Combining AHP and Topsis to Select Eligible Social and Solidarity Economy Actors for a Call for Grants

Salma Chrit, Abdellah Azmani, Monir Azmani
Intelligent Automation Laboratory, FST of Tangier
Abdelmalek Essaadi University
Tetouan, Morocco

Abstract—The procedure for selecting projects in order to offer a grant for actors of the social and solidarity economy can be a delicate task for decision-makers (Public or Private Establishments), which is based on several eligibility and refusal criteria (economic, social and environmental); the task that can sometimes take several months before returning the results. This study proposes an integrated framework based on two multi-criteria decision methods, analytical hierarchy process (AHP) and technique for order performance by similarity to an ideal solution (TOPSIS), to select and rank viable projects to obtain a grant from the INDH (National Initiative for Human Development). Initially, the projects were randomly selected from a list of submitted projects to receive a grant. Later, AHP obtains weights of various criteria through pairwise comparison, and projects are ranked using TOPSIS. The proposed methodology is empirically applied to the social and solidarity economy sector and provides a detailed and effective decision-making tool for selecting suitable actors to obtain a grant. The results indicate that the conservation of natural resources and the rate of job creation are the essential criteria in the process of selecting projects.

Keywords—AHP; TOPSIS; project selection; decision making; multi criteria decision method

I. INTRODUCTION

To create wealth, develop the economic fabric of the country, and create new jobs, the state has implemented several initiatives to support entrepreneurship and the creation of new economic structures; these initiatives focus in particular on actors of the Social and Solidarity Economy who are present in all sectors of economic activity, from energy to culture and food.

Launched on May 18, 2005, by His Majesty King Mohammed VI, the National Initiative for Human Development aimed to fight against poverty and social exclusion [1]; during the first two phases, the INDH is focused on reducing the socio-economic deficit and especially the struggle against poverty in rural areas, exclusion in urban areas and precariousness with an envelope of 28 billion MAD between 2005 and 2018 [2], and has been classified according to the World Bank in 2015, among the top three best action programs and initiatives of general interest in the world [3].

By carrying out 43,000 human development projects, the INDH has simplified access to various resources, such as access to essential services (8,200 km of tracks and roads, 230,000 households served with drinking water, 60,000 households connected to electricity), access to care (519 health centers, 240 Dar al Oumouma, 1,150 ambulances, 560 medical caravans & health campaigns), economic inclusion (9,400 income-generating activities - 64% in rural areas, where 50% of beneficiaries are women) … [3].

Launched on September 19, 2018, the 3rd phase aims to improve the economic and social situation of the population, particularly young people between 18 and 35 in vulnerable situations, through support and help for employment or entrepreneurship, with a budget of four billion dirhams.

However, each year several projects are submitted across the country to obtain a grant to help these actors start their businesses. The selection procedure becomes more and more complex, with the number of applications, the similarity between the projects, and the degree of innovation.

This implies that the response waiting time increases in parallel with the rise in the number of files submitted, this delay in response can have significant consequences for actors in the social and solidarity economy such as cooperatives, including the activity is often based on these grants and the amount offered.

The main objective of this study is to set up a decision-making tool which allows donors, investors, and public institutions to select and classify projects according to several economic, environmental, and social criteria, and this is through the combination between the AHP method and TOPSIS.

II. INSIGHT: CLASSICAL BUSINESSES VS. SOCIAL BUSINESSES

While classical businesses have several advantages and receive great public awareness nationally and internationally, the latter has the main objective of maximizing the profit of its shareholders ([4], [5], [6]) by putting set up a service or production project with specific customers and within a competitive market. Despite being considered a business, the social enterprise has a social mission that affects all aspects of its management, whose profits are a means of achieving its missions and not an end [7].

The creation of social enterprises plays a vital role in the development and revitalization of the economic fabric [8], as it makes it possible to reduce the unemployment rate, create new jobs, and reduce the informal economy, inactivity of young people, and to promote the spirit of solidarity ([9],[10]).

To establish an entrepreneurial culture among young people, and to create new innovative projects in promising sectors, to ensure integration and social growth, the governments of countries (industrialized and developing), in particular Morocco, have ensured the implementation of various public policies and initiatives, mainly for people in a situation of vulnerability (economic and social exclusion), whose central role is to provide these young people, in a case of unemployment, underemployment or those who carry out entrepreneurial activities (formal and informal), resources, means of financing, accompaniment and support [11].

These initiatives follow several stages in order to sort out the eligible projects for funding, support, and implementation, which can sometimes take up to six months or even one year.

III. THE TRADITIONAL PROJECT SELECTION

The selection of eligible projects is made on four levels [12]:

- The launch of a call for applications: this call aims to determine the ideas for innovative projects as well as the potential beneficiaries.

- The selection of project ideas: the sorting and ranking of project ideas according to two main criteria, innovation and feasibility.

- Support and strengthening of project leaders: this stage aims to carry out the studies necessary to identify the feasibility, viability, and desirability of the project, as well as the establishment of market studies, the business model, and the business plan.

- Project selection: during this phase, to select the projects eligible and viable for financing, a committee of different actors and experts familiar with the local economic context is formed.

- The selection criteria are split into two categories:

- The eligibility criteria are economic, social, and environmental.

- The criteria for refusal include the risk to the environment, the professional status of the project leader, and obtaining public aid.

IV. THE DECISION MAKING

Roy [13] (1985) defines decision support as:

"Decision support is the activity of someone who, based on models that are clearly explained but not necessarily completely formalized, helps to obtain elements of answers to the questions posed by a participant in a decision-making process, elements to favor a behavior likely to increase the coherence between the evolution of the process, on the one hand, the objectives and the system of values in the service of which this participant finds himself placed on the other hand."

The objective of decision support is to guide and enlighten the decision-maker throughout the decision-making process. However, any decision-making activity is based on two main actors, a decision-maker and a man of study; the first is always present during the process, and the second, he is only present when the decision-maker calls on him [14].

