	5	7	9	10
<b>Bidirectional LSTM</b>	0,35%	0,28%	0,30%	0,31%	0,32%	0,29%
<b>Bidirectional GRU</b>	0,36%	0,29%	0,30%	0,31%	0,34%	0,31%
<b>Simple GRU</b>	0,61%	1,28%	0,84%	0,76%	0,64%	0,30%
<b>Stacked GRU</b>	0,62%	0,64%	0,68%	0,53%	0,65%	0,60%
<b>Simple LSTM</b>	0,62%	0,51%	0,55%	0,50%	0,52%	0,54%
<b>Stacked LSTM</b>	0,64%	0,55%	0,58%	0,51%	0,55%	0,57%

TABLE VIII. VARIATION OF ACCURACY VALUES WITH DIFFERENT DEEP LEARNING MODELS AND WS VALUES. EVS =50, MFW=2

Window Size (WS)						
	1	3	5	7	9	10
<b>Bidirectional LSTM</b>	99,32%	99,65%	99,01%	99,12%	99,27%	99,68%
<b>Bidirectional GRU</b>	99,61%	99,70%	99,69%	99,66%	99,63%	99,68%
<b>Simple GRU</b>	99,32%	99,29%	99,24%	99,41%	99,29%	99,31%
<b>Stacked GRU</b>	99,31%	99,44%	99,40%	99,44%	99,42%	99,41%
<b>Simple LSTM</b>	99,28%	99,39%	99,35%	99,45%	99,40%	99,36%
<b>Stacked LSTM</b>	99,61%	99,73%	99,67%	99,68%	99,67%	99,71%

3) *The impact of window size (WS) on fake news detection performances:* Generally, Window Size (WS) has the impact of giving more importance to closer words. Smaller WS lead to similar interchangeable words. Larger WS lead to similar related words. This experiment assesses the impact of WS by using less WS values and then more WS values. The used WS ranges from WS=1 to WS=10. According to the Table VII, increasing WS values causes a small variance of loss values. When WS changes from WS =1 (small Window Size) to WS = 10 (high Window Size), the difference between the minimum and the maximum of loss values does not exceed 0,07% for Bidirectional LSTM and Bidirectional GRU, 0,15% for simple LSTM, Stacked LSTM / Stacked GRU and 1% for simple GRU.

These architectures achieve high accuracy exceeds 98% for small and high used values of WS. If WS go from 1 to 10, the approximate difference between the minimum and the maximum of accuracy values does not exceed 0,09% for Bidirectional GRU, 0,17% for simple LSTM / simple GRU, 0,13% for Stacked LSTM / Stacked GRU and 0.67% for Bidirectional LSTM (Table VIII). By testing smaller and larger WS values, the ROC curves plotted with different Window Sizes show that news title feature and FastText process provide a high Fake News classification accuracy (Fig. 15).

Fig. 15. ROC Curves with Different Deep Learning Models and WS Values. EVS =50, MFW=2.

Increasing WS values impacts slightly the ROC decision thresholds. Important improvement in Fake News classification is obtained from lower decision thresholds for all the six used models. When WS values range from 1 to 10, AUC ranges in value from 0.96 to 0.97 for LSTM architectures and from 0.96 to 0.98 for GRU architectures. As main result of these experiments, the use of News Title feature with low dimensions of Windows Size (WS between two and three) are enough to capture enough information with to detect Fake News with high performance.

4) *The impact of minimum frequency of a word (MFW) on fake news detection performances:* The hyper-parameter MFW (Minimum Frequency of Word) specifies the minimum frequency of a word in the News Titles corpus for which the word embedding will be generated. This last experiment assesses the impact of MFW by testing less MFW values and then more MFW values. The used MFW ranges from 1 to 9. As shown in the Table IX, the loss value is slightly decreased by increasing the values of MFW. If MFW go from 1 to 9, it decreases by 0,11% for Bidirectional LSTM, 0,16% for Bidirectional GRU, 0,04% for Stacked LSTM, 0,17% for Stacked GRU, 0,09% for Simple LSTM and 0,11% for Simple GRU. The minimum of loss values is observed for high values of MFW (MFW = 5 for simple GRU, MFW = 9 for all other models). The stacked GRU model shows the higher loss value for MFW between 1 and 5.

Compared to the other used models, Bidirectional LSTM and GRU models show the higher accuracy for all used MFW values. The ROC curves plotted with different MFW values show that news title feature used as input of FastText embedding layer provides a high Fake News classification accuracy for smaller and larger MFW values (Fig. 16). Increasing MFW value impacts slightly the ROC decision thresholds. Important improvement in the Fake News classification is obtained from lower decision thresholds for all the used models.

For higher values of MFW (MFW between 7 and 9), this maximum value is obtained by the simple GRU model.

The six used architectures achieve high accuracy exceeds 98% for small and high used values of MFW. According to the Table X, news title feature has a significant influence on the accuracy for all the used MFW values. As MFW values increase, the accuracy values increase slightly for all the used models. When MFW changes from MFW =1 (small frequency) to MFW = 9 (high frequency), the approximate increases in accuracy are around 0.14% for Bidirectional LSTM, 0.17% for Bidirectional GRU, 0.12% for Stacked / simple LSTM, 0.16% for Simple GRU, and 0.25% for Stacked GRU.

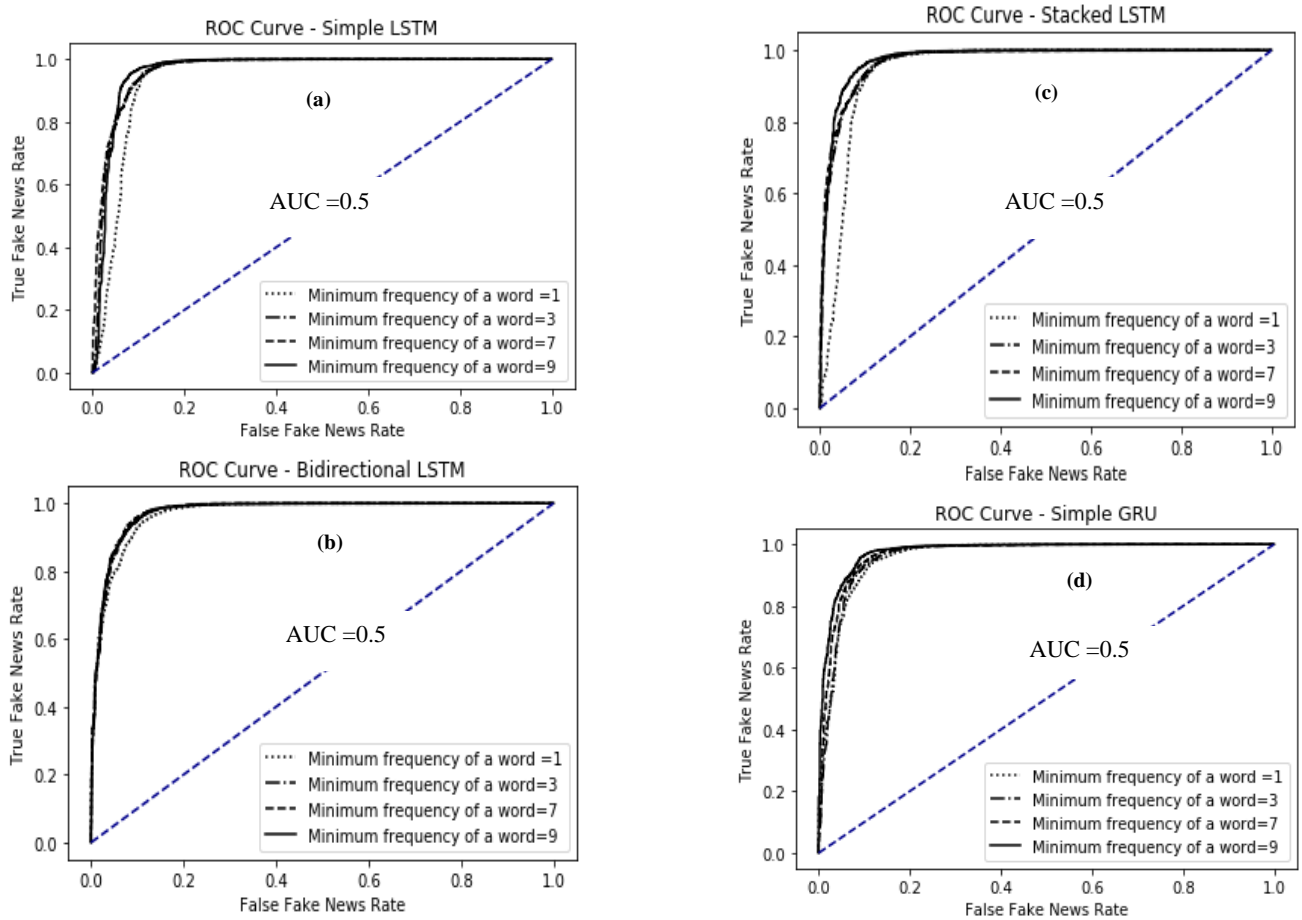

When MFW values range from 1 to 9, the AUC (Area Under the ROC Curve) ranges in value from 0.96 to 0.97 for all used LSTM architectures and from 0.96 to 0.98 for all used GRU architectures. The findings of this last experiment showed that News titles with low size of the minimum frequency of words (MFW) didn't affect significantly the performances of Fake News detection.

TABLE IX. VARIATION OF LOSS VALUES WITH DIFFERENT DEEP LEARNING MODELS AND MFW VALUES. EVS =50, WS=2

Models	Minimum frequency of a word (MFW)				
	1	3	5	7	9
Bidirectional LSTM	0,46%	0,39%	0,39%	0,39%	0,35%
Bidirectional GRU	0,47%	0,44%	0,42%	0,39%	0,31%
Stacked LSTM	0,60%	0,60%	0,58%	0,56%	0,56%
Simple LSTM	0,65%	0,59%	0,58%	0,58%	0,56%
Simple GRU	0,72%	0,66%	0,58%	0,60%	0,61%
Stacked GRU	0,75%	0,67%	0,64%	0,58%	0,58%

TABLE X. VARIATION OF LOSS VALUES WITH DIFFERENT DEEP LEARNING MODELS AND MFW VALUES. EVS =50, WS=2

Models	Minimum frequency of a word (MFW)				
	1	3	5	7	9
Bidirectional LSTM	99,56%	99,62%	99,65%	99,70%	99,70%
Bidirectional GRU	99,51%	99,55%	99,56%	99,59%	99,68%

#### IV. CONCLUSION

Today, Fake news phenomena are one of the world's top global risks. Therefore, social, political and economic environments need to be well-equipped to decipher and detect this massive, instantaneous and heterogeneous daily misinformation.

One of the promising fields of automated systems used to deal with this problem is Artificial Intelligence (AI), especially Deep Learning Networks (DLN).

In this context, the present paper focuses on the improvement of DLN Fake News detection by using Inverted Pyramid Pattern (IPP), and integrating the FastText process in many DLN architectures: Simple LSTM, Stacked LSTM, Bidirectional LSTM, Simple GRU, Stacked GRU and Bidirectional GRU. More precisely, this empirical study focuses on how news title feature and FastText embedding process can impact and improve the existing automatic DLN Fake News detection.

By testing these six architectures with many ranges of embedding layer main hyper-parameters (EVS, WS, MFW), these experiments showed that the news title feature and FastText process can have a significant improvement on DLN

automatic Fake News detection with accuracy rates exceeding 98%.

This paper is the first step of our future Fake News framework project based on many DLN architectures.

#### ACKNOWLEDGMENT

I would like to express my special thanks of gratitude to Khalid AHAJI, Hassan ELHANI, Fouad MOUSSAOUI, Abdelmoutalib MOUSSAOUI who encouraged and helped us in doing a lot of research.

Any attempt at any level can't be satisfactorily completed without the support and guidance of my parents, sisters and friends.

# Determine the Level of Concentration of Students in Real Time from their Facial Expressions

Bouhlal Meriem\*, Habib Benlahmar, Mohamed Amine Naji, Elfilali Sanaa, Kaiss Wijdane

Laboratory of Information Technology and Modeling  
Hassan II University of Casablanca, Faculty of Sciences, Casablanca, Morocco

**Abstract**—In teaching environments, student facial expressions are a clue to the traditional classroom teacher in gauging students' level of concentration in the course. With the rapid development of information technology, e-learning will take off because students can learn anytime, anywhere and anytime they feel comfortable. And this gives the possibility of self-learning. Analyzing student concentration can help improve the learning process. When the student is working alone on a computer in an e-learning environment, this task is particularly challenging to accomplish. Due to the distance between the teacher and the students, face-to-face communication is not possible in an e-learning environment. It is proposed in this article to use transfer learning and data augmentation techniques to determine the concentration level of learners from their facial expressions in real time. We found that expressed emotions correlate with students' concentration, and we designed three distinct levels of concentration (highly concentrated, nominally concentrated, and not at all concentrated).

**Keywords**—*Emotion recognition; level of concentration; transfer learning; data augmentation*

## I. INTRODUCTION

In recent years, E-learning is very popular because this type of learning system uses modern educational technologies to implement an ideal learning environment by integrating information technology into the program.

E-learning is gaining prominence in universities, colleges, and industries by examining its advantages over traditional approaches, as students can access all the data they need for their research. Through webinars, they can access information they might not otherwise be able to access in person due to finances, distances, or time constraints. Depending on the level of understanding of the student, they can study at their own pace, which may increase their satisfaction with the course and reduce their stress levels. It also helps students with special needs or having difficulty getting to school for one reason or another, such as illness or unforeseen accidents.

In traditional classroom teaching, the experienced teacher can know the level of concentration by the students from their behaviors which can be studied by heart rate, pose, gesture, gaze, height of the voice and facial expressions and, accordingly, it can adjust the pace, improve the educational system and provide content. While the online environment separates teachers from students and students from students, there is a lack of face-to-face communication to understand students' emotions and cognitive state.

An effective individualized learning system must therefore be not only intelligent but also emotional. Researchers in neuroscience and psychology have found that emotions are largely related to cognition / concentration. These eLearning system models place particular emphasis on assessing learner emotional states and adjusting teaching strategies.

Among the challenges teachers face is examining how learners acquire course content, as noted in [1]. In order to improve the educational system, it is of paramount importance to ensure student concentration through participation in the learning environment.

Virtual classrooms were introduced as early as the mid-1990s [2]. Deconcentration of students is an issue that is addressed daily.

The way that students are taught is also a factor behind student concentration. Bradbury [3] reported that between 25% and 60% of students became bored in the classroom and lost concentration for a long time [4]. According to Ekman, Friesen, and Ellsworth, [5], facial expression can be the fastest way to understand an individual's emotions. You can use a student's emotional state during their learning period (in the classroom or another setting) to determine if they are paying attention to the content.

To identify students' concentration, other authors suggest using pupil dilation, which occurs when students view images of emotional arousal [6], or the length of time the eyes are closed [1]. Students' facial expressions can be captured by using the embedded webcam in their laptop computers in a typical e-learning environment. The teacher can use this information to determine the level of concentration of the students, and measure how focused they are (or aren't). The teacher can use this information to make the learning environment cost-effective.

The concentration of learners is influenced by several factors. The emotional life of learners has a profound impact on academic success, learning techniques, and academic achievement [7]. If emotions could be recognized as impacts on motivation and concentration, educational outcomes could be improved [8]. Emotion in this context corresponds to the psychological and physiological characteristics of a being, which are individual, efficient, and personal in nature, which relates to habits, manners, thoughts, and sensations [9]. It has been shown that facial muscles move in relation to different emotions, such as happiness, sadness, anger, fear, surprise, and disgust [10].

\*Corresponding Author.

Most facial expression recognition approaches are based on a posed expression database, such as the Japanese Female Facial Expression Database (JAFFE), Cohn-Kanade Database (CK) which are built on six Universal emotions such as happiness, sadness, surprise, anger, disgust and fear due to the lack of database of facial expressions in educational environments.

The proposed system automatically identifies the emotional state of the learner based on facial expressions to know the level of concentration. This helps the teacher to identify slow learners who have difficulty understanding the lesson, therefore the lesson may be changed.

Students' engagement and concentration during learning is a prerequisite for successful learning effects and is positively correlated with students' academic success and development of higher-level abilities (Pascarella, Seifert, & Blauch, 2010). Effective detection of students' learning situations can provide information to instructors so that they can identify struggling students in real time. And this is so that a student's level of concentration and state of learning engagement can help intelligent tutoring systems provide students with individualized learning resources.

The purpose of this article is to examine the concentration level of students in a typical e-learning scenario, by analyzing their facial emotions in real time. In our analysis, we attempt to define how emotions affect concentration level and to devise a concentration index based on this. A facial emotion index is generated in real time by Python and the Keras algorithm, which is derived from the Haar-cascade algorithm and we will compare the transfer learning (a pre-trained convolutional neural network (CNN): VGG16, VGG19, XCEPTION, ALEXNET) models to determine the best performing model for our proposal.

This paper is structured as follows: Section 2 presents a review of related work; Section 3 discusses the methodology adopted for facial emotion recognition. The implementation environment, datasets, as well as the algorithms used, the experiment performed and the results are presented in Section 4. We concluded the paper by summarizing the research performed and providing some remarks in Section 5.

## II. RELATED WORK

Currently available e-learning systems have a flaw: they do not monitor student concentration. Recent years have seen increased interest in finding clues to determine student concentration. Due to the absence of a teacher and the inability to grasp emotions, emotions, etc., are particularly important for students using standalone e-learning systems. According to the study conducted by Du, Tao, and Martinez [11], there are 22 different types of emotions: seven basic emotions and twelve compound emotions. There are forty-six fundamental muscles that form the UA of the face, including those that produce facial expressions. Based on individual UA, the system classifies facial categories by combining each individual UA (Fig. 1). In the case of AU12 and 25, if the system recognizes that the image indicates a "happy" emotion (Table I), the system will classify the image accordingly (Table I).

Bidwell and Fuchs [13] used an automated gaze system to measure student engagement. Classifiers were created based on video recordings of classrooms. A face tracking system was used to track student gaze. After the automated gaze model and observations of a panel of experts were combined, a Hidden Markov Model (HMM) was constructed. HMM incorrectly categorized the data, suggesting eight discrete categories of behaviors, but they were only able to determine whether students were "engaged" or "not engaged".

TABLE I. THE UNITED STATES OBSERVED UAS IN BOTH BASIC AND COMPOUND EMOTION CATEGORIES [12]

Category	AU	Category	AU
Satisfied	12,25	Sadly, disgusted	4,10
Unhappy	4,15	Fearfully angry	4,20,25
Frightful	1,4,20,25	Fearfully surprised	1,2,5,20,25
Annoyed	4,7,24	Fearfully disgusted	1,4,10,20,25
Amazed	1,2,25,26	Angrily disgusted	4,25,26
Disgusted	9,10,17	Disgusted surprised	1,2,5,10
Happily sad	4,6,12,25	Happily fearful	1,2,12,25,26
Happily surprised	1,2,12,25	Angrily disgusted	4,10,17
Happily disgusted	10,12,25	Awed	1,2,5,25
Sadly fearful	1,4,15,25	Appalled	4,9, 10
Sadly angry	4,7,15	Hatred	4,7,10
Sadly surprised	1,4,25,26	-	-

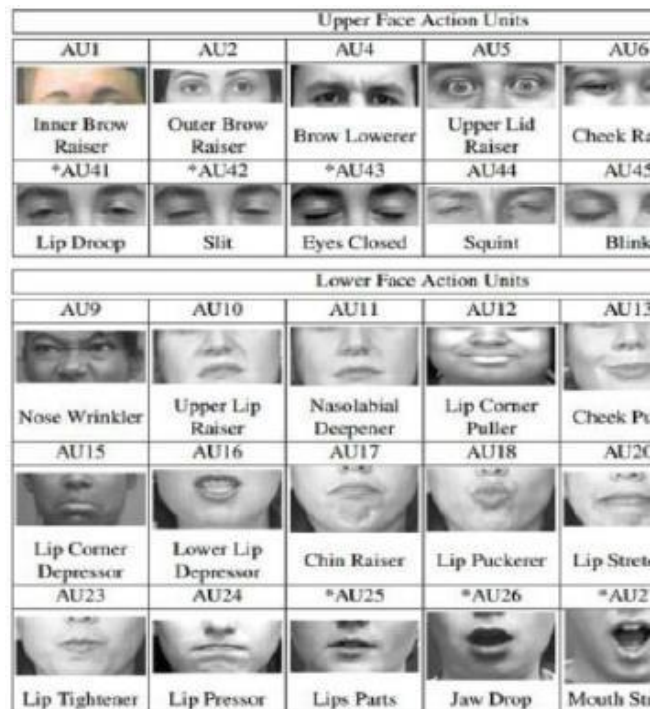

Fig. 1. Different Units of Action for the Upper and Lower Part of the Face [11].

In their paper [14,15], Cha and Kim proposed the use of webcams to measure the duration of attention and a learner's movements. The changes of these facial features were analyzed

in [14]: face up, face down, face turned, eyes closed, eyes open. It is claimed that they "determine the focus and unfocus states for the face and the eye from the coordinates of the extracted characteristic points". The authors fail to explain or define how they achieved this "focused state" or "unfocused state". When the learner's face is in a "front face" position, they conclude they are concentrated. Additionally, they claim that whether a student is "focused" or "non-focused" depends on the data obtained from "the learner's face tilts or turns sideways or their eyes open or close". However, they do not demonstrate a degree of concentration or explain how this analysis is performed. Adding a set of new features to [14], [15], the authors added smiles, surprise, sadness, anger, and closed and open mouths. In the study, "concentration" was defined as "the state of an open eye, open mouth, depressed expression, face turned, and facial expressions of emotion," while "non-concentration" was defined as "the state of a closed eye, open mouth, or dejected expression".

If both the criterion value and the value are above 0.9 milliseconds ", the learner's eyes are closed, indicating that he is not focused. The blinking eye occurs if the value is under 0.9 ms", indicating concentration. Those who do not concentrate will have their eyes closed, their mouth open, their faces turned, or facial expressions of emotion such as smile, surprise, sadness, or anger.

Students' gaze tracking behavior in front of a computer screen is studied by Yi et al. [16]. The resulting learning status is calculated. By assessing this learning status, the quality of the teaching can be evaluated. During the cognitive learning process, the eyes perform three basic actions: scanning, searching, and seclusion. According to them, pupils do not use the information captured by their eyes in a situation of inactivity on a cognitive level. This method, however, only utilizes eye movement information.

Yale and JAFFE [17], Xia Mao and Zheng Li designed an intelligent online learning system to learn about a student's emotional states through facial expression, speech, and text.

Lan Li, Li Cheng, and Kun-xi Qian explored the use of affective computing in facial expression-based e-learning system, and classify learners' emotional states into four categories such as surprise, confusion, frustration and confidence [19].

An analysis and representation of facial dynamics is described in [20]. Using facial expressions, the algorithm calculates the optical flow to determine the direction of movement.

By automatically detecting subtle changes in expressions, [21] is aimed at developing an optical flow-based approach to capturing facial expressions.

Fig. 2 illustrates the comparison of Sanchez et al.'s [22] two FER methods, which are based, respectively, on feature point tracking and dense flow tracking.

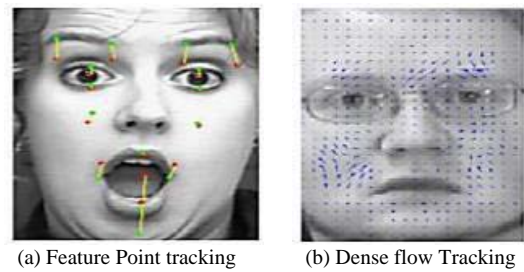

Fig. 2. Applications of Optical Flow based Methods on Facial Images in [22].

When using deep learning for FER, CNN is well suited to detect DU. FACS-based CNN-based FER methods have shown the capacity to generalize both cross-task and cross-data networks associated with FER [23]. Microexpressions are detected by the model in a well-executed manner. By using the CNN of Kim et al. [24], the LSTM is trained to learn the temporal characteristics of a spatial representation through facial expressions. We determine the most representative expressions in facial sequences regardless of the intensity or duration of their expressions as part of network learning. Kritika [25] monitors the position of pupils' eyes and heads, and generates an alert if concentration is low. Videos were analysed and dissected. MATLAB was used to implement and detect faces and Violas-Jones features using different functions. Students can find out whether they are feeling negatively in e-learning environments by using the system. Even though considerable progress has been made in this field of research, emotion and focus still need further exploration. This article attempts to establish an index of student concentration by analyzing facial expressions.

### III. PROPOSED METHOD

In this article, a system is proposed that automatically discovers the learner's state of concentration in real time from facial expressions using a web camera.

From the learner's camera, facial expressions are analyzed to determine the student's state of concentration, but there is no standard database for the teaching environment and most studies are based on databases of posed expressions based on six universal expressions such as happiness, sadness, anger, surprise, neutral and fear. These are not suitable for an online learning environment.

The datasets used in this research were collected from different datasets. Therefore, The Concentration State Ranking System consists of three modules, as shown in Fig. 3:

#### A. Face Detector

This algorithm detects and extracts the student's features quickly and efficiently by using the Haar Cascade algorithm developed by Viola & Jones. In recent years, this method has become one of the most popular methods to accomplish this purpose [26].

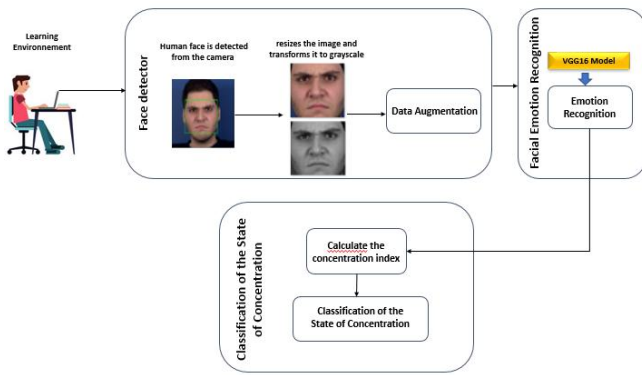

Fig. 3. System Proposed for Determining the Concentration Level of Students in Real Time from their Facial Expressions.

### B. Recognition of Facial Emotions

An alternative model (that is useful for detecting facial expressions) uses transfer learning to identify the dominant emotion represented by a student's face at any given moment. There are six categories of facial expressions based on the emotion expressed: angry, scared, happy, sad, surprised, or neutral. Transfer learning is a machine learning approach that focuses on the ability to apply relevant knowledge from previous learning experiences to a different but related problem. We used a transfer learning approach to create a phrase recognition framework using databases (CK+, fer2013, and JAFEE). We used 4 pre-trained models (VGG16, VGG19, Resnet50, AlexNet, Xception) [27], which are deep convolutional networks designed for object recognition [28] and have shown good results on the ImageNet dataset [29] for object recognition. We replaced the last fully connected layers of our models with a dense layer with six outputs. The number of outputs in the last dense layer corresponds to the number of classes to be recognized. We trained the last dense layer with images from the database using the softmax activation function and the ADAM optimizer [30].

### C. Classification of Concentration

The concentration index (CI) is calculated by multiplying the probability of dominant emotions (DEP) by the corresponding emotion weights (EW) see Table II. Another way to put it is that emotional weight is the measure of how well one's mental state reflects one's concentration at a given time. A value between 0 and 1 is assigned to it.

According to the results, a student's concentration level is classified into one of three categories: highly concentrated, nominally concentrated, and not concentrated.

TABLE II. CLASSIFICATION OF CONCENTRATION

Emotion	EW
neutral	0.9
happy	0.6
surprised	0.5
sad	0.3
fear	0.3
angry	0.25

- Very concentrated: a student falls into this category when the value of his concentration index based on facial emotion is between 50% and 100%.
- Nominally concentrated: a student falls into this category when the value of the Facial emotion concentration index is between 50% and 20%.
- Not at all concentrated: the student's concentration is in this category when the value of the facial emotion concentration index is less than 20%.

Fig. 3 shows an example of a real-time system that provides information data to teachers in real-time. Teachers and e-learning systems use these data to monitor learners in real time as they stream content, so that the teacher can adjust the teaching accordingly, that is, if the concentration level gets too low score, then the teaching material is too difficult for the learners and the difficulty level of the material can be adjusted.

## IV. COLLECTING AND PREPROCESSING DATA

To ensure that the output was not biased in favor of a particular dataset, multiple datasets were gathered.

The following standard facial databases are available online: CK & CK+ [31], FER2013 [32], and JAFEE [33]. There were 29,207 images in the training dataset prior to the increase in data.

- Class 'anger' contains 4160 images,
- Class 'fear' contains 4204 images,
- Class 'happy' contains 7453 images,
- Class 'neutral' contains 4995 images,
- Class 'sadness' contains 4945 images, and the class 'surprise' contains 3450 images.

The validation dataset contained a total of 3,533 images.

- Class 'anger' contains 467 images,
- Class 'fear' contains 496 images,
- Class 'happy' contains 895 images,
- Class 'neutral' contains 607 images,
- Class 'sadness' contains 653 images, and the class 'surprise' contains 415 images.

Examples of model datasets are shown in the following Fig. 5.

### A. Face Detection and Cropping

Detecting the location of faces from images is known as the face detection process, or face registration. The faces from the images were detected using OpenCV Cascade [34]. The face was detected and then cropped to avoid the complexity of the background, thereby improving the efficiency of the model.

### B. Converting to Grayscale

Red, green, and blue channels were added to the images to make them 224 x 224 pixels. By converting the images to

Grayscale with only one channel, we were able to reduce the pixel complexity in the dataset [18] [35]. The training process was streamlined as a result.

### C. Image Augmentation

The amount of data could be increased to improve the model's performance. An image augmentation process produces additional images by performing certain operations on existing image data sets, such as random rotation, zoom, shear, flip, etc. (see Fig. 4).

Fig. 4. Dataset Samples.

Fig. 5. Data Augmentation.

## V. EXPERIMENTAL RESULTS

### A. Comparison between the Models

Using Keras and TensorFlow (<https://keras.io/>) [15], we created a neural network and image processing system using a Python-based neural network API. The program offers many functions and models, which are important for improving the quality of images.

It provides easy-to-use tools for creating custom neural networks, which facilitate rapid experimentation. Google Colaboratory, a free cloud service that supports GPUs, was used to reduce training time.

To train our dataset, we used 100 epochs of 871 steps each. We analyzed the pre-trained models, VGG-16 and VGG-19, Xception, Alexnet.

The VGG 19 model performed excellently with a training accuracy of 90% (show Fig. 8 and Fig. 9) achieved in the 70th epoch, while the VGG16 and Xception (show Fig. 10, Fig 11 and Fig. 12 and Fig 13) model achieved its full 90% accuracy in the 50th epoch. However, the AlexNet (show Fig. 6 and Fig. 7) model was a bit long with a 91% accuracy in the 90th epoch. The accuracy of Alexnet training was 99.8%, but it could have been higher.

From Table III, we can observe that Vgg16 obtains the highest accuracy 100%. Vgg16 and Vgg19 get the most optimal scores in terms of Accuracy and error rate - 100%, 19% and 99.8%, 18%, respectively.

As a conclusion, VGG16 is a powerful deep learning model for facial emotion classification, specifically for CK+, JAFEE, and FER13 images classification. VGG16 produced the highest training and testing accuracy compared to other models. Vgg19, outperforming AlexNet, obtained Xception the second highest accuracy.

### B. Determine the Level of Concentration of Students

The concentration level can be detected by analyzing the result of the seven emotions. The level of concentration can be categorized into three levels: high, medium and low, respectively.

TABLE III. COMPARISON BETWEEN THE MODELS

Model name	Maximum training accuracy	Maximum Validation accuracy
Xception	100%	85%
Vgg16	100%	86%
Vgg19	99.8%	87%
AlexNet	99.8%	64.5%

Fig. 13. Xception Training and Validation Accuracy.

An evolution of the student's concentration based only on facial expressions. For the index of concentration to be calculated, each emotion adds its own value. Based only on facial emotion detection, we calculated the percentage concentration using the following rules shown in Table IV:

Fig. 14 shows an overview of the system operating in real time and presenting information data to the teacher. This data, which includes the learner's facial emotions, and the level of concentration detected (Very concentrated, Nominally concentrated, Not at all concentrated).

TABLE IV. CALCULATE THE LEVEL OF CONCENTRATION

Emotion	CI
neutral	$(DEP * 0.9) * 100$
happy	$(DEP * 0.6) * 100$
suprised	$(DEP * 0.5) * 100$
sad	$(DEP * 0.3) * 100$
fear	$(DEP * 0.3) * 100$
angry	$(DEP * 0.25) * 100$
Not Emotion	0 (i.e., Not at all concentrated)

Fig. 14. General view of the System Operating in Real Time.

## VI. CONCLUSION

Recognizing human emotions is one of the most challenging tasks in e-learning. In this paper, we explored emotion detection to predict students' concentration level. One of the biggest challenges and benefits of distance learning, and especially online learning, is having a system that can determine the concentration levels of students. We experimented with transfer learning models on the dataset we combined (JAFEE + FER2013+CK+) for facial expression recognition to determine the concentration level of students during educational tasks and then estimated their effectiveness. The results show that VGG16 performs better than other proposed models, while the results show that the VGG19 model could also achieve decent accuracy in facial expression recognition. In our research we present an approach to a system for detecting students' concentration level from facial expressions. Only the web camera provides information to the system. We developed a system that produces a concentration index based on the facial expressions captured by the camera. It was designed to work in real time. Three different concentration levels are presented: "highly concentrated", "nominally concentrated", and "no concentration whatsoever". This system can also help teachers to know the learning state of their students, so that the teacher can adapt the teaching material accordingly, i.e. if the concentration level is too low, the teaching material is too difficult for the learners and the difficulty level of the material can be adjusted. Furthermore, the research can be improved by including an analysis of the history of emotions detected over a given period of time in

order to establish a predictive model of when students are likely to drop out or fail in a subject.

# Medical Image Cryptanalysis using Adaptive, Lightweight Neural Network based Algorithm for IoT based Secured Cloud Storage

M V Narayana, Ch Subba Lakshmi, Rishi Sayal  
Guru Nanak Institutions Technical Campus  
Hyderabad, India

**Abstract**—Currently available modern medical system generates large amounts of data, such as computerized patient data and digital medical pictures, which must be kept securely for future reference. Existing storage technologies are not capable of storing large amounts of data efficiently. It is a key and abrogating topic of specialized, social, and medical significance and a key and abrogating subject of general interest. The results of cars, purchasers, and Internet of Things industry-based and essential segments, sensors, and other daily objects are fused with a network of the Internet and solid information abilities that promise to alter the way we operate and live future. The suggested work demonstrates a symmetric-key lightweight technique for secure data transmission of images and text, which uses an image encryption system and a reversible data hiding system to demonstrate the program's implementation. On the other hand, cloud storage services can meet demand due to features such as flexibility and availability. Cloud computing is enabled by amazing internet innovation as well as cutting-edge electrical equipment. Even though medical images may be stored on the cloud, most cloud service providers only save client data in plain text. As part of their overall strategy, cloud users must take responsibility for protecting medical data. Because attackers' increasing computing power and creativity are opening up more and more areas in this mathematical form, most existing image encryption schemes are vulnerable to the plaintext attack of choice. This article presents an image encryption method inspired by an Adaptive IoT-based Hopfield Neural Network (AIHNN) that can resist other assaults while optimizing and improving the system through continuous learning and updating.

**Keywords**—Cloud storage; IoT; medical image; neural network

## I. INTRODUCTION

There have been enormous improvements in Information Technology (IT) and analytics during the last several years. Cloud computing is one kind of technology that many businesses use for the hosting of their apps and data storage. Modern gadgets, which allow for digitalized data exchange, have established a new standard for transmitting information globally, regardless of the application. The information is shared with the public. There is a concern about the level of privacy and security that should be provided for people and confidential material [14]. Information sharing across different companies, particularly medical imaging system users, has increased in recent years, resulting in novel storage methods such as cloud edge [1]. Many online services, such as e-

commerce, telemedicine, electronic payment access, and social networking sites are hosted on the cloud.

Storage as a Service (SAS) is by far the most frequently demanded service according to most Internet of Things (IoT) devices [2], and computing has reached a pinnacle in recent years. Data security in cloud storage is a joint responsibility of customers and service providers. Thus, issues related to medical data privacy, in particular, must be successfully handled via the use of suitable cryptographic standards. It is essential for patient safety to be able to offer information security for a medical image stored in a public and shared system such as the cloud. According to the cloud data security debate, cloud service providers are focusing on security measures for cloud infrastructure, hosts, and data. User data, on the other hand, is only accessible as plain text up to a certain point in time.

To address this issue, it is suggested that data be encrypted and stored utilizing encryption methods. The authors proposed a fully homomorphic encryption (FHE) technique to encrypt photos in cloud storage in order to guarantee image security, even for small-scale images, while the complexity increased even for small-scale images [13]. There are many encryption methods available, and they may be used to encode the text, images, and audio. Despite this, the security measure used for text transmission less performs when used for image transmission due to the intrinsic characteristics of images, including such mass data capacity, also has and strong association among the pixel data; as a result, a separate security system is presented by each type of multimedia data protection. Image security becomes more critical due to the difficulties in managing pictures as contrasted to text documents. As a bonus, pictures are used to convey the context of the majority of critical applications such as telemedicine and education and biometric verification and identification. Chaos-based picture encryption methods [9] have gained popularity due to their increased vital strength, which is achieved via key sensitivity. That perhaps the key has an actual value is the reason for the importance of the turmoil. According to chaos theory, the nature of chaos is entirely dependent on the original seeds.

According to cryptanalysts, chaos-based cryptographic protocols, on the other hand, are not resistant to the chosen plaintext attack. On the other hand, most contemporary cryptographic methods are susceptible to cryptanalysis, in which the attackers undermine the cryptosystem by using

known-plaintext and chosen-plaintext assaulting strategies. The reverse exclusive-OR procedure has been integrated into picture encryption because of its advantages, including reversibility and the ability to cause bitwise confusion. It is also possible to construct a stream cipher using this method. It does, however, allow for cryptanalysis via the use of a specific plaintext attack. In this paper, the homomorphic encryption method is discussed as superior encryption technology, emphasizing cloud data security. On the other hand, the homomorphic encryption method is susceptible to cryptanalysis, wherein security keys may be recovered with less than 8s [19].

According to the initial study, most current schemes are vulnerable to plaintext attacks because of their daily use of simple XOR-based propagation and continuous operation rounds. The number of activities may enhance the complexity, but the change in processing time is unneeded, resulting in a low throughput rate. The encryption method must be complicated to avoid cryptanalysis, particularly the selected plaintext attack, and that it is irreversible, self-adaptive, and parameter aware. As previously stated, neural-based encryption methods are the preferred option for meeting the criteria. An artificial neural network (ANN) is a set of predictive classification networks capable of performing multiple classifications and optimization operations in parallel while still including essential components known as neurons. Because of the self-learning and adaptable character of ANN, it may be used in conjunction with traditional methods to provide correct results. Furthermore, ANN may learn about its environment by using real-time and training data. As a consequence, neural networks are being used in a variety of applications, including data protection, predictive analytics, medical data classification, and civil structure analysis [6][7], with data security being the focus of this study.

#### A. Artificial Neural Networks and Cloud Computing

Artificial neurons should have been able to replicate the activity of actual neurons, according to the basic principle. As a result, it is characterized by erratic behavior. Because of the security concerns, cryptography applications [12] are attracted to the chaotic activity of neurons. According to the research, the ANN model may be expanded to describe complex reversible encoders as well. ANN may also be used in combination with a non-traditional image encryption technique. The ANN may be thought of as a nonlinear encoder that might replace the traditional diffusion method. Random indexes, in addition to dispersion, are needed to achieve the appropriate degree of confusion. To produce random indices, the neural network must also show recurrent activity, which is inevitable in the generation of pseudo-random sequences for picture encryption applications.

As a result, the recurring as a major component of this paper's proposed neural blended adaptive image encryption system, an adaptive IoT-based Hopfield neural network (ANN) is presented (NBAIE). The Adaptive IoT-based Hopfield neural network is an influence exerted based on human brain features [3]. It is a one-of-a-kind neural network model that is based on human mind features. It has a time-dependent behavior. In many respects, it varies from previous neural architectures. Other neural networks are ideally suited for

classification and grouping tasks and other activities since they are made up of distinct hidden units that process the inputs.

In contrast, recurrent AIHNN contains hidden units that are linked. Time-dependent behavior is achieved by activating one of the hidden units at a certain point in time. It is helpful in applications dependent on the sequence of consecutive occurrences, like pseudo-random sequence generation, where the sequence of succeeding occurrences is essential. The following are the key differentiators of the algorithm suggested:

Because of its BPN's multi-layered architectural design and nonlinear activation device weight matrix, predicting the key is reduced.

Because distinguishing features of the image are used as input for the BPN, and the generated keys are much more highly adaptable to the input plain image than the primary image itself.

- Keys' behavior may be varied due to BPN's ability to self-learn.
- Because of its recurrent and chaotic behavior, AIHNN necessitates the use of crucial seeds which are similar to chaos, which is favourable to linear neural architectures including such BAM and BPN because the preliminary essential seed is larger in scale (size is much larger than basic image), reducing communication rate [20].
- Establishing a link between the authorized user and the public cloud computing environment Each image has its own key. As a consequence, unauthorized people will not be able to attack the image and key using a specific plaintext attack.
- Image specific pseudo-sequence creation, followed by dynamic ambiguity and diffusion, to achieve the desired effect.
- Medical picture repositories on the cloud may now have enhanced privacy protection.
- The weight matrix of the AIHNN may be modified for each picture, resulting in the creation of image-specific pseudo sequences using the algorithm.

As a result, the algorithm's prediction becomes more complicated due to the use of an Adaptive IoT-based Hopfield neural network, which is implemented in this scheme [16].

Further, this work is furnished such as in Section – II, describes about Internet of Things are discussed, in Section – III, the parallel research outcomes are analyzed and discussed for finding the bottlenecks of the current applications, in the Section – IV, the identified drawbacks and the proposed solutions are presented using The Proposed Adaptive Iot-Based Hopfield Neural Network (AIHNN), based on the mathematical models, the proposed algorithms are furnished and discussed, the obtained results from these two novel algorithms are furnished and realized, in the Section – V, and in the Section – VI, the final research conclusion is presented.

## II. THE INTERNET OF THINGS (IoT)

The Internet of Things (IoT) is expected to provide social and financial benefits to emerging and developing countries soon. Incorporating Blockchain technology addresses supported agriculture, water quality utilization, human services, and ventures managing condition, among other things [5]. The Internet of Things (IoT) also promises to become a means of achieving the Sustainable Development Goals of the United Nations. It is not new for developed countries to be confronted with the enormous scope of Internet of Things problems [10]. The benefits of the Internet of Things must also be considered by the municipalities that are developing them.

More requirements and challenges in putting this concept into action in less-developed areas must be addressed, such as frameworks, marketplace. Enterprise motivating factors, specialist skills, and approach resources, among other things, because the connections between things, the environment, and the general public are becoming more dynamic [4]. The Internet of Things today ensures that we will live in a progressive, fully connected, dazzling world]. However, the tests and concerns regarding the Internet of Things should be examined. Moreover, it should be addressed to determine the possible benefits to individuals, communities, and businesses [17]. Finally, increasing the benefits of the Internet of Things while simultaneously reducing the security risks cannot be achieved by engaging in an unending debate that pits the affirmation of the Internet of Things against its flaws. It will pledge dedication and collaboration throughout the partner meetings to provide the most acceptable ways to the public in the future. The use of Internet of Things segments prompted a slew of legal questions and gave rise to previously unaddressed legal problems relating to the Internet of Things. The inquiries are massive in scope, and the rapid evolution of IoT technology concerns the ability of the associated approach, legal framework, and regulatory zones to be changed. In this group of problems, one would be the information stream which occurs when IoT devices collect information about people within their purview and transmit it to a different location with different data security rules to advance the treatment of the information. Another issue is that the data collected by IoT devices are susceptible to misuse, which results in unsatisfactory outcomes for the customers [11]. Other legal problems associated with the Internet of Things devices include disagreements between law enforcement agencies and standards-setting organizations, information pulverization, and legal obligations for non-required uses, security, and protection concerns. The Internet of Things is now accessible because we have information internet associations, which allows us to access it. The development of information and internet association may be traced back through history and across time. The time information is sent to the Internet facilitates the efficient delivery of information to the Internet. After that, the following section provides a brief historical overview of the information era [18-24].

This study aims to develop and evaluate lightweight and asymmetric block cipher-based cryptosystems that are suitable with MANET, IoT, and wireless communication devices to achieve data security while also maintaining quality control. The following are some possible discussion points on the

work's goal. Prepare a design and simulation of a data security system that incorporates a block cipher, image processing, and reversible data concealing. To develop standard protocols that is interoperable with WSN, MANET, and the Internet of Things. Understanding and implementing the mathematical modeling of cryptographic algorithms is essential for success.

## III. PARALLEL WORKS

When it comes to security, a lightweight authentication model for the Internet of Things (IoT) provides a high degree of protection against various assaults such as impersonation attacks, man-in-the-middle attacks, and unknown key sharing attacks in the E-health domain. Based on IoT-based E-health apps, the author proposed a safe, lightweight authentication method that is easy to implement. The suggested approach, based on the Internet of Things, offers authentication, an energy-efficient system, and computing for healthcare. Elliptic curve cryptography (ECC) is a concept that defines the characteristics of the suggested model, in addition to the individuals who offer healthcare and the patients. In general, the author's motivation is to design a lightweight security scheme based on ECC principles for E-health applications based on the IoT (IoT) [8]. The author devised an authentication method based on the minor key, which offers a high degree of security for the system. They also developed a high-performance, lightweight security scheme for E-health applications based on the Internet of Things. The proposed security model is based on the RSA cryptographic algorithm. The algorithm for public-key cryptography is most widely used. In communication stacks, it is used to offer UDP/IPv6 networking to use less power and energy [8].

In [15], a protocol for robust and secure authentication in the Internet of Things systems was suggested to be efficient and safe. In order to ensure security, the proposed protocol uses a physical function that cannot be copied. The proposed protocol protects various attacks while being highly efficient in memory, computations, energy, and communication. An Internet of Things (IoT) mutual authentication mechanism was described by the author. The system is based on PUFs, which use a challenge-response mechanism to send authentication information [15]. Because the protocol offers secure authentication and creates a session key without the need for it, an IoT device does not need to store anything. The author demonstrated that the proposed protocol is highly efficient and provides security against a variety of attacks, including physical attacks, side-channel attacks, and cloning attacks, among others. One of the most important requirements for Internet-of-Things (IoT) systems is security while using as few resources as feasible. Because IoT devices are low-cost and simple, they are a great target for physical, side-channel, and cloning threats, among others. To solve the same issue, the developer developed an effective protocol for mutual authentication for Internet of Things devices.

## IV. PROPOSED ADAPTIVE IoT-BASED HOPFIELD NEURAL NETWORK (AIHNN)

AIHNN features metastable states that are triggered by external input and a previously selected state. The chaotic behavior is provided by an ANN that is constructed with a minimal number of nodes, chosen node connections, and a

suitable asymmetric weighted route. The proposed work will be utilized for the AIHNN, which consists of eight nodes. It features an AIHNN architecture with eight nodes, and each node may be connected to any other node and any external input sources. It also has a link to itself. The starting state of the input nodes and external input, as well as other variables, influence the output of each node. The weighted route links every node in the network to every other node. As demonstrated in the previous section, Fig. 1 depicts a recurrent AIHNN that has been rebuilt into a chaotic architecture with eight nodes.

Each node in chaotic design is considered as an input/output node, resulting in a faster generation of the pseudo-random sequence than in traditional architecture. As a result, it is said to be an instance of hyperchaotic architecture. Because each node in this design is not connected to every other node and weights are modified using the Hebb rule in combination with the hyperbolic activation function, this architecture has several distinguishing features. Furthermore, AIHNN has been designed with a certain number of nodes and an appropriate asymmetric weighted path to produce the desired chaotic behavior in a controlled setting.

$$W_{ij} = \begin{bmatrix} w_{11} & w_{12} & w_{13} & w_{14} & w_{15} & w_{16} & w_{17} & w_{18} \\ w_{21} & w_{22} & w_{23} & w_{24} & w_{25} & w_{26} & w_{27} & w_{28} \\ w_{31} & w_{32} & w_{33} & w_{34} & w_{35} & w_{36} & w_{37} & w_{38} \\ w_{41} & w_{42} & w_{43} & w_{44} & w_{45} & w_{46} & w_{47} & w_{48} \\ w_{51} & w_{52} & w_{53} & w_{54} & w_{55} & w_{56} & w_{57} & w_{58} \\ w_{61} & w_{62} & w_{63} & w_{64} & w_{65} & w_{66} & w_{67} & w_{68} \\ w_{71} & w_{72} & w_{73} & w_{74} & w_{75} & w_{76} & w_{77} & w_{78} \\ w_{81} & w_{82} & w_{83} & w_{84} & w_{85} & w_{86} & w_{87} & w_{88} \end{bmatrix} \quad (1)$$

$$w_{ij} = \begin{cases} \sum_{m=1}^M d_i^m d_j^m & \text{if } i \neq j \\ 0 & \text{otherwise} \end{cases} \quad (2)$$

Fig. 1. Architecture of Hyperchaotic AIHNN with Eight Nodes.

Given that the selected Adaptive IoT-based Hopfield neural network has eight nodes, the weight matrix dimension is 8x8, equivalent to W11–W88 in the preceding example. The weight

values in Equation 2 relate to the neural network strength acquired during training, which influences the accuracy of the produced result (rate of closeness among required and received output). The weight values are either integers or floating decimal numbers, depending on the activation function (identity or hyperbolic activation function). The following equation (2) and the following equation (3) are used to incrementally update each node (3). Each node in the preceding equation (2) receives a weighted signal from the other nodes, as well as external input and information from other nodes (Xi). The adjusted sigmoid transfer function is then computed using the revised Xi as shown in the equation:

- The architecture depicted in Fig. 1 produces cyclic random sequences by deriving the following equations: (2) and (3), where Cmax is the steady and Max.
- Cmax is the initial state.
- Wij is the mass function in both.

$$M_{\max} = \frac{n}{2 \log(n)} \quad (3)$$

$$C_{\max} = \frac{n^2}{2 \log(n)} \quad (4)$$

$$Q = \frac{n(n-1)}{2} \log_2(P) \quad (5)$$

Adaptive IoT based Hopfield Neural Network (AIHNN)

$$P_{\max} = M_{\max} + 1 \text{ and then}$$

$$Q_{\max} = \frac{n(n-1)}{2} \log_2(M_{\max} + 1) \quad (6)$$

This leads to:

$$\eta = \frac{n}{(n-1) \log(n) \log_2\left(\frac{n}{\log(n)} + 1\right)} n \quad (7)$$

$$\approx \frac{1}{\log(n) \log_2\left(\frac{n}{\log(n)}\right)} n \quad (8)$$

## V. EXPERIMENTAL RESULTS AND DISCUSSION

Visual information that is not medical is referred to as Image data (I), and it serves as a carrier of Critical Medical Information (CMI). As shown in Fig. 2, a Secret Key (SK) is utilized by the Steganographic embedding function (SFE) to conceal CMI, and Stego data (SD) is produced as an output (by the device at the transmitting end DT).

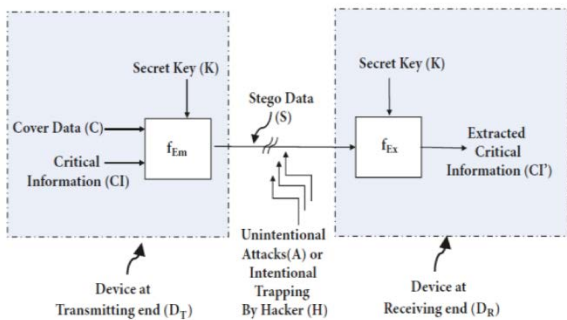

Fig. 2. Steps Involved in Reversible Hiding Algorithm.

The Steganographic extraction function (SFE) extracts CI using the precise Secret Key (K) provided by the user (as a device at receiving end DR). The stego data is CI is Extracted Critical Information, and the secrete key is the secrete key. Fig. 3 depicts a generalized hardware Steganographic data concealing device that is used in the industry. Crypto xStegoSystem is the name given to the proposed reversible data concealing system, intended for use in the implementation of a data hiding system and comprises cryptographic and Steganographic methods. The suggested approach is shown in the Fig. 3.

The central idea of the investigation may be broken down into the many shown in Fig. 3.

- 1) Ensure that low-complexity symmetrical key encryption is implemented on various platforms (JPEG-2000, JPEG, BMP, PNG, GIF).
- 2) Evaluation of the performance of the simulated method on user-defined and real-time imagery.
- 3) An investigation of incorrect key encryption.
- 4) Design and development of the Graphical User Interface for the proposed system.
- 5) An evaluation of the suggested system's execution time and memory allocation is performed.
- 6) The development of a reversible data-hiding system for picture and text multiple encryptions is underway.
- 7) Evaluation of the suggested system's AIHNN and MSE results as shown in Fig. 4 and Table I.

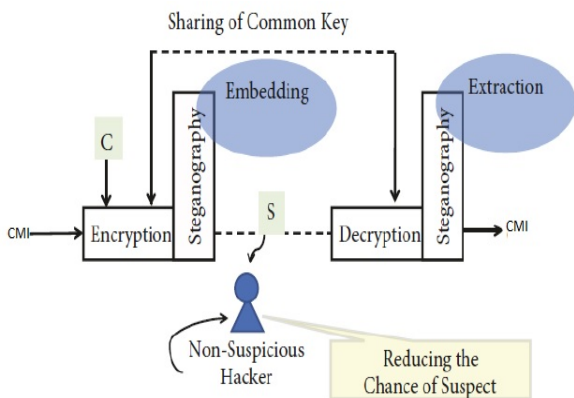

Fig. 3. Phases in Key Sharing in AIHNN Algorithm.

**Algorithm 1:** The overall process is explained as follows: -

1. Validate CI and store it in the Message Cache
2. Accept the LOOK-UP Table as an Embedding Key in Step 2. (K)
3. Parse the cover data in 8-byte chunks (C)
4. Compute the DWT of the first 8bytes of the cover data
5. Select a byte(Ym) at random from the Message Cache.
6. It was chosen using 3LSBs of the contents of the selected byte LOOK-UP Table.
7. Insert the chosen bit at DWT coefficient C3 to complete the operation.
8. Compute IDWT of 8bytes of cover data in order to get Stego information.
9. Repeat steps three within 8 for all of the bits in the Message Cache and all of the characters.

TABLE I. AIHNN ENCRYPTION AND DECRYPTION MSE

Type of Medical Image	ANN	MSE
BMP	70.543	0.0242
GIF	66.231	0.0242
JPEG	67.001	0.0231
JPEG-2000	71.643	0.0176
PNG	68.332	0.0209

Fig. 4. AIHNN Encryption and Decryption MSE.

The method presented here is to create chaotic sequences using AIHNN rather than nonlinear equations that show chaotic behavior. The image-specific key is treated as a control parameter, and the bit of color is produced using the pseudo-code shown in Algorithm 2. Followed by the tested images and its testing results mentioned in Fig. 5, Fig. 6, Fig. 7 and Table II.

**Algorithm -2:** Random sequence generation using AIHNN and image specific key

**Input:** Multiplicative identity matrix (B)  $_{(8 \times 8)}$ , Sampling rate  $T_w$ , Random initiator  $h_{(1 \times 8)}$

**Output:** Nonlinear random sequence  $\Omega$

Step 1. Initialize

$$w_{ij} \leftarrow \left[ \frac{w}{2\sigma} - w; \Psi 2w 3w 0; 3w \phi w 0; MW w 0 0 nw \right] \\ \leftarrow [1 \quad 0.5 \quad -5 \quad -1 \quad ; -0.37$$

Step 2.  $2 \quad 3 \quad 0 \quad ; 3 \quad -13 \quad 1 \quad 0 \quad ; 100 \quad 0 \quad 0$

Update the  $w_{ij}$  with new  $\sigma, \Psi, \phi$

Get  $H(0) \leftarrow [h]^T$

Step 3. For  $i, j$  11 to do

$$f(H(r)) = \tanh H(r)$$

$$H(r + 1) = (1 - BT_w)H(r) + T_w wf(H(r))$$

$$Dh = |(H(r + 1) - [|H(r + 1)|])|$$

Step 4. Until  $r \leq (\text{Image size} / 4)$  Initialize  $\Omega \leftarrow \{$  for  $f \leftarrow 1$  to 16384

Step 5. for  $i \leftarrow 1$  to  $4 \Omega((4 \times (f = 1)) + i) = Dh(i)$

Step 6. End

Step 7. End

Step 8. Return  $\Omega$

The encrypted medical image has also been stored in public cloud storage, and only authorized customers will be forced to access the clouds to get a ciphered image. The main image may only be accessed using the private key(s) that were assigned to it.

Fig. 5. Medical: (i) A Plain Image (Img); (ii) an Encrypted Image (EImg = E(Img)); (iii) A Decrypted Picture (Img = D(EImg)).

In order to arrive at exclusive encrypted pictures for each medical image, the proposed AIHNN system changes the weight matrix for each medical image. The adaptive encoding aspect of the proposed work has resulted in an average entropy of 8.11, independent of the original medical pictures used in the analysis.

Healthcare terminology:

Keys are important to the functioning of encryption systems, and key sensitivity analysis is a helpful tool for evaluating the robustness of encryption methods. Analysis of key sensitivities. For the most part, encryption techniques

utilise the same key for each image transmission. The proposed approach, on the other hand, offers an independent and adjustable key for each image based on image attributes. When the key is in double data type, it is feasible to reflect even minor changes in the image's properties.

Fig. 6. (iv) Plain (MImg); (v) Encrypted (EImg = E(MImg)); (vi) Decrypted (MImg = D(EImg)).

TABLE II. TEST IMAGES WITH ENTROPY

Test images	Global Entropy		Local entropy
	Original image	Encrypted image	No. of blocks =50 Block size: 88*88 Encrypted image
MI1	4.5	8.1245	8.1106
MI2	5	8.1263	8.1112
MI3	6.3	8.1272	8.1118

## VI. CONCLUSION

The consolidation of computers, sensors, and systems to pass the report on and control devices have been around for a long time, but as significant technological and business trends advance, the "Internet of Things" is experiencing a new

phenomenon known as the "Internet of Things." A progressive, fully linked world is promised by the Internet of Things, connecting different things and their surroundings and between articles and people becoming increasingly securely connected over time. On a basic level, it has the potential to alter how people perceive what it means to be "on the web." Even the potential is significant, and there are many obstacles to overcome – primarily in the areas of security and protection, interoperability and scales, legal problems, and human rights issues, including emerging economies. Consequently, it is necessary to recognize and address its problems while maximizing its benefits and minimizing its risks. Answers for enhancing the optimal use of IoT while also minimizing the risks cannot be found by being involved in a heated debate that pits the benefits of IoT against the concerns of cybersecurity.

There are numerous obstacles to overcome when it comes to the Internet of Things, including intensity, data transmission capacity, flexibility, security, and protection. Predefined security arrangements at each tier are nevertheless vulnerable to security-related attacks, even though they have been strengthened. Because of their openness and multi-tenancy, cloud storage systems are susceptible to a wide range of security vulnerabilities. This suggested solution provides data security for data saved in cloud storage and data in various states such as underuse, rest, and transit, among others. Creating a secure medical picture archive on the cloud is the driving force behind this project. It is crucial to highlight that the Hopfield attractor is an important component of the surveillance system for medical images stored in the cloud, and its fitness is also validated using standard metrics. The proposed research utilized a Hopfield attractor to confuse pixels, followed by diffusion, and the findings demonstrated that the system was resistant to additional attacks.

**Abstract**—Logistics companies' success is inextricably linked to the quality of their services, particularly when dealing with customer issues. Nowadays, social media is the first place that users turn to in order to express their thoughts on services or to communicate with customer service representatives to resolve problems. Businesses can retrieve and analyze these data to gain a better understanding of the factors that affect their operations, both positively and negatively. During the COVID-19 pandemic, we conducted a sentiment analysis to assess customer satisfaction with logistics services in Saudi Arabia's private and public sectors. Using a lexicon-based approach, 67,124 tweets were collected and classified as positive, negative, or neutral. A support vector machine (SVM) model was used for classification, with an average accuracy of 82%. Following that, we conducted a thematic analysis of negative opinions in order to identify the factors that influenced the effectiveness and quality of logistics services. The findings reveal five negative themes: delay, customer service issues, damaged shipments, delivery issues, and hidden prices. Finally, we make suggestions to improve the efficiency and quality of logistics services.

**Keywords**—Logistics services; sentiment analysis; lexicon-based approach; SVM; sentiment classification

## I. INTRODUCTION

Logistics adds value by meeting customers' delivery needs in a cost-effective manner [1]. As a result, logistics service performance represents a provider's ability to consistently deliver requested products within the specified time frame and at an acceptable cost [2, p. 34]. This means that the quality of the provided logistics services can be considered the most significant success guarantor of a logistics business [3]. It increases customer satisfaction, which in turn increases the business's profitability and competitive advantage [4]. Customer satisfaction will determine whether or not customers make further purchases or refer the business to others [5].

People rely heavily on social media for information, news, and entertainment. Twitter and other social media platforms are growing in popularity because they provide easy access to real-time posts on a daily basis. Tweets and mentions on Twitter contain information about current events, news, user opinions, and reviews. These data are useful to businesses because they allow them to better understand user preferences, improve their services, and increase customer satisfaction. Twitter provides an Application Programming Interface (API) through which researchers, developers, and business owners

can obtain data to analyze and learn more about topics of interest to them. Sentiment Analysis is the process of extracting, analyzing, and distinguishing opinions or emotions from text [6]. It is a branch of natural language processing (NLP) research. Sentiment analysis is currently used to analyze data posted on social media platforms or websites in order to determine opinions, attitudes, or emotions about businesses, products, or services. These classifications are beneficial to business owners because they allow them to identify their strengths and weaknesses in order to improve future services and thus increase profits. To the best of our knowledge, no previous studies have used Twitter users' opinions to analyze customer satisfaction with logistics services in Saudi Arabia during the COVID-19 pandemic. Therefore, this study aims to fill this gap and to achieve the following objectives: 1) to investigate customer satisfaction with logistics services during COVID-19 in Saudi Arabia by analyzing customer opinions; and 2) to identify the elements of logistics service quality that influence customers' sentiments toward logistics service providers.

The following is how the paper is structured. First, we review the relevant literature, and describe the methods employed to collect the data and conduct the analysis. The results are presented, followed by a discussion of the results. Finally, the managerial implications of the findings and future research directions are explored.

## II. LITERATURE REVIEW

This section begins by reviewing logistics service quality and customer satisfaction. Second, we discuss the various tools, methods, and results of sentiment analysis studies that have used Arabic tweets. We also review how researchers have used sentiment analysis to investigate customer satisfaction.

### A. Logistics Service Quality and Customer Satisfaction

Customer satisfaction is defined as the perceived difference between prior expectations and actual product or service performance [7]. It is a sign that customers' needs are being met in a pleasurable manner. According to some researchers, the ultimate goal of any organization is to meet the needs and achieve the satisfaction of its customers. Understanding the needs and expectations of customers is a necessary step in ensuring their satisfaction [8].

The research of Parasuraman, Zeithaml, and Berry [9] identified five broad dimensions of service quality that influence customer satisfaction: dependability, receptiveness, assurance, empathy, and tangibles. Dependability explains the ability to provide the promised service consistently and reliably. Receptiveness represents the willingness to assist customers and provide prompt service. Assurance symbolizes employee knowledge and courtesy, as well as the ability to convey trust and confidence, while empathy is about providing caring and individualized attention to customers. Finally, tangibles represent the appearance of physical facilities, equipment, personnel, and communications materials. Several studies have applied these dimensions to identify the quality gap in logistics and to improve the services in order to achieve customer satisfaction. For example, [10] conducted a study to validate five determinants of service quality and to investigate the service quality-customer satisfaction link in the port logistics service industry in Vietnam. According to the findings, five factors influence the quality of port logistics services: responsiveness, assurance, dependability, tangibles, and empathy. The findings additionally show that the quality of port logistics services has a positive impact on customer satisfaction.

Furthermore, Cho et al. [11] presented three factors of service quality in order to determine their effects on customer satisfaction, referral intentions, and loyalty. The study was linked to the port logistics service industry in Incheon and Shanghai. The result of their study showed that exogenous and relational quality remained important dimensions of customer satisfaction. According to their findings, relational quality included the positive attitude and professionalism of employees, partnership relations between the customers and the ports, and the ability of the port information system to provide timely information. However, the endogenous quality of services has an insignificant impact on customer satisfaction.

Uvet [12] conducted a study that investigated the aspects of logistics services that affected customer satisfaction. These included timeliness, quality of personal contact, operational information sharing, order condition and handling of order discrepancies. He applied structural equation modeling (SEM) and confirmatory factor analysis (CFA) to examine customer satisfaction by utilizing the five factors of logistics service quality. The results showed that there are significant relationships between logistics service quality factors and customer satisfaction. Additionally, the finding of this study can be applied in any business to obtain competitiveness in logistics services.

### *B. Sentiment Analysis and Customer Satisfaction*

Anastasia and Budi [13] examined Twitter opinion data to estimate users' satisfaction with the GO-JEK and Grab companies, which provide online transportation services in Indonesia. From February to March 2016, they retrieved 126,405 tweets using the Twitter API and the R programming language. RapidMiner was also used for data pre-processing and classification. The study examined the highest accuracy score using three classification algorithms: SVM, Naïve Bayes

(NB), and Decision Tree. The results showed that Grab had higher user satisfaction than GO-JEK, and that the SVM and Decision Tree algorithms had the highest accuracy with a score of 72.97%.

From September 2013 to February 2014, Gitto and Mancuso [14] conducted an exploratory sentiment analysis on passenger review data extracted from a blog called "Airport Reviews" on the SKYTRAX website. Their study looked at customer satisfaction for both aviation and non-aviation airport services. The study looked at five international airports in Europe: Amsterdam Schiphol, Frankfurt, London Heathrow, Madrid Barja, and Paris Charles de Gaulle. The researchers used KNIME, an open-source platform for data analytics, and Semantria, which uses a dictionary base and a machine learning technique, to conduct sentiment analysis and to detect positive, neutral, or negative sentiments. According to the findings, non-aviation services such as food and beverage and the shopping area had the greatest influence on passenger satisfaction levels. Non-aviation services received approximately 55% positive feedback, while aviation services received only 33%.

Bhattacharjya et al. [15] investigated the effectiveness of customer services on Twitter for logistics services provided by e-retailers. The study looked at conversations between customers and businesses rather than individual tweets to investigate the effectiveness of customer services. A large sample of 203,349 tweets from e-retailers was collected, as well as a random sample of logistics conversations. After data preparation and cleansing, a total of 16,998 tweets were analyzed. According to the findings, e-retailers and logistics service providers mostly redirect customers to other channels to solve their problems, while ignoring their customers' needs to find solutions and get their issues resolved on Twitter. The findings also revealed a lack of interaction between e-retailers and logistics service providers over providing effective customer service.

Ahmadi et al. [16] performed a sentiment analysis on public service conversations in a hospital in Yogyakarta, Indonesia. The study created the "Kata Kita" product to translate conversations into text and to help deaf people communicate with service personnel by displaying the text on the screen. Customer satisfaction was also evaluated. The study combined NLP with K-nearest neighbors (KNN) and the term frequency-inverse document frequency (TF-IDF) algorithm to classify conversations as "satisfied" or "dissatisfied". The results showed 74.00% accuracy, 76.00% precision, and 73.08% recall.

This literature review demonstrates that researchers all over the world have been focusing on customer opinions in order to better understand customers and the factors that influence their satisfaction. Furthermore, due to the significance of this type of analysis and the scarcity of studies using sentiment analysis to analyze Arabic tweets to understand customers' satisfaction with logistics services, this study will analyze customers' opinions of logistics services during the COVID-19 pandemic.

### C. Arabic Sentiment Analysis

Several studies have used Arabic sentiment analysis to gain a better understanding of various phenomena. Aldayel and Azmi [17], for example, proposed a hybrid approach that combined a lexicon-based technique with machine learning techniques to develop a sentiment analysis of Arabic tweets retrieved via Twitter's API that addressed social issues in Saudi Arabia. They used data cleaning, normalization, stop-word removal, an n-gram model to remove repeated letters, and a light stemmer for Arabic text stemming during the pre-processing phase. The training data were labeled using a lexicon-based classifier, and the classification model was built using an SVM classifier. According to the study's findings, the hybrid approach achieved an F-measure of 84% and an accuracy of 84.01%.

Al-Ghaith [18] created the SaudiSentiPlus, a Saudi dialect lexicon that includes a translation of English sentiment lexicons as well as 7,139 terms manually extracted from Saudi tweets. The dataset's polarity classification was carried out manually by three annotators who were Arabic native speakers and Saudis. They divided the dataset into three categories: positive, negative, and neutral. For each classification, the output was 300 labeled tweets. The study conducted an experiment to assess the performance of the SaudiSentiPlus lexicon, using 971,000 tweets from Saudi dialect hashtags as a testing dataset. The accuracy of their results was 81%, which is considered very good.

Al-Horaibi and Khan [19] proposed a sentiment classification system based on a combination of Arabic and English sentiment lexicons. A total of 14,984 tweets were collected from Twitter using the Twitter API and the Python Tweepy2 library. The tweets were pre-processed by the researchers, who removed @usernames, hashtag signs, symbols, numbers, non-Arabic letters, and re-tweets. Following the cleaning process, a total of 3,200 tweets were produced, and these were annotated by two native Arabic annotators. The researchers only used 2,000 tweets because the remaining tweets created uncertainty. There were 634 positive tweets, 675 negative tweets, 691 neutral tweets, and 26,349 tokens in total. A classification semantic approach that used the Arabic Sentiment Lexicon (ArSneL) and the English SentiWordNet lexicon was then employed. The findings indicated that there was a need to improve Arabic stemmer tools by including more roots to support the search process. In addition, the Arabic spelling correction tools needed to be improved, and more words needed to be added.

Al-Hussaini and Al-Dossari [20] proposed a sentiment analysis approach based on a lexicon that included a Saudi dialect lexicon. The lexicon was built using a semiautomatic building technique, with the lexicon being built manually after the data were collected from Twitter. Then, two lists were

manually constructed: one with the most frequently occurring positive sentiment words; and the other with the most frequently occurring negative sentiment words. The lexicon was divided into two columns: words and their polarities. Following classification, there were 762 positive words/phrases with a +1 value and 662 negative words/phrases with a -1 value. The results show that the developed Saudi dialect lexicon helped to improve the sentiment labeling of Arabic tweets.

### III. RESEARCH METHODOLOGY

In this section, we will present our Arabic sentiment analysis methodology, which consists of four phases: data collection, data pre-processing, lexicon-based classification, and sentiment analysis. Fig. 1 illustrates the implemented Arabic sentiment analysis methodology, and the following sections explain each stage in more detail:

#### A. Data Collection Phase

The Python Tweepy2 library was used to extract tweets from the Twitter API. In total, 67,124 tweets were collected that mentioned public and private logistics companies. These included Aramex, DHL, Fetchr, Naqel, SMSA, and Saudi Post. The retrieved tweets were tweeted during the surge of the COVID-19 pandemic, precisely from June to September 2020.

#### B. Data Pre-processing Phase

The data pre-processing phase consists of three successive stages: text cleaning, tokenization and stemming. In the text cleaning, a number of steps were performed as follows:

- Removing irrelevant tweets that includes ads and were not related to our task.
- Removing non-Arabic letters, including numbers, symbols, the hashtag sign and emojis as they are not part of the analysis.
- Replacing "@username", "www." and "https?:///" with empty strings.
- Removing the punctuation.
- Eliminating character repetition in a word by replacing it with a single character, such as "ويبيبيبي شحنتنتنتي" which is replaced with "وين شحتني".
- Normalizing some characters, including "إ", "!", and "آ" with "ا", the "ة" character with "ه", the "ى" character with "ي", and the character "ؤ" with "و".
- Removing stop words, the standard Arabic stop words, provided by the Natural Language toolkit (NLTK) library, were used.

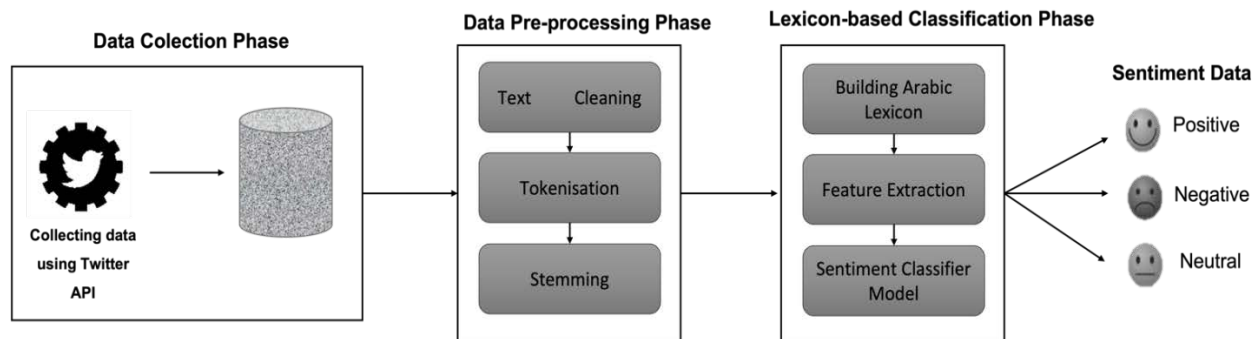

Fig. 1. The Implemented Arabic Sentiment Analysis Methodology.

Then, we split the text into tokens or words using NLTK tokenization<sup>1</sup>.

Finally, for the stemming step, we used an Arabic light stemmer called ISRI Arabic Stemmer [21] to remove prefixes and suffixes in order to obtain the root of words. The output of the stemmed words, however, was rooted into three-character words, making the majority of the words unreadable or without meaning. As a result, we did not proceed with the stemming step. According to Albraheem and Al-Khalifa [22], stemming may be ineffective for Arabic dialects as most words lack roots or have roots with more than three characters. Another study [23] confirmed that Arabic dialect does not receive adequate processing in Arabic sentiment analysis because Arabic dialectal varieties necessitate advanced pre-processing and lexicon-building steps.

### C. Lexicon-based Classification Phase

For sentiment analysis, a lexicon-based approach was used. First, an Arabic lexicon was needed to label the data before applying the classifier algorithm. There are few Arabic lexicons available, and it is difficult to find one that includes Saudi dialects. Only two studies, [24], [25], were discovered that constructed the Arabic lexicon with Saudi dialects in mind. Therefore, we updated the lexicon created by [18] for categorizing tweets as “positive” or “negative” by including words related to logistics services in each list. The resulted lexicon contained approximately 6,500 words. The lexicon was then applied to assign polarity scores to each word in the tweets: either 1, 0, or -1 according to whether they were positive, neutral, or negative, respectively. Following that, each tweet was labeled based on its maximum polarity scores, and when a tie occurred it was labeled as neutral. For instance, if a tweet contained three negative and two positive words, it was labeled as negative, and vice versa. It was otherwise labeled as neutral.

Second, the feature extraction step was performed on our dataset. This step aims to extract numerical features from text data to make it more suitable for a classification algorithm. We used the TF-IDF algorithm, which increases the weight of rare words, while diminishing the weight of words that occur frequently in the dataset.

After that, SVM was used to build the sentiment classifier model. SVM makes use of a learning algorithm that is based on statistical learning theory and optimization theory. It enables the computer to learn how to perform classification and regression tasks, to improve prediction accuracy, and to avoid the drawbacks of overfitting [26]. The main idea behind SVM is to find the hyper-plane that divides document vectors into two distinct classes [27]. According to several previous studies, SVM performs well with Arabic text. For example, [28] tested three different classification algorithms, the NB, SVM and KNN classifiers, and they found that the SVM classifier outperformed the other classifiers in terms of the precision measure. Another study confirming the ability of SVM to classify Arabic tweets was [29]. The authors tested six different classification algorithms: SVM, KNN, NB, Neural Network, and two Decision Tree algorithms including J48 and C5.0. They concluded that SVM outperformed the other tested classifiers. Moreover, they showed that using the SVM classifier without any stemming on Arabic text was better than other stemming methods [23]. Therefore, it was deemed to be suitable for this research.

### D. Experimental Setup

We used the train test split () function from the Python library SciKit-learn to split the dataset into 70% for training and 30% for testing during the training phase. The data were then subjected to a 10-fold cross-validation to ensure their accuracy and to prevent overfitting. The data were divided into ten parts in the cross-validation method. The first run included nine parts for training and one for testing. Another part was used for testing in the next run, while the remaining nine parts were used for training. The final accuracy is the mean of the accuracies obtained from the ten runs. The SVM classification model then predicted the sentiments of the tweets using the predict function to put the classification model to the test.

## IV. SVM PERFORMANCE EVALUATION

To assess the performance of the SVM classifier, we employed a variety of evaluation metrics that can fairly judge the model and assess its performance. Accuracy, recall, and precision were calculated and Table I presents these results for SVM while Table II shows classification performance by sentiment polarity. The average accuracy of the SVM classifier in this study was 82%. The results show that SVM has a superior ability in 3-class classification because it can distinguish among classes of sentiment polarity.

<sup>1</sup>NLTK (Natural Language toolkit) tokenization is the process of dividing large text into smaller parts called tokens.

TABLE I. RESULT OF SVM MODEL

Classifier	Accuracy	Precision	Recall	F1
SVM	0.82	0.81	0.80	0.80

TABLE II. RESULTS OF CLASSIFICATION PERFORMANCE BY SENTIMENT POLARITY

Classifier	Polarity	Precision	Recall	F1
SVM	Neutral	0.74	0.73	0.73
	Positive	0.82	0.80	0.81
	Negative	0.86	0.88	0.87

## V. THEMATIC ANALYSIS RESULTS

After identifying positive and negative tweets, we conducted a thematic analysis of negative opinions in order to identify the factors influencing the quality of logistics services. We used Python to search for codes in the tweets and to then identify the most frequently occurring themes. As a result, five negative opinion theme categories emerged. These themes are: customer support issues, damaged shipments, delay, delivery issues, and hidden prices. Table III displays the negative themes, along with the percentage of occurrences in the entire dataset.

### A. Customer Support Issues

Customers reported a variety of problems related to customer support, including a lack of support from customer service representatives and poor service from delivery drivers. For example, 5.7% of the tweets were associated with bad customer service. Many customers complained that customer service representatives were unable or unwilling to resolve their issues – some of the linked tweets are given below (note: translated from Arabic):

“I want to file a complaint about your company, I have been waiting for my shipment for two months and I contacted you and you replied to me, we are working to follow up the request, and I did not see anything.”

“Unfortunately, I submitted a complaint without any concern and care from you.”

“I filed a complaint and the matter was neglected as if it was an unimportant report and they did not contact me till now.”

“I sent complaints till I got bored, yet no one answers.”

TABLE III. NEGATIVE THEMES

Themes	Occurrences	Percentage
Customer Support Issues	2765	5.7%
Delay	1986	4.0%
Damaged Shipments	511	1.0%
Delivery Issues	4736	9.7%
Hidden Prices	756	1.5%

### B. Delay

Approximately 4% of the negative tweets showed negative attitudes toward delayed shipment. Customers complained that their shipments were either late or had never arrived. Some examples of these complaints are as follows:

“I hope the problem will be solved, two months have passed, and my shipment has not arrived yet.”

“My shipment was supposed to be shipped on August 1, but it was not shipped, and you were 10 days late for the supposed delivery date.”

### C. Damaged Shipments

About 1% of the negative tweets were related to receiving damaged shipments. Customers complained that their shipments had been damaged, broken, opened, or expired. Here are some examples of these tweets:

“I received my shipment very late. And I received it with damaged products, spilled products, and the shipment arrived in a very bad condition ... Who will compensate me for the damage?”

“65 days delay and the shipment arrived opened and dirty.”

“I inform you that my shipment arrived after delaying three days of calling today at 1pm, the temperature was 47 degrees Celsius. The car was not air-conditioned, and the box was at a high temperature, noting that the shipment contains vitamins, shampoo and makeup that does not bear the heat, and it has been spoiled.”

### D. Delivery Issues

About 9.7% of the data showed negative opinions about delivery issues. Customers mentioned that they faced many issues with the delivery driver while delivering their shipment. Many customers complained that the delivery drivers were unreachable. Some examples of customer’s complaints are as follow:

“A company like you should employ respectable employees who know how to deal with customer ... unfortunately your delivery driver was very bad and disrespectful today. He calls and raises his voice and talks with impoliteness to deliver the shipment! It is your duty to deliver the shipments to their owners!!”

“Respond to me first and find my shipment!! My shipment has arrived two months ago, and the delivery driver did not answer my calls, and his mobile was locked.”

“I shipped my shipment through express mail and paid extra money to deliver the shipment faster ... in the end I did not receive the shipment for two weeks.”

Customers also complained about missing items in their shipments, lost shipments, delivering to the wrong location, and failing to provide the promised door-to-door service. See the examples below:

“I’ve called and you told me that my shipment was lost, and I’ve contacted you 3 months ago, and I’ve been told that you will communicate with me, but nothing happened.”

“Unfortunately, they charge large fees for shipping shipments, and deliveries are delayed and their shipments arrive incomplete! I have a shipment about two weeks ago, and today it arrives incomplete.”

“A paid shipment arrived two weeks ago and arrived at the wrong address. I contacted you 3 times to change the location and deliver it to my home, and there is no response!”

“The delivery driver left my shipment with negligence at the end of the street and not in front of the door of the house and went, which indicates the lack of integrity of the company representative!”

#### E. Hidden Prices

Customers were dissatisfied with shipment companies’ hidden fees. Approximately 1.5% of the data showed negative attitudes toward extra charges and taxes. The following are some examples:

“Your representative asked me to pay an additional delivery fee, or he will return my shipment. I refused to pay, and he refused to deliver.”

“Why pay 30 riyals for the delivery fee? I’ve paid for the order shipping fee earlier!”

#### VI. DISCUSSION AND RECOMMENDATIONS

Based on the above results, it is clear that logistics service providers in Saudi Arabia need to improve their service quality to maintain their credibility and reputation, and to gain customers’ trust. The domain of logistics services in Saudi Arabia is still immature, although significant changes have taken place in the last decade. Logistics service providers should try to gain competitive advantages over others by providing high-quality services that distinguish them from others [12].

Communication between the customer and employees is highly important during service delivery in terms of meeting customers’ expectations [12]. Logistics service providers should offer a variety of customer support mechanisms, such as instant messaging with chatbots to answer frequently asked questions, change the location details, or reschedule delivery dates [30]. It is also critical to provide real-time support with customer service representatives in order to resolve customer issues [31], [32]. In addition, logistics service providers should provide temperature-controlled vehicles and dry gel packs for fragile shipments in order to avoid damage to goods [33].

Logistics service providers should make certain that customers are always kept up to date on the status of their shipments and any delays. Radio Frequency Identification (RFID) can be used by logistics service providers to provide real-time data about shipments, allowing them to know exactly where the shipment is from start to finish. RFID can improve shipment visibility, prevent shipment loss, prevent delivery to the incorrect destination, and reduce customer frustration caused by shipment delays by providing them with

a real-time delivery plan. RFID also reduces the amount of effort and time required to resolve these issues [34].

To resolve issues with unclear fees, transparency should be increased by creating an informed list that shows the shipping process, information required from customers, and a detailed bill. This procedure will save time and money while also increasing customer satisfaction [35]. Additionally, to mitigate the impact of delayed shipments on customer satisfaction during peak times, logistics service providers can offer customers discount coupons as a form of compensation for the delays and to reduce their disappointment and anger [36]. With regard to delivery drivers, logistics service providers’ systems should allow customers to rate their experience with the delivery drivers. This would allow the company to identify and control drivers’ behavior, improve the service quality, and ensure customer satisfaction [37]. In addition, the system could increase employee loyalty by providing bonuses to the highest-ranking employees [38].

#### VII. CONCLUSION

In this paper, we have evaluated the quality of logistics services during the COVID-19 pandemic in Saudi Arabia by analyzing customers’ opinions. Sentiment analysis was performed to analyze customers’ opinions expressed via the Twitter platform. Specifically, an SVM classifier was applied to predict the sentiment polarity of customers’ opinions; this resulted in 82% accuracy, 81% precision, and 80% recall. Our findings revealed that the majority of the opinions were negative. Further investigation using thematic analysis revealed a number of themes representing factors that had a negative impact on the quality of logistics services. Based on the findings, we developed a set of recommendations to help logistics service providers improve their service quality. We intend to expand the lexicon by adding more Saudi dialects in the future, as well as broadening our approach to analyzing customer reviews on apps. This will allow us to assess companies’ strengths and weaknesses and to assist them in improving the quality of their services via their apps.

# Investigate the Ensemble Model by Intelligence Analysis to Improve the Accuracy of the Classification Data in the Diagnostic and Treatment Interventions for Prostate Cancer

Abdelrahman Elsharif Karrar  
College of Computer Science and Engineering  
Taibah University, Medina, Saudi Arabia

**Abstract**—Class imbalance problem become greatest issue in data mining, imbalanced data appears in daily application, especially in the health care. This research aims at investigating the application of ensemble model by intelligence analysis to improving the classification accuracy of imbalanced data sets on prostate cancer. The primary requirements obtained for this study included the datasets, relevant tools for pre-processing to identify the missing values, models for attribute selection and cross validation, data resembling framework, and intelligent algorithms for base classification. Additionally, the ensemble model and meta-learning algorithms were acquired in preparation for performance evaluation by embedding feature selecting capabilities into the classification model. The experimental results led to the conclusion that the application of ensemble learning algorithm on resampled data sets provides highly accurate classification results on single classifier J48. The study further suggests that gain ratio and ranker techniques are highly effective for attribute selection in the analysis of prostate cancer data. The lowest error rate and optimal performance accuracy in the classification of imbalanced prostate cancer data is achieved using when Adaboost algorithm is combined with single classifier J48.

**Keywords**—Ensemble model; intelligence analysis; classification of imbalanced data; prostate cancer

## I. INTRODUCTION

This Prostate cancer is among the leading causes of death in men worldwide. The prostate is a glandular structure located in the male productive system and its functions is to promote spermatic health and enhance fertility by adding a nutrient-rich alkaline fluid to the semen [1]. Malignant tumors that lead to prostate cancer state to develop when the rate of cell multiplication is higher than cell death. This alters the genetic structure leading to mutations and tumor metastasis on the urothelial lining. Compared to other glands, the prostate has a higher malignancy rate due to the heavy reliance on the androgenic signaling of hormones such as testosterone, abnormal Gli-1 oncogene expression, and Sonic Hedgehog (Shh) expression, which stimulate cellular proliferation and stromal tumor growth. The process in which prostate cancer develops is known as Prostatic Intraepithelial Neoplasia (PIN) While most research studies on the pathogenesis of prostate cancer report inconclusive findings, etiological factors such as

genetic inheritance and family history, vasectomy, environmental carcinogens, low carotenoid intake, and high intake of saturated fats and other unhealthy dietary/lifestyle habits are known to increase the risks significantly.

Prostate cancer is classified as a carcinoma since its malignancy develops primarily from the epithelium lining of the peripheral glandular tissue. The epithelial structure of the prostate gland is composed of three cell types including rare neuroendocrine cells, basal cells, and luminal cells, which are responsible for the expression of androgen receptors, secretion of glycoprotein prostate specific antigen (PSA) and prostatic fluids [1]. Research studies suggest that prostate tumors that initially form from the luminal cells metastasize more rapidly compared to those from the basal cells due to the alteration of epithelial stromal tissues and the damage of glandular structure. The accuracy of clinical interventions such as the classification of diagnostic data from cancer tissues is influenced by a range of factors including the extent of cellular differentiation on histology and cyclic biochemical recurrence risk. Accurate classification of diagnostic data significantly influences the efficacy of treatment intervention through timely detection based on the Tumor, Nodes and Metastasis framework.

Data classification techniques for the diagnostic data are subject to structural imbalances and errors due to factors such as the underlying assumptions of evenly distributed training datasets. The classification approaches are highly vulnerable to bias when implemented on training data sets with severely imbalanced distribution. Insights from imbalanced training data sets may have severe practical implications on the associated decision outcomes. However, the problem of imbalanced data distribution is fairly common in real-world scenarios, especially when target classes lack uniform distribution across multiple class levels [2]. Data set imbalances occur when major classes have more instances and minor classes have relatively fewer instances. The classification of data sets with imbalanced distributions is a major challenge that has not been fully solved even by advanced machine learning algorithms with mathematical model mapping and computational prediction capabilities for identifying embedded data patterns [3].

This paper develops multiple potential approaches based on algorithmic modification, feature selection, ensemble learning, cost-sensitive learning, and sample selection methods to address the challenges of imbalanced distribution in learning data sets.

### A. Production Statement

Class imbalance is the most occurring and potentially risky analytics issue, especially in the data mining of unstructured sets from healthcare systems and processes due to the high likelihood of some classes having larger sample sizes compared to others [4]. A significant number of the current data mining techniques are structurally designed to ignore misclassification risks on minor samples while focusing on the classification of major samples. The accuracy of data classification techniques is impeded by factors such as data imbalances coupled with uneven distribution and sample size differences from one class to another. As a result, traditional classification algorithms are highly unreliable and unsuitable due to high risks of bias and inaccuracy. This explains the need to determine and test whether a data classification model based on machine learning ensemble is capable of delivering comparatively higher levels of accuracy [5].

### B. Research Questions

This research seeks to answer the following questions;

- 1) Can the implementation of machine learning ensemble model to data classification improve the classification of imbalanced data sets for prostate cancer management?
- 2) Is the application of resampling techniques based on machine learning reliable in optimizing and improving classification accuracy in imbalanced data sets for prostate cancer management?

This research paper is organized in sections including a review of recently published literature on classifiers and prostate cancer for comparisons with related studies in both fields in Section II, a detailed description of the experimental procedure, methodology, imputation process, and the general set up in Section III, and the evaluation of experimental results in Section IV. Finally, Section V of this research paper discusses conclusions based on the experimental results and provides recommendations for future studies.

## II. LITERATURE REVIEW

This section provides a conceptual description of data mining with relation to techniques such as ensemble learning and resampling to investigate the implications of data classification accuracy on the management of prostate cancer, including a review of recently published literature on classifiers and prostate cancer for comparisons with related studies in both fields.

### A. Prostate Cancer

According to 2021 prevalence statistics by the American Cancer Society, prostate cancer is the second most prevalence type cancer after skin cancer among men in the United States with approximately 248,530 new reported cases and about 34,130 deaths [6]. Data further shows that one in every 8 men develops prostate cancer, especially among adults aged above

65 of African ethnicity. Prostate cancer is ranked as having the second highest death rate from lung cancer in American males. Statistical estimates suggest that in a sample population of 41, one man dies of prostate cancer [6]. In addition to age, other risk factors for prostate cancer in men include family history through genetic inheritance, ethnicity (60% more risk among blacks), and lifestyle factors such as diet, smoking, and level of physical activity [6]. Early detection of prostate cancer is linked to significantly higher chances of survival and longevity. Studies suggest that timely detection of prostate cancer plays a significant role in the effectiveness of treatment interventions hence the need for various interventions to promote the identification and detection of early symptoms.

### B. Data Mining Process

Data mining techniques are applied used to extract trends and patterns through the Knowledge Data Discovery process (KDD) [7]. The extraction of patterns among multiple variables depends on data mining techniques, which may be predictive or descriptive. Predictive data mining methods provide a generalized description of the data attributes while predictive data mining uses historical data to make accurate trend forecast [8].

Data Mining software are designed analyze data on the basis of parameters such as sequence analysis (a pattern in which events are interdependent), degree of association (where events defined by the datasets are interconnected), clustering (where data with identical patterns are grouped), and classification (where predefined variables are used to identify new patterns) [9].

### C. Data Mining Techniques

The flow diagram shown in Fig. 1 provides a description of various techniques for data mining and retrieval based on regression, classification, clustering, and association [10].

### D. Classification Techniques

The classification approach to data mining in healthcare entails predicting and grouping a data set in sample class categories [11]. This provides important insights for the identification of unique disease patterns that associate certain risk factors to a patient population through supervised learning [12]. Binary classification is a technique where the risk factors are classified as either 'high' or 'low' while multiclass technique involves more than two classes for example 'high', 'medium', or 'low risks' [8]. The data is further divided into classes; training and testing datasets, which are used to predict the possible outcomes from a historical event.

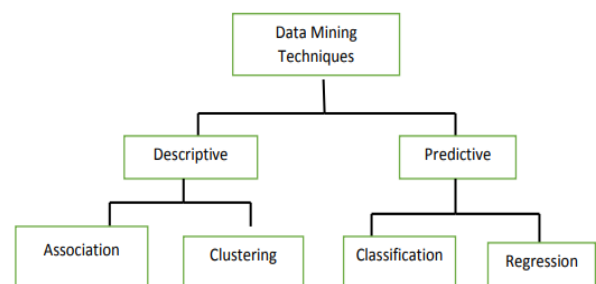

Fig. 1. A Flow Diagram Illustration of Data Mining Techniques.

1) *Decision tree*: Decision trees are used as classifier representations and are constructed using data to solve research problems such that attribute tests are denoted by non-leaf nodes and test outcomes denoted by branches while leaf nodes are assigned particular class levels [8]. Decision tree analysis is used by researchers to determine conditional probabilities for optimal decision making and class separation based on information gain. In the healthcare field, decision trees are used in the classification discrete values due to the ability to process nominal and numeric attributes while adjusting missing data values.

2) *Support Vector Machine (SVM)*: Support vector machine is an advanced classification algorithm for linear and non-linear data sets. It is applied in the transformation of original training data to higher dimensions at which an optimal hyperplane that separates class instances can be determined. Support and marginal vectors provide a framework for determining the hyperplane in SVM subject to the kernel metric  $C = J$  [13].

3) *Meta learning classifier*: This is a classification approach in which historical data is used as a learning set using algorithms such as the random subspace, adaboost, and bagging. The adaboost algorithm is applied to improving the classification accuracy by performing multiple iterations to cluster weak learning algorithms and modifying the accuracy parameters, especially in imbalanced or misclassified sets. Adaboost algorithm is implemented as shown in Fig. 2 [14].

The bagging algorithm is implemented through bootstrap aggregation, which involves deriving base classifiers from the decision tree. Bootstrap samples  $D_1, D_2, \dots, D_n$  are selected from a data set  $D$  provide the base classifiers  $C_1, C_2, \dots, C_n$  [15]. Supposing that an optimal number of votes are assigned to a class for randomly selected labels, then the algorithm extracts training object and classifier sets for bootstrapping after which an integration process based on majority voting takes place [16]. The implementation procedure for the bagging algorithm is illustrated in Fig. 3.

Ensemble learning technique describes a process in which multiple classifiers are trained to generate decision insights based on different classifiers through random subspace, bagging, and boosting approaches for increased performance [17]. The most common ensemble learning approaches include weighted averages, majority voting, and simple averages. Ensemble techniques combines multiple classifiers in determining the optimal classification model from different sub-models comprising of a base classifier layer and meta-classifier layers, which make accurate predictions [17].

Fig. 2. The Implementation Stages of Adaboost Algorithm.

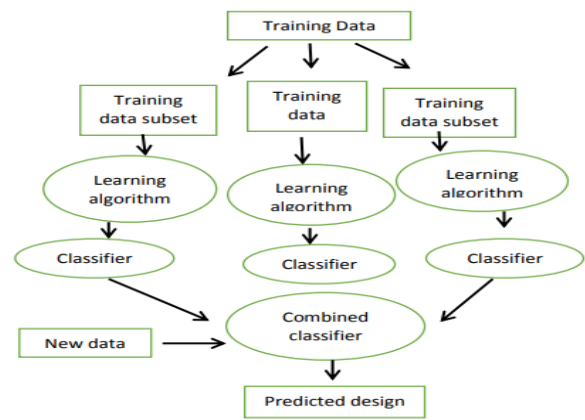

Fig. 3. The Implementation Stages of Bagging Algorithm Ensemble Learning [15].

4) *Attribute subset selection*: Attribute selection techniques play a significant role of data reduction for more efficient analysis in the data mining process. When data sets have many attributes, attribute selection is used to determine those that align to the cost of data analysis and utility for the easier discovery of patterns. Filter and wrapping categorization methods are used in evaluate the estimation accuracy of the learning algorithm [18].

5) *Resampling, oversampling, and under sampling method*: Data mining techniques are applied in healthcare to identify emerging trends from unstructured data sets. Resampling methods combine multiple approaches, which include the Random-oversampling of minor data classes, random oversampling of major classes hence providing solutions to sample distribution problems. Under-sampling removes data imbalances through the random elimination of major classes while oversampling achieves the same objective by replicating minor classes [19].

### III. METHODOLOGY

This paper utilizes an integrated methodological framework for literature review, dataset extract, and pre-processing to prepare it for analysis. The primary requirements obtained for this project included the datasets, relevant tools for pre-processing to identify the missing values, models for attribute selection and cross validation, data resembling framework, and intelligent algorithms for base classification. Additionally, the ensemble model and meta-learning algorithms were acquired in preparation for performance evaluation by embedding feature selecting capabilities into the classification model.

#### A. Dataset Description and Data Transformation

The data used for this study was obtained from the prostate cancer unit at Mayo Clinic, Rochester from a sample population of 1144 patients whose attributes such as age, size of tumor, Node-caps, degree of malignancy, metastasis, and class were recorded. Data imbalances were detected in 808 zero reoccurrences and 336 recurrences as shown in the Table I.

TABLE I. DATASET DESCRIPTION

Attribute	Description	Attribute Type
Tumor	Swollen prostates	Numeric
Age	Age of the patient	Numeric
Node	Absence or presence of node	Nominal
Metastasis	Tumor spread throughout the body	Nominal
Class	Recurrence of risk factors	Nominal
Degree of malignancy	Stage of cancer development	Numeric

WEKA open source software was selected to perform the data mining processes in this study. This tool has integrated data mining capabilities for clustering, regression analysis, classification, pre-processing, and visualization [20]. Pre-processing was performed to ensure that the attribute types of each data class was either nominal or numeric and all missing values replaced with the computed average. Imbalance problems in the dataset were resolved through resampling techniques and the attributes were selected through a dimensionality reduction technique with optimal gain ratio.

### B. Classification Algorithms Selection

The classifier algorithms selected for data mining in this study include J48, Neural Networks, Rep Trees, and SVM as the base classifiers, and meta-classifiers such as random subspace, boosting, and bagging, which were used in the building of classifier models.

1) *Decisions tree J48 algorithm*: The basic algorithm involved processes such as the construction of decision trees using the top-down divide-and-conquer approach with root training examples based on the categorical classification of attributes [21]. Recursive partitioning of the heuristic measures was implemented under conditions that all samples are assigned to the same classes and leaf classification based majority voting for all samples [22].

2) *Neural network algorithm*: The data input is embedded simultaneously into input layer after which it is weighted and adopted to a hidden layer, which is usually arbitrary. The last hidden layer contains weighted outputs which form the output layer, which produce predictive insights about the network patterns [20]. A feed-forward approach is applied to the network such that weight cycles in the input or output units are not returned to their previous layer.

3) *Rep tree algorithm*: This algorithm prunes the decision tree to allow the re-generation of the initial tree with minimal error. The data instances are segmented into multiple units such that set leaf can be assigned the lowest number of instances [23].

4) *SVM algorithm*: A relatively new classification method for both linear and nonlinear data, It uses a nonlinear mapping to transform the original training data into a higher dimension [24].

With the new dimension, it searches for the linear optimal separating hyperplane (i.e. “decision boundary”).

With an appropriate nonlinear mapping to a sufficiently high dimension, data from two classes can always be separated by a hyperplane.

SVM finds this hyperplane using support vectors (“essential” training tuples) and margins (defined by the support vectors).