These actors are not necessarily unique characters. The decision maker can be a board of directors, the managers of a company, a senior executive or manager, an individual, etc. Furthermore, the researcher can be made up of a team (engineers, mathematicians, economists, sociologists, doctors, etc.), and he is responsible for defining the decision model, the process, and the presentation of the results to the decision maker [15].

With each call for applications, several projects are submitted, even hundreds that span the whole country, making selecting and choosing eligible projects a mission that can take months to have a final answer.

In the case of the INDH ([11], [12]), and during the selection of projects, the first step consists in launching a call for the appointment of a service provider who will play the role of decision-maker and whose main tasks are the study and the sorting of ideas, the organization of support, reinforcement and orientation sessions for the selected projects. A committee composed of public and private actors proceeds to select viable projects; these projects must be subsequently confirmed by the PCHD (Provincial Committee for Human Development).

Several articles address the subject of project selection in the literature; however, when the research deepens in the literature, most works treat the subject either with a theoretical vision or they do not treat the subject as a whole and are interested in only one component, [16] determines the criteria that Istanbul technoparks companies take into consideration in their selection preferences and to select the most appropriate technopark based on these criteria, [17] combined the three methods (Delphi, AHP and TOPSIS) to provide decision methods to managers of projects in construction companies, [18] expose the selection of telecommunication projects by first using the Delphi method to convert the qualitative criteria into quantitative criteria and then, by applying the TOPSIS method.

Whereas [19] worked on combining Shannon Entropy to determine the weight of the criteria to apply the TOPSIS method thereafter to select eligible projects. [20], talk about the project selection, and evaluation process in Ivory Coast, the latter which follows the same process as mentioned in Section III, and this through several committees at each level to make a good selection, [21], in turn, discusses the process of selection of young project leaders, the expression decision-making committee and selection policy appear several times, and offer a grid of indicators that allow project leaders to be given a final note/score; the study [22], illustrates the project selection process by the BA from entrepreneurs' pitches and the decision to invest, and this selection in turn follows a process that spans four stages, and proposes an approach for assessment of investment criteria.

V. APPLICATION OF THE AHP AND TOPSIS METHODS

In order to be able to select the projects eligible for a grant, the study focused on three families of criteria, the economic, social and environmental criteria, taking into consideration the

eliminatory criteria at the start [12]. Table I presents the project eligibility criteria and sub-criteria, based on the three main criteria.

TABLE I.   PROJECT ELIGIBILITY CRITERIA

Criteria	Sub criterion
Economic	Creation of added values
	Funding requirement
	Annual budget
	Financial resources
	Number of partners
	Execution period
	Achievement amount
Social	Job creation
	Working conditions
	Improvement of the status of women
	Respect for the rights of the child
	Activity area
	Number of beneficiaries
Environmental	Conservation of natural resources
	Maintaining biodiversity
	Environmental risk management
	Production methods
	Environmental impact

The refusal criteria designate the criteria that lead to the elimination of the file from the start, namely:

- Environmental risk: any project that has a negative impact on the environment, either through the use of chemicals, the alteration of natural resources or which has harmful effects on health;

- The carrier's profession: any project whose tenderer is a civil servant, an agent of a public institution or a private sector employee is automatically eliminated;

- Obtaining public aid: any project whose initiator has already benefited from public funding, either individually or within the framework of a group, is not eligible.

In this study, only three sub-criteria per criteria (Table III) were selected, which are frequently found in the literature to illustrate the approach.

The distinction between the favorable and unfavorable criteria (Negative and Positive), was made based on the literature, and on the opinion of the experts, Table II, presents the criteria by nature (favorable and unfavorable), for each favorable criterion, the higher the score, the more positive the criterion, likewise for each unfavorable criterion, the higher the value, the negative criterion.

The input matrix is made up of ten projects, which were randomly selected from a list of projects submitted to obtain a grant (INDH: National Initiative for Human Development), the values found in this matrix are obtained by the evaluation

of the projects, each project has a value per sub-criterion, as shown in Table III.

Table V presents the pairwise comparison matrix (AHP), which is based on the judgment of the decision makers on the importance of each criterion, by combining the literature with the opinion of several experts to determine the pairwise comparison between different families of criteria ([25], [26], [27]).

After having built the input matrix, the article proceeds by using the AHP method, to have consistent weights of the criteria, for this, the first step is to establish the comparison matrix by pair, based on the Saaty scale ([23],[24]) present in Table IV.

TABLE II.   PROJECT ELIGIBILITY CRITERIA'S DESCRIPTION

Criteria	Sub-criterion	Coded	Nature	Comment
Economic	Funding requirement	Ec1	Unfavorable	The amount that the project leader requests in order to start his project.
	Financial resources	Ec2	Favorable	This criterion presents the own financial resources available to the project leader.
	Achievement amount	Ec3	Unfavorable	The Achievement Amount refers to the total cost of the project.
Social	Job creation	S1	Favorable	The number of new jobs that will be created following the completion of the project.
	Improvement of the status of women	S2	Favorable	Does the project take the gender-equality approach into consideration and propose solutions to help women?
	Number of beneficiaries	S3	Unfavorable	The number of people who will benefit from the project once implemented.
Environmental	Conservation of natural resources	En1	Favorable	Does the project make rational use of natural resources and aims to enhance them?
	Maintaining biodiversity	En2	Favorable	The protection of spaces and environments.
	Environmental impact	En3	Unfavorable	Does the project have a positive impact on the environment or not?

TABLE III. INPUT MATRIX

	N	P	N	P	P	N	P	P	N

Project 3	1	4	6	7	6	8	1	2	3
Project 4	5	5	5	3	2	3	6	5	2
Project 5	4	4	3	7	4	2	8	4	5
Project 6	5	8	7	5	2	3	6	5	2
Project 7	2	6	2	2	1	4	6	7	1
Project 8	3	1	4	4	5	5	5	3	6
Project 9	7	6	5	1	4	4	3	7	8
Project 10	8	3	6	8	5	8	7	5	2

$$r_{ij} = \frac{x_{ij}}{\sqrt{\Sigma_{i=1}^{n} x_{ij}^2}} \qquad (1)$$

Table VI shows the weighting of the criteria, again according to the AHP method [23].

This step consists in calculating the weight of each criterion, the following 3 steps summarize the procedure:

1) Sum of the values of each column.

2) Divide each element of the matrix by its column total.

3) Calculation of the average of the elements of each row of the matrix.

The central idea behind the TOPSIS method is to choose a solution that comes closest to the ideal solution (best on all criteria) and to move away as much as possible from the worst solution (which degrades all criteria) [28].

The normalization of the matrix is done based on the Euclidean distance, to obtain values between 0 and 1 according to equation 1, as indicated in Table VII.

The study then proceeds with the multiplication of the entries of the matrix by the weights associated with the criteria using Eq. 2, Table VIII exposes the results obtained.

$$R_{ij} = w_{ij} \times x_{ij} \qquad (2)$$

For each criterion, the most favorable associated value A+ is calculated, by applying Eq. 3, depending on the nature of the criterion (favorable, unfavorable).

- Favorable criterion: the maximum value of each column.

- Unfavorable criterion: the minimum value of each column.

$$A^+ = \left\{ \max x_{ij}(i \in J^+) \,\middle|\, \min x_{ij} (i \in J^-) \right\} \quad (3)$$

Table IX and X, show the results of calculation of the ideal favorable solution A+ and the least favorable solution A-.

For each criterion, the least favorable associated value A- is calculated, by applying equation 4, depending on the nature of the criterion (favorable, unfavorable).

- Favorable criterion: the minimum value of each column.

- Unfavorable criterion: the maximum value of each column.

$$A^- = \left\{ \min x_{ij}(i \in J^+) \,\middle|\, \max x_{ij} (i \in J^-) \right\} \quad (4)$$

All the deviations are expressed by the vector E+, Each deviation is expressed as a Euclidean distance between the value of each associated criterion and the associated value of A+ , following Eeq.5.

The calculation of E- is done in the same way as E+. E- is expressed as the Euclidean distance between the value of each associated criterion and the associated value of A-, following Eq. 6, the results are shown in Table XI.

$$E^+ = \sqrt{\sum_{i=0}^{n}(A^+ - r_{ij})^2} \quad (5)$$

$$E^- = \sqrt{\sum_{i=0}^{n}(A^- - r_{ij})^2} \quad (6)$$

The last step consists in calculating the coefficient associated with each alternative, which determines its rank. Each coefficient is calculated from the components associated with the vectors E- and E+ according to the quotient expressed in Eq. 7.

$$C_p = \frac{E^-}{E^- + E^+} \quad (7)$$

The proximity coefficient of each alternative, as its name suggests, measures the rate of proximity of the most unfavorable ideal solution A- compared to the most favorable ideal solution A+. It is a matter of choosing the one which is the furthest possible from the unfavorable ideal solution A- and the closest to the favorable ideal solution A+.

Note that the most favorable and worst solutions are fictitious and do not represent real alternatives. They constitute benchmarks for comparing the distances of all the alternatives.

VI. DISCUSSION

In order to have a coherent result, we opted for the use of AHP in order to calculate the weights of the criteria, after having determined the weight of the criteria using AHP, we proceeded to the normalization and the weighting of the matrix according to the TOPSIS method, then the calculation of the ideal favorable solution A+ and A-, then we calculated for each alternative, its deviation from the most favorable value, and the last step consisted in calculating the coefficient associated with each alternative, which determines its rank.

The results exposed in Table XII, the outcome obtained at the end of the application of the TOPSIS method, are ranked according to the proximity of the alternative to the ideal solution, so the projects are ranked in order of preference with project five being ranked first, project six and seven in second and third place respectively.

The combination of these two methods can have different applications, depending on the sector of activity, in this article, the emphasis has been placed on the criteria considered by the INDH, the same approach can also be applied to other set of criteria or even add more criteria to have a more specific result, or even to distribute a grant according to the order obtained at the end.

VII. CONCLUSION

The article exposed the use of the AHP method combined with the TOPSIS method in order to make the choice between 10 projects eligible for obtaining a grant. These methods, despite being simple in their use and facilitating decision-making among several alternatives, have some limits, in particular for the quantification of the parameters by the experts or the men of studies, especially at the level of the matrix of comparison of the AHP method.

In order to make this approach more solid, the consideration of combining a machine learning method, or using a method like BOCR (Benefit, Opportunity, Cost, and Risk) is in perspective, which allows the results to be more focused on the aspects of risk, benefits, opportunity and cost, which in the case of the selection of financing projects, can give a better result, similarly, in cases where we want to share the grant between the different actors according to their ranking and the importance of their project.

Batu Pahat, 86400, Johor, Malaysia

Abstract—**Diabetes is one of the most chronic diseases, with an increasing number of sufferers yearly. It can lead to several serious complications, including diabetic peripheral neuropathy (DPN). DPN must be recognized early to receive appropriate treatment and prevent disease exacerbation. However, due to the rapid development of machine learning classification, like in the health science sector, it is very easy to identify DPN in the early stages. Therefore, the aim of this study is to develop a new method for detecting neuropathy based on the myoelectric signal among diabetes patients at a low cost with utilizing one of the machine learning techniques, the artificial neural network (ANN). To that aim, muscle sensor V3 is used to record the activity of the anterior tibialis muscle. Then, the representative time domain features which is mean absolute value (MAV), root mean square (RMS), variance (VAR), and standard deviation (SD) used to evaluate fatigue. During neural network training, a different number of hidden neurons were used, and it was found that using seven hidden neurons showed a high accuracy of 98.6%. Thus, this work indicates the potential of a low-cost system for classifying healthy and diabetic individuals using an ANN algorithm.**