5) *Bagging algorithm*: This algorithm classifies datasets into training and testing categories. Multiple training sets are generated and replaced in iterative sequences to reduce the likelihood of over-fitting and control variance.

6) *Boosting algorithm*: The implementation of this algorithm follows an iterative procedure for adaptive classification of training datasets, especially the misclassified sets. The algorithm assigns equal weights to the initial records  $N$  and performs automatic adjustments unit weights are increased in the wrongly classified datasets and increased in the accurately classified data sets [25].

7) *Random subspace algorithm*

Repeat for  $b = 1, 2, \dots, B$ .

Choose an  $r$ -dimensional random subspace  $b$  from the original  $p$ -dimensional feature space  $X$ .

Build a classifier  $C_b(x)$  (with a decision boundary  $C_b(x) = 0$ ) in  $b$ .

Aggregate classifiers  $C_b(x), b = 1, 2, \dots, B$ , by majority voting for the final decision. [26].

### C. Ensemble Learning

Ensemble model was applied to a combination of classifiers to determine the point at which classification performance is optimal. Ensemble learning model is composed of the base classifier and meta-classifier layers which receive and analyze prediction inputs to generate the desired output.

### D. Evaluation Approach and Techniques

The ensemble model is utilized to classify prostate cancer data using combined sub-classifiers to improve performance and accuracy. Factors such as the relative accuracy of measures, degree of training and simulation errors, and classifier performance are used to validate the model [27]. Recall and precision measures are used to determine the accuracy of classification techniques [28]. Additionally, each classifier is evaluated on the basis of computation time matrix, which shows the rate at which algorithms make correct and incorrect predictions compared to the actual values defined in the dataset [29]. The evaluation of metrics accuracy is illustrated in the Table II.

TABLE II. EVALUATION OF CONFUSION METRICS ACCURACY

	Positive Prediction Class	Negative Prediction Class
Real Class Positive	True Positive	False Negative
Real Class Negative	False Positive	True Negative

True Positive: Accurate classification of recurrence instances.

True negative: Inaccurate classification of no-recurrence instances.

False positive: Inaccurate classification of no recurrence instances as recurrent instances.

False negative: Inaccurate classification of recurrence instances no-recurrence instances.

In order to get TP rate, FP rate, Precision, Recall, F-Measure, Accuracy were used in this research as follows:

1) True Positive (TP) rates (sensitivity/recall) – is the proportion of the actual recurrence (or no recurrence) cases correctly classified.

$$TP \text{ (recurrence)} = TP / (TP + FN)$$

$$TP \text{ (no recurrence)} = TN / (TN + FP)$$

2) False Positive (FP) rates (1-specificity/false alarms) – proportion of actual no recurrence (or recurrence) cases misclassified.

$$FP \text{ (recurrence)} = FP / (FP + TN)$$

$$FP \text{ (no recurrence)} = FN / (FN + TP)$$

3) Precision – proportion of predicted recurrence (or no recurrence) cases that were correct classified.

$$\text{Precision (recurrence)} = TP / (TP + FP)$$

$$\text{Precision (no recurrence)} = TN / (FN + TN)$$

4) Recall–Proportion of predicted recurrence (or no recurrence) cases that were correct classified.

$$\text{Recall} = TP / (TP + FN)$$

5) F—one of the performance measures that is used to retrieve data:

$$F\text{-measure} = 2 \times \text{Precision} \times \text{Recall} / (\text{Precision} + \text{Recall}) = 2 \times TP / (2 \times TP + FP + FN)$$

6) Accuracy – proportion of the total predictions that was correct.

$$\text{Accuracy} = TP + TN / (TP + TN + FP + FN). [30]$$

### E. Receiver Operation Characteristic (ROC) Curve

ROC curves are used in the summarization of classifier performance based on the analysis of error rates involving false positives and true positives. Acceptable performance metrics are defined by the area under curve and represents the optimal decision boundaries for measuring the estimated costs of instance misclassification [31].

## IV. EXPERIMENTAL PROCEDURES AND RESULTS

This section discusses the experimental procedures involving base classifiers with selected attributes, without selected attributes and resampling method in the first experiment while the second involved meta classifiers with

selected attributes, without selected attributes and resampling method.

### A. Dataset

The dataset used for these experiments was obtained from the prostate cancer department at Mayo Clinic. The instances are defined by the attributes defined in the methodology section. The data was pre-processed and analyzed using WEKA software. The table shown in Fig. 4 shows how the dataset appeared after preparation using the software.

A	B	C	D	E	F	G	H	I	J
age	tumor-size	node-cap	deg-malign	breast	Metastasi	irradiat	Class		
29	3.6	yes		3 R	yes	no	recurrence-events		
49	3	no		1 R	no	no	no-recurrence-events		
53	4.8	no		2 L	yes	no	recurrence-events		
26	1.6	yes		3 R	yes	yes	no-recurrence-events		
40	1.8	yes		2 L	yes	no	recurrence-events

26	2.7	no		3 L	no	no	no-recurrence-events		
34	2.1	no		1 L	no	no	recurrence-events		
26	2.3	no		2 R	no	yes	no-recurrence-events		

Fig. 4. Sample of Data After Preparing.

### B. First Experiments and Results

The first experiment involving base classifiers was conducted to investigate the performance of different algorithms involving imbalanced prostate cancer data sets. The algorithms were applied to data through sampling techniques, without attribute selection, and with attribute selection.

1) *Result of support vector machine:* The implementation of SVM algorithm to data classification without attribute selection had a performance accuracy of 70.63% within duration of 0.15 seconds, 0.3 mean absolute error, kappa statistic 0, relative absolute error 70.8%, and 118.99% root relative squared error as shown in the Fig. 5.

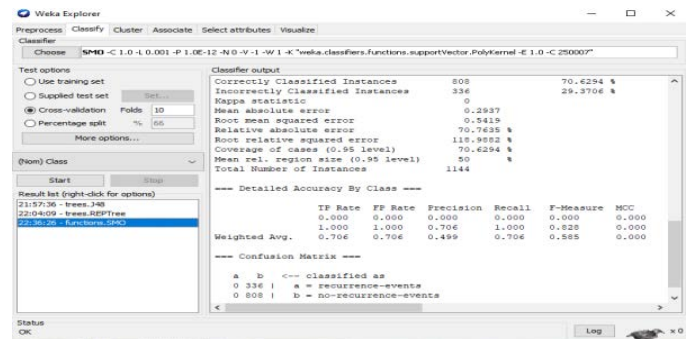

Fig. 5. Result of Classification Model using SVM without Attribute Selection.

The performance outcomes of other base classifier algorithms are shown in the Table III.

TABLE III. RESULTS OF A BASE CLASSIFIER ALGORITHMS WITHOUT ATTRIBUTE SELECTION

Evaluation Criteria	Classifier			
	J48	SVM	ANN	Rep Tree
Duration (seconds)	0.12	0.15	1.54	0.06
Correct classification	799	808	771	792
Incorrect classification	345	336	373	352
Percentage Accuracy	69.8%	70.63%	67.39%	67.39%

The experimental results of algorithm implementation of base classifiers with attribute selection are shown in the Table IV.

TABLE IV. RESULTS OF A BASE CLASSIFIER ALGORITHMS WITH ATTRIBUTE SELECTION

Evaluation Criteria	Classifier (With ranker and gain ratio)			
	J48	SVM	ANN	Rep Tree
Duration (seconds)	0	0.14	1.24	0.06
Correct classification	799	808	771	792
Incorrect classification	345	336	373	352
Percentage Accuracy	69.8%	70.63%	67.39%	69.23%

The performance of experimental parameters was evaluated based on criteria such as the mean errors and kappa statistic is shown in the Table V.

TABLE V. SIMULATION RESULTS

Evaluation Criteria	Classifier (With Ranker and Gain Ratio)			
	J48	SVM	ANN	Rep Tree
Kappa Statistic	0.0038	0	0.035	0.024
Mean Absolute error	0.414	0.294	0.411	0.042
Root mean squared error	0.462	0.542	0.472	0.472
Relative absolute squared error	99.78%	70.76%	99.06%	100.39%
Root relative squared error	101.42%	118.98%	103.63%	103.67%

2) *Experiment using rep tree with resampling method:* Resampling technique was applied on the base classifiers and implemented on decision tree rep to obtain accuracy scores in the data classification. The implementation results for each classifier algorithm are shown the Table VI.

### C. Second Experiment and Results

The second experiment involved the analysis of performance classification scores on meta learning algorithms with and without attribute selection. The relative accuracy values are shown in the Table VII and Table VIII.

1) *Evaluation of algorithms:* The algorithms were further evaluated using criteria such as the mean errors and Kappa statistics and the results are shown in the Table IX.

TABLE VI. REP TREE WITH RESAMPLING METHOD

Evaluation Criteria	Classifier (With Resampling)			
	J48	SVM	ANN	Rep Tree
Duration (seconds)	0	0.06	0.93	0.01
Correct classification	799	808	771	792
Incorrect classification	345	336	373	352
Percentage Accuracy	69.84%	70.63%	71.24%	77.27%

TABLE VII. RESULTS OF META CLASSIFIERS WITHOUT ATTRIBUTE SELECTION

Evaluation Criteria	Classifier		
	Bagging	Boosting	Random Subspace
Duration (seconds)	0.58	0.47	0.2
Correct classification	795	808	807
Incorrect classification	349	336	337
Percentage Accuracy	64.9%	70.63%	70.54%

TABLE VIII. RESULTS OF META CLASSIFIERS WITH ATTRIBUTE SELECTION

Evaluation Criteria	Classifier		
	Bagging	Boosting	Random Subspace
Duration (seconds)	0.27	0.17	0.13
Correct classification	795	808	807
Incorrect classification	349	336	337
Percentage Accuracy	64.9%	70.63%	70.54%

TABLE IX. SIMULATION RESULTS

Evaluation Criteria	Classifier		
	Bagging	Boosting	Random Subspace
Kappa Statistic	0.045	0	-0.001
Mean Absolute Error	0.414	0.411	0.413
Root mean squared error	0.4665	0.4555	0.4553
Relative Absolute error	99.7%	98.95%	99.54%
Root relative squared error	102.42%	100.01%	99.96%

## V. RESULTS AND DISCUSSION

The experimental results suggest that a combination of boosting and bagging classification algorithms achieve a higher level of accuracy when resampling is applied to SVM and rep tree. Resampling method effectively improve the accuracy of ensemble learning model when applied to imbalanced datasets on prostate cancer [32]. When each the performance of each algorithm is analyzed after resampling, algorithms with single classifiers such as SVM, neural network, rep, and J48 are more accurate and require less computational time. The experimental outcomes of all trials suggest that the implementation of ensemble learning model yields higher classification accuracy

on J48 tree after resampling compared to before resampling imbalanced datasets. The relative performance of each base classifier on the ensemble model under different conditions of resampling is shown in the Fig. 6.

Fig. 6. Comparative Graph for different base Classifiers with different Evaluation Accuracy of Ensemble Model.

## VI. CONCLUSION

The objective of this study was to develop a classification model for imbalanced prostate cancer datasets from Mayo Clinic, Rochester. The implementation of accurate classification approaches is important in the early detection and prediction of likelihood of recurrence or no-recurrence of risk factors. The experimental results led to the conclusion that the application of ensemble learning algorithm on resampled data sets provides highly accurate classification results on single classifier J48. The study further suggests that gain ratio and ranker techniques are highly effective for attribute selection in the analysis of prostate cancer data. The lowest error rate and optimal performance accuracy in the classification of imbalanced prostate cancer data is achieved using when Adaboost algorithm is combined with single classifier J48.

The following recommendations were developed based on the empirical results obtained from this study; Consider larger datasets to improve the accuracy of results, implement multiple evaluation techniques, and formulate alternative prediction models and algorithms to allow for the comparative analysis of classification results for imbalanced data.

# Dynamic Deployment of Road Side Units for Reliable Connectivity in Internet of Vehicles

Abdulwahab Ali Almazroi, Muhammad Ahsan Qureshi

University of Jeddah, College of Computing and Information Technology at Khulais  
Department of Information Technology  
Jeddah, Saudi Arabia

**Abstract**—Internet of vehicles (IoV) promises to provide ubiquitous information exchange among moving vehicles and reliable connectivity to the internet. Therefore, IoV is becoming more and more popular as the number of connected vehicles is increasing. However, the existing vehicular communication infrastructure cannot guarantee reliable connectivity because all-time information exchange for every travelling vehicle is not assured due to lack of required number of roadside units (RSUs) especially along the intercity highways. This study is aimed towards exploring the use of cost-effective dynamic deployment of RSUs based upon the road traffic density and by ensuring the Line of Sight (LOS) among RSUs and Cellular Network Antennas. The unmanned aerial vehicles (UAVs) have a potential to serve as economical dynamic RSUs. Therefore, the use of UAVs along the roadside for providing reliable and ubiquitous information exchange among vehicles is proposed. The UAVs will be deployed along the roadside and their respective placement will be changed dynamically based upon the current traffic density in order to ensure the all-time connectivity with the travelling vehicles and the other UAVs/Cellular Network antennas. The reliability of the proposed network will be tested in terms of signal strength and packet delivery ratio (PDR) using the simulation.

**Keywords**—VANET; Roadside unit; internet of vehicle; social internet of vehicles; unmanned aerial vehicle; line of sight vehicular communication

## I. INTRODUCTION

Vehicular Ad Hoc Networks (VANETs) [1] provide vehicle to infrastructure (V2I) and vehicle to vehicle (V2V) communication in order to deliver extensive range of applications spanning from infotainment to safety related applications [2, 3]. VANET is gradually evolving into Internet of Vehicles (IoV) that provides internet access to the travelling vehicles in addition to the inter-vehicular communication [4, 5]. The popularity of IoV is increasing rapidly due to its huge potential in terms of connectivity and a wide range of advantageous applications [6]. The modern vehicular communication also offers accident detection [7]. The communication in VANETs depends on the Roadside Unit (RSU) [8]. However, this massive connectivity requires optimal deployment of communication infrastructure; in which roadside units (RSUs) are important component. RSUs provide the essential link among the vehicles and other infrastructure components to fulfill the connectivity challenges of IoV [9]. RSUs connect the vehicles to the other vehicles which are outside their radio range and also with the infrastructure

components in order to provide internet access to the vehicles on the road [10].

A comprehensive strategy for installation of RSUs is proposed in [10]. In [11], RSUs are placed by utilizing geometrical methods to improve the LOS among communicating vehicle in modern road infrastructure units. Another scheme introduces deployment of RSUs efficiently in modern roads using approximation algorithm [12]. A similar approach is used in [13]. Most of the existing studies [14-16] focus on the optimized static placement of RSUs by using innovative algorithms to assist vehicular communication. On the other hand, the recent advancements in unmanned aerial vehicles (UAVs) technology can assist the vehicular communication by solving the problem of ubiquitous internet connectivity and all-time inter-vehicle communication. Therefore, a few recent studies [17, 18] tend to exploit the use of UAVs (drones)[19]as relays to assist vehicular communication where the road traffic is dense by improving the performance and reducing the network delay. UAVs are becoming efficient, lightweight and economical gradually [19, 20]. A few studies advocate the use of UAVs to assist vehicular communication; however, the focus is to improve the performance and reduce the network delay in dense environment [21]. However, the notion of modern IoV requires ubiquitous internet connectivity and all-time inter-vehicle communication especially when traveling on highways where the road traffic density is sparse; therefore, internet connectivity and vehicular communication are compromised especially in highway environment [12]. Therefore, the existing studies lack in the exploitation of UAVs to serve as potential dynamic RSU especially for the highway (sparse) environment as the RSUs have limited converge area that results in significant degradation in communication. Currently, static placement of RSUs is in practice. The placement of a RSU can be changed accordingly with change in the road traffic density by ensuring the Line of Sight (LOS) among RSUs and Cellular Network Antennas to overcome the limited coverage area issue of RSUs.

The goal of this study is to address the problem of all-time inter-vehicle communication and ubiquitous internet connectivity. Therefore, the aim of current work is to investigate the use of cost-effective dynamic deployment of RSUs based upon the road traffic density and by ensuring the Line of Sight (LOS) among RSUs and Cellular Network Antennas. The study targets the UAVs for economical dynamic deployment of RSUs due to their efficient, lightweight and

economical nature. Therefore, the use of UAVs along the roadside for providing reliable and ubiquitous information exchange among vehicles is proposed. Consequently, the current study proposes dynamic deployment and placement of UAVs along the roadside based upon the current traffic density. As a result, the proposed method ensures all-time connectivity with the travelling vehicles and the other UAVs/Cellular Network antennas.

To achieve the goal of the study, the objectives of the research are as follows:

Objective 1: To study state-of-the-art in the domain of deployment of RSUs.

Objective 2: To propose dynamic deployment of RSUs based upon road traffic density using UAVs.

Objective 3: To evaluate the proposed solution in terms of connectivity index.

Objective 4: To compare the proposed framework with and without dynamic deployments of RSUs existing solution(s).

The current study follows a research design consisting of five main steps to achieve the objectives of the work. In the first step, a review of state-of-the-art studies in roadside unit deployment is performed. Step 2 focuses on comparison of existing energy efficiency techniques. Developing a cost effective dynamic RSU deployment strategy based on efficient utilization of UAVs is the target of step 3. Evaluation of the proposed solution and comparison of proposed solution with the existing solutions are part of step 4 and 5.

The rest of the paper is organized as follows: Section 2 presents state-of-the-art studies in roadside unit deployment. This is then followed by Section 3, which describes cost effective dynamic RSU deployment strategy. The evaluation of proposed strategy is explained in Section 4. Section 5 provides a comparison between proposed strategy and existing work. The research implications of the study are highlighted in Section 6 and finally, Section 7 concludes the paper.

## II. RELATED WORK

Multiple studies were conducted in the past for the efficient deployment of RSUs in VANETs and IoVs. This subsection reviews a few important studies in the domain of RSUs deployment.

Some research utilized artificial intelligence technology to address various problems of IoV such as energy management, traffic monitoring and management, resource management, big data processing, and communication problem [8, 22, 23]. In [24], the authors used reinforcement learning approach called centralized Q-learning for energy efficiency and optimization in IoV. Similarly, [25]fuzzy quality of service is utilized for optimization of energy in IoV. The author in [22] focused on multi-media communication in IoV. On the other hand, UAVs technology has shown enormous potential to provide efficient solutions to diverse problems belonging to different fields of life due to its cost effective, lightweight and efficient nature. Currently, UAVs have wide range of applications in different domains like smart cities, traffic management, military, smart agriculture, smart healthcare, smart houses and industry [26-

29]. In smart cities, UAVs are providing many services such as traffic management, environmental monitoring, pollution monitoring, and security control [27]. The solutions provided by UAVs to traffic management include [28] that proposes a system for smart traffic monitoring to overcome limitations of existing system. Due to the recent advancements in UAVs and the cost-effective nature of UAVs, the study aims to utilize UAVs for providing all-time inter-vehicle communication and ubiquitous internet connectivity by dynamic deployment of RSUs based upon the road traffic density and by ensuring the Line of Sight (LOS) among RSUs and Cellular Network Antennas.

A mechanism to maintain line of sight (LOS) among the travelling vehicles was proposed in [11]. The study considered modern road infrastructures such as flyovers, underpass, curved roads and tunnels. The study utilizes geometrical concepts for the efficient deployment of RSUs, signal enhancers and signal reflectors to maintain LOS among the travelling vehicles. The results of the study were promising as this concept provides reliable connectivity due to the maintenance of LOS among travelling vehicles. However, this study does not consider the most important highway environment where the connectivity is compromised due to coarse density of vehicles.

A cooperative architecture for Intelligent Transportation System (ITS) [30] based upon distributed RSUs was presented in [31]. Using this architecture, the data from all the sensors was collected in a distributed fashion without the intervention of a central control system. It defines the role of each individual network element in the controlling the sensors and disseminating the information. Real-world experiments were also conducted to prove the correctness of idea. However, this study does not focus on the reliability issues of information dissemination as no discussion is presented on the efficient deployment of RSUs.

In an attempt to identify the optimal number of RSUs in a highway environment, a research was conducted that analyzed the delay of message dissemination in VANETs [32]. Based upon the analysis result, the RSUs were deployed at optimal distances from each other. The experimental results also verify optimal RSUs placement. However, this study does not consider the dynamic RSU deployment in VANET environment.

Another attempt was carried out in order to optimally deploy the RSUs using a novel concept of Minimal Mobility Pattern Coverage (MPC) [14]. Firstly, the mobility of travelling vehicle is predicted from a trace file. Secondly, based upon the extracted information, the optimal placement of RSUs is advocated by extracting minimal traversal of a hyper-graph. The authors claim that the experiment results validate the proposed research. However, this study is yet not verified at large scale. Furthermore, the deployment of RSUs is based upon predicted mobility pattern. Therefore any change in the mobility pattern will negatively affect the optimal placement of RSUs.

In a relatively recent study [33], an algorithmic approach towards optimal placement of one-dimensional RSU is presented. A strategy called "dynamic limiting" is first used for

pruning the search space. A greedy algorithm named “OptDynLim” is proposed that optimally identifies the placement of RSU. The results of the study are formally verified and validated with the help of simulations. However, this study only considers signal dimension RSU deployment problem and don not focuses on general RSU deployment.

Another study [34] exists in the literature that focuses collectively on the 2-D RSU deployment and service task assignment in the domain of IoV. A linear programming based clustering algorithm was proposed that considers the delay requirements and the task assignment. The comparison of the algorithmic output with the optimal solution proved the workability of the proposed solution. However, this study lacks in considering the changing traffic density requirement and dynamic deployment of RSUs.

A study [35] presented a state-of-the-art review of the applicability of UAVs in modern transportation system in smart city environment. This study has highlighted the potential uses of UAVs in ITS and the challenges that may encountered during the implementation. The potential applications include the accident reporting and police eye, along with the flying road side unit. Therefore, this study can also serve as a pivotal point towards the dynamic RSU deployment.

### III. PROPOSED FRAMEWORK

In this section, the proposed solution is discussed that provide efficient, light weight, and cost effective method to provide all-time inter-vehicle communication and ubiquitous internet connectivity by dynamic deployment of RSUs based on UAVs. To achieve the objective of the work, first a mathematical model is formulated, then based on the proposed mathematical model, an extensive simulation is carried out to obtained the result. The proposed solution place RSUs dynamically based upon the road traffic density and by ensuring the Line of Sight (LOS) among RSUs and Cellular Network Antennas. In the proposed solution, a road is divided into n segments and a road segment has a specific number of poles. Mostly, these poles are part of infrastructure. One UAV is assigned to every road segment. Based on the traffic density, the UAVs containing RSU can change its location dynamically from one pole to another in the same road segment. This solution is mathematically represented below:

The mathematical model of proposed solution is described below:

$$\text{Let } t \in P \text{ where } p = \{p_1, p_2 \dots p_n\} \tag{1}$$

Here p represents poles in a road segment R.

$$\text{Let } D = \{d_1, d_2, \dots d_m\} \text{ where } m < n \tag{2}$$

Here, D describes the number of drones. It is to be noted that the number of drones is less than the number of poles in a road segment R.

$$R = \{(p_1, p_2), (p_2, p_3), \dots (p_{n-1}, p_n)\} \tag{3}$$

$C_i$  represents number of vehicles in any R at time  $T_i$  and  $d_T$  is the density threshold. For no change in the scenario,  $C_i < d_T$

$$D = \forall d \in D \text{ there exists } \exists p \in P \mid (d, p) \tag{4}$$

Otherwise,

$$D = \forall d_i \in D \text{ there exists } \exists P_i \in P \mid (d_i, p_{i+1}) C_i \geq d_T \tag{5}$$

At time  $T_1$ , D may have following values depicting that which particular drone is present at which pole at the moment.

$$D = \{(d_1, p_1), (d_2, p_4), \dots (d_m, p_{n-1})\} \tag{6}$$

### IV. EXPERIMENTAL SETUP

In the current research, three scenarios are selected for performing experimental results. The details of these scenarios are presented in Table I. For the scenario 1 and 2, M2 motorway of Pakistan, and Makkah-Madinah highway are selected, respectively. Khulais, urban area of Makkah province of Saudi Arabia is selected for urban scenario. The topologies of roads selected in our scenarios are imported to SUMO simulator by utilizing OpenStreetMap utility. A total of three dynamic RSUs are deployed with a range of one Km. The minimum and maximum vehicles for highway scenario 1 and 2 are same, which are, 1 and 50, respectively. However, due the different nature of urban scenario the minimum number of vehicles is 10 and the maximum number of vehicles is 60. Further, minimum and maximum communicating vehicles are same for highway scenario while urban scenario has different minimum and maximum vehicles as depicted in Table I. For both highway scenarios a three KM segment of road is selected. On the other hand, nine square KM segment is preferred for urban scenario. Fig. 1 depicted the highway scenario 1, i.e. M2 motorway of Pakistan. Urban scenario in SUMO is portrayed in Fig. 2 and Fig. 3 shows the urban scenario with running vehicles in SUMO.

TABLE I. DETAIL OF EXPERIMENTAL SETUP

Scenarios	Minimum Vehicles	Maximum Vehicles	Minimum Communicating Vehicles	Maximum Communicating Vehicles	Area	Selected Highways
Highway Scenario 1	1	50	1	14	3 KM Segment	M2 Motorway, Pakistan
Highway Scenario 2	1	50	1	14	3 KM Segment	Makkah-Madinah Highway, Saudi Arabia
Urban Scenario	10	60	4	17	9 Square KM	Khulais, Makkah, Saudi Arabia

Fig. 1. High Way Scenario.

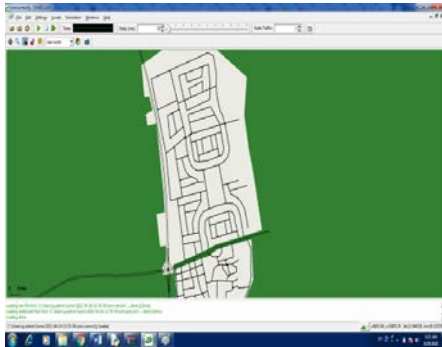

Fig. 2. Urban Scenario in SUMO.

Fig. 3. Urban Scenario with Running Vehicles.

## V. EXPERIMENTAL RESULTS

This section presents the results of connectivity index and percentage index for three selected scenarios.

Fig. 4, 5 and 6 described the connectivity index with dynamic deployment of RSUs for scenario 1, 2, and 3 respectively. The connectivity index elevates with the increased number of vehicles, however, important point to note here is, due to dynamic deployment, the connectivity index has raised 19% and 25%, respectively. Consequently, it is inferred that, with the deployment of RSUs dynamically, significant improvement in connectivity index is achieved resulting in enhanced vehicular communication. Correspondingly, connectivity index upgraded 13% in urban scenario supporting the previous inference. However, the boost in vehicular communication in urban scenario is less as compared to highway scenarios. Hence, it is concluded that the proposed dynamic deployment is more suitable to the highway scenarios as compared to urban scenario. Further, extensive research is required for the dynamic deployment of RSUs in urban scenario to take maximum advantage of the proposed deployment.

Fig. 4. Connectivity Index for Highway Scenario 1.

Fig. 5. Connectivity Index for Highway Scenario 2.

Fig. 6. Connectivity Index for Urban Scenario.

Fig. 7 exhibited the amplification in vehicular communication due to dynamic deployments of RSUs. A considerable escalation is attained in the all scenarios. For highway scenario 1 and 2, gain in connectivity is 19% and 25%, respectively. On the other hand, the gain connectivity is 13%. These results support the dynamic deployment of RSUs in highway scenarios as well as in urban scenarios. However, in urban scenarios, the connectivity gain can be enhanced by conducting further research as discussed earlier.

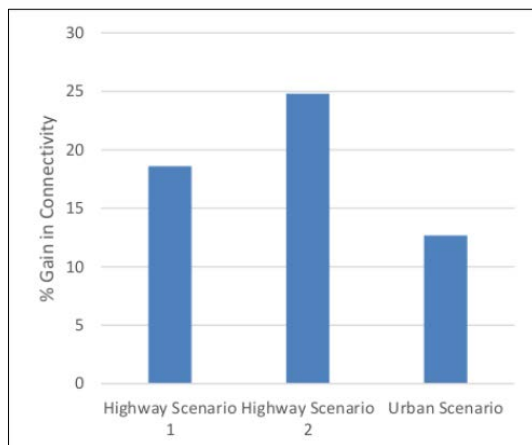

Fig. 7. % Gain in Connectivity of all Scenarios.

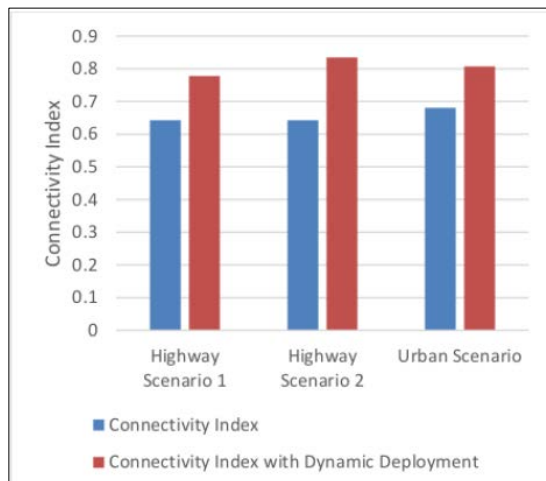

Fig. 8. Comparison of Connectivity Index with and without Dynamic Deployment for all Scenarios.

It is also important to validate the results to show the improvement in connectivity index due the proposed dynamic deployment of RSUs. For this purpose, the current work compares the connectivity index with and without dynamic deployment of RSUs for all scenarios. Fig. 8 illustrates this comparison. A superior connectivity index has achieved in all scenarios due to the deployment of RSUs dynamically. The highway scenario 2 obtained the highest connectivity index while the lowest connectivity index is associated with highway scenario 1 with the proposed method.

## VI. RESEARCH IMPLICATIONS

The findings of the studies can be beneficial to for scientific community. The findings can be utilized to design and develop new standards, applications, and protocols on the basis of the dynamic RSU deployment. It will provide a cost effective solution to the classic RSU deployment problem. Further, the implications of the findings of the study are twofold in scientific community perceptive; (i) the new standards, applications, and protocols in IoV and modern transportation domains will be evaluated considering the maximum reliability in message dissemination, and (ii) the cost deployment and maintenance of RSUs will be reduced. In the society betterment prospective, the results can be exploited in

multiple manners. In line with the vision 2030 of Saudi Arabia, the cost effective solution in modern transportation environment along the highways will be beneficial for the general public and transportation companies in terms of reliability of information exchange during the travel. Specially, the expected outcomes are advantageous for huge traffic movement during the Hajj and Umrah seasons.

## VII. CONCLUSION, FUTURE WORK AND LIMITATIONS

Currently, IoV provides Internet connectivity between moving vehicles; however, all-time connectivity among moving vehicles is not assured due to the limited number of RSUs. Consequently, busy intercity highways are facing a problem of limited connectivity to the Internet resulting in reduced information exchange. To address this limitation, the current study proposes, mathematically modeled, experimented, and evaluated a scheme to dynamically place RSUs in highways and urban scenarios. The placement of RSUs is based on road traffic density by ensuring line of sight among RSU and Cellular Network Antennas. The proposed scheme is evaluated based on connectivity index that describes the communication among vehicles. The experimental results for three scenarios: highway scenario 1, highway scenario 2, and urban scenario highlighted the superiority of proposed scheme in terms of connectivity index. The connectivity index is considerably higher in the proposed scheme for all of the scenarios resulting in increased vehicular communication. Thus, addressing the problem of vehicular communication in IoV. The study has some limitations too. First, the proposed scheme is evaluated on small scale with three scenarios. Second, for the large scale evaluation, only simulation results are presented. Third, real-world evaluation is not executed. Therefore, future directions of this work include real-world evaluation of the scheme. Moreover, more scenarios from different geographical region will be select to evaluate the proposed scheme.

## ACKNOWLEDGMENT

This work was funded by the Deanship of Scientific Research (DSR), University of Jeddah, Jeddah, under grant No. (UJ-20-093-DR)The authors, therefore, acknowledge with thanks DSR technical and financial support.

**Abstract**—This study aimed to determine an efficient framework that caters to the security and consumer satisfaction for digital wallet systems. A quantitative online survey was carried out to test whether the six factors (i.e., transaction speed, authentication, encryption mechanisms, software performance, privacy details, and information provided) positively or negatively impact customer satisfaction. This questionnaire was divided into two sections: the respondents' demographic data and a survey on security factors that influence customer satisfaction. The questionnaires were distributed to the National University of Malaysia's professors and students. A sample of 300 respondents undertook the survey. The survey results suggested that many respondents agreed that the stated security factors influenced their satisfaction when using digital wallets. Previous studies indicated that financial security, privacy, system security, cybercrime, and trust impact online purchase intention. The proposed framework in this research explicitly covers the security factors of the digital wallet. This study may help digital wallet providers understand the customer's perspective on digital wallet security aspects, therefore motivating providers to implement appropriately designed regulations that will attract customers to utilize digital wallet services. Formulating appropriate security regulations will generate long-term value, leading to greater digital wallet adoption rates.

**Keywords**—Cashless transaction; electronic payment; internet security; consumer satisfaction; e-commerce

## I. INTRODUCTION

A digital wallet platform allows individuals to perform electronic transactions using mobile devices, such as smartphones, computers, and other supporting devices. Digital wallets have multiple usages, including making purchases from websites or using mobile devices to make in-store transactions [1]. The current economy is transforming into a cashless economy where daily transactions are being performed using the digital wallet. Several e-commerce companies have developed digital wallet payment systems. The development of digitization through the internet has advanced the transition of globalization and payment systems from manual to online transactions. People have become more reliant on electronic money to perform transactions as a result [2].

The Malaysian government encourages people to go cashless and use digital wallets. A survey by Visa found that nearly half of Malaysians can live without cash. This study illustrated Malaysia's potential to evolve into a cashless society

[3]. The current advanced technologies make it easier for Malaysia to shift toward a cashless society. In support of Industry 4.0, Malaysia has taken significant initiatives to establish the status of a cashless society. According to FinTech News Malaysia's report, approximately 17% of the corporations in the Malaysian financial industry formed a sector to establish digital wallets [4]. Cashless transactions result in enhanced capability, transparency, and accountability [3].

Nevertheless, cybercrime cases still occur, and cases of internet security violations are frequent. Moreover, hackers and tricksters are prone to take advantage of such situations to damage companies and consumers [5]. Thus, customer satisfaction is greatly influenced by their perceptions of security and trust [6]. Customers in the e-banking industry are more advanced, knowledgeable, and demanding [7]. Companies and customers avoid e-commerce operations for several reasons, and security is one of the key reasons [8]. Therefore, security is a serious concern when performing financial transactions through digital transaction methods [9]. Moreover, electronic payment systems are currently facing many difficult hindrances posed by the internet. In comparison, the challenges faced by electronic payment systems are more complicated than the majority of internet security issues [10].

This work was supported by the Ministry of Higher Education Malaysia (FRGS/1/2018/ICT01/UKM/02/5) and Universiti Kebangsaan Malaysia (GUP-2020-060).

Financial services are extending their sector to include smartphones as electronic payment devices. Smartphones are popular banking, payment, budgeting, shopping, and stock trading applications for customers [11]. Due to the growth of the e-commerce industry, the electronic payment platform is becoming increasingly prominent and essential for smartphone users [12]. Smartphones and other electronic devices contain confidential information of their users, including transaction details and passwords. Consumers do not need to carry their wallets or purse while using digital wallets. However, they need to carry at least one electronic device, such as a smartphone or tablet. In the case of a stolen or lost device, the user risks losing personal and confidential information [13].

The digital wallet is still at its infancy stage in Malaysia as it is a newly introduced payment system. Electronic transactions are a safer mode for consumer payment, enabling

sellers to enhance their productivity and increase profits [14]. Electronic transactions are traceable, whereas cash transactions are not traceable. Hence, the electronic payment system is a secure way of performing transactions. However, according to the latest VMware Banking User, a 2020 study shows that nearly half or 46% of Malaysian consumers are uncertain of digital wallet protection and payment applications [15]. Consumers are concerned about privacy and security threats due to the fear of data fraud and spam [16]. Security and privacy impose a significant and positive impact on behavioral intention when using digital payment services [17]. Therefore, e-retailers should concentrate on improving consumers' protection, loyalty, and purchase intent. They should also be attentive to enhanced security when developing a consumer privacy policy [18]. Hence, the security factors have a significant impact on consumer satisfaction toward digital in Malaysia. Therefore, security factors that can affect Malaysian customer satisfaction are required to be evaluated thoroughly. Ali et al [19]. The author in proposed a framework for the security factors that influence consumers in online shopping in Malaysia. It contains five security factors, financial security, privacy, system security, cybercrime, trust, and customer satisfaction. However, the research failed to identify the specific security factors of the digital wallet.

Nevertheless, limited study has been undertaken to identify the specific digital wallet security factors affecting customer satisfaction in Malaysia. This research proposes a framework for security factors that influence consumer satisfaction in Malaysian digital wallet platforms. This model consists of six security factors: transaction speed, authentication, encryption mechanisms, software performance, privacy details, and information provided. This model is created after studying numerous previous studies from similar fields [19], [20], [29], [30], [21]–[28].

This research introduces security factors to the digital wallet industry in Malaysia that impact customer satisfaction. Besides, this research can assist policymakers of digital wallet applications to concentrate on key security factors and improve platform security while developing security regulations, resulting in a higher rate of consumer adoption. In addition, the research also attempted to study students' and professors' usage and understanding of Malaysia's available digital wallet platforms. The respondents' demographics, comprising both genders, were the students and professors in the National University of Malaysia. They have used the digital wallet services at least once for online purchases. Students between the ages of 18 to 25 were the majority of the respondents.

This research aimed to discover the numerous security concerns that may arise while using digital wallet services for electronic payments besides investigating whether the proposed security factors (i.e., transaction speed, authentication, encryption mechanisms, software performance, privacy details, and information provided) affect the consumer's decision when choosing digital wallet services. This study also aimed to identify variables that have a higher effect on customer satisfaction.

This paper is divided into seven sections. Section 1 presents the introduction and scope of this study, whereas Section 2

reviews previous research on similar topics. In Section 3, the framework and hypothesis of this study are discussed. The methods and analysis techniques of the study are presented in Section 4. Findings of the analysis, the study's limitations, and the conclusions are discussed in Section 5, Section 6, and Section 7, respectively.

## II. LITERATURE REVIEW

Digital wallet systems are developed to aid various functionalities. The functions of digital wallet systems are categorized into open digital wallets, semi-closed digital wallets, and closed digital wallet types. Mobile and wireless networking technology, such as smartphones, personal digital assistants (PDAs), and laptops, have eased customers' convenience in utilizing such devices to shop virtually via electronic transaction methods. Transactions are more accessible and transparent through this new method [31]. Nevertheless, several variables may impact the satisfaction of consumers toward electronic transactions. Security, privacy, confidence, and consistency significantly affect e-commerce consumers, among other factors [20]. Mobile perceived security risks determine the consumers' perception of security against conducting mobile transactions, especially the risk of losing important information, resulting in financial losses [32]. Customers' willingness to utilize mobile payment services is influenced by the ease of use, comparative advantage, clarity, and perceived protection.

Furthermore, prevalence and observability positively affect an individual's perception of security, whereas concerns about privacy threats negatively influence the perception [33]. Moreover, the continuous technological development and efforts to promote them are reasons for perceived security as one of the intentions to use digital wallets. Consumers would feel safer when using mobile payment if tools are available to protect the payment systems in unexpected incidences [34]. In an empirical study multiple variables were considered when studying consumer's perceived risk and their attitude toward online shopping in Malaysia. The researchers found that the consumer perceived risks negatively affect the consumer attitude, which positively and significantly affects online shopping behavior [35]. Content quality, peer influence, KOL influence, perceived interaction, effort expectation, and perceived trust all substantially impact users' intention to pay, and their tendency has an indirect impact on users' paying behavior [36].

Although the young generation's actual use of digital payments is driven by behavioral intention and promotional strategies, perceived risks are shown to have a negative effect [37]. Another empirical study asserted that customers were reluctant to use digital wallets when they assumed high perceived risk [11]. Moreover, the study also indicated that financial risks are one of the leading consumer perceived risks. Financial risks emerged as the most significant influence that adversely affects consumer attitude. One of the proposed ideas is to protect the consumers' personal information and decrease credit card fraud cases to minimize financial risks. Due to the risk factors, customers often opt-out from paying via their credit cards [35]. Many researchers concluded that security is a significant factor influencing customer satisfaction in online

shopping [38]–[40]. A study found that behavioral intention to use digital wallets is strongly and vitally associated with perceived utility, perceived ease of use, and privacy and protection [21]. According to Peikari [24], security statements and technical protection significantly impact customer loyalty in the e-commerce industry but did not find a substantial effect on privacy.

Nevertheless, Barry and Jan [22] indicated that privacy and security positively correlate with behavior intention. Consumers may feel vulnerable to digital wallet transactions due to a lack of privacy and security. Nizam et al. [8] conducted empirical research to monitor digital wallets implementation in Malaysia. According to the study's findings, the dependent variable (customer purchasing decision using the digital wallet) is positively linked to all independent variables (convenience, security, and cost-saving).

Furthermore, convenience has the maximum significant positive correlation of 0.624, whereas security showed the coefficient correlation of 0.4999 with customer buying decisions using digital wallets. Based on the analysis, it was concluded that security has a more significant positive association with digital wallets for customer purchase behavior. In addition, Razif et al. [23] conducted empirical research among Malaysian young adults between 18 and 30 years old. The study showed that several factors have a significant relationship with the acceptance of the digital wallet platform. The factors listed were behavioral intention, perceived privacy risk, perceived usefulness, trust, perceived overall risk, and perceived performance risk.

Another empirical study found that trust, security, and privacy are the main factors affecting adopting a digital wallet [25]. A survey conducted by Subaramaniam et al. [13] demonstrated that security risk problems limit the prospect of using the digital wallet in Malaysia. According to Li et al. [26], cloud computing, security, e-learning, and quality of service are four significant factors that affect customer satisfaction in e-banking services. In addition, another research suggested that trust and privacy have positively impacted behavioral intention to use mobile banking services [27]. Likewise, Putra and Sfenrianto [28] demonstrated that a good payment system's security factor and speed influenced customer satisfaction in the digital payment method. Oliveira et al. [29] suggested that the digital payment system's security and performance directly affect customer loyalty. The research also indicated that security has a significant impact on mobile banking adoption. Customers expect banks to improve their security mechanisms by providing transaction security and privacy protection, particularly over wireless networks [9]. The level of security provided by a third-party online payment provider influences customer satisfaction [41]. In addition, Tang et al. [42] found that service quality, perceived risk, perceived security, perceived simplicity of use, social influence, and compatibility all substantially impact on consumers' intention to utilize digital payment.

A variety of factors influence customer intent to use e-wallets, including consumer perceptions of privacy, security.

Thus, the desire to use e-wallets is determined by the concern for transaction security and the protection of personal information given by users [43]. Furthermore, Qatawneh et al. [30] suggested that security and privacy statistically significantly impact the adoption of electronic payment system methods.

Previous researchers did not consider relevant security factors when assessing customer behavior but studied security as a general factor as shown in Appendix A. Besides, studies have shown that the security and privacy aspect of digital wallet systems when conducting transactions using digital wallet platforms is a primary concern for customers. The list of non-bank digital wallet issuers and the banks providing digital wallet services are shown in Appendix B and Appendix C, respectively.

The digital wallet services were developed for fast payment, school fee payments, handling expenses in fuel stations, global online shopping, NFC (Near Field Communication)-based transportation's payment, money transfer, bill payments, and others. Appendix B and Appendix C show 53 active digital wallet services, with 48 of them provided by Malaysian private and government fintech companies. The remaining five digital wallets are provided by international and local banks in Malaysia [44].

### III. FRAMEWORK AND HYPOTHESES

Previous studies found that security substantially impacts consumer satisfaction in the digital wallet, but the studies examined security as an overall component. None of the research conducted identified the specific security factors in Malaysia's digital wallet. Thus, the current research proposed a six-factor security framework encompassing transaction speed, authentication, encryption mechanisms, software performance, privacy details, and information provided. Each factor was considered as a variable in this research. Fig. 1 represents the proposed framework of this study.

#### A. Transaction Speed

Transaction speed often refers to the rate at which data transfer happens from one record to another. The transfer speed is considered to be high if any transaction cannot be completed under a limited time period. An example of a real-life situation where transaction speed can be considered is the waiting time after the consumers have successfully paid for their online orders. The transaction speed of the payment application is a factor that may increase consumers' concerns [45]. The transaction speed is a characteristic that influences the development and satisfaction with any banking digital wallet technology. Numerous previous research found that transaction speed is a critical factor affecting consumer satisfaction with digital wallets [46]–[51]. Therefore, the following hypothesis is proposed:

- Hypothesis 1 (H1): There is a positive relationship between transaction speed and consumer satisfaction.

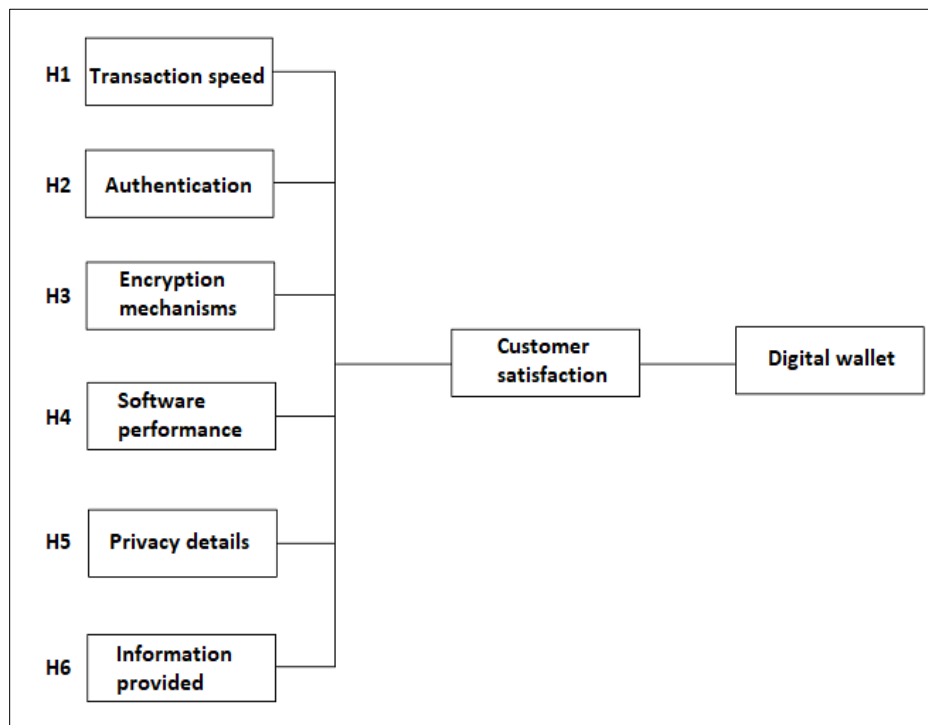

Fig. 1. The Proposed Framework for this Research.

### B. Authentication

Authentication is a term that refers to the process of verifying a user's identification to guarantee that the activity being performed is being conducted by a trustworthy and real individual. It acts as a barrier to decrease the possibilities of identity theft. An exemplary situation of this would be the OTP code verification that consumers are required to do in order to complete their payment transactions. Authentication significantly impacts on consumer experience, which impacts their digital wallet adoption decision [52]–[54]. Because confidence is a significant influencing factor, digital wallet companies must guarantee that relevant aspects such as authentication are adequately regulated to build customer confidence [55]. Therefore, the following hypothesis is proposed:

- Hypothesis 2 (H2): There is a positive relationship between authentication and consumer satisfaction.

### C. Encryption Mechanisms

Encryption mechanisms are often specific and unique steps and procedures done in turning order to encrypt data and ensure no third party or hackers can get the crucial information by encrypting the data into a gibberish form, which can only be decrypted using a unique key or mechanism corresponding to the encryption mechanism. Encryption mechanisms prevent hackers from breaking into a financial institution's server system. As a result, encryption mechanisms increase consumer confidence in conducting electronic payments [53], [56]. Therefore, the following hypothesis is proposed:

- Hypothesis 3 (H3): There is a positive relationship between encryption mechanisms and consumer satisfaction.

### D. Software Performance

Software performance directs towards the overall performance of the software being used by consumers. In this case, performance acts as an indicator of how effectively the components and functions of the software meet their requirements. One of the most significant variables that directly influences acceptance intention for digital wallet is considered to be performance expectation [23], [57]–[59]. Incorrect functional usage situations and bugs in software may raise consumer worries. Therefore, the following hypothesis is proposed:

- Hypothesis 4 (H4): There is a positive relationship between software performance and consumer satisfaction.

### E. Privacy Details

The information obtained from customers by digital services is referred to as privacy details in this context. Private information for registration purposes and authentication mechanisms are frequently included. Various previous studies have shown that customer satisfaction with digital wallets is significantly influenced by their ability to maintain their privacy [25], [60]–[65]. Therefore, the following hypothesis is proposed:

- Hypothesis 5 (H5): There is a positive relationship between privacy details and consumer satisfaction.

### F. Information Provided

Because of the information provided by digital wallet services, customers of digital wallets may learn more about security. Customers may feel more confident about the security of the digital wallet system if they are informed of the security

procedures. Similarly, if users of digital wallets are unaware of security procedures, they may not feel secure [66]. Digital payments service knowledge has an important, positive, and simultaneous impact on the customer's ongoing desire to use digital wallet services [67]. The security information given by digital wallet services may thus assist customers in learning more about security and increasing their confidence in the system. Therefore, the following hypothesis is proposed:

- Hypothesis 6 (H6): There is a positive relationship between information provided and consumer satisfaction.

#### IV. METHODOLOGY

This research adopted an empirical research method. A quantitative online survey was distributed to the students and professors at the National University of Malaysia who fulfilled the criteria of used any digital wallet platform, including mobile applications and web-based systems, at least once. Overall, 300 responses were received. The survey was divided into two sections. The respondents were requested to fill in their demographic data in the first section, whereas the respondents responded to the questionnaire on customer satisfaction in the second section. In the personal information section, respondents provided demographic data, including gender, age, occupation, and the frequency of digital wallet transactions.

A five-point Likert scale was used in the second section for respondents to specify their level of agreement on a statement. The degree of agreement is used for the study's assessment process. There were 18 questions in the second section divided into six sections, respectively. Three questions were asked for every element proposed in the framework. Factor analysis, reliability analysis, and multiple regression analysis were conducted with the recollected questionnaires. IBM's Statistical Package for Social Science (SPSS) version 22.0 software was used to assess the statistical significance. Table I shows the respondents' characteristics.

As shown in Table I, the majority of respondents use digital wallet platforms frequently, and it is famous among youngsters.

TABLE I. CHARACTERISTICS OF RESPONDENTS

Indicator	Total cell	Accuracy (%)
Gender	Male	42%
	Female	58%
Age	18-25	61.80%
	26-35	21.80%
	36-45	9.10%
	46-More	7.30%
Occupation	Student	89.90%
	Professor	10.1%
Frequency of digital wallet transactions	More than 3 times a week	30.90%
	2-3 times a week	46.40%
	Once a week	22.70%
	Less than once a week	0%

#### V. RESULTS

##### A. Factor Analysis

Factor analysis is commonly employed in multivariate data analysis to evaluate the underlying dimensions [68]–[70]. It is a data rebate technique that transforms many variables into few variables. The highly influential variables were removed from the dataset during the factor analysis. The dataset was replaced with less influential variables after extracting the highly influential variables. The Kaiser-Meyer-Olkin (KMO) sampling adequacy test and Bartlett's test of sphericity were conducted to examine the dataset's construction validity. Table II demonstrates the KMO and Bartlett's test.

According to Table II, the average value of KMO is  $.876 > 0.7$ , whereas the Bartlett test's significance level of sphericity is 0.00, demonstrating that the collected data is normally distributed. The variables explained 87.6% of the variance from the total variance. Appendix D represents factor analysis. Each question posed for the six variables was used as a sub-variable to analyze the factors. Each factor was assigned with an abbreviation. TS indicated transaction speed, AT stands for authentication, EM denotes encryption mechanism, SP represents software performance, PD signifies privacy details, IP implies information provided, and CS designates customer satisfaction. Appendix D demonstrates that factor loading variables are more significant than 0.6. The minimum factor loading value is 0.656, and the maximum factor loading value is 0.965.

##### B. Reliability coefficient

The reliability test was performed using the SPSS software to test the dataset's internal consistency and obtain the Cronbach alpha coefficients. The values of the Cronbach alpha coefficients are illustrated in Table III.

As shown in Table III, the Cronbach alpha coefficients' values for all the variables measured are above 0.700. Cronbach alpha value of 0.700 or higher denotes an internally consistent dataset [71]–[73]. Therefore, the dataset received from the questionnaire survey satisfies the rule of thumb of validity.

TABLE II. KMO AND BARLETT'S TEST

KMO and Bartlett's Test		
Kaiser-Meyer-Olkin Measure of Sampling Adequacy		.876
Bartlett's Test of Sphericity	Sig.	.000

TABLE III. RELIABILITY COEFFICIENT

Variables	Number of Items	Reliability Coefficient (Cronbach Alpha)
Transaction speed	3	.912
Authentication	3	.851
Encryption mechanisms	3	.828
Software performance	3	.942
Privacy details	3	.935
Information provided	3	.902
Customer satisfaction	3	.917

C. Regression Analysis

Regression analysis is a practical way to analyze the variables and their connection [74]. The regression analysis is performed to identify the association between the dependent variable (customer satisfaction) and separate independent variables. The dataset’s model summary is shown in Table IV.

As shown in Table IV, the R<sup>2</sup> value is .723. The value represents a positive linear connection between customer satisfaction and other factors (independent variables) during the analysis. Table V shows the analysis of variance with a significant value less than 0.05.

Therefore, it is found that the independent variables influence the dependent variable. The descriptions of the coefficients are exhibited in Table VI. The variable with the highest β-Value in Table VI is relatively most important independent variable.

The negative value of constant exhibited in Table VI defines that when transaction speed, authentication, encryption mechanisms, software performance, privacy details, and information provided values are 0, the predicted value of customer satisfaction will be less than 0. The regression coefficient calculates a unit change in the dependent variable when the β-value represents independent variable change. Based on the β-value shown in Table VI, the extent of the independent variable effect on the dependent variable can be identified. A high β-value corresponds to high effects. Table VII shows the results for collinearity when multi-regression is applied. A Variance Inflation Factor (VIF) value greater than ten and a tolerance smaller than 0.2 implies a possible concern.

TABLE IV. MODEL SUMMARY

Model	R	R <sup>2</sup>	Adjusted R <sup>2</sup>	Std. Error of the Estimation
1	.850	.723	.717	.41674

TABLE V. ANALYSIS OF VARIANCE

Model	Sum of Squares	Df	Mean Square	F	Sig.
Regression	132.793	6	22.132	127.434	.000
Residual	50.887	294	.174		
Total	183.680	300			

TABLE VI. ANALYSIS OF COEFFICIENTS

Model	Unstandardized Coefficients		Standardized Coefficients
	B	Std. Error	β-Value
Constant	-0.770	0.181	
Transaction speed	0.176	0.044	0.173
Authentication	0.247	0.049	0.213
Encryption mechanisms	0.112	0.039	0.111
Software performance	0.215	0.045	0.189
Privacy details	0.128	0.034	0.139
Information provided	0.311	0.048	0.285

TABLE VII. COLLINEARITY STATISTICS

Model	T	Sig.	Collinearity Statistics	
			Tolerance	VIF
Constant	-4.248	.000		
Transaction speed	4.024	.000	.513	1.948
Authentication	5.040	.000	.530	1.887
Encryption mechanisms	2.865	.004	.630	1.587
Software performance	4.743	.000	.593	1.687
Privacy details	3.794	.000	.701	1.427
Information provided	6.529	.000	.498	2.008

According to Table VII, The VIF values are below 10, whereas the tolerance values are above 0.2 for all the independent variables. Hence, multi-regression is appropriate for the model, and there is no collinearity problem. The value of statistical significance (p-value) less than 0.05 indicates a statistically relevant correlation between the dependent and independent variables. Table VII indicates that the level of statistical significance for the independent variables is below 0.05. Table VIII shows the relationship between each variable. The Pearson correlation values indicate that the variables have a strong and moderate association with one another.

TABLE VIII. PEARSON CORRELATION

Pearson Correlation	TP <sup>a</sup>	Aut <sup>b</sup>	EM <sup>c</sup>	SP <sup>d</sup>	PD <sup>e</sup>	IP <sup>f</sup>	CS <sup>g</sup>
TP <sup>a</sup>	1						
Aut <sup>b</sup>	.563	1					
EM <sup>c</sup>	.460	.410	1				
SP <sup>d</sup>	.524	.508	.484	1			
PD <sup>e</sup>	.459	.407	.417	.431	1		
IP <sup>f</sup>	.591	.606	.509	.469	.366	1	
CS <sup>g</sup>	.675	.681	.572	.635	.537	.712	1

<sup>a</sup>. TP = Transaction Speed

<sup>b</sup>. Au = Authentication

<sup>c</sup>. EM = Encryption mechanism

<sup>d</sup>. SP = Software performance

<sup>e</sup>. PD= Privacy details

<sup>f</sup>. IP = Information provided

<sup>g</sup>. CS = Customer satisfaction

D. Hypothesis Testing and Discussion

Table IX demonstrates the hypotheses testing. The test was conducted based on the data collected.

The hypotheses testing reveals that the p-value for the relationship between transaction speed and customer satisfaction is equal to 0.000, lesser than 0.05. Hence, H1 is supported. Therefore, it can be asserted that transaction speed has a significant positive impact on customer satisfaction. The findings suggest that students and academicians are more likely to use digital wallet systems if the transaction speed is high. According to the survey results, faster transaction speed will mitigate the security fears among digital wallet users. Users believe that fast online money transaction boosts the digital e-wallet platforms’ security.

TABLE IX. HYPOTHESIS TESTING

Hypothesis	Factor	$\beta$ -Value	P-Value	Result
H1	Transaction speed	0.173	0.000	Supported
H2	Authentication	0.213	0.000	Supported
H3	Encryption mechanisms	0.111	0.004	Supported
H4	Software performance	0.189	0.000	Supported
H5	Privacy details	0.139	0.000	Supported
H6	Information provided	0.285	0.000	Supported

In addition, the p-value for the relationship between authentication and digital wallet customer satisfaction is less than 0.05 at 0.000. Thus, the H2 is also supported, denoting that authentication has a significant positive impact on customer satisfaction. This finding shows that user's digital wallet account authentication process influences the digital wallet system's consumer satisfaction. Digital wallet users believe that user authentication keeps scammers at bay and enhances digital wallet security.

Furthermore, the p-value for the relationship between encryption mechanisms and customer satisfaction is 0.004, which is less than 0.05. Therefore, H3 is supported. Thus, encryption mechanisms are found to exert a significant positive impact on customer satisfaction. The survey participants are concerned about accepting or denying digital wallet services with the encryption mechanisms. Similarly, the participants believe that a strong encryption mechanism will avoid abuse or hacking user information while using a digital wallet.

The p-value of software performance is 0.000, which is less than 0.05. Thus, the H4 is supported, indicating that software performance significantly impacts customer satisfaction. The findings confirm that digital wallet users are aware of software performance when using digital wallet platforms. Moreover, digital wallet users suspect that software with vulnerabilities increases the risk of digital wallet fraud.

Additionally, the p-value for the relationship between privacy details and customer satisfaction is 0.000, less than 0.05. Hence, H5 is also supported, concluding that privacy details significantly impact customer satisfaction. It suggests that private data collected from digital wallet users concern them. The digital wallet users opined that security vulnerabilities could be triggered by information collected through digital wallet platforms.

According to Table IX, H6 is also supported because the information provided has a p-value of 0.000, less than 0.05. Hence, the information provided has a significant positive impact on customer satisfaction. The finding shows that information provided by the digital wallet systems allows users of digital wallets to learn more about security. Providing additional security information increases the online payment systems' credibility. Furthermore, consumers will feel reassured about the digital wallet system's security when they are aware of software performance. Therefore, the study concluded that the proposed security factors significantly influence digital wallet consumer satisfaction based on the hypotheses tested.

From Table IX, among the studied factors, the information provided has the highest  $\beta$ -value (.285), indicating that the information provided to digital wallet users most significantly influence consumer satisfaction, followed by authentication (.213), software performance (.189), transaction speed (.173), privacy details (.139), and finally, encryption mechanisms (.111). From the analysis, the six influencing factors on customer satisfaction are arranged in ascending order according to their significant influences: Information Provided > Authentication > Software Performance > Transaction Speed > Privacy Details > Encryption Mechanisms.

## VI. LIMITATION OF THE STUDY

Security was only covered as a general factor in previous studies. This study is the first research undertaken to identify the specific security factors for the digital wallet in Malaysia. However, this research was carried out based on responses from students and professors from the National University of Malaysia who may have better security factors awareness. Further research is required in this area of study. Security variables are complicated theoretical subjects for comprehension and research. An in-depth study of various populations is required to assess the factors suggested in this research. In addition, prospective researchers should also consider different security variables.

## VII. CONCLUSION

This research has proposed a six-factor security framework that influences consumer satisfaction in Malaysia's digital wallet. Conclusively, all the proposed factors in the research have a significant positive influence on consumer satisfaction. Based on the analysis, the information provided most significantly influences customer satisfaction in digital wallets, followed by authentication, software performance, transaction speed, privacy details, and encryption mechanisms. Hence, improvised information security management principles are essential for the advancement of the digital wallet industry.

Digital wallets have gained popularity in recent times for providing cashless and comfortable daily payments or transactions. Although digital wallets deal with payments or transactions, research on considering and deducing security factors when developing digital wallet payment systems is limited. The progress of the digital wallet industry may impede without a thorough understanding of security factors. This research contributes to understanding the specific security factors necessary for financial technology companies. This study identifies new security factors that influence consumer satisfaction in digital wallet payment methods. The factors have not been analyzed in previous research. Therefore, this study contributes critically to the theoretical literature in digital wallet payments.

Consumer satisfaction is a crucial factor in the future for the booming digital wallet industry. Digital wallet security must be advanced to deal with emerging hackers and frauds. The outcome of this research can assist digital wallet providers in reinforcing the security of the system and focusing on crucial security factors to enhance customer satisfaction towards digital wallets. Moreover, this study can assist future

researchers planning to study this field by considering the variables proposed in this study.

APPENDIX A

Ref	Objective	Finding	Limitation
[8]	Identify the significant factors affecting the purchasing intention of customers using E-wallet in Malaysia.	Convenience, cost-savings, and security were identified to impact customer purchasing behavior using E-wallet.	Security factors were not considered as variables.
[9]	Analyze the variables affecting the customer's decision to use mobile banking in India.	Perceived ease of use, usability, social effects, security, and perceived cost affect the decision of customers to use mobile banking.	The influence of security variables was not addressed in this study.
[11]	Examine the variables that impact the acceptance of E-wallet services in Sarawak, Malaysia.	The acceptance of e-wallet services is influenced by perceived risk, perceived usefulness, and perceived ease.	Security variables were not considered to identify the perceived risk factors.
[13]	Assess the positive and negative effects of e-wallet on Malaysian users.	The limitations of using the digital wallet in Malaysia are technological challenges and security risks.	The analysis did not classify digital wallet security risks but instead considered security as a general aspect.
[17]	Explain and recognize the nature of adopting the digital payment system in Jordan on the framework of the UTAUT2 model.	Performance expectations, social effect, price value, security, and privacy were important digital payment system acceptance indicators.	Security factors were not considered as variables.
[18]	Identify the relative primary factors that impact online purchase intentions.	Privacy, security, and delivery have a significant positive impact on customer satisfaction when it comes to online purchase intention.	The study does not identify the specific security factors for digital wallet systems.
[19]	Proposed a framework of the security factors in online shopping.	This framework has five security factors: financial security, privacy, system security, cybercrime, trust, and customer satisfaction.	The study does not identify the specific security factors for digital wallet system.
[20]	An analysis to determine the attributes that impact customer satisfaction in online shopping.	Privacy, merchandising, convenience, trust, delivery, usability, product customization, product quality, and security are the important attributes to the consumer for online satisfaction.	Specific security factors were not considered as variables.
[21]	Identify the primary factors that contribute to the acceptance of electronic payment systems.	Compatibility, the perceived security of technology, performance expectations, creativity, and social impact have important beneficial and detrimental effects on the acceptance and recommendation of electronic payment systems.	The analysis did not consider security factors but rather addressed security as a general factor to assess consumer behavior.
[22]	Investigate the variables that have a significant impact on the adoption of Jordan's electronic payment systems.	Security and privacy have a statistically significant impact on the adoption of electronic payment system methods.	This research does not identify particular security factors to assess the behavior of consumers to prevent ambiguity.
[23]	Examine the driving factors over the use of e-wallet as a payment method by Malaysian young adults.	Perceived usefulness, perceived ease of use and privacy and security have a positive and vital association with the e-wallet behavioral intention.	Security was considered as a general factor; specific security variables were not studied.
[24]	Analyze the factors influencing m-commerce use in Malaysia.	Perceived usefulness, perceived satisfaction, security, and privacy have a significant positive impact on the behavioral intention of m-commerce use in Malaysia.	The study does not consider specific security factors as variables. Security was considered a general factor.
[25]	Analyze the perceived risk that represents the ambiguity of adverse effects over e-wallets in Malaysia on consumer emotions.	The perceived risk of privacy, perceived usefulness, trust, perceived general risk, and perceived risk of performance are directly linked to the acceptance of the e-wallet platform.	The study does not specify the specific security factors for the digital wallet system.
[26]	Investigate the influence of security statements, technical protection, trust, and privacy on customer satisfaction, in the world of e-commerce.	Security statements and technical protection significantly impact customer loyalty in the e-commerce industry, and the study found no substantial effect on privacy.	The study considered security statements as a variable and did not study specific security factors.
[27]	Predict the extent of adoption of the People-to-People (P2P) services of the WeChat wallet in South Africa.	Trust, security, and privacy impact the decisions of South Africans to accept the WeChat wallet.	The research was based on WeChat wallet mainly, did not include other e-wallet services, and did not analyse security factors.
[28]	Examine the variables impacting consumer satisfaction with e-banking systems.	Cloud computing, security, e-learning, and quality of service are factors that can improve customer loyalty with e-banking.	The study did not specify digital wallet security variables.
[29]	Examine the influence of socio-cultural factors on ICT innovation, emphasizing mobile banking services in South Africa.	Trust and privacy have a significant impact on the behavior intention of using mobile banking services.	The analysis does not identify the security factors that affect consumer behavior.
[30]	Identify the variables that affect consumer satisfaction on the systems of electronic payment in Indonesia.	Customer loyalty has a significant influence on service effectiveness, benefits provided, the security of transactions, speed, active usage, benefits received, and convenience of transactions.	The analysis did not classify digital wallet security risks but rather considered the security of transactions as a general aspect.
[35]	Identify the variables that impact consumer perceived risk and their attitude toward online shopping in Malaysia.	The attitude of online shoppers is adversely influenced by product risk, financial and non-delivery risks. Convenience risk was shown to have a positive impact on the mindset of the customer.	The study does not identify the security factors that impact consumer behavior.

[36]	Identify the variables that impact users' paying behavior.	Content quality, peer influence, KOL influence, perceived interaction, effort expectation, and perceived trust all have a substantial impact on users' paying behavior.	The findings of the research do not identify which security variables influence customer behavior.
[37]	Examine the factors that influence the satisfaction of the younger generation with digital payment systems.	Perceived risks are shown to have a significant impact on the behavior intention of using digital payment services.	The research did not identify any factors relating to the security of digital wallets.
[42]	Analyze consumers' intention to utilize digital payment.	Service quality, perceived risk, perceived security, perceived simplicity of use, social influence, and compatibility all have a substantial impact on consumers' intention to utilize digital payment.	The findings of the study do not reveal which security variables influence consumers' purchase decision. In this case, security was taken into consideration in a wide sense.

APPENDIX B

No.	Issuers (Non-Banks)	Wallet name	No.	Issuers (Non-Banks)	Wallet name
1	AEON	AEON Member, Plus Card	25	Mobile Money International	Money Pin
2	Alipay Malaysia	Lazada Wallet	26	MobilityOne	eM-onei
3	Axiata Digital eCode	Boost	27	MOL AccessPortal	Razer Gold
4	Bandar Utama City Centre	IPAY	28	MRuncit Commerce	Mcash
5	Bayo Pay (M)	Construx	29	MyEG Alternative	iPayEasy
6	BigPay Malaysia	BigPay	30	TNG Digital Remittance	NAPP (Numoni App)
7	BLoyalty	B Infinite Pay	31	PayPal Pte. Ltd	PayPal
8	Chevron Malaysia Limited	Caltex StarCard Debit	32	Petron Fuel International	Petron Prepaid Fleet Card
9	DIV Services	Whalet	33	Presto Pay	Presto Pay
10	Fass Payment Solutions	Fasspay	34	qBayar	qBayar
11	Finexus Cards	Visa / Master Prepaid Card	35	Raffcomm	e-Info
12	Fullrich Malaysia	TaPay	36	Razer Pay Wallet (M)	Razer Pay
13	Gkash	Gkash eWallet	37	Serba Dinamik IT Solutions	Qwikpay
14	Google Payment Malaysia	Google Play Gift Card	38	Setel Ventures	Setel App
15	GoPay	GoPay	39	ScanPay	MyScanPay
16	GPay Network (M)	GrabPay	40	ShopeePay Malaysia	ShopeePay
17	Instapay Technologies	Instapay e-Wallet	41	SiliconNet Technologies	Sarawak Pay
18	iPay88 (M)	iPay88 e-Wallet	42	SMJ Teratai	eWANG
19	I-Serve Payment Gateway	Zapp	43	Touch 'n Go	Touch 'n Go,Prepaidcard
20	JuruQuest Consulting	QBpay e-wallet	44	TNG Digital	Touch 'n Go eWallet
21	KiplePay	kiplePay	45	U Mobile Services	GoPayz
22	ManagePay Services	Mpay	46	Wavpay Systems	Wavpay
23	Maxis Broadband	Prepaid Airtime	47	WeChat Pay Malaysia	WeChat Pay
24	Merchantrade Asia	Valyou Wallet	48	XOX Com	XOX eWallet

APPENDIX C

No.	Banks	Products
1	AmBank (M) Berhad	Prepaid Card (MasterCard)
2	Bank of China (M) Berhad	Prepaid Card (China Union Pay)
3	CIMB Bank Berhad	Prepaid Card (MasterCard) CIMB Pay
4	Malayan Banking Berhad	QR Pay
5	RHB Bank Berhad	Prepaid Card (Visa)

APPENDIX D

Variables	ID	Measurements Items	Values
Transaction speed	TS1	Slow online money transaction speed can increase the chances of becoming a fraud victim while making payments using a digital e-wallet.	.816
	TS2	Fast online money transaction speed improves the security of the digital e-wallet platform.	.847
	TS3	A faster online money transaction speed gives hackers less time to commit fraud.	.965
Authentication	AT1	User authentication has a directly proportional relationship with digital e-wallet security.	.880
	AT2	User authentication helps in ensuring the genuine cardholder is in charge while completing transactions online.	.846
	AT3	User authentication acts as another form of measure to keep scammers away.	.768
Encryption mechanisms	EM1	A good encryption mechanism can prevent the user information from being misused or hacked.	.656
	EM2	An encryption mechanism acts as a barrier between the customer and third parties with malicious intent to steal the customer information.	.681
	EM3	Encrypted data would have no value when stolen by a hacker because the data is encrypted.	.816
Software performance	SP1	A software with bugs increases the chances of fraud in the digital wallet.	.939
	SP2	The higher and better a software's performance, the harder it is for a hacker to break in.	.877
	SP3	A software with a slower performance gives a bigger scope for hackers to find the defects in the system.	.916
Privacy details	PD1	Information taken from the user can cause security issues perceived risk.	.868
	PD2	User's information is vulnerable.	.877
	PD3	The more confidential information stored results in a higher user perceived risk.	.954
Information provided	IP1	Information provided by the digital wallet system can help the user to understand more about security.	.923
	IP2	Providing more information about security improves the transparency of an online payment system.	.834
	IP3	Users will feel more assured and at ease if they are provided with more security information.	.880
Customer satisfaction	CS1	Digital wallet services have accelerated my regular activities.	.860
	CS2	Compared to conventional techniques, the digital wallet is a time-saving system.	.872
	CS3	I expect that in the near future, I would be using digital wallet systems.	.842

# Towards a Strategic IT GRC Framework for Healthcare Organizations

**Abstract**—The rapidly changing healthcare market requires healthcare institutions to adjust their operations to address regulatory, strategic, and other risks. Healthcare organizations use a wide range of IT systems producing large amounts of sensitive and confidential data. However, few tools are available to measure the data governance activities of healthcare institutions and align healthcare data management with legislation. The Governance, Risk, and Compliance (GRC) Model focused on integrating that ability to achieve organizational goals. The demand for corporate governance is crucial for protecting the healthcare system from risks. An adaptation of a modified version that includes strategy, processes, technology, people, as well as legal and business requirements was developed to analyze the factors affecting IT GRC implementation in healthcare organizations. Although about 48% of participants reported that their organizations implemented IT GRC programs, 16% stated that they are considering implementing IT GRC programs soon. In almost 71% of healthcare organizations, IT governance, risk management, and compliance are integrated. Among the factors influencing the implementation of IT GRC programs in Saudi healthcare organizations, legal context ranked as the most critical, followed by process, strategy, then technology, business, and finally, people contexts. This study shows that healthcare organizations must assess various factors for the effective implementation of IT GRC activities.

**Keywords**—Information technology; strategic; healthcare; governance; compliance

## I. INTRODUCTION

Increasing economic uncertainty, evolving market trends, and expanding regulations are escalating health organizations' risk exposure [1]. Currently, changes in healthcare systems are disturbing operations, necessitating the implementation of effective risk management systems. Hence, maintaining competitiveness and managing risk in the healthcare environment requires new actions, plans, and strategies. These changes have been facilitated by updated government regulations, organizational structures, accountability measures, and the relationship between consumers and healthcare providers [2]. In the evolving healthcare market, institutions must modify their operations to address regulatory, strategic,

and other risks. However, the need to change these models, along with the implementation of new models and organizational structures, might increase industry risks while providing lucrative opportunities. As a result, healthcare organizations are learning how to use effective models to turn those risks into profits.

The healthcare domain contains many information systems that produce massive amounts of data. These data include patient data, disease research data, healthcare professional data, and other sensitive information that must be managed with the highest levels of confidentiality, integrity, and availability (CIA) [3]. Many healthcare organizations realize that the changes in healthcare systems are disrupting their usual practices, and they need effective risk management for data governance. They also recognize that maintaining competitiveness and managing risks in the healthcare environment require new actions, plans, and strategies. The modification in government regulations, organizational structures, and accountability measures as well as the relationship between consumers and healthcare providers [4], facilitate these changes. However, there is a lack of developed tools for measuring data governance activities and aligning the healthcare organization data management with legislation.

One of the models that have been introduced in the healthcare sector to deal with these issues is Governance, Risk, and Compliance (GRC). GRC focuses on integrating a range of capabilities that assist health organizations to act with integrity, maintain consistency, address uncertainty, and achieve organizational goals [5]. As the dependency on information systems increased, the need to apply the GRC concept to IT operations became apparent. IT GRC ensures that all IT systems have proper governance, risk management, and compliance management to support healthcare organizations [6]. Although many researchers identified the need for IT GRC in healthcare organizations, only a few addressed the need to develop a strategic framework for implementing IT GRC in healthcare settings [7].

The benefits of applying IT GRC in healthcare organizations include accountability, better management for

electronic health records, alignment with legal requirements. The purpose of this study is to support healthcare organizations in identifying IT GRC practices at a strategic level. This paper evaluates the main factors affecting IT GRC in the healthcare sector to develop a strategic model that addresses various perspectives.

## II. BACKGROUND

### A. Factors Led to the Emergence of IT GRC in the Healthcare Sector

The emergence of IT GRC as an approach for protecting healthcare organizations from excessive risk and removing growth barriers has been due to numerous factors. One such factor is the demand for corporate governance. Governance is a broad term that involves individuals who administer the operations, laws, processes, institutions, and policies which define the structure that manages and directs healthcare organizations [8]. Thus, governance affects how healthcare organizations address everything, such as daily operations and patient care strategies. If any organizational operation fails, the board of directors and executives are held accountable rather than the policies or organizational culture [9]. Therefore, an accountability issue arises whether external and internal constituencies trust that the healthcare providers are doing everything to protect the quality of care and mitigate risk. Recently, there has been increased media coverage of healthcare organizations that fail to ensure the safety and protection of sensitive patient information [4]. Due to increased media attention, data breach, and the increasingly complex healthcare regulatory environment, board members and executives are more thoroughly accustomed to how their healthcare organizations operate. This increased scrutiny has ensured that the individuals in the governance have timely and accurate information regarding their organization. These individuals have the capability of making decisions that ensure compliance, prevent unnecessary risk, and reduce the impacts and chances of regulatory penalties and patient litigation [10].

Another factor that has led to the emergence of IT GRC in the healthcare sector is the increased adoption of electronic health records (EHR) that has led to greater risk. There is a growth of data in the healthcare sector, such as patient information. This growth indicates that healthcare organizations need an effective structure that clearly illustrates business requirements, data governance, and technology processes and infrastructure to support a secure data management environment [11]. Nonetheless, some healthcare organizations face challenges, such as increasing regulatory standards and requirements, a lack of funds for security initiatives, and the growing need for data sharing among collaborators and partners. These challenges have made it difficult for organizations to protect and manage all these data centers. Numerous areas have increased the risk due to the adoption of EHR, such as the global and dynamic nature of electronic information, collaborative patient care, and the utilization of electronic patient portals [3]. Due to the complexity of safeguarding health information, there is a need to have a more holistic risk management approach, such as carrying out a risk assessment on the electronic environment.

Another contribution to the emergence of IT GRC in the healthcare sector is the growth of regulatory requirements. Healthcare organizations must comply with these regulatory requirements to minimize the impact and chances of regulatory penalties and patient litigation [12]. In the healthcare sector, compliance denotes the act of adherence to regulations, along with the capability of healthcare providers to demonstrate and sustain that. Healthcare organizations need to adhere to internal policies as well as externally imposed regulations and laws. In addition to regulatory requirements, there are a more informed public, more assertive regulators, and more serious non-compliance penalties, which indicate that the organization needs to focus on compliance [13].

The boundaries of the extended healthcare enterprise are disappearing due to the far-reaching and intricate web of relationships [14]. For instance, numerous departments and constituencies share patient information. Additionally, the use of advanced technologies such as VoIP services, mobile devices, social networking, virtualization, and cloud outsourcing has led to the disappearance of conventional boundaries of a single healthcare enterprise [15]. This cross-pollination of information and services has made it difficult to determine the beginning and end of one healthcare operation. It has also led to unwanted risks. It is challenging to manage the numerous healthcare sectors that affect patient information. Additionally, many divisions in the healthcare organizations, such as radiology, the ER, and hospital labs, have burdened healthcare providers with assessments of employment practices, workflow support, privacy, security, and health and safety. Therefore, healthcare organizations need to validate their extended enterprise members to meet social responsibility practices, comply with laws, and ensure that they operate in a manner that prevents unnecessary risks. This is because new technologies generate numerous opportunities and risks [16]. For instance, the utilization of mobile devices by healthcare providers might affect the delivery of services along with creating new expectations across numerous touchpoints. At every touchpoint, there is a likelihood of introducing risks relying on the capability of health organizations to secure the connection. Hence, the disappearing boundaries in healthcare enterprises that might lead to unwanted risk have contributed to the emergence of IT GRC.

### B. IT GRC in Healthcare Settings

Researchers in [17] provided a clear GRC model based on the maturity model. The authors indicated that the GRC framework is most common among multinationals, insurance, banking, and listed corporations. However, the article acknowledged that there is a need for the GRC framework in healthcare settings. [18] indicated that in past years the GRC framework was not adopted in healthcare, although it has gained popularity among developed countries such as Germany and the U.S. The author discussed only the current state and significance of GRC in healthcare care without offering a clear IT GRC framework. [19] discussed past and future directions of information technology governance. The study did not provide a clear IT GRC framework that healthcare organizations can implement. [20] provided a clear guideline on how governance, risk, and compliance can align to ensure better decision-making. The study has indicated that, in past

years, organizations have failed to align governance, risk, and compliance. However, the study did not provide a complete GRC framework that healthcare organizations can adopt specifically for the IT GRC setting. Table I summarizes the related literature.

The literature agrees that there is a need to develop an IT GRC framework that healthcare organizations can use.

TABLE I. SUMMARY OF RELATED LITERATURE

Reference	Contribution	Limitation
[17]	GRC maturity model for hospitals	Not specific for IT GRC in healthcare organizations
[18]	Advantages of implementing GRC in healthcare care systems	No clear IT GRC framework for healthcare organizations
[19]	Past and future directions of information technology governance	No clear IT GRC framework for healthcare organizations
[20]	Clear guideline on how governance, risk, and compliance can be aligned for healthcare organizations	Partial GRC framework for healthcare organizations not specific for IT GRC

### III. RESEARCH FRAMEWORK

This research aims to assess the factors affecting the implementation of IT GRC initiatives in healthcare organizations. This paper adopted a modified version of the frame of reference for integrated GRC developed in [2]. The original frame contained four components, strategy, processes, technology, and people. This research framework adds two new components, business and legal requirements. The research framework appears in Fig. 1. The description of the research framework components are as follows:

- **Strategy:** The alignment among healthcare strategy, IT strategy, and IT GRC activities is crucial for integrating IT GRC in healthcare organizations [21]. A study conducted in Swiss hospitals found that IT directors usually make all the decisions without any discussion with related departments in about 75% of the hospitals [1].
- **Process:** IT GRC involves many processes that span various GRC domains (i.e., governance, risk management, compliance) [22]. IT governance processes must control IT risk management and IT compliance management in the healthcare organization [23].
- **Technology:** Technology plays a vital role in the integration of IT GRC activities. However, applying IT GRC technical tools in the healthcare organization requires an understanding of the nature of the healthcare business [24].
- **People:** People play different roles in IT GRC activities, such as identifying risks and managing the systems [23]. Understanding the importance of IT GRC activities in healthcare organizations is one of the success factors for implementing any IT GRC initiative in the healthcare organization [24].

- **Business:** Implementing IT GRC requires investment in technical solutions and processes. Thus, successful implementation requires approval from both business and information technology leaders to make the implementation successful [1].
- **Legal:** Regulatory compliance is one of the major drivers for any GRC program [25]. In the healthcare domain, organizations have to comply with various regulations. While some of these regulations are healthcare-specific, others could be related to IT regulations or other general laws.

Fig. 1. Research Framework.

### IV. RESEARCH METHODOLOGY

To assess the factors affecting the implementation of IT GRC initiatives in healthcare organizations, this study started with a literature review, followed by a quantitative survey. The questionnaire items fall into six categories (technology, process, people, strategy, legal requirements, and business) see Appendix 1.

Two experts (a professor and an assistant professor) reviewed the developed questionnaire to test the content validity. After making the required changes, the authors translated the questionnaire into Arabic. Then, the research was reviewed by the Research Ethics Committee at Shaqra University in Saudi Arabia to gain ethical approval.

The research team used Microsoft Forms as an online tool to distribute the questionnaire. The targeted population of this research is all staff members in Saudi healthcare organizations who are responsible for IT GRC-related activities or similar roles. The researchers used the snowball technique to reach all possible participants.

The questionnaire consists of five parts. The first part acts as a cover letter by providing information about the study and the researchers and taking the informed consent of the participants. The second part collects information about IT

GRC activities inside the healthcare organizations, such as the type of IT GRC program in the organization and who is in charge of the IT GRC program in the organization. The third part includes statements developed to assess the factors affecting the implementation of IT GRC initiatives in healthcare organizations. The fourth part collects the demographic information of the participants. The final part allows the respondents to add additional comments regarding the topic.

### V. DATA ANALYSIS

After completing all the required processes for the questionnaire development, the questionnaire was distributed to the targeted audiences of Saudi healthcare organizations members. We received 122 responses from 19 Oct 2021 to 7 Dec 2021. Four of the respondents were not accepted due to incompleteness or because they worked in the wrong industry. The analysis was conducted using Jamovi software [26]. This study implies quantitative methods as the analysis methods for many reasons such as the ability to generalization, high level of objectivity.

#### A. Sample Characteristics

Table II shows the demographic information of the participants. The gender balance among the participants was almost equal (Male 52.5%, Female 47.5%). The majority of the participants work in healthcare organizations in the Central Province (66.1 %) and the Western Province (25.4%). This was expected since most of the main locations of the healthcare organizations in Saudi Arabia reside in those two provinces, which have the majority of the Saudi population [27]. Although 67% of the participants have five years or more of experience in the healthcare sector, only 21.1% have experience with more than five years in IT GRC related activities.

#### B. IT GRC Status in Healthcare Organizations

This section discusses the IT GRC status in Saudi healthcare organizations. While 48.3% of the participants reported that their organizations implemented the IT GRC program, only 16.1% stated that their organization plans to have an IT GRC program in the foreseeable future.

High percentages of participants (28%) do not know about the IT GRC program in their organizations. These participants were not included in the analysis of the results.

Among organizations that implemented the IT GRC program, 71.9% of the participants stated that their organizations have an integrated IT GRC program that covers all of governance, risk management, and compliance processes. 77.4% of the participants also reported that the person in charge of IT GRC in the organization is from the IT department (i.e., Chief Information Officer (CIO) or equivalent or another IT director). Table III shows IT GRC status in Saudi healthcare organizations.

#### C. Reliability Testing

Cronbach's coefficient alpha test was used to measure internal consistency between items of the contexts. All of the values of Cronbach Alpha were above 0.8, which is considered above the accepted threshold [28].

TABLE II. THE DEMOGRAPHIC CHARACTERISTICS OF THE PARTICIPANT'S CHARACTERISTICS

Characteristic	Total Respondents	
	Frequency	Percentage
Gender		
Female	56	47.5
Male	62	52.5
Total	118	100
Organization location		
Central Province	78	66.1
Western Province	30	25.4
Eastern Province	6	5.1
Southern Province	2	1.7
Northern Province	2	1.7
Total	118	100
Participants' experience in years in healthcare sector		
Less than one year.	26	22.0
More than 1 year and less than 5 years.	13	11.0
More than 5 years and less than 10 years	19	16.1
More than 10 years and less than 15 years.	25	21.2
15 years or more.	35	29.7
Total	118	100
Participants' experience in years in IT GRC-related activities		
Less than one year.	65	55.1
More than 1 year and less than 5 years.	28	23.8
More than 5 years and less than 10 years	17	14.4
More than 10 years and less than 15 years.	7	5.9
15 years or more.	1	0.8
Total	118	100

#### Overall findings

This research aims to study the factors affecting the implementation of IT GRC initiatives in healthcare organizations in Saudi Arabia. The authors have addressed this by analyzing the data collected from the survey. Among the six contexts, the most important one is Legal (mean 3.85), then Processes (mean 3.82), followed by Strategy (mean 3.78), Technology (mean 3.74), Business (mean 3.62), and finally People (mean 3.61). Table IV shows the overall results of the analysis.

#### D. Comparison between Different Groups

Based on the results of the questionnaire, Saudi healthcare organizations divide into three categories. The first category is the organizations that have already utilized IT GRC solutions. The second category is the organizations that are planning to implement IT GRC programs. The third category is the organizations that do not implement the IT GRC program. The researchers conducted an Analysis of Variance (ANOVA) test to examine the means among the three groups. Table V lists the

means and standard deviations for all groups and contexts. It also presents the p-value for the ANOVA test for all contexts among the three groups. The results indicated significant differences among all six contexts between all categories. These findings show that organizations with IT GRC programs always have high mean values for all contexts. Additionally, organizations that do not implement IT GRC programs always have low mean values for all contexts. The ranking of the mean values shows differences in the importance of contexts for each category. For organizations with an IT GRC program, the processes context ranked first (mean = 4.10), and the people context was ranked last (mean= 3.89). For organizations planning to implement IT GRC programs, the legal context was ranked first (mean = 3.78), and the business context was ranked last (mean= 3.33). For organizations that do not implement IT GRC programs, the legal context was ranked first (mean = 2.77), and the process context was ranked last (mean= 3.22).

TABLE III. IT GRC STATUS IN SAUDI HEALTHCARE ORGANIZATIONS

Question	Total Respondents	
	Frequency	Percentage
Having an IT GRC program in place?		
The organization has IT GRC program.	57	48.3
The organization is planning to have IT GRC program in the foreseeable future.	19	16.1
The organization does not have any IT GRC program.	9	7.6
I do not know.	33	28.0
Total	118	100
Type of IT GRC program		
The organization has an integrated IT GRC program that covers all of governance, risk management, and compliance processes.	41	71.9
The organization has an IT GRC program that covers only two aspects of GRC processes (i.e., governance and risk management, governance and compliance, or risk management and compliance).	11	19.3
The organization has an IT GRC program that covers only one aspect of GRC processes (i.e., governance, risk management, or compliance).	5	8.8
Total	57	100
Roles leading IT GRC program in the organization?		
Chief Information Officer (CIO) or equivalent	32	56.4
Deputy CIO or equivalent	3	5.2
Chief Cybersecurity officer (CCO) or equivalent	9	15.8
Another IT director/manager	9	15.8
Internal audit officer.	2	3.4
Other	2	3.4
Total	57	100

TABLE IV. OVERALL ANALYSIS

Context	Rank	Mean	SD	Number of items	Cronbach Alpha
Legal	1	3.85	1.06	4	0.955
Process	2	3.82	1.08	4	0.950
Strategy	3	3.78	1.12	4	0.948
Technology	4	3.74	0.972	5	0.904
Business	5	3.62	1.21	4	0.956
People	6	3.61	1.19	2	0.893

## VI. DISCUSSION

The present research tries to explain the factors affecting the implementation of IT GRC programs in Saudi healthcare organizations. Legal context, which refers to the ability of healthcare organizations to meet all legal and regulatory requirements, was ranked as the most important context. This result was expected since following legal and regulatory requirements is usually compulsory. However, organizations that do not implement IT GRC programs face difficulties following or complying with these requirements since they have low mean values (2.72). This finding aligns with other studies that indicate compliance with the laws and regulations as one of the main objectives for GRC implementation [24].

The process dimension that controls various GRC domains ranked as the second most important dimension. Our study shows that organizations with well-structured processes have already implemented IT GRC since this dimension was ranked first for such organizations. This dimension ranked as the last dimension for organizations without an IT GRC implementation. Thus, they have difficulties controlling IT risk management and IT compliance management. Another study supports this finding since it showed the process level of the integration between IT GRC domains was low at healthcare organizations compared with other industries [23].

Synergy and alignment between IT GRC activities, IT strategic objectives, and business strategy are among the most crucial conditions. For organizations that plan to implement IT GRC solutions, this context ranked as the second most important. This ranking shows their willingness to offer better alignment integration between the GRC processes, IT, and business strategies. Weak strategic alignment negatively impacts IT GRC integration efforts across the healthcare organizations as mentioned in [1].

Technology context ranked as the 4th most important context. One possible reason is the use of technology as a tool to support IT GRC implementation rather than the main focus for healthcare organizations [23]. Another possible reason is the technical complexity of implementing such solutions in healthcare organizations [24].

Business context refers to the financial issues regarding the implementation of IT GRC activities in the organization. This context did not rank high in our study. This result was a surprise since financial factors are among the most important factors in many studies related to the implementation of IT in healthcare organizations [29]. A possible explanation is continuous pressure on healthcare organizations to decrease their expenditures [30].

TABLE V. CONTEXTS ACROSS DIFFERENT GROUPS

Context	Having an IT GRC program		Planning to have an IT GRC program		Do not implement an IT GRC program		P value
	Mean	SD	Mean	SD	Mean	SD	
Legal	4.05	1.009	3.78	0.942	2.72	0.947	.004*
Process	4.10	0.939	3.74	0.963	2.22	0.785	<.001*
Strategy	3.96	1.049	3.75	1.118	2.67	1.053	.011*
Technology	3.99	0.965	3.53	0.706	2.64	0.615	<.001*
Business	3.91	1.106	3.33	1.294	2.39	0.719	<.001*
People	3.89	1.005	3.39	1.329	2.28	1.034	.001*

\* Statistically Significant

People context includes human involvement in IT GRC activities in healthcare organizations. This context ranked with low mean values. The reason could be the lack of adequate staff devoted to IT GRC activities [1]. Another explanation is the unclear responsibilities for the IT GRC team [31]. Our finding also indicated a lack of expertise in the IT GRC domain in healthcare since only 21.1% of the participants have more than five years of experience in IT GRC related activities. This result shows the need for specialist training in the IT GRC domain in Saudi healthcare organizations.

## VII. CONCLUSION

Healthcare organizations face many challenges to improve their operations to respond to regulatory, strategic, and other requirements. Many organizations have implemented the Governance, Risk, and Compliance (GRC) model to help manage and comply with internal and external legal aspects. IT GRC is a subdomain of GRC that focuses on IT operations in organizations. This study analyzed the factors affecting the implementation of IT GRC in healthcare organizations. It developed the research framework that comprises strategy, processes, technology people, and legal and business requirements.

The results indicated significant differences among all six contexts between various categories of healthcare organizations. The output of our research provides a strategic roadmap for healthcare organizations that are willing to implement IT GRC activities. Additionally, Saudi healthcare organizations need to pay special attention to the role of people in IT GRC activities since this context ranked among the lowest.

The main contribution of this study is to develop a strategic framework for IT GRC in healthcare organizations. The developed framework can help healthcare organizations in improving their IT services and align them with healthcare services. Another implication of this study is the need to align technology with other aspects such as legal requirements for IT GRC holistic strategic framework.

A possible limitation of the research is the number of participants, which can be considered low. However, the low number could be because our survey requires participants to have some knowledge of IT GRC to complete the questionnaire, and these people are usually limited in

healthcare organizations. Another limitation is that the geographical context of the study is limited to Saudi Arabia.

Future work of our study includes the development of tools that integrate all the contexts to support healthcare organizations for better utilization of IT GRC concepts.

# Ambulatory Monitoring of Maternal and Fetal using Deep Convolution Generative Adversarial Network for Smart Health Care IoT System

S. Venkatasubramanian

Department of Computer Science  
Saranathan College of Engineering, Trichy-620012, India

**Abstract**—With the increase in the number of high-risk pregnancies, it is important to monitor the health of the fetus during pregnancy. Major advances in the field of study have led to the development of intelligent automation systems that enable clinicians to predict and determine the monitoring of Maternal and Fetal Health (MFH) with the aid of the Internet of Things (IoT). This paper provides a solution for monitoring high-risk MFH based on IoT sensors, data analysis-based feature extraction, and an intelligent system based on the Deep Convolutional Generative Adversarial Network (DCGAN) classifier. Various clinical indicators such as heart rate of MF, oxygen saturation, blood pressure, and uterine tonus of maternal are monitored continuously. Many data sources produce large amounts of data in different formats and ratios. The smart health analytics system proposes to extract several features and measure linear and non-linear dimensions. Finally, a DCGAN has been proposed as a predictive mechanism for the simultaneous classification of MFH status by considering more than four possible outcomes. The results showed that the proposed system for mobile monitoring between MFH is a practical solution based on the IoT.

**Keywords**—Deep convolutional generative adversarial network; fetal health monitoring; high-risk pregnancies; internet of things; smart healthcare system

## I. INTRODUCTION

Remote monitoring systems in the healthcare domain are increasing the daily reach of health for at-risk populations, especially pregnant women [1] and the elderly [2]. To identify the early disease symptoms and provide care, the patients are monitored every second by using these promising techniques in healthcare. The major functionality of the system is to diagnose and predict the health conditions of the user and provide warnings and training for the same. Nowadays, recent advances in the technologies of IoT have presented a way to enable such monitoring services 24/7. The IoT is a growing network of interconnected objects that include shared knowledge about decision-making and efficient and autonomous operation [3-6]. Various sources such as computer knowledge, communication link, and sensitivity are used by IoT in healthcare. As the content of public health, MFH is highly regarded by governments. However, medical care services, especially obstetric care, are limited, which decreases the efficiency of the medical staff and increased the pressure of high-quality service.

Although the fetus is located inside the body of a pregnant woman, the most devoted protector of the fetus is only the pregnant woman. Without the help of external technology, a mother will not be able to know the FH even when it is life-threatening. Therefore, to study the MH, monitoring the fetal is an important tool [7]. Fetal monitoring is reliable, safe, and easy to operate, which is widely practiced by MCH organizations across India [8-10]. However, the fetal monitoring used by most hospitals still traces deficiencies. First, the information cannot be shared. Monitor results must be printed in most hospitals, making them unsuitable for storage and easy to lose, and sharing tracking information and advice from multiple individuals may not feel timely.

These factors make it difficult for doctors to perform medical tasks or delay illness, which can lead to medical accidents. When pregnant women are in the obstetrics department, early warning function and intelligent real-time monitoring system are unable and they face other issues such as high risk, high emergencies, and massive flow of other pregnant women. In addition, serious consequences and life-threatening risks have occurred, when pregnant women are unable to notify doctors in time. Finally, monitoring of human health at home fails to recognize: at present, traditional health systems cannot meet the needs of continuous monitoring of pregnant women. Pregnant women, as expectant mothers, play an indispensable role in the upbringing of their children. Therefore, self-monitoring at home is an important content during the period of perinatal health care.

In recent years, communities and families are greatly entering into the comprehensive application of information platforms such as cloud computing technology, IoT healthcare, big data, communication technology, etc. It provides individuals with purposeful and personalized services, enabling them to advance from telemedicine to new ideas and ways of preventing disease and addressing major public health issues in the lives of women and children [11-13]. The IoT [14] means things are connected via the Internet that, understands the communication between objects using modern information technologies such as smart sensing, identification technology, and wireless communication. IoT-based M-Health uses wearable clinical sensors [15-17] to provide patients with real-time feedback on key symptoms and medical information and provide them with "anytime, anywhere" healthcare.

Healthcare as a Service platform architecture for cloud-based medical decision support services is developed in [18]. In [19], a coherent framework for M-Health monitoring and IoT-based remote monitoring is proposed. In [20], the IoT-based cloud service is optimized for the next generation of smart environments. In wireless heterogeneous networks, architecture of hierarchical sensor-based healthcare is developed by the work [21]. Other work [22] focused on a variety of wireless access networks and provided a framework for remote patient monitoring services. In some other cases, the software is developed by the IoT infrastructure for safe and smart healthcare [23].

An example of GAN model architecture is shown as below in Fig. 1.

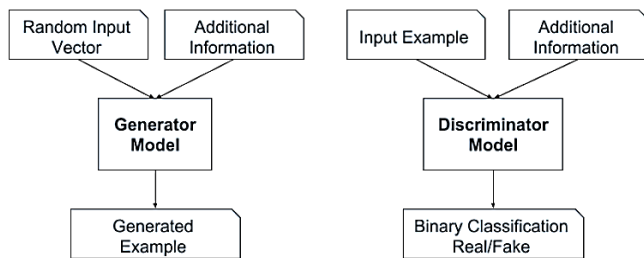

Fig. 1. Example of Generative Adversarial Network Model Architecture.

An integrated solution is proposed in this work for collecting different data from devices and sensors of IoT, linear and non-linear features are extracted, emergency alarms are used to analyze the data and finally, the MFH is automatically predicted by the DCGAN model. The most significant contributions are presented here as:

- 1) A continuous monitoring of MFH is carried out by integrating the medical devices and sensors of IoT.
- 2) To improve the diagnostic accuracy, fog computing architecture is used to develop an automated emergency subsystem with inference rules set.
- 3) The extraction of linear and non-linear features are done by a smart health analytics system.
- 4) The status of MFH is classified by analyzing the multiple metrics with the help of the DCGAN model.