Keywords—Electromyography; diabetic neuropathy; classification; machine learning; artificial neural networks

I. INTRODUCTION

According to the statistics, diabetes is one of the most common chronic diseases, with an increase in patients yearly [1]. It can lead to many serious complications, including diabetic peripheral neuropathy (DPN), a neuromuscular disease affecting up to half of all people with diabetes [2]. DPN can damage the nerves and blood vessels in the feet and legs, resulting in plantar foot ulcers, motor unit loss, and muscle volume reduction [3]. Furthermore, the peripheral nervous system, which transports currents to specific areas of the body to control muscle activity, will be disrupted by this disease. Early identification of DPN is important for people with diabetes to maintain a high quality of life by adopting a healthy lifestyle, such as eating healthy food, being active every day, and stopping smoking [4].

Electromyography (EMG) has been designed as the standard gold examination to diagnose DPN and determine nerve distribution and severity [5]. Some disadvantages of EMG include the complexity of data processing and the expense of the equipment [6]. Not many hospitals routinely do EMG analysis because commercially available equipment costs range from € 15.000 to € 20.000 [7].

Today, inexpensive and simple electrical sEMG (such as muscle sensor V3) can capture biological signals, resulting in affordable EMG equipment. As an example, Toro et al.[8], study to design of a low-cost sEMG system that allows for assessing when fatigue appears in a muscle. The author used low-cost sEMG sensors, an Arduino board, and a PC. The study proves the feasibility of a low-cost system to detect muscle fatigue reliably.

Meanwhile, the EMG signals generated by a healthy person differ from those generated by an individual with damaged muscle fibre or nerve groups. However, it is nearly impossible to discern the signals with the naked eye because they appear almost identical [9]. Classification techniques are one of the suitable alternative solutions for this problem in analysis and decision-making [10]. Automated EMG evaluation using artificial neural networks (ANNs) has become increasingly common in recent years due to the ability of these networks to analyze large amounts of multidimensional data and the strong capabilities of these networks for field recognition and classification [11].

An artificial neural network is a supervised classification technique replicating biological neurons' connection structure [12]. It comprises many interconnected neurons working together to solve problems [13].

In this study, the ANN algorithm used develops a new method for detecting neuropathy among diabetes patients at a low cost. The performance of this system is evaluated by taking actual signals from non-diabetic subjects (healthy) and diabetics. However, due to time constraints in finding suitable subjects, this study uses an increasingly popular way to overcome the issues of data availability is to use synthetic data [14]–[16]. The synthetic data was implemented by adding random noise to the original signals [17].

II. RELATED WORK

Researchers have compared the performance of the k-nearest neighbors algorithm (KNN) and ANN to classify and diagnose diseases [18]. Compared to KNN, ANN produces variable outcomes, but ANN has a higher accuracy of 80.86% compared to KNN accuracy is 77.24%.

In [19], an EMG signal-based authentication algorithm is proposed to compensate for personal certification methods' weaknesses. The pattern identification rates for the SVM and KNN algorithms were 90%. However, the results for personal authentication were just 64%. However, individual

authentication using ANN demonstrated a relatively high accuracy of 81.6%.

In [20] study compares a Support Vector Machine (SVM) to a hybrid of SVM and the ANN system as the best binary classification system for determining who has diabetes. The accuracy determined using an SVM was 77%, and when applying the ANN system, the accuracy was 87%. The results of this study show that this model, which is a mix of the SVM and the ANN, is more accurate than the SVM model.

Berina et al. [21] use machine learning techniques in the classification of diabetes and cardiovascular diseases (CVD) using Artificial Neural Networks (ANNs) and Bayesian Networks (BNs). ANN shows a greater chance of obtaining more precise results regarding the classification of CVD and diabetes. The author [22] employs artificial neural networks to determine a person's likelihood of having diabetes. The accuracy of predicting whether a person has diabetes was 87.3% after training the ANN model, which resulted in an average error function of the neural network of 0.01 and this value.

Previous studies have shown that ANNs perform well compared to other neural networks. In this study, ANN is trained with Scaled Conjugate Gradient (SCG) to perform better with a high accuracy percentage. One advantage of SCG is that it requires less time because it avoids computationally expensive linear searches [23].

III. METHODOLOGY

A. Subject

Twenty volunteer subjects were enrolled: ten healthy control (non-diabetes) subjects aged (mean ± SD) 61.9 ± 6.5 years and ten diabetes subjects aged (mean ± SD) 64.1 ± 8.3 years with duration of diabetes (mean ± SD) 17.1 ± 12.1 years. The data of subjects are shown in Table I.

The inclusion criteria were non-diabetics (healthy), and diabetic subjects were male and female gender and aged 18 to 65. In this study, the exclusion criteria for subjects with a bad general health state were; stroke, Parkinson's disease, legs with (ulcer, gout, and disability), peripheral nervous system history, and severe muscular atrophy in lower limbs because that could interfere with electromyographic recording activity [24], [25].

TABLE I. DEMOGRAPHIC DATA FOR THE SUBJECTS

	Healthy	Diabetics
Male/Female	5/5	5/5
Age (Years)	61.9 ± 6.5	64.1 ± 8.3
BMI (kg/m^2)	26.2	29.9
Duration of Diabetes (Years)	-	17.1 ± 12.1
HbA1c (%)	-	9.7

B. Low Cost Hardware Implementation

- Muscle Sensor V3

Fig. 1 shows the Muscle Sensor V3 that is used to record electrical potentials produced by contracting muscles. This sensor process the raw signal when records because its sequence is constructed of an instrumentation amplifier, rectifier, analog filter circuits, and an end amplifier circuit [26]. After recording the signal, the sensor amplifies and processes the complex electrical activity of a muscle before converting it to a simple analog signal that is easily read by a microcontroller Arduino) to convert it into a digital signal [27].

Fig. 1. Muscle Sensor v3.

- Electrode Pads

Gel electrodes are used with muscle sensor v3 to capture data. The electrode is replaced when to record for another subjects, to get the higher quality EMG signal, maintain cleanliness, and prevent the spreading of infectious diseases. This electrode has three colors, red, green and yellow as in Fig. 2, —the red electrode is (ground), the yellow electrode (reference) and the green color electrode is (the EMG signal electrode) [28].

Fig. 2. Ag/AgCl Disposable Electrode.

- Arduino Uno

Fig. 3 shows Arduino UNO with ATmega328P-based microcontroller board. It contains 14 input/output digital pins (of which six can be used as PWM outputs). Arduino UNO is used to convert analog to digital output due to the signal produced by muscle sensor v3. Muscle sensor v3 output was interfaced with an Arduino UNO microcontroller to record the signal on a laptop operating in battery mode for signal processing and classification [29]. Data will save and upload to Matlab workspace for extraction and classification [30].

Fig. 3.   Arduino Uno.

C. Electrode Location

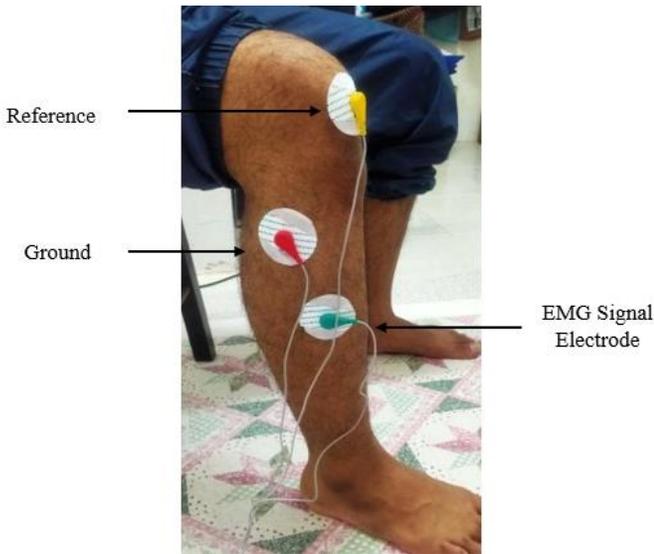
The placement of muscle EMG electrodes on muscles is based on the SENIAM (Surface Electromyography for the Non-Invasive Assessment of Muscles) group guideline [32], [33]. The anterior tibialis muscle was selected to record the data because it is the most medial muscle in the lower leg and the strongest dorsiflexor movement of the leg. As in Fig. 4, the electrode is located on the anterior tibialis muscle at 1/3 of the distance between the end of the fibula and the end of the medial malleolus. Yellow electrode placed on an inactive body section, such as the bony portion, in this study is attached to the knee. Before placing electrodes, the skin's surface must be cleaned to lower its resistance.


Fig. 4.   Electrode Location on Tibialis Anterior Muscle.

D. Experiment Procedure

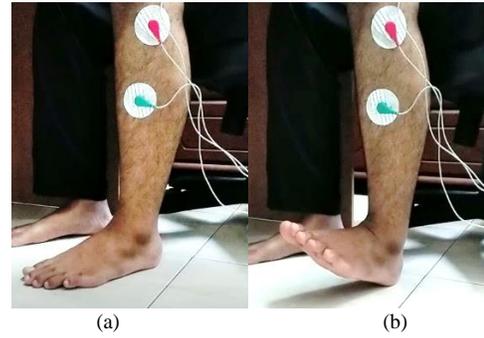
The subject is sitting on the chair and at rest for a period of five minutes after electrode placements. After five minutes, the subject is asked to slowly lift the toes and the forefoot towards the shin, digging the heel into the floor (dorsiflexion). The toes will be raised as high as they can for one minute (hold) and then slowly lower to the floor, as in Fig. 5. This method makes TA muscle contraction while minimizing the subject's movement without requiring the subject to walk.


Fig. 5.   Normal Foot Position on the Floor, (b) Foot Position During Dorsiflexion.

E. Data Collection

EMG signals were obtained from 20 subjects of different gender and ages. A total of 20 recordings samples were taken from every 20 subjects. Then, the EMG data load to Matlab workspace for synthetic data process before feature extraction. The synthetic data is repeated four times for each original sample. As a result, the original 20 samples produce 80 synthetic data and make the total for the classification procedure 100 samples (20 original and 80 synthetics).

F. Feature Extraction

The most common features for the time domain are Root Mean Square (RMS), Mean Absolute Value (MAV), Standard Deviation (STD), and Variance (VAR), which were used for this study [31]–[33]. This makes 100 samples of data divided into four characteristics for classification input (4x100).

The equations are used to determine the value of the features:

Mean Absolute Value (MAV) [34]: The mean absolute value and the moving average rectified value (ARV) are probably similar. Expression is given below.

$$MAV\ (\bar{x}) = \frac{1}{N} \sum_{n=1}^{N} x_n \qquad (1)$$

Root Mean Square (RMS) [34]: This is a measurement of the square root of the input signal, expressed as:

$$RMS = \sqrt{\frac{1}{N} \sum_{n=1}^{N} x_n^2} \qquad (2)$$

Variance (VAR) [34]: If the variable signal is squared and then divided by the mean value, then the variance is identified, which is stated as:

$$VAR = \frac{1}{N-1} \sum_{n=1}^{N} (x_n - \bar{x})^2 \qquad (3)$$

Standard Deviation (SD) [34]: Using the following expression, the threshold level of muscular contraction activity is determined:

$$SD = \sqrt{\frac{1}{N-1} \sum_{n=1}^{N} (x_n - \bar{x})^2} \qquad (4)$$

N represents the data length for each feature, while x_n represents the EMG signal in a segment or the value for each feature.