This research paper is structured as follows. The related works for monitoring the fetal and maternal status are given in Section 2. A brief explanation of the system model with a predictive model is presented in Section 3. The validation of existing techniques with the proposed algorithm is described in Section 4. Finally, the scientific contribution of the research work with its future development is depicted in Section 5.

## II. RELATED WORK

A safe and reliable monitoring framework at less cost-effective is developed by Allah et al., [24] to make the home more comfortable and mitigate the effects of preterm labor in pregnant women. Non-invasive technology is used by the system to monitor EHG defects using wireless body sensors and smartphones. The smartphone will check for contractions and alert you in case of early delivery. Using the cervical

contractility database, this smartphone app has been developed and tested for verifying reliability and performance in terms of power consumption. The analysis showed that this application serves the purposes of the framework in defining the work system.

The significance of variants with similar features between the EPL models and the current pregnancy models is proposed by Liu, et al., [25]. After the collection of embryo samples, the correlation between the heart rate of the fetus is identified, where a regression model is used to achieve the normal development of FHR. The remaining analysis reveals the importance of the FHR in determining pregnancy outcomes. To develop the computational models, this paper developed six different machine learning (ML) techniques are developed. Sensitivity is used to compare the accuracy of both the presence of FHR and conditions of absence for predicting the performance. FHR is closely related to ETD for normal development and attained a high-performance value. When compared with all techniques, the random forest has 97% of recall, F1-score, and accuracy with 0.97 of AUC; however, deep learning techniques are required for effective prediction.

During pregnancy, the exposure of incarceration and food insecurity is identified by Testa et al., [26]. From 2004 to 2015, the LR was used to determine the relationship between father and mother of a fetus' food insecurity using Pregnancy Risk Assessment System (PRAMS) results. Withdrawal of controls is associated, directly or indirectly, with a 165% increase in the risk of food instability. Attendance analysis indicates that this relationship is driven by various factors such as receiving WIC benefits, unemployment of maternal and financial hardship.

Azimi et al., [27], established a flexible decision-making mechanism to provide 24/7 health outcomes in the absence of data, despite missing policies. Various data resources are leveraged in IoT systems for providing the results and imputing the missing values. This approach was validated in the Human Maternal Health Cycle Research, where 20 pregnancies were observed for 7 months. The health status of the maternal is measured by using her heart rate in real-time applications. While comparing with existing related works, the accuracy is highly achieved by this developed method. But, the accuracy results are low, when there are large missing window size data presents.

The website is developed by Mourad M et al., [28], and the signalling site is used to study uterine contractions, their characteristics, and labour study. In this investigation, different nonlinear techniques are used to determine pregnancy and labor signals and to examine pregnancy signals before labor with Hogworth frontiers, the multifaceted nature of Lempel-Ziv, and the measurement of a fractal. In Lebanon and France, all data from 12 WBL to 1 WBL are recorded and played back using a terminal network of size  $4 \times 4$ . The engineered signals are used by these techniques for testing the sensitivity of nonlinearity modifications, which are then applied to real signals. These results show that nonlinear techniques are commonly used to detect pregnancy fluctuations and to reduce symptoms.

### III. PROPOSED SYSTEM

Fig. 3 shows an overview of the proposed structure. The flow of the methodology is depicted as follows: initially, the IoT devices are used to generate the data and then transmitted to the emergency subsystem for identifying any distress of FHS. The medical staff gets informed if any emergency is obtained. After all this, data is transferred to the cloud, where the calculation of features is processed and a prediction system based on one-dimensional DCGAN is used. At last, medical diagnoses are supported by this classification model and the results are provided to the clinical staff members for further analysis.

The medical staff only has access to patients' details and their diagnostic outcomes, where authentication, access control layer, and data encryption levels are used to provide communication protection for data privacy and confidentiality.

There are four parts in the developed solution, which are presented in Fig. 2. The integration of medical devices and sensors for the collection of data is presented in the first layer called the IoT layer, where the emergency subsystem is presented in the second layer (i.e. Fog computing layer) that is according to the inference rules and fixed clinical thresholds. The third and final part is considered as the Cloud computing layer, where signal processing techniques are used to extract the features in the third part, and classification of MFH is carried out by one-dimensional DCGAN in the fourth layer.

#### A. IoT Layer

Sensor and Equipment Devices which are used to collect medial parameters from mother and fetal.

The components that are presented in this layer are described as: Four vital signs of maternal such as blood

pressure, temperature, heart rate of both Mother and fetal and oxygen saturation. Fetal and maternal monitoring are developed by using IoT modules, where diagnostic support is also provided by non-structured data.

To continuously monitor the fetus, the heart rate of his/her is only considered, which is obtained by the sensor of Doppler with a 4 Hz sampling rate. Then, a toco-dynamometer sensor is used to monitor the uterine tonus activity of maternal with the same sampling rate. Fig. 4 shows the modelling of the IoT interface layer.

At a 1 Hz sampling rate, important signals of maternal are obtained, where a photoplethysmography sensor is used to derive the oximetry and heart rate of maternal; then digital sensor integrated with medical devices is used to acquire the blood pressure for systolic and diastolic with temperature. Then, relevant events, audio, and photo notes of maternal that are acquired by medical staff are shared with the specialists, who are added to this system.

### B. Fog Computing Layer: Subsystem for Emergency

With limited resources of technology in remote clinical facilities and developing countries for providing ambulatory support, management and adoption of a cloud computing system for monitoring the real-time data is a challenging task. Therefore, architecture on fog computing is developed for supporting the requirements by creating a layer to collect the data on clinical premises.

For the signals of UC and heart rate of fetal, this type of external sensor is ideal for sound generation depending on the situation or the mother's movements [29]. Essentially, a pre-processor is included in the model before considering the specific dimensions of noise filtering and zero detection. The selected layer develops an automated analytical system for clinically important signals, according to the set of defined limits. The system is designed using three types of diagnostics (i.e. Emergency Class as EC) given in Table I.

According to the International Guidelines for Obstetricians and Gynaecologists (IGOG) [30], detailed descriptions of each standard portal and related classifications are provided in Table II for guidance on clinical group definitions and parental criteria.

### C. Cloud Computing Layer: Subsystem for Extraction of Automatic Features

A data analytical module is created in this part for the extraction of maternal and fetus' features. To determine the parameters of UC and heart rate of fetus, signal processing techniques [31] are used and then non-linear and statistical metrics are calculated. The changes include long decelerations and baseline adjustments that need time to confirm and long-term analysis are required by interpretation of fetal's heart rate. Therefore, once the signal acquisition is done, after 10 minutes only the measures are calculated at the initial step and updated every 5 minutes for the entire examination.

There are two steps involved in this module, the initial importance is given for monitoring the fetal and finally, the vital signs of the mother has considered as second steps. For continuous monitoring, maximum information is achieved by analyzing the uterine contractions and heart rate of fetal by using signal processing techniques. In this sub-system, a total of 15 features are extracted for the analysis of the heart rate of the fetus that is established by medical experts, where the features include baseline value, baseline changes for instant and numbers, minima number, FHR minima instants, peaks for number and instants, decelerations of DIP-I and DIP-II, UC occurrences for number and instants, sample entropy for 5 and 20 minutes window, long decelerations and variable decelerations.

### D. Predictive Subsystem using DC-GAN Model

GANs (Generative Adversarial Networks) are made up of two models that are trained concurrently using an adversarial approach. As shown in Fig. 5(a) and Fig. 5(b), a generator learns to make realistic images, whereas a discriminator learns to distinguish between actual and fraudulent images.

It should be noted that a total of 6 classes are considered and included in Table III for maternal and fetal diagnostic

diagnoses based on medical group classification. In this work, a DC-GAN is used for the prediction process.

In this paper, the conditional DC-GAN is used to generate conditional deep changes according to DC-GAN [32] and cGAN [33]. In the original DC-GAN architecture, the bias was made up of step confusion layers, modular correction layers, and LeakyReLU activations.

The generator contains spasms, translucency, patches, and ReLU activations. From part 3 of the cloud computing layer, the input of the selected classifier consists of 15 features of the system to predict the six possible outputs, which are described in Table III. Fig. 5 shows the configuration of the DC-GAN state.

Instead of the original layer of convolutional-transpose, an up-sample and convolutional layer are used in a generator for avoiding the artifacts of checkerboard [34]. If standard deconvolution is used to scale up from low to high precision, it uses all of the small feature points to 'plot' a larger square. This is where the "unequal overlap" problem comes in, i.e. when these "squares" converge on the larger side. In particular, D convolutions are random nests when the size of the kernel is not divisible by a step. Overlapping pixels create an unnecessary chessboard shape on the generated images. So, to get the "de-Convolution" function, we used the sample layer above instead. We scaled the feature using the top sample layer using bilinear (or adjacent interpolation) and then the convolutional layer. To achieve better results, a RelectionPad2d layer with size 1 is added before the convolutional layer for avoiding the boundary artifacts.

TABLE I. EMERGENCY SUBSYSTEM OUTPUT'S CLASSES

Layer's Outcome	Explanation
EC1 as 1	Fetal Emergency (FE)
EC2 as 2	Maternal Emergency (ME)
EC3 as 3	Maternal and Fetal Emergency (FME)

TABLE II. LIST OF EMERGENCY LIMITS/THRESHOLDS BASED ON THE ABOVE GUIDELINES

Clinical Parameter	Threshold	Interpretation	Output Class
Heart Rate of Fetus	> 160	Normal tachycardia	1
	> 180	Severe tachycardia	1
	< 100	Normal bradycardia	1
	< 80	Severe bradycardia	1
Heart Rate of Mother	> 100	Tachycardia	2
	< 60	Bradycardia	2
Oximeter	< 90	Mother's hypoxemia	2
Temperature	> 37.5	Fever for mother	2
Systolic blood pressure	> 140	Mother blood pressure	2
Diastolic blood pressure	> 90	Blood pressure for mother	2

TABLE III. PREDICTED CLASSES FOR THE PROPOSED SUBSYSTEM

Output	Description
PC1	Normal for both Maternal and Fetal
PC2	Suspicious only on fetal
PC3	Distress on fetal
PC4	Suspicious only on maternal
PC5	Harmful for Maternal
PC6	Harmful for both

(a).Generator.

(b).Discriminator.

Fig. 5. Structure of Conditional DC-GAN.

To control the output function, the input model gets a class designation for the generator and the amplifier. The generator receives a random beep ( $1 \times 1 \times Z$ ) and a heat conditional sign ( $1 \times 1 \times C$ ), where the dimensions  $Z$  and  $C$  represent the number of categories. By default, we chose  $Z = 100$  and  $C = 60$ . They were combined and sent to the curved layer using a  $1 \times 1$  core. Output channel 8192 ( $= 4 \times 4 \times 512$ ). Later, the output data was converted to  $4 \times 4 \times 512$  format. Finally, we sent the data to several modules (except for Up-sample + Conv2D + Batch-Norm, the output layer) as high as the original DC-GAN. An equal-valued data is up-sampled, only when the data size is  $1 \times 1$ , and therefore, input data i.e. concatenation of one-hot label and random noise is not resized directly. Hence, the input noise size is kept at  $1 \times 1 \times Z$ . To make the resizing step work, an extra convolutional layer is added in this model, where the  $C$  channel is encoded with a label in the discriminator. More precisely, the function label  $n$  is the data of the  $H \times W \times C$  scale, each 1s and 0.s in the  $n$  channel. In the input layer, the feature is associated with the label: each feature is associated with the label. Channel direction label. Thus, the input channel size was  $3 + C$ . Similar to the original DC-GAN configuration, the Discriminator configuration has multiple configuration layers and a default volume layer (except for the output layer).

#### E. Training Process and Loss Function

We used the standard loss function for GANs, which is defined in [35] as follows:

$$\min_G \max_D V(D, G) = \mathbb{E}_{x \sim p_{data}(x)} [\log D(x)] + \mathbb{E}_{z \sim p_z(z)} [\log(1 - D(G(z)))] \quad (1)$$

There are two losses such as  $Loss_D$  and  $Loss_G$  used since a generator and a discriminator are presented in the GAN model. Here, the loss function is used as Binary Cross-Entropy (BCE).

A sum of  $errD_{real} = -\log(D(x))$  and  $errD_{fake} = -\log(1 - D(G(z)))$  is used to calculate the first loss, where the BCE is represented to the reality only when the fake inputs and real inputs are received by  $D$ . The prediction of false positive is carried out by calculating the BCE when the fake inputs are received by  $D$ , i.e.  $Loss_G = -\log(D(G(z)))$ .

Set the default value for Adam optimizer as learning rate = 0.0001, when the training and updating of the generator and discriminator are carried out one by one. Finally, six possible outcomes are derived and the next section will show the validation of the proposed model with existing systems.

#### IV. VALIDATION AND RESULTS

In this section, details of the datasets used in testing evaluation for a particular system are provided. Presenting the results obtained with the contingency subsystem, the following section validates the predictive subsystem feature of DCGAN with or without extrusion, using existing deep learning techniques. The performance measures used in this study are described in this section.

##### A. Dataset Description

Simulation experiments were performed on a standard antenatal CTG database from the UCI ML Repository (University of California, Irvine) [36]. CTG data were collected from 29 to 42 weeks gestation at SisPorto 2.0 in Portugal [37]. The database contains 2126 cases with 21 traits and cases classified according to FIGO guidelines by the consensus of three experts: 1655 general cases, 295 suspicious, and 176 pathological data.

##### B. Performances Metrics

In this section, major parameter metrics are discussed to validate the system model's performance. The correct identification of data samples over a total number of instances is calculated by using accuracy. An identification of MFS is often accurate by using the parameter called precision or positive predictive value. The possible outcomes are correctly classified by the proposed model is known as recall/sensitivity. The proportion of actual negatives is calculated by using the true negative rate/specificity. The harmonic average of sensitivity and precision is provided by F1-score or F-measure.

Accuracy is calculated as follows:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (2)$$

Precision is working out as following

$$Precision = \frac{TP}{TP+FP} \quad (3)$$

Sensitivity is deliberate as follows.

$$Recall = \frac{TP}{TP+FN} \quad (4)$$

Specificity and F-measure are defined as follows:

$$Specificity = TN/(FP + TN) \text{ or } (1 - FPR) \quad (5)$$

$$F1 - score = 2TP/(2TN + FP + FN) \quad (6)$$

### C. Evaluation of Proposed Emergency Subsystem

All emergencies have been classified by the organization. The results in Table IV show that the sensitivities (Caesarean deliveries as CI) for all classifiers are very low and the associated features are high. This is expected because the database is skewed in favor of genital records. Sensitivity and 95% adjusted specificity for AUC and MSE are determined using the recommended CI model.

Disagreements during the modelling phase may result in poor performance. The integrating parameters from Table II are used to add the inference rule set to the system for improving the accuracy levels. For instance, the emergency of MFH is highly calculated by diagnosing the elevated blood pressure for systolic and diastolic, the temperature of maternal, etc. After discussing with the medical team, a total of twenty-six hypothetical rules are generated and here, five samples are provided in Table V.

The performance of the emergency subsystem based on the set of standard limits is shown in the Table VI.

It is important to note that performance is unsatisfactory with FP and FN rates high and sensitivities below 80%, which is unacceptable given the critical interpretation of the contingency. The new set of proposed default rules has slightly improved the performance of the contingency.

TABLE IV. PERFORMANCE OF THE EMERGENCY SUBSYSTEM

Output	Performance of Model before setting the static threshold			
	Sensitivity	Specificity	AUC	MSE
ME	0.00(0.00,0.00)	0.99(0.99,0.99)	0.60(0.58,0.61)	0.08(0.07,0.08)
FE	0.02(0.01,0.03)	0.99(0.99,0.99)	0.68(0.65,0.69)	0.08(0.07,0.08)
FME	0.02(0.00,0.04)	0.99(0.99,0.99)	0.71(0.68,0.73)	0.08(0.07,0.08)

TABLE V. THE SUBCOMMITTEE ON CONCEPTUAL LAWS CONSIDERED TO DESCRIBE THE EMERGENCY FOR MOTHER OR FETUS

Rule	Output
[MHR > 90] and [blood pressure for systolic > 120]	ME
[Temperature < 36] and [blood pressure for systolic < 100] and [blood pressure for diastolic < 60]	ME
[MHR > 80] and [FHR > 140]	FE
[FHR > 150] and [MT > 37]	FE
[blood pressure for diastolic > 13] and [blood pressure for systolic > 13] and [MHR > 90] and [FHR > 120]	MFE

TABLE VI. EMERGENCY SUBSYSTEM PERFORMANCE UNDER EXPERT SUPERVISION AND DEFAULT RULES SET WITH FIXED LIMITS

Output	Considering the set of static thresholding			
	Sensitivity	Specificity	AUC	MSE
ME	0.76(0.70,0.81)	0.56(0.54,0.58)	0.70(0.68,0.73)	0.08(0.07,0.08)
FE	0.71(0.68,0.73)	0.82(0.80,0.85)	0.87(0.86,0.88)	0.18(0.17,0.19)
FME	0.87(0.85,0.88)	0.91(0.89,0.92)	0.96(0.96,0.97)	0.08(0.07,0.09)

The new set of proposed default rules has slightly improved the performance of the contingency subsystem. By considering only the maternal prognosis, the AUC (ME) is 70%. For fetal emergency diagnosis, the system performance is AUC (FE) 87%. This can happen because there is only one parameter that is directly related to the condition of the fetus, which is the FHR. Finally, in the worst-case scenario, when the mother and fetus have an emergency, the specific regimen performs best, with an AUC (FME) of 96%.

### D. Performance Analysis of DC-GAN Prediction Subsystem

In this section, five parameters are used to validate the proposed DC-GAN with existing techniques by considering with and without feature extraction techniques. and linear features. The existing technique called Convolutional Neural Network (CNN) [38] is designed for a smart healthcare system for monitoring the MFH. Multiple features extraction techniques are used to calculate both non-linear and non-linear features. The CNN network consists of six CLs, max-pooling, single flatten layer and output layer for the prediction process. The work [38] uses homogenous i.e. having the same neuron type in the entire network and based solely on the linear-neuron model and didn't focus on non-linear features for better prediction. The data collected from 45 patients before labor and 55 patients during labor and validated the performance of CNN with existing ML techniques. But the results are not satisfactory, while using one-dimensional CNN, which is advanced network called DC-GAN is incorporated with a smart healthcare system for monitoring the MFH. In addition, this proposed model uses the standard datasets for the prediction process and compared them with existing techniques such as CNN [38], Long-Short term memory (LSTM), etc.

1) *Validation analysis of the proposed model without feature extraction:* Initially, the experimental results of DC-GAN are compared with CNN, LSTM, RNN, and DNN in terms of sensitivity, specificity, and precision, which are shown in Table VII and Fig. 6.

The proposed DCGAN model achieved 62.32% of precision and 77% of sensitivity and specificity. But, the DNN and LSTM model achieved nearly 46% to 50% of sensitivity, specificity, and precision. The reason is that the LSTM model requires more memory and takes a long time for training and it is easy to overfit. The DNN is also extremely expensive to train due to complex data models and it requires expensive GPUs. The CNN and RNN models achieved nearly 51% to 52% of sensitivity, specificity, and the precision.

TABLE VII. COMPARATIVE ANALYSIS OF VARIOUS DL ALGORITHMS WITHOUT FEATURE EXTRACTION

DL Algorithms	Parameter Metrics		
	Sensitivity	Specificity	Precision
DC-GAN	77.66	77.66	62.32
CNN	52.27	52.27	51.65
RNN	51.52	51.52	50.73
LSTM	50.87	50.52	48.56
DNN	47.85	48.65	46.5

Fig. 6. Graphical Representation of Proposed DCGAN without Feature Extraction.

The CNN model requires more training data for accurate results, but now it has only three inputs of the emergency subsystem and provides low performance. The complex training procedures are presented in the RNN model and hence it achieved less than 60% of all parameters. Table VIII and Fig. 7 show the performance analysis of DCGAN and existing DL techniques in terms of accuracy and F1-score by implementing without feature extraction techniques.

In the accuracy analysis, DNN and LSTM achieved less performance (only 74%) than other DL techniques, and proposed DCGAN achieved high performance (i.e. 89.03%) than CNN and RNN techniques. But, the same proposed method achieved very low performance in terms of F1-score (i.e. 65.92%), because the three inputs of the emergency-subsystem are directly given to the DCGAN model and it provides low performance since it is a one-dimensional model. Even though the proposed model achieved less performance, it provides better performance than CNN, RNN, LSTM, and DNN. The reason is that these existing techniques are unable to handle the inputs of the emergency subsystem due to its structures. DNN and LSTM model achieved nearly 46% to 49% of F1-score, whereas RNN and CNN achieved nearly 50% of F1-score.

2) *Validation analysis of the proposed model with feature extraction:* In this experimental analysis, the importance of feature extraction is revealed by implementing it with all the existing DL and proposed DCGAN models in terms of various parameters. Table IX and Fig. 8 show the performance

analysis of different DL techniques in terms of specificity, precision, and sensitivity.

TABLE VIII. COMPARATIVE ANALYSIS OF VARIOUS DL ALGORITHMS WITHOUT FEATURE EXTRACTION

DL Algorithms	Accuracy	F1-Score
DC-GAN	89.03	65.92
CNN	81.66	51.72
RNN	83.63	50.24
LSTM	75.95	49.85
DNN	73.54	46.21

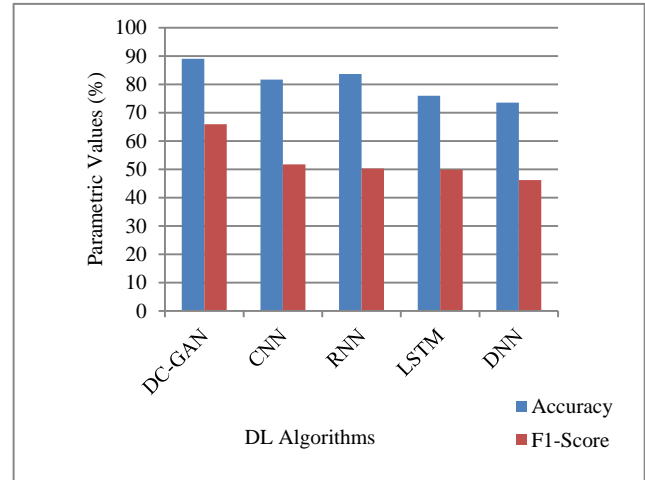

Fig. 7. Graphical Representation of Proposed DCGAN in terms of Accuracy and F1-score by considering without Feature Extraction.

TABLE IX. COMPARATIVE ANALYSIS OF VARIOUS DL ALGORITHMS WITH FEATURE EXTRACTION

DL Algorithms	Sensitivity	Specificity	Precision
DC-GAN	98.27	96.70	97
CNN	95.95	92.63	93
RNN	97.11	94.62	95
LSTM	91.62	84.57	85
DNN	90.87	81.23	83

Fig. 8. Graphical Representation of Proposed DCGAN with Feature Extraction.

When all the DL techniques are implemented with feature extraction, its performance is highly improved in terms of precision, specificity, and precision, while comparing it without feature extractions. This shows that feature extraction plays a major role in this study and the one-dimensional CNN, DCGAN, RNN, and DNN are used here and it requires feature extraction techniques for better performance. In the analysis of sensitivity, every DL technique achieved more than 90% and the proposed DCGAN achieved 98.27%. The specificity of DCGAN is less (i.e. 96.70%) than the precision (i.e.97%) of proposed DCGAN, but its performance is highly improved while compared with existing DL techniques such as CNN, RNN, LSTM, and DNN. The CNN and RNN achieved nearly 92% to 95% of specificity and precision, whereas LSTM and DNN achieved nearly 81% to 85% of specificity and precision. This analysis shows that the proposed DCGAN model achieved better performance than other existing techniques. Table X and Fig. 9 show the experimental analysis of various DL algorithms in terms of accuracy and F1-score by considering feature extraction techniques.

TABLE X. COMPARATIVE ANALYSIS OF VARIOUS DL ALGORITHMS WITH FEATURE EXTRACTION

DL Algorithms	Accuracy	F1-Score
DC-GAN	97.50	96
CNN	96.03	94
RNN	96.78	95
LSTM	89.98	86
DNN	88.58	84

Fig. 9. Graphical Representation of Proposed DCGAN in Terms of Accuracy and F1-score by considering with Feature Extraction.

In the analysis of the F1-score, the LSTM and DNN achieved nearly 85%, whereas CNN and RNN achieved nearly 94% to 95%, but the proposed DCGAN achieved 96%. The reason for the better performance of the proposed model is to introduce the conditional-based network in the DC-GAN, where the other techniques use only its basic architecture. In the experiments of accuracy, the DNN and LSTM techniques

achieved 89%, the CNN and RNN achieved nearly 96%, and the proposed DCGAN network achieved 97.50% of accuracy while implementing feature extraction. Fig. 10 shows the comparative analysis of various DL algorithms in terms of accuracy by considering with and without feature extraction techniques for better validation purposes.

Fig. 10. Comparative Analysis of DL Techniques with and without Feature Extraction Techniques in Terms of Accuracy.

## V. CONCLUSION

According to the diagnostic system's fog computing framework, an integrated solution is provided for high-risk monitoring of maternal patients, where this process relies on IoT-network-based sensors. A large data-analysis module for feature extraction techniques are used to extract features from the observed signals, and finally, an in-depth DCGAN-based classification system for predicting maternal-fetal health by the possible outcomes as PC1 to PC6 for performance analysis. The main contribution of this work in the Emergency Diagnostics Branch is the design of a set of hypothetical rules that can achieve more than 80% of the area under the curve for fetal, maternal, and emergencies. A total of 6 possible outcomes from the prediction model were considered. Compared with existing DL techniques such as CNN, LSDM, RNN, and DNN, the results show that DCGAN techniques and homogeneous systemic extraction performed better in the maternal and fetal and stage II. In the future, the efficiency of the emergency diagnostic system can be improved by modifying the selected model using different hypothetical rules.

**Abstract**—Currently, research for osteoporosis examination using dental radiographic images is increasing rapidly. Many researchers have used various methods from subject data. It indicates that osteoporosis has become a widespread disease that should be studied more deeply. This study proposes a deep Convolutional Neural Network architecture as a texture feature of dental periapical radiograph for osteoporosis detection. The subject of this study is postmenopausal Javanese women aged over 40 and data measurement result of Bone Mineral Density. The proposed model is divided into stages: 1) stage image acquisition and RoI selection, 2) stage feature extraction and classification. Various experiments with the number of convolution layers (3 layers to 6 layers) and various input block sizes and other hyper parameters were used to get the best model. The best model is obtained when the input image size is greater than 100 and less than 150 and a five of convolution layer, as well as other hyper parameters, including epochs=100, dropout=0.5, learning rate=0.0001, batch size= 16 and loss function using Adam's optimization. Validation and testing accuracy achieved by the best model is 98.10%, and 92.50. The research shows that the bigger images provide additional information about trabecular patterns in normal, osteopenia and osteoporosis classes, so that the proposed method using deep convolutional neural network as textural feature of the periapical radiograph achieves a good performance for detection osteoporosis.

**Keywords**—Osteoporosis; dental periapical radiograph; convolutional neural network; texture features; bone mineral density

## I. INTRODUCTION

Osteoporosis is defined as a systemic skeletal disease characterized by low bone mass and micro-architectural deterioration of bone tissue [1]. Therefore, osteoporosis will increase the consequences of bone fragility and susceptibility to fracture, especially for those over 50 years of age. Once a fracture happens to someone with osteoporosis, life will be greatly affected due to disability to move and prolonged

healing process. Finally, this reduces a person's quality of life and causes various economic and social problems [2].

For example, if the injured person works as a driver or as a labor worker, he might have to retire and find some disk-related job that is not easy to obtain. In some other cases, the injured person might become severely disabled and require continuous assistance, which might burden his family. Therefore, preventative measures and early treatment of osteoporosis [3-4] are the best options to address these issues. Practical scientific and technological methods to support osteoporosis diagnosis, in this context, will provide much help to overcome the disease and reduce its negative impacts.

The most accurate BMD examination and made the gold standard by World Health Organization (WHO) is using Dual Energy X-Ray Absorptiometry (DEXA). However, access to this method is still limited in many countries. BMD examination is often available in central hospitals only, and its cost is often too expensive for many people in rural areas. Furthermore, BMD is not able to reveal the internal structure of fractured bones [4-5]. Researchers, therefore, have attempted to develop alternative methods that are more practical and more widely accessible. Several studies have found that dental data demonstrate a high correlation with BMD measurements [6-16]. The data include panoramic and periapical radiographs. Besides that, of the use widespread of periapical radiographs in dental care for the elderly with increased life expectancy and the number of studies according to BMD estimates and screening for osteoporosis using periapical radiographs. It is expected to provide benefits, namely the architecture that has been produced can then be used as an architectural model in pre-train medical images for different cases specifically using medical images with the same characteristics, which tend to be low resolution. In addition, it can also help patients who perform dental checkup at the dentist to be given a referral to chiropractors for further

\*Corresponding Author

checkup, so that it can be detected early if you have osteoporosis.

Periapical radiograph is a dental radiograph technique that can image four to five teeth and their respective areas on one intraoral X-ray films [7]. At a microstructure level, images of trabecular jaw bones often show visual patterns closely related to the general condition of other bones [8,10]. Dental data have therefore become promising sources to predict Bone Mineral Density (BMD) measurements accurately. Periapical radiographs, in particular, will become the focus of this research since these radiographs are much more affordable and generally are more available. Fig. 1 shows an example of a periapical radiograph of the mandible.

The remaining part of this research is organized as follows. Section II explains some related work on osteoporosis detection using dental periapical radiograph, while Section III provides a more detailed description of the proposed method and training CNN's. Section IV contains result and discussion of the proposed method, and Section V concludes the research.

Fig. 1. Periapical Radiograph Image of the Mandibl.

## II. RELATED WORK

Several studies have been carried out to examine osteoporosis using periapical radiographs. In [8] has made one of attempts to predict bone mass from such radiographs. Data and the corresponding labels (BMD measurements) are collected from 60 postmenopausal women aged over 40. This research extracts and combines visual features such as areas, lengths, and peripheries of “bright” blobs, numbers of terminal/branch points, and clinical data such as ages, body sizes, and calcium intakes. The overall number of pixels in the RoI divides that of black pixels results in the visual features of the trabecular area. The total amount of pixels in the external of the trabeculae in the binary images displays the periphery. In other words, it represents a proportion of the entire area of the trabeculae or the entire area of RoI. The skeletonized image computes the complete area of the skeletonized trabeculae (total amount of black pixels), the number of terminal points (free ends, that is, black pixels with only one neighboring black pixel), and the number of branch points (crossing points, that is, black pixels with three or more neighboring black pixels). These are used to represent the percentage of trabecular length, area and perimeter. Classification and regression tree analysis (CART) uses patients in groups of normal or low bone mass categories. It is evident from the CART analysis of clinical and radiographic features that the main element to categorize patients as having normal or low bone mass were age ( $\pm 42.5$  years) and the number of terminal points as a function of the periphery ( $\pm 0.09$ ). This algorithm conscientiously

distinguished 22 normal patients by BMD (specificity = 100%) and 31 patients with low bone mass (sensitivity = 81%). The total accuracy was 88.33%. A denomination of the corresponding predicted and actual bone category, the weighted kappa index, was 0.76. To identify women with low BMD, trabecular morphology analysis was an alternative. Another research [9] was also conducted displaying the combination of upper and lower jaw radiographs from 505 postmenopausal women aged 45–70 years. Dense, sparse or mixed trabecular patterns were identified by five observers. The gradings were integrated into a single averaged observer score per jaw in which the RoI can be identified on each by scanned radiographs. The RoIs compounded with image analysis software measured 25 photographs' characteristics. Pearson correlation and multiple linear regressions, which were used in identifying the averaged observer score, showed that 14 image features were significantly correlated with the observer judgment for the two jaws. Other features, which give details of osteoporotic patients with fewer but bigger marrow spaces than controls, are less compatible with the sparseness of the trabecular pattern than a rather crude measure for a structure such as the average grey value. To sum up, the human concept of sparseness is emanated more from average grey values of the RoI than from geometric details within the RoI. In [11], the bone mass prediction on porosities, connectivity, and orientations of porous was shown in trabecular images and a combination of the anthropometric features (weight, height, age, body mass index). While a decision tree was used to select the feature, a backpropagation artificial neural network was used for classification. By combining age, weight, height, body mass index and features of trabecular morphology interdental bone, identifying postmenopausal women with low bone mass are much easier. In this study, however, age is considered one of the biggest contributors to loss of bone mass. Porosity, the oblique porous, and the vertical porous are crucial porous features. This study distinguishes anthropometric and radiographic features, which then is analyzed individually. Both anthropometric features and the radiographic features have high accuracy with 80.33% and 87.04%, respectively. This work has been extended further [12] that combine data from periapical and panoramic radiographs. Furthermore in [13], a method for osteoporosis identification based on the validated trabecular area was presented on digital dental radiographic images. The image RoI of the validated trabecular area on the images should be obtained through a sequence of morphological operations, which is then evaluated using the Dice similarity method. In analyzing osteoporosis, a mineral density is estimated using dual X-ray absorptiometry in two areas and by extracting RoI through statistical features (deviation, entropy, homogeneity, and correlation). Feature extraction and feature selection are used to analyze the four features. The selection process applies the C4.5 feature selection method. Subsequently, to estimate the existence of osteoporosis, a multilayer perceptron of statistical texture analysis is employed. 0.8924. is obtained as the result of the average dice similarity coefficient for all of RoIs. The most suitable method in this proposed study, achieving an accuracy of 87.87%, is a multilayer perceptron classifier.

A study on the analysis of the mandibular trabecular structure in postmenopausal women using periapical

radiographs was conducted by [14]. The mandibular trabecular structure parameter used was the thickness of the trabeculae compared with the results of BMD DXA measurements in the lumbar (spine) and femoral (hip) areas. Determine the RoI manually with a size of 100pixels x 100pixels with a position 2mm from the apical edge of the left and right posterior parts of the lower jaw (mandible). Measurement of trabecular thickness using slice geometry features, namely bone area fraction size by dividing the number of pixels classified as bone by the total pixel area in RoI and trabecular thickness 2D is the average trabecular width in RoI. These two parameters were correlated with femoral and lumbar BMD values. Then the measurement results with statistical analysis showed a statistically significant difference between the normal group and the osteoporosis group compared to the normal group and the osteopenia group, so it can be said that thinning of the trabecular structure is more clearly seen in postmenopausal women with osteoporosis, with bone quality that can be detected earlier using the trabecular thickness parameter.

Although several methods have been proposed to examine osteoporosis using dental periapical radiographs, the methods generally rely on morphological analysis and geometric features of the images [8–14]. Only a little work has been conducted to investigate the effectiveness of texture features such as [15–16] that employed features derived from the Gray Level Co-occurrence Matrix (GLCM). However, the employed features are considered to be handcrafted, which might be suboptimal for the given problem. Therefore, the facts mentioned above have suggested further investigation on the use of texture features, particularly those that are directly learned from data. This research proposes deep learning in the analysis of texture features for the prediction of osteoporosis. Deep learning has worked effectively in many areas, including computer vision, hyperspectral image processing, medical image analysis [17], and natural language processing include in tuning for hyperparameters online [18]. Compared to conventional methods such as support vector regressors and multi-layer perceptron, based on feature, deep learning has some advantages, such as working on two-dimensional data directly, less susceptibility to local optimal, and the ability to learn texture features from data [19]. The other advantages of DCNN are transferability connections and sparse connections. The transferability connections are certain layers of network architecture that can reproduce weights for different tasks. Sparse connections are infrequent connections that can reduce redundant connectivity, thereby reducing computing costs [21].

One particular model of a deep learning is convolutional neural network or also called deep convolutional neural network (DCNN). Since 2012, DCNN [17–20] has been led to a series of breakthroughs for image classification [22]. Deep learning-based computer-aided diagnosis for breast cancer [23] and lung cancer [24] has been applied in radiology. In addition, there are many other studies that use DCNN to detect or classify diseases, such as [25] comparing the performance of three CNN models (models VGG19, Resnet50v2 and Densenet201) with X-rays data sets of patients with COVID-19, pneumonia, and tuberculosis with a large number of data sets.

By considering several capabilities and advantages of DCNN, our contributions are:

- We designed and determined the best DCNN configuration model to extract in-depth features from dental periapical radiograph images from multiple image block sizes and multiple convolution layers with varying hyper parameter.
- The result of DCNN architecture or configuration can be used to detect osteoporosis disease.

Measured the effectiveness of the best model by conducting trials using data from previous researchers to achieve state-of-the-art performance for the detection or classification of osteoporosis using dental periapical radiograph.

### III. METHOD

This study proposes a deep Convolutional Neural Network architecture as a texture feature of dental periapical radiographs that can be used for osteoporosis detection. An extensive examination of the network is conducted to obtain the optimal network configuration and hyperparameters, which include input image size, number of kernels, filter kernel size, dropout value, and learning rate value. The system results will be compared with results of BMD measurements in the femur and lumbar areas using DXA.

The proposed model is broadly divided into two stages, namely the training stage and the testing stage. Each stage consists of several processes, namely, image acquisition and ROI selection, feature extraction and classification (see Fig. 2).

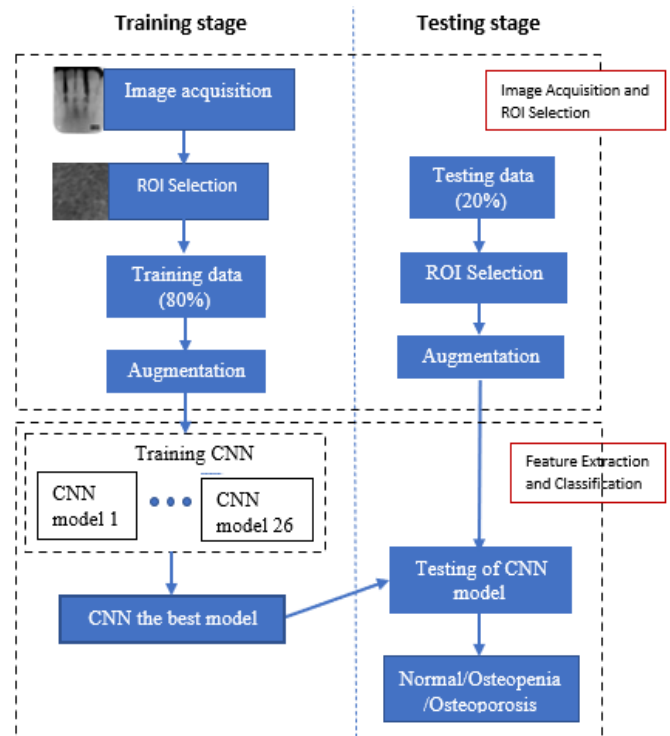

Fig. 2. Proposed Method for Osteoporosis Detection.

### A. Image Acquisition and RoIs Selection

We used a dental X-ray device to obtain digital periapical radiographs of mandibular anterior teeth of 31 postmenopausal women aged over 40 years old. This research makes use of the Villa Sistemi device with an electrical specification of 70 kVp/8 mA that uses photostimulable phosphorus plates (PSP) as image receptors. All periapical radiographs were processed from the Radiology Department, Prof. Soedomo Dental Hospital of Universitas Gadjah Mada using the DBSWin4.5 (Dürr Dental, Bietigheim-Bissingen) to produce digital grayscale images in the JPG format. All images are assessed for quality assurance by a dentist (Fig.3).

Fig. 3. Periapical Radiograph of the Mandible (a) Normal, (b) Osteopenia, and (c) Osteoporosis.

Regions of interests (RoIs) are then selected semi-manually from the images to obtain the most appropriate parts for further processing. The selection procedure marks the upper left corner of the trabecular area then moves to the lower right to form the maximal square that can be extracted from the images. so that RoIs is obtained with various sizes, at least 250x250 pixels Assuming that trabecular areas' sizes do not vary significantly across people, all the extracted RoIs are resized to a standard size of 250 x 250 pixels. It can be considered as a normalization step favoured by subsequent processes. Fig. 4 shows the RoIs selection process as well as the resized images. The resized RoIs are divided further into overlapping blocks (with 10 pixels overlap), each of which will become an input to a convolutional neural network. This process is called augmentation.

Fig. 4. RoIs Selection and Resizing (a) Normal, (b) Osteopenia and (c) Osteoporosis.

### B. Features Extraction and Classification

Feature extraction and classification is performed using a deep convolutional neural network (CNN) which takes image blocks as input and produces a prediction class as output. The prediction class in this study consisted of normal (N), osteopenia (Oa), and osteoporosis (Os) which was a further

decrease in the bone mass of the examined subjects. The deep CNN configuration used is shown in Fig. 5 or details can be seen in Table I. The deep CNN configuration consists of five building blocks, namely convolution layer, activation layer, pooling layer, fully connected layer, and soft-max layer. The first convolution layer uses a kernel size of 5x5, while the second to fifth convolution layers use a 3x3 kernel size. While in the pooling layer, all layers use a 2x2 kernel.

The Deep CNN configuration showed at Fig. 5 and Table I is the best model from the results of experiments that have been carried out on each block size and convolution layer size, activation layer, pooling layer including number of the kernel used (6, 16, 32, 64, 128) and the filter kernel size for each convolution layer as well as several parameters such as learning rate value, dropout value and number of epochs (as shown in Fig. 6-9 and Table II-III).

CNN's themselves are inspired by a neuro-biological process in which connectivity patterns between neurons resemble the visual cortex model [26] and [27]. CNN's work on two-dimensional data of multiple depths and operate in a layer-by-layer order [28].

Convolution layers serve to extract features from an input image (edges, corners, or crosses) using responses to some special character presenting in the input. Activation layers determine "relevant" convolutional kernels. The layers produce stacks of feature maps, each of which parts within the produced feature maps to be used in subsequent processing. Relevant parts, in this case, will be "active" after passing through the activation function, which is the rectified linear units (ReLU).

The ReLU layer is an activation function obtained through the equation.

$$ReLU(x) = \max(0, x) \tag{1}$$

Where x is the input to the neuron and the transfer function is finely approximated to the rectifier into an analytic function.

Pooling layers help the network avoid overfitting by reducing some network parameters and the respective computations. The pooling layers work as a non-linear down-sampling process that divides outputs of activation layers into subregions and collects maximum values from the subregions. From an  $n \times n$  input, with  $n$  represented of size of image and  $k$  represented from size of kernel, a pooling layer will produce an  $\left(\frac{n}{k}\right) \times \left(\frac{n}{k}\right)$  output.

Fig. 5. Architectural Model of CNN for Osteoporosis Detection.

TABLE I. CONFIGURATION MODEL OF CNN FOR OSTEOPOROSIS DETECTION

LAYER TYPE		INPUT SIZE	NUMBER OF KERNEL	FILTER KERNEL SIZE	OUTPUT SHAPE
Input layer	input	140x140x1	-		140x140x1
Conv. layer 1	convolution	140x140x1	6	5x5	136x136x6
	activation	136x136x6	6		136x136x6
	max pooling	136x136x6	6	2x2	68x68x6
Conv. layer 2	convolution	68x68x6	16	3x3	66x66x16
	activation	66x66x16	16		66x66x16
	max pooling	66x66x16	16	2x2	33x33x16
Conv. layer 3	convolution	33x33x16	32	3x3	33x33x32
	activation	33x33x32	32		33x33x32
	max pooling	33x33x32	32	2x2	16x16x32
Conv. layer 4	convolution	16x16x32	64	3x3	16x16x64
	activation	16x16x64	64		16x16x64
	max pooling	16x16x64	64	2x2	8x8x64
Conv. layer 5	convolution	8x8x64	128	3x3	8x8x128

	max pooling	8x8x128	128	2x2	4x4x128
	Dropout 0.5	4x4x128			4x4x128
FCNN	flatten	4x4x128			2048
	dense128	128			128
	activation (ReLU)	128			128
	Dropout 0.5	128			128
	dense3	3			3
output softmax	activation (softmax)	3			3

In CNN's, a convolution layer is normally tied with an activation layer and a pooling layer (showed Fig. 5). This bundle is repeated several times to produce a "thick" stack of down-sampled feature maps at the end of the sequence. Fully connected layers take the vectorized (flattened) form of this

stack and are also tied with some activation layers to produce output vectors. The lengths of these vectors are normally equal to the number of prediction classes. Values within these vectors are converted into probability values by SoftMax layers at the end of CNN's. The output layer present in the last layer of CNN to the normalized exponential function or softmax is a generalization of the logical function of a k-dimensional z vector into a k-dimensional  $\sigma(z)$  vector with a real number value between [0, 1]. The SoftMax function is written in the following equation (2):

$$\sigma: R^k \rightarrow [0,1]^K \quad (2)$$

$$\sigma(Z) = \frac{e^{z_j}}{\sum_{k=1}^K e^{z_k}} \text{ for } j=1, \dots, K$$

where  $\sigma$  is softmax notation symbol, z is a vector of the inputs to the output layer, K is dimensions of vector z, and j is the index of the output unit. Table I shows the specifications of the model configuration.

### C. Training of CNNs

To build the proposed system, data are collected from postmenopausal Javanese women aged over 40 years. A total of 31 subjects have agreed to participate in the research and have signed informed consent. Ethical clearance has also been obtained from the ethics and advocacy unit of the Faculty of Dentistry of Universitas Gadjah Mada (UGM) with the number: 0061/KKEP/FGK-UGM/EC/2019. Some criteria are used to exclude subjects from the research. These include suffering from cancer with bone metastases, kidney failure, metabolic diseases (hyperparathyroidism, hypoparathyroidism, osteomalacia, renal osteodystrophy, and osteogenesis imperfecta), and taking drugs that affect bone metabolism.

After dental periapical radiographs are acquired from the Radiology Department, Prof. Soedomo Dental Hospital of Universitas Gadjah Mada, the women went for bone density examination at the Radiology Department of Dr Sardjito Hospital Indonesia. Periapical radiographs used in this research have gone through an assessment process to ensure their quality. As for bone density estimation, a lunar prodigy primo DEXA densitometer (GE Lunar Corporation, Madison, WI, USA) is used to scan the subjects' spine and femur regions at an exposure of 42  $\mu$ Gy for 1.27 minutes. Bone density values were converted into T-scores to determine osteoporosis, osteopenia, or normal. These categories were then used as the labels for the collected periapical radiographs. The conversion was conducted using the standard procedure specified by the World Health Organization (WHO). Based on BMD measurements of 13 subjects, three subjects were classified as normal, six subjects were classified as osteopenia, and four subjects were classified as osteoporosis.

Training is carried out by varying sizes of image blocks (as input), numbers of convolution layers, the use of dropout layers, and sizes of kernels. The max function is used in the pooling layers with sizes of kernels of 2x2 and strides of 2. Overlapping blocks are extracted from the collected images and are augmented by applying small random rotation, scaling, and vertical flip. This process produces thousands of image blocks that are further divided into a training set and

test set. The training set contains 80% of the overall data, while the test set contains the remaining 20% of the data. Table II, shows a summary (minimum, average, and maximum) of training and validation accuracy on 26 CNN models from 3 to 6 layers for each image size.

IV. EXPERIMENTS AND RESULT

A. Experiments Models

This section presents the experiments of the proposed model for osteoporosis detection. The first part of the experiment investigates the optimal configurations of CNNs. For this purpose, we evaluate different sizes of image blocks, namely 40x40, 50x50, 60x60, ..., 150x150 pixel. CNN's are built with 3 and 4 convolutional layers, and when the sizes of image blocks are greater than 100x100 pixel, the networks are also built with 5 and 6 convolutional layers. Two sizes of convolution kernels are applied during the experiments, i.e. 3x3 and 5x5. The strides of the convolution kernels are fixed to 2, and padding is used to maintain the inputs' original sizes during the convolution. Besides, in the 5th convolution layer block, a dropout layer of 0.5 is added. To facilitate classification by providing rules for removing or keeping neurons with probability values between 0 and 1, and the value of the learning rate used = 0.0001. See Tables II (A)-(D), Table III and Fig. 6 to Fig. 8 summarizes performance of CNNs with the different configurations.

Based on 26 CNN models that have been trained (see Tables II(A)–(D), it is known that in the experiment with five layers and an image block size of 140x140, the minimum, average, and maximum values are higher than the number of convolution layers and other image blocks (see red text in Table IIC). This means that the configuration of five layers, the image block size of 140x140, and some hyper parameters as in table I are the best models of the 26 existing models. The best CNN model means a model that can differentiate trabecular patterns in the normal class, osteopenia, and osteoporosis.

Fig. 6-8 also shows experimental results in finding the best model.

Fig. 6 is a graph of the image blocks size against the accuracy of each convolutional layers. From Fig. 6, it is known that the larger the image blocks size (input blocks size greater than 100), the accuracy tends to increase, especially on the five-layer and four-layer CNN. Indicates that the image blocks size greater than 100 provides additional information on osteoporosis examination.

Fig. 6. Graph Accuracy Vs Input Size Graph with Kernel Size 3x3.

In Fig. 7, it is known that a CNN with five layers and an image size greater than and equal to 100 indicates increased accuracy.

Fig. 7. Graph Accuracy Vs Number of Layers.

Fig. 8 shows the effect of the Dropout (DO) value on accuracy, the DO value = 0.5 has a better training and validation accuracy.

Fig. 8. Graph Accuracy Vs Dropout.

The following Table III shows the experimental results of the best model from the input image size of 40x40 pixels to 150x150 pixels with epoch = 20. And look (highlight) the best of accuracy is at 140x140 pixels.

TABLE III. TRAINING ACCURACY AND VALIDATION ON THE BEST MODELS FOR EACH BLOCK SIZE WITH EPOCH = 20

Block Size	Accuracy		Loss	
	training	validasi	Training	Validation
40x40	0.865	0.713	0.293	0.746
50x50	0.908	0.749	0.207	0.690
60x60	0.929	0.772	0.163	0.722
70x70	0.949	0.798	0.120	0.653
80x80	0.970	0.837	0.072	0.526
90x90	0.970	0.846	0.071	0.462
100x100	0.956	0.866	0.106	0.373

120x120	0.974	0.903	0.066	0.224
130x130	0.966	0.890	0.079	0.290
140x140	0.977	0.956	0.056	0.091
150x150	0.973	0.916	0.064	0.227

### B. Training Models

The total number of training data is 40,755 images, 32,617 images for training, and 4069 images for validations. The dimension of the image input on this model is  $140 \times 140$  pixels. The batch size is 16, the learning rate value is 0.0001, DO=0.5 and number of epoch = 100. Then the loss function uses Adam optimization.

Training is executed on a computer with specifications processor Intel Core i7-7500U processor specifications, 8 GB RAM, GPU: NVIDIA GeForce GTX 840, Windows 10 operating system, Python 3.7 Programming Language with an editor spyder (python3.7).

Fig. 9(a)-(b) shows the trend accuracy and loss of the training process and the validation of the best models (using architecture and configuration in Fig. 5 or Table I)

Research on osteoporosis examination using dental periapical radiograph images has been carried out with a satisfactory level of accuracy and can represent a computer-aided diagnosis system. Besides, it can enrich the extraction of textural features, which is currently known for the examination of osteoporosis with dental periapical radiograph images, which previously mostly using morphological features.

(b)

Fig. 9. (a) Graph the Accuracy of the Training and Validation Process of the Best Model, (b) Graph the Loss of the Training and Validation Process of the Best Model.

### C. Testing Models

We use 4,069 images as sample test data. Model performance measured using four performance measures parameters, namely Precision, Recall, F1 score and Accuracy. The Precision, Recall, F1 score, and Accuracy values of the best model testing result see Table IV.

TABLE IV. OSTEOPOROSIS – TESTING REPORT

	Precision	Recall	F1 Score
<b>Normal</b>	0.88	0.88	0.88
<b>Osteopenia</b>	0.84	0.98	0.93
<b>Osteoporosis</b>	0.83	1.00	0.91
<b>Accuracy</b>	0.92		
<b>Macro avg</b>	0.97	0.97	0.97
<b>Weighted avg</b>	0.85	0.92	0.90

Table V shows a comparison of the performance of the osteoporosis examination between the proposed methods and those of other previous researchers. In the testing process using datasets from previous researchers [11], the dataset Augmented first so that the amount of data used in the testing process is proportional to the amount of data used in this research.

When compared to previous related work, our method has the highest validation accuracy and testing accuracy, with a validation accuracy of 98.10% and a testing accuracy of 92.50%.

TABLE V. PERFORMANCE COMPARISON OF EXAMINATION OSTEOPOROSIS

Parameters	Authors		
	<i>Licks etc. (2010) [8]</i>	<i>Sela etc. (2015) [11]</i>	<i>This Research</i>
Subject	Women over 40 years age	Women over 40 years age	Women over 40 years age
Number of training data	60 (22 normal and Osteopenia, 38 osteoporosis)	54 (11 normal, 22 Osteopenia, 21 osteoporosis)	13(3 normal, 6 osteopenia, 4 osteoporosis) augmented: 32,617 (7,527 normal, 15,054 osteopenia, 10,036 Osteoporosis)
Number of testing data	60 (22 normal and Osteopenia, 38 osteoporosis)	54 (11 normal, 22 Osteopenia, 21 osteoporosis) Augmented: 4,069 (939 normal, 1,878 osteopenia 1,252 osteoporosis)	4,069 (939 normal, 1,878 osteopenia 1,252 osteoporosis)
Gold- standard (Classtarget)	Lumbar/Fe-moral BMD DXA (Normal, osteopenia/osteoporosis)	Lumbar/Fe-moral BMD DXA (Normal, osteopenia, osteoporosis)	Lumbar/Fe-moral BMD DXA (Normal, osteopenia, osteoporosis)
Type of Feature extraction	Analysis of morphological (The trabecular area, the periphery, a proportion trabecular length, area, and perimeter (M1-M14)	Analysis morphological (porosity, the size of porosity and orientation of porous)	Texture feature (feature map CNN)
Method of Classification	Classification and Regression Tree Analysis (CART)	C45 (3,6,9-fold validation)	Fully Connected Neural Network (FCNN)
Accuracy	88.33%	86.67%	98.10%
Accuracy from joint of number of testing data [11] and this research	-	-	96.10%
Accuracy from of number testing data [11]	-	-	92.50%

## V. CONCLUSION

As shown in Table I, the highest validation accuracy is achieved when the block size is 140x140, the number of convolution layers is 5, and the size of the convolution kernel is 5x5 for the first layer and 3x3 for the other layers. It can then be concluded that the bigger the image block, the higher the validation accuracy. This tells us that bigger images provide additional information that helps discriminate trabecular patterns in normal, osteopenia, and osteoporosis classes. The improvement in accuracy, though, does not change much when the block size is increased from 140x140 to 150x150. This indicates that 140x140 has provided most of the information required by CNNs to distinguish osteoporosis. The training and validation accuracy achieved by the best model is 99.50% and 98.10%, respectively, while the loss of training and validation is 1.30% and 5.40%. Then the testing accuracy is 92.50%.

## VI. FUTURE WORK

For this reason, research on osteoporosis examination using dental periapical radiograph images can continue to be carried out, considering that research for osteoporosis examination using dental periapical radiograph images is still rarely used compared to dental panoramic images. This study can be developed by adding a process to increase the

resolution of dental periapical radiographs that tend to be a low resolution at the pre-processing stage and applying the automatic ROI selection method [29].

Further, it can also increase the number of data collections for normal and osteoporosis classes and can use variations in the image of the trabecular bone area of the left and right posterior mandibles.

## ACKNOWLEDGMENT

The authors would like to thank the Universitas Gadjah Mada and the Universitas Bumigora Mataram for funding this research. The author also would thank the Radiology Department, Prof. Soedomo Dental Hospital of Universitas Gadjah Mada and the Radiology Department of Dr Sardjito Hospital Indonesia. for supporting this research in acquisition image.

**Abstract**—Diabetes is a long-term disease. Inappropriate blood sugar level control in diabetic patients can lead to serious issues like kidney and heart diseases. Obesity is widely regarded as a major risk factor for type 2 diabetes. In this research, a model proposed to predict diabetic obese patients based on Expectation Maximization, PCA, and SMOTE Algorithms in the preprocessing and feature extraction phases, and using Fuzzy KNN classifier in the prediction phase. The model applied on real dataset and the accuracy of prediction results reflects the positive effect of the preprocessing techniques. The accuracy of the proposed model is 95.97% and outperforms other model applied on the same dataset.

**Keywords**—KNN classifier; SMOTE; PCA; diabetic obese patients

## I. INTRODUCTION

Using Data Mining (DM) and Machine Learning (ML) techniques in data mining research are a common way for making use of large amounts of available knowledge-based data. Machine Learning is extremely essential in the realm of medical diagnostics. Data mining is a great goal in science and medical research, which necessarily generates massive amounts of data owing to the special societal effect of the serious disease. As a result, Machine learning and data mining approaches are unquestionably of great importance for aspects of clinical administration, diagnosis, and treatment. As part of this work, challenges were undertaken to examine the recent literature on ML and DM methodologies in many diseases especially in the diseases of the chronic diabetes. Diagnosis in the healthcare sector is an ideal subject for ML algorithms [1]. Many of these may be identified using pattern recognition on large amounts of data. An algorithm should be trained on a small number of tests to be useful in the field, medical diagnostics must be able to tolerate noisy and empty datasets. Many researches on machine learning in the sector of healthcare have been undertaken. Healthcare ML has emerged as a top goal for many academics. Different data mining approaches and procedures in hidden pattern recognition can be used to gain insights. The medical science primary roles are to prevent or help treat diseases. One of the chronic illnesses marked by hyperglycemia is Diabetes mellitus. It can lead to a slew of difficulties [2]. As a result of higher mortality rates in recent years, According to WHO (World Health Organization) forecasts by 2040, the world's population of diabetes is

anticipated to reach 642 million [3], suggesting that one out of every ten people would suffer from diabetes in the future. There are three types of Diabetes [4], namely; Gestational Diabetes, Type-1 Diabetes Mellitus, Type-2 Diabetes Mellitus. Type-2 diabetes mellitus patients are frequently classified as having a fatty liver disease in which it could be either nonalcoholic or alcoholic fatty liver disease (NAFLD|AFLD) [5]. Type-2 diabetes mellitus has been postulated as a primary cause of NAFLD development, or nonalcoholic steatohepatitis, which likely reflects in Type-2 diabetes mellitus with rapid advancement of weight gain and resistance of insulin. Obesity and diabetes, both multifactorial, difficult illnesses, have become major public health issues across the world [6]. Many conditions, on the other hand, may be prevented. Obesity is a significant growing health concern; some refer to it as the New World Syndrome [7]. The occurrence of obesity and fatty liver in persons with diabetes of Type-2 has long been documented as they are strongly associated with each other [8]. It is often viewed as an accidental finding with small to no therapeutic value. Sedentary lifestyles or poor dietary habits result in weight gain. It may also increase the chances of facing a metabolic syndrome over time. Avoiding the significant consequences that result in massive issues in health, since early detection is the beginning point for a good life without the disease reflects the significance of using the recommended method for predicting patients suffer from diabetes and affected by obesity and NAFLD. Diabetes mellitus and its consequences, in particular, must be prevented and managed in poor and middle-income countries. The following is how this paper is arranged; Section II outlines the related work. Section III, details the suggested model as well as the dataset used. The Section IV offers the obtained results, followed by the conclusion and the future work in Section V.

## II. RELATED WORK

In [9], Kumar purposed various data mining approaches in medical sector to highlight data mining applications based on the nature of the information; In order to predict Parkinson's illness, Support Vector Machines and Artificial Neural Networks were used and resulted in 95 percent accuracy. In addition, it improved detection rate by employing an ANN to diagnose cancer of breast to 98.8 percent, and employed Artificial Neural Networks. Basma Boukenze et al. in [10] assessed the DM techniques performance in medical health

sector using multiple learning techniques. The result simulation indicated that the decision tree (DT) performed better than other learning techniques in forecasting kidney failure chronic disease. Furthermore, M. Abdullah and S. Al-Asmari in [11], clarified the same DM approaches to designate the type of anemia patients suffer from anemia. DT executed with an accuracy result of 93.75 percent. While only support vector machine algorithm was used in categorizing diabetes disease, while in [12] Kumari and Chitra used the Matlab tool version 2010a in order to identify the diabetic patients by 78 percent accuracy. Developing DT and DM classification approaches assists medical practitioners in gaining better medical judgments to detect diseases timely [13]. El-Halees and Shurrab in [14] developed a model that can discriminate between individuals with blood tumors and normal blood illness utilizing multiple association rules and ANN, results with 79.45 percent accuracy. In addition, in order to predict diabetes in many circumstances various researches have been conducted in which the authors of [15] used a regression-based approach of DM to introduce diabetes therapy predictive analysis. The Oracle Data Miner was used as a mining software to forecast diabetic treatment methods. For the experimental investigation, the support vector machine technique was applied. They conclude that pharmacological therapy for patients under the age of 18 can be postponed to minimize negative effects. The authors used four classifiers in [16] to categorize the diabetes mellitus risk. First, four categorization models were investigated: DT, Logistic Regression, ANN and Naive Bayes. Then, to improve the resilience of such models, Bagging and Boosting strategies were examined. According to the findings, the Random Forest (RF) algorithm performs the best in illness risk categorization. They suggested an early diabetes prediction model in [17], and they discovered a high correlation between diabetes, glucose level and body mass index (BMI), that was retrieved using the Apriori technique. Diabetes was predicted using RF, ANN, and K-means approaches. The ANN approach achieved the highest accuracy of 75.7 percent. For the prediction of diabetes, the authors of [18] employed KNN and the Naïve Bayes approach. Their method was implemented as a program of expert software, in which users submit input in the form of patient data and the determination of whether or not the patient is diabetic. The authors of [19] propose an attribute selection technique of firefly and cuckoo search-based for the PIMA Indian diabetes database from University of California Irvine (UCI), with the goal of greater accuracy and lesser training overhead. They also said that the proposed structure promises to be more accurate than the usual technique. The authors of [20] applied a ML model to forecast the occurrence of Type-2 Diabetes mellitus, using information from the present year ( $Y$ ). From 2013 to 2018, electronic health records were collected at a private medical facility for this investigation. Key characteristics were initially picked for the prediction model using chi-squared tests, ANOVA tests and recursive variable reduction approaches. Based on these variables, they used random forest, logistic regression, XGBoost, SVM and ensemble ML methods in order to foresee the result as diabetic, non-diabetic or pre-diabetic. The model performed pretty well in anticipating the occurrence of Type-2 diabetes in the Korean population. The authors of [21] applied two machine-learning

techniques for two-phase classification; SVM and ANN to predict diabetes mellitus. They used a real dataset from Al-Kasr Al-Aini Hospital in Egypt. In the first phase, they used SVM to predict patients with fatty liver disease with accuracy of 95%. Then in the second phase they used ANN for prediction of diabetic patients based on phase 1 and another 8 different attributes.

### III. PROPOSED SOLUTION AND DATASET

As the dataset of this problem was collected manually as will be described in next section, it had many issues like missing values, and the data was unbalanced, so we applied a preprocessing phase for the dataset. The algorithms used in the proposed model are described in this section.

#### A. Expectation Maximization Algorithm for Estimating the Missing Values

Dempster et al. 1977 in [22], demonstrated that the Expectation Maximization (EM) algorithm can be applied when  $X_{MIS}$  (the missing data joint distribution) and  $X_{OBS}$  (the observed data) is candid. For all  $(\theta \in Rd)$ , let the density function probability of  $(;)$  be  $X=(X_{OBS}, X_{MIS})$ . The estimation of  $\theta$  get the most out of the observed data log eventuality in which the expectation maximization algorithm aims to find.

$$(\theta; X_{OBS}) = \log(X_{OBS}; \theta) = \log \int f(X_{OBS}, X_{MIS}; \theta) dX_{MIS} \quad (1)$$

In general, because this number cannot be estimated explicitly, the EM method calculates the MLE by iteratively maximizing the anticipated log-likelihood of complete-data in (2)

$$l(X; \theta) = \log f(X_{OBS}, X_{MIS}; \theta) \quad (2)$$

Begin with a value of  $\theta^0$  and let  $\theta^t$  be the estimate of at the  $t^{\text{th}}$  iteration, then below is two steps of the next EM iteration:

E step: Calculate the expectation of log-likelihood of complete-data in relation to the missing covariate conditional distribution parameterized by  $(\theta^t)$ :

$$Q(\theta, \theta^{(t)} = E[l(X; \theta) | X_{OBS}; \theta^{(t)}] = \int l(X; \theta) f(X_{MIS} | X_{OBS}; \theta^{(t)}) dX_{MIS} \quad (3)$$

M step: Define  $((t+1))$  by maximizing the Q function:

$$\theta^{(t+1)} \in \text{argmax}_{\theta} (Q(\theta, \theta^{(t)})) \quad (4)$$

#### B. Feature Reduction using Principal Component Analysis Algorithm

Principle Component Analysis (PCA) is an extracting features statistical approach that employs to turn a set of possibly associated annotations to a set of variables uncorrelated transformed linearly known as principle components. PCA may be used to reduce the feature dimensions [23]. Because the eigenvectors number exceeds the columns number, the dimension of the projected output data is smaller than the dimension of the input data. The method of PCA utilized in the feature reduction step is as follows.

**Algorithm 1 " PCA"**

Assume: samples of N ( $x_1, \dots, x_N$ ) each  $x_n \in R^D$   
 Aim: D dimensions data project to K dimensions ( $K < D$ )  
 Then captures the projected data maximum possible variance

Consider

( $u_1, \dots, u_D$ ) be the principle components, assumed to be  
 orthogonal such that:  $u_i^T u_j = 0$  if  $i \neq j$  and should be  
 orthonormal such that  $u_i^T u_i = 1$

Each peincipal component is a vector of size  $D \times 1$

We will select the frirst K principal components

1: Compute the mean of the data

$$\bar{X} = \frac{1}{N} \sum_{n=1}^N X_n \tag{5}$$

2: Compute the Covariance matrix

$$s = \frac{1}{N} \sum_{n=1}^N (x_n - \bar{x})(x_n - \bar{x})^T \tag{6}$$

3: Find the eign values 4

4: Take the top k eign vectors according  
 ( corresponding to the top k eign values)

5: Call these vectors as  $u_1, u_2, \dots, u_k$

( such that  $\lambda_1 \geq \lambda_2 \dots \dots \geq \lambda_{k-1} \geq \lambda_k$

$$6: Z_n = U^T \times X_n \tag{7}$$

**C. Handling the Un-Balanced Data using SMOTE Algorithm**

Chawla presented the Synthetic Minority Oversampling Technique (SMOTE) in 2002 [24]. In contrast to random oversampling, in the SMOTE method the minority class is oversampled by producing samples of synthetic rather than oversampling with replacement. The SMOTE method generates fake instances based on similarities between existing minority cases in feature space rather than data space [24, 25]. These synthetic instances are constructed by connecting a portion or all of the minority class's K-Nearest Neighbor (KNN). Neighbors from the KNN are picked at random depending on the quantity of oversampling necessary. Algorithm 2 represents the used SMOTE algorithm for handling the un-balanced dataset.

**D. Fuzzy KNN Classifier**

Keller et al introduced the fuzzy KNN classifier[26], which assign to each sample a class memberships, as a function from of its KNN training samples of each sample's distance. Because it is easy and provides information on the certainty of the classification result, the fuzzy KNN classifier is a popular choice for applications. According to Keller et al, the major benefit of utilizing the FKNN model may not be the reduction in error rate. More crucially, the model provides a level of assurance that may be combined with the "refuse-to-decide" option. Objects with overlapping classes can thus be discovered and treated independently as in Algorithm 3.

**Algorithm 2 " SMOTE"**

The input:

X: original set of training sample

N: percentage of oversampling

K: nearest neighbors value

The output: the oversampled training set

n ← # observations

m ← # attributes

nmin ← # min observations

if N < 100 then

Stop: warning "N should be greater than 100"

end if

N ← int(N/100)

S<sub>(n\*N)\*m</sub> ← empty array for synesthetic samples

for i ← 1 → n<sub>min</sub>

Do

Discover the KNN for each i then save the indexes in the m newindex ← 1

while N ≠ 0 do

K<sub>c</sub> ← number between (1& K) randomly

for j ← 1 → m

do

$$\text{dif } f \leftarrow X[\text{nn}[K_c][j]] - X[i][j] \tag{8}$$

gap ← uniform(0, 1)

$$\text{synthetic}[\text{newindex}][j] \leftarrow X[i][j] + \text{gap} \times \text{dif } f \tag{9}$$

end for

newindex+ = 1

N- = 1

end while

end for

Return (X & synthetic)

**Algorithm 3 " Fuzzy K-Nearest Neighbor**

From sample x, get the KNN.

Soft labels, input x, a membership vector

$$\mu(x) = [\mu_{c_1}(x), \dots, \mu_{c_i}(x), \dots, \mu_{c_l}(x)]$$

$$\mu_{ih}(x) = \mu_i(x_i) = \begin{cases} 0.51 + \left(\frac{n_i}{k}\right) * 0.49, & \text{if } c(x_j) = i \\ \left(\frac{n_i}{k}\right) * 0.49, & \text{if } c(x_j) \neq i \end{cases} \tag{10}$$

- Membership function calculation

$$\mu_i(x) = \frac{\sum_{j=1}^k \mu_{ij} (1 / (\|x - x_j\|^{2/(m-1)}))}{\sum_{j=1}^k (1 / (\|x - x_j\|^{2/(m-1)}))} \tag{11}$$

- The target class  $\max \mu_i(x)$

### E. Dataset Description

The dataset used in this study was obtained from Cairo University, Faculty of Medicine, Al-Kasr Al-Aini Hospital [21]. The dataset contains 30 variables; Gender, Age, Alcohol consumption, Smoking, Schistosomiasis, steroids, History of hypertension, Oral contraceptive pill, Waist circumference, Body Mass Index, Hemoglobin test (HGB), Liver disease, Primed lymphocyte test, Basic Insulation Level, Aspartate Aminotransferase (AST), Alanine Aminotransferase (ALT), White blood cells (WBCs), Albumin level in blood (ALB), Protein C test, Alkaline phosphatase (ALP), Gamma-Glutamyl Transferase (GGT), Total cholesterol, Triglycerides test (TGs), High-density lipoprotein (HDL), Low-density lipoprotein (LDL), International Normalized Ratio (INR), Spleen size, Fasting blood sugar, History of diabetes, and Hemoglobin A1c (HBA1C). This was preprocessed as will be shown in the proposed model section through different phases. The algorithms used in the data-preprocessing phase are expectation maximization algorithm, which estimate missing values. PCA algorithm is used in feature reduction phase, while SMOTE algorithm used to generate new sample in the minority class to overcome the unbalanced data issue that affects the measures.

### F. Proposed Model

Fig. 1 shows the basic steps used in the proposed model for the prediction of diabetic obese patients. At the first, we read the dataset and apply a data preprocessing phase on it. The first step in the data preprocessing is estimating the missing values by the EM algorithm. The next step is applying the PCA algorithm to reduce the features in the dataset. The basic steps of the PCA are calculating the covariance matrix, then calculating the Eigen values, then sorting the attributes in descending order, then normalizing the values, and calculating the weight value for each attribute. The third step is solving the unbalanced data using SMOTE algorithm described in last section above. The SMOTE algorithm used for generating new sample in the minority class. The last step in the proposed model is classifying the new samples using fuzzy KNN classifier.

Fig. 1. Proposed Model Steps for Prediction of Diabetic Obese Patients.

IV. EVALUATION METHODS AND RESULTS

A. Evaluation Method

Evaluation of the performance of algorithms using the precision and recall criteria is very valuable. When making a choice, precision is the proportion of the time that the model properly predicts a good outcome. Precision is defined as the accurately identified or predicted positive examples divided by all the positive examples given. The proportion of properly recognized positives out of all existing positives is referred to as recall; it is calculated by dividing by the truly categorized positive cases by all the number of genuine examples in the set of positive testing. An optimal model must have both high recall and great accuracy. The F-measure is the consistent measure of accuracy and recall. The F-measure runs from zero to one, in which one indicating a classifier that properly captures accuracy and recall.

$$Precision = \frac{TP}{TP+FP} \tag{12}$$

$$Sensitivity = \frac{TP}{TP+FN}, \tag{13}$$

$$F - measure = \frac{2(Precision)(Sensitivity)}{(Precision)+Sensitivity} \tag{14}$$

In which, the true positive (*TP*) represent the positive cases that predicted positive, the false negative (*FN*) represents the cases that were positive. However, it predicted negative and the false positive (*FP*) are the negative cases that were positively predicted.

B. Results

In this part, we report the findings obtained when the fuzzy KNN classifier used with the proposed model on the dataset described, and applying the fuzzy KNN classifier on the raw data of the dataset. Table I shows the proposed model output applied on the dataset after preprocessing compared to the same classifier but without data preprocessing.

TABLE I. FUZZY KNN (PROPOSED ) WITH DATA PREPROCESSING COMPARED TO FUZZY KNN WITHOUT DATA PREPROCESSING

	FKNN Proposed Model Fuzzy Parameter = 0.5 & K= 5	F-KNN Raw data Fuzzy Parameter = 0.5 & K= 5
Sensitivity	1.0000	0.7156
Precision	0.9197	0.5735
Accuracy	0.9579	0.6577
F1 Score	0.9582	0.6367

Table I and Fig. 2 shows that the data preprocessing steps, estimating the missing values, feature reduction and solving the problem of unbalanced data enhanced the all measurement values resulted from the classifier.

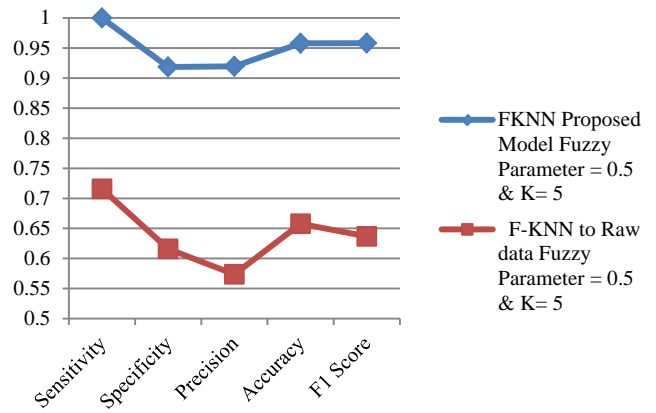

Fig. 2. Proposed Model with Data Preprocessing Vs Fuzzy KNN without Data Preprocessing.

The obtained results were compared to the results obtained in [21], as they used the same dataset. They proposed a two-phase classifier for predicting the potential diabetic obese patient as mentioned in related work section. Table II shows the basic differences in the proposed model and the model in [21].

TABLE II. THE DIFFERENCE IN METHODOLOGIES USED IN THE PROPOSED MODEL WITH THE MODEL IN [21]

	Proposed model	Model in [21]
Estimating missing values	Expectation Maximization Algorithm	weighted sum of linear interpolations from the closest accessible points.
Feature reduction	PCA algorithm	Correlation Feature Selection
Handling unbalanced data	SMOTE algorithm	Using K-fold cross validation
Classification	Fuzzy KNN classifier	SVM for phase1 and ANN for phase 2

Table III shows the comparison between results of the proposed model and results in [21].

TABLE III. ACCURACY COMPARISON BETWEEN PROPOSED MODEL AND MODEL IN [21]

	Proposed model	Model in [21]
Accuracy	95.97%	86.56%

From Tables II and III, we can observe that the algorithms and techniques used in the proposed model to prepare the data before training and testing were affected positively the data especially the steps of estimating missing values and handling unbalanced data, also the proposed classifier introduces a promising classification accuracy compared to the results introduced in [21].

## V. CONCLUSION AND FUTURE WORK

In this research a model for prediction of Diabetic Obese Patients was proposed, the model was based on Expectation Maximization, PCA, and SMOTE Algorithms in data preparation and preprocessing phase, and the fuzzy KNN classifier was used in prediction phase. The dataset used in this research was obtained from Cairo University, Faculty of Medicine, Al-Kasr Al-Aini Hospital. The algorithms used in the preprocessing enriched the clearness and effectiveness of the dataset which reflected in the prediction phase as shown in the results. The prediction accuracy reached to 95.97% in the proposed model and this result outperforms a corresponding model applied on the same dataset mentioned in the related work. We can suggest some improvements in the preprocessing phase afterwards like adopting another feature selection algorithm and other algorithms for handling imbalanced data, and estimating the missing values. In addition, an ensemble model can be provided on more than one classifier in order to enhance the precision value.

**Abstract**—The present study evaluates the prediction performance of the multi-machine learning models (MLMs) on high-volatile financial markets data sets since 2007 to 2020. The linear and nonlinear empirical data sets are comprised on stock price returns of Karachi stock exchange (KSE) 100-Index of Pakistan and currencies exchange rates of Pakistani Rupees (PKR) against five major currencies (USD, Euro, GBP, CHF & JPY). In the present study, the support vector regression (SVR), random forest (RF), and machine learning-linear regression model (ML-LRM) are under-evaluated for comparative prediction performance. Moreover, the findings demonstrated that the SVR comparatively gives optimal prediction performance on group1. Similarly, the RF relatively gives the best prediction performance on group2. The findings of study concludes that the algorithm of RF is most appropriate for nonlinear approximation/evaluation and the algorithm of SVR is most useful for high-frequency time-series data estimation. The present study is contributed by exploring comparative enthusiastic/optimistic machine learning model on multi-nature data sets. This empirical study would be helpful for finance and machine-learning pupils, data analysts and researchers, especially for those who are deploying machine-learning approaches for financial analysis.

**Keywords**—Support vector regression; random forest; machine learning-linear regression model; optimal prediction performance; currencies exchange rates; stock price returns

## I. INTRODUCTION

Since several decades, a lot of researchers and data analysts have been applying traditional econometric models (TEM) for hypothetical testing and financial-nonfinancial market evaluation. But there have some constraints with TEM as nonlinear approximation, future prediction developments of the markets and data prediction accuracy. On the other hand, nowadays, the supervised and unsupervised machine learning approaches have quite famous to precisely evaluate the different nature of big data. So, the analysis effectiveness is directly associated with the prediction accuracy the model.

The machine learning approaches are successfully employed into different domains with respect to their applications. But it is usually used for speech recognition, image processing, wind-speed frequency scaling, network filtering and financial markets prediction [1-4]. Furthermore, the evaluation of stock market and forex market returns with machine learning approaches are very hot topic nowadays.

Moreover, the financial-nonfinancial future markets predictions are very helpful for those who are willing for financing in the market and for hedgers to hedge their financial assets [5, 6]. The machine learning algorithms (MLAs) have capability to analyze the linear-nonlinear data [7]. For example, the forex market is very dynamical market due to globalization. In prior era, the researchers and data analysts were used TEM to examine the forex market returns. But since last decade, the researchers and data experts have been rapidly diversifying from TEM to machine learning approaches for financial market prediction [8-10]. In fact, the MLMs are most powerful and very effective approaches to predict the high-volatile and nonlinear data financial data [11, 12]. So, the key purpose of present study is to evaluate the prediction performance of underlying machine learning models on different nature financial data sets, such as the group1 comprised on stock price returns of KSE 100-index of Pakistan which is illustrated in Fig. 1.

Fig. 1 indicates that the stock price returns of KSE 100-index is very dynamic financial market. This diagram is comprised on original data, rolling mean and average which collectively demonstrates the good returns (positive returns), bad returns (negative returns) and no returns (zero returns). The group2 contains on the PKR exchange rates against five major currencies (USD, Euro, GBP, CNY & JPY) which is illustrated in Fig. 2.

Fig. 1. Daily Stock Price Returns of KSE 100-index.

\*Corresponding Author.

Fig. 2. PKR Exchange Rates against Five Major Currencies.

Fig. 2 demonstrated that the PKR exchange rates against entire currencies have been steadily increasing over the period, which indicating the domestic currency (PKR) has

been depreciating since 2007 to till 2020. Furthermore, these both empirical data sets will be evaluated by SVR, RF and ML-LRM. These empirical machine learning models are commonly used for classification and regression problems. But the present study will be executed the prediction performance of entire machine learning models on nonlinear and high-frequency data sets which quite effective for researchers and data analysts.

The remaining sections of study comprised as: the Section 2 will be contained on most similar literature on the stock markets and the forex markets which executed by MLMs. The Section 3 will be contained on data collection process, data preparation and mathematical interpretation and application of the models. Similarly, the Section 4 will be contained on results and discussion and forecast optimal prediction model. Finally, the Section 5 will be contained on conclusion-based sound evidence, limitation of the study and significant future developments of the study.

## II. SIMILAR STUDIES

Since the last decade, the researchers and data analysts have been rapidly diversified from TEM to flexible and experimental machine learning approaches for optimal prediction. In the modern era, the MLAs are typically used to determine the returns of dynamical stock markets. To predict the next day price index of the Taiwan index feature, [13] have deployed hybrid SVR with SOFT (self-organized feature map) approach by filter-based feature selection to improve the prediction accuracy of the model and mitigate the cost of training time. The findings of this study demonstrates that the hybrid SVR improves the training time and prediction accuracy. Another study has employed SVR for prediction stock prices on daily and up to the minute. The findings of this study shows that the SVR has absolute predictive power, whenever apply the new strategy of model periodically [14]. The hybrid prophet-SVR model is outperformed than relatively other approaches by using time series demand with seasonality in stock index [15]. [16] have applied the machine learning based RF to examine the future predictions of stock prices of key listed firms. Moreover, [17] have been executed the trend of the Thai-stock market by deploying the SVR, multi-layer perception (MLP), and partial least square classifier models (PLSCM). The scholars have concluded that the Thai-stock market is rapidly growing while the investors are absolutely acquaintance about market dynamics. Similarly, some studies have evaluated the factors of stock prices returns via the reinforcement learning approach [18]. A lot of other studies have executed the real impact of prices by using mixed methodologies. Moreover, the Long-Short Term Memory (LSTM) is an artificial recurrent neural network (RNN) architecture which works on feedforward standards. Especially, it employed for outliers' detection problem in given big data set by fixing threshold, hence, this approach is very useful to investigate the dynamical stock market [19-21]. But the present study will execute the stock price returns of KSE 100-index of Pakistan and subsequent evaluate the optimal prediction performance model.

Furthermore, the forex market is quite significant for those who want to be financing into the international market for

economic privileges. Because the currency exchange rates may bring probabilistic effects on economic value of their imperative assets. For currency risk management, a researcher community has been predicted the future currency exchange rates on voluntarily currency selection by using MLMs. For instance, The stochastic volatility model with jumps to SVR in order to account for sudden big changes in exchange rate volatility [22]. So the experimental studies demonstrate that the empirical new model has the ability to improve the forecast accuracy. The author in [23] had predicted the exchange rates of major currencies of developed countries. This study deployed the mixed methodologies as the deep neural networks, MLMs and econometric approaches to predict the currencies exchange rates. Besides, this study concludes that the currencies exchange rates of developing countries are more volatilized than developed countries. So, the traditional models may not properly investigate to the nonlinear approximation. According to econometric assumption, the empirical data should be in linear format for econometric modelling. But the empirical data lost their originality whenever it transformed from nonlinear to linear scale through the natural logarithm or another approach. But the MLMs have ability to evaluate every kind of data. Therefore, the usage of MLAs have been precipitously increasing over the period for optimal prediction to nonlinear approximation. The author in [24] has analyzed the couple of currencies exchange rates (USD/CHF, USD/CAD and USD/JPY) along with the shuffled frog leaping algorithm (SFLA). Moreover, a lot of other scholars executed MLMs prediction performance along with different currencies exchange rates data. Another study executed the currency exchange rate is a certain cause of domestic inflation by using the Dorn-busch approach. Besides, they also investigated that the USA housing prices raised 7% with excluded currency ERs. But in the last decade, the USA housing prices 40% grown-up by variation into local currency exchange rates [25]. After intensely viewed to the comprehensive literature, we summarized that the MLMs are excessively used to predict the stock market and forex market returns.

### III. EMPIRICAL DATA AND RESEARCH METHODOLOGY

#### A. Data Collection and Preparation for Analysis

The empirical data set of the present study is divided into two certain groups. The group1 is contained on the stock price returns of KSE 100-index of Pakistan. In addition, the group1 data is dragged from the official website of the KSE of Pakistan (<https://www.psx.com.pk/>). This study measures the price returns from given stock prices as follow: Lumley [26].

$$R(t_0, t_1) = \left( \frac{P_{t_1} - P_{t_0}}{P_{t_0}} \right) * 100 \quad (1)$$

In Equation 1, the stock price returns are executed as the  $P_{t_0}$  is daily stock prices at the time  $t_0$  subtract from the stock price  $P_{t_1}$  at time  $t_1$  and divided by  $P_{t_0}$  and multiplied by 100, whereas the  $P_{t_1}$  denotes to current stock prices and  $P_{t_0}$  denotes to the previous stock price of the stock market. As Fig. 1 is showing the stock price returns are high-volatile while this study follows [27-29] for normalizing the empirical data set.

$$y = \ln(r + \sqrt{r^2 + 1}) \quad (2)$$

Moreover, the group2 is contained on PKR exchange rate against five major currencies (USD, EUR, GBP, CHF, JPY). The thirteen-year daily currencies exchange rates data set dragged by the official website of the central bank of Pakistan (<http://www.sbp.org.pk/>). The Fig. 2 discretely exhibits the volatility of currency exchange rates against each given currency.

#### B. Research Methodology

The certain methodologies play an important role in the empirical studies to execute the hypothetical examination. But before to mathematical interpretation of the models, we must take keenly overview the whole process of performance evaluation of the models. Fig. 3 showed that the primarily both kinds of raw data sets are uploaded into the data repository of jupyter notebook and subsequently refine the data and scaled the data and become in specific format to optimize the machine learning algorithm. Furthermore, the scaled data set would split into train and test, whenever 80% will use for training purpose and rest of data will use for testing purpose. Furthermore, we shall train the model and evaluate the prediction performance of training model with average loss function. This study would execute the prediction performance of the models, if the train predicted error  $\xi_t < \xi_e$  expected error otherwise update the training data set.

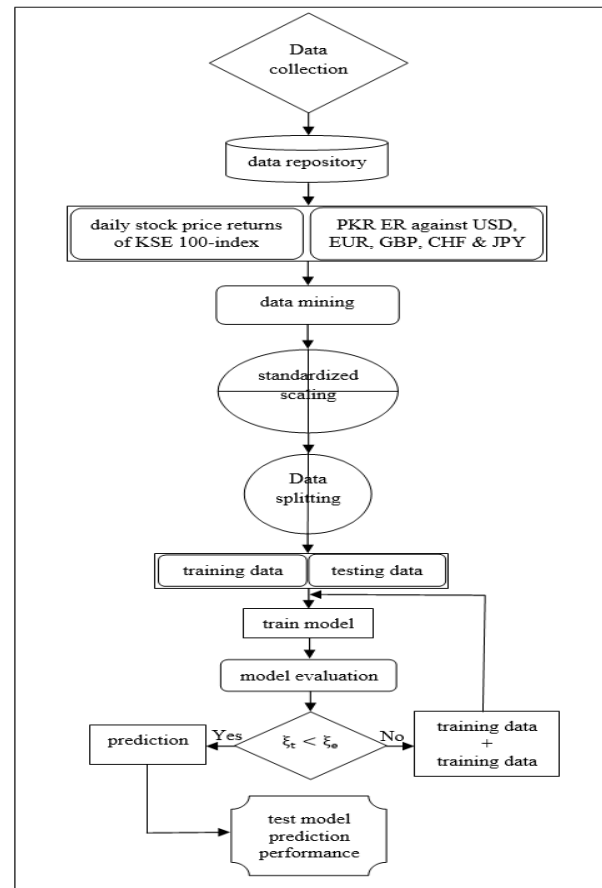

Fig. 3. Flowchart of Models' Prediction Process.

1) *Support vector regression*: The support vector regression model is popular as supervised learning approach which used for sort regression analysis [30, 31]. The support vector machine (SVM) was primarily built for structural risk measurement, but subsequent the researchers and data analysts had customized it for regression purposes, especially for time-series data. The SVM has the ability to measure linear and nonlinear approximation. The authors in [32] have employed the support vector machine (SVM) for the statistical problem. For the execution of the model prediction performance, the present study follows [33, 34].

In Fig. 4,  $x_i \in \mathbb{R}_n$  is an input function whereas  $i - th$  is  $n - th$  number of  $x$  as  $i = 1, 2, 3, \dots, n$ . and  $y_i \in \mathbb{R}_n$  is an output function where  $i - th$  is  $n - th$  number of  $y$  as  $i = 1, 2, 3, \dots, n$ . where  $k - th$  is  $x$  vector at  $n - th$  number of vectors which associated with specific weights  $\bar{\alpha}$  at  $m - th$  number of  $k - th$  vectors and summation  $b$  bias. For instance, we have a time-series data set where  $z = (x_i y_i), 1 \leq i \leq N$ . The core idea dragged by [35]. Let suppose  $\bar{\alpha}_m = W^t$ , the problem may solve as follows:

$$f(x_i) = W^t \varphi(x_i) + b \tag{3}$$

In equation 3, the  $w^t$  represents to specific weight at  $n - th$  number of  $x$  vector and  $b$  denoted to biases. Moreover,  $x$  is considered as input vector taken by  $\varphi$  into a higher dimensional space. The model performance can be improved by optimization the weights and bias of the model as below:

$$\min_{(w, b, \varepsilon_1, \varepsilon_2)} \frac{1}{2} \|\omega\|^2 + C \sum_{i=1}^n (\varepsilon_1^i, \varepsilon_2^i) \tag{4}$$

In equation 4, the  $C$  is makes swapping between two models' simplicity and generalization ability. If  $Y_i - W^T(\phi(x)) - b \leq \xi + \varepsilon_1^i$  and  $W^T(\phi(x)) + b - y_i \leq \xi + \varepsilon_1^i$ , the error position is determined by slack variables as  $\xi$  &  $\varepsilon_i$ . We can map high volatile and nonlinear data set from the original vector space by using the kernel approach. However, this is a pretty way to drag the SVR model as below:

$$y_i = \int(x_i) \sum_{i=1}^n ((\alpha_1 \alpha_m) K(x_i, x_n)) + b \tag{5}$$

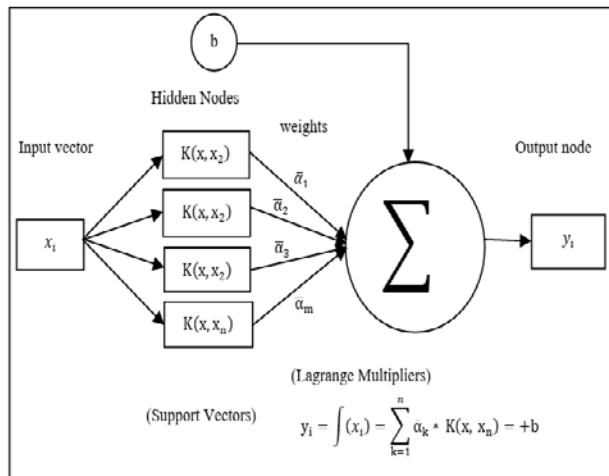

Fig. 4. Structure of Support Vector Regression.

Whereas.

Here  $\alpha_1 \alpha_2$  both are represented to langrage variables multiplier. The below equation indicates that the extensive utilization of kernel by Gaussian Function concerning the size of  $\sigma^2$ :

$$Z(x_i x_k) = \exp\left(\frac{-\|x_i - x_n\|^2}{2\sigma^2}\right) \tag{6}$$

2) *Random forest*: The RF is an ensemble approach which keeps the capability of performing as both regression and classification problems. In addition, it can handle binary and multi-classification problems. Moreover, the present study uses bootstrap aggregation for absolute random selection as follows [36]. For instance, when the explained variable is a continuous variable and  $\theta$  is getting random vector then it promotes to decision trees of RF for regression purpose. Moreover, the  $x$  and  $y$  are random vectors and training data set taken systematically. Besides,  $h_i(x)$  is a single decision tree from multi decision trees where  $k - th$  denote the number of decision trees for prediction  $h(x, \theta_i)$ , where the  $k - th$  number of outputs by  $i - th$  random vectors as  $i = 1, 2, 3, \dots, k$  as follows [37].

$$H(x) = \frac{1}{k} \sum_{i=1}^k h_i(x) \tag{7}$$

In equation 7, the  $H(x)$  demonstrates the output of combined RF regression models. Moreover, in the training data set  $k - th$  shows the number of values represented in the model.

$$H(x) = \underset{Y}{\operatorname{argmax}} \sum_{i=1}^k I(h_i(x) = Y) \tag{8}$$

Whereas  $I^*(\cdot)$  is an appropriate linear function of the model and  $Y$  denotes an outcome. Similarly,  $h_i(x)$  and  $h_k(x)$  are training data sets that collection of  $X, Y$  vectors.

$$\int(x, y) \equiv \hat{P}_k I(h_k(x) = Y) - \max_{j \neq y} \hat{P}_k I(h_k(x) = j) \tag{9}$$

For example,  $A$  is the outcome from classifier  $h_k(x)$  from random vectors that can be optimum ensemble as  $\hat{p}(A) =$  proportion of classifiers  $h_k(1 \leq k \leq K)$ , whenever event  $A$  occurs. In addition, the analysts acknowledge that they optimize the model prediction performance by making more generalizations to stochastic error ( $e$ ).

$$Pe^* = P_{x,y}(\int(x, y) < 0) \tag{10}$$

According to the theorem, the stochastic problem can be determined as below equation whenever the number of decision trees may increase.

$$Pe^* \xrightarrow{K \rightarrow \infty} P_{x,y} [P_{\Theta}(h(x, \Theta) = y) \max_{j \neq y} P_{\Theta}(h(x, \Theta) = j) < 0] \tag{11}$$

In equation 11, the  $P_{x,y}$  denotes problem in  $x, y$  random vectors and  $k - th$  denotes the total number of decision trees in the model. In addition, if the decision trees grow up the generalization of PE will tend to upper bond. Hence, the RF algorithm has worthy convergence and can prevent over-fitting [38, 39].

3) *Machine learning-linear regression model:* The regression approach is very useful for linearity approximation. Although the traditional approaches have been employing for execution the high-frequency and nonlinear data sets, but traditional approaches (linear regression) cannot properly investigate the nonlinear data sets [12]. However, the present study is applying the ML-LRM Fig. 5 for best prediction performance. For instance,  $x_i$  is input parameter where  $i - th$  is  $n - th$  number of input parameters as  $i = 1, \dots, 2, \dots, 3, \dots, n$  and every input parameter takes specific weight which denotes by  $w_i$  with  $i = 1, 2, 3, \dots, n$  at  $n - th$  number of weights. At the time of training model, the weight multiplied with input parameters and summation biases weights. Moreover, the  $n$ th denotes the number of values of the training model. Primarily, we train our model on training data set and test the model output  $y_i$  by using the testing data set and execute the prediction performance of the model.

In mapping function  $\Phi$  makes typical function with  $x$  input parameter as  $\Phi: X \rightarrow \mathbb{R}^N$ . A linear function of hypothetical set: weight and bias are associated with mapping function as  $x \rightarrow w \cdot \Phi(x) + b$ :  $w \in \mathbb{R}^N, b \in \mathbb{R}$ . Moreover, the exclusive weight leads to risk minimization and optimization of the typical model.

$$\min_{w, b} F(w, b) = \frac{1}{m} \sum_{i=1}^m (w \cdot \Phi(x_i) + b - y_i)^2 \quad (12)$$

$$F(W) = \frac{1}{m} \|X^T W - Y\|^2 \quad (13)$$

$$X = \begin{bmatrix} \Phi(x_1) & \dots & \Phi(x_m) \\ 1 & \dots & 1 \end{bmatrix} \in \mathbb{R}^{(N+1) \times m} \quad (14)$$

So,

$$X^T = \begin{bmatrix} \Phi(x_1)^T & 1 \\ \vdots & - \\ \Phi(x_m)^T & 1 \end{bmatrix} \quad W = \begin{bmatrix} \omega_1 \\ \vdots \\ \omega_N \\ b \end{bmatrix} \quad Y = \begin{bmatrix} y_1 \\ \vdots \\ y_m \end{bmatrix} \quad (15)$$

Additionally, the convex and differentiable functions executed as:

$$\nabla F(W) = \frac{2}{m} X(X^T W - Y) \quad (16)$$

$$\nabla F(W) = 0 \Leftrightarrow X(X^T W - Y) = 0 \Leftrightarrow XX^T W = XY \quad (17)$$

Fig. 5. Structure of ML-LRM.

Equation 17 is explained that if the  $w = 0$ , then the hypothesis set would also be zero / no fraction between input-output parameters of the model.

#### IV. RESULTS AND DISCUSSION

Table I summarizes the significant information of both group data. The group1 is contained on daily stock price returns of KSE 100-index of Pakistan and group2 is contained on PKR currency exchange rate against five major currencies of the world. The above statistics demonstrated that the total number of values are 3187 and 3464 in group1 and group2, respectively. Moreover, in group1, the mean and standard deviations are 0.04 and 1.19, respectively, indicating that the group1 data set is highly deviated over the period. In group2, the mean of currencies exchange rates is 97.06, 121.7, 146.9, 98.4 and 0.96, and the standard deviation of currencies exchange rates is 23.4, 21.3, 20.9, 26.9 and 0.22, respectively. According to group 2 statistics, the PKR has been depreciated since 2007 to 2020. Furthermore, the other descriptive statistics are illustrated in the above table as like minimum, maximum, etc.

Table II executes the augmented dickey fuller (ADF) approach to investigate whether the particular parameters have unit-root (non-stationary) or not (stationary) at specific critical level. Although the machine learning algorithms have capability to analyze the nonlinear approximation, but with respect to econometric assumptions, the empirical data should be to stationary (normal distributed) before to diagnosed. So in Table II, the statistics demonstrated that the t-value > critical value at 1%, 5% & 10% confidence interval at 1<sup>st</sup> difference. However, the unit root is not existed in the significant model.

TABLE I. DESCRIPTIVE STATISTICS

statistics	KSE 100-Index	Currency Exchange Rates

	6.207	0.755**	13.174
	6.990	0.889**	13.574
	4.304	0.650**	10.412
	0.056	0.005**	0.1690

Note: In Table V, \*\* indicate comparative best prediction performance model on certain data group.

Tables III, IV and V execute the prediction performance of MLMs on different nature of data sets. In 1st experiment, the present study used daily stock price returns of KSE 100-index to evaluate the prediction performances of MLMs through mean absolute error (MAE), mean Squared error (MSE) and root mean squared error (RMSE). Consequently, the output shows that the SVR gives relatively optimal prediction performance than RF and ML-LRM on group1 data set; hence, the MAE, MSE and RMSE of SVR is less than RF and ML-LRM. But the ML-LRM is giving best prediction than RF on the corresponding data group. So, on the 1<sup>st</sup> experiment, the absolute prediction performance is summarized as SVR > ML-LRM > RF. Furthermore, in 2nd experiment, we used group2 data regarding currencies exchange rates for the prediction performance of MLMs. In addition, the loss of RF < SVR < ML-LRM while the RF is giving optimal prediction performance than SVR and ML-LRM. In addition, the SVR gives best prediction than ML-LRM at the same experiment. In 2nd experiment, the prediction performance of MLMs is categorically assembled as RF > SVR > ML-LRM. In fact, the empirical data set is nonlinear nature in 2nd experiment and linear regression algorithm is operating in ML-LRM while relatively the ML-LRM doesn't properly investigate the data. On the other hand, the RF is typically used for classification and regression problems. So the RF algorithm is best recognizing the typical data set, even though the data is

nonlinear. However, the RF is comparatively given the optimal prediction performance in 2nd experiment.

Fig. 6. Graphically Evaluation of Prediction Performance of MLMs on Group1.