G. Classification

The classification used Matlab (nprtool) to solve a pattern-recognition classification problem. In this tool, an input layer, hidden layers, and an output layer make up a feedforward neural network. Scaled backpropagation of the conjugate gradient (trainscg) used to train the network. This study used default settings and parameters bt Matlab because possible to set the parameters and settings manually except for the number of hidden neurons.

A feedforward neural network load with the sample data (4x100) as inputs and binary numbers 10 for healthy and 01 for people with diabetes as outputs (2x100). At the same time, different hidden layers and training functions were tested as affected factors were tested with (1-10) hidden neurons.

ANN requires three data sets for the inputs and outputs of the system: training, validation, and testing. It required 30% (15 % for validation and 15% for testing), leaving 70 % for training. 100 samples were divided into 70 samples for training, 15 for testing, and 15 for validations.

IV. RESULT AND DISCUSSION

This section discusses the evaluation of the results and performance of the proposed model. An ANN was created to distinguish between diabetics and healthy subjects using Matlab. After training, the network gives a confusion matrix to indicate the correctness network. The confusion matrix is constructed to compare classification during the training, testing, and validation processes.

The confusion matrix provides details about the distribution for each output class, and then it uses color coding: green for accurate classification and red for inaccurate classification. Four confusion matrices are shown, one for each stage, namely the training, validation, testing processes, and overall classification, as shown in Fig. 6.

Fig. 6. Result from the Confusion Matrix.

The performance of ANN is tested with the different number of hidden neurons (1-10) used during training. Matlab nnstart toolbox was utilized during training and development of the neural network. Based on the results, using seven hidden neurons shows the highest overall accuracy archive with 98.6% as shown in Table II.

TABLE II. CLASSIFICATION PERFORMANCE OF DIABETICS AND HEALTHY SUBJECTS

No Hidden Layer	Training (%)	Testing (%)	Validation (%)	Overall (%)
1	92.9	95.2	76.2	90.7
2	92.9	90.5	100	93.6
3	85.7	85.7	90.5	86.4
4	94.9	85.7	81.0	91.4
5	96.9	100	95.2	97.1
6	94.9	81.0	85.7	91.4
7	99.0	95.2	100	98.6
8	94.9	90.5	90.5	93.6
9	93.9	100	100	95.7
10	91.8	85.7	81.0	89.3

The result showed that the number of hidden neurons was significant in characterizing the network's performance, which should not be too large or too small [35]. If there are more hidden units than needed, the network may not work well because it will take longer to process everything, affecting backpropagation in the long run. If less than the required number of hidden units is made, some information may lose, and the prediction may not be right [36].

The obtained network will be less complex since the number of neurons in hidden layers is fixed correctly without any least significant neurons. It will be more accurate because backpropagation is used to adjust the weight after each change is made to the network [37]. With the help of the backpropagation algorithm, the network with the best training gives the best results. Besides, the selection of scaled conjugate gradient backpropagation technique also helps the best result. In [38] study results prove that scaled conjugate gradient backpropagation is the most effective choice than other backpropagation algorithms that give high accuracy.

Table III shows performance comparison between this study and other works. This comparison is based on the study that does the classification signal from the self-study data collection on diabetic or neuropathy patients.

TABLE III. A COMPARISON BETWEEN THIS STUDY AND PREVIOUS

Reference	Classifier Method	Accuracy
Ahmed et al [9]	SVM ANN	70% 85%
Yousfat et al. [39]	-	93%
Bhusari et al. [32]	KNN	70%
This Study	ANN	98.6%

V. Conclusion and Recommendation

This paper shows the performance of low-cost EMG acquisition boards using artificial neural networks (ANN) in proposing an approach for detecting diabetes neuropathy. Based on the results, the highest accuracy is 98.6% when trained with the SCG algorithm. According to the recorded EMG data, the ANN is an effective way to classify these two classes of subjects. This system can assist in the correct initial detection of diabetic neuropathy so that appropriate treatment will be given.

For future work, with more time and funds, more samples can be measured for model validation. With a larger sample size, a more accurate system is likely to be studied, thus allowing higher accuracy in classifying neuropathic pain to be carried out. High accuracy results also indicate opportunities to develop a system not only to know neuropathy pain but also to know the severity of neuropathy faced by diabetic patients.

Abstract—**Convolutional Neural Network (CNN), a type of Deep Learning, has a very large number of hyper-meters in contrast to the Artificial Neural Network (ANN) which makes the task of CNN training more demanding. The reason why the task of tuning parameters optimization is difficult in the CNN is the existence of a huge optimization space comprising a large number of hyper-parameters such as the number of layers, number of neurons, number of kernels, stride, padding, rows or columns truncation, parameters of the backpropagation algorithm, etc. Moreover, most of the existing techniques in the literature for the selection of these parameters are based on random practice which is developed for some specific datasets. In this work, we empirically investigated and proved that CNN performance is linked not only to choosing the right hyper-parameters but also to its implementation. More specifically, it is found that the performance is also depending on how it deals when the CNN operations require setting of hyper-parameters that do not symmetrically fit the input volume. We demonstrated two different implementations, crop or pad the input volume to make it fit. Our analysis shows that padding performs better than cropping in terms of prediction accuracy (85.58% in contrast to 82.62%) while takes lesser training time (8 minutes lesser).**

Keywords—Neural networks; convolution; pooling; hyper-parameters; CNN; deep learning; zero-padding; stride; back-propagation

I. INTRODUCTION

Convolutional Neural Networks (CNNs) have proved to be the perfect machine learning choice for a wide range of application fields, such as pattern classification and analysis of video, image, speech, and text (natural language processing). However, no doubt using CNNs requires much work compared to other machine learning solutions such as random forest, Support Vector Machines, etc. This added work is primarily due to the vast optimization space of parameters and hyper-parameters, which interact with each other in a very complex way. Furthermore, making this problem even more complex is that there is still no universal, robust theory that supports hyper-parameters optimization. That would enable us to choose the right hyper-parameters for the right problem at hand and give the best performance with less effort and time. Setting hyper-parameters without robust theory is like

working blindly, as quoted by the German philosopher Immanuel Kant:

"Experience without theory is blind, but theory without experience is mere intellectual play".

Deep convolutional neural networks often have numerous layers piled on each other and are taught to do a specific task. At the end of each layer, the network learns a variety of low, medium, and high-level features. There are several papers in the literature with different approaches to setting CNN hyper-parameters, but none of them has presented a generalized and robust systematic approach to the problem. Thus, hyper-parameters optimization is not a problem that is ever entirely solved. This work aims to investigate empirically the impact of two different strategies to deal with input volume in CNN, that is, cropping and padding.

II. THE CHALLENGE OF HYPER-PARAMETERS TUNING IN A CNN

Setting the best CNN hyper-parameters for a particular classification problem could be challenging. If the results are not making any sense or bad accuracy was achieved after the first trial, then there is no prior knowledge about what went wrong; anything of the following could be a reason:

- Activation function for every layer or set of layers.
- Learning rate.
- Momentum.
- Regularization type and factor value.
- Size of filters in a specific layer(s).
- The stride of convolution or pooling in a particular layer(s).
- Padding type (e.g., zeros, first and last values, values repeated cyclically).
- The number of convolution, pooling, and activation layers in the network.
- Order of layers e.g., conv-conv-pool; or conv-activation-pool-conv.

---

*Corresponding Author.

- Type of cost function.

- The approach to encoding the output is not appropriate.

- Backpropagation gradient implementation is incorrect (sanity check was not done or was not efficient).

- Dataset was not split correctly into proper ratios.

- Not enough datasets for training.

- Imbalanced dataset.

- Not pre-processed the dataset, e.g., not normalized at all or normalized incorrectly.

- Wrong label assignment during training could happen when a new split ratio is needed.

- The performance measure metric is not appropriate for the given problem.

- The mini-batch size is not appropriate for Stochastic Gradient Descent.

- Different approaches to weight initialization.

- Maybe CNN is not the right solution to the problem at hand.

Moreover, often the wrong choice of one hyper-parameter (e.g., sigmoid activation function) will never let the network converge no matter how all other hyper-parameters were chosen. So, it is straightforward to get frustrated and lose in the hyper-parameter space and this makes CNN debugging a challenging task. Some heuristics could be used to set the right hyper-parameters by developing a workflow that enables quick debugging. These heuristics are just rules of thumb, and they are not guaranteed to give the best possible results because the behaviour of the CNN entirely depends on the specific dataset of a particular problem. Also, this is what makes it hard to establish one universal solid theory of defining the appropriate hyper-parameters for any given problem.

A. Related Work

In contrast to the manual search for finding an optimum set of hyper-parameter values, automated search approaches were adopted by many research works, and here we highlight a small portion of them:

In [1], a grid search method and a manual search technique were investigated for neural networks and particularly for deep belief neural networks. According to their findings, the grid search method is not an optimal choice for setting the hyper-parameters of the neural networks. On the other hand, it was found that random search can be used to obtain a baseline result in order to assess the performance of the other hyper-parameter optimization methods. In [2], the issue of hyper-parameters tuning is addressed by formulating the problem as a constrained optimization task. Then, a derivative-free optimization technique is opted for tuning the parameters. As a result, a more accurate and automated technique is developed for tuning of the hyper-parameters. Moreover, it is found that this technique is not consistent to achieve the global optimum. In [3], the Taguchi method was utilized to obtain

optimal hyper-parameters which can provide faster training and enhanced classification accuracy. In [4], the authors utilized a Bayesian learning technique by employing Gaussian process-based sampling to develop a learning model for designing the tuning parameters of the algorithm. It was reported that the proposed technique for evaluating the optimum values of hyper-parameters can provide significantly faster learning compared to the learning performance of the baseline methods. In [5], a probabilistic model is developed that can deal with early learning termination in the case a bad performance is detected.

Deep convolutional neural networks often have numerous layers piled on each other and are taught to do the specific task. At the end of each layer, the network learns a variety of low, medium, and high-level features.

Different variants of deep neural networks, including CNN, have been employed on various signal processing and machine learning tasks. However, their claimed performance is specific to a certain problem and dataset. In [6], an evolutionary algorithm was developed for designing of optimal hyper-parameter for different CNNs and their performance was investigated on the MNIST dataset. In [7], the hyper-parameters for the deep neural network were optimized using Nelder-Mead and coordinate search methods. In [8], a bandit-based strategy was proposed to solve the task of hyper-parameter optimization. Datasets CIFAR-10, MNIST, and Street View House Numbers were investigated and it is found that the proposed method is faster than the existing Bayesian optimization algorithms. Another work in [9] developed a faster algorithm for the tuning of hyperparameters by employing the strategy of Boolean functions analysis. Its performance was tested using deep neural networks on the CIFAR-10 dataset, and they proved that the proposed technique has much better performance than the existing baseline methods. In [10], a non-parametric regression model-based adaptive technique was designed to calculate the optimum value of the learning hyper-parameters in a short time. The proposed idea was applied on CNN and it was shown via various experiments that the proposed algorithm performs faster than the existing state-of-the-art techniques. In [11], Bayesian optimization-based generative model was developed to analyse the validation error w.r.t. the size of the training data. Again deep neural networks were utilized to test the performance of this algorithm and it was shown that the proposed method finds better hyper-parameters in lesser time. In [12], a novel technique for optimizing the hyper-parameters was developed which was based on the combination of the input features. The NMA was used with CNN for the CIFAR-10 dataset for testing the performance of the proposed model and it was shown to achieve better classification accuracy. In [13], the Covariance Matrix Adaptation Evolution Strategy was used to develop a novel optimization technique for designing the tuning parameters for CNN and it is found to be very effective.