Fig. 6 executes the graphical prediction performance of SVR, RF and ML-LRM at group1. The output demonstrated the SVR model is given optimal prediction than RF and ML-LRM, hence, the red line is very closed to true line. But the RF predicted plots are slightly away from true line. Similarly, the ML-LRM prediction line is comparatively less close to true line. So, the whole prediction performance of MLMs from Fig. 6 executes as follows: SVR > ML-LRM > RF. Thus, the SVR can comparatively best predict than RF and ML-LRM on a high-volatile time series data set. Some previous studies are supporting to findings of current study as: [40] determined the comparative prediction performance between SVR and ensemble empirical mode decomposition (EEMD) through Singular Spectrum Analysis (SSA) on Shanghai stock price index. Moreover, this study correspondingly examining the market tendency, market fluidity, economic topographies of the market. The output shows that the SVR can relatively best predict to the fluidity of forex market and stock market than EEMD. So, this is sound evidence about the SVR can gives more efficient and accurate prediction than generic TEM and MLMs on high-frequency data which supported to findings of current study.

The Fig. 7 executes the graphical prediction performances of five empirical models on group2. Each model has relatively summarized the prediction performance of SVR, RF and ML-LRM. In addition, the output of every model is categorically presented along with specific color as follows: SVR with dark-red, RF with yellow-green, ML-LRM with dark-orange and original input data with light-blue color. The model 7(a) in our 2<sup>nd</sup> experiment exhibits the prediction performance of MLMs by taking the PKR exchange rate against USD on the y-axis and the number of time steps on the x-axis. Consequently, the RF is giving relatively best prediction than SVR and ML-LRM while yellow green line is extremely closed to the true line. In model 7(b), again the RF is relatively giving the best prediction while the yellow green line is very closed to light blue line. Similarly, the output of models c, d & e is accompanied as previous two models. With respect to our

2<sup>nd</sup> experiment, the findings concluded the RF can comparatively best predict to the nonlinear approximation than SVR and ML-LRM. The findings of 2<sup>nd</sup> experiment is supported by [41].

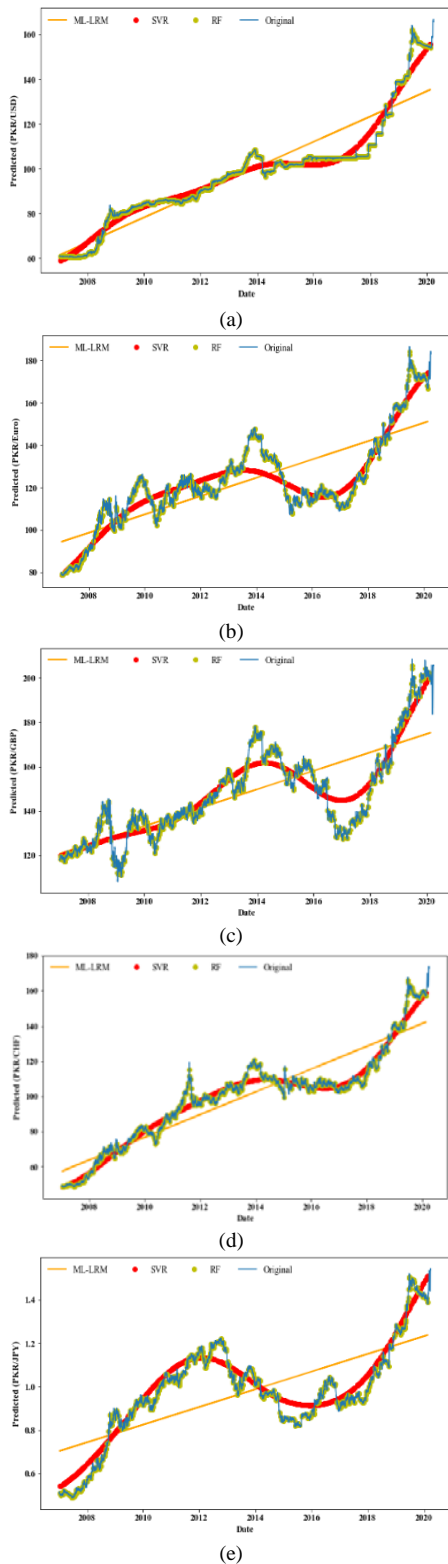

Fig. 7. Graphically Evaluation of Prediction Performance of MLMs in Group2.

## V. CONCLUSION

The stock market and forex market both are highly dynamical financial markets. The usage of machine learning approaches are rapidly growing in financial markets for economical analysis. Therefore, the key purpose of the present study is to investigate the best predictor machine learning model by giving different nature of high frequency financial data sets. So, the empirical findings demonstrated that the SVR and RF have ability to optimistic prediction on high-volatile and nonlinear data sets respectively. In fact, the SVR is a supervised learning approach which works on the principle of support vector machine (SVM) to solve the classification and regression problems. Hence, the SVR is very useful approach for complex and high volatile data. On the other hand, the RF is usually used for classification problems. However, the RF has given best prediction on nonlinear approximation. Moreover, this study had targeted only forex market and stock market of a country, hence, the study may more robust by using panel financial market data. Further research directions are using hybrid deep neural networks with filter-based feature selection to improve the prediction accuracy and reduce the cost of training time and compare the performance with RF and SVR by using more complex financial data.

**Abstract**—Multi-hop Wireless Network (MWN) requires the existing of wireless nodes that communicate via a wireless channel. Thus, selecting optimal paths between the communicant nodes is a major challenge. Many researchers are focusing on this topic and proposed some routing protocols that help the nodes to learn multi-hop paths. Multi-hop wireless network is used for several types of applications, like military, medical care and national security. These applications are important and critical, so they require a certain level of performance and security during data communication. Securing the transmission of data in a multi-hop network is a challenge since the devices have limited resources like memory and battery. In this paper, we propose an optimal and secure routing protocol. The main goal of this proposal is to improve the performance and the security of such network by selecting a secure route between the source and its target destination. To secure data transmission phase, we propose to create a key shared between the source and the destination. Since the devices have limited energy, we propose to take into consideration the energy of the intermediate nodes of the selected route. Extensive simulations are performed using the Network Simulator (NS2) to validate the proposed protocol. This proposal is compared with the secured Ad-Hoc On-demand Distance Vector (SAODV) in terms of end-to-end delay, overhead and number of compromised devices.

**Keywords**—Multi-hop wireless network; routing protocol; Diffie-Hellman; Weil Pairing; NS2

## I. INTRODUCTION

Multi-hop Wireless Networks (MWNs) like Ad Hoc networks, sensor networks and Internet of things (IoT) compose of wireless and discrete devices that communicate with each other directly without needing any fixed infrastructure [1]. Thus, the main function of such network is to route the information from the source to the destination from a node to another. This is performed by exchanging route information across different devices of the network. Many researchers are interested in this important topic and try to propose routing protocols which allow the devices to learn some multi-hop route between them. The routing protocols are classified into three categories: reactive, proactive and hybrid protocols.

In the proactive protocol, each node maintains a routing table that contains information about existing routes. When a node tries to transmit data, it uses a route already exist in this routing table. Many proactive routing protocols are proposed like Optimized Link State routing protocol (OLSR) [2], Destination Sequence Distance Vector (DSDV) [3] and

Wireless Routing Protocol (WRP) [4], etc. However, in the reactive protocol, only one active route is required to reduce the overhead in the network like Dynamic Source Routing (DSR) [5], Temporarily Ordered Routing Protocol (TORA) and Ad-Hoc On Demand Distance Vector (AODV) [6]. The hybrid protocol is a combination of the reactive and the proactive protocols.

Many challenges may affect the use of multi-hop wireless networks to support many applications due to their specific characteristics like the unstable topology, energy efficiency and mobility, etc. Therefore, it is important to take into account these challenges when designing and improving the functions of MWN such as the multi-hop routing protocols.

Another important issue must be taken into consideration when designing a routing protocol for MWN, is the security due to the participation of the nodes in the routing process. Indeed, an attacker can participate in the route discovery phase to become a member of the selected route and it can later perform different types of attacks like dropping, forging or injecting data packet. However, introducing security in multi-hop routing protocols needs extra resource consumption and extra storage due to the underlying computation cost required. This is not desirable in MWN as the limited resources of the nodes. Thus, when securing the routing in MWN, an efficient use of resources should be considered, in particular the energy resource.

However, many proposed protocols handle the resource efficiency and the security separately.

The security of routing protocols is mandatory to provide the protection of the exchanged data from the source node to the destination node. Most of the proposed protocols ensure the security from sharing secret keys between each two neighbor nodes. Thus, the number of the shared keys increases with the increase of the nodes in the network. This is lead to high resource consumption, which is not efficient, especially for some critical networks like the sensor networks due to the limited resources of the sensor nodes.

In this paper, we propose a new multi-hop routing protocol for MWN. This proposal selects secure and optimal path that ensures security in terms of authentication, confidentiality and integrity. For achieving the anonymity, we propose to use a temporary identity for each node in the communication process. The battery life of the selected nodes is taken into account in the proposal to achieve the performance of such

network. Indeed, during the route discovery process, only the nodes with high energy can be selected. When a destination receives several request packets, it selects the shortest and the longest lifetime route based on a proposed cost function.

The current paper is organized as follows: Section 2 offers an overview on some related works. Section 3 provides a detailed description of the proposed routing protocol. The last section makes the conclusion of the work and suggests the future research.

## II. RELATED WORK

Many routing protocols are proposed in the literature to optimize the performance of the MWNs. Indeed, in [7], a multi-hop routing protocol using cellular virtual grid in internet of thing environment is proposed. The goal of this proposal is to prolong the network lifetime through the balancing of energy consumption. The cost of the path between the source and the destination nodes is computed based on the residual energy and the distance. In [8], O. Salwa et al. proposed a fuzzy logic based on-demand routing protocol for multi-hop cellular networks. To optimize the performance of the network, the authors combine three metrics which are Signal to Interference and Noise Ratio (SINR), residual energy and gain time, based on the fuzzy logic system. In [9], a low-overhead multi-hop routing protocol for device to device communication in 5G is proposed. The proposal is based on the DSR protocol to select an optimal route for 5G in a short time. The overhead is reduced through the minimizing of the exchanged control messages, so the time and the energy are saved during the route discovery process. These three protocols [7-9] improve the networks performance in terms of energy consumption and lifetime.

However, the main drawback of these proposals is that they do not take into account the security requirements.

Other works are proposed to secure and optimize the routing protocol for multi-hop networks. Indeed, in [10] H. Kojima et al. proposed to secure DSR protocol using sequential aggregate signature in order to sign the routing information. In this proposal, the communication between devices requires a centralized key generation center to distribute the keys in the network. Thus, any new device cannot join the network without authentication to this center. In [11], G. Singh et al. proposed a routing protocol called Expiration Time based Routing Protocol (LETSRP) which based on a one-time signature scheme to authenticate the exchanged data in the network. Before sending any packet, each node computes the time expiration of its links using a greedy algorithm. The number of the sent packets depends on the available bandwidth. In [12], a secured and optimized routing protocol for MANET is proposed by A. Bhusari et al. This work was designed to optimize the performance of the routing protocol by minimizing the overhead and the delay. To secure this proposed protocol, a new metric based on cross layer design is provided to defend several attacks. To secure the request phase, the source node signs the RREQ with the group signature based on its private key. The destination node decrypts the received packet using the public group signature key.

However, the disclosure of the generated signature may cause the disclosure of the entire network. This is because the nodes use the same key during the communication process.

In [13], A. Vinitha et al. proposed a secure multi-hop routing protocol for wireless sensor networks. To secure the proposed protocol, the authors employed a trust model using several trust factors like indirect trust, direct trust, forward rate factors and integrating factor. To ensure the optimization of the proposal, the trust factors are integrated with other parameters such as delay, distance, energy, intra-cluster distance and inter-cluster distance. Before selecting the optimal route, the network is devised into a several cluster. The cluster heads are selected based on the Low Energy Adaptive Clustering Hierarchy (LEACH) protocol.

In [14], K. Hamouid et al. proposed a secure tree-based routing protocol for wireless sensor networks. The authors use ID-Based authentication key-agreement protocol to secure the data routing between the nodes in the network. The confidentiality and the authenticity are provided in the proposed protocol with low cost. Indeed, each node in the network is preloaded with a private key used to generate shared keys with its neighbor nodes. Moreover, to reduce the communication overheads a single message is transmitted by each node for both key establishment and routing-tree construction. However, in this protocol, each node must perform complex operations to generate security keys. This may increase the energy consumption by the nodes.

In [15], Zapata et al. proposed a secure routing protocol called Secure Ad Hoc On-Demand Distance Vector (SAODV) which is an extension of the AODV protocol to guarantee its security in terms of authentication, integrity and non-repudiation. To achieve the authentication, the source and the destination nodes add their signatures based on their private keys. The intermediate nodes only check the validity of this generated signature without any authentication performed between each other. However, to achieve the integrity of the hop-count field, a hash chain is used. The function used to compute the hash value is added to the hash function field. The SAODV protocol uses several mechanisms to secure the route request phase, but it remains vulnerable to many types of attacks. This fact is due to the lack of the authentication between neighbor nodes. Indeed, an adversary can participate in the selected path without modifying the hop-count field by using the same hash value. Thus, the legitimate nodes cannot detect this attack. In [16], M. Surajuddin et al. proposed a routing protocol that takes into account multiple factors such as packet loss reduction, congestion, malicious node detection and security of data transmission. Indeed, the source broadcasts a RREQ packet, which contains a fake destination address and sequence number. Only an attacker will respond with a RREP packet. In this case, the source maintains the address of this attacker in a black list and propagates this information to the other nodes in the network. Moreover, each node has a trust value calculated based on the opinion of its neighbors. Through this trust value, the nodes can identify the malicious nodes which have a trust value less than a threshold. However, this proposed protocol is not secured against several types of attacks like the impersonation attack and Sybil attack.

To overcome some limitations of the existing works like the lack of authentication between the neighbor nodes and the complex operations to compute a shared key, etc., we propose a new protocol described in the following section.

### III. PROPOSED PROTOCOL

#### A. Weil Pairing

In the proposed protocol, we are based on Weil Pairing tool for key generation. Indeed, the Weil Pairing [17] is an important method used in elliptic curve systems, key generation and identity-based encryption.

Let two groups  $G_1$  and  $G_2$  of order  $q$ , note that  $G_1$  is an additive cyclic group over an elliptic curve and  $G_2$  is a multiplicative cyclic group.  $P$  is a generator of  $G_1$ . The admissible bilinear map:

$\hat{e}: G_1 \times G_1 \rightarrow G_2$  has the following properties:

- Bilinear: for all  $P, Q \in G_1$  and for  $a, b \in \mathbb{Z}$ ,  $\hat{e}(aP, bQ) = \hat{e}(P, Q)^{ab}$ .
- Non-degenerate: if  $P, Q \in G_1$  such that  $\hat{e}(P, Q) \neq 1$ .
- Computable: for all  $P, Q \in G_1$ ,  $\hat{e}(P, Q)$  can be computed efficiently.

#### B. Network Model

In the proposal, we consider a MWN which consists of multiple devices distributed randomly in a geographical area and a trusted party (TP). Each device has a unique identity in the network (ID). We assume that these devices are not secured and so they can be compromised, but we suppose that TP is secure and trustworthy. Thus, we suppose that the TP is responsible for the generation and the record of the system parameters in a secure way.

These parameters are as follows:

- $p$  is a large prime number,
- $G_1$  and  $G_2$  are two cyclic groups.
- $g$  is a generator in  $\mathbb{Z}_p^*$ ,
- $P$  is a generator of  $G_1$ ,
- $H$ : is a hash function,  $\{0, 1\}^* \rightarrow G_1$ ,

The TP generates a private key called  $s \in \mathbb{Z}_q^*$ , and a master key  $P_{pub} = sP$ . Then, it bootstraps the devices with initial secret parameters in offline before network deployment. Indeed, it assigns a private key for each device;  $S_i = sQ_i$ , where  $Q_i = H(\text{ID}_i || t)$ ,  $t$  is the timestamp initiated by the TP in order to prevent the network against replay attack. Before the route discovery process, each device  $D_i$  must compute and share a secret key with the devices located at  $n$  hops. For that reason, it generates a random value called  $R_i$  and sends to the neighbor devices the following value:  $P_i = R_iP$  used to compute the shared key. This value is based on Pairing Discrete Logarithm Problem (PDLP) which is a complex problem because finding the integer  $R_i$  is hard.

#### C. Description of the Proposed Algorithm

The proposed routing protocol is divided into three phases: route request, route reply and data transmission phases. This protocol is proposed for MWN which is a hostile environment where it can be intercepted by different types of attacks. Thus, a high level of security must be achieved to secure each phase among the phases listed below. In addition to security challenge, the MWN face other major challenges like energy constraint of devices. Indeed, energy is a critical resource in MWN as its lifetime depends on battery depletion of mobile devices. More energy consumed in the routing process leads to reduce the network lifetime. For that reason, in the proposed routing protocol, we ensure an efficient use of the limited resources, in particular the energy consumption.

1) *Route request phase*: When a source device (S) intends to communicate to a destination device (D) and it does not have a valid route, it initiates the route request phase by broadcasting a route request (RREQ) packet to all its neighbors. It is based on Location based-Multiple metric (LoMM) to reduce the number of the devices that can receive the RREQ packet. This is to exclude the devices that are further away from D to participate in routing data. By this way, the end-to-end delay and the signaling load are reduced. Moreover, this metric reduce the complexity of the computational operations as all devices are participating in computing a group key and so reducing the energy consumption in the network.

To secure the request phase, each two neighbor devices share a secret key. During this step, the two devices perform a mutual authentication between each other at the same time. To reduce the computational complexity, the neighbors perform just a single evaluation of the Weil Pairing as compared with other schemes like Smart-Chen-Kudla scheme.

The generation of the shared key  $K_{ij}$  between each two neighbor devices  $D_i$  and  $D_j$  is performed as follows:

$D_i$  computes  $K_{ij}$  using the following equation (1):

$$\begin{aligned} K_{ij} &= \hat{e}(S_i; R_jQ_j + R_iQ_j) \\ &= \hat{e}(sQ_i; R_jQ_j + R_iQ_j) \\ &= \hat{e}(Q_i; Q_j)^{s(R_i+R_j)} \end{aligned}$$

In the other side  $D_j$  computes also  $K_{ji}$  as the following function:

$$\begin{aligned} K_{ji} &= \hat{e}(R_iQ_i + R_jQ_j; R_j) \\ &= \hat{e}(R_iQ_i + R_jQ_j; sQ_j) \\ &= \hat{e}(Q_i; Q_j)^{s(R_i+R_j)} \\ &= K_{ij} \end{aligned}$$

Where,  $R_i$  and  $R_j$  are random values generated by  $D_i$  and  $D_j$  respectively, and exchanged based on Pairing Discrete Logarithm Problem as mentioned above.

The source initiates the route request phase by broadcasting a RREQ packet to all its neighbors. The format of the RREQ is as follows:

RREQ: {ID<sub>S</sub>, E(K<sub>sj</sub>, ID<sub>D</sub> || seqNb || TTL || Hop-count || K<sub>PK\_S</sub>(g<sup>R<sub>S</sub> mod p) || ME) || MAC<sub>Ksj</sub>(ID<sub>S</sub>, ID<sub>D</sub>, seqNb, TTL, Hop-count, K<sub>PK\_S</sub>(g<sup>R<sub>S</sub> mod p), ME))}</sup></sup>

Where,

- K<sub>sj</sub> is the shared key between S and each of its neighbor D<sub>j</sub>. It is calculated as the function (1) in order to encrypt the RREQ packet between each other and so to provide the confidentiality of this packet.
- ID<sub>S</sub> is the source address,
- ID<sub>D</sub> is the destination address,
- seqNb is the sequence number which prevents the RREQ packet against replay attack,
- TTL: is the Time To Live which limits the propagation area of the RREQ packet,
- Hop\_count: is a value incremented by each intermediate node to count the number of hops in the discovered route,
- g<sup>R<sub>S</sub> mod p</sup>: is a value used to compute a shared key between S and D, where R<sub>S</sub> is a random number generated by S. For more security, this value is encrypted by the private key of the source. Finding R<sub>S</sub> is hard as it is difficult to resolve the Diffie-Hellman problem in prime order.
- ME: is the minimum remaining energy which represents the lifetime of the discovered route.
- MAC<sub>Ksj</sub>: is a function used to check the integrity of the RREQ packet.

When an intermediate device D<sub>i</sub> receives a RREQ packet from a neighbor D<sub>j</sub>, it performs the following steps:

- Decrypts the received packet using the shared key K<sub>ij</sub> with the sender device, which is calculated as the function (1). If this decryption is performed successfully, so that a mutual authentication is provided between them because only these two devices can calculate this shared key.
- Computes the MAC function to verify the integrity of the received packet. If there is no problem with the integrity, D<sub>i</sub> passes to the next step, otherwise, it discards the received packet.
- Checks if it is the target destination by comparing its own address and ID<sub>D</sub>. If it is the target destination, it sends back a response to the source via the reverse route if not, it performs the next steps,
- Checks if TTL is zero, it discards the received packet, if not it decrements this field and increments hop\_count field,

- Computes its residual energy and compares it with the ME field, then it reassigns the ME field with the minimum value among them.
- Maintains the address of the sender in its routing table, and adds its address in the RREQ packet.
- Computes the MAC function using the key shared with each neighbor,
- Sends the RREQ packet to the neighbors after encrypting it by the secret key shared with each of these neighbors.

The RREQ packet is sent until it reaches the destination in a secure way.

#### D. Route Reply Phase

When the destination receives a RREQ packet, it waits for a definite time to receive other RREQ packets. Then it performs the following steps:

- It decrypts the received packets and checks their integrity. Then, it calculates the cost (C) of each discovered path as the following equation:

$$C = \frac{ME}{hop\_count}$$

- It selects the path with the largest cost C. By this way, it chooses the path that has the greatest remaining energy and the smallest number of intermediate nodes (shortest path).
- Computes the shared key with the source based on Diffie\_Hellman problem as the following equation:

$$K_{DS} = g^{R_S * R_D} \text{ mod } p$$

Where, R<sub>D</sub> is a random value generated by the destination. R<sub>D</sub> is sent to the source using Diffie\_Hellman problem g<sup>R<sub>D</sub> mod p</sup> to recalculate the shared key with the source as follows:

$$K_{SD} = g^{R_D * R_S} \text{ mod } p$$

Thus, the same key is obtained by the source and the destination:

$$K_{SD} = K_{DS}$$

- Generates the RREP packet:

RREP: {ID<sub>D</sub>, E(K<sub>Dj</sub>, ID<sub>S</sub> || ID<sub>D</sub> || K<sub>PK\_D</sub>(g<sup>R<sub>D</sub> mod p) || MAC<sub>K<sub>Dj</sub></sub>(ID<sub>S</sub>, ID<sub>D</sub>, K<sub>PK\_D</sub>(g<sup>R<sub>D</sub> mod p))))}</sup></sup>

The RREP is encrypted by K<sub>Dj</sub> which is the shared key between the destination and the intermediate device j of the selected route. K<sub>Dj</sub> ensure also a mutual authentication between the two communicants.

MAC<sub>K<sub>Dj</sub></sub> is used to check the integrity of the packet.

g<sup>R<sub>D</sub> mod p</sup> is encrypted by the private key of the destination for more security.

The RREP is sent through the reverse route until it reaches the source device.

When the source receives the RREP packet, it re-computes the shared key with the destination and triggers the transmission data phase secured by the shared key between the source and the destination.

#### IV. SECURITY ANALYSIS

In the following section, we analyze the security of the proposal against several threats by showing that it achieves the security constraints:

##### A. Confidentiality

The messages exchanged in the request and reply phases of the proposed protocol are encrypted with the keys shared between the neighbor devices. To compromise these keys, the attackers need to know the secret parameters used to calculate each key, and so they have to resolve the PDLP which is a hard problem.

Furthermore, the data transmission phase is secured based on the shared key between the source and the destination. To compromise this key, the attacker needs to resolve the Diffie-Hellman problem.

Thus, the proposed protocol ensures the confidentiality of the exchanged messages.

##### B. Authentication

In the proposed protocol, each two neighbors have to share a secret key based on Weil Pairing scheme. This method provides an implicit mutual authentication between the communicants using some secret parameters. Indeed, every device computes and shares a secret key with its neighbor; only a legitimate device can compute this key as it is based on the private key of the TP. Moreover, the source and destination authenticates each other through the shared key between them, which is calculated based on Diffie-Hellman problem.

Thus, the proposed protocol achieves the authentication.

##### C. Integrity

In the proposal, to check the integrity of each transmitted message, the sender adds the MAC function to this message. To forge the integrity of such packet, an attacker must decrypt it and re-compute the MAC function of the modified packet. However, this is not possible as the attacker does not learn the secret key used to encrypt the received packet.

##### D. Sybil Attack

Sybil attack occurs when an attacker use unauthorized identities to perform neighbor relationships with other legitimates devices. In the proposal, when an attacker sends messages to a legitimate device using a forged identity, it fails in performing a mutual authentication as it has not a valid key issued by the TP. Thus, to perform a Sybil attack, the attacker must generate its own private key, which is impossible because it is hard to solve PDLP problem and hold the private key of the trust party. For that reason, the proposal is secured against Sybil attack.

##### E. Replay Attack

The attacker tries to falsify the destination by retransmitting many authorized packets. The proposed protocol is secured against this type of attack for many reasons. First, because the source generates a sequence number for each new request packet. Second, the private key of each device is computed based on a timestamp initiated by the source. Moreover, the shared keys are based on a random number generated by legitimates devices in each session without any links with the values generated in the previous session. Thus, the proposed protocol is secured against replay attack.

##### F. Impersonation Attack

In this type of attack, the attacker uses a legitimate identity to perform a neighbor relationship or to participate in the selected route as an intermediate device. In this proposal, to impersonate a device, the attacker must compute a shared key with this device. However, it cannot obtain the same key computed by the legitimate device as it does not hold a private key assigned by the TP. Then, it is not feasible to resolve the PDLP and discover the private key of TP. Thus, it is not possible to impersonate a legitimate device.

#### V. SIMULATION RESULT

To evaluate the performance of the proposed routing protocol, we conduct extensive simulations using the network simulator (NS-2). We add to this simulator the security library Crypto++ as it supports many tools of security mechanism. The network is composed of 60 devices that move by Two Ray Ground model in 1000m\*1000m area.

The parameters of the simulation are summarized as the following Table I.

The compromise of the legitimate devices is a major challenge which is hard to defend. If a device is compromised, the attacker can participate in the selected route and access to the exchanged messages and security parameters. Thus, all the devices can be affected. To evaluate the robustness of the proposed protocol against the malicious nodes, we introduce several attackers that held black hole attack. They pretend to be the target destination by sending RREP packets while it receives a RREQ packet, or they try to become members of the selected route.

TABLE I. SIMULATION PARAMETERS

Parameters	Value
Routing protocols	Proposed protocol, SAODV
Simulation time	200 seconds
Simulation area	1000*1000
Traffic type	Constant Bit Rate (CBR)
Packet size	512 bytes
Queue length	250 packets
MAC protocol	MAC/802.11
Mobility model	Two Ray ground
Initial energy	150J
Transmission energy	0.5 W

The proposed protocol is compared with the SAODV protocol, then, we measure three metrics as follows:

- 1) End-to-end delay: is the average delay between the time of packet generation and the time of its reception by the receiver.
- 2) Overhead: is the average of the amount received messages by each device during the route establishment phase.
- 3) Number of compromised devices: is the total number of devices compromised by the attackers during simulation time.

Fig. 1 represents the results of the end-to-end delay as a function of the number of attackers. As we can see, the proposed protocol has less value of end-to-end delay than SAODV protocol. This is due to the fact that, the proposal selects the shortest secured path. Moreover, in the proposal, the risk that an attacker compromises a device and participates in the selected route is less than SAODV protocol. Indeed, if an attacker becomes a member of the selected route, it maintains the received packets more time to handle its content and extracts the needed information from these packets. Therefore, the delay required for a packet to reach the destination is increased.

Fig. 2 presents the results of the overhead versus the number of attackers. As we can see, in the proposed protocol the message load is reduced compared with the SAODV protocol when the number of attackers increases. This is because; in the proposal when a device receives a packet from an attacker it drops this packet, but with SAODV the devices resent every received packet. Indeed, in our proposal, the neighbor devices authenticate each other by checking the shared key used to encrypt the received packet. However, in SAODV no mutual authentication is achieved.

Fig. 1. End-to-end Delay Versus Numbers of Attackers.

Fig. 2. Overhead Versus Number of Attackers.

Fig. 3. Number of Compromised Devices Versus Number of Attackers.

Fig. 3 shows the results of the number of compromised devices as a function of the number of attackers. As we can see, the number of compromised devices in our proposed protocol is very less than SAODV protocol. This is because in our proposal when a device is compromised, only its private key is also compromised. The other devices are not affected, as the attacker cannot perform a mutual authentication with them because it cannot compute shared keys with these legitimate devices. However, in SAODV protocol from a compromised device, an attacker can compromise also its neighbor devices as the mutual authentication is achieved only between the source and the destination.

## VI. CONCLUSION AND FUTURE WORK

The special characteristics of the MWNs have a major impact on the security of routing data between the communicants. Indeed, secure a routing protocol in this type of network is exposed to many challenges like the limited battery of the devices and their small memories. Moreover, the routing is performed hop by hop through ordinary nodes, so an attacker can easily compromise some nodes and participate in the selected route. In this context, we have proposed a secure and optimal routing protocol for MWN. This proposal takes into consideration the battery life of the intermediate devices that participate in the selected route. Moreover, security requirements like the confidentiality and authenticity are achieved during the routing process based on a proposed key-agreement method. Integrity is also achieved through the verification of the MAC function. To secure the request phase, we assumed that the neighbor devices compute shared keys between each other based on Weil Pairing scheme. To secure the data transmission phase, the source and the destination share a secret key where the parameters exchanged during the request phase. In this proposed protocol, we tried to fit inexpensive cryptography mechanisms in each phase to make it robust against many types of attacks.

As a future work, we plan to integrate an intrusion detection system to detect the malicious nodes and so to improve more the security in MWNs.

## ACKNOWLEDGMENT

The author gratefully acknowledge the approval and the support of this research study by the grant no SAT-2018-3-9-F-7704 from the Deanship of Scientific Research at Northern Border University, Arar, K.S.A.

**Abstract**—Weather prediction is the key requirement to save many lives from environmental disasters like landslides, earthquake, flood, forest fire, tsunami etc. Disaster monitoring and issuing forewarning to people, living in disaster-prone places, can help protect lives. In this paper, the Multiple Linear Regression (MLR) model is proposed for humidity prediction. After exploratory data analysis and outlier treatment, Multiple Linear Regression technique was applied to predict humidity. Intel lab dataset, collected by deploying 54 sensors, to form a wireless sensor network, an advanced networking technology that existed in the frontier of computer networks, is used for solution build. Inputs to the model are various meteorological variables, for predicting weather precisely. The model is evaluated using metrics - Mean Absolute Error (MAE), Root Mean Square Error (RMSE) and Mean Absolute Percentage Error (MAPE). From experimentation, the applied method generated results with a minimum error of 11%, hence the model is statistically significant and predictions more reliable than other methods.

**Keywords**—Data mining; wireless sensor network; multiple linear regression; outliers treatment; r-square; adjusted r-square

## I. INTRODUCTION

Earlier information processing was done using general purpose devices like Mainframes, laptops, palmtops etc. In many applications these computational devices are used to process human centered information. But in some applications, controlling and monitoring action is required by focusing on physical environment. For example, in a chemical factory, processes can be controlled for exact temperature. Here controlling operation is embedded with computation without human intervention. Due to the technological advancement, another important aspect needed along with computation and control is communication. This processed information needs to be transferred to the place where it is necessary, a user or an actuator. Wired communication is expensive compared to wireless communication; even wires restrict devices from moving and prevent sensors and actuators being close to the event under observation. Hence, an implementation of a new network called wireless sensor network appeared. Sensor networks are built with a number of sensors, having sensing, processing and communicating capabilities, used in real time data analysis and monitoring applications like habitat monitoring, healthcare applications, environmental monitoring and tracking of objects to mention a few. Nodes are not costly but have memory, processing and energy limitations. An example sensor network is as shown in Fig. 1.

Recently Sensor Networks (WSN) have transformed largely due to the advancement in wireless communications, Micro Electro Mechanical Systems (MEMS), distributed processing and embedded systems. These networks are widely used in various areas such as agriculture monitoring, monitoring of habitat and surveillance [1]. The most crucial system of real time monitoring and controlling is environment. Nodes in WSN are small in size and consist of microcontroller, transceiver and memory, capable of short range communication. These battery operated nodes measure temperature, humidity, light and voltage of natural event from the place of deployment and send to the sink node. Sink nodes with enough processing capability compared to end nodes perform required pre-processing on the received raw data of sensors and forward to the base station. Base stations with embedded controlling and monitoring functionalities further process the data collected from sink node for knowledge extraction and decision making to ultimate user.

Weather forecasting is a major challenge in the meteorology department due to recurrent climatic changes [2]. There are very few solutions in generating weather reports with several limitations [3]. Many outdoor activities are affected due to wind chill, rainfall and snow, the results of frequent changes in weather [4]. Inaccurate weather reports will put someone into a dangerous state [2] if the climatic conditions are not safe. There are many existing data mining techniques for processing and evaluating huge amount of weather dataset. To predict weather, data mining process has three stages—data pre-processing, Model training and then prediction.

Fig. 1. An Example Wireless Sensor Network.

## II. RELATED WORK

An important section of research work is literature survey, facilitating researcher to gain knowledge in the relevant field and identifying challenges. This section presents the identified best works of considered domain.

N. Krishnaveni and A. Padma [5] introduced a decision tree based algorithm called SPRINT, which builds and constructs a decision tree with relevant data. Here an enhancement in observation is made using an open source historical dataset collected from weka tool (<https://storm.cis.fordham.edu/~gweiss/datamining/datasets.html>), a tool which permits direct mining of SQL databases. Using weka on the weather parameters of considered dataset, like temperature, outlook, and humidity and windy, weather is predicted as sunny, rainy or overcast. Results proved that SPRINT is more efficient and precise compared to the existing Navie Bayes algorithm proving the performance of the work.

Munmun et al. [2] proposed an integrated method for predicting weather in order to analyze and measure environmental data. Classification is done using Naive Bayes and Chi-square algorithms. A web application states weather information taking inputs as temperature, current outlook, wind and humidity condition. Accordingly implemented system is capable of predicting weather.

Taksande et al. [6] presented forecasting of weather by Frequent Pattern Growth Algorithm. Predicting rainfall is the major goal of implementation. Dataset was collected by Nagpur station from Jan 2010–Jan 2014 and computed using Frequent Pattern Growth Algorithm. Defined variables used for predicting rain are temperature, humidity and wind speed. The implemented model worked on these parameters and provided 90% of attainment. Wang et al. [7] implemented data mining method using cloud computing in order to predict weather. Decision tree and Artificial Neural Network Algorithms are applied on meteorological data gathered at appropriate time and place. This method worked effectively on averaged weather parameters and resulted in better classification.

Sushmitha Kothapalli et al. [3] presented Auto-Regressive Integrated Moving Average (ARIMA) model for analysing and forecasting real time data. The dataset contained humidity, temperature, wind and rainfall as variables. This gathered data was stored as CSV, JSON, and XML formats in the cloud. In this work, the author was able to achieve efficient results with correlation analysis on values followed by ARIMA model.

Salman et al [8] developed a deep learning method for predicting weather. The idea was to explore internal hierarchical pattern of the dataset. For experimenting, BMKG (Indonesian Agency for Meteorology, Climatology, and Geophysics) data was considered. Recurrence Neural Network (RNN), Conditional Restricted Boltzmann Machine (CRBM) and Convolutional Network (CN) models were used on the dataset. Prediction results of these models helped the agriculture and tourism sectors.

Maqsood et al [9] introduced a group of neural networks to predict weather. Here, the groups of artificial neural networks (ANNs) were compared considering relative humidity, wind speed and temperature as the key parameters. The predictive

models used for experimenting were radial basis function network (RBFN), Elman recurrent neural network (ERNN), Hopfield model (HFM), multi-layered perceptron network (MLPN) and regression techniques. Comparative analysis showed RBFN model is better while HFM gave lesser accuracy.

Almgren et al [4] utilized Hadoop distributed system for climatic prediction. This work showed that, prior prediction diminishes event planning disasters. Here data is stored in HDFS and then processed by MapReduce programming. Outdoor events can then be planned, by obtaining processed results about weather, location and time. Oury and Singh et al. [10] created Hadoop technique for weather data analysis. Climatic conditions were investigated using precipitation, snowfall and temperature as evaluation parameters. Utilizing Apache PIG and Hadoop map reduction executed dataset. Python language was used to present output in visual form.

Manogaran and Lopez et al. [11] introduced spatial cumulative sum algorithm to detect climatic changes. MapReduce technique was applied on weather data stored in Hadoop Distributed File System (HDFS). Climatic changes were detected by applying spatial autocorrelation. Mahmood et al. [12] produced a data mining technique for predicting weather. This paper presents a data mining technique called Naive Bayes algorithm.

## III. PROPOSED WORK

The newly-created model considers meteorological data to predict values for humidity by technically analysing the data and then applying multiple linear regression algorithms. In the previous work of data cleansing and pre-processing step, it was found that variables - humidity, light and voltage had a few missing values, but since the percentage of missing values is very negligible (<2%), can omit them. In the initial phase of technical analysis, data pre-processing is carried-out to gain insights into underlying source data. Exploratory analysis was carried out on pre-processed data to understand underlying relationships between dependent and independent variables. In the next phase multiple linear regression algorithms is applied on the processed data, considering key attributes as voltage, light, temperature and humidity. The model is built, trained and validated by dividing the data into Train and Test sets. For experimenting, there are many ways to partition data. But the most approved one is partitioning data into Train/Test sets or cross validation. The first set called Train data is used for model fitting and the second set called Test data to test trained model. This was followed by Model build, and, later test data was used to score the Model and obtain predicted value, which is then validated.

The master dataset needs to be divided into training and testing data - 70 percent is trained and 30 percent is testing data. Previous works presented exploratory analysis on pre-processed data to understand underlying relationships between dependent and independent values. This was followed by Model build, and, later testing data was used to score the Model and obtain predicted value, which is then validated. In the initial phase of data [13] analysis having 0.2 million samples, outliers treatment is carried out to handle extreme values.

The proposed method is shown in Fig. 2.

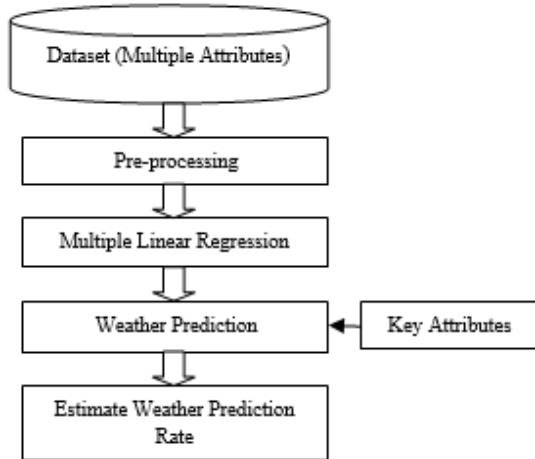

Fig. 2. Proposed Method Block Diagram.

### A. Outliers Treatment

A measurement of variability called interquartile range (IQR) can be obtained by dividing data into quartiles. Depending on division the values are named as first, second, and third quartiles; denoted with Q1, Q2, and Q3, respectively. In the initial set of data, Q1 is the “middle” value given by equation 1.

$$Q1 = \left(\frac{n+1}{4}\right)^{th} \text{ term} \quad (1)$$

Median is Q2. Middle value is Q3 given by equation 2.

$$Q3 = \left(\frac{3(n+1)}{4}\right)^{th} \text{ term} \quad (2)$$

Fig. 3. Outliers.

The outliers in the master data are depicted in Fig. 3.

$$IQR = Q3 - Q1 \quad (3)$$

$$\text{Low outliers: } Q1 - 1.5IQR \quad (4)$$

$$\text{High outliers: } Q3 + 1.5IQR \quad (5)$$

Outliers in the data-set are replaced by their corresponding nearest quantile values. Data values outside the upper-boundary (high outliers) are replaced with corresponding third quartile values, similarly, data values outside lower-boundary (low outliers) are replaced with corresponding first quartile

values. Outlier treatment is carried-out for all key variables. Outlier detection is an essential step in data analysis since the un-treated outliers can affect the model results and predictions. Generally, outliers can be treated, suppressed or amplified. Our approach is to treat outliers as detailed above. Fig. 3 shows the outlined values for the four attributes which are in black colour.

The next step is weather prediction using multiple linear regression technique.

Multiple linear regression formula is:

$$y = \beta_0 + \beta_1 X_1 + \dots + \beta_n X_n + \epsilon \quad (6)$$

In equation 6, relying parameter predicted value is  $y$ ,  $\beta_0$  defines  $y$ -intersection ( $y$ -value with other variables made 0). A predicted ‘ $y$ ’ value change with an increase in independent variable is given by  $\beta_1 X_1$  or the first independent variable ( $X_1$ ) with regression coefficient ( $\beta_1$ ). This step of predicting  $y$  is repeated for all remaining independent variables to be tested. Finally the regression coefficient of the last independent variable is  $\beta_n X_n$ . Error present in the model is denoted by  $\epsilon$ .

Important parameters required for identifying a best-fit line to each independent value in multiple linear regressions are:

- Coefficients resulting least error.
- t-statistic of the model. Z.
- The p-value.

t-statistic and p-value for each regression coefficient in the model is calculated and compared to determine statistical significance of the variable on outcome plus the magnitude of effect on outcome variable( $y$ ).

Regression analysis involves identification of residual data characteristics by means of assumption tests before Model build. Assumption tests are explained in the following subsection followed by model build. Regression analysis is essentially a parametric method and hence, validating assumptions is important. If underlying assumptions are violated Model results will not be accurate and predictions will be more prone to errors.

### B. Regression Analysis Assumption Test

This section depicts assumption tests, which should be validated before regression analysis.

1) *Linearity*: Ideally, no fitted patterns are shown in the residual plot. It means, the red straight line shown in Fig. 4, should be approximately horizontal at zero. The model is found linear with the existence of a pattern, or a possible non-linear relationship. Here, there is no definitive pattern, and a linear relationship between the independent and dependent values seen, hence linear model suits.

2) *Normality of residuals*: For normality check, residuals can be visualized using QQ plot. As per normality assumption the residuals plot should be a straight line. In the given data, all the observations follow the defined reference straight line as shown in Fig. 5; hence normality assumption can be made.

Fig. 4. Linearity.

Fig. 5. QQ Plots.

3) *Homoscedasticity*: Fig. 6 shows how residuals are evenly spread along the range of predictors. The red line in the plot is nearly horizontal with similar dense distribution of points on either side. We can assume homogeneity of variance.

Fig. 6. Homoscedasticity.

4) *Durbin-Watson (DW) test*: DW test examines whether the error terms are autocorrelated. Null hypothesis states that no autocorrelation exists. The statistical DW test was performed and based on the p-value, we conclude that no autocorrelation exists. Statistical DW test yields the test result as  $\sim 1.9$ , which means, no autocorrelation exists. Hence, this assumption is validated.

5) *VIF for multicollinearity*: On examining variable inflation factors for predictor variables, it was found that they do not exceed 5, hence, no multi-collinearity exists in the data set, which means, and the assumption of no multicollinearity is validated.

6) *Residual v/s Leverage*: The most influential 3 values are shown on the plot in Fig. 7; however, they can be exceptions, or, outliers. In this case, data does not present any high influence points.

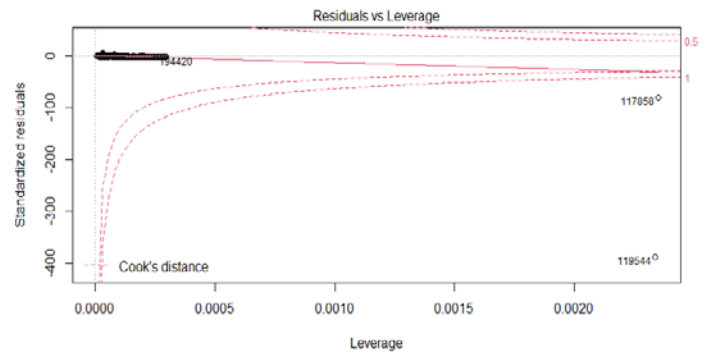

Fig. 7. Residuals vs Leverage.

7) *Cook's distance*: This score considers the combined values of leverage and residual parameters to determine an influential value. Regression analysis results will change with the inclusion or exclusion of influential value. An influential value has a larger residual. In linear regression analysis all outliers (or extreme data points) are not significant. Residuals show nearly even spread along the range of predictors. The red line in the plot is nearly horizontal with similar dense distribution of points on either side. We can assume homogeneity of variance.

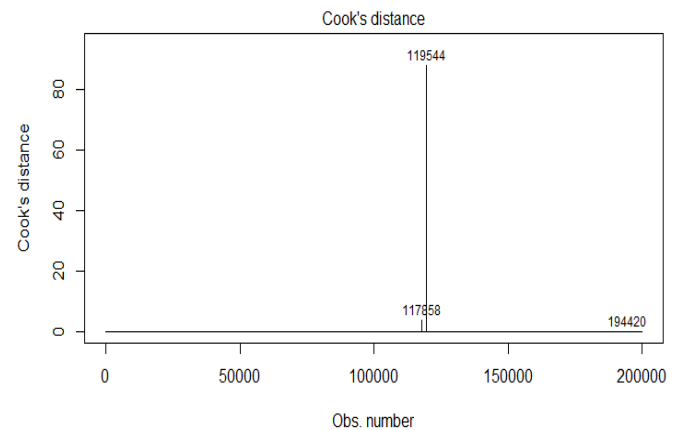

Fig. 8. Cooks Distance.

Cook's distance aids in determining the influential value. Here the thumb rule is, observations will have larger influence, if Cook's distance is more than  $4/(n - p - 1)$  [14]. In the expression  $n$  represents the count of observations and  $p$ - the number of predictor variables.

In the given data, Cook's distance is too small as depicted in Fig. 8 and does not have significant influence on regression analysis. However, outliers, if any, must be detected and suitably handled.

### C. Multiple Linear Regression Model

MLR is a statistical approach for predicting the output of a dependent variable by considering multiple independent variables [15]. MLR is capable of building a linear relationship between predictor variables and response values. Data is collected from the Intel Research Labs. Initially to eliminate noisy values, data pre-processing is done, avoiding reduction in prediction accuracy. Now, pre-processed data must be divided

into training and test data. The proposed algorithm needs to be trained utilizing training data for establishing relationship with several parameters. The final model will predict outcome of any new given data set containing data for same independent variables.

1) *Evaluation parameters:* The Model built is evaluated using various statistical metrics as listed below.

a) *R-square:* In MLR models r-square is used to measure a goodness-of-fit. Purpose of using this statistic is to judge how independent variables can mutually explain the dependent variable variance in percentage.

$$R - \text{Square} = \frac{\text{Variance explained by full model}}{\text{Total Variance}} \quad (7)$$

R-square increases every time a new independent variable is added to the Model. While a higher R-square is desirable, one has to vary about over-inflating the results and overfitting the Model.

b) *Adjusted R-square:* In regression Models, this statistic is used for comparing the goodness-of-fit with independent variables. The number of terms in the Model is adjusted with adjusted r-square. Importantly this parameter is mainly used to check an improvement in the Model fit with a new term. The adjusted R-squared value will automatically decrease whenever the new term fails to enhance the model fit by an adequate amount.

In our situation, r-square and adjusted-r-square are above-average values, and acceptable.

c) *Mean Absolute Error (MAE):* While predicting a set of values MAE is used to measure errors average magnitude, independent of direction.

With all equal weighted individual differences, MEA is computed as the test samples average parameter, considering the absolute differences between actual and prediction observations.

$$MAE = \frac{1}{n} \sum_{j=1}^n |y_j - \hat{y}_j| \quad (8)$$

Where, n – Number of samples,  $y_j$ -Expected value and  $\hat{y}_j$ -Predicted value.

d) *Root Mean Squared Error (RMSE):* RMSE is a squared output used for measuring average score of error.

It's the square root of the average of squared differences between prediction and actual observation.

$$RMSE = \sqrt{\frac{1}{n} \sum_{j=1}^n (y_j - \hat{y}_j)^2} \quad (9)$$

Where, n – Number of samples,  $y_j$ -Expected value and  $\hat{y}_j$ -Predicted value.

MAE and RMSE values lie between 0 and  $\infty$ , and are independent of the direction of errors. Both the metrics can be used for error prediction, expressing the variables in the interest of values units. For efficient modeling lower values are preferred, since both MAE and RMSE yield negative results.

Usually squared values of errors are taken before averaging, since RMSE gives relatively more weight to larger errors. Hence, RMSE is most suitable for large number of undesirable errors. Though RMSE penalizes larger errors, MAE has better interpretability, hence is considered.

The size of the dataset was decided by extracting random samples from the master dataset which keeps the distribution at a defined significance level. Basically, in order to achieve higher statistical significance, a machine learning model must be trained for larger dataset. But to save time sub-samples are selected maintaining other statistics same. Data distribution is fairly normal.

#### IV. RESULTS

All data pre-processing, exploratory analysis, Model build, tune and validation were performed using R language. In order to predict humidity, data pre- processing followed by multiple linear regression method was used. Existing data mining methods worked on homogeneous data, but the presented model is capable of handling heterogeneous data. The model performance was evaluated by using statistical metrics like  $R^2$ , MAE, RMSE, etc.

1) *Intel dataset:* For experimentation, freely available Intel Lab dataset [16] was used. This dataset has nearly 2.3 million records collected by deploying 54 sensors in the Intel Berkeley Research lab. Sensors used were Mica2Dot, capable of collecting time-stamped weather information. The values are recorded by in-network query processing TinyDB system and these are recorded once every 31 seconds with humidity, temperature, light and voltage as key variables. The dataset format is given by: date, time, epoch, mote ID, temperature, humidity, light, and voltage. All the sensors are numbered with ids ranging from 1-54. Some sensor's values are missing or approximated. These measured variables are represented as, temperature in degrees Celsius, humidity ranging from 0-100% and its temperature corrected relative humidity. Light is recorded in Lux (1 Lux is equivalent to moonlight, 400 Lux corresponds to a bright office, and 100,000 Lux is equivalent to full sunlight). Voltage is in the range 2-3, measured in volts. Lithium ion cell batteries were used for providing constant voltage to sensors for their lifetime. It is observed that voltage variations are highly correlated with temperature.

##### 2) *Model Results and Evaluation Metrics*

a) *R-square:* 0.692: Higher the R-square value, better it is. This statistical value shows variation between the dependent and independent variables. R-square is 0.692, which is considered a good-fit. Independent variables are able to explain a large amount of variance in dependent variable.

p-value : <2.2e-16 => Model is statistically significant.

b) *Metrics:* As observed in Table I, average error is ~11%, hence we say Model is accurate upto 89%. MAE and RMSE are very small, hence our Model is very good; predictions generated from this Model will be very accurate.

c) *Residuals:* Table II gives residuals statistics for outliers treatment.

TABLE I. STATISTICS OF RESIDUALS

MAE	MSE	RMSE	MAPE
0.113799	0.03070434	0.17522655	Inf.

TABLE II. STATISTICS OF RESIDUALS FOR TREATING OUTLIERS

Min	1Q	Median	3Q	Max
-0.93682	-0.08049	0.00572	0.08174	0.97949

d) *Coefficients:* Table III lists the model coefficients for variables temperature, voltage, light and their correlations.

TABLE III. MODEL COEFFICIENTS

Variables	Estimate	Std. Error	t Value	Pr(> t )
Intercept	0.936820	0.002421	386.889	< 2e-16 ***
Temperature	-0.919190	0.003173	-289.665	< 2e-16 ***
Voltage	-0.134744	0.003269	-41.224	< 2e-16 ***

voltage:light	-0.008874	0.010172	-0.872	0.383
temperature:voltage:light	-1.228874	0.038373	-32.024	< 2e-16 ***

Signif. codes: 0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 0.1732 on 139994 degrees of freedom.

Multiple R-squared: 0.6919, Adjusted R-squared: 0.6918.

F-statistic: 4.49e+04 on 7 and 139994 DF, p-value: < 2.2e-16.

3) *MLR Model with Interaction effects:* From the Model statistics, it can be seen that most co-efficient are statistically significant when seen individually, as well as with interaction effects. The interaction term co-efficient are statistically significant, suggesting an implicit interaction relationship between predictor variables (other than voltage and light). Model equation can be represented as below:

$$\text{humidity} = 0.936 - 0.92 * \text{temperature} - 0.13 * \text{Voltage} - 0.08 * \text{light} + 1.49 * (\text{temperature} * \text{voltage}) + 0.14 * (\text{temperature} * \text{light}) - 1.22 * (\text{temperature} * \text{voltage} * \text{light})$$

## V. CONCLUSION

Changes in weather affect lives of various living beings. Main idea of this paper is to analyze the data collected from WSNs of Intel Lab and make appropriate decision in order to convey right information at right time to help save lives.

Machine Learning techniques are used for weather prediction, and MLR algorithm is built using temperature, humidity, light and voltage as the key variables. We have evaluated the Model and model results are documented above. The resultant model can predict with high degree of accuracy and can be expanded for further work. Values of statistical parameters indicate that the proposed model is statistically more significant compared to other existing techniques.

# Detecting Diabetic Retinopathy in Fundus Images using Combined Enhanced Green and Value Planes (CEGVP) with k-NN

Minal Hardas, Sumit Mathur, Anand Bhaskar  
Electronics and Communication Engineering  
Sir Padampat Singhania University (SPSU), Udaipur, India

**Abstract**—Diabetic Retinopathy (DR) is a disease that causes damage to the blood vessels of the retina, especially in patients having high uncontrolled blood sugar levels, which may lead to complications in the eyes or loss of vision. Thus, early detection of DR is essential to avoid complete blindness. The automatic screenings through computational techniques would eventually help in diagnosing the disease more accurately. The traditional DR detection techniques identify the abnormalities such as microaneurysms, hemorrhages, hard exudates, and soft exudates from the diabetic retinopathy images individually. When these abnormalities occur in combination, it becomes difficult to predict them and the individual detection (traditional 4 class classification) accuracy decreases. Hence, there is a need to have separate combinational classes (16 class classification) that help to classify these abnormalities in a group or one by one. The objective of our work is to develop an automated DR prediction scheme that classifies the abnormalities either individually or in combination in retinal fundus images. The proposed system uses Combined Enhanced Green and Value Planes (CEGVP) for processing the fundus images, Principal Component Analysis (PCA) for feature extraction, and k-nearest neighbor (k-NN) for classification of DR. The suggested technique yields an average accuracy of 97.11 percent using a k-NN classifier. This is the first time that a 16-class classification is initiated that precisely gives the ability and flexibility to map the combinational complexity in a single step. The proposed method can assist ophthalmologists in efficiently detecting the abnormalities and starting the diagnosis on time.

**Keywords**—Combined enhanced green and value plane; diabetic retinopathy; fundus image; image processing; k-NN; principal component analysis

## I. INTRODUCTION

Diabetes is an epidemic affecting millions of people worldwide [1]. DR is a chronic retinal disorder that is caused by the long-term impact of diabetes mellitus [2]. It is a disease that is characterized by gradual progressive alterations in the retinal microvasculature. People with diabetes and less controlled blood sugar are likely to suffer from DR. It occurs when high blood sugar levels damage the walls of small blood vessels in the retina [3]. These vessels can swell, leak, or close, stopping blood from passing through them. Frequently, there is an accumulation of fluid in the part of the retina called macular edema [4]. Sometimes, in more advanced cases, the supply of blood to the retina is cut off, which results in the growth of abnormal new blood vessels called neo-

vascularization. These new fragile vessels can bleed, creating vision-impairing hemorrhages, scar tissue, and separation of the retina from the back of the eye. In DR, blood vessels leak fluid and blood on the retina. These vessels form features such as microaneurysms, hemorrhages, hard exudates, and soft exudates or cotton-wool spots [5]. The microaneurysms are hypercellular saccular out pouching of the capillary wall. They appear as deep-red dots varying from 25 to 100  $\mu\text{m}$  in diameter and have distinct margins. Retinal microaneurysms are usually the first ophthalmoscopic sign of DR [6]. They are located predominantly within the inner nuclear layer and in the deep retinal capillary network. Microaneurysms are the hallmark of Non-Proliferative Diabetic Retinopathy (NPDR) [7]. Intraretinal hemorrhages are another predominant feature of NPDR. It results from ruptured microaneurysms, capillaries, and venules, and is mostly within the outer plexiform and inner nuclear layers. Retinal hemorrhages are blot-shaped or flamed-shaped. Hard exudates are an ophthalmoscopic feature of background diabetic retinopathy [8]. They result from an increase in vascular permeability and the leakage of fluid and lipoprotein in the surrounding tissue. The hard exudates are fat-filled (lipoidal) histiocytes. They are small white or yellowish-white deposits with sharp margins in the outer layers of the retina, deep in the retinal vessels. Soft exudates or cotton-wool spots are localized infarctions of the nerve fiber layer with secondary coagulative necrosis of the retina [9]. They appear as pale yellow or white lesions with ill-defined edges in the superficial retina. The presence of soft exudates is the symbol for the onset of progressive change in DR. A cotton-wool spot can occur singly or in conjunction with hemorrhages and microaneurysms and represent retinal microvasculopathy.

The retinal appearance of diabetes mellitus is broadly classified as Non-Proliferative Diabetic Retinopathy (NPDR) or Proliferative Diabetic Retinopathy (PDR). NPDR occurs when there are only intraretinal microvascular changes, such as altered retinal vascular permeability and eventual retinal vessel closure [10]. In advanced NPDR, non-perfusion of the retina may develop and lead to the proliferative phase. The PDR is characterized by the formation of new vessels.

Contrast Limited Adaptive Histogram Equalization (CLAHE) is the process that reduces the noise amplification and it is the type of adaptive histogram equalization [11]. It operates on small regions of the image and works with neighboring tiles to avoid noise enhancement. Top hat filter is

a morphological filtering operation that works on grayscale images [12]. This filter relies on the structuring element size and, when fine tuned, it can increase the visibility of the features like red-colored veins in a fundus image. Tunable top hat filters are used for DR detection and when combined with CEGVP, it improves the accuracy of the proposed system.

Although some work has been done in the past, none of the methods have shown combinational identification of the abnormalities that are present in the retinal fundus image. It is quite desirable to have a combinational class because individual detection of these abnormalities may lead to false detection during segmentation, affecting the performance of the system. Hence, a separate class was required for predicting the combined abnormalities, as most of them occur in combination. The major contribution of the proposed method is 16 class classification using CEGVP, which is further passed through machine learning algorithms to diagnose DR. The CEGVP output was further improved using CLAHE and top hat and bottom hat approach. The features were then extracted using PCA and a 16 class classification of the abnormalities was carried out using a k-NN classifier.

The following sections of the paper are organized as follows: Section II presents an explicit literature review, Section III describes the methodology, Section IV highlights the results and discussions. Finally, Section V concludes the study.

## II. LITERATURE REVIEW

The researchers have investigated and developed several algorithms for detection of DR. A new technique was developed by Lachure et al. [13] for diagnosing PDR and NPDR. Their work consisted of detecting the abnormalities such as microaneurysms using morphological opening operations and exudates using morphological closing operations. The splat and Gray Level Co-occurrence Matrix (GLCM) features such as entropy, contrast, homogeneity, and energy were extracted and the image was further classified into PDR and NPDR using machine learning classifiers. The performance of SVM was better than compared to k-NN classifier. Safitri et al. [14] have proposed a new method for classifying the DR into three grades. Their work comprised segmentation of green channel image, applying morphological and masking operations, and computing the values of fractal dimensions using the box-counting method. These values were analyzed and classification of DR was performed using the k-NN classifier. The proposed method provided the best accuracy of 89.17% for K=3 and K=4. Labhade and his team [15] had presented an automated method for the detection of DR. Their work included preprocessing, feature extraction, and classification using machine learning algorithms. The preprocessing comprised grayscale conversion and histogram equalization for enhancing the contrast of grayscale fundus images. Textural features were extracted using GLCM by considering 3 angles of 0, 45, 90 degree, and 2 distances. The statistical moments were computed and the retinopathy grade between 0-3 was assigned for each of the fundus images. The SVM classifier provided better accuracy of 88% as compared with other classifiers. Kushol and his group [16] had presented a new blood vessel enhancement technique that separates the

blood vessels from the background image. The top-hat and bottom-hat transformations with optimal structuring elements were used to enhance the image. The proposed method yielded an average accuracy of 0.9379 and 0.9504 on DRIVE and STARE datasets, respectively. Kaur et al. [17] had proposed a reliable method of exudate segmentation using dynamic decision thresholding in the diagnosis of DR. Their work includes enhancement of retinal image, segmentation, and elimination of anatomical structures such as optic disc and blood vessels, and segmentation of exudates using adaptive image quantization and dynamic decision thresholding process. The proposed method resulted in a mean sensitivity, specificity and accuracy of 94.62%, 98.64%, 96.74%, respectively, at image based evaluation. Marin and the team [18] had presented a feature-based supervised classification technique for detecting Diabetic Macular Edema (DME) in fundus images. Their work comprised detecting the exudates by using digital image processing algorithms. Edge strength-based features and the features based on responses from the Gaussian and Difference of Gaussian (DoG) filter bank were computed. The final detection of exudate was obtained by considering only the regions whose probability exceeded a certain threshold value and the severity was graded using supervised classification techniques. The k-NN and SVM classifier resulted in an accuracy of 0.955 and 0.97422 for diagnosing the retinopathy disease. Issac and his team [19] have developed a method for detecting red and bright pathologies for diagnosing DR. A normalization process followed by anisotropic diffusion was used for segmenting bright lesions. A shade-corrected green channel image along with morphological flood filling and regional minima operations were used for detecting the red lesions. A quantitative analysis was performed to grade the severity of the disease. The proposed method using SVM based classifier obtained an average accuracy of 92.13% with a sensitivity of 92.85% and specificity of 80% on the DIARETDB1 dataset. A novel method was presented by Chetoui and his group [20] that comprised texture features, namely Local Ternary Pattern (LTP) and Local Energy-based Shape Histogram (LESH) for diagnosing DR. The histogram was computed using the extracted features and the performance of the system was evaluated for various kernels of SVM classifier. It was observed that LESH outperformed best in terms of accuracy and ROC characteristics. The accuracy of 0.904 and ROC of 0.931 was obtained using the SVM Radial Basis Function kernel. Amin and his team [21] had developed an automated method for the detection and classification of DR using hybrid features. Their work included lesion enhancement using the local contrast method, optic disc elimination, and lesion segmentation. The geometrical and statistical features were extracted for each candidate lesion. Abnormal and normal images were differentiated using multiple classifiers. The proposed method validated on the DIARETDB1 dataset resulted in an accuracy of 92.3% using k-NN and SVM classifier. Sahu et al. [22] have proposed denoising of fundus images using CLAHE. They could achieve an improvement of 7.85%, 1.19%, 0.12%, and 1.28%, in Peak Signal-to-Noise Ratio (PSNR), Structural Similarity Index (SSIM), Correlation coefficient (CoC), and Edge preservation index (EPI), respectively, over the existing methods. Huda et al. [23]

proposed an automated approach for diagnosing DR. Their study contained normalization, data standardization, and feature extraction from the retinal samples. The feature importance property was used to select the important features from each sample. The scores of each feature were generated and a higher score feature was selected. Their method resulted in six class classifications of the disease and their performance was evaluated using different classifiers. The proposed method with a logistic regression model achieved a precision of 97% and recall of 92%. Reddy et al. [24] have introduced an ensemble-based machine learning model for detecting DR. The grid search parameter tuning optimization method was used for choosing the optimal hyper parameters and the voting mechanism was used to make predictions for each classifier model. It was concluded that the ensemble machine learning model outperforms the individual machine learning algorithms. A study conducted by Alabdulwahhab and his team [25] had introduced a novel method for detecting DR. Their work comprised identifying the most discriminative interpretable features using socio-demographic and clinical information. The factors such as HbA1c, duration of diabetes, body mass index, systolic blood pressure, and the use of medication were used to discriminate the DR patients. Thus, a combination of ophthalmology and ML was integrated for diagnosing the disease pattern. The random forest classifier outperformed best by accurately classifying 86% of the DR patients. The author Sharma and his team [26] have developed an automated system for detecting DR using a combination of image processing and machine learning. Their work included pre-processing techniques such as gray scale conversion, canny edge detection and morphological operations to obtain a clear fundus image. The statistical features were extracted from the images and the performance of the system was evaluated using various classifiers. The weighted k-NN provided an accuracy of 85.8%, SVM with 87.2% and decision tree with 88.6%.

The literature review has highlighted the implementation of several machine learning algorithms applied independently on retinopathy datasets for detection of DR. As reviewed, there was a maximum of 6 class classification performed for diagnosing DR. Each of these techniques contributed to an individual detection of the abnormalities in the fundus images because of which the performance of the system was affected. The authors could achieve a maximum accuracy of 95.55%. The sensitivity computed for most of the methods was between 90% to 93%. AUC of 1 was obtained for very few methods. None of the techniques could identify the combination of the abnormalities as most of the time these abnormalities occur in combination in the retinal fundus images. Hence, a 16 class classification comprising a unique combination of CEGVP and dimensionality reduction approach using PCA is proposed that accurately classifies the four abnormalities either individually or in a group for diagnosing DR.

### III. METHODOLOGY

The proposed method consists of classifying four types of abnormalities, such as hard exudates, soft exudates,

microaneurysms and hemorrhages, either individually or in combination from a fundus image using CEGVP and k-NN classifier. Fig. 1 shows the conceptual diagram of the proposed system. A fundus camera captures the images of an eye, which is then processed using CEGVP. The features are extracted and fed into the k-NN classification algorithm, which classifies each image into one of the 16 categories. All 16 categories represent various abnormalities that may or may not be present in a fundus image. The diagnosis can be made based on the category into which the k-NN algorithm classifies the given test image.

The suggested technique combines four steps: preprocessing, segmentation, feature extraction, and classification. The input image is converted to grayscale. This grayscale image is used for a mass generation and binarization. The green color plane is enhanced by stretching the histogram and applying the mask. CLAHE is used to extract blood vessels from images using the Lab color space and exudates are extracted using top hat filtering. After enhancement, the combined green and value plane is passed through a Canny edge detector and subjected to morphological operations for object detection after binarization. Finally, the binary objects are combined, and the principal component is extracted as a feature for the k-NN algorithm. Fig. 2 shows the overall process of the proposed work.

The first step of processing comprises reading the original colored image (Fig. 3(a)) from the database and converting it into grayscale (Fig. 3(b)). The height and width of the input image was compared and the larger dimension was set to 640 and the other dimension was scaled, such that the aspect ratio of the image was maintained (Fig. 3(c)). A binary image (Fig. 3(d)) was generated from the grayscale image by using a threshold of 0.05 on the scale between 0 and 1. The resized original input image (colored) was again converted into a grayscale image. Each pixel of the new grayscale image was checked. If the value of a pixel was less than 10, then that pixel value was set to 0. Otherwise, if the value of a pixel was greater than 10, then that pixel value was set to 255, achieving the mask for the fundus (similar to Fig. 3(d) but with the dimension of 640 pixels on the larger dimension).

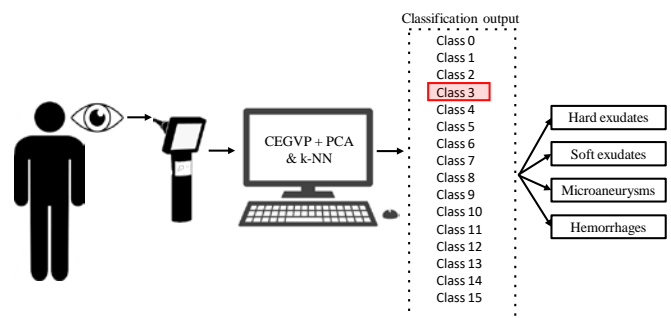

Fig. 1. Conceptual Diagram of the Proposed System. The Eye Images Captured by the Fundus Camera are Processed using CEGVP. The PCA Features are Extracted and then Fed to k-NN Classifier. Each Class out of 16 Classes Represents a Unique Combination of Abnormalities that may be Present in a Fundus Image.

Fig. 2. Proposed Methodology for Extraction of different Abnormalities from a Fundus Image using CEGVP and k-NN. The Input Image is converted to Grayscale as well as HSV, Lab, and RGB Color Planes are extracted. The Green Color Plane is enhanced using Histogram Stretching and Application of the Mask. Lab Color Space is used to extract the Blood Vessels from an Image. Top Hat Filtering is used to Extract Exudates. The CEGVP is Passed through a Canny Edge Detector and Subjected to Morphological Operations Post Binarization for Object Detection. Finally, all the Binary Objects are merged and the Principal Component is extracted as a Feature for the k-NN.

Fig. 3. Output at Various Stages of CEGVP for the Fundus Image. (a) Original Input (b) Grayscale Converted (c) Resized (d) Background Masked Image with a Threshold of 0.05 (e) Extracted Green Color Plane (f) Enhanced and Masked Green Color Plane with Background Removal.

Red and green color planes were extracted from the original input image with green color plane as shown in (Fig. 3(e)). A structuring element was defined that had a size of 350 pixels and a shape of a disk. Morphological opening operation was performed on the green color plane. For the morphological operation of opening previously defined structural element was used on the green color plane. The output of the opening operation was then subtracted from the original green color plane. A maximum pixel value of this subtracted image was found out. The mask image was then used for masking the outer region with white color (pixel value of 255) as seen in (Fig. 3(f)). A copy of this processed image was made for further processing. All the dark pixels in

the green channel were preserved whereas all the lighter pixels with a value greater than 50 were whitewashed. The copy image of the green channel was then contrast stretched between 0 and 255 (Fig. 3(f)).

The original image was used yet another time to extract the red, green, and blue color planes. A mask was applied to the green color plane and the same color plane was contrast enhanced for maximum value (255). A secondary mask was created with the help of the green channel having the threshold of 60 on a scale of 0 to 255. All the pixel values below 60 were made 0, and 255 otherwise. A blue color mask was used, similar to green color with a threshold of 130. A similar operation was performed on the blue color plane. The color pane of the original image was changed to HSV from RGB and further hue, saturation, and value planes were separated. The value plane was then masked, and contrast-enhanced between 0 to 255 (Fig. 4(a)). Similar operations were performed on saturation and hue color planes. The hue color plane was enhanced 18 times. The combinational color plane was generated using the enhanced green plane and the value color plane (Fig. 4(b)). Further, all the max values were replaced with mean values to ensure that contrast enhancement can be done properly. Because of this operation, all the regions of the mask were neglected. The combinational plane was then contrast enhanced (Fig. 4(c)) and the entire image was rescaled to a smaller matrix of 3X3 to extract a single-valued function available at the center of these 3X3 images (Fig. 4(d)).

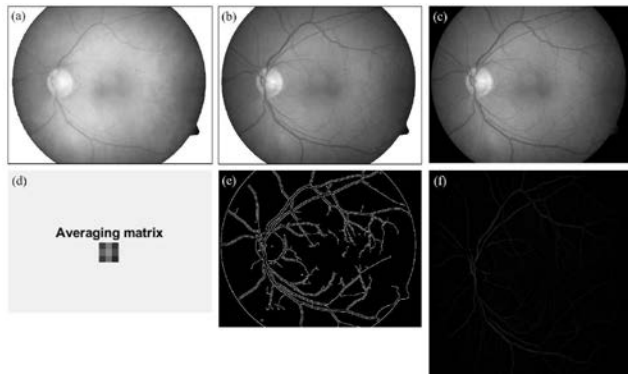

Fig. 4. Outputs at different Stages for the Input Image under Consideration. (a) Masked and Normalized Value Color Plane. (b) Combinational Green and Value Color Plane. (c) Enhanced Combinational Green and Value Color Plane. (d) Averaging Matrix with 3 X 3 Dimensions. (e) Canny Edge Detector. (f) Morphological Bottom Hat Operation.

The combination image of the green color plane and value color plane was masked using the mask image and further enhanced with the saturation values at the bottom and top 1% amongst all pixel values. The image was rescaled to 3X3 and the entire process was repeated. Finally, a Canny edge detector was applied to this enhanced combinational color plane (green & value plane) with a factor of 0.1 (Fig. 4(e)). Simultaneously, adaptive binarization was applied to the enhanced combinational color plane (green & value plane). All pixels in the output of the binarization process that had a value of less than 200 were removed. A structuring element of disk shape with size 15 pixels was used to call a morphological opening operation on the enhanced combinational color plane. Further, the background was then removed using the image which was operated using the opening operation. The overall contrast was then enhanced and all the objects touching the border were removed. A 4-pixel neighboring connectivity was checked for connected components and areas of all the objects segmented from this neighboring pixel connectivity were used to find the maximum area. All the segregated objects were then binarized and the entire image was resized to 512 X 512 pixels. This resizing ensured that machine-to-machine variability is not affecting the classification results. The original input image was then passed through the color channel separator to segregate the green color channel component. A structuring element with a disk shape of 5 pixels was then used on the green channel to achieve bottom hat filtering (Fig. 4(f)).

The same green channel image was also simultaneously passed through a top-hat filter (Fig. 5(a)) but with a structuring element of disk shape having a size of 8 pixels. Finally, a bottom hat filtered image was subtracted from the top-hat filtered image, and binarization with a threshold of 0.1 was carried to extract the hard exudates (Fig. 5(b)). The original image was resized to 584 X 656 pixels and converted into a Lab color space to extract the principal components from the converted image using PCA. The entire image was then normalized and contrast enhanced using CLAHE (Fig. 5(c)). An averaging filter of 9 X 9 pixels was used to exclude the background. Thresholding was performed on the background removed image and then the entire image was converted to binary with a level of 0.08% lower than the

automated thresholding level to extract the blood vessels as shown in (Fig. 5(d)). Small objects less than 100 pixels were removed and then the image was inverted. Finally, the entire image is resized to 512X512 to merge with the earlier results. All the three outputs detecting microaneurysm, hemorrhages, and exudates in their binary form were added and scaled by a scalar of 85 to produce a final grayscale output (Fig. 5(e)) which can then be given to the feature extraction algorithm. The final image was then passed to extract the first 64 components. Finally, a class is assigned to these 64 extracted components based on the supervisory dataset DIARETDB0 [27], DIARETDB1 [28], and Indian Diabetic Retinopathy Image Dataset (IDRid) [29].

Fig. 5. Outputs at different Stages of CEGVP. (a) Morphological Top-Hat Operation (b) Hard Exudates (c) Contrast-enhanced Lab Color Space using CLAHE (d) Blood Vessel Detection (e) Combined Output from CEGVP, Morphological Top-hat, CLAHE, and Canny Edge Detector. The Image is converted to Grayscale with Four different Levels: 0, 85, 170, and 255.

The novelty of the proposed methods lies in the combination of the green sub-color plane from RGB planes and the value sub-color plane from the HSV color planes (CEGVP) to enhance the overall features. This is the first time a unique combination of combined color planes and 16 class classification has been performed for predicting the abnormalities in the fundus image for detection of DR. This work presents the combination of image processing techniques for enhanced feature extraction and classical machine learning approach, such as k-NN for classification. The performance of the proposed method was tested using three publicly available databases. In all 300 images with DIARETDB0 (130 images), DIARETDB1 (89 images), and IDRid (81 images) were used respectively.

#### IV. RESULT AND DISCUSSION

A 5-fold cross validation was used for the analysis and experimentation purposes. The ratio in which the images were split was chosen to be 70% for training and 30% for testing. To verify the performance of the designed system, 450 images were chosen randomly from the test dataset.

##### A. Result Analysis

1) *Performance measures*: The performance measures such as accuracy, sensitivity, specificity and area under the curve (AUC) were used to evaluate the performance of the proposed method. Table I and Fig. 6 shows the performance metrics of various classifiers for PCA feature vector 8x8 using 16 class classification.

TABLE I. PERFORMANCE METRICS USING PCA FEATURE VECTOR 8x8

Classifiers	Metrics			
	Accuracy (%)	Sensitivity (%)	Specificity (%)	AUC
KNN	97.11	98.47	91.64	1
SVM	95.77	93.66	97.43	1
Decision Tree	87.3	61.3	64.7	1

Fig. 6. Comparison of Performance Metrics using 8x8 PCA. k-NN Performed Best in Terms of Accuracy and Sensitivity as Compared to other Classifiers, Whereas in Terms of Specificity SVM was Most Superior amongst All.

It was observed from the graph that the highest accuracy of 97.11% and sensitivity of 98.47% was obtained for k-NN classifier. SVM achieved the best specificity of 97.43% as compared to other classifiers. The decision tree classifier performed very low in terms of all the performance measures. The AUC for all classifiers was found to be 1. Thus, it was seen that k-NN was the most optimal classifier for the proposed system.

To increase the ability of the system, bag-of-words concept was used that provided more images for training and testing purpose. Fig. 7(a) shows the confusion matrix for 16 class classification using k-NN. The three classes 4, 9, and 14 were not found in the confusion matrix, as there were no images for training and testing for these classes in the datasets. The worst accuracy was found for class 5, where all the images were mapped to class 7. Other than classes 11, and 15, all the classifications were 100% accurate. Whereas for class 15 and 11, the number of images were more, which resulted in a fraction of misclassification, which is roughly 4.6%. There were maximum of 148 images of class 15, followed by 124 images of class 11 and 55 images of class 2.

Fig. 7(b) shows the scatter plot after PCA features were extracted for the 16 classes and the top 2 features were plotted. It can be visually seen that no straight line can separate various classes from each other, and hence k-NN was the preferred method over the traditional SVM.

The Receiver Operating Characteristic (ROC) curve with the false positive and true positive rates is as shown in Fig. 7(c).

2) *PCA feature vector of optimal sizes vs accuracy*: To select the most optimal method of classification and the optimum size of the PCA feature vector, a separate study was carried out as shown in Table II and its output was summarized in the graph shown in Fig. 8.

(a). Confusion Matrix for 16 Class Classification using k-NN. The Images in the Categories 4, 9, and 14 were missing as there were no Images for these Particular Classes in the Datasets. Maximum Images were of Class 15 followed by Class 11 and Class 2.

(b). Scatter Plot for 16 Class Classification using k-NN. As Observed, it is Very Difficult to Segregate a Linear Line among the Various Classes and Hence k-NN is the most Suited Strategy.

Fig. 7. (c). Area Under Curve (AUC) for 16 Class Classification using k-NN Class 15 has an Area under the Curve (AUC) of 1.0.

TABLE II. COMPARISON OF PCA FEATURE VECTOR WITH ACCURACY

PCA Feature Vector	Accuracy (%)		
	KNN	SVM	Decision Tree
1x1	91.6	39.6	57.3
2x2	96.4	90.2	68.7
3x3	96.9	96.9	81.3
4x4	96.7	96.4	83.6
5x5	95	95.8	86
6x6	95.6	95.3	85.9
7x7	96.9	96	86.9
8x8	97.1	95.8	87.3
9x9	95.3	95.2	86.6
10x10	94.1	94.1	86.2

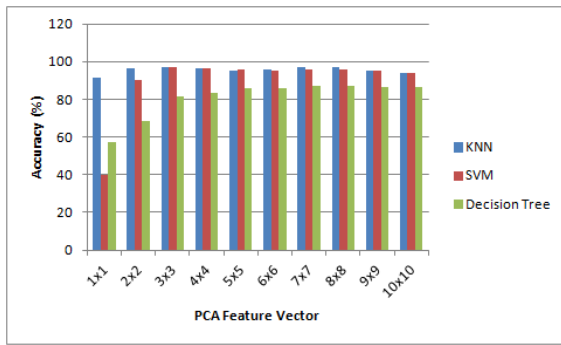

Fig. 8. PCA Feature Vector Size with Accuracy for SVM, k-NN, and Decision Tree Algorithms. The 8x8 PCA Vector Size was found out to be the Best for k-NN that had Maximum Accuracy. SVM Achieved Higher Accuracy only when PCA Vector Size was 3X3 but showed Poor Performance for PCA Feature Vector Size 1X1. The Decision Tree Always had approximately 10% Less Accuracy than k-NN for all the Feature Vector Sizes.

It was observed that all the algorithms do get affected if the feature vector size was varied. Since k-NN had the least variation, it was considered being less dependent on the size of the feature vector. The decision tree was highly dependent on the feature vector size. It has a bimodal distribution of accuracy making it difficult to recognize the correct PCA feature vector size.

The 8X8 PCA feature vector size was discovered to be the optimum vector size for k-NN and 3x3 for SVM, as highest

accuracy was obtained by both the classifiers for these vector sizes. SVM performed badly with less than 40% accuracy at PCA feature vector size 1 X 1. The decision tree, for all conceivable feature vector sizes always had approximately 10% less accuracy as compared to k-NN. As a result, 8X8 PCA feature vector was found to be the most suitable vector size for KNN classifier.

**B. Discussions**

Table III shows the comparative analysis of the proposed work with the existing approaches, as reviewed in the literature. The proposed method achieved the highest accuracy compared to all the similar methods that use k-NN or SVM classifiers. Marin et al. [18] have achieved a similar accuracy, but their sensitivity and specificity were poor. The sensitivity obtained using k-NN classifier was highest using the proposed technique. Lachure et al. [13] could achieve 100% specificity, but they have considered only three classes and overall accuracy was 90%. AUC for the proposed method was comparable to the others as reported in the literature, whereas the number of classes that are segregated in our work is at least 2.5 times than every method ever reported. The overall performance of k-NN is better as compared to SVM and hence we proposed KNN classifier for abnormality detection in fundus images. Some other methods perform better in terms of accuracy, but they are neither working on 16 class classification nor using KNN and SVM classifiers hence, they were excluded from the comparison table.

## V. CONCLUSION

The early diagnosis of DR is a critical step in avoiding total blindness. The goal of our proposed method is to create an automated DR prediction system using Combined Enhanced Green and Value Planes (CEGVP) with k-nearest neighbor (k-NN) classifier in retinal fundus images to classify illnesses either individually or in combination. This was the first time that a 16 class classification was proposed that precisely gives the ability and flexibility to map the combinational complexity in a single step. The proposed work removes the requirement of four different binary classifiers for each abnormality detection and thus saves a lot of computational time, as well as error propagation from each method is also avoided. Our novel technique of 16 class classification using k-NN classifier achieved an accuracy of 97.11%, sensitivity of 98.47%, and specificity of 91.64% on DIARETDB0, DIARETDB1 & IDRid datasets. This new technique can help ophthalmologists discover problems more quickly and begin their diagnosis sooner. Future work includes improving the accuracy of the proposed system by using different machine learning classifiers. Besides RGB and HSV color planes techniques, other color planes can be explored and the useful plane can be merged to extract better features for DR detection.

## ACKNOWLEDGMENT

The authors would like to thank colleagues from Sir Padampat Singhania University.

# A Novel Secure Transposition Cipher Technique using Arbitrary Zigzag Patterns

Basil Al-Kasasbeh

Faculty of Computer Studies, Arab Open University (AOU), Riyadh, Kingdom of Saudi Arabia

**Abstract**—Symmetric cipher cryptography is an efficient technique for encrypting bits and letters to maintain secure communication and data confidentiality. Compared to asymmetric cipher cryptography, symmetric cipher has the speed advantage required for various real-time applications. Yet, with the distribution of micro-devices and the wider utilization of the Internet of Things (IoT) and Wireless Sensor Network (WSN), lightweight algorithms are required to operate on such devices. This paper proposes a symmetric cipher based on a scheme consisting of multiple zigzag patterns, a secret key of variable length, and block data of variable size. The proposed system uses transposition principles to generate various encryption patterns with a particular initial point over a grid. The total number of cells in the grid and its dimension are variable. Various patterns can be created for the same grid, leading to different outcomes on different grids. For a grid of  $n$  cells, a total of  $n! * (n-1)!$  total patterns can be generated. This information is encapsulated in the private key. Thus, the huge number of possible patterns and the variation of the grid size, which are kept hidden, maintain the security of the proposed technique. Moreover, variable padding can be used; two paddings with different lengths lead to a completely different output even with the same pattern and the same inputs, which improves the security of the proposed system.

**Keywords**—Cryptography; symmetric cipher; block cipher; transposition algorithms

## I. INTRODUCTION

Data confidentiality can be ensured using both asymmetric cipher and symmetric cipher. Symmetric cipher has the advantage of low computational requirements compared to asymmetric cipher cryptography, which is commonly used for key exchange and authentication purposes [1]. Asymmetric cipher is commonly referred to as public-key encryption [2]. On the other hand, the symmetric cipher is commonly referred to as private-key encryption and has two main types: the block cipher and the stream cipher. The stream cipher encrypts each bit of the message with each key's bit using operations, such as the exclusive-or (XOR) [3].

On the other hand, block cipher uses substitutions and transposition operations on an  $n$ -bits block, as illustrated in Fig. 1. Block cipher encrypts a data block of predetermined length using private key principles. Both stream and block ciphers have their applications, advantages, and disadvantages. The stream cipher is fast and requires low computational power compared to the block cipher. Block cipher is widespread and is used in various other applications, such as stream cipher, hash function, pseudorandom number generator, and message authentication [4]. Besides, the block cipher is more secure than the stream cipher, subject to the strength of the utilized

private key [5]. The security level of the block cipher algorithm is evaluated based on the complexity, the performance, and its strength against possible cryptanalyses, such as linear and differential analysis and the homegrown crypto that is created afterthought [4, 6, 7].

Block cipher algorithms use predefined block sizes. A multiple of 8-bits block sizes is commonly utilized as compatible with most processors. Besides, the large size is avoided as it leads to padding, increasing computational requirements. Similarly, small size blocks give more chances for dictionary attacks on the ciphertext blocks to succeed [8]. For a variable-length message to be encrypted, the message is first divided into blocks of the predetermined size, padded if necessary to meet the required size. Then each block is encrypted using the cipher algorithm with a private key. Advanced algorithms for block cipher have been developed, such as Advanced Encryption Standard (AES) and Data Encryption Standard (DES), which are the most utilized encryption algorithms worldwide [4, 9]. These algorithms depend on mathematical operation and substituting the plaintext bits and characters by other bits and characters; these are called substitutional algorithms. Besides the substitution cipher, another block cipher type is called transposition cipher, such as rail fence and columnar. Compared to the substitution cipher, the transposition cipher is faster, as it depends on transposition shuffle rather than mathematical operations. Yet, because the shuffle is limited and known in advance, and the algorithms are operated on very small keys, the security of these algorithms is weak. Surprisingly, vast number of the existing substitutional algorithms has been solved by the cryptanalysis [4, 5, 10, 11].

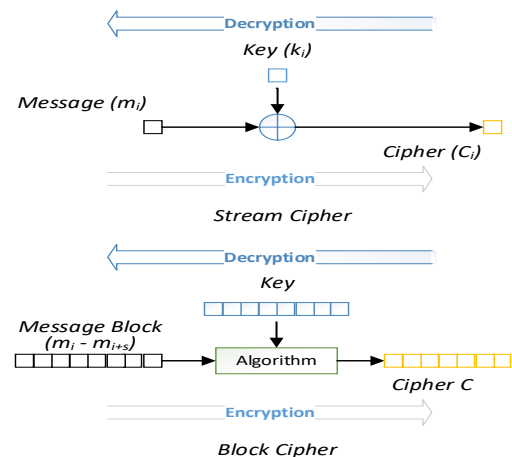

Fig. 1. Stream Cipher vs. Block Cipher.

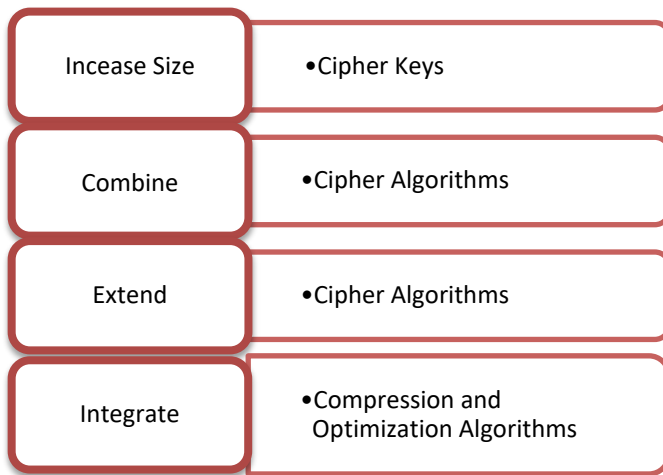

Fig. 2. Modern Cryptograph Directions.

Accordingly, various modern cipher techniques have been proposed to improve the security of the block cipher. Various ways have been followed to extend the existing algorithms. As illustrated in Fig. 2, these are 1) Proposing various encryption modes, in which the block ciphers are related to each other or related to randomly created vectors to increase the complexity of the generated cipher. 2) Combining various cipher algorithms to create a more secure system. 3) Combining cipher algorithms with optimization and compression algorithms. 4) Extending the cipher algorithms by increasing the size of the key or modifying their structure. Although these directions improve the security of the cipher algorithms, most of them have increased the computational requirements of the encryption and decryption process. The complexity of the modern techniques for data encryption leads to the inapplicability of these techniques to be utilized in most of the modern applications, such as real-time applications, sensor networks [12], and Internet-of-Things (IoT) [13], which demands secure yet highly performance encryption techniques [14].

Accordingly, this paper proposes a new technique for block cipher encryption. The proposed system follows different directions compared to these mentioned previously in improving the security of the symmetric cipher cryptography [15]. The goal of the proposed technique and the creative direction is to improve security while maintaining low encryption and decryption processes requirements. The proposed technique improves the security using different transposition zigzag patterns while solving one of the major transposition cipher problems: the limited possible shuffle operation of the cipher algorithm. Moreover, the proposed technique used variable grid size maintained secret in the private key, similar to the columnar algorithm. Thus, before the encryption is made available for the sender, various patterns are created and saved with their identification number in the system. These patterns are shared publically between the sender and the receiver. However, trying all these patterns is impossible for cryptanalysis because of the vast possible patterns. Then, the proposed system allows the sender to freely choose among different patterns and select the grid size on

which the patterns are drawn. The size and the pattern form the private key of this cipher system. A variable-length message can be divided into blocks of various lengths, padded if necessary to meet the required length. Each block is encrypted using different patterns and keys.

## II. LITERATURE REVIEW

Transposition ciphers are implemented based on designed patterns to scramble the plaintext. Examples of some of the transposition ciphers are presented in Fig. 3. The rail fence used the number of rows as the key. Then, a grid is created with the specified number of rows and number of columns equal to the length of the message to be encrypted. The plain text is placed diagonally downwards on successive rails on an imaginary fence, followed by upwards moves as the movement reaches the grid's last row. The letters are read row by row to create the ciphertext [16]. In the columnar cipher, the key determines the number of columns and the columns' order. Then, a grid is created with a specific number of columns and rows to accommodate all the letters in the message to be encrypted. The plain text is placed on the grid row by row and in order. Then, the columns are permuted based on the key. The letters are read column by column to create the ciphertext [16-19].

The route cipher is another grid-based transposition cipher with longer keys than the rail fence and columnar. The key represents the number of columns or rows and the patterns to read the letters in the grid. The plaintext is written in the grid row by row and in order. Then, the ciphertext is produced by reading the grid upwards or downwards clockwise or zigzag patterns up and down. Double or multiple columnar ciphers are used to improve the security of the single columnar cipher. The same key can be applied, or other keys are required in multiple rounds of the columnar cipher process [18]. Myszkowski is a variation of the columnar cipher with a key of repeated letters that are given the same order. Accordingly, columns with unique numbers are read downward, and columns with recurring numbers are transcribed left to right. Disrupted transposition is another grid-based cipher with irregular spaces added between the plaintext letters. Overall, various transposition ciphers have been proposed. These transposition ciphers depend on a grid to scramble the plaintext. Yet, the problem of these ciphers is the limited patterns with a small key space that can be discovered in the cryptanalysis processes that are searching the keyspace [20].

Various modern techniques were proposed by modifying the transposition cipher algorithm. Sokouti, Sokouti [21] added 8-bits padding to each 8-bits in the message, structured these bits in a binary tree, and traversed this tree using an in-order traversal algorithm. However, such complex processes increase the complexity of the transposition cipher. Twum, Hayfron-Acquah [22] extended columnar cipher with a modified Rubik's cube puzzle with a higher level of security as the cube represents a 3-dimensional instead of the 2-dimensional space utilized in the original columnar cipher. The number of such modified algorithms is enormous. Block cipher surveys were presented by Surya and Diviya [23], Albermany and Radhihamade [10], and Mandal [24].

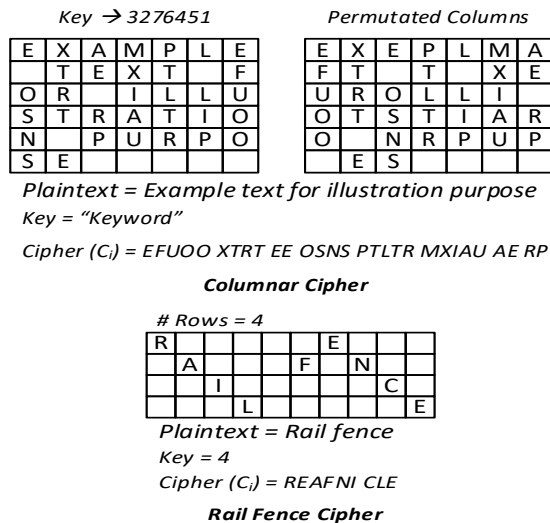

Fig. 3. Example Transposition Ciphers.

Lasry, Kopal [18] extended columnar cipher with a two-phases hill-climbing algorithm in combining cipher algorithms with optimization. The main goal of the developed algorithm is to increase the size of the key to improve the security of the cipher. Hill climbing is an optimization algorithm that starts with a random solution and iteratively finds optimal. With columnar cipher, hill climbing is used to swap columns and increase the adjacency score of the resulting cipher. Various other schemes combined cipher algorithms with optimization algorithms, such as genetic algorithm (GA) [25, 26]. Using the Fibonacci code algorithm, Siregar, Fadlina [19] integrated columnar cipher and data compression. The columnar output is input to the Fibonacci algorithm, which produces the final ciphertext.

Encryption modes describe how the blocks of a single message are related to each other to improve the security of the message. The electronic codebook (ECB) encryption mode for block cipher encrypts each block individually. The advantages of this mode are the ability of out-of-order decrypting, non-propagation of errors between blocks, speed, and parallelism. Yet, as the same key is utilized, the same input plaintext produces the same cipher, which is deterministic and can be attacked through traffic analysis [4]. To overcome this limitation, several encryption modes have been developed; these are cipher block chaining (CBC), cipher feedback (CFB), output feedback (OFB), and counter (CTR) mode [11]. These modes operated based on the concept of using extra data besides plaintext and the key for creating probabilistic encryption. CBC encrypts the first block together with a randomly initialized vector. The vector is combined with plain text before the encryption process. The ciphertext is then used with the second block in place of the random vector, and the output is used with the third block and so on. In CFB, the random vector is encrypted and combined with plaintext, which emulates the self-synchronizing stream cipher. OFB is similar to CFB except that the encrypted vector is sent to the next block instead of the ciphertext, similar to the synchronous stream cipher concept. CTR mode initializes a unique vector for each block, encrypts the vector then combines the output

with the plaintext to produce the ciphertext [27]. These modes aim to scramble the output, avoid repeated patterns, and provide semantic security, to prevent inference of any information from the ciphertext under an unknown key [4, 11]. Yet, these modes create various disadvantages, mainly related to the computational power and the required processing time. Generally, these modes have been developed with substitution encryption in mind. Although these modes applied for transposition, less attention has been given to this encryption scheme, mainly because of the limitation related to its weak security, resulting from the weakness of their keys, and the limited variation of the transposition shuffle [28-30].

In the integration direction, Srikantaswamy and Phaneendra [31] integrated columnar transposition cipher with Caesar substitution cipher. The secret key is generated randomly based on a selected seed value. Then, Caesar cipher is implemented with alphabets, symbols, and numbers as an extension to the original version that uses alphabets only. Finally, columnar is implemented using a randomly selected number of columns. Kester [17] integrated columnar transposition cipher with Vigenere substitution cipher. Columnar is implemented using a randomly selected number of columns. The generated ciphertext is then used as the key for encrypting the plaintext using the Vigenere cipher. Dar [16] integrated columnar cipher, Caesar cipher, and rail fence cipher to improve the security of the ciphertext. The aforementioned cipher algorithms are implemented in order; as such, the output of the columnar is used as input to Caesar, and the output of Caesar is used as input to the rail fence, which produces the final ciphertext.

As noted, these extended techniques rely on more processing rounds and complex calculation and transposition to secure the data. Yet, those techniques cannot be applied for micro-devices with limited resources or real-time applications requiring rapid encryption-decryption processes [32]. Accordingly, this research proposed a strong security technique resulting from the possible variation with low processing requirements.

### III. THE PROPOSED SYSTEM

The proposed technique relies on predefined zigzag patterns drawn on a two-dimensional grid and can be extended to three-dimensional as required. The patterns can be created manually, as illustrated in Fig. 4, or automatically using graph-based search, or randomly depending on the application and the device. In a typical implementation of the proposed techniques, these patterns are made publically available and exchanged between the sender and the receiver. Yet, to make the system secure, the number of these patterns should be large enough to avoid brute-force solving of the ciphertext. Moreover, some patterns can be made secret and shared only between the sender and the receiver.

Besides, these patterns are saved in the sender and receiver devices in two arrays, one for the x-axis and the other for the y-axis, as illustrated in Fig. 5. If a three-dimensional cube is utilized, another array is used for the z-axis. Such representation requires low memory and can be traversed with O(n) complexity, where n is the size of the grid. The vast number of possible patterns maintains security. For a grid of n

cells, a total of  $(n!)$  can be generated. Moreover, given that  $n$  is variable,  $(n! * (n-1!))$  total patterns can be generated if  $n$  is hidden. The value of  $n$  can be made invisible as the proposed technique allows for arbitrary padding at the end of the message before and after encryption. For example, for a message of length 6, 720  $(6!)$  patterns are drawn on a grid of size 6  $(2*3)$ . Yet, after encryption padding, the message can appear of size 9, for example. Thus, for cryptanalysis to try all possible patterns, all patterns of the grid of sizes  $\{9, 8, \dots, 1\}$  should be examined.

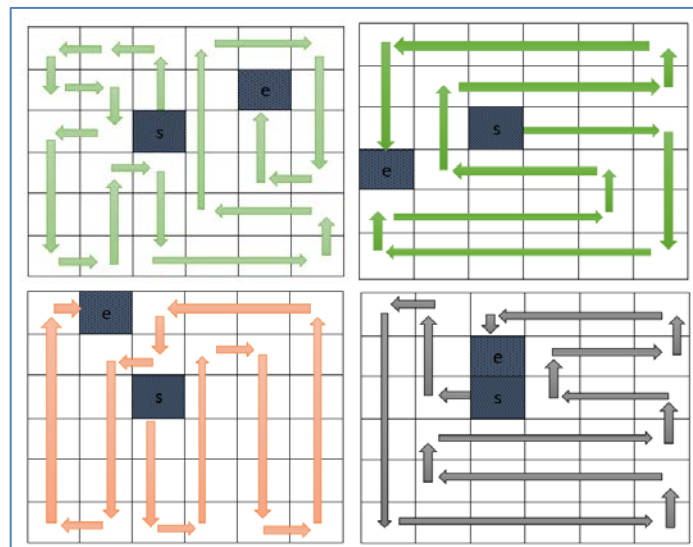

Fig. 4. Zigzag Patterns Examples.

Fig. 5. Example of Array Representation of a Zigzag Pattern.

#### A. Pattern Generation

The pattern by which the transposition processes are implemented can be created in two forms and three ways. The zigzag patterns, which do not include any line-crossing, can be generated either manually or using graph-based techniques, as listed in Table I.

TABLE I. PATTERNS LIST OF THE PROPOSED TECHNIQUE

Pattern Type	Generated Mechanism	Advantages
Non-crossing Zigzag	Manual	Visually interpreted and verifiable.
Returnable Pattern	Graph Traversal (In-order, pre-order, and post-order)	Visually interpreted and verifiable and created automatically
Crossing-Line Pattern	Manual or Randomly	Easily created with wide varieties

The line-crossing patterns can be created manually but preferably using random number generation. The grid size and the initial cell  $s$  are determined to generate a manual pattern. Then, the pattern is created following zigzag directions visiting all the cells once and terminating the traversing at the arbitrary final cell,  $e$ . The coordinates of the cells are preserved in the arrays based on the traversing order. Each pattern is saved with a unique identifier to reference between the sender and the receiver. Besides, a generated pattern can be kept secret and exchanged with the private key because the pattern can be represented as two arrays in a two-dimensional grid. Although the zigzag patterns required manual attention to avoid line-crossing, these zigzag patterns can be generated using a graph representation of the grid and graph traversals mechanisms, such as in-order, pre-order, and post-order, as illustrated in Fig. 6. Nevertheless, as illustrated in Fig. 7, line-crossing patterns do not affect the security of the proposed technique. Instead, such line-crossing patterns allow for random patterns without the need for human attention or graph representation and traversals.

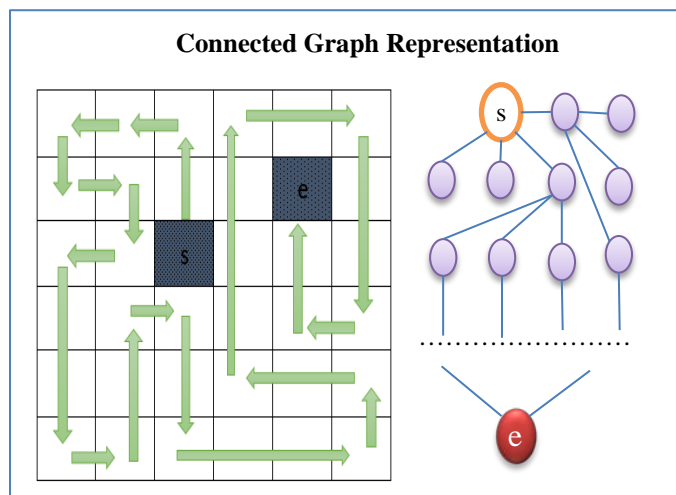

Fig. 6. The Graph Representation for a Zigzag Pattern Generation.

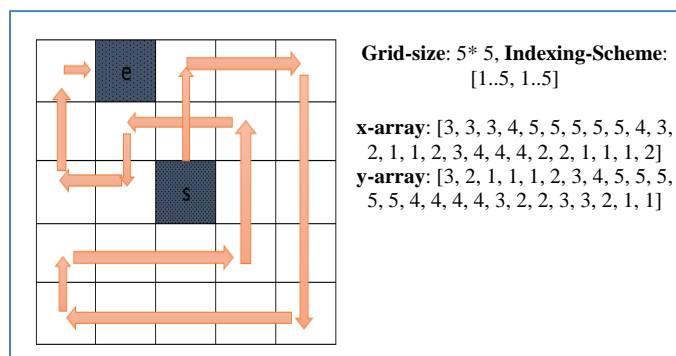

Fig. 7. Crossing-Line Pattern.

#### B. Secret Key Value

The secret or the private key of the proposed technique is represented with an integer value, which can be converted into binary as required. The private key of the proposed cipher technique referred to the grid size, the pattern to be utilized, and the padding options. There are two options for determining

the pattern, either a secret pattern embedded into the private key or the unique identifier of a public pattern. A secret pattern can be identified as starting by -1 value. The public pattern is identified with a unique positive identifier. The identifier can be of any length to continuously add patterns without limits. There are also two padding options to improve the security of the proposed technique, as listed in Table II. Table II lists the private key components in the proposed technique with examples.

TABLE II. PRIVATE KEY COMPONENTS OF THE PROPOSED TECHNIQUE

Components		Description	Example
Length		Four digits: The first digit indicates using public (0) or secret pattern (1). The next two digits indicated the length of the pattern (either length of the identifier or length of the included pattern). The next digit indicates whether padding is done before (0) or after encoding (1). If no padding occurs, then this digit can take any value.	0160 → using public pattern identified by 16 digits with padding implemented before encrypting
Grid size		4-digits for the two-dimensional	0610 → six rows and ten columns
Pattern	Public Identifier	Variable number of digits for the unique identifier	Can be any number
	Secret Pattern	Two concatenated arrays of size equal to the grid size (identified by the size field in the pattern)	21211212 → two concatenated arrays [2121] and [1212] that describe a pattern over 2*2 grid
Padding	Before encoding	Two digits to indicate the length of the padding at the end of the grid	05 → padding of length 5
	After encoding	Two digits to indicate the length of the padding at the end of the ciphertext	04 → padding of length 4
Example Keys			
1501 0505 3334555554321123444221112321112345555444432233211 06			
A secret pattern consists of 50 digits of the secret pattern or a 5x5 grid with six digits padding before encrypting			
0101 0505 0125214578 06			
A public pattern has an identity consisting of 10 digits with the same specification as the previous one			

### C. Encryption

The encryption process is implemented based on the specifications stated in the secret key. First, the grid is created based on the predetermined dimensions, utilizing the secret key components. The plain text components are placed inside the grid based on the pattern represented by the x-array and the y-array. The ciphertext is produced by reading the grid row by row as the grid is filled. If padding is implemented before encoding, then the padded code (either 0's in case of encrypting binaries or X's in the case of encrypting letters) is considered in the last row(s) of the created grid. For example,

if a 3x3 grid is utilized with two padding bits before encoding, then the value of the cells  $\{(2,3), (3,3)\}$ , will be zeros, and these cells will not be filled with the components of the plaintext as will be explained. If padding is implemented after the encoding, the padded code is attached after the ciphertext is produced. Algorithm 1 presents the encryption process. The significance of the padding is that, even with the same pattern and the same inputs, different pad lengths for the before encoding padding leads to a completely different output.

### Algorithm 1: Encryption

```

1 Input: mb, K (cols, rows, xs [], ys [], beforePadding, afterPadding)
2 Output: cb
3 Grid [[]]:= Create-Grid (cols, rows)
4 xPadding [],yPadding []:= IdentifyPaddingCells(beforePadding)
5 For-Each x,y in xs, ys
6     IF (x,y ∈ xPadding , yPadding)
7         Grid [x,y] := 0
8     ELSE
9         Grid [x,y] := mbi, i++
10 For-Each c in Grid
11     cbi := c
12 IF (afterPadding > 0)
13     Concatenate (cb, pad)
    
```

### Notations:

*mb, cb*: message block and the cipher block, respectively  
*k*: private key  
*cols, rows*: number of columns, and rows as determined by the private key, respectively  
*xs, ys*: the x-array and y-array of the pattern, respectively.  
*beforePadding, afterPadding*: length of the padding before and after encryption, respectively.

As given in Algorithm 1, line 3 created the grid used by the encryption. The padded cells used before encryption are identified based on their numbers, as the last cells in the grid, as given in line 4. Lines 5-9 fill the grid following the pattern with the message (lines 8-9) or with padding (lines 6-7) if the pattern comes across the padding cell. Lines 10-11 create the ciphertext by reading the grid row by row. Finally, lines 12-13 concatenate after encryption pads if it exists as determined in the key.

### D. Decryption

The grid is created based on the predetermined dimensions after receiving the encrypted message (bit sequence or letter sequence) at the receiver side. The grid is filled in a row by row manner, similar to how the sender created the ciphertext in the last stage. Then, to retrieve the plaintext, the receiver will implement the same pattern as utilized in the receiver side, but this time to read the cells and reproduce the message. The padded code cells are skipped while reading the grid components if padding is implemented before encoding. At the same time, if padding is implemented after encoding, the last components of the received ciphertext will be removed. Algorithm 2 presents the decryption process.

Algorithm 2 represents opposite operations. Line 3 created the grid. After encryption pads are removed, then in lines 5-6. Then, the grid is filled in lines 7-8. Lines 5-9 read the grid following the pattern and filling the message (lines 12-13) or skip padding (lines 10-11) if the pattern crosses the padding cell.

**Algorithm 2: Decryption**

```

1  Input: cb, K (cols, rows, xs [], ys [], beforePadding, afterPadding)
2  Output: mb
3  Grid [][]:= Create-Grid (cols, rows)
4  xPadding [],yPadding []:= IdentifyPaddingCells(beforePadding)
5  IF (afterPadding > 0)
6    Eliminate (cb, pad)
7  For-Each c in Grid
8    cbi := c
9  For-Each x,y in xs, ys
10   IF (x,y ∈ xPadding , yPadding)
11     continue
12   ELSE
13     mbi := Grid [x,y], i++
    
```

**Notations:**

*mb, cb*: message block and the cipher block, respectively  
*k*: private key  
*cols, rows*: number of columns, and rows as determined by the private key, respectively  
*xs, ys*: the x-array and y-array of the pattern, respectively.  
*beforePadding, afterPadding*: length of the padding before and after encryption, respectively.

**E. Multiple Encryption-Decryption**

Multiple patterns can be used with the same block with multiple rounds while considering the computational requirements at the sender and the receiver, as given in Fig. 8. Accordingly, multiple private keys are required for such a purpose. Nevertheless, multiple rounds can be done with the same key, as each round will contribute to the scrambling of the input.

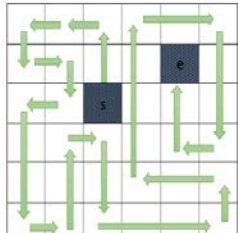

Fig. 8. Multiple Encryption-decryption.

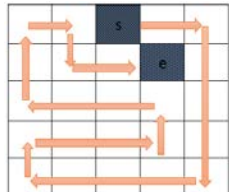

**IV. EXAMPLES**

An example of encrypting and decrypting a plaintext represented using a binary code and a private key, which specify the size of the grid and the pattern, is given in Fig. 9. A single block is encrypted and decrypted using the given key in the example. The rest of the blocks can be encrypted and decrypted in the same way if the same key is utilized. Otherwise, different grid-size and different patterns are utilized.

Fig. 10. Example of Letters Encrypting and Decrypting .

As shown in Fig. 10, the second example represents the encrypting and decrypting of letters and numbers. The process is identical to the previous examples. Using different keys leads to using different grid sizes, different patterns, and different encoding padding. The letters in the example can be encrypted directly as given in the example or converted into binary code and encrypted bit-wise.

As given in Fig. 11, the third example represents the encrypting and decrypting of binary code before encoding padding. As noted, the results were contributing to more scrambling of the message.

Fig. 11. Example of Binary Encrypting and Decrypting with Padding.

**V. SECURITY CONCERNS**

Unlike the substitution cipher, attacks on transposition cipher do not depend on linear and differential cryptanalysis [33, 34]. Instead, the attacks on transposition cipher depend on guessing the key with statistical analysis of the n-gram of the language [35]. In such a process, the optimization algorithms reduce the time required by the brute-force approach. Accordingly, there are two strength issues to defeat such cryptanalysis: increasing the key space and increasing the possibilities of the transposition and scrambling processes. In the proposed technique, the key size has been increased to variable size, given that the size can be encapsulated into the private key itself. Although the size of the block can reveal much about the grid possibilities, using padding in two ways increases the block's size and leads to variable block size. Accordingly, padding the text with long pads are preferable to increase the security of the proposed technique. Moreover, as the encryption patterns are hidden in the private key, it is hard to implement all possible patterns to discover the correct one. Semantic security is granted in the proposed technique as it cannot infer any information from the ciphertext under an unknown key. To summarize, the security of the proposed technique can be listed as given in Table III.

The proposed system's validation is implemented based on various texts encrypted with random keys and with reference to the frequency distribution graph of the standard English letter, as illustrated in Fig. 12. This validation assumes that the

attacker captures the ciphertext without knowing the key. Accordingly, the attacker implements frequency distribution to analyze the captured ciphertext. An example of this graph is given in Fig. 13(a). The attacker then compares the frequency distribution graph with the Standard English Letter. Matching is then implemented by shifting the distribution graph to match the distribution graph of the English letters. As given in Fig. 13(b), the matching can be found by shifting the ciphertext graph by 3 letters. Shifting has been determined as the letter "E" is the most frequent in English, while letter H is the most frequent letter of the ciphertext graph, as it has been used in padding. Yet, the plaintext was not obtained as the reverse shifting is implemented. Accordingly, frequency analysis of 1000 different samples and shifting is determined by matching the frequency graph of each sample with the letter "E". The obtained results after shifting did not match any input text of these samples.

TABLE III. STRENGTH ASPECTS OF THE PROPOSED TECHNIQUE

Strength Aspect	Description
Vast patterns	The number of patterns that can be created is large
Variable grid size	Using padding, the actual size of the grid is hidden
Long key	The key length can be large with patterns included or long pattern identity
Hidden pattern	Secret patterns make the process of breaking the cipher harder

## VI. CONCLUSION

In this paper, a technique for a transposition block cipher is proposed based on arbitrary grid size, initial point, and arbitrary zigzag patterns. The proposed technique improves the security of the ciphertext by scrambling the letters or the bits of the plaintext in an unpredicted manner. The time and memory requirements of the proposed technique are maintained as low as possible to cope with the requirements of currently utilized micro-devices and real-time applications. Accordingly, the proposed technique is of  $O(n)$  complexity, where  $n$  is the grid's size. High security is maintained using a large key, data block of variable size with vast possible patterns. To defeat the cryptanalysis, the block size is increased using padding in two ways. Two similar paddings, yet with different lengths, lead to a completely different output even with the same pattern and the same inputs, which improves the security of the proposed system. Accordingly, hiding the patterns, the block size, and the padding in the private key makes it hard to implement all possible patterns to discover the correct one. The frequency analysis implemented proves the security of the proposed technique.

## ACKNOWLEDGMENT

**Abstract**—Composites being the key ingredients of the manufacturing in the aerospace, aircraft, civil and related industries, it is quite important to check its quality and health during its manufacture or in service. The most commonly found problem in the CFRPs is debonding. As debonds are subsurface defects, the general methods are not quite effective and require destructive tests. The Optical Pulse Thermography (OPT) is a quite promising technology that is being used for detecting the debonds. However, the thermographic time sequences from the OPT system have a lot of noise and normally the defects information is not clear. For solving this problem, an improved tensor nuclear norm (I-TNN) decomposition is proposed in the concatenated feature space with multilayer tensor decomposition. The proposed algorithm utilizes the frontal slice of the tensor to define the TNN and the core singular matrix is further decomposed to utilize the information in the third mode of the tensor. The concatenation helps embed the low-rank and sparse data jointly for weak defect extraction. To show the efficacy and robustness of the algorithm experiments are conducted and comparisons are presented with other algorithms.

**Keywords**—Improved tensor nuclear norm; low-rank decomposition; concatenated feature space; optical thermography

## I. INTRODUCTION

For the task of extracting weak defect information in the thermal sequences of carbon fiber reinforced polymer (CFRP) debonds using the optical pulse thermography (OPT) based technology, post-image processing techniques are generally used. In [1], principal component analysis (PCA) is used along with the OPT for detecting the debonds in the CFRP. The PCA algorithms decompose the thermal sequence data into a low dimensional space using either the eigenvalue decomposition or the singular value decomposition (SVD). The algorithm provides reasonable results for detecting the debond defects in the CFRPs. In [2], another decomposition-based algorithm is proposed called the independent component analysis (ICA). The algorithm is similar to the PCA and provides reasonable results for detecting the debonds in CFRPs. In [3], the authors propose a polynomial-based decomposition algorithm called the thermal signal reconstruction (TSR). It works in the logarithmic domain and performs the polynomial fitting to extract the defect information in the thermal video sequences. The algorithm performs a little better than PCA and ICA however, it has a long-running time. In [4], [5], pulse phase thermography (PPT) is proposed. It employs an extension to the TSR algorithm in the frequency domain and extracts the amplitude and phase information for defect analysis. The PPT algorithm utilizes the Fourier Transform for extracting the

defects information in the thermal sequences. In [6], [7], sparse principal component thermography (SPCT) is proposed for debonding detection in composites. This algorithm is an extension of the PCA algorithm. It induces sparsity into the algorithm. This algorithm works well for the flat shape specimen. In [8], feature embedding is proposed which uses the joint feature space for low-rank and sparse analysis. In [9], a tensor decomposition algorithm is proposed called the ensemble variational Bayes tensor factorization (EVBTF). It employs a multilayer architecture with tensor decomposition. The algorithm is used for detecting the debonds in the CFRP specimen using optical pulse thermography. The specimen under test was the flat rectangular shape CFRPs with debond defects at multiple depths and with multiple diameters. Another multilayer decomposition approach is proposed in [10] called a sparse mixture of Gaussian (S-MoG) for debond detection in composites. The algorithm provides reasonable results for the flat shape CFRP. Also, this algorithm is tested for the irregular shape CFRP V-shaped having debond defects at the elbow location.

The problem with existing approaches and algorithm is that as the depth of the defect on the specimen increases or the diameter of the defect on the specimen decreases, the detection performance gets worse and the algorithms fail to detect the defects. Also, when the existing algorithms were tested on an irregular (V-Shape) specimen their performance is not good [10]. The time consumption that is the running time of the algorithms representing their computational efficiency is another problem that needs to be dealt with for meeting the requirements of the online NDT.

In this paper, we solve the task of debonding detection in CFRP composites using optical thermography by using the concatenated feature space where the sparse data, low-rank data, and reconstructed data are used in a joint concatenated matrix. Further, the eigendecomposition is used to represent this joint feature space. It helps embed the sparse and low-rank data in single feature space for optimization. Further, this is solved by an improved tensor nuclear norm (I-TNN) based core singular matrix utilization tensor decomposition framework. This utilization allows exploiting the tensor data in its third mode which is not fully utilized [11] and helps decrease the computational cost of the overall algorithm due to faster convergence. The I-TNN with core matrix decomposition helps extract the weak debond defect information. The proposed approach is compared with general and state-of-the-art optical pulse thermography-based NDT algorithms. The experiment is carried out with two different

CFRP specimens with a flat and irregular shape having multiple debond defects with multiple depths and diameters. The results reflect the efficacy of the proposed algorithm in detecting the weak and noisy defect information from the irregular shape CFRP specimen with less computation time where other algorithms fail.

The rest of the paper is organized as; Section 2 presents the related work; Section 3 presents the proposed algorithm. Section 4 gives information about the experiment setup and specimen. Section 5 presents results and discussion. Section 6 concludes the paper.

## II. RELATED WORK

The algorithms used for the debond detection in CFRP using optical thermography can be classified as post-processing techniques that are used to enhance the defect contrast and resolution and to remove the unwanted background noise from the thermal sequences. The debonds are the subsurface defects with varying depths and diameters that are difficult to detect by using only optical thermography due to uneven heating and thermal noise present in the thermal video sequences. To remove this thermal noise such that the defects are visible in the thermal sequences, post-image processing techniques are used. However, by using these techniques the debond defects with small depth and larger diameters are easily detected, but the debond defects with higher depth and smaller diameter are still a challenge. Further, if these debonds are on irregular shape specimens such as elbows and joints, the debond detection problem becomes much more severe. Some of the recent methods and techniques to cater to this problem are discussed below.

In [15], the authors proposed a new excitation method based on the laser thermal excitation for the debonding defect detection in the concrete specimen reinforced by fiber plastics. The authors validate their approach by providing numerical results and feasibility studies. In [16], the authors proposed a deep learning-based thermal image segmentation approach to quantify the debond defects in CFRP using optical thermography. The authors present a temporal and spatial deep network by integrating the cross-network learning strategy. The probability of detection is carried out as a quantitative measure in comparison with other algorithms and experiment results are presented for different CFRPs with debond defects. In [17], the authors present the wavelet feature-based thermal image segmentation for detecting debond defects in the CFRP using optical thermography. The PCA-based features are extracted from the thermal images which are further processed using the Gaussian Low Pass filtering in the wavelet domain. The F-score based comparison is presented with other recent algorithms. In [18], the authors propose a sparse low-rank matrix decomposition method for debond detection in CFRP. A joint decomposition is proposed with iterative sparse modeling. The visual results along with F-score based results are presented to prove the efficacy of the proposed model. In [19], the authors present a comparative study of extracting subsurface defects in thermal patterns. The non-negative matrix factorization methods are used and compared on the thermal data and results are presented in terms of detection accuracies. In [20], the authors present a comparison of tensor-

based defect detection using the eddy current thermography. The importance of using tensor-based algorithms is highlighted. Further matrix and tensor decomposition-based algorithms are also compared. In [21], the authors propose a method of defect depth estimation in a CFRP specimen with flat bottom holes using pulsed thermography. The analysis is presented to characterize the defect depth with regard to specimen thickness and defect size. In [22], the authors propose an automated defect detection method in thermal sequences using important frame selection, feature extraction, and image segmentation to detect the defect size. In [23], the authors propose a Levenberg-Marquardt algorithm to remove the uneven heating noise in thermal sequences. A comparison is also presented with the existing algorithms in terms of noise removal and image resolution. In [24], the authors propose an image segmentation algorithm using artificial intelligence and fuzzy clustering for defect detection in thermal sequences. Experimental analysis is carried out to show the efficacy of the proposed model.

## III. PROPOSED METHODOLOGY

First, given the thermographic video sequences  $\mathcal{X} \in \mathfrak{R}^{n_1 \times n_2 \times n_3}$ , where  $(n_1, n_2)$  are the spatial resolution and  $n_3$  is the frame number. In tensor-based terminology, this is a three-way tensor [11], [12]. We propose a multilayer joint decomposition structure [9], [10] of low-rank ( $L$ ) and sparse components ( $C$ ) as;

$$\mathcal{X}^1 = \mathcal{L}^1 + \mathcal{C}^1 \quad (1)$$

For the second layer;

$$\mathcal{X}^2 = \mathcal{L}^2 + \mathcal{C}^2 + f^1(\mathcal{X}^1) \quad (2)$$

For the  $n^{th}$  layer;

$$\mathcal{X}^n = \mathcal{L}^n + \mathcal{C}^n + f^{n-1}(\mathcal{X}^{n-1}) \quad (3)$$

where  $f^n(\mathcal{X}^n)$  is the activation used for the multilayer data modeling. To extract the defect information we propose the following optimization problem [11], [12];

$$\min_{\mathcal{L}, \mathcal{C}} \|\mathcal{L}^n\|_* + \partial \|\mathcal{C}^n\|_1 \text{ s.t } \mathcal{X}^n = \mathcal{L}^n + \mathcal{C}^n \quad (4)$$

where  $\|\cdot\|_*$  represents the tensor nuclear norm,  $\partial$  is the regularizing parameter and  $\|\cdot\|_1$  is the  $l_1$  norm. The problem in (4) is solved in the concatenated feature space using two steps. In the first step, the low-rank term is solved in the other step the sparse term is solved. Given the thermographic sequences and initializations a concatenated Eigen matrix decomposition is proposed as;

$$\mathbf{Y}^n = \begin{bmatrix} \mathbf{X}^n \\ \mathbf{X}^n - \mathbf{C}^{n-1} \\ \mathbf{C}^{n-1} \end{bmatrix} \quad (5)$$

Where  $n$  is the layer number  $\mathbf{X} = \beta(\mathcal{X})$  is the tensor to matrix transformation and  $\mathcal{X} = \beta^{-1}(\mathbf{X})$  is matrix to tensor transformation, same is used for  $\mathbf{C}$  and  $\mathcal{C}$ . By joint concatenation of the low-rank and the sparse data, two benefits are obtained. First, we retain the original features of the thermographic sequences which helps prevent the estimated low-rank features to deviate from the original. Further, the residual data and sparse data allow us to embed the sparse

component into low-rank modeling which significantly helps to extract the weak defect information. It should be noted here, that this concatenation firstly occurs in the matrix feature space and the low-rank and sparse modeling is solved in the tensor feature space. This tensor-matrix sparse low-rank decomposition enables us to utilize both tools simultaneously. The problem in (5) is solved using a simple eigendecomposition as;

$$Y^n = UV^T \quad (6)$$

Where  $U$  and  $V$  are the left and right Eigen matrices and  $\Gamma$  is the diagonal matrix containing the eigenvalues. The first six principal components are selected after the decomposition. Based on the repeated experimental analysis the first six components contain the most useful low-rank information namely.

Here  $svt_{\partial_1}(\bar{S})$  is the singular value thresholding for the matrix,  $sth(\mathcal{Y})$  is the soft thresholding for tensor [11] and  $t - svt_{\frac{\rho}{2}}(\bar{L})$  represents the tensor singular value thresholding for the tensor [12]. For the parameters we set  $\partial_1 = \frac{1}{\sqrt{n_{max}}}$ ,  $n_{max} = \max(\min(n_1, n_2), n_3)$ . Here  $(n_1, n_2, n_3)$  are the frames and rows and columns of core tensor respectively.  $\partial = \frac{1}{\sqrt{\max(n_1, n_2)n_3}}$ ,  $\rho = 1.1$  and the stopping condition is set as;  $\|\mathcal{L}_{k+1} - \mathcal{L}_k\| \leq \varepsilon$ ,  $\varepsilon = 1e - 5$  based on our experimental analysis. For other applications, the parameters can be tuned accordingly.

$$y^n = \beta^{-1}((UV^T)_{1 \text{ to } 6}) \quad (7)$$

#### A. Improved TNN with Core Tensor Decomposition

Let  $\mathcal{A} = \mathcal{U} * \mathcal{S} * \mathcal{V}^*$  be the tensor singular decomposition (t-svd) of  $\mathcal{A} \in \mathfrak{R}^{n_1 \times n_2 \times n_3}$ . The tensor nuclear norm of  $\mathcal{A}$  is given as [12];

$$\|\mathcal{A}\|_* := \langle \mathcal{S}, \mathcal{J} \rangle = \sum_{i=1}^r \mathcal{S}(i, i, 1) \quad (8)$$

Where  $r = rank_t(\mathcal{A})$  is the tensor tubal rank,  $\mathcal{S}, \mathcal{J}$  is the singular value and identity tensor. To utilize the information in the third mode of the tensor svd we use the core singular matrix decomposition. The related operators are  $\bar{\mathcal{S}} = \beta(\mathcal{S})$  and  $\mathcal{S} = \beta^{-1}(\bar{\mathcal{S}})$ , where  $\beta$  and  $\beta^{-1}$  are the transforms between the core tensor  $\mathcal{S} \in \mathfrak{R}^{n_1 \times n_2 \times n_3}$  and core matrix  $\bar{\mathcal{S}} \in \mathfrak{R}^{n \times n_3}$ , where  $n = \min(n_1, n_2)$ .

Further, the most significant components of this core tensor are found by approximating very few significant singular values. The core singular matrix approximation of the I-TNN rank is given as;

$$rank_i(\mathcal{A}) = [rank(\bar{\mathcal{S}}), rank_t(\mathcal{A})]^T \quad (9)$$

Based on the above rank the I-TNN with core matrix approximation is given as;

$$\|\mathcal{A}\|_* = \|\bar{\mathcal{S}}\|_* + \gamma \sum_{i=1}^r \mathcal{S}(i, i, 1) \quad (10)$$

Where  $\gamma$  is the balancing term. Based on the improved tensor nuclear norm and core matrix decomposition the problem in (4) can be solved iteratively using ADMM [13] for each layer.

$$\mathcal{L}_{k+1} = \arg \min_{\mathcal{L}} \|\mathcal{L}\|_* + \frac{\rho}{2} \left\| \mathcal{L} - \mathcal{Y} + \mathcal{C}_k - \frac{\mathcal{D}_k}{\rho} \right\|_F^2 \quad (11)$$

$$\mathcal{C}_{k+1} = \arg \min_{\mathcal{C}} \partial \|\mathcal{C}\|_1 + \frac{\rho}{2} \left\| \mathcal{L}_{k+1} - \mathcal{Y} + \mathcal{C} - \frac{\mathcal{D}_k}{\rho} \right\|_F^2 \quad (12)$$

$$\mathcal{D}_{k+1} = \mathcal{D}_k + \rho(\mathcal{Y} - \mathcal{L}_{k+1} - \mathcal{C}_{k+1}) \quad (13)$$

Where  $\rho > 0$  is the augmented lagrangian penalty parameter,  $\mathcal{D}$  is the dual variable,  $k$  is the iteration number. For the problem in (11), it is solved using ADMM [13] in two steps. The first step solves the core matrix problem and the other.

step solves the tensor nuclear norm problem. The optimization model for the two-step problem can be formulated as [11].

$$\bar{\mathcal{L}}_{k+1} = \arg \min_{\beta(\mathcal{S})} \|\beta(\mathcal{S})\|_* + \frac{1}{2\partial_1} \left\| \mathcal{T} - \mathcal{Y} + \mathcal{C}_k - \frac{\mathcal{D}_k}{\rho} \right\|_F^2 \quad (14)$$

Where  $\delta_1$  is the regularizing parameter and  $\mathcal{S}$  is from the t-svd and  $\mathcal{T}$  is a temporary variable. The tensor with a low-rank core matrix can be given as;

$$\mathcal{Z}_{k+1} = \mathcal{U} * \beta^{-1}(\bar{\mathcal{L}}_{k+1}) * \mathcal{V}^T \quad (15)$$

The other step minimized the tensor nuclear norm as follows;

$$\mathcal{L}_{k+1} = \arg \min_{\mathcal{L}} \|\mathcal{L}\|_* + \frac{\rho}{4} \left\| \mathcal{L} - \mathcal{Z}_{k+1} \right\|_F^2 \quad (16)$$

The details are given in the Table I.

TABLE I. MULTILAYER ADMM FOR I-TNN WITH CORE MATRIX DECOMPOSITION

Input: Tensor data $\mathcal{X} \in \mathfrak{R}^{n_1 \times n_2 \times n_3}$	
Initialization: Given $\rho, \partial_1, \partial, \mathcal{L} = 0, \mathcal{C} = 0, \mathcal{D} = 0$	
For each layer $n$ solve;	
1.	Solve the concatenated problem in (5) by (7) to get $\mathcal{Y}$
2.	While not converged do:
3.	Compute $[\mathcal{U}, \mathcal{S}, \mathcal{V}] = t - svd(\mathcal{Y} - \mathcal{C} + \frac{\mathcal{D}}{\rho})$
4.	Update $\bar{\mathcal{S}} := \beta(\mathcal{S})$
5.	Compute $\bar{\mathcal{L}} := svt_{\partial_1}(\bar{\mathcal{S}})$
6.	Update $\mathcal{Z} := \beta^{-1}(\bar{\mathcal{L}})$
7.	Update $\bar{\mathcal{L}} := \mathcal{U} * \mathcal{Z} * \mathcal{V}^T$
8.	Update $\mathcal{L} := t - svt_{\frac{\rho}{2}}(\bar{\mathcal{L}})$
9.	Compute $\mathcal{C} := sth_{\frac{\rho}{2}}(\mathcal{Y} - \mathcal{L} + \frac{\mathcal{D}}{\rho})$
10.	Update $\mathcal{D} := \mathcal{D} + \rho(\mathcal{Y} - \mathcal{L} - \mathcal{C})$
11.	End while
Output: $\mathcal{L}^n, \mathcal{C}^n, \mathcal{D}^n$	

#### IV. EXPERIMENTAL SETUP AND SPECIMEN DETAILS

Regarding the experimental setup, the OPT system available at our lab can be seen in Fig. 1. In the OPT system, halogen lamps are used as an excitation source to induce heat into the specimen. A  $ZY - B$  type excitation source is used at the back of the halogen lamps with model *ITECH - IT6726G*. This model supports an adjustable power source that can be

tuned up to 3kW. In our experiments, we set the power of the excitation source to 2kW. The experiments are conducted in the reflection mode configuration [14]. The 85cm distance is selected between the lamps and the specimen. To capture the thermographs of the sample an infrared camera is used model A655sc. The output resolution of the infrared camera is set to 640 × 480 per frame. The infrared camera used has a thermal sensitivity of 0.05°C. Further, a sampling frequency of 50Hz is selected for our experiments.

To validate the proposed model, two different CFRP specimen is selected. The CFRP specimen was obtained from the Chengdu Aircraft Design Institute of the China Aviation Industry. The obtained specimen is similar to the ones used in the design and manufacturing of aircraft and related components. The first specimen has a rectangular shape and a flat surface. The second sample is like a V shape with joints and edges. Both the specimen have debonded defects created

by inducing the Teflon inserts at various depths and different diameters. The detailed information about the specimen shape and defects can be found in Table II.

Fig. 1. The Optical Pulse Thermography System.

TABLE II. INFORMATION ABOUT THE CFRP SPECIMEN

Number	Defect Profile	Dimension(mm)	Defect Information(mm)	Picture
1		250×250×24.2	<b>Depth:</b> 1, 2 <b>Diameter:</b> 2,4,6,8,10,12,16, 20	
3		100×100×80	<b>Depth:</b> 1.5, 1.75, 2, 2.25, 2.5, 2.75 <b>Diameter:</b> 9, 10	

### V. RESULTS AND DISCUSSION

In this section, the results are presented from the experiments. The visual results along with the F-score [9] and computation time are presented. The experiments are carried out using the optical pulse thermography system shown in Fig. 1. The repeated experiments were carried out to collect the thermographic sequences used. The reflection mode configuration is used with the standard camera, excitation source, and specimen distance given in [9]. The algorithms used in competition with the proposed algorithm are PPT [4], TSR [3], SPCT [6], EVBTF [9], and S-MoG [10]. The F-score and computation time results are given in Table III. The proposed algorithm was run up to four layers and the third layer results were found to be clear with better resolution and contrast for detecting the debond defects.

The defect detection results from the algorithms in comparison are given in a tabular form shown in Fig. 2. All the results for both specimens can be seen in Fig. 2. Fig. 2(Row 1) shows the comparative results for specimen 1. It is a rectangular-shaped specimen having a flat surface and 10 debond defects. The depths of the debonds are ( 1mm and 2mm ) with varying diameter sizes. All the algorithms are run on a single computer to avoid any unfair processing advantage. From Fig. 2 (Row 1) it can be seen that most of the algorithms can detect at most 9 out of 10 defects. However, the strong noise is still present which limits the performance of algorithms in the scenario when the information about the defects is unknown. The proposed algorithm gives reasonable results with a reduction in noise and improvement in the resolution contrast of the specimen. The proposed algorithm can detect all defects where other algorithms fail.

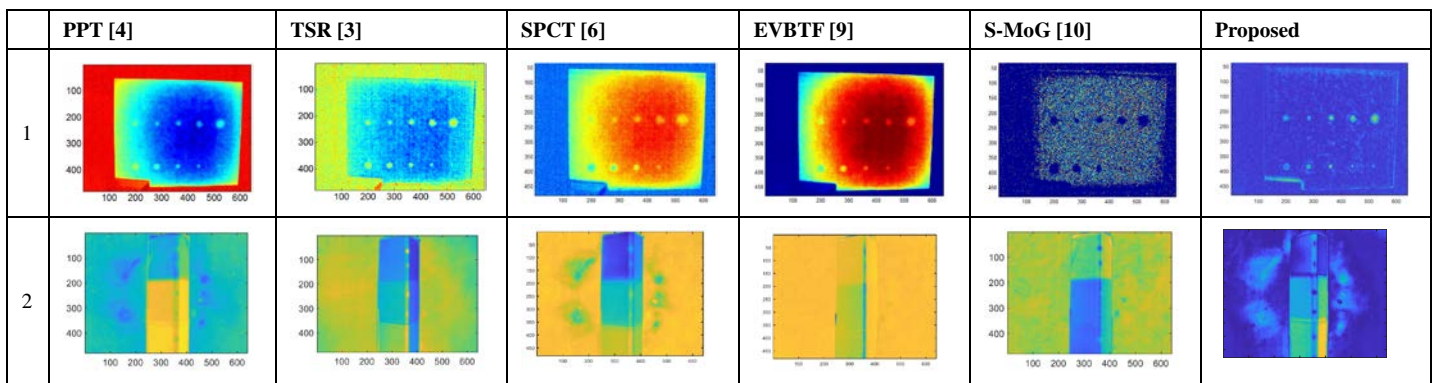

Fig. 2. The Comparative Analysis of different Algorithms.

TABLE III. COMPARATIVE RESULTS F-SCORE (LEFT) AND TIME TAKEN (RIGHT IN SECONDS)

Specimen Number	PPT [4]		TSR [3]		SPCT [6]		EVBTF [9]		S-MoG [10]		Proposed	
1	0.94	135	0.94	271	0.94	40	0.94	1342	0.94	173	<b>1</b>	<b>26</b>
2	0.75	146	0.88	601	0.88	43	0.75	753	0.88	125	<b>1</b>	<b>6</b>
Average	0.84	140	0.91	436	0.91	41	0.84	1046	0.91	149	<b>1</b>	<b>16</b>

Fig. 2(Row 2) shows the results for the second specimen. It has a V shape with an irregular surface. It is a more challenging specimen with defect depths ranging from (1.5, 1.75, 2, 2.25, 2.5, 2.75)mm. Here, the defect diameters are (9 and 10)mm. It can be seen from Fig. 2(Row 2) that almost all algorithms fail to detect the debond defects. The strong noise is present and the resolution of the defects is quite poor. The proposed algorithm can detect all the defects with reasonable noise reduction and acceptable resolution. As the proposed algorithm utilizes a multilayer structure, the results in Fig. 2 are obtained by two layers of the algorithm. This layer number is selected based on the experimental analysis with multiple experiments on different data. However, due to the concatenated feature space where low-rank, sparse, and raw data are decomposed using a single feature space further layering does not significantly improve the results but in turn, incurs the additional computation cost. From the visual results, it can be argued that the proposed I-TNN with core matrix decomposition using a concatenated feature space in a multilayer architecture can detect smaller and deeper debond defects using OPT-NDT.

Table III shows the F-score and computation time results. For both specimens, the results are averaged in the last row of the Table III. On average, the PPT [4] and EVBTF [9] algorithms have the detection efficiency of 84% with 140sec and 1046sec as the average computation time. The TSR [3], SPCT [6] and S-MoG [10] algorithms have the 91 average percent of defect detection. Their running times are 436sec, 41 sec and 149sec respectively. The proposed model has 100% defect detection accuracy for the specimen under test. Using the concatenated feature space a simple eigen decomposition is carried out and only 6 principal eigen components are selected which help significantly in reducing the computation time enhancing the resolution of defects by multilayer I-TNN core matrix decomposition approach. The average computation time taken by the proposed model is 16sec.

## VI. CONCLUSION AND FUTURE WORK

In this paper, a joint concatenation of the low-rank and sparse features is proposed. The I-TNN algorithm with core matrix-tensor decomposition in multilayer architecture is proposed for iteratively solving the feature space. The proposed approach is used for detecting the debond defects in the CFRP specimen using optical pulse thermography. By multi-layering, the low-rank and sparse components in a concatenated feature space help boost the convergence, eliminating the noise and detecting the debond defects with small diameter and varying depth. The comparative analysis with general OPT-NDT and other low-rank sparse and tensor modeling algorithms proves the debond detection capability of the proposed algorithm.

The possible future extensions of this work will be the testing of this work on several new and different CFRP specimens. Further, the proposed algorithm can be tested and validated on the eddy current thermography data, microwave thermography data, and other thermography data. Further apart from the debond detection the algorithm can also be used for other defects using as delaminations and crack in CFRP and other metal structures.

**Abstract**—Online Nurse Test for Indonesian Nurse Competency (ONT UKNI) is a mobile application that was developed to help increase the success rate of nurse competency test participants. By using this application, users can learn more about the materials tested and conduct try out as a competency test simulation. However, ONT UKNI has not yet passed adequate testing stages, especially in terms of User Interface/User Experience (UI/UX). The Covid-19 pandemic situation presents challenges in the UI/UX testing process. Testing process which is ideally carried out face-to-face with respondents to get further insight, have to be carried out using another approach following the new normal protocol. This study aims to test the usability of UI/UX with an unmoderated remote testing approach on ONT UKNI application using a USE questionnaire. The test was performed using 26 respondents and all were nursing profession students of Universitas Muhammadiyah Yogyakarta. Respondents performed 8 tasks on ONT UKNI and answered set of questionnaire that will be tabulated and analyzed. The results indicate that usefulness, ease of learning, and satisfaction variables get the Very Good category while the ease of use variable gets the Good category. Overall, usability testing using an unmoderated remote testing approach can be carried out and able to provide information about areas where users are satisfied with ONT UKNI application. However, some areas still have room for improvement such as better UI design and implementation of gamification.

**Keywords**—Mobile learning; nurse competency test; unmoderated remote testing; usability

## I. INTRODUCTION

Mobile-based learning media is not a new thing in an effort to improve the quality of educational outcomes. Rapid growth of mobile technology and its application gradually replace the role of computer [1]. The author in [2] conducted research on the effectiveness of using Android-based learning media for biology subjects in high school students. From the research conducted, it is known that the learning media has a positive impact. Android-based learning media increases interest and motivation in learning which indirectly increases the effectiveness of learning outcomes. Android-based learning media provides several advantages such as attractive designs, both in terms of images, colors, and writing. Learning media is also easy to use independently either at school or outside of school. In another study conducted by [3], it is known that school students are easier to accept learning materials in digital form than in written or oral form. Digital learning media such as Android-based learning media application have several advantages, such as ease of use, can be used for learning

anywhere, and can be used offline [4]. This shows that mobile applications are increasingly popular for use in education area.

Online Nurse Test for Indonesian Nurse Competency (ONT UKNI) is a mobile application that was developed and aimed to increasing the success rate of nurse competency test participants [5]. By using this application, users –in this case are nursing profession students- can learn about the materials tested at competency test and conduct try out as competency test simulations. However, ONT UKNI has not passed adequate testing stages, especially in terms of user experience or User Interface / User Experience (UI/UX). This is important because user experience determines the success or failure of a product [6]. If product's usability cannot satisfy user, it will hinder the overall quality of the application. Thus developer should consider usability when design an application so it will meet its purpose [7]. Furthermore, [8] added that the mobile app needs to go through a thorough testing phase due to several factors such as the limited screen size. For this reason, it is necessary to conduct user-oriented testing to ensure feasibility and user experience.

Usability testing can be used to test feasibility and user experience [9]. The author in [10] conducted research related to usability testing on the online guardianship application STMIK AMIK Bandung by using a USE questionnaire as a research instrument. Although USE questionnaire lack of evidence in reliability and validity, it provides insight for researchers in terms of usefulness, satisfaction, and ease of use [11][12]. The author in [13] conducted usability testing research on YouTube websites among Malaysian teenagers using the same 3 criteria, namely usefulness, satisfaction, and ease of use. Apart from the USE questionnaire, there are also several other usability testing instruments, such as the User Experience Questionnaire (UEQ) and the System Usability Scale (SUS) [14][15]. The author in [16] performed usability testing on the MyTelkomsel mobile application using 5 criteria, namely: learnability, efficiency, memorability, error, and satisfaction. The data collection technique used was a survey with SUS instrument, observation, and direct interviews. Based on this research, it can be seen that the interview technique helped researchers to get further insight and find solutions to the problems that respondents complains about the MyTelkomsel application. The author in [17] also used a survey and interview techniques in usability testing with certain variables, such as demographic information, using experience, ease of use, and usefulness.

The Covid-19 pandemic situation presents challenges in the UI/UX testing process. The author in [18] even stated that

based on a study conducted by researchers from Harvard University, Covid-19 protocols such as physical distancing will last until 2022. This conditions certainly become obstacles and challenges in various sectors, including the software testing sector. UI/UX testing, which ideally be carried out in-person with respondents to get optimum feedback, should be carried out using another approach following the new normal protocol policy [19][20]. This can be overcome by conducting UI/UX testing with an unmoderated remote usability testing approach [21]. Unmoderated remote usability testing offers flexibility within time and distance constraints.

Based on the explanation above, the researcher decided to conduct usability testing on ONT UKNI application using an unmoderated remote testing approach. Unmoderated testing is a test where respondents try the product being tested and provide an assessment without being accompanied by a moderator [22]. The moderator creates a test scenario for respondents to follow who will then provide an assessment. Remote testing approach can solve problems related to distance since respondents can be located anywhere [23][24]. Thus, remote testing considered suitable to be used considering physical distancing protocol during Covid-19 pandemic situation. USE questionnaire instrument was used to obtain qualitative data then processed further to determine user experience in terms of usefulness, satisfaction, ease of use, and ease of learning. This research contributes to theoretical and practical basis of using USE questionnaire in unmoderated remote testing and encourages professionals to adopt this approach.

## II. ONT UKNI BACKGROUND

Nursing education is one area that can benefited of Android applications as a learning media for the preparation of the Indonesian Nurses Competency Test (UKNI). UKNI is a process to determine whether or not someone is eligible to become a nurse in Indonesia [25]. The author in [26] stated that the graduation rate in 2018 was 57.1% with 26,208 graduates, in 2019 it was 58.6% with 29,240 graduates, and in 2020 it was 54.4% with 23,663 graduates. This figure is quite low considering the need for the nursing profession in Indonesia is quite high. Indonesian Central Statistics Agency predicts that the need for nurses in Indonesia is 48,253,428 nurses with a ratio of 180 nurses per 100,000 population [27]. The need for an additional number of nurses in Indonesia in 2019 is predicted to be 372,534 nurses [28]. This is in line with the statement of the Professor of the Faculty of Nursing Universitas Indonesia, Achir Yani Hamid, who stated that the number of Indonesian nursing personnel was only 60% of the total population where the world standard was 80% [29].

The author in [30] stated that the obstacles faced by UKNI participants were lack of focus and lack of time to prepare, considering that most UKNI participants were students who were practicing the nursing profession. Another reason was the participants' ignorance about the UKNI concept, especially regarding the UKNI test grid. The author in [31], [32], and [33] analyze the factors that influence UKNI graduation, including try out, Grade Point Average, learning style, and learning motivation.

ONT UKNI was developed to overcome problems that have been stated before. It is a mobile application which has features such as learning material and try out simulation as shown in Fig. 1. Learning materials and try out given have been adapted to the material being tested at UKNI to provide real experience regarding nurse competency test.

Fig. 1. ONT UKNI Mobile Application.

## III. METHODOLOGY

This study used a four-step procedure. Fig. 2 shows the research methodology used in this study. The authors start from literature review, requirement analysis, usability testing and data tabulation, and analysis.

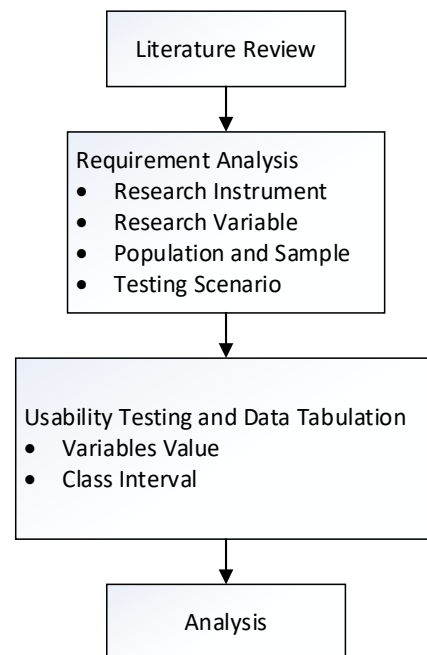

Fig. 2. Research Methodology.

### A. Literature Review

The authors examine several theories sourced from books, reputable online sources, or journals. Several theories used in

this research include usability testing, USE questionnaire, testing, population, sample, data tabulation. This stage also aims to explore and find references related to previous studies.

**B. Requirement Analysis**

Research instruments and variables will be determined in this phase. The research instrument used to perform usability testing on a number of respondents. Sample size of respondents were taken from the population who are potential users of ONT UKNI application. Respondents will be asked to perform several steps contained in the test scenario that has been given by the author. Respondents were given 30 days to try the ONT UKNI application with the aim of getting as much user experience as possible. After that the respondents will fill out a questionnaire provided by the author.

**C. Usability Test and Data Tabulation**

At this stage the respondents will fill out an online assessment questionnaire based on the experience they have gained while using ONT UKNI application. The usability testing process is carried out remotely using Google Forms and is not moderated by researchers. Calculation of the value of each variable used in usability testing is carried out. Each variable used will be categorized based on class intervals.

**D. Analysis**

Usability test and data tabulation results were analyzed to find out how the results of each research variable were used. Recommendations regarding applications were analyzed to give ONT UKNI developer insight.

**IV. RESULTS AND DISCUSSION**

**A. Requirement Analysis**

1) *Research instruments and variables:* At this stage the authors determine the instruments and research variables used. The assessment scale used in the questionnaire is Likert scale with descriptive statements converted into numerical values as in Table I. USE questionnaire developed by Arnold M. Lund in 2001 was used as a test instrument [12]. USE questionnaire consists of 30 statements which are divided into four variables of assessment variables, namely: usefulness, ease of use, ease of learning, and satisfaction. Usability instrument has been modified according to the scope of the research as shown in Tables II to V.

TABLE I. LIKERT SCALE ASSESSMENT CRITERIA

Statement	Mark
Strongly agree	5
Agree	4
Neutral	3
Disagree	2
Strongly Disagree	1

2) *Research population:* The population in this study were prospective users of ONT UKNI application, namely students

of the nursing profession at the Universitas Muhammadiyah Yogyakarta who were at PKU Yogyakarta Hospital. This population was chosen because UKNI is a test for professional students to get nurse certification. Thus respondents were in a preparation for UKNI. From the entire population of nursing profession students of Universitas Muhammadiyah Yogyakarta who were interns at PKU, several samples taken to become respondents in usability testing.

TABLE II. USEFULNESS QUESTIONNAIRE INSTRUMENT

No	Questions
U1	Does ONT UKNI application help me to be more effective in preparing for UKNI?
U2	Does ONT UKNI application help me to be more productive in preparing for UKNI?
U3	ONT UKNI application is very useful in preparing for UKNI.
U4	ONT UKNI application makes me more flexible in managing my study time to face UKNI.
U5	ONT UKNI application makes the learning process to deal with UKNI easier to do.
U6	ONT UKNI application saves me time in preparation for UKNI.
U7	ONT UKNI application fulfills my needs in preparation for UKNI.
U8	ONT UKNI app did a lot of what I expected with regards to UKNI preparation.

TABLE III. EASE OF USE QUESTIONNAIRE INSTRUMENT

No	Questions
EU1	ONT UKNI application is easy to use.
EU2	ONT UKNI application is practical to use.
EU3	ONT UKNI application is user friendly.
EU4	ONT UKNI application requires a few steps when I want to use a feature in the application.
EU5	This application is very flexible.
EU6	Using ONT UKNI application does not require a lot of effort.
EU7	I can use ONT UKNI application without requiring written instructions or guidance.
EU8	I did not find any inconsistencies in ONT UKNI application.
EU9	Users who regularly or only occasionally use ONT UKNI application will love this application.
EU10	I can solve errors in using ONT UKNI application easily.
EU11	I managed to use ONT UKNI app every time.

TABLE IV. EASE OF LEARNING QUESTIONNAIRE INSTRUMENT

No	Questions
EL1	I was able to quickly learn how to use ONT UKNI app.
EL2	I can easily remember how to use ONT UKNI application.
EL3	ONT UKNI application is easy to learn.
EL4	I quickly became proficient in using ONT UKNI application.

TABLE V. SATISFACTION QUESTIONNAIRE INSTRUMENT

No	Questions
S1	I am satisfied with ONT UKNI application.
S2	I will recommend ONT UKNI application to my friends.
S3	Using ONT UKNI application is very fun.
S4	ONT UKNI app worked as I expected.
S5	ONT UKNI application has a nice display.
S6	I feel the need to use ONT UKNI application in preparation for UKNI.
S7	ONT UKNI application is convenient to use in preparing for UKNI.

3) *Sample size:* The sampling technique used is simple random sampling where each member of the population has the same opportunity to become a respondent. The size of sample is determined using the Slovin formula approach as described as in (1).

$$n = \frac{N}{1+N(e)^2} \quad (1)$$

Where:

n = Sample size

N = Population Size

e = error rate

The population size of nursing profession students at Muhammadiyah Yogyakarta University who are at PKU Yogyakarta Hospital is 27 students. The error rate used in the search for the sample size is 5%. By using (1), it can be calculated the sample size used in the usability test. The sample size used was 25.292 respondents which were rounded up to 26 respondents.

$$n = \frac{27}{1+27(0,05)^2} = 25,292$$

4) *Testing scenario:* Testing is carried out without moderation and remotely considering the Covid-19 pandemic situation. Remote testing is possible in the presence of a test scenario [34]. Test scenario consists of 8 steps in a task-based form and aims to ensure that respondents have tried and understood the features of ONT UKNI application. Table VI shows the scenarios that will be carried out by respondents remotely without moderation. Test scenario is made as simple as possible to make it easier for respondents to follow and does not require any clarification from researchers [24][35]. 26 respondents in this study carried out a number of activities

following the scenario given by the research team. Respondents were given 14 days to try ONT UKNI application and carry out the given scenario and try ONT UKNI application. After 14 days, the respondent will assess the usability of ONT UKNI application using the provided instrument.

### B. Usability Testing and Data Tabulations

Tables VII to X shows post-usability test results that were tabulated and compiled. From the test results, it can be calculated the value of each variable used. Equation (2) used to determine the usability variable, ease of use, ease of learning, and satisfaction value.

$$\text{Nilai Variabel} = \frac{s}{nr \times np} \quad (2)$$

Where:

s = Total value

nr = Number of respondents

np = Number of statements

$$\text{Usefulness variable value} = \frac{876}{26 \times 8} = 4,21$$

$$\text{Ease of Use variable value} = \frac{1190}{26 \times 11} = 4,16$$

$$\text{Ease of Learning variable value} = \frac{447}{26 \times 4} = 4,29$$

$$\text{Satisfaction variable value} = \frac{766}{26 \times 7} = 4,20$$

TABLE VI. TASK SCENARIO

S7	10	15	1	0	0	26	3	5	4,35	0,551

To be able to determine the category of assessment class based on known variable values, a class interval size is needed [36]. Equation (3) shows the formula used to calculate the length of the class interval.

$$P = \frac{Dx - Dy}{n} \quad (3)$$

Where:

P = Interval length

Dx = Biggest value

Dy = Smallest value

n = Number of classes

$$P = \frac{5 - 1}{5}$$

P = 0,8

Based on  $P = 0.8$  obtained from (3), an assessment table of the results of the usability test analysis can be made which is then used to determine the category of each variable. Table XI shows the length of the interval for each category. Table XII shows the results of the analysis carried out. The usability variable gets a value of 4.21 and is included in the good category class interval. The ease of use variable gets a value of 4.16 and is included in the good class interval. The ease of learning variable got a value of 4.29 and was included in the good class interval. The satisfaction variable gets a value of 4.20 and is included in the very good class interval.

TABLE XI. CLASS INTERVAL LENGTH

No	Interval Length	Category
1	1.00 – 1.79	Very low
2	1.80 – 2.59	Low
3	2.60 – 3.39	Pretty good
4	3.40 – 4.19	Good
5	4.20 – 5.00	Very good

TABLE XII. VARIABLE CATEGORY BASED ON INTERVAL

No	Variable	Total Value	Average Value	Category
1	Utility	876	4.21	Very good
2	Ease of Use	1190	4.16	Good
3	Ease of Learning	447	4.29	Very good
4	Satisfaction	766	4.20	Very good
Average variable value			4.21	Very good

Usefulness variable gets a value of 4.21 and is included in the Very Good category. ONT UKNI application has learning and tries out features that are in accordance with the needs of application users who are students of the nursing profession in preparation for joining UKNI. In addition, ONT UKNI application has discussion feature so that users will better understand the questions and exact answers given which are very useful, efficient, and can increase user productivity in the preparation for UKNI. One aspect that needs to be considered is the aspect of the responsiveness. Application responsiveness is one of the factors that can further increase user productivity and efficiency in using applications [7].

Ease of use variable gets a value of 4.16 and falls into the Good category. Button design and layout is easy to reach. It has minimalist feature by having 2 main buttons for the main features, namely the learning feature and the try out feature. Users can also use the application even though it is not accompanied by a user guide and at any time. Consistent selection of text and colors also helps users. However, there are still some areas that could be improved. Color selection and interface design are 2 factors that have the potential to be improved to provide better interaction and user experience [37].

Ease of learning variable gets a value of 4.29 and was included in the Very Good category. It shows that ONT UKNI easy for user to understand. It is intuitive enough for first time user to follow. The application has a consistent design which helps user to get familiar faster which is an important aspect in ease of learning [38]. The placement of buttons accompanied by text makes it easier for users in the learning process to use

this application. In addition, the selection of clear and contrasting colors between the buttons, written text, and background also helps the use of ONT UKNI application.

Satisfaction variable gets a value of 4.20 and is included in the Very Good category. ONT UKNI application was built with the aim of helping students of the nursing profession in dealing with UKNI. Based on the test results, it can be seen that users feel confident to use ONT UKNI application in preparation for UKNI. Application design that is attractive, easy to use, and easy to learn is also a factor that determines user satisfaction [39].

## V. CONCLUSION AND FUTURE WORK

This study was aimed to conduct usability testing on ONT UKNI application. The test has been carried out on 26 respondents who are nursing profession students of Universitas Muhammadiyah Yogyakarta who were interns at PKU Yogyakarta Hospital. The test was conducted using a USE questionnaire remotely and without any moderation from the research team. USE questionnaire gives insight on 4 variables, namely usefulness, ease of use, ease of learning, and satisfaction. The usability variable gets a value of 4.21 and is included in the Very Good category. The ease of use variable gets a value of 4.16 and falls into the Good category. The ease of learning variable got a value of 4.29 and was included in the Very Good category. The satisfaction variable gets a value of 4.20 and is included in the Very Good category. However, there are several areas to improve the user experience of ONT UKNI application, such as color selection, application interface design, and implementation of gamification into ONT UKNI application. Overall, usability testing with unmoderated remote testing approach using USE questionnaire can be done and able to provide information about areas that users are satisfied with or areas that need improvement.

Future work should focus on improving ONT UKNI application by redesign UI and implementing gamification. Further test with intervention using quasi experiment also possible to be conducted to see whether ONT UKNI application really meets its purpose, which is to help nursing profession student preparing for UKNI.

## ACKNOWLEDGMENT

The authors gratefully acknowledge Universitas Ahmad Dahlan for funding assistance in this research and School of Nursing Universitas Muhammadiyah Yogyakarta for research collaboration.

**Abstract**—Many authorities like Project Management Body of Knowledge (PMBOK) and Capability Maturity Model Integration for Development (CMMI-Dev) lend a hand to software development organizations in management of their crucial projects. Though this area needs focused research, such models are not dedicatedly available for the academic projects developed by students of computer science and engineering where software project development is considered as one of the criteria for the award of degree to the future professionals of the IT industry. With this motivation, we explored 4PTRB, 3PR and software project management practices, approaches as well processes framed and provided by PMBOK and CMMI-Dev. The main aim of this research is to introduce and propose a software project management framework for the academic domain. The proposed framework contains identification and description of 7 and 26 quantifiable parameters and sub-parameters respectively. The framework is called 4PCDT for People, Process, Product, Project, Complexity, Duration and Technology for the academic software projects. To validate the proposed framework, an online survey of 113 faculties was conducted to rank and weigh the quantifiable parameters. The results show that People, Process and Technology management parameters are top 3 ranked parameters. The robustness of the approach is further evident from the results of experimentation on 18 actual academic software projects of final year post graduate students of the IT domain. Not only the proposed work is first of its kind, but also it is bound to generate an excellent ripple effect in the research community.

**Keywords**—Academic; CMMI-Dev; PMBOK; project management; software project; student

## I. INTRODUCTION

Software project management plays a critical role in software project development. To manage project efficiently is considered as an art as well as a major demanding task in the Information Technology (IT) domain. The art and challenging role make both project development as well as management an extremely imperative research object in society. Project management has become a key process area as well as given a due importance irrespective of industry domain. To effectively deal with and manage project is considered as one of the decisive success causes for any software project [11]. Today software project management is deemed to have equivalent significance as those of applying software engineering concepts in software development environment and these both are considered as driving aspects to deliver a successful as well a qualitative software project outcome [15].

Software project development also has a significant importance in academic courses of computer science and engineering as well as information technology. Through this project development, practical knowledge of software development is imparted to students. During academic software project development students are provided with strict guidelines as well as instructed to mandatorily execute all the phases of system development life cycle [5][6]. One of the universal observations found in academic software project development is failure of students to accomplish software project development within a predetermined timeframe. There may be numerous causes behind this failure, but the most vital cause is inappropriate management of software project by students. It is extremely imperative to make students acquainted with guiding principles regarding proper software project management from the very preliminary period of software project development in order to endow them with intellectual IT proficiency.

The intention of study is: (a) to explore and evaluate software project management in software project development; (b) to indicate the significance of software project management in academic framework; (c) to propose an comprehensive methodology and framework that assists in managing software project considering academic context on the basis of rich literature review on software project management to encourage student's software project success probability; (d) to introduce a software project management framework by examining and incorporating earlier project management methodology/ frameworks that will guide, assist project mentors and students to deliver successful software project. The layout of the paper is as follows: a concise literature evaluation is discussed in Section 2. The planned framework is introduced in Section 3. Experiment and Result of the anticipated framework is presented in Section 4. Lastly conclusion and future enhancement drawn from this research is highlighted in Section 5.

## II. LITERATURE REVIEW

According to Chang et al. [1] software project management is a problem-solving activity and task like other activities that are involved in software development process. Further, Chang et al. [1] also proposed a software project management model termed as SPMNet for resource allocation, scheduling and to track and handle project status. Marinho et al. [11] in their research work focused on various uncertainties that can be effectively managed using project management

\*Corresponding Author.

techniques. The major contribution provided by Marinho et al. [11] are – (a) a systematic review for academic community to clearly understand about various challenges and uncertainties in project management, (b) techniques and strategies to deal with these uncertainties. Cristobal et al. [9] summarized project complexities and also discussed how to address these complexities using effective project management. Sajad et al. [15] define software project management as a process which starts from proper planning and then flow towards organizing, staffing, monitoring, controlling and leading a software project. He has presented a comparative analysis of various project management tools and also predicted about project management tools that will have greater impact on software development and quality. Mac and Pinto [10] stated that software project management has become a focused discipline in software engineering domain. Further, risk management was the major factor on which they proposed their findings in consideration with software project management. According to Mahdi et al. [14] planning and assessment are important activities of software project management and are considered to have immense effect on project performance and its outcome. Author's also presented an in-depth review on use of various machine learning algorithms in software project management. Cunha et al. [8] conducted a methodical literature evaluation on software project management and concluded through empirical study that decision making is one of the most important criteria in software project management and stated that more studies are needed to carry out to understand decision making fact from this naturalistic perception. Barghothet al. [13] affirmed that project management plays a central role for making software project a success story. They proposed a framework named 4PTRB which consist people, process, product technology, risk, and business management areas. The said methodology provides a complete and exhaustive support to software project administrators to get better their project administrating managing skills and efficacy.

In their research work, Alok and Deepti [12] focused that software processes applied as well as software project management are having due weight-age for developing a qualitative software. Also, they presented a comparative study of various project management tools that can be utilized for effective management of software development activities. Varajaoa [7] asserts that project management is discipline that has achieved a notable identification in research domain. Also, author states that irrespective of industries relevance of good project management practices leads to a successful project. Mira and Pinnington [3] in their research work tested the association between project management performance and project success and for their investigation they considered empirical data of project management professionals. Rehman and Hussain [20] reported exhaustive study on different project management methodologies and their importance in project management. Also, authors examined and presented a parameterize comparison between various project management methodologies with PMBOK.

Dey et al. [17] explored and described contemporary drift in software project management. Authors in their work analyzed and highlighted all categories of risks that are related

with technology, financial, scheduling, legitimate, principle, operational, security, communication, project and personnel as well as all these risks require timely involvement as well as proper follow-up and controlling needed in project management. The research work of Nakigudde [16] focused on foremost decisive factors that lead to the success as well as failure of the project. Author also explained the significant role played by project management model in making software project a successful journey. Demir et al. [2] examined and presented diverse approaches to examine the efficiency of project management in software development life cycle. Singh and Lano [19] worked out on techniques and framework of project management and their finding states that different techniques are suited and can be applied in different types of software project development. Kwak [21] scrutinized and presented in-depth history of project management as well enhancements that have taken place in domain of project management. Raj and Sinha [18] provided proposal on handling as well as enrichment in project management considering agile framework. Packer et al. [4] proposed a model that provides support in project management decisions in agile development considering the issues and difficulties faced in using GitHub repositories.

### III. PROPOSED FRAMEWORK

For the present research work, a study and examination of previous project management models such as Project Management Body of Knowledge (PMBOK), Capability Maturity Model Integration - Development (CMMI-Dev) processes and 4PTRB (People, Process, Product, Project, Technology, Risk, and Business) [13] was carried out.

These project management models provide with a set of software project management approaches, procedures as well as directive philosophy for software project management discipline. Software project management framework 4PTRB [13] is considered as fundamental base model for research work. Since the said proposed framework is been implemented in academic context we borrowed People, Process, Product, Project and Technology software management areas from 4PTRB [13] and instead of software management areas we coined and define it as software management parameters. Parameters namely risk and business of 4PTRB [13] were not considered since our proposed framework is for educational project hence no risk factors need to be examined and evaluated similarly educational project are not developed considering business and other profit earnings. Also, these software management parameters are termed as quantifiable parameters since they are considered as a metrics for measuring software project management. Furthermore, two software management parameters are integrated to the existing 4PTRB [13] model framework.

One of the software management parameters concerned with academic domain is duration and the other one is complexity. The reason behind considering duration parameter is that academic software projects need to be completed within the stipulated time duration. Similarly, project mentors and students both have to examine and consider the complexity level of the software to be developed. In Table I, we present listing of identified software management parameters of the

proposed framework along with concise clarification of each parameter.

TABLE I. THE PROPOSED FRAMEWORK 4PCDT PARAMETER(S)

Sr. No.	Parameters	Depiction
1.	People	People are considered as one of the most important components of a project. Some of the assigned role in academic software project is team members and mentors.
2.	Process	Process is the clearly and well-defined roadmap that needs to be followed during software project development. In academic software development, students are strictly bound to follow defined process methodology.
3.	Product	Product refers to the outcome of the project, the main objective of the project. The students (team member) need to explain the product scope to the mentors and concerned authority so that the end results are understood to all the stakeholders.
4.	Project	The next parameter but not the least component is the project. This is where the huge role and accountability of the team members and mentors are under the limelight. The students need to execute as well as handle major development task as well as to ascertain timely completion of the phases and functionality of the software project development. Whereas, mentors have the task of overseeing the project, guiding and assisting team members with issues, and trying to ensure the project stays on track with the well-defined deadlines.
5.	Complexity	Complexity of software to be developed
6.	Duration	Stipulated time duration for completion of software project development
7.	Technology	Technology used for developing software

After preparing software project management areas list, next step is to identify and map sub-parameters for individual and main software project management parameters. 4PTRB software project management model [13] contains 28 sub areas. Further we revised the sub areas for the said proposed framework considering relevance and importance in academic software development and the same which is presented in Table II.

As revealed in Table II there are total seven main parameters and 26 sub-parameters for the proposed framework. The comparative analysis of main parameter(s) and sub-parameter(s) of proposed framework and 4PTRB [13] are summarized in Tables III and IV.

The primary objective of the research is to measure academic software project management efficiency based on the software project management parameters introduced in the anticipated framework. Therefore, a formula for measuring

project management effectiveness namely Academic Software Project Management efficacy (ASPME) is been introduced and the formula consists of the summing up of each main quantifiable parameters of software management. The formula for Academic Software Project Management Effectiveness (ASPME) is mentioned below [1]:

$$\text{ASPME Score} = \text{PeoplePW} + \text{ProcessPW} + \text{ProductPW} + \text{ProjectPW} + \text{ComplexityPW} + \text{DurationPW} + \text{TechnologyPW}$$

Here, ASPME Score = Academic Software Project Management Effectiveness Score, PeoplePW = People Parameter Weight, ProcessPW = Process Parameter Weight, ProductPW = Product Parameter Weight, ProjectPW = Project Parameter Weight, ComplexityPW = Complexity Parameter Weight, DurationPW = Duration Parameter Weight and TechnologyPW = Technology Parameter Weight.

Also these seven quantifiable parameters are not having equal weight-age. An online survey has been executed to endow with a rating to these academic software project management parameters. In the next section, the validation of the proposed framework including survey results and experimentation is presented.

TABLE II. IDENTIFICATION AND LISTING OF SUB-PARAMETERS

Sr. No.	Quantifiable Parameters	Proposed Framework (Sub-Parameters)	Sub Parameters Total
1.	People	Communication, Co-ordination, Team, Mentor and Team work	5
2.	Process	Project Identification, Project Feasibility, Project Planning, Project Monitoring & Controlling and Project Development Guidelines	5
3.	Product	Phase/Task verification & validation and Quality assurance	2
4.	Project	Phase/Task Definition, Phase/Task Allocation, Requirement Management, Reporting and Change Management	5
5.	Complexity	Project Domain, Project Scope, Team Size	3
6.	Duration	Task Duration Estimation, Monitoring & Controlling Task Duration and Verification & Validation of Task Completion	3
7.	Technology	Identification of Technology, Team Skills and Expertise and Knowledge Management	3
<b>Total</b>	<b>7</b>		<b>26</b>

TABLE III. COMPARISON OF MAIN PARAMETER(S) OF 4PCDT WITH 4PTRB [13]

Sr. No.	Software Project Management Model	Main Parameter	Total
1.	4PCDT	People, Process, Product, Project, Complexity, Duration and Technology	7
2.	4PTRB [11]	People, Process, Product, Project, Technology, Risk and Business	7

TABLE IV. COMPARISON OF SUB-PARAMETER(S) OF 4PCDT WITH 4PTRB [13]

Sr. No.	Main Parameter	Sub-Parameters		Total of Sub-Parameters	
		4PCDT	4PTRB [13]	4PCDT	4PTRB [13]
1.	People	Communication, Co-ordination, Team, Mentor and Team work	Communication, Teamwork, Leadership, Organizational Commitment, Project Manager, Stakeholder involvement, Staffing and Hiring	5	7

#### IV. EXPERIMENTAL RESULTS

For simplicity and enhanced inclusive research, the phased process was followed. These phases are presented below:

- Execution and analysis of online survey for assigning weights to parameters.
- Weight calculation for each parameter.
- To conduct experiment on data set.
- Analysis of the experiment result.

##### A. Execution and Analysis of Online Survey

Further, after identifying and listing these quantifiable parameters and sub-parameters attributes next procedure is to assign weights to these seven quantifiable parameters. For assignment of weights, we randomly selected one quantifiable parameter to begin with and going on to other parameters while keep on comparing the already assigned weights and the parameters to which weights are to be assigned.

This procedure was acknowledged by conducting an online survey for assigning weights to 7 quantifiable parameters by 113 faculties engaged in post graduate streams of information technology as well as computer science and engineering. These faculty members are having more than 10 years of academic experience as well as providing mentorship to students in their software project development. The averaged based on the values provided by 113 faculties are mentioned in tabular format in Table V.

It is significant to declare that each of the 7 quantifiable parameters were assigned weight out of 100 and it was not necessary to have the total of weights of 7 parameters as

break-up of 100. This course of action in principle is based on human perception and general aptitude.

##### B. Weight Calculation for each Parameter

In the next phase of research weights need to be calculated for each quantifiable parameter. The procedure implemented for the same is to divide average weight of each quantifiable parameter by total weight average as shown in Table VI.

TABLE V. AVERAGED VALUE OF QUANTIFIABLE PARAMETERS

Sr. No.	Quantifiable Parameters	Average (%)
1.	People	82.10
2.	Process	80.13
3.	Product	63.90
4.	Project	69.12
5.	Complexity	65.98
6.	Duration	70.04
7.	Technology	73.09

TABLE VI. WEIGHT AVERAGE TO QUANTIFIABLE PARAMETERS

Sr.No.	Quantifiable Parameters	Average (%)	Weight
1.	People	82.10	0.1621
2.	Process	80.13	0.1582
3.	Product	63.90	0.1261
4.	Project	69.12	0.1365
5.	Complexity	65.98	0.1308
6.	Duration	70.04	0.1383
7.	Technology	73.09	0.1443
Total	7	506.36	1.0000

TABLE VII. SIGNIFICANCE OF 4PCDT

Results	Choices						Total
	Very Significant	Significant	Somewhat Significant	Neutral	Not Significant	No Opinion	
Number of Respondent(s)	61	31	13	5	3	0	113
Percentage (%)	53.98	27.43	11.50	4.42	2.65	0	100

In the online survey form given to the respondents, the respondents were also asked about the significance of the proposed framework called 4PCDT. The respondents were informed that this framework could be employed as a guiding principle for the software project management for the academic domain. The results were analyzed, summarized and presented in Table VII.

### C. Experiment on Dataset

The perform experiment on dataset is an imperative element of the research. Similarly, the practical execution of the proposed framework was executed in our organization. For experiment, software project developed by Master Degree students were considered. Final year students need to develop this academic software project within six months. We inspected and assessed 18 large academic software projects developed during the three consecutive years 2016-2017, 2017 – 2018 and 2018-2019 and led by 5 faculties and there mentored the same software projects. Further free online Software Project Management Effectiveness Evaluator (SPMEE) tool named Wrike was used to perform the experiment of the proposed framework. This tool provides with a facility where by we can design self-administered project management effectiveness questionnaire. A structured and organized set of closed-form questionnaire was prepared considering academic software project development life cycle based on the implementation of the proposed framework taking into consideration quantifiable parameters introduced.

### D. Analysis of Experimental Result

The academic software projects considered for experiments are presented in Table VIII. Further, all faculty participants were provided with project management effectiveness questionnaire. In the next step, academic project success scores need to be provided by each faculty members using this online software project management efficacy evaluator and project management effectiveness scores calculated were in-between range 0 to 10. Where 0 means a software project is not successful stating that least effective project management parameters have been functionally applied by students and mentors. While a score 10 denotes an extremely successful academic software project were at most care is taken as well as foremost efficient software project

administration and execution has been functionally implemented.

Finally, we compared the results obtained by us through the 4PCT model, which is the modified 4PTRB model with 4PTRB [13] project management model itself. The implementation was done on the said 18 academic software projects and the software project management effectiveness was measured. Each academic software projects were solely varied from other projects in the dataset. The development time duration for each academic software projects was 6 months whereas each project varies in domain, functionality, team size, technology, complexity. In Table IX in-depth experiment result analysis and comparison of proposed framework and 4PTRB [13] is presented. Software project management score is automatically measured by the online Software Project Management Effectiveness Evaluator (SPMEE) considering the Academic Software Project Management Effectiveness (ASPME). These analysis and findings strengthen the legitimacy of the proposed framework.

It has been found that project success score and software project management effectiveness (PME) are closely associated with each other and have a strong correlation. The same is graphically presented in Fig. 1. Also the association between proposed framework PME score and success score is stronger than 4PTRB [13] PME score and success score. Further, the Pearson correlation co-efficient is 0.9754, while it is 0.9288 when the 4PTRB [13] framework is applied. Thus, it can be wrapped up that employing the proposed framework highlights the higher probability of delivering as well as managing software project more effectively and successfully. Also, it can be observed that score generated by proposed framework 4PCDT and Success rate score is closer in comparison to 4PTRB [13].

## V. CONCLUSION AND FUTURE ENHANCEMENT

In the present research we proposed an academic software project management framework named as 4PCDT which is developed with consideration of multiple parameters. Seven main quantifiable parameters and 26 sub-parameters were recognized and listed based on their relevance. The primary aim of categorizing these parameters was to provide with the academic software project management framework which is best suited in consideration with academic context. Existing software project management frameworks like 4PTRB [13],

3PR and various guidelines were explored for proposing the academic software project management framework. However, the proposed framework is having unique characteristics because we revised the parameters and sub-parameters which were included in earlier versions of project software management framework and introduced list of new parameters and sub-parameters to cover more facets and propose a more holistic and comprehensive framework for managing academic software projects. Validation of the identified quantifiable parameters and sub-parameters was done through more than 100 faculties of post graduate courses of computer

science, computer engineering and information technology. All chosen faculties were active mentors for academic software project development. The results showed that 'People' management has been considered with maximum significance followed by 'Process' and 'Technology' in the academic software project management domain.

In the present work 18 academic software projects were used to experiment and validate the proposed framework. The academic project development work was carried out during the academic years 2016-2017 to 2018-2019. In the next step of research we prepared project management questionnaire and was provided to five faculty participants. Faculty members used this questionnaire on these 18 academic software projects and provided project success scores, project management effectiveness score using online Software Project Management Effectiveness Evaluator (SPMEE) tool. Further, scores were calculated considering the range 0 to 10, where 0 signifies that a software project is not successful and the cause behind this is least effective project management parameters has been practiced by students and mentors. While a score 10 means an extremely successful academic software project were at most care is taken as well as foremost effective software project management has been functionally implemented. Same technique was considered in the previous framework and their studies stated a positive association and relationship between software project success score and project management effectiveness.

Similarly, the finding and analysis of present research shows a strong and optimistic interrelationship between software project success score and project management efficiency with 0.9754 value of Pearson correlation coefficient whereas it is 0.9288 when 4PTRB [13] framework is applied. Thus, it can be concluded by findings of the analysis that the proposed framework is hypothetical, optimum, applicable and appropriate to be used in academic software project management. Considering the same we deem that academic courses that are having major as well minor software project development as a part of their core curriculum should emphasis, consider and endow with course of action as well as models and methodologies regarding software project management in software project development.

The extensive framework presented through this research work will definitely assist the faculty mentors as well as the students in the domains like Information Technology, Computer Science, Computer Engineering, and Computer Application to manage the academic software development projects more effectively. Proceeding with the research, we would execute the work in direction to introduce software project management effectiveness model for academic domain in consideration with proposed framework. In the current research work only 18 academic software projects were included in the experiment; hence if the size of dataset for validating the framework is increased it may disclose novel dimensions. Also, the proposed framework considered the academic context whereas 4PTRB [13] framework was designed considering software projects developed in IT industries. Hence at last, we express that the proposed framework for academic software project management is

unconditional independent, reliable, prescribed as well as shows a better participation of students and faculty mentors and can be effortlessly employed in academic outline irrespective of project categories.

# Neuromarketing Solutions based on EEG Signal Analysis using Machine Learning

Asad Ullah, Gulsher Baloch, Ahmed Ali, Abdul Baseer Buriro, Junaid Ahmed, Bilal Ahmed, Saba Akhtar

Department of Electrical Engineering  
Sukkur IBA University, Airport Road Sukkur  
Sindh, Pakistan

**Abstract**—Marketing campaigns that promote and market various consumer products are a well-known strategy for increasing sales and market awareness. This simply means the profit of a manufacturing unit would increase. "Neuromarketing" refers to the use of unconscious mechanisms to determine customer preferences for decision-making and behavior prediction. In this work, a predictive modeling method is proposed for recognizing product consumer preferences to online (E-commerce) products as "Likes" and "Dislikes". Volunteers of various ages were exposed to a variety of consumer products, and their EEG signals and product preferences were recorded. Artificial Neural Networks and other classifiers such as Logistic Regression, Decision Tree Classifier, K-Nearest Neighbors, and Support Vector Machine were used to perform product-wise and subject-wise classification using a user-independent testing method. Though, the subject-wise classification results were relatively low with artificial neural networks (ANN) achieving 50.40 percent and k-Nearest Neighbors achieving 60.89 percent. Furthermore, the results of product-wise classification were relatively higher with 81.23 percent using Artificial Neural Networks and 80.38 percent using Support Vector Machine.

**Keywords**—*Electroencephalogram (EEG); brain-computer interface; neuromarketing; machine learning; artificial neural networks*

## I. INTRODUCTION

E-commerce is a growing field these days. People want to expand their businesses, so they spend money on marketing to learn about their customers' preferences. Neuromarketing is a developing field with enormous potential for application marketing, brand management, and advertising. It emerges as a result of combining relevant concepts from the fields of neural science, psychology, human neurophysiology and even neuro chemistry. It connects consumer behaviour research with neuroscience [1]. Consumer behaviour quite often undermines the effectiveness of traditional marketing methods.

This is because the consumers' reactions vary when they are exposed to advertisements. Neuromarketing is the key to gaining insight into the minds of consumers. Because neuromarketing does not necessitate the consumer's conscious participation. It operates on the unconscious state of the brain.

Neuromarketing assesses the brain's reaction to any advertising stimuli. It differs from self-reports that consumers

provide during surveys. The truth can be revealed by studying the EEG signals directly [21]. As several reported studies show those two systems- conscious and subconscious can provide contradictory interpretations at times. Individual choices influence the decision-making process not only through individual and cognitive assessments, such as questionnaire responses but also through objective and implicit assessments, such as eye movement and neural activities. Recent findings from functional magnetic resonance imaging (fMRI) and EEG studies have linked movements in the frontal theta and posterior gamma bands to the development of individual choice. These findings show that before deliberate decision making, the physical reaction is caused by implicit desires. As a result, such neural behaviors associated with attention-related tasks, such as eye moments, can influence the consumer's preferences at an unconscious level. Despite this, there have been few neurological studies on the relationship between visual attention and subjective interest: the causes of subjective preference choices, such as the amount of visual perception and attention, are impossible to assess when using attractive faces with a wide range of visual features (e.g., facial contour, eye color, and hair length) [2].

Several commercial efficacy metrics can be calculated using neuromarketing. Emotional commitment, memory retention, purchase purpose, novelty, perception, and attention are the factors to consider. When customers make decisions, they are influenced by their emotions. The emotional interest level causes the emotional commitment level to rise. It can also help predict when customers will purchase by observing how their brains react to advertising stimuli. When customers decide to buy a product, the level of encoding of marketing stimuli influences our decision [3].

Neuromarketing provides knowledge that traditional marketing methods cannot provide. The significant advantage provided by neuromarketing techniques is that these techniques, which collect quantitative data, could be used before the launch of a new product, increasing the likelihood of that product's success [3].

Electroencephalography (EEG) was developed to record brain signals. EEG is used to study brain activity by recording postsynaptic potentials generated by neurons. With the development of tools, EEG is no longer limited to medical applications but has now been extended to other fields. Medical, Brain-Computer Interface (BCI), and neuromarketing are examples of EEG applications [4]. In the

[10-11], the authors have proposed a predictive modeling method based on EEG signals to understand customer preferences for E-commerce products in terms of "likes" and "dislikes". EEG signals were recorded while volunteers of various ages and gender browsed through various consumer goods. The tests were performed on a dataset containing a variety of consumer goods. The accuracy of choice prediction was calculated using a user-independent testing approach and hidden Markov Model (HMM) classifier. The prediction results appear to be promising, and the methodology can be used to create business models [11].

In comparison to the previous study, this study introduces subject-wise classification as well. The previous study has only done on the product-wise classification. The goal of this study is to assist marketing researchers in making appropriate decisions for further increasing the sale of products using imaging techniques by developing an EEG-enabled model that can replace expensive methods of current day neuromarketing. In addition, by analyzing EEG signals, a Neuro-marketing system will be provided to predict customer choices while viewing E-commerce products.

As such, the main objective of this study is to investigate the various tuning of artificial neural networks and other classifiers for improving the classification rates of product-wise classification and for the first time doing subject-wise classification. Section II presents the background and related works in the field of neuromarketing. Section III presents our approach towards building an EEG-based prediction model. Section IV presents the results of our study and Section V concludes the paper with possible future recommendations.

## II. RELATED WORK

We looked at recent studies that linked EEG signals to predict customers' response, behavior and emotions based on self-reported ratings. All these studies mostly focus on studying the relationship between brain imaging and customer decision-making. Kumar, Singh, et al. (2015) investigated the current state of neuromarketing, as well as the activities involved, which included neuroimaging, EEG, fMRI, and eye-tracking. The customer dialectic is examined in the paper: "consumers contradict themselves, saying what they want but doing what they feel." The authors focused on four aspects of consumers: physical body, mind, heart, and spirit [5].

W. Anderson, Sijercic et al. (2007) worked on the classification of EEG Signals from four subjects while performing five mental tasks. Half-second segments of six-channel EEG data were trained to be graded into one of five groups, each of which corresponds to one of five cognitive tasks completed by four subjects. Two and three-layer feed forward neural networks were trained using 10-fold cross-validation and early stopping to avoid over fitting. To represent EEG signals, autoregressive (AR) models were used. The average percentage of correctly classified test segments ranged from 71% for one subject to 38% for another. The Clustering of the hidden-unit weight vectors of the resulting neural networks shows which EEG channels were most important in this discrimination problem [6, 20].

Solhjoo, Nasrabadi, Golpayegani, et al. (2005) investigated chaotic signal classification using hmm classifiers and EEG-based mental task classification. The analysis of mental activities using brain signals, based on EEG provides a better understanding of human brain functions. Furthermore, the author stated for EEG chaotic signals it is critical to determine whether probabilistic and statistical signal processing tools (such as HMM-based classifiers) can handle chaotic signals. The author has examined how well HMMs perform in classifying various types of synthetically formed chaotic signals. The performance of such classifiers in classifying mental tasks based on EEG was then evaluated. The results in both cases indicate good performance [7].

Guo et al. (2013) developed the new recommender system for 3D e-commerce using EEG signals. The author proposed a novel augmented reality recommender framework for the world of e-commerce. The system makes recommendations based on customer preferences, taking into account both pre-purchase and post-purchase scores, as well as post-purchase ratings in general. Positive emotions among users are evaluated using EEG signals before interacting with 3D virtual products. Pre purchase ratings work in tandem with post-purchase ratings to address two major challenges that traditional recommender systems face: data and cold start. By properly utilizing both pre-and post-purchase scores, user preference can be more reliably modeled. The author claimed that it has boosted the effectiveness of modern recommender systems and force traditional ecommerce applications to adapt [8].

The authors of [9] conducted an experiment on EEG signal classification using the wavelet transform. The author used an artificial neural network (ANN) technique in conjunction with a feature extraction technique, namely the wavelet transform. The artificial neural network used to classify the data is a feed-forward network with three layers that implements the back propagation algorithm for error learning. After that, the network with wavelet coefficients was trained. Over 66% of the normal class was correctly graded, and 71 % of EEGs in the schizophrenia group were positive.

Murugappan, Celestin Gerard et al. (2014), the goal of their research is to use wireless EEG signals to identify the most popular automotive brand in Malaysia. This work is taken into account a community of four major vehicle brand advertisements, including Toyota, Audi, Proton, and Suzuki. The participants (9 male and 3 female, ages 22-24) were simulated using a 14 channel wireless Emotive headset with a sampling frequency of 128 Hz, and the brain activity responses to the stimuli were obtained using a 14 channel wireless Emotive headset with a sampling frequency of 128 Hz. The obtained signals are filtered using a Surface Laplacian filter and a 4th order Butterworth band pass filter with a cut-off frequency of 0.5 Hz - 60 Hz is used to filter the obtained signals. The alpha frequency band (8 Hz - 13 Hz) of EEG signal information was obtained using the same Butterworth 4th order filter. The Fast Fourier Transform (FFT) was used to extract three statistical features from EEG signals using the Alpha band frequency spectrum: power spectral density (PSD), spectral energy (SE), and spectral centroid (SC). The feature vector is constructed using extracted features extracted

from all of the subjects via four different advertising stimuli. This feature vector is fed into two non-linear classifiers, K Nearest Neighbor (KNN) and Probabilistic Neural Network (PNN), to classify the subject's intention on advertising [10].

### III. SYSTEM SETUP

In this study EEG signals were recorded from 15 healthy people using a Muse 2 headset – which is a neuro-signal acquisition wireless device – connected to a mobile app called Muse Monitor, as shown in Fig. 1. The device has 4 channels for EEG data that are located at AF7, AF8, TP9, and TP10 positions as per the International 10 - 20 system. Internally Muse 2 headband is sampled at a frequency of 256 Hz. The EEG data is stored in a CSV file and then transferred to computer for further processing. EEG headset was mounted onto the head of participants and asked to view shopping products as shown in Fig. 4.

We recorded 450 EEG signals, each lasting 4 seconds. Because the Muse 2 device has four sensors, it is the most user-friendly data acquisition device. We get raw data from four sensors. Fig. 2 shows the raw signal from AF7 Channel. Fig. 3 is the graph of RAW signals from AF7, AF8, TP9 and TP10 sensors. Fig. 4 shows the products we have used. While the user was viewing an item EEG signals were collected simultaneously. After the watching, each consumer was asked to rate the product in one of two categories: like or dislike. Then the signal passes through certain signal pre-processing techniques and feature extraction steps. Next, classification models are built, trained, and tested based on the user's choice.

#### A. Data Preprocessing and Feature Extraction

Pre-processing is the necessary step in EEG processing because it converts the signal into a usable format. The Initial pre-processing was done in excel to ensure that each recording was exactly 4 seconds long. Fig. 3 shows the unfiltered raw EEG signals from different channels: AF7, AF8, TP9 and TP10.

#### B. S-GOLAY Filter

Researchers have successfully used the S-Golay filter in signal smoothing. It is implemented using least squares or polynomials to reduce the noise in signals and smooth them out by fitting consecutive sub-sets of neighboring signal points with low-degree polynomials and linear least squares. The S-G filter has two parameters: polynomial degree and frame size. PRO and SNR (signal to noise ratio) is the output evaluating variables for denoising EEG signals using the S-G filter. The experiment results show which type of polynomial degree value is best [13].

The S-Golay filter can be applied to obtain a smoothed signal for a signal  $S_j = f(t_j)$ , where  $(j=1, 2, \dots, n)$  with length of  $n$  as mathematically defined below.

$$Q_j = \sum_{i=-\frac{m-1}{2}}^{\frac{m-1}{2}} c_i S_{j+1}, \frac{m+1}{2} \leq j \leq n - \frac{m-1}{2} \quad (1)$$

Where  $m$  is defined as frame span,  $c_i$  represents convolutional coefficients number and  $Q_j$  is the smoothed output signal. Fig. 4 depicts the RAW signal from a single

channel, while Fig. 5 depicts the smooth signal after applying the S-Golay filter.

### C. Wavelet Transform Wavelet Transform (DWT) based Features

The most important part of distinguishing objects from one class to another is feature extraction. It is the process of converting raw signals into useful features. It is required to proceed to the next steps. For the classification of the EEG signal, we used discrete wavelet transform (DWT) [14] based on features. The DWT typically produces five signals: alpha, beta, theta, gamma, and delta bands of varying frequencies. Eq. 2 provides a mathematical explanation of DWT.

$$\phi(x) = \sum_{k=-\infty}^{\infty} a_k \phi(Sx - k) \quad (2)$$

When S is used as a scaling factor, it is usually set to 2. DWT is commonly used in biomedical signal processing because it denotes a signal in the time and frequency domains. The basic idea, behind DWT, is to use multistage decomposition to transform the signal input signals into small waves. A signal's wavelet analysis based on transformation can be performed at different frequency bands by decomposing it into approximation (A) and information (D) coefficients. To begin, two digital filters, the Low Pass Filter (L) and the High Pass Filter (H) are used to process the signal (H). A low-pass filter (L) is applied to the signal, which eliminates high-frequency fluctuations while preserving slow patterns.

### D. Classification

Following the feature extraction step, we used those features for classification. Support Vector Machine (SVM) [15], Logistic Regression [16], Decision Tree [17], Random Forest [18], and Artificial Neural Networks [19] are among the classifiers employed. These features were classified subject-wise as well as product-wise on different bands. The dataset were divided into training and testing sets, with 80 percent of our data used for model training and 20 percent used for model testing.

## IV. RESULTS AND DISCUSSION

As the features are fed into the Artificial Neural Network, various classifiers such as SVM, LDA, Logistic Regression, Random Forest, and Decision Tree are employed. The following are the ANN results.

### A. Subject Wise Classification

We used 14 subjects in our experiment to collect EEG data from them while they are watching and selecting the products, and a K-fold cross validation of 10 folds was used to validate our experimental results. Different models are trained and accuracies are obtained using 5 different bands: alpha, beta, theta, gamma, and delta. These accuracies are evaluated for each product separately to carry out subject-wise classification.

### B. Hyper Parameter Tuning on Theta Band for Model Selection

ANN is trained on 14 subjects using theta band with columns named Theta AF7, Theta AF8, Theta TP9, and Theta TP10.

Table I displays the tuning of the ANN model's model parameters. To achieve the best results, the hidden layers, the number of neurons, activation function on layers, and optimizer are all varied. As a result, the number of hidden layers should be one and the number of neurons should be two to achieve the best result of 50.40 percent for theta band.

ANN Model is trained using theta, alpha, beta, gamma, and delta bands using 10 folds on 14 subjects. Different parameters of ANN models have been tuned to achieve the best overall accuracy for each band.

Subject-wise accuracy of 50.40 percent, 50.02 percent, 50.39 percent, 50.14 percent, and 50.21 percent is obtained using Artificial Neural Networks on the Theta band, Alpha band, Beta band, Gamma band, and Delta band, as shown in Table II by testing different classifiers to obtain the best subject-wise accuracy. Using Decision Tree, K-nearest Neighbors, and Logistic Regression, we achieve the highest accuracy on the Delta band of 57.30 percent, 60.89 percent, and 51.34 percent, respectively. Hence, K-nearest neighbors proved to be best algorithm for classification of the Delta band signals.

Fig. 6 shows the accuracy of theta band tested number of times. Fig. 7 shows the maximum attained accuracy by alpha band is 51.5 %. Fig. 8 illustrates the minimum accuracy for beta band is 49.2 % and maximum accuracy is 50.5 %. Fig. 9 and Fig. 10 depict that minimum accuracy for delta and gamma band almost same that is 45.5 % with having maximum accuracy of 52 %.

Fig. 6. Accuracies obtained on Theta Band.

TABLE I. SUBJECT-WISE ACCURACY TUNING FOR THETA BAND USING ANN

No of hidden layers	No of Neurons	Activation function on layers	Optimizer	Accuracy mean
1	2	[Relu, relu,Sigmoid]	Adam	49.85%

Fig. 8. Accuracies obtained on the Beta Band.

Fig. 10. Accuracies obtained on Gamma-band.

### C. Product Wise Classification

The K-fold cross validation with 10 folds is applied for the product as well as subject-wise classification. Training and testing accuracies are obtained for various models using five different bands: alpha, beta, theta, gamma, and delta. Fig. 11 depicts the accuracy graph of the ANN model, which was trained using 14 products 1 subject. The model has learned completely after 15 epochs.

As shown in Table III, the average product-wise results are obtained accuracy of 78.73 percent, 76.14 percent, 81.23 percent, 74.12 percent, and 82.19 percent on the Alpha band, Theta band, Beta band, Gamma band, and Delta band using Artificial Neural Networks. To achieve product-specific accuracy, a variety of classifiers have been used.

The highest accuracy on the Delta band is 90.71 percent, followed by 92.21 percent, 82.37 percent, and 83.51 percent using Decision Tree, K-nearest Neighbors, Logistic Regression, and Support Vector Machine (SVM), as shown in Fig. 12. In our study, SVM and ANN performed better than in the previous study [11], and the results obtained are good enough to be used for practical business models.

Gamma	76.02%	74.12%
Delta	75.17%	82.19%

Fig. 12. Accuracies obtained using different Machine Learning Classifiers (Average Accuracy of Products).

### D. HEAT Map

The proposed physiological heat map tool allows for the representation of the relative distribution of physiologically inferred emotional or cognitive states of users on a given interface. To make a heat map in MATLAB-based EEGLAB, first select the channel location, then perform the independent component analysis (ICA), and finally plot a 3D component map. Fig. 13 illustrates the 3D heat maps for a consumer's choices. This figure clearly depicts the difference in the heat maps for products with "like" and "dislike". The EEG signals for like are mainly concentrated on the right hemisphere while that for dislike are concentrated on the left hemisphere of the brain.

### E. ICA (Independent Component Analysis) Component

The independent components analysis generates a set of weights for all electrodes such that each component is a weighted sum of operation at all electrodes, and the weights are designed to isolate brain electrical signal sources. Components with blink artifacts are possibly the easiest to detect. We have taken a careful approach and only deleted components from the data if you were confident they contained artifacts or noise with no or very little signal. ICA can be used to clean data, separate objects, and exclude certain components from the data, or reduce data. When the individual component analysis is used as a preprocessing method, components can be judged as containing objects based on their topographies, time courses, and frequency spectra. ICA also helps in removing high frequency noise from the EEG signal.

Fig. 13. Heat Map of Consumer Feelings towards the Product.

### F. Discussion

In this work, we used EEG data to predict users' product preference using neuroscience. The outcome demonstrates the efficacy of the proposed framework and offers an additional option to existing methods of predicting product market success. This study investigates and improves the classification accuracies of subject-wise and product wise choice preferences. From results it is evident that our proposed

system gives classification accuracy of up to 92.21 percent on the Delta band. The classification accuracies for all five bands are calculated both subject-wise and product-wise. Because there is more randomness in EEG signals of subjects, product-wise accuracy is higher than subject-wise accuracy because EEG signals of the same products are more similar and accurate. The other strong point is that our neuromarketing tool is simple, as we used four dry electrode sensors that can be easily placed on the forehead.

## V. CONCLUSION

Using EEG signals, we predicted a customer's product selection preference. The brain activity of 14 participants was recorded while they were viewing products. The Muse 2 headset, which has four sensors, was used to record EEG signals. Further, the filters were applied to make signals smooth and classified using Artificial Neural Networks and other classifiers like SVM, decision tree, logistic regression, and K-Nearest Neighbors. Using all of the above-mentioned classifiers, we obtained subject-and product-level accuracies. Our obtained results demonstrate the effectiveness of the proposed framework, which has provided a superior solution than traditional methods of predicting product success in the market. By extending existing models, the framework can aid in the development of market strategies, research, and forecasting market success.

In the future, this work can be extended by analyzing fictitious responses to product preferences as compared to neutral responses. To improve prediction results, more powerful features and algorithm combinations could be developed.

**Abstract**—Plant diseases cause low agricultural productivity. Plant diseases are challenging to control and identify by the majority of farmers. In order to reduce future losses, early disease diagnosis is necessary. This study looks at how to identify tomato plant leaf disease using machine learning techniques, including the Fuzzy Support Vector Machine (Fuzzy-SVM), Convolution Neural Network (CNN), and Region-based Convolution Neural Network (R-CNN). The findings were confirmed using images of tomato leaves with six diseases and healthy samples. Image scaling, color thresholding, flood filling approaches for segmentation, gradient local ternary pattern, and Zernike moments' features are used to train the pictures. R-CNN classifiers are used to classify the illness kind. The classification methods of Fuzzy SVM and CNN are analyzed and compared with R-CNN to determine the most accurate model for plant disease prediction. The R-CNN-based Classifier has the most remarkable accuracy of 96.735 percent compared to the other classification approaches.

**Keywords**—Fuzzy Support Vector Machine (SVM); Convolution Neural Network (CNN); Region-based Convolution Neural Network (R-CNN); color thresholding; flood filling

## I. INTRODUCTION

Tomatoes are a major commercial crop grown all over the world. It is sensitive to various illnesses, which reduces tomato quality and yield while also causing significant economic losses. Tomato grey leaf spot is a common disease that damages and kills the leaves of tomatoes, preventing them from growing and producing fruit. The infection that produces grey leaf spots on tomatoes is brutal to remove. Contact, invasion, latency, and onset are the four phases of infection for the pathogen that causes tomato grey leaf spot. As a result, early preventative and control methods are suitable before a large-scale pandemic. Early disease detection can also aid in reducing pesticide usage and pollution, as well as the quality, safety, and health of tomatoes. Traditional disease detection systems cannot meet large-scale planting demands due to low diagnostic efficiency and fast disease transmission, and plants typically miss the appropriate management time [1, 2].

Manually detecting leaf disease with the naked eye needs a team of professionals and ongoing monitoring. When the farm is large, it is costly. As a result, image processing techniques may be used to automatically detect illnesses in leaves, saving time, money, and effort as compared to traditional methods. The early detection of illnesses in leaves improves crop productivity. Disease-affected leaves may be found at an early

stage using image processing techniques like as segmentation, identification, and classification, and crop yield and quality can be improved. Many farmers lack the resources or understanding on how to contact specialists, which makes it more costly, time-consuming, and inaccurate. In this case, the suggested approach proved to be more advantageous in terms of crop observation. The technique is more accessible and less costly when plant illness is detected using leaf symptoms. It takes less time, effort, and precision to use an automated detection technique. Manually detecting leaf disease with the naked eye needs a team of professionals and ongoing monitoring. When the farm is large, it is costly.

As a result, image processing techniques may be used to automatically detect illnesses in leaves, saving time, money, and effort as compared to traditional methods. The early detection of illnesses in leaves improves crop productivity. Disease-affected leaves may be found at an early stage using image processing techniques like as segmentation, identification, and classification, and crop yield and quality can be improved. In this case, the suggested approach proved to be more advantageous in terms of crop observation. The technique is more accessible and less costly when plant illness is detected using leaf symptoms. It takes less time, effort, and precision to use an automated detection technique.

Image processing technology can quickly and accurately diagnose illnesses based on their features. Disease prevention approaches may be applied fast, and efforts to avoid additional illnesses can be performed using this strategy. People used to identify tomato ailments based on their own experiences, but the ability to discern between various diseases is limited, and the process is time-consuming. Machine learning and image processing technologies are fast expanding and more widely employed in various industries, including agriculture. The following are two key contributions of this research: R-CNN framework for classifying leaf diseases ii) comparison of different classifiers. The remaining sections of this work are organized as follows: Section 2 did a background survey. Section 3 is about methodology. In Section 4, we give experimental data and analyze it by comparing the best classifiers that may be employed based on the findings of our previous study. Section 5 summarizes the proposed work of this paper.

## II. LITERATURE SURVEY

Traditional plant disease detection approaches based on computer vision technologies are commonly utilized to extract the texture, shape, color, and other features of disease spots. This method has a low identification efficiency because it relies on an extensive expert understanding of agricultural illnesses. Many academics have conducted significant research based on deep learning technology to increase the accuracy of plant disease detection in recent years, thanks to the fast growth of artificial intelligence technology [8]. The majority of existing techniques to plant disease analysis are based on disease classification [12].

Mohanty et al. [3] utilized GoogleNet and AlexNet to classify 54,306 plant leaf pictures as healthy or sick in the Plant Village dataset, revealing that GoogleNet had a slightly more significant average classification impact than AlexNet. The trained deep convolutional neural network model has a 99.35 percent accuracy on the test set. Building a deep learning model on a growing and publicly available photo dataset is a simple way to employ clever mobile phones to diagnosis plant diseases in horticulture crops.

Picon et al. [4] employed a deep residual neural network-based upgraded algorithm to identify many plant illnesses in real-world acquisition conditions. For early illness identification, several improvements have been recommended. According to the data, all of the illnesses evaluated had an AuC score of higher than 0.80.

Selvaraj et al. [5, 9] utilized the transfer learning approach to retraining three CNN architectures. Deep transfer learning was utilized to build networks using pre-trained sickness detection models to provide accurate predictions.

Deep learning was proposed by Fuentes et al. [6, 7] for identifying diseases and pests in tomato plant photos acquired at varying camera resolutions. Deep learning meta-architectures, as well as multiple CNN object detectors, were utilized. Data expansion and local and global class annotation were utilized to boost training accuracy and decrease false positives. A large-scale tomato disease dataset was used for end-to-end training and testing. The system correctly detected nine different pests and diseases from the complicated scenarios.

## III. METHODOLOGY

Our primary objective is to develop a model to categorize input plant leaf pictures as healthy or unhealthy. The disease kind is also determined if a disease is detected on a plant leaf. Our study compares the R-CNN Classifier to previously established tomato leaf disease detection utilizing fuzzy SVM [15] and CNN [16] Classifiers to detect and categorize tomato leaves suffering from common illnesses. Fig. 1 shows the architecture of the R-CNN-based plant disease detection system. The proposed technique includes image capturing, pre-processing, segmentation, feature extraction, classification, and performance assessment.

### A. Dataset Description

The dataset utilized for this investigation has seven primary classifications. Six leaves classes represent unhealthy, while

one represents the healthy leaf class. Each class has 105 examples for a total of 735 leaf images. A classification strategy is required to categorize input photos into one of the classes specified in Fig. 2 for a given image of an apple leaf.

### B. Image Pre-processing

The visual noise of the tomato leaf is made up of dewdrops, dust, and insect feces on the plants. The input RGB image is transformed to a grayscale image for accurate results to remedy these concerns. The image size in this circumstance is relatively large, needing image resize. The image size is reduced to 256 \* 256 pixels.

### C. Image Segmentation

Plant disease detection and categorization rely heavily on image segmentation. The image is simply divided into various things or sections. It analyses visual data to extract information that may be used for further processing. Our prior work [15] is used to accomplish color thresholding and flood filling segmentations.

### D. Classification using R-CNN

Rectangular regions are combined with convolutional neural network characteristics in R-CNN (Regions with Convolutional Neural Networks). The R-CNN algorithm employs a two-stage detection procedure. The first stage identifies a set of picture areas that includes a diseased part. In the second stage, each region's object is categorized.

1) *R-CNN procedure*: The following three approaches are employed to build an R-CNN based algorithm, as shown in Fig. 3.

a) To find regions in a photograph that could contain a diseased part. Region suggestions are the names given to these locations.

b) Extract CNN characteristics from the region suggestions.

c) To categorize the objects, use the characteristics that were retrieved.

The R-CNN generates region recommendations using a mechanism similar to Edge Boxes [10]. The proposed elements have been chopped and scaled out of the image. CNN then classifies the clipped and resized regions. Finally, a support vector machine (SVM) trained on CNN features refine the region proposal bounding boxes. A visual illustration of the problem is shown in Fig. 3.

A pre-trained convolution neural network is used to build an R-CNN detector, also known as transfer learning (CNN).

As a starting point for learning a new task, we will use a pre-trained image classification network that has already learned to extract robust and informative features from raw photographs. A portion of the ImageNet database [10], which is used in the ImageNet Large-Scale Visual Recognition Challenge (ILSVRC) [11], is used in the great majority of pre-trained networks. These networks have been trained on over a million photographs and can categorize a large number of them. Transfer learning with a pre-trained network is typically much faster and easier than training a network from the ground up.

Fig. 1. Architecture of R-CNN-based Plant Leaf Disease Detection.

Fig. 2. Tomato Leaf Images with its Diseases.

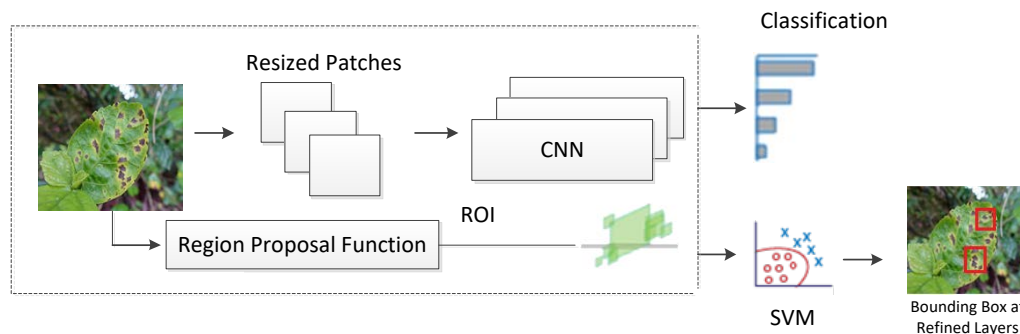

Fig. 3. Process of R-CNN Model.

2) *Transfer learning methodology*: The transfer learning method is employed a pre-built and pre-trained model rather than developing and training a CNN from scratch [13]. Transfer learning is a method based on transferring a model that has been trained on an extensive dataset to a smaller dataset. Early convolutional network layers are retained for object recognition and train the final few levels to generate predictions. The theory is that the convolutional layers extract broad, low-level properties from numerous pictures, such as edges, patterns, and gradients. On the other hand, the last layers identify individual characteristics inside a picture. Fig. 4 depicts the principle of transfer learning [14].

Fig. 4. Concept of Transfer Learning.

A general framework for object recognition transfer learning is as follows:

- a) Insert a CNN model trained on an extensive dataset and is ready to use.
- b) Freeze the parameters of the model's bottom convolutional layers (weights).
- c) Add a custom classifier with many layers of trainable parameters to the model.
- d) The task's training data should be used to train layers of classifiers.
- e) Fine-tune hyperparameters and unfreeze more layers as needed.

This strategy has been proven to be effective in several sectors. It is a terrific tool to have in our arsenal, and it is generally the first thing we do when confronted with a new image recognition challenge.

3) *Transfer Learning Characteristics:*

- a) It requires transferring information from one source task to the target task to learn and grow.
- b) DNN trained on raw pictures has been observed to demonstrate an unusual occurrence in which the network's initial layer appears to gain Gabor filter-like properties.
- c) The first layer's characteristics were found in a variety of datasets.
- d) The initial layers' general characteristics disregard the picture dataset, task, and loss function.
- e) The filters learned by specific ResNet layers can be reused by other ResNet layers if they learn the same feature. In convents, this practice is called extremely successful transfer learning.
- f) While overcoming data shortage, transfer learning saves time and money in training.

4) *R-CNN model design:* To generate R-CNN models based on a previously trained CNN for image classification. The R-CNN model is built on the foundation of a pre-trained network. The last three categorization levels are eliminated, and new layers customized to the item types wish to detect are added in their place.

As shown in Fig. 5, the final three layers in this network are fc1000, fc1000 softmax, and ClassificationLayer fc1000; the last three levels in this network are fc1000, fc1000 softmax, and ClassificationLayer fc1000. Fig. 6 depicts the removal of the final three layers.

As indicated in Fig. 7, add the new categorization layers to the network. The layers are put up to categorize the number of items that the network should detect.

5) *Convolution neural layers of RCNN model:* The input layer, the initial layer of the R-CNN architecture, delivers raw data to the network. The 32\*32\*3 raw image was recorded. The properties are extracted via the convolution layer, the transformation layer. As a result, this layer's inputs were leaf pictures. The R-CNN model's first convolution layer consists of 32 different 3\*3 filters, each having one stride and one

padding. After the convolution layers, the rectified linear unit layer (ReLU) is the most often utilized rectifier unit for neuron outputs. Pooling, commonly employed after the ReLu layer, decreases the subsequent convolution layer's input size (width and height). Fig. 8 depicts the entire structure.

Fig. 5. Layers of ResNet-50 Pre-trained Network.

Fig. 6. Layers of ResNet-50 Network by removing Three Layers.

Fig. 7. Layers of ResNet-50 Network after addition of New Layers.

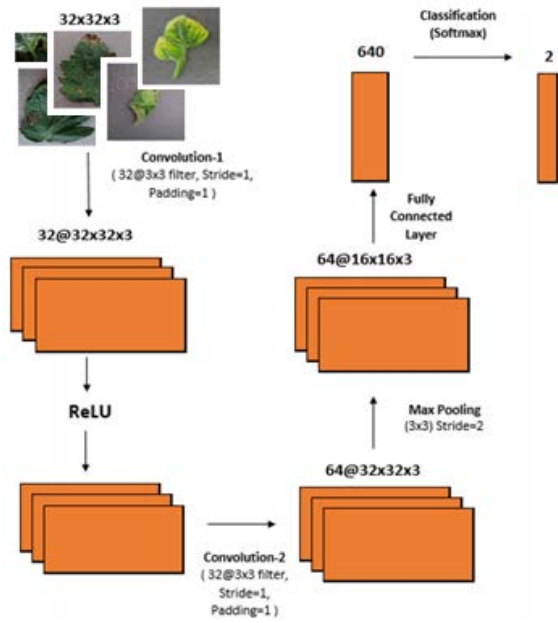

Fig. 8. Architecture of CNN Inside R-CNN.

The sub-maximum area's value was forwarded to the max-pooling layer. The scale value must be carefully controlled to avoid the attribute size reducing too quickly, the image attributes becoming rough, and the attributes getting lost in the max-pooling layer. There are layers for convolution, ReLU, and max-pooling before the finally linked layer. A 64-node fully connected layer was employed in the R-CNN. As a result, this layer is linked to the prior levels' core constituents. This layer is followed by the classification layer, which performs classification. A softmax classifier is a multi-class classifier based on an extension of the logistic function. The output map is connected to the Softmax function, the final layer of the proposed architecture, through the final convolution layer. It establishes the likelihood of each class.

#### IV. EXPERIMENTAL RESULT AND ANALYSIS

This section evaluates the performance of several classification techniques such as Fuzzy SVM, CNN, and R-CNN and shows that the Fuzzy SVM classification methodology surpasses the others. The datasets for tomato leaf disease are split into two categories: training data (70%) and testing data (30%). The Tomato Plant Disease dataset contains 735 pictures and seven classes named Bacterial Spot, Mosaic Virus, Yellow Leaf Cur Virus, Early Blight, Late Blight, Leaf Mold, and Healthy.

The implementation of these classifiers takes place in MATLAB 2019B. The input images as illustrated in Fig. 9, are pre-processed in this experiment to decrease noise, and then segmentation is performed using Color-thresholding and flood filling. The contaminated section of the leaf is then removed, and the GLTP and Zernike moments of that infected area are determined. Then, Classifiers are employed to determine the illness name.

The confusion matrix is a metric for evaluating the performance of a machine learning classification task with two or more classes as output. There are four distinct combinations

of projected and actual values in this table. It's great for assessing things like recall, precision, specificity, accuracy, and, most crucially, AUC-ROC curves. The confusion matrix of R-CNN is shown in Fig. 10.

A Receiver Operator Characteristic (ROC) curve is a graphical representation of a classifier's diagnostic capabilities. The ROC curve depicts the sensitivity vs. specificity trade-off. Classifiers with curves that are closer to the top-left corner perform better. The ROC curve that was developed for R-CNN is shown in Fig. 11.

Fig. 13. Confusion Matrix of Fuzzy SVM Classifier.

Fig. 14. Comparison between Classification Techniques.

Fig. 15. Precision, Specificity and Sensitivity of Classifiers.

Previously developed models are used for performance comparison using the confusion matrix. The following is a quick summary of these models: The confusion matrix for R-CNN findings for 735 input leaf samples is shown in Fig. 10.

A healthy and unwell people database is produced in a Fuzzy SVM-based Classifier [15]. There are six distinct illnesses and 735 photos in the classes in the input database. Color thresholding and flood filling are the two segmentation techniques used. For greater accuracy, the output of both algorithms is integrated using ROI (region of interest). The diseased section of the leaf's characteristics was extracted using the segmented picture. The Color Covariance Vector (CCV) and Gradient Direction Pattern (GDP) algorithms are employed. This phase extracts a total of 56 color features and 256 gradient characteristics. With 420 photos in four classes and a parentage accuracy of 97.142, this Fuzzy SVM algorithm provides the best results. However, increasing the number of photos from 420 to 735 reduces performance to 66.938 percent. A CNN-based classifier is employed to increase performance.

The CNN-based Classifier [16] includes 735 healthy and ill plant leaves. Among the seven forms of tomato leaf diseases in the database are Bacterial Spot, Mosaic Virus, Yellow Leaf Cur Virus, Early Blight, Late Blight, and Leaf Mold. The images were all shot in a lab environment. The images of leaves were divided into two categories: training and testing. Leaf images are separated into two groups to test performance: 70–30 (70 percent of the photos are for training, and 30 percent are for testing). The segmented section is used to retrieve the unhealthy portion of the leaf.

## V. CONCLUSION

Machine learning and image processing technology benefits from traditional manual diagnostic and recognition procedures for crop disease diagnosis. A small number of unhealthy image samples is necessary. Deep learning is one of the most well-known methods of artificial intelligence. Computer vision is one of the many fields where deep learning is used. It is capable of picture categorization, object identification, and semantic segmentation.

The disease diagnostic approach based on the deep convolutional network (CNN) minimizes comprehensive picture pre-processing and feature extraction methods

compared to standard pattern detection techniques. It employs an end-to-end structure to simplify the detecting procedure. In this study, we compared the best classifier for effectively classifying tomato leaf disease with an accuracy of 96.735 percent.

## VI. CONFLICTS OF INTEREST

The authors declare no conflict of interest.

Rajesh Kumar Singh<sup>2</sup>

Department of Computer Applications  
SUS Institute, Tangori, Punjab, India

**Abstract**—For quite some time, the usage of many sources of data (data fusion) and the aggregation of that data have been underappreciated. For the purposes of this study, trials using several medical datasets were conducted, with the results serving as a single aggregated source for identifying eye illnesses. It is proposed in this paper that a diagnostic system that can detect diabetic retinopathy, glaucoma, and cataract can be built as an alternative to current methods. The data fusion and data aggregation techniques used to create this multi-model system made it conceivable. As the name implies, it is a way of compiling data from a large number of legitimate sources. The development of a pipeline of algorithms was accomplished through iterative trials and hyper parameter tweaking. CLAHE (Contrast Level Adaptive Histogram Equalization) approaches, which increase the gradient between picture edges, improve segmentation by raising the contrast between picture edges. The Gabor filter has been shown to be the most effective method of selecting features. The Gabor filter was selected using a hybrid optimization method (LION + Cuckoo), which was developed by the author. For automation, the Support Vector Machine (SVM) radial is the most effective method since it delivers excellent stability and accuracy in terms of accuracy and recall, as well as precision and recall. The discoveries and approaches detailed here provide a more solid foundation for future image-based diagnostics researchers to build on in the future. Eventually, the findings of this study will help to improve healthcare workflows and practices.

**Keywords**—Content-based image retrieval system; CLAHE; Gabor filter; Cuckoo search; LION optimization; support vector machine

## I. INTRODUCTION

The covid-19 pandemic has forced rethinking about the effectiveness of clinical workflows and practices [1]. The current advances in image processing and machine learning algorithms make it imperative that new algorithms and methods be incorporated into health care technologies and systems[2]. Current research trends and evidence point out that creating multi-model systems requires using multiple protocols, stacks of technologies, and an array of algorithms and multiple data sources[3]. Choosing a specific technology stack and pool of algorithms for building a reliable system has become tedious work and confusing. The primary reason is the availability and choice of ready-to-use frameworks, APIs, libraries, and technological stacks. Hence, finding and appropriating existing algorithms requires exhaustive

experimentation and optimization e.g., at the data processing level: importing, validating, cleaning, converting, normalizing, and pre-processing the data requires a lot of experience and intuitiveness for selecting the suitable method, which would yield the best possible outcomes [4]. Application of methods such as data fusion, aggregation and argumentation also need to be explored, especially when the number of data instances of particular class are less and there is an imbalance in the dataset.

The term "pipeline" in computer science has broader connotations in the current context [5]. It is referred to as multi instructions performed as a unit. The computer unit may be some software module or hardware such as Graphics Cards. HTTP pipeline is a sequence of steps taken to handle HTTP traffic and tasks in the context of the research work. "Algorithm Pipelining" is more appropriate as this research work involves constructing algorithms, frameworks, and systems sequences that can perform tasks such as prediction of corona virus with the help of experiments with high reliability [6]. A pipeline is another method of defining an experiment [7]. An experiment whose objectives are known and defined and the outcome helps construct a fully functional system. In this research work, an attempt will be made to identify an accurate workflow of the methods (image processing and machine learning) that would yield a high-performing system that can detect at least three types of eye diseases, i.e.; diabetic retinopathy, glaucoma, and cataract. Hence, in the next section, the workflows, approaches, and methods are discussed which are used these days to construct multiple-model eye disease detection systems.

## II. REVIEW

Medical imaging technology has significantly progressed, which has helped to reduce the burden of detection of numerous diseases. Machine learning algorithms and their comprehensive frameworks have greatly helped the image segmentation field [8][9]. However, the biggest problem that the researcher faces in this context is building diagnostic systems related to the characteristics of the data set [10]. By analyses of the publically available medical image data set e.g. eye diseases, it can be observed that many of these data sets belong to particular or specific modalities, and at the same time, they are poorly annotated [11][12]. Many data sets are not labelled as per the stage of the disease; in many cases, the

dataset is not as per the requirement of machine learning modelling [13]. Due to this challenge, multi-model disease detection systems are hard to realize [14]. In simple words, it means that highly specialised systems of detection can be constructed. However, detection system for a specific domain is hard to construct; for example, the current literature quotes many examples of handling diabetic retinopathy detection systems[15], but few new systems are illustrated in high impact journals that deal with the detection of multiple diseases such as glaucoma, cataract, and diabetic retinopathy at the same time [16][17][18]. This industry faces two kinds of problems: the first is limited annotated data sets, and the second one is weak or incomplete annotations in the data set as per medical grade system. Contemporary literature cites different solutions to overcome the problem depending upon the problem.

The most frequently used technique is data aggregation [19], data augmentation [20][21] and data fusion [22]. In data augmentation, the existing data set size is increased by adding more synthetic data to it, or learning from the existing annotated data is done for constructing a more significant size data set; this way, multiple diseases and modalities can be covered. Such methods also help overcome the imbalance in the data set and help leverage active learning. The most significant advantage is that multi-disease detection systems can now be constructed using multiple data sets or data fusion techniques. Data fusion algorithms leverage multiple disease data sets for constructing image processing functions that work on heterogeneous disjoint sets that can support multi-disease detection systems [23]. Some authors refer to such procedures as data adaptation also. Data adaptation is a process by which a data set is constructed, which helps the learning component of the detection system to discriminate between the various disease modalities and come out with an effective solution. Data augmentation, data fusion, and data adaptation help immensely overcome the challenge of building generic systems of detection [24]. However, the current literature also points out that there are limitations in using single algorithms for building multi-disease detection systems. Research in this context also shows that building classification systems relying on specific features and single classification methods may not yield a stable numerical system. There is always a need to use various methods and solutions for detecting multiple diseases. Hence, many researchers have concluded that the usage of hybrid techniques and combination approaches is far better than training a specific machine learning model. This way, a robust model for constructing multiple disease detection systems can be realised and implemented.

From the current literature it is amply clear that as a strategy for building medical detection systems, three possible path ways can be used for constructing systems of disease detection [25]. The first uses purely statistical methods, the second uses optimization methods, and the third uses machine learning algorithms or deep learning models. It should be however be noted that Image segmentation is a precursor for using these three approaches because extracting the object of interest from the medical images is a fundamental step in

building disease systems. An important gap that is generally visible in the current literature is that few scholars are building systems can multiple diseases detection in medical domain. Generally, the focus of research paper is to work with a single medical modality with specific dataset. However, the need to hour is to construct models that can automatically detect multiple ailments in a comprehensive way. It became critical in context of detecting eye problems due to covid-19 pandemic norms.

In short, it can also be observed from the current research works in context of most relevant approaches are statistics, machine and deep models. Statistical methods such as descriptive statistics, correlation, f-test, t-test, etc., are generally used to understand the nature of the data and identify the suitability of the data for machine learning model [26]. The optimisation algorithms [27][28] such as Genetic Algorithm, ant-colony-optimisation [29], differential-evolution,cuckoo-search [30], particle-swarm-optimisation, firefly, metaheuristic swarm-optimisation, Harris-hawks-optimisation, bat-algorithm, lion-optimiser, grey-wolf-optimiser, moth-flame-optimisation, flower-pollination-algorithm whale-optimisation-algorithm, etc. are used for constructing feature engineering hypothesis for attaining the best possible solutions [31][32][33]. The automation of diagnose comes with implementing machine learning and deep learning algorithms. Current literature gives ample evidence that authors are primarily citing hybrid methods for producing high-precision systems of medical disease detection [34][35]. Large amounts of citations can be found that are showing the most frequently used machine learning algorithms for detecting eye problems include K-Means, K-nearest neighbour (KNN), support vector machine (SVM), ANN or neural networks , decision trees, logistic regression.

This research attempts to analyse three pipelines that would yield a numerically stable multi-disease detection system. The selection of methods used in each type of pipeline is based on the previous research works done by contemporary technical people. Secondly, it is a sincere attempt to find a novel pipeline of methods that can offer consistently repeatable performance detecting multiple eye diseases.

### III. MATERIALS AND METHODS

In this section, the steps that make up the workflow of this research are given. It explains techniques, procedures, and algorithms used for building a system designed for eye diagnostics. The research flow block diagram Fig. 1 may be referred to for better understanding. The dataset used in this research work is publically available ([https://github.com/palavibhangu/retina\\_dataset](https://github.com/palavibhangu/retina_dataset).)The dataset has 300 images of each of three types (diabetic retinopathy, cataract, glaucoma) of eye diseases and healthy eye images.

The aggregated size of the dataset of 1200 images was realized with the help of operation referred as data fusion. As mentioned earlier, in data fusion, multiple datasets are stacked and organised to act as single source of dataset. This has been done to overcome the challenge of low availability of particular class of instances of medical data.

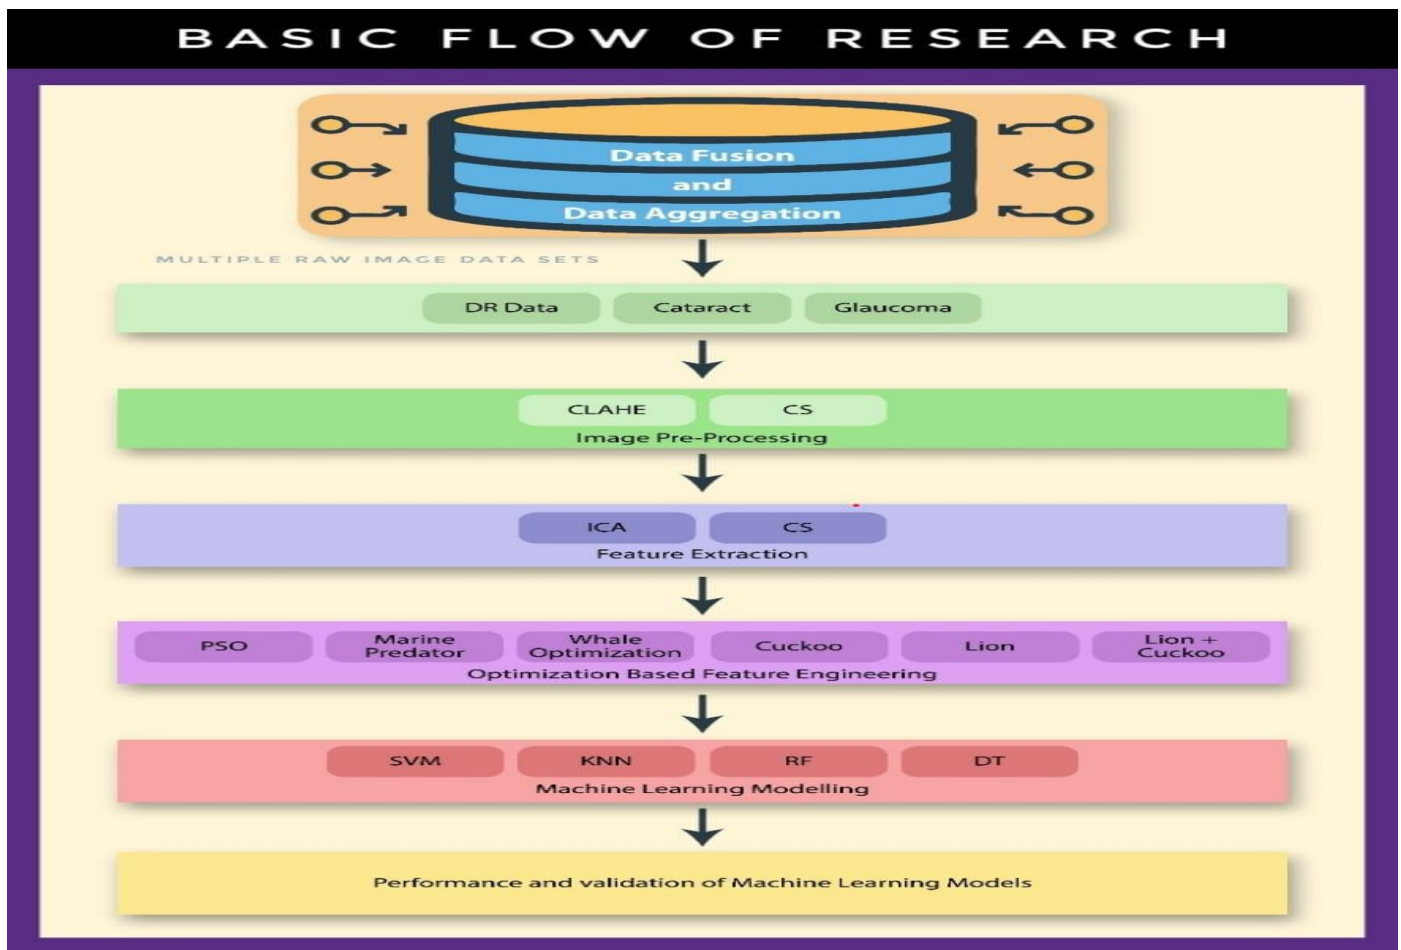

Fig. 1. Basic Flow of Research.

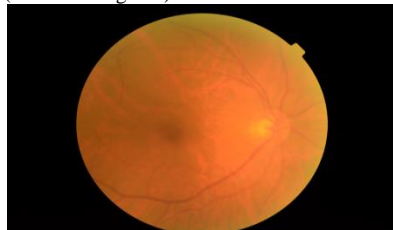

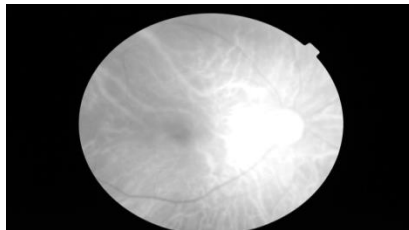

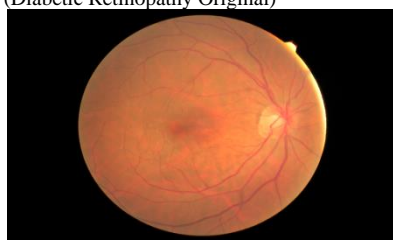

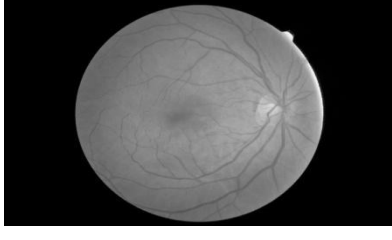

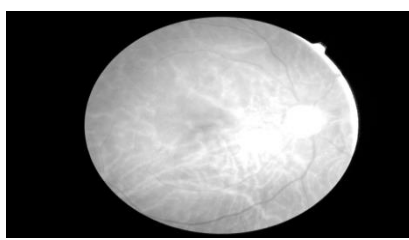

### A. Image Processing

In this section, demonstration of the pre-processing steps that include selection of appropriate contrast methods and performance assessment of this step is discussed. It is apparent that for building a generic system of eye problem detection, the images were subjected to pre-processing operations such as contrast enhancement. The purpose of the contrast enhancement is to increase the differential between the various segments of the images. Increasing the differential between the object's pixels that have higher values will attain higher intensity levels and the similarity of the lower-intensity pixels will acquire lower levels of intensity. This process is quite helpful when the segmentation process has to be done as an essential step. Therefore, technically it refers to any technique that uses a function to exaggerate the apparent difference between adjacent structures created during image processing. This helps characterize objects of interest, i.e., a characteristic that can hint at eye problems. Multiple algorithms are available in the image processing domain to improve the images' medical quality. These include histogram-based methods such as adaptive histogram equalisation and contrast

stretching (CS) methods such as min-max stretching. In the context of the problem undertaken, after a lot of experimentation and quality grading, it was found that the CLAHE method[36] is most suitable for the said purposes. The CLAHE method has step operations with which it increases the contrast. The first step divides the image into tiny regions and creates a local histogram for each region. A map of the local histogram is constructed. After this, a clipping point of the histogram is identified for each region. As the contrast process iterates, every region's noise is also reduced with the help of the subtraction method. The result is redistribution of the intensity values of the image. Table I gives the output of the CLAHE.

It can be observed from the comparison that the CLAHE algorithm produces better levels of differentiation between the various entities embodied in the fundus eye images. The selection of the CLAHE algorithm is based on the assessment of output given in the next section. It should also be noted that classical histogram equalization method was initially evaluated and it was found that dynamic or adaptive methods always perform better.

TABLE I. CONTRAST OUTPUT TABLE

Original Image(s)	CLAHE	1) <i>Min-Max Contrast Stretching</i>
(Healthy Original) 	Image I (Healthy 012) 	
(Glaucoma Original) 	CLAHE Image I (Glaucoma 01 ) 	
(Cataract Original ) 	CLAHE Image I (Cataract 007 ) 	
(Diabetic Retinopathy Original) 	CLAHE Image I (Diabetic Retinopathy 082 ) 	

It is difficult to objectively evaluate the quality of contrast that an algorithm may provide in photographs from a technical standpoint. The use of a subjective judgment of the image is more appropriate in these situations. The advantage is that domain experts will make decisions in accordance with the medical grade standard of care. Thus, two judges (Judge 1 & Judge 2) were assigned the task of evaluating four factors related to the quality of the images changed by contrast algorithms: distortion in the image, artefacts, noise and information gain that can be valued after the contrast enhancement operation. A questionnaire was developed, and judges assigned scores between 1 and 3 on a scale of 1 to 3. The number 3 indicates that there is no introduction of noise,

distortion, or artefacts as a result of contrast. The number 1 represents the presence of 100 percent noise, distortion, or artefacts in the freshly produced images. If a number 2 is assigned, the value signifies a 50 percent chance of noise, distortion, and artefacts occurring. The same is true for the factor information gain: one indicates that there is no information gain when the contrast algorithm is performed, and 3 indicates that there is a 100 percent gain in the information, indicating that the contrast transformation will be beneficial in better segmentation. There were two experts participated in the evaluation process, and the inter-rater agreement (using average score) between them was computed, since, there are four medical modalities the results are shown in Tables II, III, IV and V, respectively.

TABLE II. HEALTHY IMAGES (RANDOM SAMPLE = 25)

Healthy Samples CLAHE vs CS

TABLE IV. CATARACT IMAGES

Cataract Samples CLAHE vs CS				
	Factors	Judge 1 Mean Score	Judge 2 Mean Score	Average Score
CLAHE	Noise	2.68	2.64	2.64
	Distortion	2.92	2.68	2.8
	Artefacts	2.8	2.8	2.8
	Information Gain	2.76	2.8	2.78
CS	Noise	2.2	2.2	2.2
	Distortion	2	2	2
	Artefacts	2.2	2	2.1
	Information Gain	2	2.2	2.1

TABLE V. DIABETIC RETINOPATHY IMAGES

Diabetic Retinopathy Samples CLAHE vs CS				
	Factors	Judge 1 Mean Score	Judge 2 Mean Score	Average Score
CLAHE	Noise	2.8	2.68	2.78
	Distortion	2.8	2.8	2.8
	Artefacts	2.76	2.68	2.72
	Information Gain	2.88	2.88	2.88
CS	Noise	2	2	2
	Distortion	2.2	2	2.1
	Artefacts	2	2.4	2.2
	Information Gain	2.1	2.1	2.1

Observations from Table II to V demonstrate that CLAHE method is more effective than contrast stretching. In all healthy images, Glaucoma, Diabetic Retinopathy and Cataract, the evaluation shows the CLAHE method is the most stable and reliable algorithm for the said purpose. This may be attributed to the fact; the correct parameters were selected for

taking maximum advantage of the CLAHE algorithm. The parameters; Windows size = 8, Clip limit = 0.4, Bin size 255) of CLAHE and use of Rayleigh (alpha value = 0.35) based distribution for construction of the histogram yield a better output. Min-Max Contrast Stretching is intensity normalization; this is a typical well established pre-processing step taken by many researchers; nevertheless, in the current

context, it is performing not well as compared to the CLAHE method. In the case of Min-Max Contrast stretching intensity increases but loss of information/pixels is also happening. It is now time for extracting features from these quality enhanced image dataset. The coming section discuss the process of extracting and selecting appropriate optimization algorithm that produces highest possible accuracy of the detection system that is based on machine learning model.

### B. Optimization based Feature Engineering

It is possible to take full advantage of machine learning when one looks for recognisable patterns in large quantities of data. With conventional statistics, data consolidation and reduction is the key, and the quality of diversity of the data is given a lower mark. However, machine learning depends on extensive data and high levels of detail (think variety) (think columns or attributes). *Feature engineering* is used to get manual and automated analyses to speed up by adding more features/attributes and providing more details on existing data[37]. Feature analysis can help developers exploit and investigate data with more profound patterns. They are helpful for many machine learning procedures and vital to spot trends that can give real-time hints on diseases in our context. There are two main ways to expand features: ingesting more data after pre-defined features are created or training data to increase available features. The feature selection process includes selecting combinations of variables with large discriminative values to support the detection of various types of classes in the dataset.

As indicated in recent publically available literature assessments, critical variables for diagnosing eye abnormalities include an examination of the eyes' colour, texture, and form. The Gabor Filter was used to analyse the texture [38][39] and it was compared to a independent component analysis (ICA) method [40] for determining the most acceptable features in the image dataset. ICA assists in the discovery of a reduced projection picture or sub space of the original image with decreased dimensions. This reduces overhead while extracting the best feasible statistically independent information from each image. Additionally, ICA method encompasses a wide range of kurtosis and skewness values. The fixed objective function is determined by the differential equation (1).

$$f'(x) = (x-a) f(x) / (b_0 + b_1 x + b_2 x^2) \quad (1)$$

Where a, b<sub>0</sub>, b<sub>1</sub>, and b<sub>2</sub> are distribution parameters. When the source distributions are known (as they are in this scenario), the score functions are the ideal choice for the objective function. The Pearson ICA system's scoring function is defined as  $f'(x) = -f'(x) / f(x) = (x-a) / (b_0 + b_1 x + b_2 x^2)$ . The parameters a, b<sub>0</sub>, b<sub>1</sub>, and b<sub>2</sub> are estimated using the moments approach.

The Gabor filter helps to extract features of images by computing features at different frequencies and by changing the theta angle. This way features from multiple orientations and directions are extracted. Mathematically, it is computed using equation (2).

$$g(x, y, \lambda, \theta, \phi, \sigma, \gamma) = \exp\left(\frac{-x'^2 + \gamma^2 y'^2}{2\sigma^2}\right) * \cos(2\pi \frac{x'}{\lambda} + \phi) \quad (2)$$

Where

$$x' = x \cos \theta + y \sin \theta, y' = -x \sin \theta + y \cos \theta$$

After applying the Gabor filter and extraction of Gabor vector and ICA components, the dataset was transformed into a feature matrix of 1000x100 with the help of the reshape function of Matlab. This was done so that uniform sets of features are used from each image for machine learning. It is expected that as a result of application of these feature selection methods, the chosen features will have a smaller classification error and a higher degree of generalisation when machine models will be constructed.

The analysis for finding the best optimisation algorithm for feature selection depends on four performance factors. The first one is the coverage percentage: it constantly desired that it should be 100% so that no feasible area during the optimisation process is left uncovered to find the optimal solution to the problem. For example, the PSO is not a global optimisation algorithm [41]; hence, it cannot guarantee convergence to a local optimum. Due to this fact, the stability of the solution may be questionable. The excellent level of coverage is reflected in the accuracy parameter. The second performance analysis is about the computational time the optimisation solution takes to reach the most feasible solution. It is better to have feasible solutions fast. Then, the number of features that the algorithm finds useful is critical. It is generally expected that the lower the number of features, the lower is the overhead for the machine learning algorithms for building an appropriate solution.

All these optimization algorithms were executed using standard parameters values such as the number of iterations = 10 and solutions=100. Each algorithm has specific parameters that need to be configured before these algorithms can be executed. It can be observed from Table VI that cuckoo and LION algorithms [42] are most competent in terms of accuracy and number of selected features. However, it is better to use a hybrid approach and combination of the LION and cuckoo as it further reduces the overhead and keeps the accuracy levels a bit higher than individually using the LION or Cuckoo algorithm. The optimization algorithms' performance analysis shows that applying a hybrid algorithm helped obtain the best possible solution in terms of the number of features. The coverage of the hybrid algorithm is excellent, which lead to the selection of a feature matrix that has the lowest number of features (18).

The PSO, Whale Optimization and Marine Predator algorithm give a good level of accuracy (above 90%), but the number of features are more than the Hybrid approach. In the next section, however, an examination of the machine learning models will be done to ascertain the performance of classifiers using these selected features.

TABLE VI. FEATURE SELECTION USING OPTIMIZATION

S.No	Optimization Algorithm	Accuracy	Number of selected features
1	Cuckoo's	92.5	40
2	LION	87.14	28
3	Particle Swarm Optimization	95.7	64
4	Marine Predators	92.1	22
5	Whale Optimization Algorithm	90.9	20
6	<b>Cuckoo+LION (Hybrid)</b>	<b>98.9.0</b>	<b>18</b>

#### IV. RESULT AND DISCUSSION

The accuracy of machine learning entirely depends on the quality of data it processes for learning patterns of data. This section explains the procedure followed for finally automating detecting four medical conditions of the eyes. For automation, four classifiers (KNN, SVM (Radial), DT, RF) were chosen based on the previous work done by other researchers and organisations.

The feature matrix of eighteen numerical features was selected using a hybrid feature selection algorithm (Cuckoo and LION), and it was subjected to all the four classifier

models. However, The rigorous experimentation showed that the accuracy of the SVM radial after full hyper parameter search and tuning give 95% accuracy as shown in Table VII. Correspondingly, the recall and precision values are also high. The better performance of the SVM radial algorithm can be attributed to the fact that the feature engineering process is paying off here. Secondly, to evaluate the consistency and validation of all classifier models, the ten-fold validation process was followed, and the standard deviation of each metric was noted. From Table VII and Table VIII, it can be observed that SVM radial have the lowest standard deviation for almost all the metrics, including recall and precision.

TABLE VII. PERFORMANCE ANALYSIS OF MACHINE LEARNING MODELS

Metric   Algorithm	KNN	SVM (R)	DT	RF
Accuracy Cuckoo	0.84	0.88	0.84	0.80
Accuracy Lion	0.85	0.88	0.84	0.80
<b>Accuracy Hybrid</b>	<b>0.89</b>	<b>0.95</b>	<b>0.83</b>	<b>0.83</b>
F_ScoreCuckoo	0.87	0.89	0.83	0.82
F_ScoreLion	0.87	0.89	0.84	0.82
<b>F_ScoreHybrid</b>	<b>0.87</b>	<b>0.91</b>	<b>0.83</b>	<b>0.82</b>
PrecisionCuckoo	0.87	0.83	0.84	0.82
PrecisionLion	0.87	0.89	0.84	0.82
<b>Precision Hybrid</b>	<b>0.87</b>	<b>0.91</b>	<b>0.83</b>	<b>0.83</b>
Recall Cuckoo	0.80	0.84	0.83	0.82
Recall Lion	0.80	0.89	0.81	0.81
<b>Recall Hybrid</b>	<b>0.80</b>	<b>0.91</b>	<b>0.84</b>	<b>0.85</b>

TABLE VIII. STANDARD DEVIATION VALUES OF PERFORMANCE METRICS OF MACHINE MODELS

Metric   Algorithm	KNN	SVM (R)	DT	RF
Accuracy Cuckoo	0.047589	0.041732	0.055656	0.055328
Accuracy Lion	0.044991	0.040143	0.053754	0.056553

\*KNN=k-nearest Neighbours, SVM= Support Vector Machine, DT= Decision Tree, RF= Random Forest.

It can further be noted that the KNN algorithm is second best in terms of accuracy, and its performance metrics have higher levels of deviations compared to the SVM radial. Similar observations can be made for Decision tree and random forest algorithms. Both these algorithms have performed in a range of eighties per cent with higher levels of deviations in their results when evaluated for validations and reliability using the ten-fold method. It should be emphasised that the selection of these machine learning algorithms was made after conducting a bibliographic examination of the relevant literature. The methods that are most frequently employed to handle the challenges of classification and limited datasets have been incorporated into this book in their most basic forms. Because the dataset used in this study is an aggregate of various datasets, this research report includes a comparison of the dataset utilised in this study with the current dataset.

## V. CONCLUSION AND FUTURE SCOPE

There have only been a few studies in which numerous medical eye problems have been investigated using a single method. The same can be said for identifying relevant picture features using a combinational technique. It was completed through a rigorous procedure that included a great deal of experimenting. The process of developing a generic pipeline of algorithms to facilitate feature selection and automation of the classification process has been followed to completion. An in-depth investigation of the optimization process was carried out in order to identify the most appropriate features and methods that could be used for the construction of the feature matrix, and further investigation resulted in the development of a numerically stable pipeline of the algorithms. It should also be mentioned that the KNN method is the second most accurate algorithm in terms of accuracy, and that its performance metrics have larger levels of deviations when compared to the SVM radial algorithm. Observations similar to these can be made about the decision tree and random forest algorithms. When examined for validation and reliability using the ten-fold approach, both of these algorithms performed within an eighty percent confidence interval, with larger degrees of variances in their results than when evaluated for accuracy.

Following a review of the literature on three keywords, the researchers chose the machine learning models for this work. The keywords were data fusion, eye illness classifiers, and image processing of the eyes. The procedure of picking the most accurate and stable classifier among the candidates was carried out with the assistance of a ten-fold algorithm, which was used to narrow down the field of candidates. This guaranteed that no time was wasted later on while assessing different machine learning models in the field. When hybrid algorithms (Cuckoo and LION) are used for feature engineering and dimension reduction, it has been discovered that there are extra benefits, and that this results in the generation of matrices with decreased features but complete coverage. This research was conducted under the guidance of an exploratory experimentation regime, and it has been discovered that the SVM radial algorithm is the most suited machine-learning model for the development of a multi-modality system that can detect eye abnormalities. In addition,

it was discovered that some degree of hyper-parameter adjustment was required in some cases. After conducting an extensive grid search based on hyper-parameter tuning and feature engineering, it was discovered that the optimization strategy resulted in a higher accuracy level (0.95) for SVM than the previous approach.

In this study project, we attempted to develop a multi-disease detection system that would be capable of detecting three different forms of eye diseases: diabetic retinopathy, glaucoma, and cataract, among others. It is recommended that other diseases be added to the scope in the future, and that the detection range be broadened as well. This way, the scalability and generality of the model can be further strengthened.

## ACKNOWLEDGMENT

Authors are highly thankful to the RIC department of IKG Punjab Technical University, Kapurthala, Punjab, India for providing the resources and opportunity to conduct this research work.

## DECLARATIONS FUNDING

The authors received no specific funding for this work.

## CONFLICT OF INTEREST

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

## AVAILABILITY OF DATA AND MATERIAL

The data that support the findings of this study is publically available on [https://github.com/palavibhangu/retina\\_dataset](https://github.com/palavibhangu/retina_dataset)

## AVAILABILITY OF CODE

The code will be provided once the paper has been conditionally accepted.

# Educational Data Mining to Identify the Patterns of Use made by the University Professors of the Moodle Platform

Johan Calderon-Valenzuela, Keisi Payihuanca-Mamani, Norka Bedregal-Alpaca  
Universidad Nacional de San Agustín de Arequipa  
Arequipa, Perú

**Abstract**—Due to the events caused by the COVID-19 pandemic and social distancing measures, learning management systems have gained importance, preserving quality standards, they can be used to implement remote education or as support for face-to-face education. Consequently, it is important to know how teachers and students use them. In this work, clustering techniques are used to analyze the use, made by university professors, of the resources and activities of the Moodle platform. The CRISP-DM methodology was applied to implement a data mining process, based on the Simple K-Means algorithm; to identify associated groups of teachers it was necessary to categorize the data obtained from the platform. The Apriori algorithm was applied to identify associations in the use of resources and activities. Performance scales were established in the use of Moodle functionalities, the results show the use made by teachers was very low. Rules were generated to identify the associations between activities and resources. As a result the functionalities that need to be enhanced in the teacher training processes were identified. Having identified the patterns of use of the Moodle platform, it is concluded that it was necessary to use a Likert scale to transform the frequency of use of activities and resources and identify the rules of association that establish profiles of teachers and tools that should be promoted in future training actions.

**Keywords**—Clustering; educational data mining; moodle; usage patterns; k-means algorithm; a priori algorithm

## I. INTRODUCTION

The pandemic caused by COVID-19 brought with it a mandatory social confinement that forced societies to change customs and models and to face the need to enhance the use of technological tools to give rise to teleworking and tele education.

The face-to-face educational system necessarily migrated towards virtual teaching-learning environments, which generated new ways of understanding the educational process. Integrating information and communication technologies (ICT) to the educational process implies changes in the forms of communication, in the contents and forms of evaluation, changes in the role of the teacher and students, ICT can be used by teachers as technical-pedagogical support and by students as a tool for autonomous learning [1].

Although some educational institutions were gradually integrating ICTs as a means of enhancing their educational processes, in the context of the pandemic, many of them had

to abruptly assume, without considering the context of their educational community, the use of virtual scenarios to carry out their educational activities.

Although some educational institutions were gradually integrating ICT as a means of enhancing their training processes, in the context of the pandemic, many of them had to assume abruptly and without considering the context of their educational community, the use of virtual scenarios to carry out their training activities. In particular, universities had to adapt to this transformation by assuming educational models that use technological tools of support and accompaniment to improve conventional teaching and learning processes. Within these tools are virtual educational platforms or LMS (Learning Management System) that enable new teaching-learning modalities. For [2] in the b-learning modality, which combines face-to-face with non-face-to-face teaching, the LMS favors learning. In the e-learning modality, the use of Internet-based technologies provides a wide range of solutions that promote the acquisition of knowledge and development of skills [3].

Training processes in virtual environments imply changes in the roles of their actors, the student stops being a passive consumer and becomes a producer of information and knowledge; for [4], the students must be autonomous and independent in their information search skills, must create new content in an innovative way and transform it into knowledge and must communicate effectively by decoding messages and transmitting information. For his part, the teacher assumes the role of guide and incorporates technology adequately and effectively, that is, incorporating technological tools with a pedagogical approach [5].

In this information context, in order for students to achieve meaningful learning, the teacher must use the LMS tools to manage resources and activities in a way that enhances the autonomous work of the student and favors the development of competencies and skills such as search and organization of information, teamwork and communication with their peers and with the teacher. That is why this research focuses on improving university teacher performance and consequently student learning.

For the analysis and evaluation of the use of LMS, data mining is a tool that allows determining patterns of behavior in the data obtained from the platform and identifies the factors associated with the success of online learning [6]. In

[7, 8] they found that most works focus on the usability of LMS, limiting themselves to the student's role and neglecting the teacher's work process.

In [9] a statistical analysis is made of how mathematics teachers in a face-to-face model supported by the Moodle platform develop cognitive and action competencies in elementary school students. In [10] educational data mining is applied to the Moodle LMS to identify behavior patterns in students to identify the resources and activities that are best suited to the students' needs; it concludes that there is a correlation between the level of activity and their academic performance.

In [11], the authors investigated the use of Virtual Learning Environments by professors in a higher education institution; they sequentially combined three methods: processing of VLE logs, surveys, and interviews. In [12] data is collected in some Spanish universities to study the uses that university professors make of the virtual campus and the methodology they propose to students. The model of courses carried out concludes that the universities studied make minimal use of the platform and focus on making materials available to the student and that the model is characterized by the presence of basic, complementary, and organizational teaching materials, together with a proposal of individual and group activities.

Works such as [13, 14, and 15] have used the CRISP-DM methodology to implement data mining processes aimed at describing students' academic behavior.

In [16], the authors use data mining tools and techniques for academic improvement of the student performance and to prevent drop out. Four classification methods, the J48, PART, Random Forest and Bayes Network Classifiers were used, the data mining tool used was WEKA.

The authors in [17], propose two different guidelines: Learning Analytics focused on descriptive processes, and Educational Data Mining for predictive processes, directing activities adjusted to this environment for obtaining satisfactory results.

In light of the above, the objective of this work was to analyze the use of resources and activities of the Moodle platform, made by teachers at the National University of San Agustín de Arequipa (Peru). The importance of the work carried out is that based on the results obtained, recommendations can be made to enhance the use of this platform and favor the use of interactive and collaborative activities within the framework of a socio-constructivist pedagogical model.

## II. THEORETICAL FRAMEWORK

### A. LMS Moodle

Modular Object-Oriented Dynamic Learning Environment (Moodle) is a learning management tool or LMS developed to create and manage online training environments. Known by its acronym, Moodle is one of the most widely used content management systems globally. It provides a powerful set of learner-centered tools and collaborative learning environments that empower both teaching and learning.

Moodle fosters active and participatory virtual environments by enabling teachers and students to interact on the platform through chats, forums, videoconferences, among others. Consequently, it facilitates to the teacher the possibility of extending the limits of the classroom to spaces and moments different from the face-to-face class, it gives students autonomy to consult multimedia content and to interact and participate in learning communities [18].

### B. Educational Data Mining

Data mining is a set of techniques and technologies that, in an automatic or semi-automatic form, allows the exploration of large databases; the objective is to find repetitive patterns, trends, or rules that explain the behavior of the data in a specific context. Data mining involves the interaction of different techniques and procedures from computer science, statistics, mathematics, and information science. The extraction and analysis of data has become important in multiple areas, because through the application of various techniques, it allows to transform that data into information and knowledge of great utility [19].

In the educational field, there is talk of educational data mining (EDM); which focuses on the development of discovery methods that use data from LMS to understand and improve virtual teaching-learning environments. The EDM builds analytical models that uncover interesting patterns and trends in the use of an LMS [20].

### C. CRISP-DM Methodology

CRISP-DM (Cross Industry Standard Process for Data Mining) is a standard and open analytical model of the data mining process [21]. It includes a description of the phases of a data mining project, the tasks required in each phase, and an explanation of the relationships between the tasks. CRISP-DM provides an overview of the life cycle of a data mining process.

CRISP-DM divides the data mining process into six main phases (Fig. 1).

Fig. 1. CRISP-DM Phases. Source Shearer (2000).

The sequence of phases is dynamic; it is possible to move forward or backward through the phases. The result of each phase determines which phase, or which particular task of a phase, is to be done next. The arrows indicate the most important and frequent dependencies. The advantages of using CRISP-DM include replicability, independence of the application context, and its tool neutrality [22].

### III. MATERIALS AND METHODS

#### A. Context

The research was conducted at the National University of San Agustín (UNSA) in Arequipa, Peru. Traditionally it works under a face-to-face model supported by the use of the Moodle platform. The University Directorate of Information Technologies (DUTIC-UNSA) is the unit in charge of the administration and management of the Moodle platform, in addition, it provides training and technical support services to teachers and students.

As a result of the COVID-19 pandemic, the UNSA migrated towards a mixed model in which face-to-face sessions are carried out through a videoconferencing system and arranged the mandatory use of the Moodle platform to dynamize and enhance the training process.

#### B. Methodology

Cross-sectional descriptive-exploratory research has been carried out.

To develop the data mining process, the steps of the CRISP-DM methodology have been followed.

#### C. Data

The study considered a universe composed of 4809 virtual classrooms implemented in the 2020-A academic semester. These classrooms correspond to the three academic areas of the UNSA: engineering, social and biomedical.

### IV. DEVELOPMENT OF THE PROPOSAL

#### A. Phase 1, CRISP-DM Methodology: Understanding the Business

Tasks related to understanding project objectives and requirements were performed to turn them into technical objectives and a project plan.

Objectives: This research focuses on analyzing the use that teachers make of the activities and resources available on the Moodle platform. It is intended to:

- Investigate if there are differences in use between the three academic areas: Natural and Formal Sciences and Engineering, Social Sciences and Biomedical Sciences.
- Identify associated groups of teachers in the use of resources and activities using the Unsupervised Learning Algorithm Simple K-Means.
- Identify associations in the use of resources and activities using the A-priori association algorithm.

Resources:

- Technological: Computer, Google Collaboratory platform in Python language for data processing and model development.
- Technical: Data mining techniques.
- Human: The Researchers.
- Data source: Moodle platform usage logs during the 2020-A Academic Semester.

#### B. Phase 2, CRISP-DM methodology: Understanding the Data

A first contact with the data was made to familiarize themselves, identify their quality, define the first hypotheses and establish the most obvious relationships.

1) *Data collection*: The data was obtained from the records of the Moodle platform. For the data to have meaning it was necessary to integrate different tables. The "teacher" table with the correlative code of each teacher and their full name. The "course" table contains the correlative code of each virtual classroom, the short name and the full name of the corresponding subject. Both are related through the "course\_teacher" table. The "resource\_activities" table contains the number of times that the 13 activities and 7 resources available on the virtual platform have been used. This table relates to "course\_teacher" through the course and teacher correlates. Fig. 2 shows the entity-relationship diagram of the integration performed.

2) *Verification of data quality*: Initially, the database considered the 4809 classrooms configured on the virtual platform. Data was cleaned considering that some classrooms had not been used or had not been assigned a teacher; 2 duplicate teacher records were deleted, 219 classrooms that had the Teaching field blank, and 335 classrooms that had less than or equal to a resource or activity used. As a result, we worked with data from 4255 classrooms.

Fig. 2. Entity-relationship Diagram.

3) *Data exploration*: The use of classrooms was analyzed for each academic area, Fig. 3 shows the percentage of classrooms implemented and the number of teachers who were in charge in each of them. The differences found are explained by the number of professional schools that are integrated into each academic area.

At UNSA, the academic areas are divided into Schools and these into Professional Schools. Table I shows the number of virtual classrooms implemented in the different schools, as well as the number of professors administered them.

Tables II and III show the frequency of the use of Moodle resources and activities in each academic area and the amount of total usage.

Fig. 3. Classrooms Percentage and Number of Professors in each Academic Area.

### C. Phase 3, CRISP-DM Methodology: Data Preparation

In this phase, the necessary activities are carried out to build the data set that will serve for the modeling.

Each classroom was evaluated according to the frequency of use of each activity and resource. Finally, only the activities or resources used in at least 97% of the classrooms in each area were considered (Tables IV and V).

Consequently, in the academic area of Social Sciences ten tools were considered: Attendance, Chat, Questionnaire, Forum, Glossary, Task, File, Folder, Label and URL.

In the Engineering area, eleven tools were included: Assistance, Chat, Questionnaire, Forum, Glossary, Task, File, Folder, Label, Page and URL.

In the area of Biomedical Sciences, twelve tools were considered for the study: Attendance, Chat, Questionnaire, Forum, Glossary, Pdf Annotator, Task, File, Folder, Label, Page and URL.

In order to complement the information, Tables IV and V show the number of classrooms that have never used the activities or resources indicated by area of knowledge.

Task	70	226	255
Wiki	437	1827	1948

Calculated the frequencies of use of the Moodle functionalities, it was found that the values were very dispersed so it was necessary to reduce them. Considering that scale transformations are efficient instruments for reducing a data set, it was decided to transform the values from numeric to nominal.

On the cleaned data, the maximum and minimum values of the frequency of use of each activity and resource were identified. With these values the range was calculated and divided into five parts of equal length, obtaining the values to construct a five-level Likert scale. The scale values and weight of each level assigned were:

- 0 = Very low
- 1 = Low
- 2 = Medium
- 3 = High
- 4 = Very high

*D. Phase 4, CRISP-DM Methodology: Modeling*

In this phase, the most appropriate modeling techniques are selected for the specific data mining project.

The Simple K-Means classification algorithm was applied, using the elbow method. It was looked the part of the graph

where the line changes abruptly which forms an "elbow"; that number of clusters will help when classifying the data. The appropriate was 30 iterations to determine the optimal number of clusters, obtaining  $k = 5$  (Fig. 4).

The objective was to group similar observations and discovers patterns in the use of Moodle resources and activities in the transformed data based on the Likert scale.

It was worked with 4255 classrooms; each classroom has 30 fields including: area, faculty, school, course, teacher, activities and resources. Each classroom has the amount of resources and activities used numerically, therefore the Likert scale was applied to have a standard score from 0 to 4 with respect to usability; then, we eliminate columns that are not going to be trained, the data set used consists of 20 fields between activities and resources, which will be grouped using the K means algorithm, resulting in 5 groupings, cluster 1, 2 and 4 have less usability, cluster 5 has a medium usability followed by cluster 3 (Fig. 5) and Table VII.

To identify associations in the use of resources and activities, the A-priori association algorithm was applied in each academic area.

First, we converted the data into 0's (activities and resources with score 0) and 1's (activities and resources with score 1,2,3 and 4) to work the model.

Fig. 4. Elbow Method to Determine the Optimal value of k.

Fig. 5. Clusters Determined by Simple K-Means.

In the social area, associations were obtained with the tools file, URL, and task. In the biomedical area, associations were obtained with the questionnaire, homework, URL, and attendance. However, in the engineering area no association was found; therefore. Due to these differences, it was decided to perform the process again with the total data set.

Considering the definition of support given by [23], the association rules were constructed with a minimum support of 0.8; increasing the number of associations, where the following is true: antecedent = is used => consequent = is used, the probability of each association is observed in the "Confidence" column, the Lift column shows the increase in the probability of use when considering both tools rather than only the antecedent tool. (Table VI shows the results).

TABLE VI. ASSOCIATIONS FOUND WITH THE APRIORI ALGORITHM

Antecedent	Consequent	Support	Confidence	Lift
URL	file	0.840	0.988	1.009
forum. URL	file	0.810	0.987	1.009
task	file	0.859	0.987	1.009
task, forum	file	0.830	0.987	1.008
task	file, forum	0.830	0.954	1.008
URL	file, forum	0.810	0.953	1.008
File	task	0.859	0.878	1.009
file, forum	task	0.830	0.877	1.008
file	URL	0.840	0.858	1.009
file, forum	URL	0.810	0.856	1.008
file	file, forum	0.830	0.848	1.008
file	forum, URL	0.810	0.828	1.009

### V. RESULT AND DISCUSSION

When analyzing Tables II and III, it can be affirmed that the resource "File" has been used primarily, followed by the resource "URL"; it follows then, that the virtual classroom is being used primarily as a repository of content and links to web content. Likewise, the activity "Homework" has been mostly used, followed by the activity "Questionnaire"; which means that the virtual classroom is being used to collect assignments and make assessments through questionnaires.

Table VIII (at the end of the paper) shows the results obtained by applying the Simple K-Means algorithm to the processed data. The nominal values of the Likert scale were considered for each of the tools in the clusters, since the distribution of the frequency of use is asymmetric, the value of the model was taken as a representative measure. Table VIII also shows that the teachers' use of Moodle activities and resources was classified with very low performance. Although this situation differs slightly in the areas of Social Sciences and Biomedical Sciences, it was found that in Engineering there was not enough support to find association rules.

There are no reasons to assume that teachers do not know how to use the different functionalities of the virtual platform; however, these results suggest the need to reinforce teacher training in the use of the activities and resources provided by Moodle. The training process should focus on the use of the virtual platform as a support to the synchronous sessions conducted by the teacher so that learning outcomes are enhanced through the implementation of active teaching-learning methodologies that can be easily implemented with the functionalities provided by Moodle [24,25,26].

Table VII shows the association rules obtained as a result of applying the Apriori algorithm to the cleaned data corresponding to the three academic areas. The association rules relate to the use of Moodle activities and resources.

TABLE VII. ASSOCIATION RULES OBTAINED FROM THE APRIORI ALGORITHM

#	Rules of association	Interpretation in Natural language
1	URL = is used=> file= is used	If the URL tool is used in the classroom, then the file tool will be used.
2	forum, URL = is used => file = is used	If both the forum and URL tools are used in the classroom, then the file tool will be used.
3	task = is used => file = is used	If in the classroom the task tool is used, then the file tool will be used.
4	task, forum = is used => file = is used	If both task and forum, are used in the classroom, then the file tool will be used
5	task = is used=> file, forum = is used	If in the classroom the task tool is used, then the file and forum tools will be used.
6	URL = is used => file, forum = is used	If the URL tool is used in the classroom, then the file and forum tools will be used.
7	file = is used => task = is used	If the file tool is used in the classroom, then the task tool will be used.
8	file, forum = is used => task = is used	If in the classroom the tools file and forum are used, then the task tool will be used.
9	file = is used => URL = is used	If the file tool is used in the classroom, then the URL tool is used
10	file, forum = is used => URL = is used	If both the file and forum tools are used in the classroom, then the URL tool will be used.
11	file = is used => task, forum = is used	If the file tool is used in the classroom, then the task and forum tools will be used.
12	file = is used => forum, URL = is used	If in the classroom the file tool is used, then the forum and URL tools will be used.

Association rules have been generated and they have allowed the identification of associations between activities and resources, rules that give evidence of the activities and resources that need to be enhanced in the teacher training processes. For example, from rules 5, 6, and 11 it can be inferred that if the teacher uses the task activity and the resources file and forum, then it is very likely that he/she will implement discussion forums among the activities to be implemented in the virtual classroom; therefore, he/she will not only be imparting knowledge but also supporting the development of communication skills and critical thinking.

## VI. CONCLUSION

With the development of this work, it was possible to identify the behavior patterns of university professors in the use of the activities and resources offered by the Moodle platform.

The use of a Likert scale to transform the frequency of use of activities and resources allowed to reduce the spectrum of values and to be able to find associations when applying the K-Means algorithm; using the elbow method with 30 it was determined that the optimal was to work with 5 clusters.

The activity of the teachers was characterized and it was found that the activities: chat, wiki, lesson, workshop, questionnaire, games and survey are not used despite their great potential as didactic material that can enhance the results of the teaching and learning processes.

The results obtained in this work will serve to implement teacher training processes focused on the proper use of Moodle activities and resources that allow the development of virtual or blended courses based on constructionist and social constructivist approaches.

Applying data mining techniques to the large amount of information generated by the Moodle platform can contribute to the creation of dynamic profiles in the development of a virtual course. In addition to improvements in the teacher's use of resources and activities, students' behavior patterns could be considered in order to adapt courses to their level of learning.

# Assessing the Quality of Educational Websites in Sudan using Quality Model Criteria through an Electronic Tool

Asim Seedahmed Ali Osman  
College of Computer Science and Engineering  
University of Hafr Al Batin, Hafar Al Batin, Saudi Arabia

**Abstract**—The application of internet has grown in recent years. Due to this, there is an increase in the number of websites which creates diversity in the services. This leads the researchers to do more research in the quality of websites in order to set standards and models to maintain its quality. The main objective of these standards is to support the trust and speed which is the cornerstone which are the basis for using websites. Various statistics reports show that the sites of institutions and companies which applied the quality standards have achieved high rates in terms of the user satisfaction and the number of visitors. This study has incorporates the concept of website and electronic gates, its objectives, advantages, types and in addition to its quality and standards of e-websites. It also touched on previous studies conducted on website in the world, the Arab world and African peninsula and also in the Sudan in support of the development of Sudanese websites. The proposed models consist of important metrics to evaluate the application, quality of content, aesthetic aspects, multimedia, reputation and security etc. This paper also proposed an application for evaluating the quality of websites based. This model is applied on Sudanese websites such as governmental, educational, and commercial etc. The authors used the object oriented programming approach to build the proposed model using the PHP language with the combination of CSS and Java script.

**Keywords**—Website quality; e-websites; education; information technology; PHP language

## I. INTRODUCTION

Information Technology plays an important and tangible role in our scientific life. Many institutions have adopted the use of it and are considered as a mediator in the learning and communication process in universities. This improves and develops the product of education and its implementation for various programs or sites. This also helps the students to join these educational institutions. In this paper, a new methodology is proposed to evaluate the various educational website in different universities present inside the Sudan.

The educational website of various universities contains different entities such as the main pages of various site, the glimpse about the respective university, its vision, mission, various colleges and its departments etc [1]. It also consists of main page of the course, information about the course, information about the faculty members who are working in the particular college, the announcements and video meetings, topics related to homework, study materials and activities,

course content and electronic reference list, information about virtual classes, events done in the conference rooms and the explanations about synchronous and asynchronously communication etc.

The universities faced various problems during the instance of providing the important components of website, especially at the process of evaluating the educational websites of Sudanese universities at the international level [3]. The evaluation process may be carried out low often due to the lack of control and failure to considering some requirements of quality. This is due to the non-application of international quality standards such as (ISO),(OSI) [4] which are the set of internationally recognized technical specifications used for the purpose of evaluating the websites. It can be done in order to operate the production and commodity processes, models, performance and management, which includes the esthetically aspects etc. Content Quality Standard is done in the search engine, information guide, maps and automatic updating for site where, the site also requires a standard Multimedia which is represented by video, audio and motion systems which make the site more attractive, smoother interaction, smoother in clarify the content etc.

The main aim of this research it is study the analysis part of the various Sudanese educational websites [4] using different quality standards for the purpose of assessing the quality of educational sites and along with its services. This paper also indents to develop a comprehensive framework model which contains all the main quality elements and accompanying indicators for accessing a quality of website discussed in previous researches. Based on the previous researches, we proposed this paper to achieve the following goals:

- To define of quality standards for educational website.
- To define the standards and quality models for educational websites.
- To apply various standards of quality to Sudanese educational websites.
- To disseminate and support the Sudanese e-government and to perform its services with high efficiency and interactivity.

- To propose a model for evaluating the quality of educational websites based on appropriate standards and measurements for determining its quality.
- To improving the work environment and to change the quality of performance of Sudanese educational websites.
- To improving the confidence of customers using these educational websites.
- To make decisions based on real information from educational websites.
- To create websites in an integrated way to develop the product of education.

In order to achieve these goals, it is necessary to design a form for evaluating the educational websites [7] by knowing the performance quality of these educational websites of Sudanese universities. The form allows the entry of an educational website URL for the university and the evaluation is carried out by the user and the system administrator by clicking the evaluation button. The site is evaluated based on the calculations and equations of the quality criteria that have been mentioned. It shows the evaluation result and the outcome of each websites evaluation in addition to a graph showing values of criteria. There are also details about the reports of evaluation when selecting evaluation details of websites.

Remainder of the paper is summarized as follows. Section 2 depicts the review of various methods for accessing the quality of normal websites and also the educational websites. Section 3 provides an attribute of the proposed methodology with its functional architecture and its working principle. Section 4 explains the various criteria for evaluating the quality of website along with its working principle and various formulas. Section 5 proposes the evaluation results for various university websites present in the Sudan. Section 6 shows the conclusion of this paper.

## II. LITERATURE REVIEW

Recently, the internet has created a new environment enabling any organization to conduct its entire set of processes and practices of business especially through online [1]. E-learning and its associated activities is any process performed via an Internet-based, computer-mediated network [2]. There are many categories of e-learning which tend to be used interchangeably leading to policy incoherence. Majority of these learning practices were done by the application of Websites.

Web based artifacts have been developed over the past few years. The increasing acceptability of websites increases the challenges, for instance, in knowing or assessing where we are standing regarding the quality of product, and how it can be improved [3]. However, there is still no methodology which is widely recognized as quantitative process for the evaluation of quality of websites. One of the main goals in the evaluation of website is qualitative and comparison based process. This is done in order to understand the entire process which a set of quality characteristics and attributes etc. Various methods

have been proposed by earlier researchers [4-10, 20] in this process.

Authors in [11] proposed a quantitative evaluation approach to assess the websites quality called Website Quality Evaluation Method (QEM). This approach might be useful to evaluate and compare characteristics quality and attributes of a Web product lifecycle in different phases. Particularly, the authors evaluated their proposed methodology in six academic websites sites. At the end of the evaluation process, a ranking is obtained for each selected site. Specifically, the evaluation process generates elemental, partial, and global indicators or quality preferences that can be easily analyzed, backward and forward traced, justified, and efficiently employed in decision-making activities.

Educational websites are analyzed in different perspectives. Authors in [12] developed a theoretical based framework for evaluating the quality of website from the perspective of user satisfaction. Other researchers concentrated on some specific features of websites such as authors in [13] developed a framework to measure the importance of usability of websites, while authors in [14] investigated and evaluated the design of university websites. Other researchers, while assessing the websites of universities considered various other features. Authors in [15] designed criteria to evaluate the resources of websites for maximum utilization of the scholarly context and research within the area of the art and history. Authors in [16, 19] tried to find solutions to problems among the user and involved evaluating various university websites inside the South African based on certain factors.

Author in [2] emphasized the learning practices by the application of various websites. Authors in [1] stress the importance of E-learning and its associated activities through the intern and on-line based applications. Website Quality Evaluation was done by [11] where, the characteristics quality and attributes of a Web product lifecycle in different phases were evaluated and compared. It can also be used in the decision making activities. User satisfaction is considered by authors in [12]. They proposed a theoretical based framework for evaluating the quality of website based on the user satisfaction. Usability of websites was considered and a framework was developed for it by authors [13]. Their framework also empathizes to define the standards and quality models for various educational websites. The main drawback behind their framework is applied only for the educational websites. Authors in [16, 19] found various solutions to problems among the user of various university websites inside the South African based on certain factors. Main drawbacks of their works is it is applies only inside the South African University websites.

## III. PROPOSED METHODOLOGY

Authors developed a standard which depends on various ISO based Quality model for assessing the quality of educational websites. It is divided into six levels based on their different purposes and topics. It is further directed to evaluate the sites particularly belongs to the Sudanese educational institutions. Various criteria proposed in [18] were applied in the proposed model. The proposed quality model

shown in Fig. 1 includes various metrics which represents the frameworks for determining the quality of the educational website in terms of its content, structure and presentation. These metrics are as follows:

- Aesthetics
- Ease of Use
- Rich Contents
- Multimedia
- Reputation
- Security

A. Aesthetics

Aesthetic aspects of an element maintain a fundamental importance in evaluating the quality of websites since, it leaves a positive impact for the visitor of the educational website. It works on by monitoring the interaction between the user and the educational website. It also monitors some aspects of the Human-Computer-Interaction (HCI) [17] branch and also by the incentives to interact with the site such as availability which includes:

- Image: 40%.
- Colors taken 20%.
- Tables and text, backgrounds, etc.
- Resolution and standard Table takes 40%.

The aesthetics scale is calculated based on the following equation:

$$\text{Aesthetics} = \text{images} * 0.4 + \text{tands} * 0.2 + \text{color} * 0.2 + \text{underline} * 0.2 \quad (1)$$

B. Ease of Use

One of the most important problems in the factor for ease of use is the measurement of Usability is for websites or for the products of software etc. Various criteria or models have been proposed earlier for measuring and assessing the usability within societies interacting between human being and the software engineering based societies.

This metric contains of various sub-metrics like:

- The Navigation offer consists of 30%.
- Annotation alerts and routers consist of 30%.
- CSS consists of 40%.

The scale for ease of use is calculated based on the following formula:

$$\text{Ease of Use} = \text{cssl} * 0.4 + \text{nav} * 0.3 + \text{ann} * 0.3 \quad (2)$$

C. Rich Contents

The quality of the website contents can be described by the availability of various elements such as:

- Search Engine, which takes 20%.
- Graphs, which takes 30%.
- The Information Guide, which takes 30%.
- Avoiding Auto-refresh, which takes 20%.

Other elements that make the website more responsive to the requests of visitors and users fall under the content quality scale. It can be calculated based on the following formula.

$$\text{Rich Contents} = \text{bulletin} * 0.3 + \text{guide} * 0.3 + \text{searchenginge} * 0.2 + \text{autorefresh} * 0.2 \quad (3)$$

D. Multimedia

Multimedia represents the video and audio elements, movement systems etc. When these elements were used inside the site, it will make the website more attractive, interactive and smoother in terms of working. The multimedia elements such as sound and image can be appropriate as content of the site. This can be as follows:

- One Media in one Page takes 30%.
- Using thumb mails takes 30%.
- Attributes of multimedia and its components take 10%.
- Plug-in support takes 30%.

The vision differs from the aesthetic aspects and ease of use of application. The multimedia scale is calculated based on the following formula:

$$\text{Multimedia} = \text{plugin} * 0.3 + \text{thumbnail} * 0.3 + \text{attribute} * 0.1 + \text{minone} * 0.3 \quad (4)$$

Fig. 1. Various Criteria of the Proposed Model.

E. Reputation

The reputation of a website defines the extension of reliability of it and the extent of interaction which is accepted by the environment for which it is directed or by the local, regional or international bodies. These are accredited to measure the quality of the websites which covers the following:

- Web Traffic efficiency takes 30%.
- Customer Feedback takes 30%.
- Information and Publicity takes 20%.
- Domain Name takes 20%.

The reputation scale is calculated based on the following formula:

$$\text{Reputation} = 0.3 * \text{feedback} + 0.2 * \text{domain} + 0.3 * \text{traffic} + 0.2 * \text{publicity} \quad (5)$$

F. Security

Information security plays an important role in the protection of assets of an institution. We often hear about security incidents of information security, such as site distortion, server piracy, and data leakage etc. Hence, there is an urgent need to devote more resources to protecting information assets. It is as follows:

- The login mechanism takes 40%.
- The firewall takes 30%.
- User display levels and usage of session variables when interacting with the site takes 30%.

The security scale is calculated based on the following formula

$$\text{Security} = 0.3 * \text{firewall} + 0.3 * \text{sesion} + 0.4 * \text{login} \quad (6)$$

IV. IMPLEMENTATION OF THE EVALUATION REPORT SCREEN

Following are the various outputs of evaluation reports done in different types of Sudanese educational websites. Implementation of the evaluation details screen is shown in Fig. 2 which is one of the implementation result of the proposed system.

Fig. 2. Implementation of the Evaluation Details Screen.

The above figure depicts the implemented image of the evaluation details screen with all the details of the evaluation of the website, details of all standards such as aesthetics and multimedia, quality of content, reputation, ease of use and security etc.

Fig. 3. Implementation Screen of the Content Quality Details.

Fig. 3 shows the implementation of the content quality and the details screen. It has various criteria for measuring the quality of the content in addition to the value of the criterion in the evaluation of result of the actual website.

V. EVALUATION RESULTS OF VARIOUS EDUCATIONAL WEBSITES

The proposed system is tested for the various Sudanese educational websites. The following diagrams represent the evaluation results of the various educational websites. Fig. 4 evaluation results of (www.neelain.sd), Fig. 5 evaluation results of (www.sustech.edu), Fig. 6 evaluation results of (www.uofk.edu), Fig. 7 evaluation results of (www.uofg.edu.sd), Fig. 8 evaluation results of (www.aau.edu.sd), Fig. 9 evaluation results of (www.siu-sd.com), Fig. 10 evaluation results of (www.bahri.edu.sd), Fig. 11 evaluation results of (www.iau.edu.sa), Fig. 12 evaluation results of (www.oiu.edu.sa), Fig. 13 evaluation results of (www.mu.edu.sd), Fig. 14 evaluation results of (www.usd.edu.sd) and Fig. 15 evaluation results of (www.ribat.edu.sd).

The final evaluation of educational websites is calculated based on the following formula:

$$E.W=0.1*tot\_aesthetic+0.3*tot\_easeofuse+0.1*tot\_multimedia+0.1*tot\_richcontent+0.2*tot\_reputation+0.2*tot\_security. \quad (7)$$

- The scale of aesthetics, obtained from the sum of its sub-elements, takes the 10%.
- The measure of ease of use resulting from the sum of its sub-elements takes the 30%.
- The quality measure of the content generated from the sub-component takes a total of 10%.
- The resulting multimedia scale takes the 10% of its subgroups.
- The reputation scale obtained from the sum of its sub-elements is 20%.
- The resulting security measure takes 20% of the sub-component totals.

Table I depicts the Sudanese educational sites and its various evaluation results based on the proposed model. In this method, the authors took a sample of the Sudanese educational websites and evaluated them and put them in the form. The numbers that express the number of websites, for ease of presentation, the comparison and the analysis. This comparison is done after analyzing it through the following table. This will lead us to reach the various deficiencies in the educational sites in order to take care of them and then to address them.

## VI. CONCLUSION AND FUTURE ENHANCEMENTS

The Internet has shown a rapid growth in terms of education which led to a new definition of almost all aspects of teaching. The Internet created a new teaching environment far different from anything that has come before. The explosion of the web has determined the need of measurement criteria to evaluate the aspects related to the quality of educational websites. Awareness of issues in quality issues has affected every websites in recent years, since an educational organization with a website is difficult to use and interact with gives a poor image on the Internet and weakens the position of it. Hence, it is important for a website especially the educational website to assess the quality of its e-service, in order to improve its quality. This paper proposes general criteria for evaluating the quality of Sudanese educational website in various evaluation criteria such as Aesthetics, Ease of Use, Rich Contents, Multimedia, Reputation and Security are depicted in detail long with its formulas. These criteria can be used by web site developers and its designers to create and to maintain the quality of educational websites do that the electronic service can be easily improved.

**Abstract**—With an increasing adoption of Internet-of-Things (IoT) over massively connected device, there is a raising security concern. Review of existing security schemes in IoT shows that there is a significant trade-off due to non-adoption of inter-domain routing scheme over larger domain of heterogeneous nodes in an Internet of Things (IoT) via gateway nodes. Hence, the purpose of the proposed study is to bridge this trade-off by adopting a new security scheme that works over an inter-domain routing without any apriori information of an attacker. The goal of the proposed framework is to identify the malicious intention of attacker by evaluating their increasing attention over different types of hop links information. Upon identification, the framework also aims for resisting attacker node to participate in IoT environment by advertising the counterfeited route information with a target of misleading the attackers promoting autonomous self-isolation. The study outcome shows proposed scheme is secure compared to existing scheme.

**Keywords**—Internet-of-things; security; inter-domain routing; gateway node; attacker

## I. INTRODUCTION

Internet-of-Things (IoT) is one of the evolving technologies toward data acquisition and controlling of large number of objects, digital and mechanical machines, computing devices, etc. without any form of dependencies toward human intervention [1]. Owing to the connection of different types of devices (or machines), there is an increasing security threats [2]. The first security threat in IoT device is inappropriate access control due to usage of same default password as the underlying firmware basically runs a default setting of all IoT devices of same model [3]. The second prominent threat is there is a larger base of attacker as different number of machines is connected over internet with an open port [4]. As IoT has an inclusion of large number of connected machines so eventually it suffers from regular updating of software. Conventional IoT device doesn't uses sophisticated encryption process and hence it gives rise to man-in-middle attack and denial-of-service attack in IoT [5]. Absence of reliable and trusted operating environment is another reason behind the security threat which often gives rise to privacy preservation issues. Due to usage of large number of machines, it is less feasible to offer reliable physical security towards IoT device. Apart from this, the conventional IoT nodes perform communication using various types of routing protocols [6] while Datagram Transport Layer Security (DTLS), Internet Protocol Security (IPSec), and Routing Protocol for Low-Power and Lossy Networks (RPL) are known to offer security.

However, there are different ranges of literatures which have reported of security pitfalls in existing routing protocols in IoT. Out of all this, one elementary concern is that IoT which runs on heterogeneous nodes doesn't seem to consider adopting inter-domain routing protocols. At present, there are such protocols reported to work over internet, however, they were never meant to be functional over IoT architecture, which is more complex form of architecture to be used in Future Internet Architecture [7][8]. Some of the challenges of implementing inter-domain routing scheme in IoT are as follows: i) developing a routing strategy among different forms of devices with multiple roles is definitely not an easy task considering the massiveness of the network, ii) developing both centralized as well as decentralized trusted authority connected to gateway node in IoT is one of the tedious task to be accomplished, iii) existing firewall system in IoT application is dependent on definition of patch and hence they are incapable of identifying new form of threats that are not defined in firewall system, iv) usage of conventional encryption process also comes with different forms of operational and communication challenges over resource constrained IoT devices [9]. All the above reasons serves as a motivation factor as well as reason towards develop a robust security protocol which is compliant of inter-domain routing as well as which is computationally efficient for practical implementation of complex environment of an IoT. The primary objective of the proposed manuscript is to introduce a novel solution where hop-based behaviour for all the nodes are observed to identify the malicious intention of attacker node, assuming its originality is unknown to the system. The secondary objective of proposed study is to resist attack in the form of novel inclusion of guard node. This new variant of node is meant to offer forged information of routes to attacker node in order to force them to accept the wrong direction of data dissemination. The objective of this operation is to ultimately results in either exclusion of attacker or their complete drainage of resources.

The organization of this manuscript is as follows: Section II discusses existing literatures of secure communication in IoT followed by discussion of research problems that are identified to be addressed in proposed study in Section III and proposed solution towards resisting unknown threat using inter-domain routing in IoT is briefed in Section IV. Section V discusses about algorithm design and implementation for secure route formulation and resisting malicious node participation followed by discussion of result analysis in Section VI. Finally, the conclusive remarks are provided in Section VII.

## II. RELATED WORK

This section presents a briefing of the existing research implication being carried out towards securing communication in IoT as a continuation of our prior study [10]. The recent study carried out by Yilmiz et al. [11] have presented a discussion of a machine learning approach for securing IoT device using Routing Protocol for Low-Power and Lossy Network (RPL) protocol. Yazdinejad et al.[12] have used blockchain-based method for securing software defined network in IoT in the form of clustering. Study towards prevention of intrusion event is carried out by Haseeb et al. [13] considering the case study where sensors are used in IoT considering multi-hop routing and blockchain-based scheme. The work of Mick et al. [14] has presented a unique authentication scheme considering named data networking adhering to the concept of hierarchical routing. The work carried out by Xu et al.[15] have presented a secure routing scheme for resisting jamming attacks in IoT using game theory for exploring the optimal secure path for data delivery. Raof et al.[16] have presented discussion of existing threats and countermeasures exclusively towards frequently used RPL protocol in IoT. Haseeb et al. [17] have presented a security scheme where secret shares has been used for data communication with energy efficiency. Usage of reinforcement learning scheme has been noticed in work of Guo et al. [18] to ensure balance between security and quality of service at same time. Raof et al.[19] have presented an improved security scheme for RPL when subjected to different forms of attacks in IoT. The work carried out by Shin et al.[20] have developed an optimization mechanism for routing process in IoT focusing on securing authentication process. Wadhaj et al.[21] have developed a preventive technique towards attack on IoT device using RPL protocol with a target to maximize the reliability score of attacker identification process. Saleem et al.[22] have used a bio-inspired approach towards securing IoT communication over 5G. Ramos et al.[23] have carried out an investigation toward analyzing security aspects of resource-constrained IoT devices using probabilistic model. Liu et al. [24] have implemented a scheme towards resisting sink hole attack in IoT using probing routes considering consumption of network energy. Usage of geometric-based communication scheme anonymously is presented by Sun et al.[25] where hashing-based encryption has been utilized to ensure data privacy. Haseeb et al.[26] have presented a trust-based security scheme for mesh network in IoT considering cost of link and dissemination of data. Similar scheme has been carried out by Jhaveri et al.[27] towards trust-based security in IoT focusing on identifying the pattern of attack. Sathyadevan et al. [28] have introduced an authentication scheme using key generation technique exclusively meant for edge computing IoT device. Trust-based security scheme using provisioning approach was presented by Dass et al. [29] considering transport system in IoT. Agiollo et al. [30] have presented a unique scheme of identification of routing attack when standard RPL is deployed in IoT. Hence, there are different variants of security scheme toward safeguarding communication system in IoT. A closer look into all the above research implication has proven its substantial benefits from security perspective; however, they are highly symptomatic in nature of attack and is also

associated with various limitation. The next section outlines the identified research problem from the above stated literatures.

## III. RESEARCH PROBLEM

The discussion of the research problem is carried out with respect to observed limitation and research gap as briefed below:

### A. Limitation

The limitations that have been identified in proposed study are as follows:

- Existing security techniques towards IoT mainly uses either trust-based, or machine learning, or block chain in increasing pattern, which are sophisticated process for low resource IoT device.
- All the existing schemes has a well definition of attack and their strategy to initiate an attack is well known prior implementing security scheme.
- There are no reported study towards identification of threats on the basis of hops and malicious behaviour of attackers in heterogeneous nodes in IoT.
- There are no reported inter-domain routing scheme in IoT apart from the standard routing scheme which are exercised from long time.

### B. Research Gap

The prime research gap of existing system is that with an increase of dynamicity and uncertainty in attack behaviour, existing security solutions over an IoT are yet not equipped to meet security demands both from hardware, software, and network perspective. The prime justification behind this research gap is that-it can be seen that there are various ranges of literatures that emphasize towards resisting attacks in IoT system, however, their work is not carried out over inter-domain routing system. This will be the prime reason that existing models are just theoretical model with theoretical proof of concept. The moment, such models are implemented over a gateway node, there is a need of a drastic revision towards such model in terms of network configuration as well as threat modelling. Hence, there is a vast gap between the security demands and the conclusive claims of existing studies.

Therefore, the problem statement of the proposed study can be stated as “Identifying an unknown attacker and resisting them in large IoT heterogeneous network using inter-domain routing scheme is quite a challenging task”. The next section discusses about the solution towards this problem.

## IV. PROPOSED SYSTEM

The proposed study is a continuation of our prior framework of inter-domain routing with scalability [31] and interoperability [32] which offers a concrete baseline of two heterogeneous domains and wireless nodes within it to communicate via base station in IoT. The proposed system introduce security on the top of the previous framework for two purpose viz. i) to offer secure communication among communicating nodes and ii) to prevent any form of malicious nodes participating in data dissemination process. The

architecture of proposed system is as shown in Fig. 1. The core ideology of proposed secure inter-domain routing scheme is that every IoT device is communicated via a relay node controlled by base station which mainly broadcast hello message and instructions to control the topology. Hence, it becomes important for system to safeguard such relay nodes as well as other regular IoT nodes. The core operation is classified into secure route formulation and preventing attackers node to join the network on the basis of evaluation of links and control messages. A target node (exploited node) is assessed using

primary and secondary rule to find out if they are completely compromised or could have feasibility to be secured. Further, all the double hop links are evaluated in order to find out presence of malicious nodes. The novelty of proposed system is the formulation of guard node which is meant for preventing the malicious node from participating in data forwarding process. The next section of the paper elaborates about the algorithm design and implementation towards secure inter-domain routing in IoT.

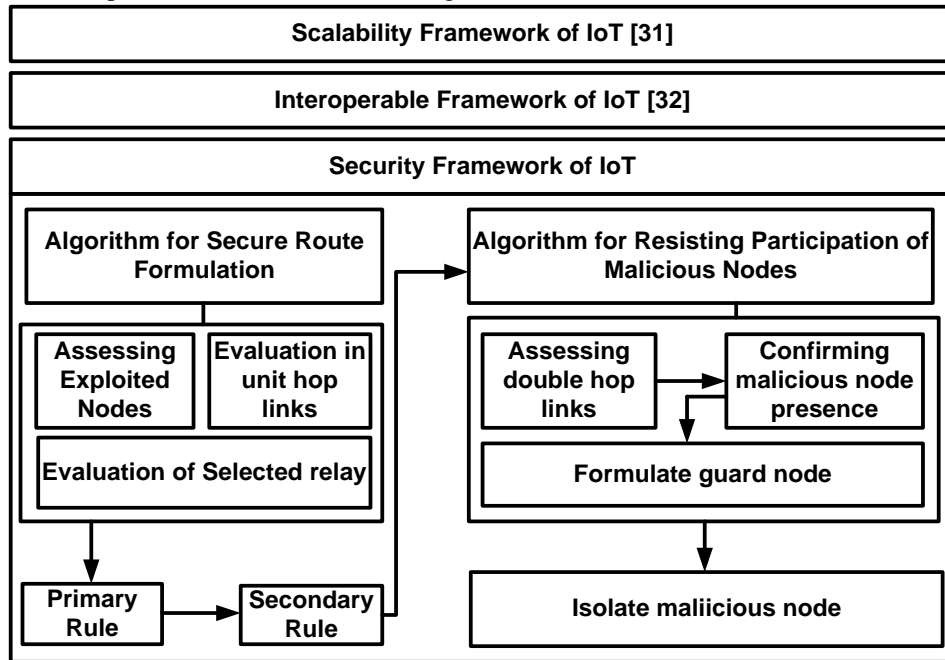

Fig. 1. Proposed Architecture of Secure Inter-domain Routing in IoT.

## V. ALGORITHM IMPLEMENTATION

This section discusses about the algorithm design used for securing the proposed inter-domain routing system focusing on IoT use case [31] [32]. It should be noted that both these framework has already offered scalability as well as interoperability features while performing data transmission. This part of implementation focusses on embedding secure communication of inter-domain routing among all the participating nodes in IoT. The complete algorithm implementation is carried out using two discrete modules i.e. securing route formulation and resisting participation of malicious node. The description of algorithms design is as follow:

### A. Algorithm for Secure Route Formulation

The main purpose of this algorithm is to initiate a secure topology in inter-domain routing connecting all sorts of nodes with an emphasis towards the exploited node (or compromised node). However, the degree of exploitation is yet not ascertained prior to implementation of this algorithm and the basis task of this algorithm is also to restrict all the communication system with unit hops in order to prevent collateral spread of exploitation by the unknown malicious node. The algorithmic flow is shown in Fig. 2 and its steps are as follows:

### Algorithm for Secure Route Formulation

**Input:**  $n$  (wireless nodes)  
**Output:**  $M$  (matrix storing network information)  
**Start**  
 1. **For**  $i=1:n$   
 2.  $x_7 \rightarrow bc(uh(x_7))$   
 3.  $\Phi$  confirm  $n_{dec}(x_7) \notin uh(\Phi)$   
 4. **For**  $j=1:\alpha$   
 5.  $\Phi$  assess  $\beta \in uh(\alpha)$   
 6.  $\beta \notin bc(msg)$   
 7.  $\beta \rightarrow (uh+2)\Phi$   
 8. **End**  
 9.  $M=[\Phi \beta uh]$   
 10. **End**  
**End**

The algorithm takes the input of all the participating wireless nodes  $n$  which after processing should yield a matrix  $M$  that stores network information to be used further for secure routing. The algorithm implements two set of rules to offer security. The primary rule is that the node  $x_7$  will broadcast  $bc$  a unit hop links of  $x_7$  node (Line-2). In such case, the exploited node  $\Phi$  is required to confirm that declaration given by node  $x_7$  should not belong to unit hop links of itself i.e.  $uh(x_7)$  (Line-3).

This is possible by evaluating the previous broadcast message to assess if they have declared the transmitting node as its adjacent nodes. It is necessary that node  $x_7$  must choose relay node in double hop  $dh(x_7)$  in order to reach all the nodes present in double hop i.e.  $x_1$  and  $x_4$ . However, there is also a possibility that  $x_7$  could opt for selecting  $\Phi$  as its relay node in order to protect  $x_1$  and  $x_4$  nodes. Hence, according to security definition of non-repudiation, the node  $\Phi$  is not permitted to deny the selection process. In such condition, the node  $\Phi$  is incapable of confirming the fact if node  $x_7$  is really an attacker node. However, it is feasible for the node  $\Phi$  to assess if node  $x_7$  has selected different relay node from the double hop links i.e.  $dh(x_7)$  i.e. either  $x_2$  or  $x_5$  (Fig. 2). Therefore, a secondary ruleset is developed which states that if there is a presence of a different node  $\alpha$  (Line-4) that is declared in the control message of inter-domain routing, than it is basic duty of the node  $\Phi$  to find out if there is presence of some other new node say  $\beta$  which is already existing in unit hop links of  $\alpha$  i.e.  $uh(\alpha)$  (Line-5). It is also required to ensure that the node  $\beta$  is not declared in the transmitting message broadcasted (Line-6) as well as it is also required to ensure that this node  $\beta$  is positioned with a difference of three hops from the node  $\Phi$  (Line-7). Once, this condition is evaluated, than the system undergoes another level of assessment which is to check if the node  $x_7$  has selected some other new node which is a present in definition of unit hop links of node  $x_7$  i.e.  $uh(x_7)$  as relay node in order to protect other node  $\beta$ . All this information are stored in a matrix  $M$  (Line-9) which is consistently updated in every round of communication by the participating node. The core idea is to ensure that no unknown node is given the right to select some other undefined node from both the forms of link (unit/double) as the relay node.

The contribution of this algorithm are as following: i) a secure link is formulated among all the participating nodes, ii) multiple level of assessment is carried out to double-check the presence of relay node and its connection with all the adjacent nodes, iii) the algorithm is completely non-iterative and its information gets periodically updated in matrix  $M$  stating that there is a less computational complexity associated with it.

Fig. 2. Process Flow for Algorithm for Secure Route Formulation.

### B. Algorithm for Resisting Participation of Malicious Nodes

This algorithm is basically responsible for confirming the presence of an unknown malicious nodes followed by a unique process of isolating them from the rest of the resured network formulated in matrix  $M$ . The core target of this algorithm is equivalent to first algorithm i.e. protecting the relay nodes from wrongly appointed by any attacker node. The prime concept underlying in this process is that attacker node is always curious to travel in double hop links in order to propagate their malicious code and the idea of this algorithm is to stop this process. The algorithmic flow (Fig. 4) and its respective steps are as follows:

#### Algorithm for Resisting Participation of Malicious Nodes

**Input:**  $\Phi$  (exploited node),  $M$  (matrix of links)

**Output:**  $s_r$  (secure removal)

**Start**

1. **For**  $i=1:\Phi$
2.   **For**  $cond=True$
3.      $\Phi$  add  $n_g$
4.     Ensure  $dist(\alpha, \beta) < (uh+2)|M$
5.      $n_g \notin uh(\Phi)$
6.      $\beta \rightarrow bc(n_g)$  & goto step-3
7.   **Else**
8.     remove  $n_g$
9.   flag  $s_r \rightarrow$  secure removal of malicious node
10. **End**

**End**

The prime ideology of this algorithm are as follows: i) the node  $x_7$  should demand to know only the nodes which is advertised by unit hop links of  $\Phi$  i.e.  $uh(\Phi)$ , ii) the node  $x_7$  selects relay node in order to achieve coverage to nodes mentioned in double hop links i.e.  $dh(x_7)=x_1, x_4, x_2, x_5, x_8$  etc. It will mean that node  $x_7$  is likely not to opt for  $x_4$  node as its relay node can reach node  $x_2$  via node  $x_5$  as shown in Fig. 3.

Fig. 3. Considered Test Topology.

The proposed algorithm formulates a condition  $cond$  (Line-2) which means for all the nodes  $\beta$  that is a part of  $dh(\Phi)$  if there exist any node  $\alpha$  that is an element of unit hop of  $\Phi$  i.e.  $uh(\Phi)$  (Line-1). Therefore, the algorithm selects a guard node  $ng$  to be added for all node  $\Phi$  (Line-3) such that spatial distance among all the nodes i.e.  $\alpha, \beta$  is less than 3 hops (Line-4) obtained from matrix  $M$ .

The algorithm also ensure that this guard nodes  $ng$  is not advertised by unit hop links of node  $\Phi$  i.e.  $uh(\Phi)$  (Line-5) in order to protect them from getting disclosed to attacker node. The node  $\beta$  starts declaring guard node  $ng$  as a regular node in order to attract the attention of attacker (Line-6). In this case, as the attacker is also obeying the policy of undeniability of service in proposed secure inter-domain routing, therefore, it has to agree on accepting the counterfeited route information provided by  $\beta$ . This causes the attacker node to explore all the nodes which doesn't exist as well as which are never mentioned in either of the unit/double hop links of  $\beta$  or  $\Phi$  or  $x_7$  node. By following the counterfeited routes, the attacker allocates all its resources to capture information of the nodes and it drains all its resources until it either chooses to leave the network or stays in the network until its resources are completely drained. At the same time, it is also required to eliminate the guard node identity from the advertised message after the work of transmitting the counterfeited message is accomplished in order to offer more security. It also prevents the attacker even to guess the formation as well as trend of guard node message especially in case of multiple attackers. Finally, a flag message of secured removal of malicious node is disseminated in the network reporting the identity of the attacker node that prevents the same attacker node to intrude the network. The next section discusses about result being obtained.

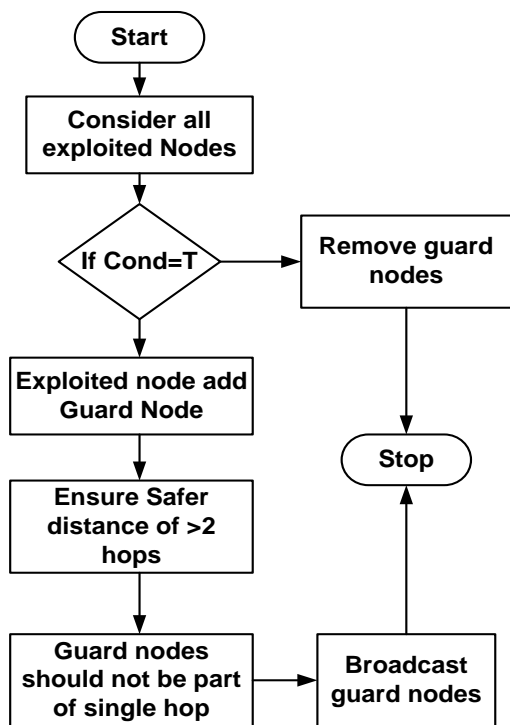

Fig. 4. Process Flow for Resisting Participation of Attacker.

## VI. RESULT ANALYSIS

This section discusses about the results obtained after implementing the proposed algorithm discussed in prior section. A simulation area of  $1000 \times 1000$  m<sup>2</sup> is used where 100 sample wireless nodes are deployed adhering to the inter-domain routing scheme [32]. The proposed logic is scripted in MATLAB where different test environment of undefined attacker is considered. The outcome of the study has been evaluated by different parameters. Table I and Fig. 5 highlights the frequencies of an attack event for 800 node density that clearly highlights the reduction of attack event with progressive density of nodes. The justification behind this outcome is that with more events of positively identified attacks, the routing tables gets updated which can be accessed via any gateway node to upgrade heterogenous domains under communication. Hence, the proposed system offers better control of malicious nodes in inter-domain routing scheme.

Fig. 5. Percentage of Attack Event.

TABLE I. NUMERICAL SCORE OF ATTACK EVENTS

Density of Nodes	Percentage of Attack Events
1	0.489
2	0.275
3	0.17
4	0.15
5	0.13
6	0.09
7	0.11
8	0.14

The proposed system has been compared with existing security protocol in IoT Routing Protocol for Low-Power and Lossy Networks (RPL), which is claimed to offer balance between security and resource efficiency. The idea is to assess the control towards overhead as well as dependencies of guard nodes. Fig. 4 highlights that proposed system offers reduced overhead that is computed by every extra data being forwarded by the transmitting node. It is because although RPL offers great security but it suffers from long delays especially when

exposed to unknown form of attacks under node formation in tree. However, proposed system performs parallel confirmation of node legitimacy as well as data transmission causing reduced overhead.

Discussion: From the tabulated information as well as graphical data, it can be seen that proposed system is potential enough to control the attacker (Fig. 5) as well as it can also reduce the overhead (Fig. 6 and Table II). The significance of this outcome is quite high as usage of conventional scheme of IoT secure routing results in increasing overhead. When subjected to inclusion of multiple hardware in the form of network devices, it is quite inevitable that IoT device will incur more number of queued packets resulting in overhead. However, this is not the case with proposed scheme for two reason viz. i) all the hop information are basically shared among all the regular nodes and hence accessibility becomes easier, and ii) permission for data transmission is granted only after a node is confirmed to be a legitimate node in progressive round.

Fig. 7 and Table III highlights that proposed system offers reduced dependencies of guard node in order to prevent the malicious node as compared to existing protocol of RPL. Fig. 8 highlights the comparative analysis of processing time which shows that proposed system consumes much less time in contrast to existing RPL protocol.

Fig. 6. Comparative Analysis of Overhead.

TABLE II. NUMERICAL SCORE FOR OVERHEAD ANALYSIS

Density of Nodes	Existing System	Proposed System
1	10.38	11.93
2	12.96	21.87
3	23.91	24.48
4	20.94	36.96

Density of Nodes	Existing System	Proposed System
1	0.7913	0.9539
2	0.4774	0.5594
3	0.3952	0.4516
4	0.3211	0.3735
5	0.271	0.3235
6	0.2947	0.286
7	0.2434	0.2983
8	0.2502	0.2677

Fig. 8. Comparative Analysis of Algorithm Processing Time.

Discussion: The prime reason behind this outcome shown in Fig. 7 and Fig. 8 is as follows- because RPL protocol performs assessment of security instantly and performs secure encryption ignoring the fact that if the same attacker has compromised some other set of links in its far neighboring nodes. On the other hand, proposed system gather more information about attacker node via guard node and this gets updated in the form of matrix, which is easily accessible via gateway node. This causes the attacker node to completely

eliminate from network by spending all its resources towards counterfeited nodes advertised by guard node and if the same attacker or its connected attacker with multiple strategy is trying to launch an attack from different nodes. The proposed system easily captures that information via double hop links. Greedy attackers have more concentration of response towards double hop links and that makes the identification quite easier. It is seen that RPL completely works on directed acyclic graph without any edges outgoing. Apart from this, owing to inclusion of number of control messages used, there is a huge consumption of time especially when working on higher number of heterogeneous nodes. This causes much consumption of its time, whereas proposed system formulates a simplified logic of capturing the attacker intention via their response message over the dual hop links. Identification operation becomes much easier by accessing a single hand matrix for faster detection. Hence, proposed system can be considered almost instantaneous in offering its response time, which is an additional benefit from secure routing.

## VII. CONCLUSION

This paper has presented a unique solution towards confirming the malicious intention of an attacker over proposed secured inter-domain routing in IoT. The summary of research findings are as follows: i) one prime indicator of an attacker node is to assess their intention to carry out routing from the nodes with maximum hop, ii) trust computation always works well when it is splitted to local trust and global reputation system, iii) acceptance of global reputation system should be followed by authenticating the legitimacy of the neighboring nodes, iv) updating hop table as well as limiting hop access is one of the safest means to restrict the propagation of uncertain threats. The summary of the proposed method are i) proposed method is capable of working over an inter-domain routing in presence of uncertain threat, ii) proposed model exploits the hop-based detailed information to formulate the attack possibilities as well as malicious intention, iii) proposed model offers robust security even without using conventional encryption process in IoT. The summary of contribution of the proposed system are i) it presents a novel architecture where secure inter-domain routing is implemented for resisting unknown attacker, ii) the complete analysis of malicious intention is based on attacker response towards different types of hops, iii) the framework also present an inclusion of a guard node which is meant for forwarding forged routing information to mislead the attacker node. The novelty of the proposed study are as follows: i) the model is independent of any form of attack definition unlike existing system which demands proper definition and types of attack, ii) a novel selection of relay node is developed unlike any secure routing scheme in IoT for topology control, iii) a completely non-encryption-based approach whereas majority of standard approaches uses cryptography.

**Abstract**—Service Oriented Architecture (SOA) has emerged as a promising architectural style that provides software applications with high level of flexibility and reusability. However, in several cases where legacy software components are wrapped to be used as web services the final solution does not completely satisfy the SOA aims of flexibility and reusability. The literature review and the industrial applications show that SOA lacks a formal definition and measurement for optimal granularity of web services. Indeed, wrapping several business functionalities as a coarse-grained web services lacks reusability and flexibility. On the other hand, a huge number of fine-grained web services results in a high coupling between services and large size messages transferred over the Internet. The main research question still concerns with “How to determine an optimal level of service granularity when wrapping business functionalities as web services?” This research proposes the Snowball framework as a promising approach to integrate and compose web services. The framework is made up three-step process. The process uses the rules in deciding the web services that have an optimal granularity that maintains the required performance. To demonstrate and evaluate the framework, we realized a car insurance application that was already implemented by a traditional approach. The results show the efficiency of snowball framework over other approaches.

**Keywords**—Service oriented architecture (SOA); web service granularity; web service composition; software flexibility; snowball composition framework

## I. INTRODUCTION

SOA allows software systems to be composed as a group of loosely coupled software components called services [1]. SOA aims to provide cost effective flexible solution to business organizations [2, 3]. However, SOA had not gained an extreme popularity until the emerging of web service technology in early 2000s [4]. Since that time, web service became the main trend to implement SOA systems [5]. Several organizations tend to wrap legacy software components in the form of web services to implement SOA-based applications [6]. Wrapping legacy software into web services reduces the cost of implementing new software systems. However, in several cases where legacy components are wrapped to be (re)used as web services, the final solution does not completely satisfy the SOA aims of flexibility and reusability. The reason behind that is the unsuitable level of service granularity. Service granularity has two different perspectives: business perspective and IT perspective. From a business perspective, service granularity is associated with the amount of business tasks fulfilled with that

service. On the other hand from IT perspective, web service granularity is associated with size of data transferred from or towards the service as well as its code length [7].

Service granularity affects reusability, efficiency and performance of the services. Wrapping several business functionalities as a coarse-grained web services leads to a single use service [8]. Such service lacks reusability and flexibility since the separation of concerns and cohesion are missing. On the other hand, composing business tasks from large number of small fine-grained services leads to high coupling between services. Such situation leads to communication complexity and degraded performance. That is, an incorrect service granularity leads to bad performance, low reuse possibilities, inappropriate abstraction levels, and services without business value [9].

It is critical to balance between coarse-grained and fine-grained web services while mapping SOA design to individual web services [10]. Unfortunately, the literature lacks detailed studies about service granularity and its impact on reusability, flexibility, and performance [11].

Consequently, one of the main problems that faces developers while developing web services-based SOA is the difficulty to determine optimal service granularity, especially as there is no theoretical definition for service granularity in the literature.

The main research question still concerns with “How to determine an optimal level of service granularity when wrapping business functionalities as web services?”

This research proposes the Snowball as a promising approach to compose web services in SOA-based applications. Snowball is framework made up of a set of rules and a three-step process. The process uses the rules to check the right and optimal granularity of the services. It first decomposes a Business Process (BP) into smaller sub-processes that are further decomposed into business tasks, each of which is a set of activities. Next, it maps the tasks into individual fine-grained web services. Then it checks the fine-grained web services against the rules, in order to allow their integration. Finally, it optimizes the granularity.

Snowball aims at providing web services that have the optimal granularity while maintaining the required flexibility, reusability, and high performance in terms of low size of data transferred. It is meant to be used by organizations that want to

offer its functionalities to users as web services, and can also be used by organizations to build up their own business applications.

To demonstrate and evaluate the framework, we realized a car insurance application that was already implemented by a traditional approach. The results show the efficiency of snowball framework other traditional approaches.

Moreover, the proposed framework has an advantage over other composition frameworks that generally use Business Process Execution Language (BPEL). It integrates and composes services functionalities before the implementation phase. Hence, the framework allows three different modes of services: wrapping legacy components, invocation from a service provider, or creation from scratch (coding). Therefore, Snowball eliminates the utilization of glue code languages such as BPEL, which leads to degraded performance and hard validation tests.

This paper is organized as follows: Section 2 presents related work. Section 3 develops the Snowball framework, i.e., rules and methodology. Section 4 presents the results of the empirical study. The conclusion section summarizes the contribution, its limitation, its impacts, and future work.

## II. RELATED WORK

One of the main challenges in web service applications concerns with the granularity of services. This section analyzes different popular methodologies for SOA applications, with respect to the granularity of web services. Several models tried to formalize different processes for an organization to adopt SOA [12]. However, fewer researches focused on services granularity and size of service messages.

SOMA is a popular SOA design framework, introduced by IBM, that models business functionality as coherent individual services. To implement new software for an organization, SOMA defines a domain decomposition approach to perform the design phase. The main idea is to decompose the business into logical coherent functional areas. Each area consists of related processes that are further split to smaller sub processes [13]. Each sub process is decomposed into a set of activities which are listed together to form service portfolio [14]. Each service's functionality in the service portfolio is assigned to a web service. SOMA has no restriction on service granularity or on the size of service messages, whether the service is from the legacy system or from external services. Hence, several SOMA designs that lead to large services that perform several individual functionalities, hence, missing the required flexibility [15]. Such situation leads to a set of non-reusable services neglecting SOA aims of software reusability [16]. On the other hand, SOMA application might be implemented with extremely high number of fine-grained services. Such implementation may lead to large size of data transfer while aggregating these services together [17].

Another popular model for SOA adoption is Service Oriented Architecture Maturity Model (SOAMM). SOAMM defines a model for monitoring different levels of development, implementation, and usage of SOA [18]. SOAMM defines a set of characteristics for organizational architecture that are essential for any organization to be able to implement web

services-based SOA. SOAMM defines service selection and collaboration between services from the business point of view only [19]. However, SOAMM does not define rules for service granularity from IT perspective such as size of input/output messages.

Thomas Erl [20] defined Mainstream SOA Methodology (MSOAM) as a framework to design, implement, test, and deploy web services. MSOAM identifies seven activities during analyses and design phases. It starts by Ontology definition, then perform business model Alignment. Further it performs service oriented design to develop services that fulfill each process of business functionality. This framework has an advantage in defining dependencies between services. However, it does not define how these dependencies can affect service granularity. Thus several MSOAM applications suffer from coarse-grained web services lacking flexibility and reusability.

Business Process-driven Methods [21] is considered one of the most common strategy used to identify services in SOA. This method uses clustering algorithm to identify services from the business perspective. Business elements are divided into rules and requirements, and then a syntax analysis is applied to perform service selection for each BP [22]. Such method focuses on BPs, and gives less attention to data transfer. The main drawback of this method is the extremely fine-grained services that lead to large amount of communication overheads between services. Implementing web service application with large number of fine grained services increases the size of messages required for services communication [23, 24].

This figures out the problems associated with service granularity while implementing SOA by using web services. The literature lacks theoretical methods to define optimal service granularity. Unsuitable level of service granularity leads to significant drawbacks in flexibility, efficiency and performance of SOA based applications [25]. The proposed framework assists developers in deciding the optimal granularity of web services that maintains flexibility and high performance.

## III. PROPOSED SNOWBALL FRAMEWORK

The proposed snowball framework provides a systematic approach to determine the optimal service granularity for web services-based SOA, in terms of performance and efficiency.

It defines a set of rules and a three-step process. The rules specify mapping business tasks to IT web services. The rules also define the conditions under which two services or more should be integrated together. The three processes define the actions taken to apply the rules to the business tasks step by step till getting a suitable level of service granularity. It aims at assuring an optimal service granularity that satisfies lower coupling and higher cohesion.

### A. Service Granularity

The framework considers two different properties of service granularity: (1) the business functional granularity, representing the number of elementary business tasks fulfilled by the service, and (2) the data granularity, concerning with size of input/output data included in the service messaging.

From the business perspective, the fine-grained service is the service that performs an atomic task [23]. While from IT perspective, a fine-grained service is the service that has a limited size of data transfer. Thus a service could be fine-grained from a business perspective, and coarse-grained from a data granularity perspective. For instance, a service that displays a map performs a single business task but carries a huge size of data.

### B. Snowball Rules to Optimize Service Granularity

The framework provides two sets of rules to optimally and efficiently integrate fine-grained services together, considering both functional granularity and data granularity. Dependencies between services are also a point of concern.

1) *Rules to map business tasks into IT services:* Mapping business tasks into IT services consists in assigning each single business task to an elementary web service, i.e., an elementary coherent fine-grained service.

a) *Rule 1:* If a legacy software component satisfies a single business task, then it is wrapped to act as a web service with only one single operation.

b) *Rule 2:* If the required functionality exists in public/private registries as a web service with one operation, then select it.

c) *Rule 3:* If the service is to be locally implemented (by coding), then the code includes only one single operation.

Applying these rules results in a high flexibility and reusability of mapped web services. However, increasing the number of individual web services in an application affects its complexity and performance in terms of response time and large size of network traffic [26, 27]. Therefore, there is a need to integrate and compose service into an optimal granularity by using the following rules.

2) *Rules to integrate IT services:* After assigning elementary business tasks to IT service, the output is a set of fine-grained service. The following rules are applied to these services to achieve optimal granularity.

a) *Rule 1:* Two services  $S_i$  and  $S_j$  are integrated together if:

- The business workflow requires execution of the two services sequentially.
- The input parameters for  $S_i$  are the same as  $S_j$  or the output of  $S_i$  is the required input for  $S_j$ .

b) *Rule 2:* Two services  $S_i$  and  $S_j$  are integrated together if:

- $S_i$  and  $S_j$  are in the same business domain and are connected to the same database tables and.
- $S_i$  and  $S_j$  should be at the same branch of business workflow.

3) Factors that manages services integration:

Factor 1:  $S_i$  and  $S_j$  have sequential execution.

Factor 2: The output of  $S_i$  is an input for  $S_j$ .

Factor 3:  $S_i$  and  $S_j$  have the same I/O.

Factor 4:  $S_i$  and  $S_j$  have connection to the same database.

Factor 5:  $S_i$  and  $S_j$  have data dependencies, i.e.,  $S_j$  cannot be executed until  $S_i$  is completed as  $S_j$  has one (not all) of its inputs passed from outputs of  $S_i$ .

### C. Snowball Steps to Optimize Service Granularity

The Snowball process, shown in Fig. 1, consists of three main steps that should be completed to provide SOA applications with the required flexibility, reusability, and high performance of the services that compose them. Step 1 identifies business tasks, step 2 maps each business task into an IT service, whereas step 3 optimizes the service integration.

1) *Service identification:* Each BP is broken down into smaller sub-processes and then to single elementary tasks. An elementary task performs atomic coherent business functionality. Then all the elementary tasks are listed in a task table, as exemplified in Table I.

2) *Mapping business tasks into IT services:* This step uses the first aforementioned set of three rules to map business tasks into IT services. Mapping business tasks to a web service means selecting a web service that fulfills the business functionality of the task. Each atomic business task is mapped to an elementary web service that would be wrapped from the legacy systems or discovered over web service registries, or even implemented as a new web service. Different activities of mapping atomic business functionality to web services are shown in Fig. 2.

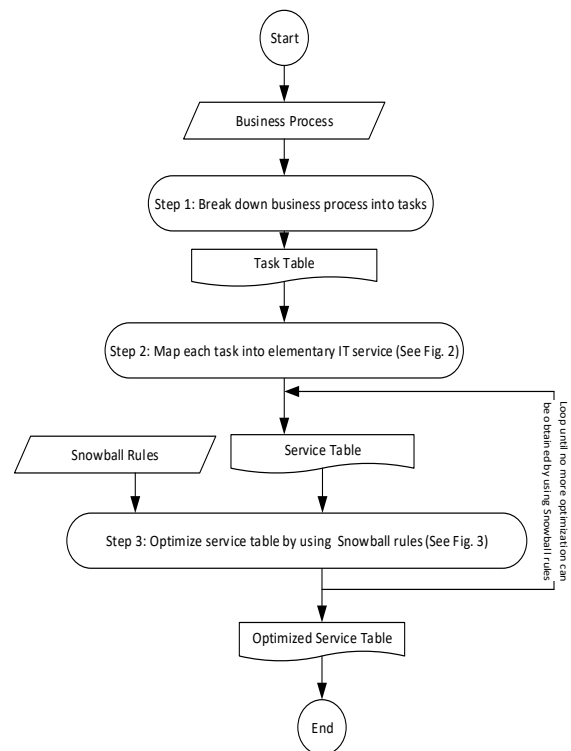

Fig. 1. Snowball Process.

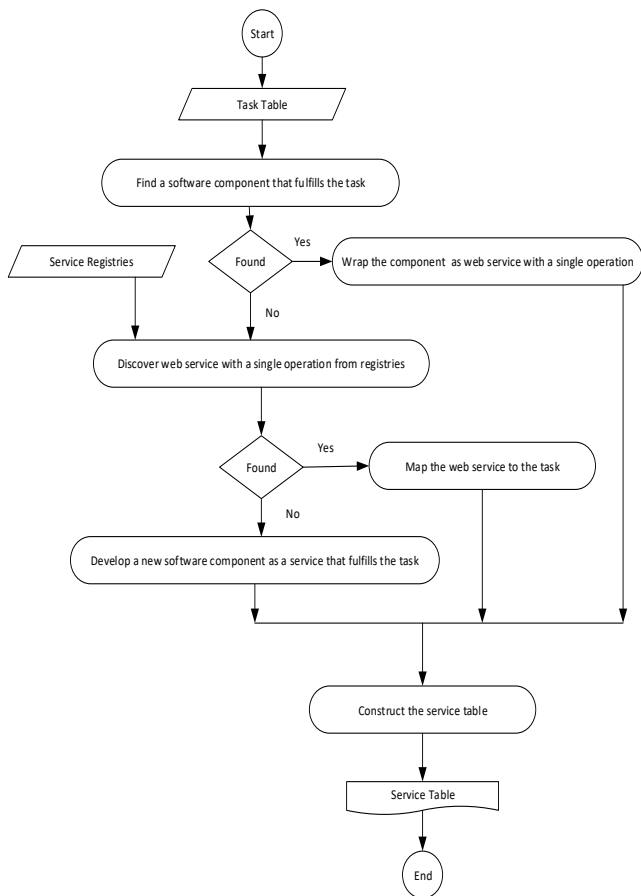

Fig. 2. Details of Step 2 of the Snowball Process.

Up till this step the system is composed of fine-grained IT services that ensure a high level of cohesion. All the atomic services are then listed in a services table. The services table lists all the used services, including their business functionality, I/O parameters, connected database, and dependent services. The dependency between services is divided into control flow dependency and dataflow dependency. The I/O parameters and connected database are chosen as they have the most effect on services coupling. The dependency between services is further used to construct the criteria of integration between two services or more.

3) *Optimization of the service table*: The third step is responsible of optimizing the integration of different individual services together. Such integration avoids building applications from fine-grained web services that increases the interaction between the application and outer invoked services. This scenario leads to poor performance. The integration process would reduce the total size of I/O messaging of the client application to maintain high performance. Unlike traditional composition such as BPEL, the integration in the Snowball process consists of adding the business functionality of the first service to the functionality of second service. Thus, the integration of two services functionalities results in new service that performs the functionalities of both services. Snowball integrates services with each other in recursive rounds. In each round, a service is

added to the existing one(s) to constitute a new integrated service. The newly integrated services will act as elementary services in the next round and so on till we get a service where no more integration process can be applied according to the rules. After each round the service table is updated to list the newly integrated services with their parameters. Hence, services integration process is repeated in recursive order by applying the second aforementioned set rules, in order to control service integration, as shown in Fig. 3.

In this step, Snowball framework applies the aforementioned second set of rules in order to achieve two main objectives for services integration regarding size of transferred data and database connections.

First objective: Minimize overall service interface messages.

This objective is achieved by applying rule1 regarding both the business workflow and the size of transferred data. If S1 and S2 have the same input parameters, they are integrated together in a new service S3. During runtime S3 will be invoked with the input parameters of S1 and returns the output parameters of S2 rather than sending the same data twice from S1 and S2. The decrease in the sent and received data between the application and outer web services has a great effect on performance, especially for huge size of parameters.

Second objective: Minimize Database connections.

This objective regards the connection between web services and databases. Rule 2 may not be available for discovered services as the Web Service Describing Language (WSDL) file almost contains the input/output parameters without information about database connections. However, if the web services are wrapped from the legacy software asset or implemented as new services, information about connections between data bases and services are available.

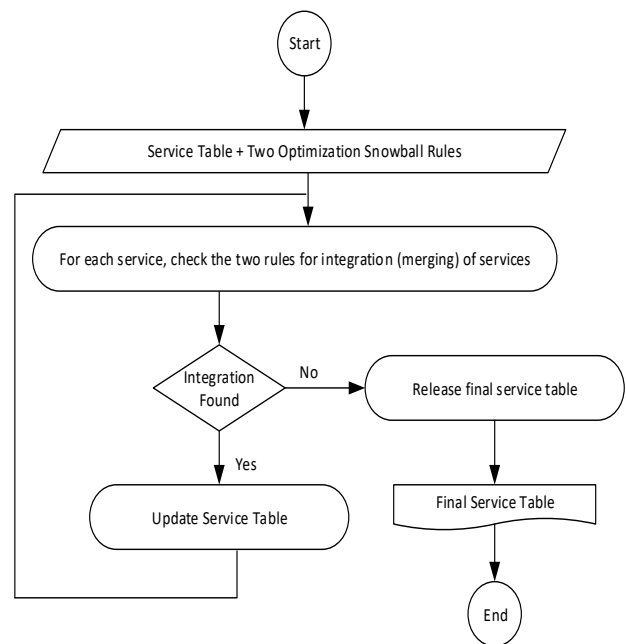

Fig. 3. Step 3: The Optimization Process.

#### IV. EVALUATION

To proof the significant enhancement of the proposed framework we focused on two main factors that affect SOA applications. The two factors are performance and efficiency. These two factors provide a clear measurement value that reflects how optimal a service granularity is. Performance is measured by calculating the response time between a service invocation and its reply. Efficiency is measured by calculating the total size of message used during the process of service request and reply. An insurance company was selected to evaluate the proposed work because insurance applications combine different functionalities from different business domains.

##### A. Case Description

The insurance company has many valuable software assets that support many of its running business processes. The company would like to offer the existing software functionalities and any newly created ones as web services. The focus is on the SOA-application that support car insurance claim BP, whereby a client request insurance reimbursement for his/her car. To prove the significant enhancement of the proposed framework the system functionalities are built using two approaches. In the first approach the system is designed using traditional SOA approach. In the Second approach, the required functionalities are built using Snowball framework. For the two approaches the response time and the total size of data transferred (message size) are calculated starting from receiving a user request till the claim process is completed.

##### B. Applying Traditional Method and Snowball Framework

For a traditional approach, each one of the listed in Table I one and representing different business tasks is mapped to an individual web service. Then a service portfolio is constructed without regarding the service granularity.

For snowball, the three-step processes mentioned above were executed as follows:

Step 1: The first step takes the car insurance claim BP as input and breaks it down to elementary tasks, which results in a task table, as shown in Table I.

Step 2: The second step takes the task table as input and maps each of the tasks to an elementary web service with single operation according to the first set of rules, as shown in Fig. 2.

Table II shows the resulting services. Each service describes the mapped task, the input and output parameters, the database to which it is connected, and its dependency to other services.

Step 3: The third step takes the service table as input and performs optimization according to the second set of rules, as shown in Fig. 3. The optimization is a recursive, where each iteration updates the service table according to the new integrated services. The process ends when there are no more services to be integrated. Every service in the service table is tested whether it can be integrated with another service according to the five factors defined in section 3.B.

Applying such factors to the service table presented in Table II results in the following integrations, as shown in Table III.

The three services S2, S3, and S4 require the same input: client ID, client name, and insurance document ID. Moreover, the three services are connected to the same databases: client database and the insurance document database. The three services also have control dependency as they all should be executed sequentially before S5 is invoked. Accordingly, the three services S2, S3, and S4 are aggregated into one service, named Sa. The three services S6, S7, and S8 can also be aggregated together, as they have client ID as an input parameter. The three services are also connected to the same database that is cars database. S6, S7, and S8 should be executed as prerequisite condition for S9 and S11. Accordingly, the services S6, S7, and S8 are aggregated into one service, named Sb.

Table III shows the final services produced by Snowball. These are S1, S5, Sa, Sb, S9, S10, S11, and S12. For each integrated service, Table III describes the service functionality, the input and output parameters, the database to which it is connected, and its dependency to other services.

##### C. Experimental Results

The insurance application is built as a web services-based application by two different approaches: SOMA and Snowball.

- Traditional SOA application build up using 12 separated services.
- Snowball designed application that is built up using only 8 services after integrating the dependent services.

1) *The experiment:* The two applications were built using C# in .Net environment. The services were implemented on IBM server with processor Xeon E5, whereas, the service invocations were applied from a desktop with CPU core i7 and 16 M Byte memory. SOAP-UI was used as a testing tool to calculate the message size and the response time. The experiment was repeated ten (10) times and the average value was calculated. The response time and message size were calculated.

TABLE I. THE ELEMENTARY TASK OF THE BP

- Receive a claim
- Check insurer payment
- Check whether the claim is in the insured period
- Check whether the insurer have many claims (manipulator)
- Take a decision for the claim
- Get car year
- Get car making company
- Get car model
- Get car price
- Calculate estimated cost
- Get new car cost
- Get a decision for payment
- Payment

TABLE II. RESULTING SERVICES SHOWING THE ELEMENTARY TASK OF THE BP

Service	Functionality	Input parameters	Output parameters	Connected Database	Dependent services
S1	Receive a claim	- Request from client			
S2	Check insurer payment	- -Client ID - -Client name - -Insurance document ID	- Boolean value	Client DB Insurance Document DB	S3, S4
S3	Check whether the claim is in the insured period	- -Client ID - -Client name - -Insurance document ID.	- Boolean value	Client DB Insurance Document DB	S2, S4
S4	Check whether the insurer has many claims (manipulator)	- -Client ID - -Client name - -Insurance document ID.	- Boolean value	Client DB Insurance Document DB	S2, S3
S5	Take a decision for the claim	- -Three Boolean values	- Boolean value		S2, S3, S4
S6	Get car year	- Car ID	- Car year	Cars DB	-
S7	Get car making company	- Car ID	- Making company	Cars DB	-
S8	Get car model	- Car ID	- Car model	Cars DB	-
S9	Get damaged component prices	- -Car year - -Car making company - -Car model	- Damaged component price	External DB	S6, S7, S8
S10	Calculate estimated maintenance cost	- -Damaged component price - -Maintenance cost	- Maintenance cost		S9
S11	Get new car cost	- -Car year - -Car making company - -Car model	- New car cost	-External DB	S6, S7, S8
S12	Get payment decision	- -Maintenance cost - -New car cost	- String		S10, S11

TABLE III. FINAL SERVICES COMPOSITION BY SNOWBALL FRAMEWORK

Service	Functionality	Input parameters	Output parameters	Connected Database	Dependent Services
S1	Receive a claim	Request from client			
Sa= integration of S2, S3, S4	Check insurer payment: check whether the claim is in the insured period and whether the insurer has many claims (manipulator)	- Client ID - Client name - Insurance document ID	- 3 Boolean values	- Client DB - Insurance Document DB	
S5	Take a decision for the claim	- 3 Boolean values	Boolean value		Sa
Sb= integration of S6, S7, S8	Get car year, car making company, and car model	- Car ID	Car year Making company Car model	- Cars DB	
S9	Get damaged component price	- Car year, - Car making company - Car model	Damaged component price	- External DB	Sa
S10	Calculate estimated maintenance cost	- Damaged component price - Maintenance cost	Maintenance cost		S9
S11	Get new car cost	- Car year - Car making company - Car model	New car cost	- External DB	Sb
S12	Get payment decision	- Maintenance cost - New car cost	String		S10, S11

- Reply time: calculated using SOAP-UI

2) *Results:* The results listed in Table IV show a significant enhancement in the message size and respond time while maintaining the same flexibility and reusability features.

Fig. 4 shows the difference between traditional application and Snowball application across three metrics: message size (Fig. 4a), response time (Fig. 4b), and database connection (Fig. 4c).

TABLE IV. EXPERIMENTAL RESULTS

Approach	Size of transferred message	Response time	Number of connected database
Traditional SOMA	850 Kbyte	370 msec	11 databases
Snowball framework	510 Kbyte	190 msec	5 databases

(a)

(b)

(c)

Fig. 4. (a) Total Message Size in Kbyte, (b) Total Response Time in Msec, (c) Number of Connected Databases.

#### D. Discussion

The experimental results show a significant enhancement in two important parameters that affect the SOA applications. The first parameter is the performance that is measured by the response time of the invoked service. The average response time decreased by 48% from 362 in case of traditional applications, to be 188 msec using Snowball framework. The second parameter is the application efficiency that is measured by the size of transferred data. The transferred data significantly decreased by 39 % to be 530 KB in snowball application rather than 869 KB in case of traditional application. Such decrement in data size provides better network utilization specially when using wireless connections with narrow band width. Another significant enhancement was decreasing the number of connections between web services and database to only 5 databases rather than 11 in traditional applications.

Such results proof the significant enhancement of SOA applications while using snowball approach. Using snowball frame work defines an optimal service granularity that significantly decreases the application response time and its total transferred l data size.

It is worth mentioning that the experiment is meant to evaluate three criteria in a specific testing configuration: response time, size of the message, and number of DB connections. It also considers only one running BP to clarify our idea without adding more complexity in designing and implementing more BP.

Adding other metrics that measure a quality SOA-based application may result in a tradeoff.

#### V. CONCLUSION

The granularity of individual services that compose web service-based SOA is an important issue. Service granularity has significant impacts on the quality of the services regarding performance and efficiency. This work has tackled the issue of how to find an optimal service granularity. The Snowball framework was proposed to adjust web service granularity to maintain flexibility, performance, and efficiency of SOA systems. The framework is made up of two sets of rules and a three-step process.

The proposed framework was demonstrated and evaluated through the development of a web-services-based SOA application that supports the car insurance claim BP of an insurance company. The application was developed by traditional SOMA approach and Snowball framework. The experimental results show significant enhancement of Snowball over SOMA, in terms of response time, message size and DB connections. The snowball is limited to the optimization of the granularity from the perspective of performance of the services and the applications composed out of them.

The framework has practical and theoretical impacts. The developers of SOA-based applications can use it to optimize the granularity of their services to enforce their reuse and consequently the time to market. From, a theoretical perspective, the proposed work opens issues related to the optimization of the service granularly with respect to other quality criteria.

The future work will discuss the security enhancement offered by Snowball approach. Also our future work will analyze the problems associated with web service run time failure while using Snowball approach.

**Abstract**—Requirement Elicitation is key activity of requirement engineering and has a strong impact on design and other phases of software development life cycle. Poor requirement engineering practices lead to project failure. A sound requirement elicitation process is the foundation for the overall quality of software product. Due to criticality and high impact of this phase on overall success and failure of projects, it is very necessary to perform the requirements elicitation activities in a perfect and specific manner. The most difficult and demanding jobs during Requirement Elicitation phase is to select appropriate and specific technique from a wide array of techniques and tools. In this paper, a new approach is proposed using an artificial neural network for selection of requirement elicitation technique from a wide variety of tools and techniques that are available. The training of Neural Network is done by back propagation algorithm. The trained and resultant network can be used as a base for selection of requirement elicitation techniques.

**Keywords**—Requirement elicitation; requirement engineering; neural network; back propagation

## I. INTRODUCTION

The process of Requirement Engineering (RE) starts with requirement gathering i.e.; requirements elicitation[1][2]. Requirement elicitation provides a base for a RE, has a strong impact on the software project success and quality [3]. The first stage in requirement engineering is requirement elicitation that uses various techniques to elicit requirements related to software project from various stakeholders. According to [4] in requirement elicitation process, the meaningful information is collected in the form of requirement from various stakeholder and users. Requirement Elicitation is the collection of requirements; the other terms used in this context are capturing of facts, knowledge acquisition, determination of essentials, gathering of information. Sometimes following terms are used such as identification, invention, development, knowledge discovery, and fact-finding. The other terms that have been used are insufficient to represent real meaning, facts, derived knowledge. But now it is well understood and minutely documented and universally accepted that requirements are captured or collected, instead the requirement are elicited [5]. Another definition for requirement elicitation is that it is the process of identification of key software requirements that are elicited from various elicitation techniques such as formal interviews, brain storming, model workshops, workflow analysis and other techniques [6]. “Requirement elicitation refers to as the

process as trawling for requirements”. During requirement elicitation, requirements are elicited in consultation with different stakeholders. The stakeholders, as they are distinct individuals, they have their specific means to recognize and store the knowledge. They express their knowledge about the problem domain in their unique way; a single method as suggested by other researchers will not be sufficient enough to elicit requirements in requirement elicitation phase from different sets of stakeholders [7]. However, it is a well-known fact that if requirements are not properly elicited then it will lead to failure of software product. To improve the success rate of software projects requirement elicitation process should be followed minutely and effectively [8]. Requirement Elicitation can be considered as a prerequisite for all other software development activities. It signifies that the developed software product is of good quality and will work properly according to the expectation [3]. The success and failure of the project is dependent on the quality of requirements that are gathered. Software’s project success and failure depends upon requirement elicitation specially selection of requirement elicitation techniques [9]. It is established fact that process of software requirement elicitation has a major and decisive impact on quality of the final product [10][11]. The main goal of effective requirement engineering is to develop a software product in such a way that fulfills all the customer needs budget, cost and schedule. Many surveys and research have been analyzed to investigate the major cause of software project failure and their statistics. Standish reports [12] suggest that rate of success of software project is 28% only. The major factor for such low rate of software successful software is imprecise and unclear requirements [13]. Another survey suggests that only 12.7% out of (nearly) thousand software projects were successful. According to survey main reason for the software project failure was unclear and incomplete requirements [14]. These survey and reports also suggest that for successful requirement engineering, requirement elicitation phase should be carried out in such a way that all the effective requirements are gathered which lead to the successful software projects. In [15] author suggests that 90% of large-scale software projects are failure due to poor requirement engineering specially requirement elicitation. This work was reflection of [16] according to author “poor software requirements management can lead to 71% percent of software projects failure; greater than badly used technologies, slipped deadlines and change management. The cost of software project failure is high”. Researchers also suggest that 70% of the total software errors and bugs are due

\*Corresponding Author.

to poor requirements gathering and remaining 30% are due to poor and faulty design. It is well documented from various surveys and researchers that requirement elicitation phase has a major impact on software product quality [17]. The most important and critical task in requirement elicitation is requirement elicitation technique selection from a wide varieties of techniques[[18]. Hence there is need to understand requirement elicitation techniques, also the application of requirement elicitation techniques for successful requirement elicitation in requirement engineering phase of SDLC [19].

Many frameworks define requirement elicitation process, or describe specific elicitation technique which is performed during requirement elicitation. But none of framework proposed by various researchers has defined a unified model for the requirement elicitation process. That takes into consideration, the basic issues and the knowledge required for effective elicitation of requirements from various stakeholders. Requirement elicitation framework suggested by various researchers are theoretical and there is lack of mathematical knowledge[19]. An efficient framework is required for effective requirement elicitation. There are various techniques of elicitation but how to select the appropriate techniques from a set of techniques is the real challenge. The elicitor must decide which technique is best suited for specific situation from set of techniques [20]. Inappropriate selection of elicitation technique leads to gathering of faulty requirement which results in project failures. Because of variety of stakeholder or rather non homogeneity of stakeholders, process of requirement elicitation must be carried out effectively by applying the appropriate elicitation techniques. In this research paper important key factors are identified from various researchers and practitioners of software industries that directly or indirectly contribute towards selection of techniques of requirement elicitation. These factors are fed as input to neural network and the intelligent approach is applied for requirement elicitation technique selection from a set of various techniques and tools.

## II. RELATED WORK

During requirement elicitation phase or requirement engineering the level of scope for the system need to be established. The details regarding the needs and requirement of key stakeholders should be investigated using variety of elicitation techniques. Requirement elicitation technique is related to eliciting of requirements of the organization within the organization environment including project goals, project rules, processes work flow, various assumptions market, constraints along with details of implementation. In [21] researches suggest that it is important to elicit different types of information during elicitation process. To have the complete knowledge of the systems including all the details of current and existing system in a specific domain, along with the current list of existing requirement engineering problems their goals including issues, ideas and risk. This is known as perspective of concept modeling. In this modeling elicitation of requirements is done for processes, data and behavior of large-scale software projects [22]. This model is also supported by SA/SD view of large-scale software project [23].

The important components of the elicitation process are priority, source and rationale of the software requirements along with the goals [24]. Each elicitation technique has some key features and also some limitations [25], Interview is most common and natural elicitation technique[25], there is no support for this elicitation process and even no specific guideline for eliciting requirements [26]. In researcher suggested that there is no elicitation techniques that provides detailed description of the problems [27]. Suggested that there are two types of requirement gathering techniques firstly the techniques that are less expensive as well as information provided by them is less[28][29]. Secondly the techniques those give favorable result but are expensive. The elicitor may be well versed with some elicitation techniques but no one elicitation technique is able to elicit all the requirements entirely[30]. Hence more than one requirement elicitation technique is used to capture the requirements for software systems. Because of wide range of elicitation techniques, it is therefore possible to use alternatively available requirement elicitation techniques in different scenarios with enriched flexibility, providing more options to the elicitor.

The elicitation techniques are informal in nature that deeply involves human interaction. Group work is one technique that is effective as it involves groups and is able to deal with complex scenarios such as elicitation process. This is far better than individuals because each individual is unique and possesses wide range ability. Group work techniques are better in gathering of requirement as they involve stakeholder and customers. It fosters discussion, generation of ideas and fact-finding solution. The major benefit of Requirements Workshops is that they glue well techniques of elicitation. The group techniques are important in eliciting requirements because software engineering is a group activity [31][32]. In [33] suggests that one to one interview is the most suitable method for requirement gathering. In [34] researchers suggest that workshop is most suitable technique for small scale software projects whereas [35] suggest that DSDM is suitable for large scale software projects. In [36] researchers provide guidelines for effective requirement elicitation technique selection.

The works done in [37][38][39][40] suggests novel approaches for elicitation of requirement. The above researchers proposed many process models for elicitation of requirement over the period of time [40][41][42]. Mentioned approaches provide us flexibility and take into consideration the individual software projects. The approaches do not provide guidelines as number of tasks are performed during elicitation phase. Many problems are faced by elicitor as there are many techniques available to make the software development task simple. The elicitation is carried out over different sessions to capture every detail in parallel with Software Development Life Cycle process. The author in [43] suggests that elicitation involves the understanding of both problem and business domain of the large organization and also to find out how the system works along the understanding of the application domain of the current working software project. In [44] recommends that object setting, knowledge acquisition and requirement gathering from stake holder are requirement for a standard elicitation process.

In [45] researchers suggested a step wise approach using the ISO 9126 quality characteristics as a guideline for the requirement elicitor to capture social, organizational and human factors that can improve overall quality of software product. In [46] researchers suggested the analytic network process, based on multi-criteria decision making for requirement elicitation technique selection. In [47] researcher analyzed for IT professionals the cognitive structure based on various factors that directly affect the use of the laddering as requirement elicitation techniques selection. In [48] researcher suggests that interview is best technique for requirement elicitation technique selection. The results of elicitation are analysed using children education application as case study. The outcome of this research is interview along with prototyping method of requirement elicitation technique selection are the most suitable methods. Although there are various framework and guidelines for requirement elicitation technique selection till date but most of them are theoretical in nature and lacks mathematical concepts. We required a more effective and intelligent approach that provide researchers with detailed guidelines for carrying out elicitation technique selection process empirically.

### III. PROBLEM DEFINITION AND SCOPE

The software projects failure is main issue of the software development industry. Researchers had tried to investigate the cause of failure in software projects failure statistically. Empirical research in organizations has demonstrated that requirement engineering process which is well defined has a positive impact on the quality, cost of software developed as compared to projects that do not follow well defined process models. Chaos Report suggests the problems of delay in software development, over-budget software and failed software are major concerns for software industry. To develop high quality software is also one of the concerns. Some researcher suggests that the poor requirement elicitation led to 50% of the total failure of software project. Significant efforts have been made in requirement elicitation research; there exist gap between theory and actual practice. In order to improve success rate in software developed an efficient and effective approach is needed for requirement elicitation. In Elicitation process there are number techniques available still it is difficult for requirement elicitor to decide which technique is most suited for the task [13][14]. It is due to inability to understand the available techniques. This inability to understand the technique leads to improper selection of requirement elicitation technique which leads to project failure. So, it is imperative for requirement elicitor to know about the existing requirement elicitation techniques [2][8]. Although elicitors have a number of elicitation techniques at their disposal still flexible guidelines for effective approach of requirement selection are needed, which are beneficial in selection of appropriate elicitation techniques [6].

### IV. ATTRIBUTES FOR THE REQUIREMENT ELICITATION TECHNIQUE SELECTION

Selection of Elicitation techniques are depended based on various attributes. Attributes plays an important role in

selection of requirement elicitation techniques. These key attributes are identified after intensive literature survey and consultation of professionals working in different software houses. There are 9 different attributes which are identified for selection of elicitation techniques. These attributes are known as evaluating factors for selection of requirement elicitation technique. The attributes are shown in Table I.

#### A. Software Project Scaling

Software Project Scaling can happen in Man-hours, code-size, number of interfaces, number of requirements and cost. Scaling happens with headcount, as large numbers of developers are required to develop large software hence more developers should produce more code. The size of products is proportional to size of the code. Many products can be developed simply by rearranging the code. Or in other words several products can be developed from the single product. On the other hand, if a single-person develops the software then the cost of mistakes is usually lesser. Software developers usually take shortcuts to achieve their goals. In small software projects developer and manager is a same person. In large software projects, the roles are distributed among many persons hence there is the need for coordination. So from the above discussion it is justified that software can be classified into small scale software and large scale software. The classification is based on the following Attributes described in the Table II.

TABLE I. EVALUATING FACTORS FOR SELECTION OF REQUIREMENT ELICITATION TECHNIQUES

Attributes	Values
Domain	Understanding the Domain
	Acquiring Domain Knowledge
	Domain Characteristic identification
Stakeholder	Stakeholder Identification
	Stakeholders Classification
Elicitation	Identification of Requirement Sources
	Tool Selection
Others	Budget Constraints
	Quality concerns
	Project Status

TABLE II. PROJECT SCALING ATTRIBUTES

Attribute	Small Scale Project	Large Scale Project
Man-hours	Small	Large
Interfaces	Less	More
Requirements	Small	Large
Features	Simple	Complex
Cost	Low	High
Quality	Minimum QA	Larger QA
Deadlines	Flexible	Stringent

## V. SUITABILITY ANALYSIS OF REQUIREMENT ELICITATION TECHNIQUES

There are varieties of Elicitation Techniques but the challenge is to select the right one from a wide variety of requirement elicitation techniques. To select the evaluating factors for selection of requirement elicitation techniques, literature was surveyed intensively and professionals working in different software houses were consulted.

After literature survey and discussion with professionals, 9 evaluating factors are identified which play important role while requirement elicitation technique selection. The impact of evaluating factor for selection of requirement elicitation techniques are studied and documented for small scale & large-scale projects. The selection of requirement elicitation techniques in small scale and large-scale projects based on the evaluating factors are shown below in Table III and Table IV.

TABLE III. SELECTION OF ELICITATION TECHNIQUES IN SMALL SCALE PROJECTS

Requirement Elicitation Technique									
Evaluating Factors	Interface prototyping	Observation	Brainstorming	Interview	Group Meetings	Workshop	Questionnaires	Expert Interviews	Scenarios
Understanding the Domain	x			x					x
Acquiring Domain Knowledge		x		x			x		
Domain Characteristic identification		x	x		x			x	
Stakeholder Identification				x		x			x
Stakeholders Classification			x	x	x			x	
Identification of Requirement Sources		x	x	x		x			
Tool Selection	x			x			x		x
Budget Constraints		x	x		x	x			
Project Status			x	x			x		x

TABLE IV. SELECTION OF ELICITATION TECHNIQUES IN LARGE SCALE PROJECTS

Requirement Elicitation Technique									
Evaluating Factors	Interface prototyping	Observation	Brainstorming	Interview	Group Meetings	Workshop	Questionnaires	Expert Interviews	Scenarios
Understanding the Domain	x	x		x		x			
Acquiring Domain Knowledge			x	x		x	x		x
Domain Characteristic identification		x		x	x	x			
Stakeholder Identification				x	x	x	x		x
Stakeholders Classification			x	x	x		x		
Identification of Requirement Sources	x		x	x		x			x
Tool Selection	x			x					
Budget Constraints	x							x	x
Project Status			x				x	x	x

## VI. SELECTION OF REQUIREMENT ELICITATION TECHNIQUES: A NEURAL NETWORK BASED APPROACH

Neural Networks possess the computing capability of the brain of human. The neural network consists of computational units that are functionally similar to neurons that are there in the human brain. A neural network is composed of several layers of neurons. Every neuron performs calculative work that will contribute to the learning of the neural network. Neurons consist of activation function, synaptic weights and an adder. If  $x_j$  is the input to neuron named  $i$  then  $w_{ij}$  is the synaptic weight that is related with neuron and input signal. In a multi-layer feed forward neural network there is a layer that is used for input for non-computational units. There are several layers of computational units that are hidden. Lastly there is output layer that consists of computational units. For the training of multi-layer feed forward network, Back propagation is used. This algorithm forwards the input signal and backward the error signal through the network. Multi-layer feed forward neural network solves complex problems and back propagation method is used to train the network.

In requirement elicitation the requirements are elicited from various sources using various elicitation techniques. There are wide varieties of elicitation techniques the major challenge is to select the appropriate elicitation technique which provides support to the elicitor and also understanding their needs and requirements [7]. Many of the elicitor think that only one of the elicitation technique is used in all types of projects and applicable to all situations, but one elicitation technique is not sufficient for all types of projects and situations [1][2][3][4][5]. In requirement elicitation elicitor selects a particular elicitation technique from a set of techniques for one reason or the other. (1) The elicitor is well versed with only one specific technique. (2) In all the situations the elicitor's favours that technique. (3) The elicitor uses a particular methodology, and the methodology is supported by a particular technique. (4) The elicitor understands spontaneously that the elicitation technique is efficient for current circumstance. From the above discussion it is evident that the fourth reason is mostly supported by the elicitor. Here neural network approach is applied for selection of requirement elicitation technique and implemented using MATLAB NNtool [11] as shown in Fig. 1.

### A. Proposed Algorithm: Neural network-based model for Requirement Elicitation Technique:

#### RequirementElicitation()

```
{
Input: (elic1, elic2, . . . ,elicn) // For each project r1,r2...rn are new set of
requirements gathered using requirement elicitation technique.
```

```
elic (Ri, Prs, Ti) //Each step in Requirement elicitation process is expressed
as a combination of elicited requirements, situation of project and
elicitation technique.
```

```
Ri = Ri+1;
```

```
Prs = Prsi+1;
```

```
// For each step i of the elicitation, elicitation technique ti when situation Si
exists and Ri captures the current state of requirement. The outcome of this
step is a new requirement with new project situation.
```

```
Ti ∈ Et //The selected elicitation technique is Ti which one is selected from
a group of requirement elicitation techniques
```

```
Ei. // Pr is Project whose requirements are elicited by applying elicitation
technique.
```

```
For the selected project Pr requirement elicitation techniques are selected
on the basis of Project attributes A represented by function.
```

```
£(Ri, Prsi, Efv(Et)) : C ∈ Et Where Et ∈ T // Efv represents evaluating factors
on the basis of these factors elicitation techniques are selected.
```

```
Ri = Et (Pri) ∪ Req where Reqi = {Req1, Req2 ....Reqn}
```

#### NNReqElic() // A Neural network based approach is for selection of Elicitation Technique

- ```
{
1. v: Assigned as Input vector //
2. t: Assigned as Target values
3. Feed Forward Neural Network is created
4. Neural network is trained using Back-propagation
4. Result of training is obtained
6. Neural network is simulated
7. Results are analyzed
}
```

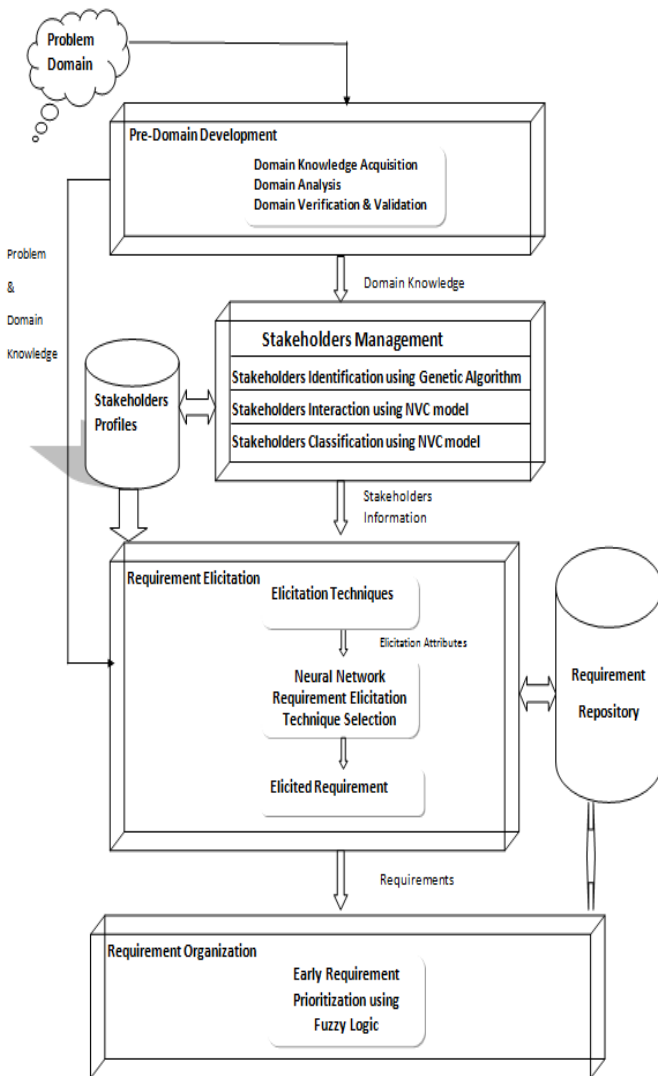

Fig. 1. Proposed Framework for Requirement Elicitation.

**B. Description of Algorithm**

Method followed for selection of Requirement Elicitation Technique.

1) Table III and Table IV of requirement elicitation techniques along with their impact are analyzed for both small scale projects & large-scale projects.

2) Matrix A is obtained from Table III and matrix B is obtained from Table IV.

$$A = \begin{bmatrix} 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 1 & 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 1 & 1 & 0 & 0 & 1 & 0 \\ 0 & 1 & 1 & 1 & 0 & 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 \\ 0 & 1 & 1 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 & 1 & 0 & 1 \end{bmatrix}$$

$$B = \begin{bmatrix} 1 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 \\ 0 & 1 & 0 & 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 1 & 0 & 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 0 & 0 & 0 & 1 & 1 & 1 \end{bmatrix}$$

3) Using MATLAB for Requirement Elicitation Technique selection.

- a) Neural network is created.
- b) Input vectors (v) values are Assigned.
- c) Assign target values (t).
- d) Create neural network.
  - i) Name: Requirement Elicitation.
  - ii) Network properties are used as per neural network description.
- e) Neural Network for Selection of Requirement Elicitation Technique.
- f) Training of neural network.
- g) The result of training.
- h) Simulating the neural network.
- i) Result of neural network-based approach.

The proposed neural network-based approach for selection of Requirement Elicitation Technique is implemented using MATLAB tool. The algorithm is implemented using NNTool box. The NNTool box is used for creating neural network. The working of MATLAB NNTool for selection of requirement elicitation technique is shown in Fig. 2, 3(a) and 3(b).

Input vector(v) are assigned following values  $V = \{1 \ 0 \ 0 \ 1 \ 0 \ 0 \ 0 \ 0 \ 1; 1 \ 1 \ 0 \ 1 \ 0 \ 1 \ 0 \ 0 \ 0\}$ .

Target values (t) are assigned as following values  $T = \{1 \ 1 \ 0 \ 1 \ 0 \ 1 \ 0 \ 0 \ 1\}$ .

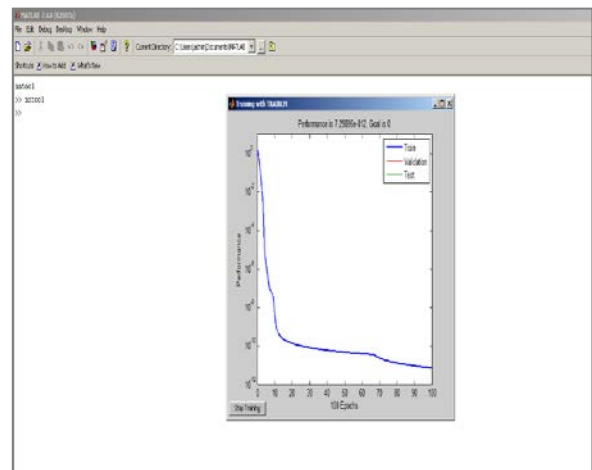

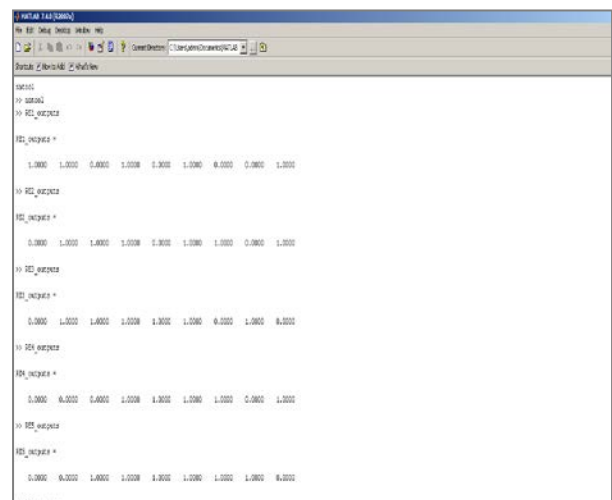

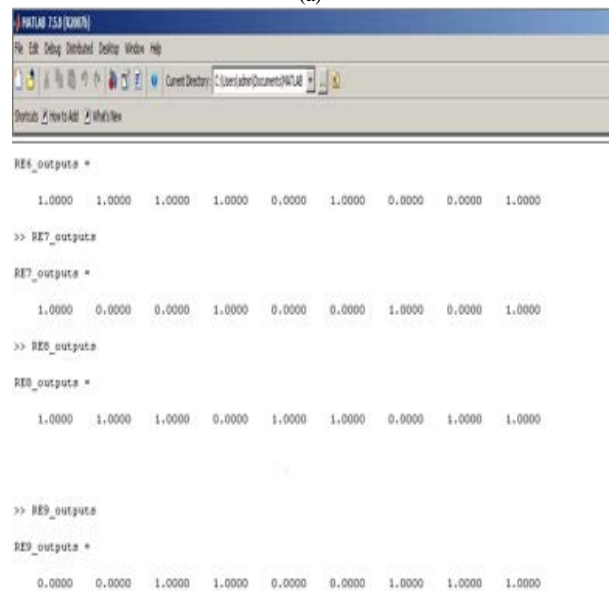

Fig. 2. Training Result.

(a)

(b)

Fig. 3. (a). Output of Neural Network (Part-1). (b). Output of Neural Network (Part-2).

The neural network (Requirement Elicitation) is created. Feed forward Back propagation is the network type. The input range is [0,1;0,1] and the Training Function TRAINLM. LEARNGDM is used as Adaptation learning function. MSE is used as performance function total no of layers is 2. Finally, the requirement elicitation neural network is trained and training results are generated. Requirement elicitation neural network is simulated.

VII. ANALYSIS OF RESULT

The Result is analyzed as ‘1’ in the output vector will corresponds to the elicitation technique being used for the evaluating factor of requirement elicitation and ‘0’ in the output vector corresponds to the technique being discarded for the given evaluating factor of requirement elicitation as shown in Matrix R. The result of neural network for selection of requirement elicitation technique is shown in matrix R

$$R = \begin{bmatrix} 1 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 1 \\ 0 & 1 & 1 & 1 & 0 & 1 & 1 & 0 & 1 \\ 0 & 1 & 1 & 1 & 1 & 1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 1 & 0 & 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 \\ 1 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 \\ 0 & 0 & 1 & 1 & 0 & 0 & 1 & 1 & 1 \end{bmatrix}$$

From the above findings weight count (Wc) is assigned to each of the corresponding elicitation technique as shown in the Table V. A scale of 2-10 is assigned to each technique. The technique with highest weight count will be the most effective technique of requirement elicitation and lowest count is least effective.

Results shown in Table V conclude that Interview is the most effective technique for requirement elicitation and workshop is the second efficient technique for requirement elicitation. Interview is most effective technique that starts with a set of pre-defined questions. The most preferred and easy technique to gather requirements from different set of stakeholders is Interview. Interview is the elicitation technique which provides a support to understand the problem domain of the existing system. The most formalized and pragmatic technique for requirement elicitation is Workshop and brainstorming. Brainstorming and workshop session provide ideas that are well suited on voting technique and/or other criteria. The most expensive technique for requirement elicitation is Prototyping as compared to other elicitation techniques. The best technique for data collection from a mass variety of sources is Questionnaire which is also cost effective. The most recommended elicitation technique for complex and critical requirements is Scenario. This will help to remove any ambiguity in the requirements. Scenarios are also effective for the projects which have to be completed in short time window or the projects in which process improvement is needed. There are various elicitation

techniques out of these techniques the elicitor selects the techniques that fit perfectly into the software projects. In this paper an approach is proposed for requirement elicitation technique selection and used this as base for selecting the combination of elicitation techniques that is best suited for effective requirement elicitation. The study suggests that single elicited techniques are generally used for requirement elicitation process, but combination of elicitation techniques for requirement elicitation process gives better result. There are various combinations of techniques denoted by  $T_{c1}, T_{c2}, T_{c3} \dots T_{cn}$ , the combination with high score as defined in the neural network approach for selection of requirement elicitation technique which is best suited for efficient requirement elicitation. As per the findings and the scores calculated in Table VI, appropriate techniques selection is done. From the findings in most cases,  $T_{c2}$  the techniques combination with the highest score is selected according to the case study. If there are no other factors that are to be considered in the final decision making then  $T_{c2}$  will be the final choice of the requirement elicitation techniques selection. These combined requirement elicitation techniques are selected for effective requirement gathering in software projects.

If new evaluating factor Ev added in further studies of projects the condition still holds the same.

TABLE V. WEIGHT COUNT OF ELICITATION TECHNIQUES

| Techniquet          | Weight Count Wc |
|---------------------|-----------------|
| Observation         | 5               |
| Brainstorming       | 8               |
| Interview           | 10              |
| Group Meetings      | 2               |
| Workshop            | 9               |
| Questionnaires      | 6               |
| Ethnography         | 3               |
| Scenarios           | 7               |
| Interface Prototype | 4               |

TABLE VI. COMBINATIONS OF ELICITATION TECHNIQUES AND THEIR SCORES

| Technique Combination $T_{c,t}$ | Techniquet                                         | Scoret |
|---------------------------------|----------------------------------------------------|--------|
| $T_{c1}$                        | Observation, Brainstorming, Interview              | 23     |
| $T_{c2}$                        | Brainstorming, Interview, Workshop                 | 27     |
| $T_{c3}$                        | Interview, Scenario, Interface Prototype           | 21     |
| $T_{c4}$                        | Group Meetings, Workshop, Interview                | 21     |
| $T_{c5}$                        | Workshop, Ethnography, Questionnaire               | 18     |
| $T_{c6}$                        | Questionnaires, Interface Prototype, Group Meeting | 12     |
| $T_{c7}$                        | Interface Prototype, Workshop, Observation         | 18     |

A. Statistical Analysis of Proposed Approach

In addition to the theoretical validation, an experimental statistical analysis is equally important in order to make the claim acceptable. In view of this fact, a statistical validation is performed to assess the performance of the proposed framework. One way ANOVA test is implemented using SPSS tool for statistical validation of requirement elicitation technique selection approach. In one way ANOVA only one factor is considered and investigated to find the differences amongst its various sample categories having numerous possible values. In this work evaluating factors Ev are used as factors defined in the table. There are total 9 factors and their values are shown in the Tables III and IV.

SPSS tool is used for implementing ANOVA test on two set of Sample data. One set sample data for small scale project and other set of sample data for large project considering evaluating factors. Result obtained from small scale projects while considering three evaluating factor Ev for selection of requirement elicitation technique and for large scale projects considering six evaluating factors for the same. The conclusion drawn from the results shown in Fig. 4 and 5, is that in samples (small scale & large scale project) the value of  $p < .05$  (For small scale projects  $p = .009$  and for large scale projects  $p = .001$ ) and the value of F in both samples is greater than the tabular value ( $F = 8.575$  for small scale and  $F = 7.713$  for large scale) means that there is significance difference between the groups. If there is significance difference between groups in small scale and large-scale projects, then there is sufficient evidence to prove that evaluating factors defined in both types of projects for selection of requirement elicitation technique are sufficient.

| ANOVA          |                |    |             |       |      |
|----------------|----------------|----|-------------|-------|------|
| Technique      | Sum of Squares | df | Mean Square | F     | Sig. |
| Between Groups | 81.088         | 5  | 16.218      | 7.713 | .001 |
| Within Groups  | 27.333         | 13 | 2.103       |       |      |
| Total          | 108.421        | 18 |             |       |      |

VIII. CONCLUSION

In requirement elicitation there are varieties of elicitation techniques but the challenge for the elicitor to select the effective technique or a combination of technique which is most suited for problem domain, stakeholders, project type, organizational structure and project to be developed. In this paper an approach using neural network is proposed for selection of requirement elicitation techniques from a large array technique. If the elicitor follows the proposed approach the problem related to selection of elicitation technique is minimized and effective requirements are elicited.

**Abstract**—Currently, the common method to predict personality implicitly (Implicit Personality Elicitation) is Personality Elicitation from Text (PET). PET predicts personality implicitly based on statuses written on social media. The weakness of this method when applied to a recommender system is the requirement to have minimal one social media account. A user without such qualification cannot use such system. To overcome this shortcoming, a new method to predict personality implicitly based on demographic data is proposed. This proposal is based on findings by previous researchers stating that there is a correlation between demographic data and personality trait. To predict personality based on demographic data, a personality model (rule) is needed. This model correlates demographic data and personality. To apply this model to a recommender system, another model is needed, that is preference model which connects personality and preference. These two models are then applied to a personality-based recommender system for fashion. From performance evaluation, the precision of and user satisfaction to the recommendation is 60.19% and 87.50%, respectively. When compared to precision and user satisfaction of PET-based recommender system (which are 82% and 79%, respectively), the precision of demographic data-based recommender system is lower whereas the satisfaction is higher.

**Keywords**—Implicit personality elicitation; demographic data; personality-based recommender system; personality trait

## I. INTRODUCTION

The first method to be used in a recommender system was content-based filtering which recommend items based on similarity between keywords on item description and on user's profile [1][2]. However, as it turned out, a content-based filtering has several weaknesses, one of which is its inability to distinguish the quality of items. This is because a good quality item will have the same keyword as a bad quality item [1].

Because of the glaring weakness in content-based filtering method, a new method, collaborative filtering, is used. The inability of content-based method to differentiate between different item qualities is solved by collaborative filtering by asking users to rate all the consumed items. This rating data is then used to calculate the rating of all new items [3], then this method will select top N items with highest ratings and then recommend these items along with the estimated ratings [4]. In practice, a rating-based collaborative filtering also has several

weaknesses, one of which is cold start problem or the new user problem [5]. This issue occurs when a recommender system is unable to provide a new user with accurate recommendations, because a new user does not have a record of what items has been consumed and the rating (the user profile is still empty).

To deal with the cold start problem, a user profile must be made available as soon as a new user becomes a member of a recommender system. The trick is that new users must fill in certain data when registering as a new member. Data that can be used in this case is personality trait. Afterward users will be given recommendations that match their personality traits. There are three advantages of using this personality trait [6]. The data pertaining to personality trait can be obtained in two ways, i.e. explicitly (Explicit Personality Elicitation) and implicitly (Implicit Personality Elicitation). The explicit method requires the user to answer a personality trait questionnaire to predict the personality trait. The commonly used personality trait questionnaire is based on the Big Five. As the name implies, Big Five consists of five factors/traits, namely: openness, conscientiousness, extraversion, agreeableness, and intellect. There are many Big Five based questionnaires that are available free of charge ranging from the longest with 504 questions to the shortest with only 10 questions [7].

If a recommender system utilizes the explicit method to obtain a user's personality traits, the user must answer a personality trait questionnaire before becoming a member of the system. Despite the fact that the method can accurately predict a user's personality traits; however, this method is burdensome and time-consuming for the user; therefore, the explicit method is only suitable for use in laboratory studies [8].

To overcome the weaknesses of the explicit personality elicitation method, a researcher may opt to use the implicit personality elicitation method. By using the latter method, a user's personality trait can be predicted, albeit indirectly. The current technique is called the Personality Elicitation from Text (PET). As the name implies, the users' personality traits are predicted from the posts they write, in this case on social media [9][10][11][12][13][14]. However, this method has one obvious weakness when applied to a recommender system, i.e. the user must have at least one active social media account.

In order to cope with the shortcoming of PET, a novel method of implicit personality elicitation is proposed, that is based on demographic data. In this new method, the user's personality is predicted based on demographic data.

To date, demographic data has been applied directly to a recommender system, hence the name Demographic Recommender System. Here the demographic information about the users is used by the classifiers to learn about how to find correlations between certain demographic data with ratings or buying tendencies [15]. However, there has been no research on the use of demographic data to predict human personality traits. The research is useful to overcome the weakness of implicit personality elicitation method, which is based on writing. This is where the gap lies in the personality-based recommender system research, specifically the implicit personality elicitation. This paper presents the result of the work in creating personality model connecting demographic data and personality traits. Next, the model is applied in a personality-based recommender system.

The idea to apply demographic data to predict personality traits come from the results of previous studies which found relationship between personality traits and demographic data. According to [16], one's personality can change or is stable at certain period in the course of his or her life. Except [17], other researchers such as [18] and [19] found that gender also affected personality traits.

Other demographic data such as race/ethnicity/country, hobbies, sport, occupation, zodiac, blood type, and color are known to also affect personality traits. Reference [20] found that persons from different countries have different personality traits. Furthermore, people with different personality traits tend to have different hobbies. An example is a person with a high score in openness is more likely to enjoy something abstract. Therefore, they are most likely are connoisseur of the arts and other forms of culture. Regarding sport, psychologically, a person's preference for a certain type of sport will be supported physically along with preference for a certain movements. Researchers also believe that different personalities will favor different movements.

Researchers also found correlation between personality traits and demographic data such as occupation [21], zodiac [22], blood type [23], and color [24].

The potential benefits of this new method of implicit personality elicitation are that it can be applied to any personality-based recommender system such as in an online shop, library, and travel company. By using this method, the system can give accurate and satisfying recommendations based on the users' demographic data instead of the users' rating history.

A summary of research trends in the recommender system and the proposed method is presented in Fig. 1.

The goal of this research is to create personality and preference models that when applied to a recommender system, then such system:

1) Can be used by any users without the need to have social media account or write status with certain length.

2) Has quite high users' satisfaction.

To achieve the goals, the following research questions must be answered:

1) Which demographic data or combination of demographic data that makes up the best model?

2) When the model is applied to a recommender system, how is the precision of the recommendation and satisfaction to the items recommended?

This paper is structured as follows: the next section, Section II, talk about the methods that are used in processing the data. Results and Discussion is presented in Section III. Section IV concludes the paper.

Fig. 1. Research Trends in the Recommender System and the Proposed Method.

## II. METHODS

The detailed survey methods has been presented in [25]. Below is the summary.

A total of 1014 respondents from several cities in Indonesia were involved in the current study. The questionnaire used in this study consists of three parts: i.e. demographic data, personality traits, and preferences.

In this survey, personality questionnaire based on Big Five was used. From a number of Big Five personality trait questionnaires that are available, the Indonesian IPIP 50 questionnaire [26] was chosen. The difference between IPIP 50 and the other Big Five-based questionnaires is that IPIP 50 does not use the term neuroticism; in its place, it uses the term emotional stability which is the opposite of neuroticism. Moreover, IPIP 50 also does not use the term openness; it uses the term intellect instead. To assess the personality traits, respondents were asked to score each question with a score of 1-5 where 1: strongly disagree, 2: disagree, 3: neutral, 4: agree, and 5: strongly agree.

In this survey, the following demographic data were collected: year of birth, marital status, city of residence, sport, occupation, hobbies, ethnicity, favorite color, zodiac, and blood type.

To learn more about preferences, data on respondents' preferences with regard to clothing styles were collected. There

are seven main clothing styles, i.e. Rebellious, Natural, Feminine, Elegant Chic, Dramatic, Creative, and Classic. It should be pointed out that initially this classification of clothing styles was intended for female users; hence, the styles are referred to as feminine and elegant chic. If the terms were applied to a male user, then obviously they would not be referred to as feminine and elegant chic. The term feminine for male users would be substituted with a style that matches the gender, i.e. masculine, whereas, the elegant chic style for male users would simply be referred to as fashionable.

As many as 105 samples of clothes that match the seven clothing styles, or 15 samples for each clothing/fashion style were provided. The respondents were asked to choose samples of clothes they liked. If they liked all the samples then they must choose all and vice versa, if they did not like any of the samples then they did not have to choose any.

After collecting the data, a three steps initial data processing were performed: (1) converted the year of birth into age, (2) calculated the total score of personality traits for each trait, (3) classified the data on the clothes samples selected by the respondents for each clothing style and counted the total number. The number of items selected by the respondent is used to determine the respondent's level of preference for a particular clothing style. If the number of selected items ranges from 1 to 5, then the level of preference is weak. If the number is from 6-10, then the level of preference is moderate. And if the number is greater than that, i.e. between 11 and 15 items, then the level of preference is strong. After that, the three most preferred clothing styles were determined, i.e. the three clothing styles with the highest number of selected items.

While doing the initial processing, the Cronbach alpha value was also calculated to determine the internal consistency of the data. Cronbach alpha was calculated using the following formula:

$$\alpha = \frac{N.c}{v+(N-1).c} \quad (1)$$

where:

$\alpha$  = Cronbach alpha.

N = the number of items.

c = average covariance between item-pairs.

v = average variance.

From the calculation, the following values were obtained: 0.801 for extraversion (good internal consistency), 0.773 for agreeableness (acceptable internal consistency), 0.844 for conscientiousness (good internal consistency), 0.908 for emotional stability (excellent internal consistency), and 0.749 for intellect (acceptable internal consistency).

It should be noted that the questionnaires for the research was made using Google Forms that does not put a limit on how many times a respondent can fill in the questionnaires. Therefore, a check needs to be done to find respondents who fill in the questionnaires more than once. During this check, as many as 25 such respondents were found; therefore, one of the duplicate data was deleted.

In addition to checking for duplicate data, another thing that needs to be checked was the presence of a certain respondent known as a self-enhancer. The presence of a self-enhancer is characterized by a high interscale correlation value, which is the value of the correlation coefficient between attributes. To calculate the interscale correlation, Pearson's correlation coefficient (r) formula was used:

$$r_{xy} = \frac{n(\sum x_i y_i) - (\sum x_i)(\sum y_i)}{\sqrt{[n \sum x_i^2 - (\sum x_i)^2][n \sum y_i^2 - (\sum y_i)^2]}} \quad (2)$$

where:

$r_{xy}$  = correlation between variables x and y.

n = the sample size.

$x_i$  and  $y_i$  = the  $i^{\text{th}}$  sample points.

Since there are five traits, there are 10 correlation coefficients must be calculated such as correlation between extraversion and agreeableness, correlation between extraversion and conscientiousness, etc. All these correlation coefficient values are then averaged to get the average interscale correlation.

The high interscale correlation value can happen because when filling in the questionnaires, self-enhancers tend to rate themselves higher than they should. For that reason, a self-enhancer will show a high level of personality traits in all traits. Therefore, to search for the presence of a self-enhancer, the total scores of personality traits of each respondent must be checked. Respondents who have a maximum score or near to the maximum score on all traits are considered as self-enhancers. In their study, [19] obtained an interscale correlation value of 0.19 and they claimed that such a value indicated that there were not many self-enhancers in the data. However, since a value of 0.38 was obtained, it was assumed that there were quite many self-enhancers in the data. After checking the data, 94 self-enhancers were found. After the data were deleted, the interscale correlation value dropped to 0.24.

When checking the data, data that did not make any sense at all were found. The data were from respondents who rated themselves with a score of 3 on all questions. Therefore, the data were deleted. After deleting the unwanted data, the remaining data is 894.

In building the model, the attribute that act as dependent attribute is level of personality traits. There are two levels: i.e. high and low. The level of personality trait was obtained in the following way: (a) by calculating the average score for each trait, (b) scores that were smaller than averages were designated as low level and scores that were higher than average were labeled as high level.

Additionally, in the modeling, the respondents' age group (categorical type) was used instead of age (numerical type). Therefore, the age data were grouped according to the classification laid down by the Indonesian Ministry of Health [25]. Based on the classification, the respondents were grouped into three groups, i.e. the middle age, adulthood, and adolescents.

The last stage in data processing was to remove some of the attributes that will not be used in the modeling stage. In the modeling, the following attributes were used: blood type, occupation, favorite color, gender, hobby, sport, zodiac group, zodiac component, age group, marital status, ethnicity, intellect level, emotional stability level, conscientiousness level, agreeableness level, extraversion level, preferred clothing style 1, preference level 1, preferred clothing style 2, preference level 2, preferred clothing style 3, and preference level 3.

### III. RESULT AND DISCUSSION

#### A. Modeling

It takes two models to build a personality-based recommender system for fashion; first, a personality model that links the demographic data with personality traits and the other one is a preference model that links the personality traits with a person's preference over fashion. Accordingly, in this stage, the two models were built.

1) *Personality model*: The process to create personality model has been presented in detail in [25]. Below is the summary.

The attributes that were used in the personality trait modeling were blood type, occupation, favorite color, gender, hobby, sport, zodiac group, zodiac component, age group, marital status, ethnicity, intellect level, emotional stability level, conscientiousness level, agreeableness level, and extraversion level. The first eleven attributes are demographic data that serve as independent attributes in the modeling using a decision tree. In addition to using the demographic data individually, a combination of two demographic data (e.g. blood type-occupation, blood type-age group) is used. By combining two demographic data, as many as 54 combinations are obtained, so the total number of demographic data used in the modeling is 65. Hence for each trait, as many as 65 models were created. Meanwhile, the level of personality traits (intellect level, emotional stability level, conscientiousness level, agreeableness level, and extraversion level) were used as the dependent attribute. To evaluate the model, a 10-fold cross validation was used.

Only one model will be used at a later stage. To select the model, the following criteria were used: (1) to make sure that the model can be used by everyone repeatedly at a later date, it has to be made certain that the demographic data in the model will never change, (2) it has to be also made sure that the model are fairly accurate. Based on these criteria, the model

based on age group and gender is chosen [25]. Another reason to choose this model is because previous research found that age and gender has very close relationship to personality traits [19]. Table I presents the model.

2) *Preference model*: As in the personality model, the detailed process in making this preference model has been presented in [27]. The summary is presented.

In the data processing stage, three preferences data and their level (preferred clothing style 1, preference level 1, preferred clothing style 2, preference level 2, preferred clothing style 3, and preference level 3) were selected from each respondent. However, before building the model, a preference data for each clothing style must be created. The data was obtained by combining the respondent's three preferences data into one. Table II shows example preferred data for Natural clothing style that will be used in the modeling. Preferred data for other clothing styles, i.e. Dramatic, Classic, Elegant Chic, Creative, Rebellious, and Feminine were also created.

The data used in building the preference model comprises the levels of the five personality traits and preferences. In the modeling, the class association rule method was used with personality trait's levels as antecedents and preferences as consequent or class.

Association rule is a method to discover a rule that connect items on a transaction. There are at least two measures that are used to identify good rule: support and confidence. If N is the number of transaction, then support of item X, Y is defined as:

$$Support(X) = \frac{Frequency\ of\ X}{N} = P(X) \tag{3}$$

$$Support(X, Y) = \frac{Frequency\ of\ XY}{N} = P(X \cap Y) \tag{4}$$

Meanwhile confidence of  $(X \rightarrow Y)$  is defined as:

$$Confidence(X \rightarrow Y) = \frac{Support(XY)}{Support(X)} = P(Y|X) \tag{5}$$

The personality trait model shown in Table I reveals that the levels of personality traits for extraversion, agreeableness, and conscientiousness are the same for all groups, they are: low for extraversion, high for agreeableness and conscientiousness. Therefore, in this preference modeling, only data with low extraversion, high agreeableness, and high conscientiousness were used. The modeling also only used the data with moderate and strong preference levels. Since it is not possible to recommend men's clothing to women and vice versa; therefore, the men and women were separated.

TABLE I. PERSONALITY MODEL (E: EXTRAVERSION, A: AGREEABLENESS, C: CONSCIENTIOUSNESS, ES: EMOTIONAL STABILITY, I: INTELLECT)

|                    | E   | A    | C    | ES   | I    | Group |
|--------------------|-----|------|------|------|------|-------|
| Adolescence Male   | Low | High | High | Low  | High | 1     |
| Adulthood Male     | Low | High | High | High | Low  | 2     |
| Middle Age Male    | Low | High | High | High | High | 3     |
| Adolescence Female | Low | High | High | Low  | Low  | 4     |
| Adulthood Female   | Low | High | High | High | Low  | 5     |
| Middle Age Female  | Low | High | High | High | Low  | 6     |

TABLE II. SAMPLE OF PREFERRED DATA ON NATURAL CLOTHING STYLE

| Preference   | Level    |
|--------------|----------|
| Elegant Chic | Strong   |
| Natural      | Weak     |
| Natural      | Strong   |
| Natural      | Moderate |
| Natural      | Moderate |
| Rebellious   | Strong   |
| Natural      | Strong   |
| Natural      | Moderate |
| Natural      | Weak     |
| Natural      | Moderate |
| Feminine     | Moderate |
| Natural      | Moderate |

TABLE III. PREFERENCE MODELING RESULT. THE YELLOW CELLS SHOW THE PREFERRED CLOTHING STYLE OF EACH PERSONALITY GROUP (E = EXTRAVERSION, A = AGREEABLENESS, C = CONSCIENTIOUSNESS, ES = EMOTIONAL STABILITY, I = INTELLECT, CL = CLASSIC, CR = CREATIVE, DR = DRAMATIC, EC = ELEGANT CHIC, FE = FEMININE, NA = NATURAL, RE = REBELLIOUS.)

| Group | Personality Traits |      |      |      |      | Fashion Style |      |     |     |     |     |     |
|-------|--------------------|------|------|------|------|---------------|------|-----|-----|-----|-----|-----|
|       | E                  | A    | C    | ES   | I    | Cl            | Cr   | Dr  | EC  | Fe  | Na  | Re  |
| 1     | Low                | High | High | Low  | High | 0,6           | 0,5  | 0,5 | 0,4 | 0,7 | 0,8 | 0,4 |
| 2     | Low                | High | High | High | Low  | 0,5           | 0,7  | 0,7 | 0,8 | 0,5 | 0,8 | 0,7 |
| 3     | Low                | High | High | High | High | 0,6           | 0,26 | 0,3 | 0,7 | 0,6 | 0,9 | 0,3 |
| 4     | Low                | High | High | Low  | Low  | 0,6           | 0,4  | 0,4 | 1   | 0,3 | 0,9 | 0,4 |
| 5     | Low                | High | High | High | Low  | 0,5           | 0,3  | 0,4 | 1   | 0,3 | 0,8 | 0,3 |
| 6     | Low                | High | High | High | Low  | 0,5           | 0,3  | 0,4 | 1   | 0,3 | 0,8 | 0,3 |

TABLE IV. THE PREFERENCE MODEL

| Group | Personality Traits |                    |                        |                          |                | Favorite Fashion Style |
|-------|--------------------|--------------------|------------------------|--------------------------|----------------|------------------------|
| 1     | Low Extraversion   | High Agreeableness | High Conscientiousness | Low Emotional Stability  | High Intellect | Natural, Feminine      |
| 2     | Low Extraversion   | High Agreeableness | High Conscientiousness | High Emotional Stability | Low Intellect  | Elegant Chic, Natural  |
| 3     | Low Extraversion   | High Agreeableness | High Conscientiousness | High Emotional Stability | High Intellect | Natural, Elegant Chic  |
| 4     | Low Extraversion   | High Agreeableness | High Conscientiousness | Low Emotional Stability  | Low Intellect  | Elegant Chic, Natural  |
| 5     | Low Extraversion   | High Agreeableness | High Conscientiousness | High Emotional Stability | Low Intellect  | Elegant Chic, Natural  |
| 6     | Low Extraversion   | High Agreeableness | High Conscientiousness | High Emotional Stability | Low Intellect  | Elegant Chic, Natural  |

Two preferred clothing styles for each personality group are selected based on the highest confidence value. The two fashion styles with the highest confidence value were chosen as the preferred clothing styles (Table III). After selecting the two preferred clothing styles, the preference model can be created and is presented in Table IV.

### B. System Performance

1) *System architecture*: The author in [7] developed a personality-based recommender system in which personality traits were predicted using a questionnaire (explicit method).

Basically, the system consists of two parts, i.e. a part for predicting the personality traits and a part to find the nearest neighbors. Meanwhile, [28] used the personality elicitation from text (implicit method) to predict personality traits in their system. The system they propose basically also consists of two parts, i.e. a part for predicting the personality traits and a part to find the nearest neighbors.

In reference to the two studies above, the recommender system that is built also consists of two parts, i.e. a part for predicting the personality traits and a part to find the nearest neighbors (Fig. 2).

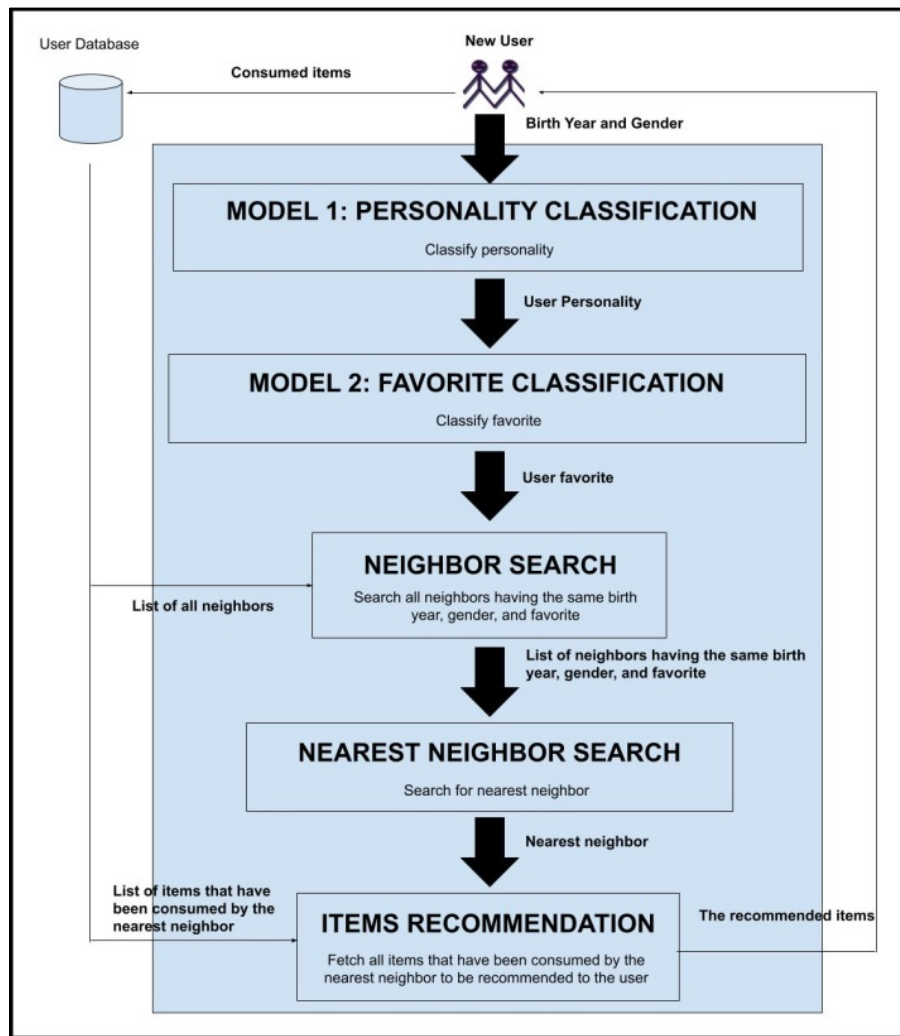

Fig. 2. The Architecture of the Proposed Recommender System.

Before discussing the model, it is necessary to explain what is meant by neighbors—neighbors are respondent's data collected during the data collection stage and modeled at the modeling stage. When the respondents were filling in the questionnaire, they were asked to pick the items that they liked; therefore, this data were treated as data about users who had consumed certain items. These data were stored in the user database as a basis for providing recommendations.

The built system includes a personality model (Model 1) and preference model (Model 2) which was obtained in the previous stage. As mentioned before, the personality model contains rules that link the demographic data to personality traits. Meanwhile, the preference model contains rules that link the personality traits to preferences.

The system starts working when a new user enters the year of birth and gender into the system. Using these data, the system will classify users into certain personality traits (predicting the user's personality traits) based on Model 1 (personality model). These personality traits are passed along to Model 2 (preference model) that will classify user's preferences based on the user's personality traits (predicting user's preferences).

After generating user's preferences, the system will retrieve all neighbors in the user's database in search of all neighbors whose year of birth, gender, and preferences are the same as the user's year of birth, gender, and preferences. The result is a list of neighbors with the same year of birth, gender, and preferences as the user.

By using the filtered list of neighbors, the system will search for the nearest neighbor. It should be explained that in this study, all users are using the model for the first time. Therefore, the user has never consumed any items. Because of that, at this stage, the system looks for the nearest neighbor based only on the same year of birth. If there are several neighbors with the same year of birth, then the system will pick one neighbor.

After the nearest neighbor is obtained, the system will collect all the items that have been consumed by the nearest neighbor. These are the items that will be recommended to the users. After consuming some or all of the recommended items, the new user data will be saved to the user database.

2) *System evaluation:* A number of researchers have used direct method to evaluate the systems they have built. A survey

conducted by [29] involved 21 students as the respondents. In the survey, the respondents were asked about the novelty of the items recommended, the accuracy, and satisfaction with the recommendations given. In another study, [30] also carried out a direct survey to users to find out the respondents' level of satisfaction with the built model.

To evaluate the performance of the proposed recommender system, a direct survey involving 74 respondents was conducted. In the survey, the respondents were asked to interact with the system.

- Relevance of the recommended items. In this experiment, the system recommends a number of items to the user. The system provides a Like button on all recommended items. When checking the recommended items one by one, if the button was pressed, it means that the item is relevant. Then the precision of the relevant items can be calculated. Precision is the percentage of relevant items from all the recommended items.

$$\text{Precision} = \frac{\text{Number of relevant items}}{\text{Number of recommended items}} \quad (6)$$

Here each user has one precision value, whereas the system's precision is the average precision of all users.

- Satisfaction to the recommended items. To find out user's satisfaction, the CSAT method is used. By using the method, user's satisfaction can be gauged by asking them how satisfied they are with the goods or services they used. There are five scales used to assess user's satisfaction, i.e. very dissatisfied, dissatisfied, neutral, satisfied, and very satisfied. The percentage of satisfaction is calculated using the following formula:

$$\text{Satisfaction} = \frac{\text{Number of responses}}{\text{Total number of responses}} \times 100\% \quad (7)$$

Note that the responses used in the formula are only Satisfied and Very Satisfied ones.

In the study, the system will ask the question: "How do you rate the recommended items?" immediately after the respondent finished checking the recommended items. The respondents were supplied with five answers as follows: very dissatisfied, dissatisfied, neutral, satisfied, and very satisfied. The percentage of user satisfaction is only calculated from the responses that give the value of Satisfied and Very Satisfied.

### C. Evaluation Result

From the evaluation, the following facts were obtained:

- 1) Precision of the recommendation was 60.19%.
- 2) Satisfaction to the items recommended was 87.50%.
- 3) There were as many as 17 respondents whose precision less than 50%, nevertheless satisfied or even very satisfied with the recommendation.
- 4) There were as many as 5 respondents whose precision more than 50%, yet dissatisfied (neutral) with the recommendation.

From the facts above, it can be said that a respondent with low precision can still be satisfied with the recommendation. In opposite, a respondent with high precision can be dissatisfied with the recommendation. Therefore, it is hypothesized that satisfaction correlates with level of preference, and not with precision. The statement on satisfaction has no correlation with accuracy has been confirmed by [31] and [32]. Note that precision is one of accuracy metrics used in recommender system besides recall, MAE, and MSE.

User's satisfaction is a psychological condition that can be measured from the user's expectation. A user will satisfy if the products or services offered to them exceeds or at least the same as the expectation. On the contrary, a user does not satisfy if the experience when using the products or services below the expectation [33]. Based on this, the reason why 17 respondents with low precision still satisfied or very satisfied with the recommendation is because they like the items recommended very much (high preference level) despite they only like a few of the many items recommended. In other word, the user's expectations are fulfilled. Meanwhile, in the case of 5 respondents with high precision but dissatisfied; it is because they do not really like the items recommended (medium preference level). As a result, they dissatisfied with the recommendation although they like many items. In other word, the user's expectation still not met.

The author in [29] reported that the precision and satisfaction of PET-based system were 82% and 79%, respectively. Compared to demographic data-based system performance, the precision of PET-based system is better but demographic data-based system is better in satisfaction. In recommendation system, accuracy is important but accuracy alone is not enough. This is because user satisfaction is more important. The next paragraph explains about this.

According to [31] two main tasks of accuracy metrics in recommender system are:

- 1) To measure the accuracy of single prediction. This is called predictive accuracy metrics. This metric calculate how close the predicted rating from the actual rating. Mean absolute error (MAE) and mean squared error (MSE) are used in this metric.
- 2) To evaluate the effectivity of the system in selecting the high quality items from a set of available items. This metric is called decision-support metrics and uses precision and recall to declare the accuracy.

Furthermore, [31] stated that building a recommender system with high accuracy was not enough. This is because the most accurate recommendation based on those metrics above, is sometimes not the useful recommendation for or liked by the users. This causes dissatisfaction to the users. In other word, user satisfaction does not always correlate with high accuracy [32][31]. Knowing the importance of user's satisfaction, [31] and [34] stated that it is not fair to judge a recommender solely from its accuracy. The users must be taken into account since they do not care with the algorithm to increase the recommendation accuracy. They only want to have useful recommendations.

Back to the performance comparison between demographic data-based system and PET-based one where the demographic data-based system has lower accuracy but higher satisfaction. Based on the above explanation, recommender system whose satisfaction is higher is better. In other word, demographic data-based system is better than the PET-based system.

#### IV. CONCLUSION

A research has been carried out to find model connecting demographic data and personality traits. As many as 65 models of each trait were created. From those models, the one based on age group and gender was selected as the working model since it satisfied two criteria. Besides that, previous research also found that age and gender had very close relationship to personality traits.

From the performance evaluation, precision and satisfaction of the demographic data-based recommender system were 60.19% and 87.50% respectively. When compared to PET-based system, demographic data-based system is lower in precision but higher in satisfaction. Other advantage of demographic data-based system compared to PET-based system is there is no obligation to have social media account.

Despite the strength of demographic data-based system compared to PET-based system, this research has some limitations:

- 1) The fashion classification may differ from other classifications. So, when a clothing is classified into a certain clothing style, others may classify it into different clothing style.
- 2) Some of the respondents may be come from low-income communities who do not care with fashion hence the choice of preferred clothing different from other respondents with the same category (e.g. age group – gender).

To test the hypothesis about the relationship between satisfaction and level of preference, another experiment is needed. In the experiment the respondents are asked not only to determine whether they like an item or not, but also the level of preference to the item. One way to obtain the level of preference is by providing five stars on each item. The more stars given by a respondent to an item, the higher the level of preference of the respondent to that item.

**Abstract**—Semester planner plays an essential role in students' society that might help students have self-discipline and determination to complete their studies. However, during the COVID-19 pandemic, they faced difficulty organizing time management and doing a manual schedule. It resulted in substantial disruptions in learning, internal assessment disturbances, and the cancellation of public evaluations. Hence, this research aims to optimize the recommended semester planner, Timetable Generator using a greedy algorithm to increase student productivity. We identified three-set control functions for each entered information: 1) validation for the inserted information to ensure valid data and no redundancy, 2) focus scale, and 3) the number of hours to finish the activity. We calculate the priority task sequence to achieve the best optimal solution. The greedy algorithm can solve the optimization problem with the best optimal solution for each situation. Then, we executed it to make a recommended semester planner. From the test conducted, the functionality shows all the features successfully passed. We validate using test accuracy for the system's reliability by evaluating it compared to the Brute Force algorithm, and the trends increase from 60% to 100%.

**Keywords**—Greedy algorithm; optimization; recommendation system; semester planner

## I. INTRODUCTION

The COVID-19 pandemic has made a huge impact on the educational system around the world, forcing lockdown in schools, universities, and colleges. Hence, Singh and Kant [1] claimed it caused a significant disrupted student learning, internal examinations, and the termination of public exams for qualification due to inferior alternatives. Based on the research, most students are not well prepared for classes. The condensed class schedule negatively impacts their learning experiences [2]. It corresponded with low experiences and academic achievement by the student.

A survey conducted towards 126 students of Universiti Teknologi MARA Melaka Kampus Jasin. They responded that they used paper and pen to organize semester planners manually, and 84.9% of students found it challenging to organize semester planners with upcoming quizzes and tests.

Additional time to new learning content is taught to enhance their performance. However, the effect of this treatment is a slight difference throughout the distribution of student performance. While the most benefit is for high-performing students, low-performing students do not benefit. Foulkes et al. [3] highlight that the research argued that it is crucial to determine the content of additional time instruction to explain this pattern.

Besides, balancing studying with the fun stuff in life can be challenging to maintain. Unstructured academic lifestyle is one of the impacts of poor sleep quality in university life [4]. It increases mental the risk of mental illness and poor academic achievement. Panda et al. [5] mentioned that based on research on academic stress students, the stress factors include many assignments, competition with other students, failures, financial problems, poor relationships, lectures, or family matters.

Thus, planning a scheduler is an effective solution to organize and navigate students' time management [6]. A semester planner is an organized schedule where students can create outlines and awareness of the study methods and the effectiveness of their study practices for the current semester and learning goals. Students become self-discipline, deterministic, and more confident [7]. In addition, it helps them build self-regulated learning skills to succeed in various learning environments and workplaces. As a primary time management tool, a scheduler comes in a list of times when events and actions occur. Brioso et al. [8] supported that planning and controlling did not starve due to insufficient input in an intrinsically challenging task.

The primary substance of time management is reducing stress [9]. Of course, building a schedule for the current semester is a tedious task. Students need to fit all the courses into a single scheduler, which would take time and patience. The time management principle is time management on how to plan the specific tasks and work and organized. Otherwise, it can affect entire planning and work. Based on the same survey, 83.8% of the students claimed they never use revision planners' automated class timetable generator.

The research was sponsored by Universiti Teknologi MARA Cawangan Melaka under the TEJA Grant 2021 (GDT 2021/1-28)

Therefore, to overcome the problem, a recommended semester planner using optimization of the greedy-based algorithm was used quickly to find an approximate solution in the optimization prickly. This parallel with the greedy-based algorithm concept, to solve problems in getting the globally optimal solution with the choice seems best by making a locally optimal choice [10]. Moreover, the greedy allocation is compatible with a dynamic heterogeneous resource environment linked to the scheduler via a homogenous communication environment [11]. Thus, Choudhary and Peddoju [12] claimed that it is easier to assess the run with more efficient use of available resources. It allows UiTM students to identify peak study load times to ensure they have plenty of time to complete all assignments. The achievement of each target would bring in the motivation to achieve another target.

## II. RELATED WORK AND TECHNIQUES

This section describes the related works in scheduling and related techniques related to the study.

### A. Related Work in Scheduling

There are some related works in scheduling such as course timetables, high school timetables [13], exam timetables, and some of the other schedules used in the workplace. Although many intelligent practices have been used in recent years to solve course timetabling, there are still many areas for improvement. Wang et al. [13] claimed that to effectively solve the Greedy Algorithm and provide a high-performance initial Genetic Algorithm population, they suggested using a Greedy and Genetic Fusion Algorithm. The hybrid Cat Swarm Optimization algorithm-based application solves the school schedule problem. It is efficient, easy to use, and fast. The demonstration conducts by experiments with real-life input data to test the efficiency and performance. The test case uses the same timetable and the same description statistics. The result shows that the hybrid CSO-based algorithm performs better in less computational time than many other existing approaches.

For timetable examination, a new proposed combination of three approaches: multiple criteria, maximum independent set, and heuristic graph to solve the problem of timetable examination [14]. There is also have some related work on schedulers in the workplace, such as flight schedules. Optimization control and algorithm design have also been hot issues in China's research into unusual flights. Based on a better knowledge of the NP problem under the flight recovery model, the researcher validates the usefulness of the greedy random adaptive algorithm in the problem-solving process [15].

### B. Related Techniques

An algorithm is a step-by-step approach to problem-solving, widely used for data processing, calculation, and other related mathematical and computer operations. Different algorithms can easily and quickly perform operations or solve problems in terms of efficiency. There are three related techniques: Evolutionary Algorithm (EA), Greedy Algorithm, and Brute Force.

The Evolutionary Algorithm (EA) development has been significant among the research and optimization techniques set in the last decade [16]. EAs are a set of modern heuristics used with great complexity in many applications. It was the engine of a field known as Evolutionary Computation (EC) that successfully solved complex problems [17]. The advantages of EC techniques derived from gaining fitness and flexibility to the goal combined with robust behavior. Nowadays, EC is considered an adaptable problem-solving concept, particularly in complex optimization problems.

A greedy-based algorithm produces a good solution to some math but not others. As mentioned by Prabhakaran et al. [18], most of the issues they are working on will have two properties; firstly, a greedy choice property is defined as the best way to make any choice to solve sub-problems that might arise later. A greedy algorithm's choice might depend on the decision but not the future or all the subproblem's solutions. It makes iteratively one greedy choice to minimize a problem into an optimal solution. Secondly, an optimal substructure is an optimal solution to solve the problem includes optimal solutions to the subproblem. Then a will problem displays optimal substructure. The problem of optimization is finding the best solution that seems all feasible [19].

Brute Force defines a straightforward problem strategy, commonly dependent on problem statement and concept definition. Definition of 'force' is a computer strategy but not intellect. Another approach to describe Brute Force is 'Just do it', and sometimes, the technique is easiest to use [20]. Exhaustive or Brute Force searches can generate and test the basic solving problem method and algorithm paradigm. Mahoor et al. [21] claimed it consists of the listed systematic potential candidate for solution and testing if each candidate meets the problem statement. Therefore, this approach is used commonly when the problem is small enough that heuristics can reduce the number of possible solutions to a manageable number. Also, identifying a solution recovery model takes more time than speed.

As a result, an evolutionary algorithm is beneficial with conceptual simplicity, while Brute Force is widely applicable and known for its simplicity. However, the greedy-based algorithm is more accessible to implement and faster than the other two. Although the Greedy-based algorithm has not always reached the optimal global solution, most of the time reaches the sub-optimal solution. Thus, greedy-based techniques are the best solution for this project in schedule recommendation of timetable generator with semester planner.

## III. METHODS

This section divides research methodology into four phases: gather information, design and development and system validation.

### A. Gather Information Phase

The survey was conducted on 126 respondents of students from UiTM Cawangan Melaka Kampus Jasin on their experience to understand better the real problem faced by them. Table I shows the summary of survey information. About 85.70% of respondents agreed that they have difficulties organizing their study planner, while the rest, 14.30%, voted

with no issues. Some of them never use study planners with 58.13%, followed by book or handphone planners with 24.78%, sticky notes with 14.60%, and timetable 2.49%.

TABLE I. SURVEY DETAILS AND RESPONSES TO GATHER INFORMATION

| Questions                              | Item Response          | Percentage Response |
|----------------------------------------|------------------------|---------------------|
| Difficulties To Organize Study Planner | Yes                    | 85.70%              |
|                                        | No                     | 14.30%              |
| Current Method Study Planner           | Never                  | 58.13%              |
|                                        | Book/Handphone Planner | 24.78%              |
|                                        | Use Sticky Note        | 14.60%              |
|                                        | Timetable              | 2.49%               |

**B. Timetable Generator Flowchart**

We use the flowchart as in Fig. 1 to design how the timetable generator operates by defining the system’s module, data, and architecture to specify the system requirements. It starts with key-in details information for the user’s hobby, extracurricular, and subject details for the current semester. We set the control functions for each information: 1) validation for the inserted information to ensure valid data and no redundancy, 2) focus scale, and 3) the number of hours to finish the activity. The information entered by the user can be updated or deleted before we generate the planner using the Greedy algorithm.

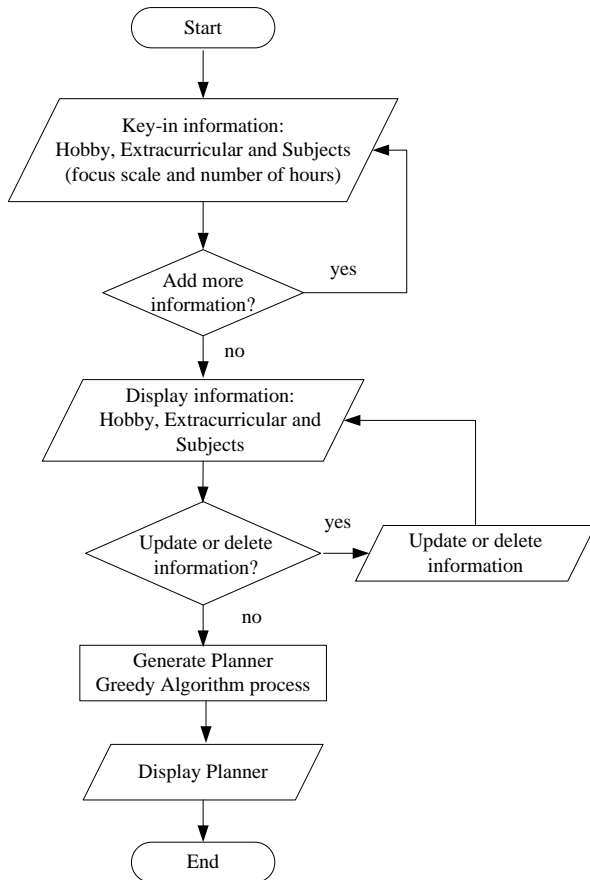

Fig. 1. Flowchart for Timetable Generator Planner.

**C. System Interface**

System design or user interface design is designing an interface in software or computerized devices focusing on looks or style. This research aims to design an interface that is easy to use and understandable by the user. User interface design usually refers to graphical user interfaces.

**D. Greedy Algorithm Development**

Fig. 2 shows the Greedy algorithm flowchart of the phase involved in this algorithm to achieve the best optimization result. The algorithm needs to solve scheduling problems in tasks that need to be completed, required time to complete each task, and priority of each task. Three main processes involved:

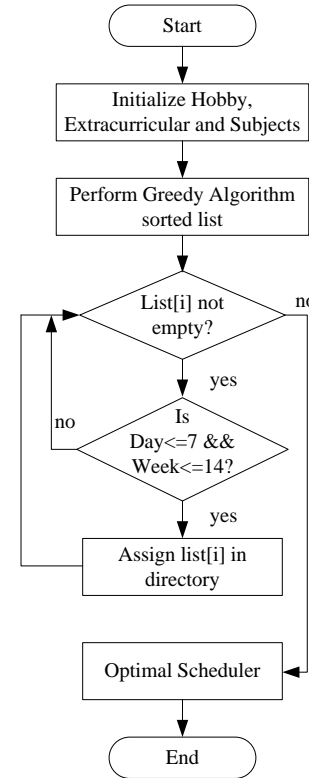

Fig. 2. Phases in Optimizing Greedy Algorithm for Timetable Generator.

1) *Step 1: Initialization:* The algorithm initializes all user variables and sorts the list with the greedy approach. The data will be classified into three lists: name, focus scale, and complete time.

2) *Step 2: Sort list:* Sort the tasks based on decreasing order of priority. However, in some cases, the priorities of different tasks are the same. This algorithm recommends the list of tasks that require a higher focus scale and the shortest time completed the task to minimize the problem. The algorithm would give preference to a higher focus scale and tasks that take less time to complete so that the higher focus scale will lead to a higher score, and more time needed will reduce the score. After being classified into a list, this phase has created another list of pairs [key, value] as shown below. Each of the list pairs is a combination of hobby, extracurricular, and subject.

- Complete time [complete time, name].
- Focus scale [focus scale, name].
- Priority [(focus scale/complete time), name].

Then, the system would proceed with the sorting process for each list in decreasing the order of “key”. After all the variables have been sorted, the algorithm will assign lists in a directory with a specific condition.

3) *Step 3: Optimal scheduler:* Assume that task in priority sequence is  $n$ , set  $priority = \{(8, ICT662), (7, Badminton), \dots, n\}$  and tasks use the same resources from of hobby, extracurricular and subject task, with priority score for each task. The algorithm use planner set to store the selected task. The task chosen is ICT662, and Monday is initialized “ICT662”. Then the algorithm will go through 14 weeks to check whether the task has an assignment, quiz, or test week. For example, ICT662 has a quiz on week five, then Monday on week five is initialized “Quiz 1 ICT662”. An algorithm will proceed initialized in planner set with next day and weeks until all the task in the priority list is empty.

#### E. System Validation

Lastly, we proceed with system validation to test the functionality and reliability of the system. A functionality test runs to test whether the system’s function is running smoothly or not. If there are bugs when running the functionality test, we need to correct the function to ensure it meets the requirements. Functionality testing tests and identifies which function is performed with or without error. If an error occurs in this phase, we need to fix the error before the implementation. For the reliability test, we compare the result of the Timetable Generator with the Brute Force algorithm to check the result’s accuracy. We tested this testing phase with developers, lectures, and UiTM Jasin students to know whether this project is performing well or not.

### IV. RESULT AND DISCUSSION

#### A. Functionality Testing

We have to test and check the core’s function application, input, button, table, and more during this phase. To test the system’s functionality, Table II describes consideration of

features criterion where we test it accordingly and fill up the result. There are six features involved: registration and login, subject, hobby and extracurricular, updating user’s details, a sequence of the focus scale, complete time and priority, planner and print planner.

The output of Timetable Generator, as in Fig. 3, display the sorted list based on the focus scale, complete time and priority in the list box. These list boxes show the pair between focus scale and complete time with all user tasks. The sorted priority list box is the greedy algorithm result sequence with the score and name of each task. Finally, Fig. 4 shows the output result of the Timetable Generator or the semester planner with an optimal scheduler. We successfully passed all the features, and finally, users can print a semester planner in pdf form as the last feature development.

#### B. Reliability Testing

We validate the reliability testing based on the system’s accuracy in this phase and use ten tests to run the validation. The system’s response might have a different condition with different sequences of priority and Brute Force result on the hobby, extracurricular, and subject enrol. Table III shows the output from the system prototype and Brute Force algorithm result by manual calculation. We test the accuracy testing based on these two rules: First, give preference to higher priorities, leading to a higher score. Second, give preference to tasks that take less time to complete, so tasks that take more time will reduce the score. Next, we calculate the accuracy based on the similarity result sequence of Brute Force and Timetable Generator.

Table IV shows the summary comparison on the research accuracy result,  $p$  between Brute Force and our proposed study. Only attempt 1 has a slight difference out of five; only three items have similar according to the result sequence. The rest outcome gained is similar for both reliability tests.

We constructed the visualization of an accuracy graph from the result of 10 output. Fig. 5 shows the 2-axes graph, increasing from 0.60 (60%) to 1.0 (100%). It proves that the Timetable Generator system is accurate and can be used for the student to overcome the problem.

TABLE II. FEATURES COMPARISON BETWEEN RECOMMENDATION TECHNIQUES

| Features                                              | Details                                                                                                                                                                                                                                                                                                                | Status |
|-------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| Registration and login                                | The system can register a new account with an encrypted password and allow users to login into the system with the correct combination of attributes needed.                                                                                                                                                           | Passed |
| Subject, hobby and extracurricular                    | The system can store the user’s subject, hobby, and extracurricular details in the database. Before storing the details, the system will check whether all of the data are inserted or not. The incomplete information would not allow being stored in the database.                                                   | Passed |
| Updating user’s details                               | The system retrieved all user details from the database and displayed them in a grid view. Users can update some data and store it back in the database.                                                                                                                                                               | Passed |
| A sequence of complete time, focus scale and priority | The system can list decreasing order of complete time, focus scale and priority.                                                                                                                                                                                                                                       | Passed |
| Planner                                               | The system prescribes a schedule of semester planners that is the best based on the priority sequence. The schedule will be displayed in the form of a table that contains seven days and 14 weeks of a semester. Thus, the system will display the subject details based on assignment week, quiz week and test week. | Passed |

## V. CONCLUSION

We presented a recommended semester planner using the optimization technique greedy optimization. Optimization is done to suggest a semester planner according to the user's preferences and at the same time recommend the planner with scheduling all user's activities, including study, hobby and extracurricular for a semester. We managed to validate the Timetable Generator using a reliability test by testing the system's accuracy with the Brute Force algorithm with the achievement of 100% accuracy. Future work is recommended to enhance the system's security. We need to hold the private and confidential data and propose using progressive web applications for a better view and suitable for handphones.

**Abstract**—Electricity consumption has continued to go up rapidly to follow the rapid growth of the economy. Therefore, detecting anomalies in buildings' energy data is considered one of the most essential techniques to detect anomalous events in buildings. This paper aims to optimize the electricity consumption in households by forecasting the consumption of these households and, consequently, identifying the anomalies. Further, as the used dataset is huge and published publicly, many research used part of it based on their needs. In this paper, the dataset is grouped as daily consumption and monthly consumption to compare the network topologies of all other works that used the same dataset with the selected part. The proposed methodology will depend basically on long short-term memory (LSTM) because it is powerful, flexible, and can deal with complex multi-dimensional time-series data. The results of the model can accurately predict the future consumption of individual households in a daily or monthly consumption base, even if the household was not included in the original training set. The proposed daily model achieves Root Mean Square Error (RMSE) value of 0.362 and mean absolute error (MAE) of 19.7%, while the monthly model achieves an RMSE value of 0.376 and MAE of 17.8%. Our model got the lowest accuracy result when compared with other compared network topologies. The lowest RMSE achieved from other topologies is 0.37 and the lowest MAE is 18% where our model achieved RMSE of 0.362 and MAE of 17.8%. Further, the model can detect the anomalies efficiently in both daily electricity consumption data and monthly electricity consumption data. However, the daily electricity consumption readings are way better to detect anomalies than the monthly electricity consumption readings because of the different picks that appear in the daily consumption data.

**Keywords**—Anomalies detection; deep learning; electricity consumption forecasting; LSTM

## I. INTRODUCTION

Global electricity consumption has grown rapidly faster than the rate of energy consumption where the electricity consumption in both commercial and residential buildings has significantly increased and can account between 20% and 40% in developed countries [1-2]. During 1980-2013, energy consumption went up from 7300 TWh to 22100 TWh. Also, it has grown even faster since the twenty-first century by 1.2 percentage points more than the average annual rise in energy consumption. In 2013, the annual electricity consumption of the world reached 3048 KWh per capita which is up to 42.3%

from 1990. In Asia, Bahrain, South Korea, and United Arab Emirates are the top three consumers where they exceeded 10000 KWh [2].

As a result, the energy demand will steadily be increased shortly due to the rise in population, comfort levels of buildings and spending a long time inside buildings. Thus, optimizing energy consumption and the efficiency of energy in buildings is a primary concern for anyone wishing to save energy [1]. Although the extensive modeling techniques that investigate designing buildings with a low level of energy consumption, buildings (especially commercial) often exceed the promised energy-saving design by some anomalous events, such as lighting equipment faults. These anomalous events can reach figures between 2-11% of the total energy consumption in commercial buildings [3].

To this end, detecting anomalies in buildings' energy data is considered one of the most essential techniques to detect anomalous events in buildings. Therefore, metering buildings' electricity provides data that have a significant impact on energy-saving opportunities due to analyzing energy usage, managing energy consumption and, thus, identifying anomalous patterns which if corrected will improve the comfort level of buildings with the least power consumption.

At a household level, the electricity consumption includes a high amount of noise, and the time series data is considered nonlinearly because of the seasonal changes' effects. Thus, this is a motivative of using machine learning field because of its capability to capture the nonlinearities among the time series data. In particular, LSTM models have proven effective in this type of context and in learning complex nonlinear patterns [4]. In this study, the aim is to solve the high volatility and uncertainty of electricity consumption in households by forecasting the consumption of these households and, consequently, identifying the anomalies.

Therefore, the proposed approach can deal effectively with a large number of smart meters data. After training and implementing the appropriate parameters, the resulting model will have the ability to forecast the future consumption of households that were not included in the training process. Hence, the resulting model has a great potential to forecast big data accurately. The validity of the proposed approach is tested based on an extensive real-world dataset that contains

thousands of households' consumption in several years so, several seasonal patterns. The used dataset is originally published in [5]. It is a collection of 104057 records of London's households from 2011 to 2014. In addition to the date and time, it consists of a unique household identifier, Acorn group categories, which is a classification of neighborhoods. Furthermore, historical weather data for London area during the same dates of smart meters registers was merged with the original dataset, which can be found in [6]. The weather dataset consists of the date of the day, maximum and minimum temperature of that day, high and low apparent temperature, wind bearing, dewpoint, cloud cover, wind speed, pressure, visibility, humidity, UV index, and moon phase.

The paper is organized as follows. Section II outlines historical selected works performed within electricity consumption forecasting. Then, the model is proposed in Section III. In Section IV, the results of the electricity consumption forecasting with the proposed model are discussed and shown. Finally, Section V concludes the paper and Section IV shows the future work.

## II. RELATED WORK

Recently, many machine learning models have contributed very well to estimating energy consumption by prediction models. The following section mentions some of the recently published researches in the areas of predicting energy consumption by using different machine learning approaches.

In references [7-9], they reviewed the state of the art of machine learning models of all kinds of energy systems including demand prediction, cost prediction, energy consumption prediction, load forecasting, etc. They identified the highest popularity models in energy systems which are Multilayer Perceptron (MLP), Artificial Neural Networks (ANN), Adaptive Neuro-Fuzzy Inference System (ANFIS), Support Vector Machines (SVM), Extreme Learning Machine (ELM), Wavelet Neural Network (WNN), ensembles, deep learning, and hybrid machine learning models. Nevertheless, the hybrid machine learning models have significantly increased the performance of energy models.

Besides, García-Martín et al. illustrated in [10] the recent approaches used to estimate the energy consumption especially from data mining and neural networks perspectives. They revealed some emerged works, such as NeuralPower and SyNERGY that allow energy evaluation in machine learning. NeuralPower evaluates the energy by building a prediction model to estimate the energy consumption while SyNERGY builds energy estimation models based on integrating tools to the current machine learning suites. Further, they presented some challenges faced by current modeling approaches, such as the rapid changes in hardware, implementation and design of neural networks.

In [11] the authors proposed a hybrid approach that combines ELM with stacked autoencoders (SAE) to predict the energy consumption in buildings. Firstly, they used SAE to extract the features of energy consumption in buildings. Then, for prediction, they employed ELM to get precise prediction results. Their results showed that their proposed approach has

the best prediction performance compared to other approaches, such as SVM, multiple linear regression, backpropagation neural network (BPNN) and the generalized radial basis function neural network (GRBFNN). Also, in [12], they used deep extreme learning machine and SVM techniques to predict the energy consumption. Their proposed model obtained an accuracy of 90.70%.

J. Y. Kim and S. B. Cho. [13] proposed an autoencoder model to predict electricity consumption based on LSTM. The proposed model defines a state that represents the demand information, then, the future energy demand is predicted according to this state. The state contains information like the input values features, produced data features and the expected energy consumption. Moreover, this model allows inserting conditions to predict the electricity demand according to these conditions, such as economy or weather information and that is what makes it more efficient compared to other works. In addition to [13] and [11], Y. Jin *et al.* [14] proposed a clustering analysis method to analyze the daily electricity consumption based on an autoencoder algorithm. Their suggested method has a limitation of outlier detection when there are large outlier data.

In [15], they used different machine learning algorithms such as linear regression (LR), DTs, deep neural network (DNN), recurrent neural network (RNN), gated recurrent units (GRUs) and LSTM to evaluate their performance. They forecasted the data based on the ACORN groups in London. Then, they forecasted number of step-ahead like 1, 2, 12, 24, 48. LSTM achieved the lowest MAE compared to other algorithms for all forecasting types where they were 19%, 21.7%, 23.5%, 24.2%, and 25.6%, respectively. On the other hand, forecasting one step ahead has the lowest MAE and the worse was forecasting 48 steps ahead, as shown in Fig. 1. Furthermore, the authors in [16] proposed a machine learning-based ensemble model to improve the electricity consumption prediction. The model combines Cat Boost (CB), Gradient Boost (GB) and Multilayer Perceptron (MLP) algorithms. Moreover, they employed the genetic algorithm to get optimal features to be used for the model. They obtained RMSE of 5.05 and MAE of 3.05.

F. Z. Abera et al. proposed in [17] a method that uses the CLARA clustering technique to group their dataset into three clusters based on the mean of the consumption values. Then, SVM and ANN classifiers are used to predict the appliance that consumes more energy. They proved that ANN and SVM are worthwhile methods for analyzing and forecasting smart meter data with an accuracy of 99%.

| M  | Regression Model |       |       |       |       |              |

Fig. 1. Forecasting Results of [15].

D. H. Nguyen et al. proposed in [18] a machine learning-based approach called iRBF-NN to predict the electricity consumption based on historical consumption and weather data. They demonstrated the relation between weather parameters (temperature, humidity, precipitation, sunshine duration and wind speed) and electricity consumption. They found that the humidity and temperature parameters have the highest relation to electricity consumption. Other parameters such as population and sunshine also affect the electricity consumption, however, according to the hardness of collecting their data and the simplicity of the model they did not consider them. The prediction performance of the proposed approach was good; however, the weather prediction was not accurate. E. Y. Shchetinin. [19] proposed a method to estimate the electricity consumption in commercial and business buildings by using a gradient boosting algorithm (GBM). Their results showed that GBM has the ability to estimate the accuracy of energy consumption prediction more than other machine learning algorithms like random forest and regression. Conversely, X. M. Zhang et al. used in [20] support vector regression to predict residential electricity consumption (rather than commercial consumption) according to their daily consumption and hourly consumption. Their results showed that the MAPE error is 12.78 and 22.01 for daily prediction and hourly prediction, respectively, and that means predicting daily consumption is better than predicting hourly consumption since it mitigates the effect of the randomness of behaviors in hourly family members.

S. Aman et al. proposed in [21] a novel model namely REDUCE (Reduced Electricity Consumption Ensemble) that combines outputs from three base models. These three models are called pre-DR (demand response), in-DR and all-day consumption sequences. Their results showed that the model is strong for buildings that do not follow a strict schedule of electricity consumption and they do not have enough historical demand response data.

On the other hand, Eisses, J. used in [22] three different machine learning techniques to detect anomalies in electricity consumptions data which are k-nearest neighbors (KNN), SVM and ANN. They conclude that ANN has the best accuracy performance with an error of 14%. Furthermore, K. Hollingsworth et al. [23] proposed an application for detecting anomalies in energy. Their application is based on the combination of two types of machine learning algorithms: ARIMA and LSTM. Their application correctly identified the anomalies and provided the time of the incident. Also, it provides higher accuracy by benefiting from both separated models' abilities. In [24], they combine K-means and DNN to identify the anomalies in energy consumption. Firstly, K-means is used to cluster the customers based on their similar electricity consumption behavior. Then, DNN algorithm is used to accurately identify the anomalies of each consumer.

### III. METHODOLOGY

Long short-term memory (LSTM) is a recurrent neural network (RNN) that is used widely in the deep learning field. RNN has the ability to process any hidden patterns that exist in the data since it takes into consideration the sequential nature

of the data. Therefore, it does not feed all the information to the network at once, but it feeds them as a chain structure where one element is processed and then passed to the second element in the sequence. In other words, RNN is recurrent in nature since it implements the same function for each input of the data whilst the output of the current input relies on the previous computation. Once the output is produced, it is copied and sent back into the recurrent network [25-26]. Fig. 2 shows the unrolled recurrent neural network where  $X_t$  is the input of the state,  $h_t$  is the output of the state and  $A$  is the activation function of the state. Firstly,  $X_0$  is taken from the sequence of the input and then outputs  $h_0$ . After that,  $h_0$  and  $X_1$  will be input for the next step. Similarly,  $h_1$  from the next step with  $X_2$  will be the input for the next step, etc.

Despite the stability of RNN, it has challenges in practice. It suffers from a well-documented problem called vanishing gradients.

The vanishing gradient is encountered when training a large number of samples since it requires many layers. Therefore, the gradient reduced dramatically because it propagated through the network [27].

LSTM can solve the issue of the vanishing gradient by capturing long-term dependencies. It's a well-known branch of deep learning and gained wide attention to forecasting time series data in recent years.

In this study, the aim is to solve the high volatility and uncertainty of electricity consumption in households by forecasting the consumption of these households and, consequently, identifying the anomalies.

#### A. Data Description and Preprocessing

The used dataset is real data of electricity consumption that was originally published in [5]. In particular, the dataset consists of electricity consumption readings of 5567 London households from November 2011 to February 2014. Readings measured in kWh were taken in half-hourly intervals. The dataset contains date and time, unique household identifier, Acorn group categories, which is a classification of neighborhoods. Furthermore, historical weather data for London area during the same dates of smart meters registers was merged with the original dataset, which can be found in [6]. The weather dataset consists of the date of the day, maximum and minimum temperature of that day, high and low apparent temperature, wind bearing, dewpoint, cloud cover, wind speed, pressure, visibility, humidity, UV index, and moon phase. Since the length of the samples varies from one household to another and it might that one household may have only one reading sample, we must assure that each household contains at least two readings one for each year, therefore, the others are excluded.

Fig. 2. Recurrent Neural Network.

As clarified earlier, the original electricity consumption data contains 167,932,474 lines of half-hourly readings for 5567 households in, approximately, four years. Nevertheless, there exist some missing consumption values. Therefore, to avoid the undesirable impact on the forecasting model data cleansing process should be done. Firstly, all NULL values are replaced with NAN. Meanwhile, there are 27858 of 0s in the consumption column where we consider them as inconsistent values. Therefore, they are replaced with NAN. After that, all NAN values are imputed by the average of the electricity consumption column. Fortunately, there are no missing or inconsistent values in the weather dataset. From the resulting dataset, 80% of the data are considered as training set and the other 20% for the testing set.

The proposed methodology is general and can deal with high-frequency time series data. However, the dataset is huge, and it contains more than 167 million records even after cleaning. Therefore, to reduce the dimension and volatility, the dataset is aggregated into daily intervals by calculating the mean consumption of each day for each household, as shown in Fig. 3. Moreover, for a comparison purpose, the average monthly electricity consumption is calculated for each household, as shown in Fig. 4. Fig. 3 illustrates the daily electricity consumption sorted by households' id. Although most of the consumption runs on average, there are many picks on different days that have high consumption. On the contrary, there is a clear difference between the monthly consumption in Fig. 4 and the daily consumption in Fig. 3 because when considering monthly consumption, it is mostly going to the average except for a huge pick in the middle. This potentially signs to get better results when using daily measurements for detecting anomalies rather than the monthly consumption because of the detailed data that appear in the daily readings.

### B. Proposed Model

Generally, the proposed methodology depends basically on LSTM because, as mentioned earlier, it is powerful, flexible, and has the ability to deal with complex multi-dimensional time-series data.

Further, an important reason behind using LSTM is that its performance is affected by the size of the data. Therefore, the main idea of the proposed model is to train a single model for all the considered data. The model is trained using long history to have the ability to predict new smart meters that were not used in the training process.

Fig. 3. Average Daily Electricity Consumption of London Households.

Fig. 4. Average Monthly Electricity Consumption of London Households.

To perform the electricity consumption prediction, firstly we set LSTM to do the time series forecasting with the historical data. Then, for detecting anomalies, the difference between the actual value and the predicted value will be calculated. A consumption is classified as an anomaly if its error is above a selected threshold. The threshold is selected intuitively depending on the density of the errors, as it will be clarified later.

To implement LSTM, the TensorFlow tool is used which is an open-source library developed to handle large datasets, optimization algorithms, and automatic differentiation. First, since the used data is time-series data, 3-dimensional units are defined to be used in the LSTM. The first dimension is the number of samples which is, in this case, the number of daily reading samples of the training set. The second dimension is the time steps that are used to forecast the current day (t) by given historical consumption and weather information at the prior time step, 30 in daily electricity consumption case and 15 in monthly electricity consumption case. The third and last dimension is the features which are the meteorological variables that it is defined earlier (like the weather conditions).

Next, the parameters of the model are adjusted as the following, the model is built with two LSTM layers. The first layer has 100 neurons and the second layer has 32 neurons. The 'relu' activation function is used to convert the output of each unit to be an input for the next layer. Further, a dropout layer is added with a rate of 20% to avoid overfitting. Finally, a dense layer is added with one unit to provide the corresponding forecast.

Immediately by designing the topology of the network, it compiles by defining the optimization algorithm and the loss function. the mean absolute value is selected for the loss function and Adam optimizer as the optimization algorithm. Indeed, all the previous parameters have been chosen after testing multiple network topologies. Once the network has been compiled, the associated weights are fitted which is a very expensive step in the methodology from a computational point of view. Then, the trained model is used to predict one step ahead for all the desired smart meters in the future.

The model needs to identify the number of epochs that indicate the number of passes of the entire training dataset. We select 40 epochs. Every epoch will be divided into a fixed-sized number from the training set, namely batch. In the daily

data, a batch size of 5000 days is selected since it is a big dataset. Hence, every epoch has 425 batches. However, for the monthly data, a batch size of 1000 days is selected, therefore, every epoch has 74 batches.

#### IV. RESULTS AND DISCUSSION

In this section, a summary of the main numerical results obtained from our proposed model in both daily electricity consumption and monthly electricity consumption is provided.

##### A. Electricity Consumption Forecasting

The forecasting model is designed to work with LSTM on both daily and monthly electricity consumption for each household. To explore the forecasting accuracy, two evaluation metrics are used are the root mean squared error (RMSE) and the mean absolute error (MAE) which can be calculated as follows:

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (Y - \hat{Y})^2} \quad (1)$$

$$MAE = \frac{1}{n} \sum_{i=1}^n |Y - \hat{Y}| \quad (2)$$

In general, the smaller values of the performance metrics provide higher forecasting accuracy. Table I presents the forecasting results obtained from the proposed model and compares it with other works presented in [28], [15], [29] and [30], where the same dataset is shared. However, the used dataset is a huge dataset and its size is about 11 GB. Therefore, every research used part of it based on their needs, as illustrated in the second column of Table I. In this work, daily electricity consumption and monthly electricity consumption datasets are used to explore how the performance will be affected when using different network topologies in the same dataset. As it is clear from Table I, the proposed dataset and the dataset used in [28] are the most complicated and longest since we have not excluded any reading from the original dataset. However, in [28], they used only three weather conditions which are humidity, wind speed, and temperature whereas, in this work, all the weather conditions are used without excluding any influencing factor. The lowest RMSE value is achieved from [28] where it is equal to 0.05. On the other hand, the worst RMSE value obtained from [29] where is 3.35. To the research that used MAE performance measure, the lowest MAE was achieved by [16] when forecasting one step-ahead where they got MAE of 19%, whereas the worst MAE was obtained from the same research when forecasting 48 steps-ahead where they got MAE of 25.6%. Although the proposed model does not provide the best result when compared with other works, it got the lowest accuracy result when compared with other compared network topologies, as shown in the 12 and 13 columns in Table I.

To give a graphical representation of the daily electricity consumption model's results, Fig. 5 illustrates the forecasted consumption in comparison with the original consumption in both training and test data. As it is clear from the figure, there is some difference between the original values and the predicted ones. This might be because of the different

consumption habits of every household which increase and decrease without a clear pattern, as illustrated earlier in Fig. 3.

Though the proposed model appears as it did not forecast the daily electricity consumption perfectly, Fig. 6 can approve that the electricity consumption pattern forecasted well. In Fig. 6, the plot of test loss drops below training loss which means the model overcomes the overfitting problem and learned perfectly. Moreover, the proposed model achieves RMSE value of 0.362 and MAE of 19.7% which are the lowest values achieved when compared with other network topologies used in Table I.

After implementing the forecasting model for the monthly electricity consumption dataset, Fig. 7 shows the graphical representation of the true monthly electricity consumption and the forecasted values for both the training and testing process.

As it is clear, the graphical representation forecasting result of the monthly electricity consumption is better than the graphical representation of the daily electricity consumption prediction in Fig. 5. This approves the assumption that the daily electricity consumption contains a lot of high and low picks in the consumption which is contrary to the monthly electricity consumption data that run mostly in the average pattern.

| Proposed model | Monthly electricity consumption data                                    | 164        | 40               | Adam      | 2           | 100 for the first layer and 32 for the second layer            | ReLU                | MAE           | Forecasting one day ahead                              | MAE: 17.8%<br>RMSE: 0.376 |        | -                                  | -                                    |    |       |

Fig. 7. Original Monthly Electricity Consumption Data and Prediction Results of LSTM.

Further, the loss plot of the daily electricity consumption data and the loss plot of the monthly electricity consumption data drop below training loss which means the model overcomes the overfitting problem and learned well for both datasets, as shown in Fig. 6 and Fig. 8.

Besides, the model of the monthly electricity consumption data achieves RMSE value of 0.376 and MAE of 17.8%. The RMSE value of the monthly electricity consumption is higher than the RMSE value achieved from the daily electricity consumption model. However, The MAE value for the monthly electricity consumption model is lower than the MAE of the daily electricity consumption model.

### B. Anomalies Detection

In the previous section, a model has been built to accurately forecast electricity consumption. Now, this model can be used to identify the anomalies in all considered data. The main idea is to forecast the electricity consumption at time  $t$ . Then, the difference between the actual value and the predicted value is calculated. A consumption is classified as an anomaly if its error is above a selected threshold. The threshold is selected intuitively depending on the density of the errors, as shown in Fig. 9 and Fig. 10. Fig. 9 illustrates the plots of the mean absolute error values of the daily electricity consumption data. Here, as shown in the figure the density of the errors is around zero and it is going up to 25. The large errors of the daily electricity consumption forecasting occur because of metering the different daily consumption habits of every household.

Fig. 8. Training and Testing Loss of Monthly Electricity Consumption for 40 Epochs.

Fig. 9. Mean Absolute Error between the Original Consumption's Value and the Predicted Value of the Daily Electricity Consumption Data.

Fig. 10. Mean Absolute Error between the Original Consumption's Value and the Predicted Value of the Monthly Electricity Consumption Data.

Further, the density of the error of the monthly electricity consumption data is around zero; however, it is going up to 8 which is much lower than the errors in the daily consumption forecasting, as illustrated in Fig. 10.

After trying several attempts and adjustments, the proper threshold found is 7 for the daily electricity consumption data and 3 for the monthly electricity consumption data. Fig. 11 and Fig. 12 show the anomalies detected in the daily electricity consumption and the monthly electricity consumption, respectively. The blue line is the consumption, and the red dots are the anomalies.

Generally, the consumption is concerned as an anomaly because of the unexpected trend changes in the data like the sudden increase of the consumption that is different from the normal consumption.

As you can see from Fig. 11 and Fig. 12, it is clear that the model can detect the anomalies efficiently in both daily electricity consumption data and monthly electricity consumption data. However, the daily electricity consumption readings are way better to detect anomalies than the monthly electricity consumption readings because of the different picks that appear in the data. It has been already assumed that in Fig. 3 and Fig. 4 the daily readings will impact the forecasting results and that was true. The daily smart metering has larger errors between the true values and the predicted values than the monthly smart metering which helps detect the anomalies in the data.

Fig. 11. Detected Anomalies in Daily Electricity Consumption Data.

Fig. 12. Detected Anomalies in Monthly Electricity Consumption Data.

To conclude, both daily readings and monthly readings provide similar forecasting performance, however, using daily readings can provide detailed data for households more than the monthly readings. Therefore, using daily metering provide effective results for detecting the anomalies.

## V. CONCLUSION

This work is focusing on detecting anomalies in electricity consumption data by using the long short-term memory (LSTM) approach. The anomalies are identified in two steps: forecasting future consumption and thus anomalies detection. The proposed model is tested using a large real-world dataset with thousands of households segregated into daily consumption and monthly consumption to explore how these may impact the forecasting accuracy of the model. Since the used dataset is huge and published publicly, many research used part of it based on their needs. In this work, we did not exclude any information from the dataset. Instead, the average daily consumption and the average monthly consumption are calculated for comparison purposes.

In conclusion, the proposed model got the lowest accuracy result when compared with other network topologies. The lowest RMSE achieved from other topologies is 0.37 and the lowest MAE is 18% where the proposed model achieved RMSE of 0.362 and MAE of 17.8%. Moreover, both daily and monthly readings have similar forecasting performance; however, the daily readings provide more detailed data for households than the monthly readings. Therefore, using daily metering provides effective results to detect anomalies.

## VI. FUTURE WORK

In this work, the used dataset is public electricity consumption data. In the future, we aim to collect the electricity consumption data of Saudi Arabia's buildings. Furthermore, the weather information of the collected years will be added. Finally, there is a plan to construct an efficient energy management system that identifies the anomalies in daily real-time buildings' electricity consumption.

## ACKNOWLEDGMENT

The authors would like to thank Qassim University for supporting this research.

**Abstract**—Technology-enhanced learning (TEL) continues to grow gradually while considering a multitude of factors, which underpins the need to develop a TEL maturity assessment as a guideline for this gradual improvement. This study investigates the potential application of TEL's expert knowledge presented in various research articles as qualitative data for developing assessment questionnaires. A mixed-method approach is applied to analyze the qualitative data using systematic literature review (SLR) with automated content analysis (ACA) as quantitative data processing to strengthen the trustworthiness of the findings and reduce researcher bias. This process is carried out six steps: conducting SLR, data processing with ACA using Leximancer, organizing resulting concepts with facet analysis, contextualizing each TEL facet, constructing the assessment questionnaire for each context, and establishing TEL maturity dimensions. This study generates 64 questionnaire statements grouped according to the target respondents, namely students, teachers, or institutions. This set of questions is also grouped into dimensions representing aligned context: student performance, learning process, applied technology, contents, accessibility, teachers and teachings, strategy and regulation. Further research is required to distribute this questionnaire for pilot respondents to design the improvement roadmap and check data patterns to formulate maturity appraisals and scoring methods.

### I. INTRODUCTION

Technology-enhanced learning (TEL) exploits technological advancement for continuous learning improvement. However, these advances cannot always be applied simultaneously in every region or educational institution. Several factors influence TEL application success, including accessible technology, supporting infrastructure, the conditions of learners, teachers, and the institution where learning takes place. These factors imply that TEL must be applied at different rates but gradually improved. Therefore, guidance for the application of TEL is required, as conceptualized in the TEL maturity model with its assessment instruments.

This research generates an assessment questionnaire grouped in related dimensions to build this instrument, which

constructs a TEL maturity model. In related works, questionnaire formulations are derived from similar questionnaires in existing research, such as the capability maturity model (CMM), as seen in the maturity model for mobile learning [1]. Another example is a study about digital game maturity, which does not use CMM but still formulates the maturity's instrument based on the defined game development process [2] [3]. However, the maturity referred to in this study, namely the conditions for TEL application and how to gradually improve it, is inconsistent with maturity assessments emphasizing the maturity process. The other techniques in related work utilize qualitative analysis to exploit experts' knowledge or implement literature reviews from previous articles with a similar topic [4]. Combining these two techniques opens the prospect of developing TEL assessment instruments consistent with the previously determined TEL maturity context.

Regardless, issues with previous studies concern researcher bias affecting the process and the reliability of the terms used during the coding process in the qualitative analysis. However, in a deeper view, TEL practitioners and experts have made their knowledge explicit in various research journals. Thus, this study employs a literature review approach investigating experts' knowledge captured within related research articles.

The most common method for conducting a literature review is by searching for relevant articles. For example, this research has searched for various studies containing the keyword "TEL" and specifically discussing affecting factors, TEL assessment, or certain technology maturity. However, this process is considered insufficient because the obtained articles' scope of discussion does not meet the previously defined TEL maturity context. Furthermore, the existing literature review approach has shortcomings, such as the method's reliability in finding relevant articles, the possibility for researcher bias, and cognitive limitations in extracting knowledge from the vast amount of available research articles. Moreover, the requirement to assess TEL maturity requires understanding the entire scope of the TEL discussion. Thus, a systematic literature review (SLR) approach may reduce researcher bias and meet the requirement for a TEL maturity assessment.

In SLR-related works, statistical data processing has used only specific attributes from the selected articles. However, there is potential to uncover the underlying experts' and

researcher's knowledge in those articles. Additional approaches include research that seeks to automate the process of qualitative analysis [5]. Some of these approaches underlie why this study exploits automated content analysis (ACA) as a text analysis method using a tool called Leximancer. ACA produces a set of concepts (key terms) and themes (clustered concepts based on relevance). Previously, interpretation of ACA results, particularly those using Leximancer, have been limited to describing a topic's state of the art or research trends, as shown in [6], [7]. Nevertheless, the potential is enormous. Depending on how to organize the resulting knowledge, this collection of concepts can be interpreted from various perspectives.

Facet analysis is one method for organizing knowledge [8], including data that form a collection of concepts. As a cross-disciplinary approach, facet analysis is primarily used as a library classification method. Facet analysis can help represent the content of a broad discussion covering many documents. This study analyzes TEL facets, which can then be interpreted in various ways depending on the research objective, which in this work is to construct assessment instruments and dimensions for TEL maturity. Thus, this research examines the research question of how SLR and ACA can be used to develop a TEL assessment instrument.

The following five sections are structured to address the research question. Section 2 describes the rationale for this research's importance. Section 3 explains underlying theories and concepts to understand the research context. Then, Section 4 presents the methodology of conducting SLR using ACA, including structuring and interpreting the result. The following section discusses the interpretation of the previous step's results, which later become assessment questionnaires. The last section concludes the study and suggests further work to refine the instrument into a complete working framework for TEL assessment.

## II. RATIONALE

### A. Requirement for a TEL Maturity Assessment

Technology continues to advance, including learning technology. Various initiatives in implementing technological advances are also increasing, focusing on digitization, process acceleration, and learning improvement. The continuous application of technology advancement is the underpinning principle of technology-enhanced learning. According to Kirkwood [9], TEL represents the use of information and communication technology (ICT) for learning and teaching. Programs for implementing technology to improve learning typically use a top-down mechanism, which refers to how policymakers implement programs at the operational level. However, these programs do not always consider preexisting conditions such as the availability of supporting infrastructure and differences in students' abilities to access and use technology.

As a result, we require guidelines for implementing TEL that consider a variety of factors and gradual improvement. This gradual mechanism is encapsulated in the concept of a maturity model and its assessment instruments. However, Nicoll et al. [10] stated that research articles exploring TEL

evaluation remain limited. This study attempts to build this maturity model, which is intended for TEL evaluation and a gradual improvement guide.

The TEL maturity model has essential components including model domains, attributes, appraisal and scoring methods, and improvement roadmaps [11]. Two components are constructed: (1) an assessment questionnaire as model attributes and (2) dimensions as model domains. The concerning issue is establishing these attributes and domains considering that TEL covers an enormous scope of discussion. The subsequent issue is what point of view objectifies the TEL maturity concept. Thus, this study implements a qualitative analysis that explores the underlying knowledge from the entire scope of TEL discussion.

Previous research has attempted to formulate a conceptual framework for TEL, incorporating discussions about technology and learning [12]. However, there are two drawbacks: the object discussed is e-learning, where the term is not quite suitable for the research context. The second is that the result is insufficient to be further analyzed as a working framework. Thus, this study tries to answer these shortcomings.

Moreover, TEL is a broad field of study as it covers both technology and learning discussions. Therefore, it is difficult to determine the scope of discussion of TEL, particularly if the purpose of the research is to find the dimensions of TEL. This challenge suggests a systematic literature review, as explained in the next section.

### B. SLR with ACA to Gain the Whole Scope of TEL Discussion

The research context is the TEL domain, which includes discussions on technology's progression and application to learning advancement. The context is building a model that evaluates TEL maturity to recommend a strategy to improve the impact of technology use on learning. Then, the challenge is to find the factors representing TEL as a subject matter, which become the objects to be measured. Extracting insightful knowledge through literature reviews is an attempt to overcome this challenge.

Determining the factors to be measured is typically done by collecting knowledge from experts using the focus group discussion method or in-depth interviews. Meanwhile, every scientific publication article in renowned conferences and journals is also a form of knowledge externalization from experts or knowledgeable people in the TEL domain. This knowledge base justifies why the literature review may be used to acquire knowledge, followed by knowledge organization, with the result used to develop TEL maturity instruments.

According to Kitchenham [13], a systematic literature review is essential because evidence-based rather than expert opinion is also required. The article states that evidence can be in the form of a synthesis of best-quality scientific studies on a particular topic. In contrast to an expert review using ad hoc literature selection, an SLR is a methodologically rigorous review of research results. The objective of SLR is not merely to aggregate all existing evidence on a research question, it is also intended to support the development of evidence-based guidelines for practitioners.

The SLR uses specific criteria to select the papers to be reviewed. The review process is followed by statistical analysis and interpretation, resulting in understanding the subject under discussion. However, the literature review should draw on substantial knowledge suggested in the articles. Also, there is a requirement to extract knowledge in model development research that can be justified, reflecting the more thorough subject-matter discussion.

This research expands the technique of implementing quantitative data analysis on SLR by processing the entire content of the text from research articles rather than only particular attributes. An ACA approach is used to target this goal, employing the Leximancer tool. The concept of ACA is derived from text analysis, where all the terms in the various data source articles are parsed, cleaned, assigned weights, and sorted. Then, the relevance of each term to each other is calculated. Leximancer helps data processing visualize conceptual maps by generating main concepts contained within the text and determining how they are related. ACA with Leximancer is usually utilized for sentiment and data marketing analysis, as seen in [14] and [15]. Though, the resulting concepts and themes may deliver many useful insights with further analysis. It is then become one of the background idea in this research.

Regarding ACA, similar activities have been done in previous works using simpler text analysis techniques, as shown in Fig. 1. The first research utilized text analysis with the help of mini program built using Python, with a resulting list of key terms sorted by frequency of occurrence. Regarding interpretation of results, the previous study used Luhn's theory, which describes the relation of curves to Bradford-Zipf distributions to determine significant words [16]. These sorted words are located in between the upper and lower cut in the Zipf law distribution. In more recent research, the determination of the upper cut and lower cut was still not clearly stipulated, though a pattern was seen [17]. This provision of Luhn's theory was again adopted in this study. In the Methodology section, we discuss how this determination is established. The result of this study is a collection of TEL characteristics. However, this result cannot be directly converted into TEL assessment instruments.

Another work attempted to adopt the term frequency-inverse document frequency method [18] rather than a simple frequency count as a basis to sort the resulting list of key terms. However, this study also has a limitation in that it processed only 100 articles; therefore, its suitability for this research objective is dubious. Another study has already employed ACA [19], however, a drawback in the work is a lack of clarity on interpreting the results. In that study, the dimensions were directly derived from themes generated from Leximancer without further analysis, yet the underlying knowledge lies in the concepts generated. The resulting list of concepts requires different processing methods, which is what underlies the use of facet analysis.

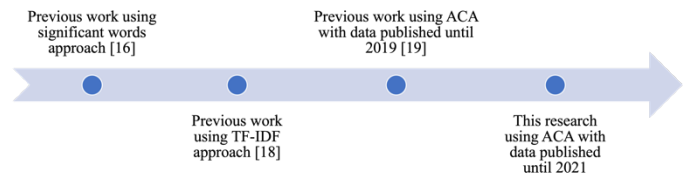

Fig. 1. This Research Series Timeline.

### C. Facet Analysis for Knowledge Interpretation and Organization

The output of ACA is a collection of key terms that are considered the most relevant and represent the scope of the TEL discussion, called the concept. However, these results require further analysis to establish dimensional candidates and assessment questionnaires. Quantitative data processing, automated with Leximancer, needs to be counteracted with interpreting the result, which is the significant proposal of this study.

Facet analysis departs from the classification theory originated by Ragnathan [20]. The technique recognizes several aspects of a topic of discussion and summarizes these aspects to appropriately describe the concept. A "facet" is a collection of terms that have the same relationship with the global subject, reflecting the application of a fundamental principle of division. Certain subjects are delivered in various perspectives so that the representation of knowledge can be in its entirety, not as a subordinate of something else.

According to Usman et al., facet analysis is one of the most frequently used classification structures in education and computer science [21]. In addition, the discussion of TEL is multidimensional and multiperspective (facets). Facet analysis is also widely studied in social science (21%), and computer science (11%), both of which are also domains that frequently examine TEL. Thus, facet analysis is not new in computer science and may be suitable to be applied in this study.

## III. METHODOLOGY

This study addresses the research question by following the steps depicted in Fig. 2. The diagram shows how each step has inputs and outputs and employs particular techniques. In the following subsections, each step is explained.

### A. SLR for Data Gathering

After various data selection processes applied to 1,030 articles filtered by inclusion, exclusion, and quality-assessment criteria, 792 journal articles were obtained. Inclusion and exclusion criteria include Scopus-indexed journals, in English, published between 2010 and 2021, available for full-text download, and mentioning "technology-enhanced learning" in the titles or abstracts. The process continued by performing text analysis on the entire content of the selected articles using the ACA method. The aim of the analysis was to explore underlying knowledge representing the overall scope of the TEL discussion rather than only specific attributes.

Fig. 2. Methodology with Detailed Input, Output and Techniques used.

B. ACA with Leximancer

Leximancer assists the ACA process by importing data, generating concept seeds, generating a thesaurus, and visualizing the results. The process begins with importing previously selected articles. Then, the tool parses the terms from all articles, weighting them based on both the frequency and likelihood of occurrence. This weighting score becomes a basis for sorting terms, eliminating low-scoring terms, and assigning high-scoring terms as resulting concepts. The data learning process is continuous, starting with selecting a concept seed from the list of terms. A *concept* is a highly relevant term that represents the topic in a collection of research articles as data.

The concept seed is the starting point of the definition of such a concept. The process then adds any highly related terms into the concept’s definition. Thus, if there are more relevant terms than the seed, a new concept seed can be generated. This process continues until all terms have been processed. The term with the highest weighting score becomes a concept that represents the various meanings of the terms. The concepts that are highly related to each other will be clustered into a higher level of data representation, called a theme.

Leximancer will then visualize the formation themes and the sequence of concepts based on the count of hits, as shown in Fig. 3. The illustration depicts the resulting concepts (relevant and meaningful terms) and themes (a group of interrelated concepts). The themes are frequently analyzed as dimension candidates in related works, though they can change according to the theme size setting. However, there is also no exact formula for the optimal size. In addition, some of the generated themes are a collection of outliers, namely concepts that are not closely related to the central concept. Such outliers are inappropriate for this study, which looks for concepts and dimensions capable of representing TEL. In the previous work [19], the selection of candidate dimensions was done only by the highest score concepts.

Selection of candidate dimensions in this research adopts Luhn’s theory, using concepts’ hits of occurrence as the basis for analysis. The related work also used this theory [18] for choosing the key terms (called concept in this research). This study chooses the main themes for candidate dimensions by determining an upper and lower cut. The size setting for the theme is determined with prudence at 25%, considering the condition where the bar chart could present the hits of occurring numbers with a clear distinction between the upper and lower cut, as shown in the Analysis Synopsis tab in Fig. 3. This setting represents a condition where several themes located between the upper and lower cut can be assumed to be the most relevant, themes above the upper cut are considered too general, and those below the lower cut are less relevant. The resulting themes cover “Students,” “Used,” “Study,” “Different,” “Educational,” and “Teacher.” These selected themes will be further examined during facet analysis.

The next step is to break down each selected theme into a list of concepts as the output. The Luhn theory [16] is also used in this process. The concepts are examined based on the terms’ occurrence counts and the likelihood of occurrence related to the theme as the main concept. Fig. 4 and Fig. 5 show graph illustrations that present sorted concepts based on the occurrence likelihood and count. The detailed theme in the figures is Students.

Fig. 3. Resulting Concepts and Themes in Leximancer.

Fig. 4. Graph for Choosing Relevant Concepts in the Students Theme based on Likelihood.

Fig. 5. Graph for Choosing Concepts in the Students Theme based on Count.

The likelihood is the possible percentage of the occurrence between two concepts. In the likelihood graph (Fig. 4), the concepts on the left side lower cut are chosen, which is the condition before the curve is flattened. The count is the frequency of the related concept and the topic of discussion. The chosen concepts have counts located between the upper and lower cut. The lower cut is when the curve starts to flatten, while the upper cut is when the curve starts to decrease, but not too sharply. Next, the resulting list of concepts from Fig. 4 and Fig. 5 are cross-compared to the concepts that occur in both, thus generating a list of concepts for a theme. Each chosen theme is further explored following this approach.

C. Facet Analysis for Organizing ACA Results

The output of ACA is a collection of the most relevant concepts representing the scope of the TEL discussion. These findings, however, cannot be directly converted into assessment questionnaires. Accordingly, the contribution proposed in this research is how to interpret this list of concepts and translate it into expected results according to the research objective.

The generated concepts serve as the TEL key terms. The next step is to apply facet analysis by examining each concept using the specific criteria. The first criterion, which is listed in the concepts in the topic guide, is one of Leximancer’s outputs, representing a subject index for an extensive document collection. The second is listed concepts that are not topic-specific or highly related to research and writing terminology, such as conjunctions, verbs, or adjectives.

This resulting concept collection is then organized into a logical classification, written as hierarchical structures. It is the performed process to construct TEL facets. Every structure represents a distinct aspect of a story related to the topic under discussion. Several alternative methods exist to develop a facet: drawing from Leximancer’s topic guide as it is (clear description); structuring several concepts into a make-sense facet (need analysis), and digging deeper into sub-concepts to attain the meaning (need deeper analysis). The three alternatives may become a recommendation if weighting is required in the TEL maturity assessment.

The results of the facet analysis for the Students theme can be seen in Fig. 6. The first result, referred to as a “clear description,” is the “problem students” facet, which has a sub-facet covering problems, skills, thinking, and understanding. The “need analysis” is a student facet due to the logically structured various concepts using the meaning of terms. The school facet covers “teachers,” “classroom,” “class,” and “digital” as sub-facets. The last step is incorporating another concept (term) to the chosen concepts to deliver helpful insight, which is part of the “needs deeper analysis.” For example, in the student inquiry facet, the concept of “questions” complements the meaning. This process is repeated for all the themes, resulting in the TEL facets. The next concern is how to obtain useful knowledge from this collection of the TEL facets.

D. Quotation Analysis to Contextualize TEL Facets

The next step is to investigate the underlying insight from TEL facets by putting them into context. Facet analysis allows us to comprehend the topic of discussion using various aspects. A quotation is used to learn the context of an aspect, which is a phrase or sentence in which the facet occurs. The process searches for quotations that contain the facet, covering a combination of concepts. Table I shows an example of examining the context of a TEL facet by finding several relevant quotations from the Students theme. Each facet may contain more than one aspect and insightful knowledge.

For example, the facet on student problems delivers the context as learning objectives. This context is determined using quotations about learning objectives, student activities in class, and technology to improve learning. The quotation search also employs Leximancer by defining searching query using a combination of concepts with the help of an “AND” operator.

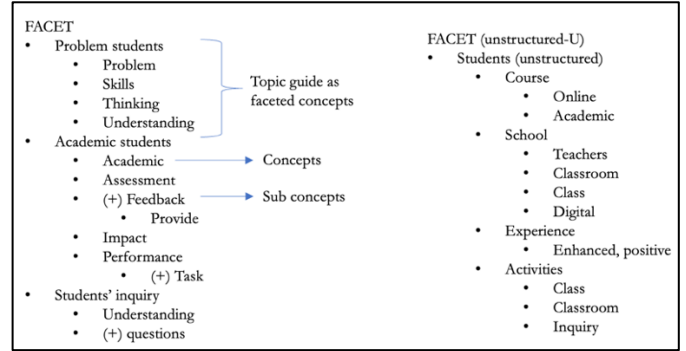

Fig. 6. Graph for Choosing Concepts in the Students Theme based on Frequency.

TABLE I. ILLUSTRATION OF PUTTING CONTEXT INTO TEL FACETS USING QUOTATION ANALYSIS

| No | Facets                                                       | Quotation Examples                                                                                                                                                                                                                                                                                                                                                                                                                      | Context Conclusion                                                             |
|----|--------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| 1  | Problem students (Problems, Skills, Thinking, Understanding) | <ul style="list-style-type: none"> <li>• “Using these scaffolds, and WISE as a meta-context, students constructed and solved problems.”</li> <li>• Help students find or generate their own goals in the problem solving</li> <li>• Students’ learning processes in technology-enhanced ..... and students exercised .... skills and developed understanding .... design thinking, problem-solving, critical thinking, .....</li> </ul> | Problem-solving, exercise skills, thinking, and understanding in class lessons |
| 2  | School (Teachers, Classroom, Class)                          | <ul style="list-style-type: none"> <li>• Every classroom was fitted with an interactive whiteboard; there was a class set of wireless laptops as well as a small ICT suite; and each teacher had their own laptop.</li> <li>• Classroom teachers and students reported new possibilities ... use of digital technologies ... laptops and interactive whiteboards for starting lessons and introducing new tasks.....</li> </ul>         | The use of technology in class                                                 |

This process repeats to analyze each aspect of each chosen theme. The use of concept combination queries, such as using two or three combinations, is also expected. For example: “problem + students” or “student problem” as a compound word, or “problem students + skills,” and so on. This alternative query combination is used to improve the quality of the obtained quotations. After many iterations searching for a facet quotation, the process starts to deliver quotations with the same meaning. The process is reasonable considering that each facet together represents one main topic. As a result, the redundancy elimination process must begin at this point. These collections of concluded contexts became the basis for formulating the TEL questionnaire.

#### E. Interpreting TEL Facets to Formulate Assessment Questionnaires and Dimensions

This advanced step explains how to formulate the TEL assessment questionnaire by understanding the TEL facet’s context, with the illustration shown in Table II. A row corresponds to a facet. Each context is associated with one or more statements. A questionnaire is then designed as a series of statements accompanied by a Likert scale asking how much the respondent agrees with the statement. Each context and the questionnaire item are also scrutinized for its type of respondent target.

This process is repeated until all possible contexts for each candidate dimension have been discussed. Further analysis is performed to compare each question representing each candidate dimension to reduce the possibility of redundant statements. The result is a distributed array of statements for each candidate dimension.

This process repeats until all possible contexts for each theme have been analyzed. Further analysis is performed by comparing each theme’s questionnaire statements to reduce the possibility of redundant statements. As a result, we can finally obtain the complete questionnaire formulation. The resulting statements are naturally clustered into groups based on the dimensions candidates generated in the previous step (subsection B). However, this study conducts more clustering processes to determine additional representable groups with aligned and explicit ideas, called dimensions. These findings are consistent with the grouping of questionnaire statements that have minimized redundancy.

## IV. RESULT AND DISCUSSION

The discussion includes insight about assessment weighting recommendations from the quotation analysis, constructed

questionnaire examples, and the dimensions covering the questionnaire.

#### A. Quotation for Context

In line with the facet determination process, three criteria related to the difficulty of the analysis process also determine the quotation analysis. The process begins by identifying quotations that clearly describe the context, those that require simple analysis, and quotations requiring further analysis. The ease of performing the analysis is related to the context’s relevance to TEL.

The relevance is high if the meaning is clear and explicit, and vice versa. Establishing the quotation may also become a basis for defining the TEL assessment weighting. Thus, every facet has different measure in depicting the data story as follows: clear description: High; needs simple analysis: Medium; requires deeper analysis: Low.

#### B. TEL Maturity Assessment Questionnaires

Table II shows an example of the statement formulation for the Students dimension, with the sample questionnaire for each dimension as delivered in the Appendix. There are several concerning issues, however, in constructing the questionnaire statements. The first is translating the English context into Indonesian Bahasa statements. This study was conducted in Indonesia; therefore, the prospective respondents are Indonesians who are not English natives.

The second issue is a requirement to identify respondents’ demography. Therefore, preliminary questions are needed to help understand the characteristics of the respondents, that is, respondents’ assessment questionnaires. The questions are not formulated from the previously described process but are customized to the needs of the research. As a result, the customized preliminary questions reduce potential confusion when applied to pilot respondents. The information is then used to improve the questionnaire before it is widely distributed.

Concerns are also evident regarding what role is appropriate for a respondent for a specific question. Based on the analysis, it was discovered that the students could not answer all of the questions. As a result, the respondents’ selections became broader; namely, students, teachers, both students and teachers, and institutions. The expanded scope raises the question of how to process the data and regulate the proportion of each respondent’s role in the TEL maturity assessment.

TABLE II. ILLUSTRATION OF HOW TO DEVELOP A TEL MATURITY ASSESSMENT QUESTIONNAIRE

| No | Contexts                                                                                                                                                                                                                                                                   | Target Respondent  | Questionnaire Statements                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1  | Problem-solving, exercise skills, thinking, and understanding in-class lessons                                                                                                                                                                                             | Students, teachers | Existing technology can assist students in comprehending the solutions to problem or questions encountered during a learning activity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 2  | <ul style="list-style-type: none"> <li>Technology to improve academic achievement</li> <li>Technology helps student assessments</li> <li>Technology enables more detailed feedback</li> <li>Technology has both good and adverse effects on student performance</li> </ul> | Students, teachers | <ul style="list-style-type: none"> <li>[student/teacher] Technology can help students improve their academic performance (improvement of grades).</li> <li>[teacher] Existing technology can aid in the process of evaluating student learning outcomes.</li> <li>[student/teacher] Technology has been used to reach all students for them to receive feedback (comments, improvements) on the outcomes of their work on their assignments.</li> <li>[student/teacher] Technology positively impacts student learning outcomes (e.g., quiz/exam scores).</li> <li>[student/teacher] Technology harms student learning outcomes (interference) (example: due to cellphone addiction for less-productive matters)</li> </ul> |

Another concerning issue arises when establishing the context of the collection of quotations. It may be possible that researcher subjectivity is present. However, this study includes efforts to reduce researcher bias and subjectivity while increasing the trustworthiness of the research by conducting quantitative data processing using ACA before the context analysis. This subjectivity may be assumed as part of the researcher’s reasoning when analyzing and interpreting the data.

### C. TEL Maturity Assessment Dimensions

The following seven dimensions were determined based on the initial dimension candidates, context adjustment, and regrouping the generated questions with an aligned idea. Each dimension represents influencing factors and being influenced by technological usage. Table III describes the dimensions and the corresponding assessment questionnaire statements. In previous work [19], the result only consists of three general dimensions: technology advancement, improved learning design, student’s achievement.

TABLE III. TEL MATURITY DIMENSIONS

| Dimensions                      | Number of Questions | Descriptions                                                                                   |
|---------------------------------|---------------------|------------------------------------------------------------------------------------------------|
| Student Performance             | 9                   | Relates to improving student performance                                                       |
| Teachers & Teaching             | 9                   | Related to improving the ability of teachers and improving teaching                            |
| Learning Process                | 8                   | Related to improving learning                                                                  |
| Accessible & Applied Technology | 9                   | Related to access to various uses of technology                                                |
| Contents                        | 9                   | Related to content and learning resources                                                      |
| Strategy & Regulation           | 9                   | Related to the formulation of learning strategies using technology and conformity to the rules |
| Technology Governance           | 9                   | Regarding technology, governance to support learning                                           |

The number of questionnaire statements for each dimension is determined by general statistical provisions stating that the number of related questions should not be excessively different. The method assumes that each dimension is equally important in achieving a level of TEL maturity. The following

activity tests the questionnaire on pilot respondents. Thus, the weight of each dimension influencing TEL maturity can be recalculated in future research. Moreover, the formulation of these dimensions can be helpful in the construction of a TEL working framework. Recommendations for improving the TEL maturity assessment results will also be made for each dimension.

## V. CONCLUSION AND LIMITATIONS

This study investigates how to use SLR in conjunction with ACA to create TEL maturity assessment instruments constituting questionnaires and dimensions. This research attempts to combine automatization in qualitative data analysis using ACA and qualitative data interpretation using facet analysis. The methodology include data gathering using SLR, data processing using ACA, organizing resulting concepts using facet analysis, searching quotations matching the meaning of TEL facets, inferring contexts from TEL facets, and determining dimensions of TEL maturity.

This research is part of a more extensive study to determine the TEL maturity assessment instrument, which attempts to take a novel approach. The approach used in this study can become a recommendation for how SLR can help novice researchers formulate assessment questionnaires through a literature review and discover how qualitative analysis can be initiated with a quantitative approach to reduce bias and subjectivity of the researchers.

In this study, 64 questionnaire statements were assembled and categorized based on the respondents’ target, either the institution, the student, the teacher, or both. This questionnaire statement set is also grouped based on the TEL maturity constructs, which are referred to a dimension. The seven dimensions are students’ performance, learning process, applied technology, contents, accessibility, teachers and teaching, and strategy and regulation.

This study has some limitations, including a critical point in implementing certain stages. The first obstacle is when the context is reduced to questions in different languages (from English to Indonesian) so that pilot respondents are still required to accept the predetermined questionnaire formulation. The second is the point of view used in developing the questionnaire: a higher education institution in this study. As a result, the findings may not apply to other

educational levels. The third issue is that the focus on which instrument was built in the use of technology primarily from the learner's perspective to improve learning, so the pedagogical aspect is not discussed in depth. The fourth issue is how to justify the influencing portion of each type of respondent on the measurement results.

Future research is required to test the questionnaire on pilot respondents to see if they can understand, conform with the assessment's objective, and examine the correlation between questionnaire statements and dimensions as a mutually exclusive entity. These findings would then be used to develop a maturity appraisal and scoring method, including the weighting to establish the TEL maturity working framework. Furthermore, the questionnaire's development results are used as a reference for developing TEL improvement roadmap.

APPENDIX

This section contains detailed questionnaire statements for each dimension.

APPENDIX. I. QUESTIONNAIRE: STATEMENTS FOR DIMENSION: STUDENT PERFORMANCE

| No | Questionnaire Statement                                                                                                                                         | Respondent      |
|----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| 1  | The existing technology can help students understand problem solutions/answer the questions in a learning activity.                                             | Student/Teacher |
| 2  | The existing technology can help students practice skills and understanding in a learning activity                                                              | Student/Teacher |
| 3  | Technology can help students improve academic achievement (improving grades)                                                                                    | Student/Teacher |
| 4  | Technology does not have a bad influence (distraction) on student learning outcomes (example: addiction due to social media, gaming, or less productive things) | Student/Teacher |
| 5  | The existing technology makes it easier for students to get answers to questions/curiosity/explore things related to learning topics                            | Student/Teacher |
| 6  | The existing technology can help all students, both those who have good and bad grades                                                                          | Student/Teacher |
| 7  | Students have been able to use technology for learning activities.                                                                                              | Student         |
| 8  | The use of technology for learning improves students' digital literacy skills                                                                                   | Student         |
| 9  | Spending more time using technology for learning improves student learning outcomes                                                                             | Student         |

APPENDIX. II. QUESTIONNAIRE: STATEMENTS FOR DIMENSION: TEACHERS AND TEACHING

| No | Questionnaire Statement                                                                                          | Respondent      |
|----|------------------------------------------------------------------------------------------------------------------|-----------------|
| 1  | Existing technology can help facilitate the process of assessing student learning outcomes                       | Teacher         |
| 2  | The teaching process has used technology to support collaboration in group learning                              | Student/Teacher |
| 3  | The learning process has used technology as a medium for assessment, evaluation, and feedback.                   | Student/Teacher |
| 4  | There are adjustments to instructional design that allow for improved learning using technology                  | Teacher         |
| 5  | The successful use of technology requires digital literacy skills in using various applications                  | Student/Teacher |
| 6  | The successful use of technology requires digital literacy skills in utilizing technology to support teaching    | Teacher         |
| 7  | Development of an online learning environment requires knowledge of technology and teaching and learning content | Teacher         |
| 8  | The teacher's role is to facilitate independent learning, not the giver of knowledge                             | Student/Teacher |
| 9  | Teachers have confidence in using technology for teaching                                                        | Teacher         |

APPENDIX. III. QUESTIONNAIRE: STATEMENTS FOR DIMENSION: LEARNING PERFORMANCE

| No | Questionnaire Statement                                                                                                                | Respondent      |
|----|----------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| 1  | Technology has been used so that all students can get feedback (comments, improvements) on the results of working on their assignments | Student/Teacher |
| 2  | Existing technology allows students to explore things related to learning topics in several ways                                       | Student/Teacher |
| 3  | Existing technology allows student learning to be carried out in a blended or full online manner.                                      | Student/Teacher |
| 4  | Students enjoy using technology to help with learning activities.                                                                      | Student/Teacher |
| 5  | The learning process has used technology to support the exploration process (inquiry).                                                 | Student/Teacher |
| 6  | Learning methods and technology allow students to learn independently                                                                  | Student/Teacher |
| 7  | All learning activities have used digital technology                                                                                   | Student/Teacher |
| 8  | The use of technology has supported collaboration and collaboration of students in learning and gaining understanding                  | Student/Teacher |

APPENDIX. IV. QUESTIONNAIRE: STATEMENTS FOR DIMENSION: ACCESSIBLE AND APPLIED TECHNOLOGY

| No | Questionnaire Statement                                                                                                                                     | Respondent      |
|----|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| 1  | Technologies such as laptops, tablets, smartphones, or computers are available to access the online classroom.                                              | Student/Teacher |
| 2  | Technologies such as learning management systems (e.g., Moodle) and MOOCs are available for learning activities.                                            | Student/Teacher |
| 3  | The learning process has used various digital technologies and applications that can help students learn, as well as improve their understanding and skills | Student/Teacher |
| 4  | The learning application used can be accessed via a computer/laptop or cellphone (mobile devices).                                                          | Student/Teacher |

|   |                                                                                                                                            |                 |
|---|--------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| 5 | Learning has used a variety of the latest technologies as learning media (such as games, mobile applications, virtual classes, and others) | Student/Teacher |
| 6 | Learners can access a variety of learning technologies that suit their needs                                                               | Student         |
| 7 | The learning process has used technology such as social media as a means of interaction, communication, collaboration in a virtual space   | Student/Teacher |
| 8 | The success of applying technology to improve learning is influenced by an understanding of the technology                                 | Student/Teacher |
| 9 | Good understanding of the use of technology to support learning                                                                            | Student/Teacher |

APPENDIX. V. QUESTIONNAIRE: STATEMENTS FOR DIMENSION: CONTENTS

| No | Questionnaire Statement                                                                                                        | Respondent      |
|----|--------------------------------------------------------------------------------------------------------------------------------|-----------------|
| 1  | Existing technology allows all learning content to be accessed online and openly                                               | Student/Teacher |
| 2  | Technology can help teachers, educational institutions, and students create learning content that can be used for all students | Student/Teacher |
| 3  | Learning content continues to be improved so that students continue to learn with the help of technology                       | Student/Teacher |
| 4  | Learning content (materials, assignments) can be accessed anytime (open, available) by learners                                | Student/Teacher |
| 5  | Learning content and media can be accessed online, anywhere, anytime                                                           | Student/Teacher |
| 6  | Learning content can be accessed anytime via mobile devices                                                                    | Student/Teacher |
| 7  | Easier access to learning resources improves the continuity of the learning process                                            | Student/Teacher |
| 8  | The class has used various learning materials (not only one) to give to students                                               | Student/Teacher |
| 9  | Availability access to online learning content and resources                                                                   | Student/Teacher |

APPENDIX. VI. QUESTIONNAIRE: STATEMENTS FOR DIMENSION: STRATEGY AND REGULATION

| No | Questionnaire Statement                                                                                          | Respondent                   |
|----|------------------------------------------------------------------------------------------------------------------|------------------------------|
| 1  | Existing technology can help students learn and explore both inside and outside the classroom.                   | Student/Teacher              |
| 2  | The learning process uses e-learning as a tool for learning management that can be accessed anywhere             | Student/Teacher/ institution |
| 3  | Utilization of technology supports the learning process following applicable laws and regulations                | Teacher/institution          |
| 4  | Learning and teaching has been student-centered (focused on students)                                            | Student/Teacher//institution |
| 5  | Existing learning has implemented personalized learning for students according to their needs                    | Teacher/institution          |
| 6  | Curriculum and teaching strategies have included technology usage as one of the considerations                   | Teacher/institution          |
| 7  | The rules and procedures in teaching activities have supported the use of technology and its development         | Teacher/institution          |
| 8  | All supporting administrative for learning activities have used digital technology                               | Teacher/institution          |
| 9  | Classes have been able to facilitate students with diverse backgrounds and abilities with the help of technology | Teacher/institution          |

APPENDIX. VII. QUESTIONNAIRE: STATEMENTS FOR DIMENSION: TECHNOLOGY GOVERNANCE

| No | Questionnaire Statement                                                                                                      | Respondent           |
|----|------------------------------------------------------------------------------------------------------------------------------|----------------------|
| 1  | There is teacher participation in determining the development and use of technology for learning                             | Teacher/ Institution |
| 2  | There is a continuous development of technology for learning                                                                 | Teacher/ Institution |
| 3  | The success of applying technology to improve learning is influenced by the duration of technology use                       | Teacher/ Institution |
| 4  | Institutional management supports the development of pedagogy for the improvement of learning using technology               | Teacher/ Institution |
| 5  | Utilization of technology has been aligned with instructional design and teaching strategies                                 | Teacher/ Institution |
| 6  | Teachers have sufficient time to enhance learning with existing technology                                                   | Teacher/ Institution |
| 7  | There has been an evaluation of the learning environment using technology based on learning methods, access, and ease of use | Teacher/ Institution |
| 8  | Technology usage is already based on the need to improve teaching                                                            | Teacher/ Institution |
| 9  | Technology usage promotes cost-effective learning                                                                            | Teacher/ Institution |

# A Knowledge-based Expert System for Supporting Security in Software Engineering Projects

Ahmad Azzazi<sup>1</sup>

Dept. of Software Engineering  
Applied Science Private University, Amman, Jordan

Mohammad Shkoukani<sup>2</sup>

Dept. of Computer Science  
Applied Science Private University, Amman, Jordan

**Abstract**—Building secure software systems requires the intersection between two engineering disciplines, software engineering and security engineering. There is a lack of a defined security mechanism for each of the software development phases, which affects the quality of the software system intensively. In this paper, the authors are proposing a framework to consider the security aspects in all the phases of the software development process from the requirements until the deployment of the software product, with three additional phases that are important to automatically produce a secure system. The framework is developed after analyzing the existing models for secure system development. The key elements of the framework are the addition of the phases like physical, training, and auditing, where they improve the level of security in software engineering projects. The authors found so a solution for the replacement of the knowledge of the security engineer through the construction of an intelligent knowledge-based system, which provides the software developer with the security rules needed in each phase of the software development lifecycle and it improves the awareness of the software developer about the security-related issues in each phase of the software development lifecycle. The framework and the expert system are tested on a variety of software projects, where a significant improvement of security in each phase of the software development process is achieved.

**Keywords**—Knowledge-based systems; security engineering; software development process; expert systems

## I. INTRODUCTION

Software-intensive systems are a major factor in many business areas. There is an increasing need for such software systems that could help us in the daily life. These software systems must fulfil certain requirements. The usage of the internet as a platform for electronic commerce and online banking pushes the need for securely reliable software systems. The software systems must be secured against potential threats and attacks. Attackers are looking for security holes in these software systems to increase their chance of getting sensible information that could be used in an illegal way. As a result of all these facts, the software developers must think about building secure software systems before beginning with the real software systems, and a process of ensuring a secured software system must be followed [1].

There are many disciplines involved in such a process for developing a secure software system, where software engineering is one of the most important disciplines. To develop software in general the authors need a software engineer. The task of such an engineer is to produce quality

software within the given constraints such as time, cost, etc. The software engineer must follow a generalized development process suitable for the desired software [2].

There are many stages in a software development process, the requirement definition, system design, systems implementation, and other stages. In all these different important stages security must be considered and developed in each stage and for each stage. Therefore, there is a need to integrate the security related tasks into each stage of the software development process. The role of a security engineer appears as a part of the software development team. The need for a security engineer or software development enforces the whole development of a software system to interact with different influencers on the final software product [2, 17].

One of the most important dangerous practices during software development is the lack of detailed security requirements. The system requirements must include those ones related to security requirements. The security requirements must be specified and integrated into the whole software development.

The security of existing software majority was built as ad hoc solution that means after the development of the software, security was added to the system, even for security critical systems. The Development of secured software gives us the interaction between two disciplines, software engineering and security engineering. Building secure software is a process in which software security is considered in all phases of a software engineering life cycle [3, 16].

The focus will be on the security activities at each phase of software development, and the authors will present a Knowledge-Based Expert System for Supporting Security in Software Engineering Projects.

The paper is organized as follows: section one is the introduction, section two is the background section which provides a description about software, software engineering, software process, software engineering for Security, security engineering and knowledge-based system for secure software development. Section three is the security software engineering framework using a knowledge-based system provides the proposed framework solution for the research problem stated in this paper. The fourth section includes the Web-Based Security Expert System for Software Engineering Projects. Section five discusses the contribution. Finally, section six is the conclusion.

## II. BACKGROUND

In this section, the authors are giving an overview of the most important terms used in this research. First, the authors are introducing the term software, software engineering essentials, and software engineering for security-critical systems. Secondly, the authors are describing the information security essentials, the common protection mechanisms, and security engineering. Finally, a brief description of the knowledge-based system to support security in the software process is introduced.

### A. Software

Software could be defined as the computer programs, data and documentation which support processes to do an automatic problem-solving task [2].

Due to “pressman,” the software is a vehicle for delivering a product, which supports or directly ides system functionality, controls other programs like an operating system, effects communications like, networking software or helps building other software like, software tools [4].

To deliver software as a product, many properties should be considered, among the most important characteristics is the security of the software as a software system, which could be defined as the system attribute that reflects the ability of the system to protect itself from external attacks that may be accidental or deliberate the resources, the prevention of unauthorized disclosure of information, the extent that the software itself must be hidden or obscured, the trustworthiness of data or resources [3].

The main principal security issues are availability, confidentiality, and integrity. There are other extended properties like non-reputability, accountability, and authenticity.

### B. Software Engineering

Software engineering deals with a detailed production of quality software. There must be a way of organizing the various stages of software development, a process. There is a need for different tools, technologies, and techniques due to the given software problem with the consideration of resources and constraints to be applied. It is the targeted provision and systematic use of principles, methods; process models, concepts, and tools for the development of software systems with a quality focus [4].

### C. Software Engineering for Security

Secure Software development usually requires the engagement and usage of a defined software process which includes the intensive usage of tools, methods, techniques, and technologies. Security errors appear from the lack of a detailed definition of security in the requirements stage, design stage, or coding stage. Therefore, an urgent need for a security engineer appears before going into a stage of the software development process. One must carefully consider the security aspects of the software product from the beginning with requirements and moving on through later lifecycle activities, ending with the deployment and the administration of the software product [5, 15].

### D. Security Engineering

The duties of a security engineer are to ensure the security of software systems during and after the software development process. Security engineering requires cross-disciplinary expertise, ranging from cryptography and computer security through hardware tamper-resistance and formal methods to knowledge of applied psychology, organizational and audit methods [3, 18].

### E. Security in the Software Engineering Life Cycle

Through all the phases of the software engineering phases, a deep consideration of the security aspects must be done for each phase. Beginning with the requirement phase, one should describe the security requirements of the software. In the analysis, a deep analysis of the security requirements should be made. Also, in the design phase, the security design consideration of each designed software component should be considered. In the coding phase, an immense value is given to secure coding and with the deployment phase, all aspects of the security issues must be considered [6].

## III. PROPOSED FRAMEWORK

Knowledge is a justified true belief. Knowledge is a higher level than data or information in a way that it is higher than both, the information is higher than data in its level of abstraction. It is the richest, deepest, and most valuable of the three [7].

There are two kinds of knowledge. The First one is the explicit knowledge, which can be expressed in words and numbers and shared in the form of data, scientific formulae, product specifications, manuals, universal principles, and so forth. This type of knowledge is transmitted in a formal and systematic way among all individuals. Knowledge is another type of knowledge; it is a personal level of knowledge, with difficulties in formulation of it, sharing and communicating it with others. The term knowledge-based stands for the internal structure to process symbols, which represents the information of the real world to achieve intelligent behavior.

The main components of a knowledge-based system are the knowledge base component, the inference component, the user interface, the knowledge acquisition component, and the explanation component [7]. There are diverse types of known knowledge-based systems; the most important types of them like the rule-based systems and expert system, which is a class of software systems, which serves based on expert knowledge to the solution or evaluation of certain problem definitions. Knowledge is represented in diverse ways in expert systems like, the production rules, the semantic networks, and the logic statements representation [7, 14].

Secure Software Systems are associated with a solid software process implementation. Therefore, one must have a security engineer in the software team, who will then guide the software team with security related knowledge through all the phases of the software development life cycle. The lack of security engineers could represent an obstacle in the software development process [8, 13].

Security Engineers could not be available for each software engineering project. In some cases, security engineers are too rare to be found for all the needs of security critical software projects. In other cases, it is too expensive to get extra security engineers into the development team. Also, in some geographical areas it is difficult to find these security engineers. If the security experience of the software development team is not sufficient, this leads to no secure software and the failure of other software. At the end, the software product may completely fail due to the fact of the lack of the security engineers [9, 12].

Therefore, the authors suggest in this work the use of a knowledge-based system to assist the software engineers with the needed security engineering activities. This knowledge-based system is then integrated into the software development framework.

The researchers are proposing a new software engineering framework using some of the knowledge gathered.

Some reasons to choose such a framework are that:

- It covers all aspects of software development life cycle.
- It includes a knowledge base for each phase with the appropriate security related knowledge for each phase.
- It checks the security related activities in each phase.
- The knowledge is adaptive and increased with time.
- Additional phases are easily added to include the security activities in additional phases to ensure more security.
- It is easily implemented and accessed.

The new framework should consider the security aspects in all the phases of the software development process from the specification of the requirements until the construction and after that the deployment of the software product to the security training of the end users.

The framework focuses on the security activities on each phase of the software development process using the general process activities of the software engineering process with knowledge-based system, which helps the developer to get the expert knowledge of a security expert in each phase of the development lifecycle [10, 11].

There are many advantages when using a knowledge-based system (expert system) in the proposed framework like:

- A security knowledge-based system is an intelligent information system, in which security knowledge with methods of knowledge representation and knowledge modeling.
- A knowledge-based system is easy to understand.
- It is more easily to update it according to the increasing level of security knowledge.
- The security expertise feature, where a security expert can make expert level decisions about security.

- The symbolic reasoning feature, where the knowledge is represented symbolically and is given back through a reasoning mechanism.
- The deep security knowledge feature, where a security knowledge base for the different software development lifecycle contains complex security knowledge.
- The security self-knowledge feature, where the system can examine their own reasoning and is able to explain why a specific conclusion is reached.
- They have advantages over conventional systems like; they do not require all initial facts, changes in rules are easily implemented, execution may be done by heuristics or logic, and the effective manipulation of large knowledge.
- They have many benefits when they are used like; increased outputs, increased productivity, decreased decision-making time, increased process, and product quality, reduced downtime, capture of scarce expertise and flexibility.

There are some limitations when using expert system like; that the knowledge is not always readily available, it is sometime difficult to extract expertise from humans, where we have different approaches for the knowledge extraction, and one faces lack of end user trust when using the expert system. Therefore, the researchers have divided the knowledge-based system into many knowledge-based systems for each phase of the different phases of the software development lifecycle to make it easier to get new rules for the expert system extracted from the different sentences of the security expertise.

The proposed framework consists of several steps leading to the development of secured software as shown in Fig. 1.

The Framework begins with the requirement phase, which is specially designed for secured systems and in which the Framework collects the security engineering activities needed for obtaining the security requirements of the software products.

After obtaining the security requirements, the system performs a security test of obtained requirements. The analysis phase of the previous phases follows with the conjunction of the security activities designed for this phase with feedback to the requirements phase to make changes on the requirements of any new requirements that arise in the analysis phase. After it the system begins with the design phase for building the secured product, which has its own security engineering activities designed for this phase. The authors have then a special test for the security validation of the design phase. After that the authors begin with the coding phase with the consideration of the security engineering activities for this phase. The next step in the proposed framework is the security testing of the code that the authors have constructed in the previous step with feedback to the coding phase, to repair any security holes in the code of the product. In the next step, the authors have the deployment of the security-critical system with the security engineering activities that must be done for this phase. The last step in the framework is the security test for the software after the deployment; it includes the feedback

to the deployment phase for making any changes regarding the secure deployment of the software product.

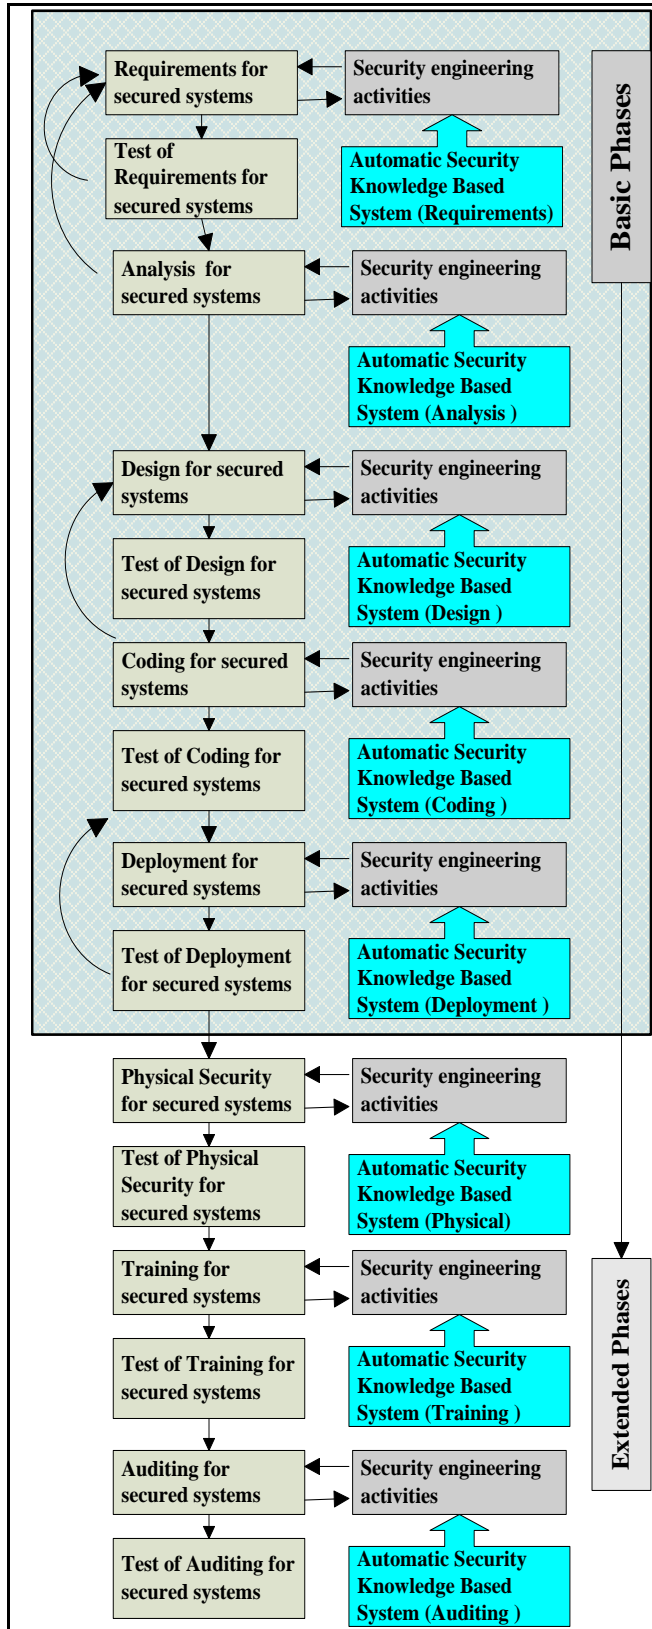

Fig. 1. Security Software Engineering Framework using Knowledge-based System.

The proposed framework is a framework that concentrates on highlighting the security activities to be done in each phase of the general software development lifecycle. It includes an intensive testing of security after each phase. All that leads to the development of a highly secure software product.

The Framework is simple; it could be followed easily from a software engineering perspective. The use of a knowledge-based system assists the software engineers with the needed security engineering activities in different phases of the software development lifecycle.

As shown in Fig. 1 the authors gain the security engineering activities in the requirement phase through an automatic security knowledge-based system especially designed for the requirements phase. For the design phase of the software process lifecycle, the authors have another automatic knowledge-based system for the security activities in this phase.

For the coding phase the authors have also another automatic knowledge-based system as a source for the security engineering activities. For the deployment phase the authors have an automatic knowledge bases system for the security engineering activities as a source. The complicated work the security engineer is done through the usage of different automatic intelligent knowledge-based systems.

Three additional phases are added to the general phases of the software engineering lifecycle, the physical security phase, where it is concerned about the physical security of every essential asset of the whole system, the security training phase, where it is concerned about receiving appropriate information about security training in a software project and the security auditing phase, where it is concerned about involving auditing and monitoring activities of the security requirements of the whole system.

Some limitations of the proposed framework are:

- The availability of knowledge in each phase.
- The changeability of the knowledge over time.
- The amount of knowledge which can increase dramatically.

#### IV. WEB-BASED SECURITY EXPERT SYSTEM FOR SOFTWARE ENGINEERING PROJECTS

In this research, the authors tried to find a suitable solution for security in software projects, where most of the existing software, even software for security-critical systems, has been built and is being built in an ad hoc, unsystematic fashion. In this work, the researchers are representing the interaction between the software engineering discipline and the security engineering discipline. The researchers have made a deep study of the concepts from scientific literature, gathered the knowledge needed to propose a new software engineering framework for security critical systems.

In the proposed framework the researchers are considering the security aspects in all the phases of the software development process from the specification of the requirements until the construction and after that the

deployment of the software product. This consideration of all the security activities is not an ad hoc solution to the software product. In the proposed framework security issues are implemented more efficiently. In the proposed framework the researchers considered all the phases of the general software engineering activities with the three additional for security important phases, the physical phase, the training phase, and the auditing phase. In all these phases, the researchers build up an appropriate knowledge base system (expert system) that should help the developers in applying the needed security engineering activities simple. The separation of the knowledge base system into knowledge base systems for each phase of the framework is made, so that the addition of new rules is specially done for each phase separately, which is simpler to do and requires minimal knowledge of security engineering knowledge.

To prove the need of the proposed framework the researchers conducted a deep survey, which provided us with more information about the security implementation issues in the software project.

This survey helped us in developing rules for each phase of the software development life cycle for the security knowledge-based system. This survey is a sample for descriptive analysis and hypotheses testing, to set up conclusions and recommendations about the usability of the proposed framework.

To prove the proposed framework, the researchers constructed an expert system case tool, the Web-Based Security Expert System for Software Engineering Projects (WB-SES-SEP). The construction of the distinct phases of the overall proposed framework is done in a web environment for many important named reasons. In the (WB-SES-SEP) one could select each phase of the 8 phases of the proposed framework, where one could begin with each phase, or the user could easily add new security rules to the knowledge-based system of each phase.

#### V. CONTRIBUTION

The main contribution of this research is the new framework for secure software development using a knowledge-based system, where the modeling of security activity rules on each phase of the software development process using the general process activities of the software engineering process in done. In this framework the researchers added three additional phases, which are essential to get better secured software through the software development lifecycle. These three additional phases are not common in the software development lifecycles. The Framework is simple; it could be followed easily from a software engineering perspective. The use of a knowledge-based system assists the software engineers with the needed security engineering activities in different phases of the software development lifecycle, which solves the problem of the availability of security experts at software engineering projects.

The researchers found that the proposed framework consists of several steps leading to the development of better secured software, through the implementing of a case study,

where the proposed framework is simply used through the case tool, which we built for this work.

Another contribution of the work is the results of the deep survey, which provided us with important information about the security implementation issues in software projects like:

- Most of the projects have security objectives, but the integration of security to the product is on average done.
- Only on average of the projects was the notice taken that security must be manageable.
- Very few of the project members have enough exposure to principles and techniques of secure application development.
- Security is considered and implemented as an ad hoc solution.
- Only very few of the projects have a person responsible for reviewing security.
- The security rules are very weak implemented in all the phases of the general software engineering phases.
- The availability of any information security policy is very weak.
- The physical security of the software project is rarely implemented.
- The security related training of people is not done in a good way.

#### VI. CONCLUSION

The researchers proposed a new framework for secure software development using a knowledge-based system, where the modeling of security activity rules on each phase of the software development process using the general process activities of the software engineering process in done. In this framework the researchers added three additional phases, which are essential to get better secured software through the software development lifecycle.

The researchers conducted an analytical survey and the test of the framework with the own built case tool led to the following features of the framework:

- One constructs better secured software when following the proposed framework.
- The security knowledge-based system for each phase of the framework consists of all the needed security rules for each phase.
- The framework is easily understandable and easily used. It is simple implemented and followed.
- Through the analysis the researchers gained very important security rules for each phase of the software development lifecycle and the additional cycles of the framework.
- New rules could be added very simply to the existing rules.

- The inference engine of the knowledge-based system, in which the researchers built, contains very accurate decision tables with a rule importance and a rule implementation level.
- The inference engine of the knowledge base system could decide about any implementation level of the rules in each phase separately, or about all the rules in the phase or about the security implementation level of the phase itself.
- With the case tool, the (WB-SES-SEP), the developer can gain experience about the rules to be implemented in a specific phase and one can repeat the processing of the phase rules until he reaches a satisfied level of security for the phase very easily.
- With the case tool, the (WB-SES-SEP), the developer can get a graphical analysis of the current implementation of all security rules in a specific phase very easily.
- The framework is easy assessing the software developer with the needed security engineering activities through a web-based interface accessible globally and all the time.
- The added phases to general software development life cycle phases are improving the level of security in a software engineering project.
- The case tool, the (WB-SES-SEP), could be used as training tool for software developer in a security critical software project so that, they could identify certain security related problems that face the project members during each phase of the software development lifecycle.
- The case tool, the (WB-SES-SEP), could make the project members more concerned about security by displaying the needed security activities needed in each software engineering phase.

#### ACKNOWLEDGMENT

The authors are grateful to the Applied Science Private University, Amman, Jordan, for the full financial support granted to this research.

**Abstract**—Speech recognition systems are widely used for smart applications. The smart application-based speech recognition system has different requirements for processing the human voice. The most common performance in the speech recognition system is essential to observe, since it is necessary to design smart application-based speech recognition systems for people's needs. Moreover, feature matching is the principal part of speech recognition systems since it plays a key role to authenticate, separate one human voice from another, and their different articulation. Therefore, this work proposes a performance comparison of speech recognition systems based on feature matching using Lab-VIEW and MATLAB. The feature extraction involves calculation of Mel Frequency Cepstral Coefficients (MFCC) for each frame. For the matching process, the system was tested 100 times for each five speeches by making changes in articulation with the same vocal cords. This matching process uses DTW (Dynamic Time Warping), and then the testing is based on the most common performance in the speech recognition system's comparison between Lab-VIEW and MATLAB such as accuracy rate, execution time, and CPU usage. Based on experimental results, the average accuracy rate of MATLAB is better than Lab-VIEW. The execution time testing indicates that Lab-VIEW has a shorter execution time than MATLAB. On the other hand, Lab-VIEW and MATLAB have almost the same CPU usage. This result indicates that the performance comparison is able to be used according to the requirements of smart application-based speech recognition systems.

**Keywords**—Speech; articulation; feature matching; Lab-VIEW; MATLAB

## I. INTRODUCTION

In general, the instrument for creating the human voice can be confined into three parts, i.e., lungs, vocal strings, and verbalization [1]. The combination of the vocal strings with verbalization can create an assortment of discourse. The discourse quality, counting unforgiving, tense, breathy, or whispery voice, can be influenced by emotion and temperament [2]. In the last decade, there has been an automated method of identifying words spoken by the human voice and converting them into readable text. This automated method is called speech recognition. Furthermore, the human voice can also be utilized in computer technology by using the speech recognition system.

Speech recognition is utilized to change over talked shape into content to help people needs [3]. The speech recognition

system is widely used for smart applications, e.g., intelligent wheelchair, Google assistant, Alexa, Cortana, Siri, and home assistant [4], [5]. Each smart application-based speech recognition system has different requirements for processing the human voice. Typically, the speech recognition system works through four stages, i.e., speech analysis, feature extraction, modeling, and testing techniques (matching process) [6]. In the speech analysis stage, speech data contains different types of information that appear a human voice identity. The next stage is feature extraction, which takes on features that might be used to match the digital signal of the human voice to a particular pattern. Then, the modeling stage is used to generate speaker models using speaker-specific feature vectors. In the last stage, the speech-recognition system matches a detected word to a known word using testing techniques (matching process). Feature matching is the most important stage of speech recognition since it plays an important role in authenticating and separating one human voice from another and their different articulation. The matching results then identify similarities [7].

In the last decade, some works have observed the performance of speech recognition system separately [8], [9], [10], [11]. However, since the most common performance of speech recognition systems based on feature matching was not observed at all. Thus, it is needed to observe of all the most common performance of speech recognition systems based on feature matching.

To this end, this work proposes a system that can identify a speech using features matching the most common performance of speech recognition systems. The work is aimed to recognize the speech built in two programming languages Lab-VIEW and MATLAB. They were selected since they have been widely used for designing smart application-based speech recognition systems [12], [13]. In Lab-VIEW programming, the structure of the graphical piece of a program chooses the execution stream in which the computer program design interfacing center points by drawing wires [14]. Furthermore, Lab-VIEW programming is able to combine the virtual instrumentation technology and speech recognition system; and also provided password authentication [15]. On the other hand, MATLAB permits framework control, plotting of a work and information and calculation usage. In spite of the fact that numerically nuanced, a tool compartment that employments a typical machine permits get to the computer logarithmic capabilities [16]. Moreover, in

order to address the analysis and testing issue an appropriate software tool is developed using MATLAB that enabled unified framework for tracking the performance of all necessary functions of speech recognition system [17]. These programming language performances were compared when identifying speech to determine the parameters used for processing human voice.

This work focuses on the method of how the system can recognize the speech based on previously stored voice features sequence as the reference signal. This work implemented the voice recognition based on feature matching with changing articulations. Structurally, the speech recognition system requires a dataset used to train the system's sensitivity to speech patterns. In this work, the stored training data is called the dictionary. This dictionary is used as the database in matching the spoken word.

This work organizes the rest of this paper as follows. Section II presents a review of related works. Section III describes the detail process of feature matching. In Section IV express the materials and system design includes the detail description of the data used in this work and the design of proposed system. Section V presents the result and discussion of the performance comparison between Lab-VIEW and MATLAB on feature matching-based speech recognition system. Finally, Section VI is dedicated to conclusion and further works.

## II. RELATED WORK

The speech recognition system is widely used for smart applications. A study [18] estimated that speech recognition needs to achieve close to a 90% accuracy rate for designing smart homes assistants. One of the factors needed in its design is data communication between devices so as to provide security and convenience that meet people's needs [19]. Moreover, the slower or faster time execution of an intelligent wheelchair is according to their current resistance [20]. Afterwards, the voice assistant technologies (such as Google

Assistant, Alexa, Cortana, Siri, etc.) require addressing restrictions like CPU and memory limitations [21]. This is to achieve an efficient on-device streaming speech recognition system. Thus, this work considers that the accuracy rate, time execution, and CPU usage could represent the most common performance in the speech recognition system. Therefore, the consideration of these parameters is important to observe.

According to A. A. A. Zamil, et al. [8], the extricated highlights of the obscure discourse and after that compared them to the put away extricated highlights for each diverse speaker in arrange to distinguish the obscure speaker using a voting mechanism. However, the key process of selecting the extracted features is minimizing the difficulty of speech recognition system computing for matching processes [9]. Therefore, another study has observed the performance of speech recognition system computing [10], [11]. Nevertheless, the most common performance of speech recognition systems based on feature matching was not observed at all. Therefore, the observation of all the most common performance of speech recognition systems based on feature matching (i.e., the accuracy rate, time execution, and CPU usage) is needed.

## III. FEATURE MATCHING

Before the recognition process, pre-emphasis was applied to the voice signal [22]. Pre-emphasis was aimed to suppress high-frequency parts during the production mechanism of the human voice before performing the framing and windowing process. The framing and windowing process was intended to split the speech signal into smaller parts [23] because it needs to be assumed as a stationary signal. Finally, energy detection was performed on each frame to detect the existence of pronunciation in that frame [24].