There are various techniques in the literature focused on optimizing the tuning parameters of the CNN. For example, a Grid Search method was proposed in [14] to optimize the CNN parameters. A Random Search based optimization of hyper-parameters of the CNN was proposed in [15]. There

exist optimization techniques that employ Bayesian optimization strategy for designing CNN parameters such as those proposed in [16], [17], [18]. A Differential Evolution based optimization algorithm was proposed in [19]. A similar task was obtained using the Harmonic Search method in [20]. Reinforcement learning-based techniques were developed in [21] and [22]. Recently, in [23], the Micro canonical Optimization algorithm was employed for the automatic selection of the hyper-parameters in CNN.

In summary, all these existing works on the selection of hyper-parameters in CNN are concerned with the development of any automated algorithm that can provide optimum or near optimum values of these hyper-parameters. The primary relevant outcome of these related works is that they always link the accuracy and performance of the neural network to the hyper-parameters optimization of the micro and macro-structural levels of the model. However, we claim that in addition to the structural levels of the CNN model another factor affects the accuracy and performance of the model. The factor is the way of implementation of certain inter-layer operations in CNN. Our preliminary results on a single dataset with lesser details were published in [24]. In this work, we provide a more detailed analysis on various datasets in this context.

B. Main Contributions

The main contributions of our work can be summarized as follows:

1) In this work, we provide a framework to empirically investigate the effect of the way of implementation of certain inter-layer operations in CNN.

2) More specifically, we compare two different inter-layer operations namely cropping and padding the input volume to make it fit for the next layer operation.

3) Our investigation is based on analyzing the CNN performance in terms of classification accuracy, processing time, and generalization by implementing two models: one using crop and the second employing padding of the input volume on Digits, MNIST, Merch, Flowers, and CIFAR-10 datasets.

4) Our work provides a foundation for future investigation of the effects of other inter-layer operations in a CNN.

C. Problem Definition

A common practice in the research of deep learning is to use built-in CNN libraries, such as Tensorflow, Caffe, and Keras. However, users do not have control over the low-level implementation of different blocks of CNN which are implemented differently in different libraries. For example, in order to deal with input volumes when the stride hyper-parameter value results in a non-integer pre-calculated output, there are two standard approaches: first is cropping the volume and second is padding the volume. To understand these approaches, consider an example where an input volume of $90 \times 70 \times 100$ which corresponds to 70 channels with mini-batch size of 100. The pooling layer with a window size of 4×4 and a stride of 4 is used with no padding. The pre-

calculated dimension for the output of both convolution and pooling is given as follows (see [25] for the formula used):

$$Feature\ Map\ Size = \frac{I-F+2P}{S} \quad \frac{90-4+(2\times0)}{4} + 1 = 22.5 \qquad (1)$$

where:

I: Row or column size of the Input volume

F: Row or column size of the filter

P: Zero-padding

S: Stride

It can be observed in the calculation provided in Eq. (1) that both the axes of the feature map gave the same measure (22.5). Otherwise, Eq. (1) can be used to calculate the dimension size separately for each case. It is to be noted that the calculation of Eq. (1) results in a float number (22.5) for this example. Thus, the pooling size used was not appropriate to fit the input volume. This problem can come across in any layer type and any layer number. Now, it is important to know how this issue is handled in different libraries. There are three possible solutions to this issue; the first is to go back to choose a different value of the hyper-parameter and check again its feasibility; the second is to crop the input volume in order to fit the volume for the next layer; and the third is to pad (usually zero-padding is employed) the volume to fit the volume. The question is: Are these approaches going to perform the same? Hence, there are Constraints on choice of hype-parameters in the design of CNNs.

D. Objectives

The issue to investigate is how both approaches will affect the network's performance. This will tell us whether non-optimal performance is purely due to the wrong choice of hyper-parameters or is it also partially due to how the library is handling that type of hyper-parameters (that gives a non-integer value for the pre-calculated output). The outcome of this work will be a reference for both CNN library users and those designing CNNs and other deep learning paradigms from scratch.

Two models are going to be implemented from scratch, the first model implementation will involve the first approach that crops the input volume, and the second model will present the implementation of the second approach that involves zero-padding the input.

III. DATASETS

The used datasets in this work are Digits, MNIST, Merch, Flowers, and CIFAR-10. The MNIST dataset contains 70,000 images of handwritten digits having a size of 28×28. For machine learning applications, this dataset is split into 60%, 25%, and 15% for training, validation, and testing, respectively. The dataset is almost balanced among different classes, so the performance measure will not be misleading, at least from this side. Also, different image size datasets were chosen with a small to a reasonably large number of images. The number of classes ranges from 5 to 10. Table I. shows some of the characteristics of the datasets used. The experiments for the rest of the datasets were performed using

the original images and no transformation such as conversion to grayscale, rotation, etc. has been performed.

TABLE I. CHARACTERISTICS OF DATASETS USED

Dataset	Image dimension	Classes	Total images
Merch	227 x 227	5	75
Flowers	224 x 224	5	3670

IV. TERMINOLOGIES

There are terms used in the paper and what they entail for each one in the experiments. The terms are Channels, Filter, Stride, Padding, Dilation Factor, Output Size, Number of Neurons, Network Architecture, and Layer Size Calculation. Which are used from the MATLAB software [26].

We start by channels; if the number of channels is one, then the images are grayscale whereas it is three for colored images referring to the RGB spectrum. The filter convolves the input where a set of weights are applied to a specific image area. It can move either in horizontal or vertical directions or both at the same time. Stride determines the movement of the filter. The step size with which the filter moves determines the size of the output. Usually, the size of output reduces with increasing strides. The stride value is usually specified as an integer rather than a decimal. Padding refers to adding values on the border of images horizontally and/or vertically. It is used to control the output size of the layers. The dilation factor is the number of spaces used inside the filter. It expands the

filter by inserting zeros between the filter elements. The adequate size of the filter can be computed as $(Filter\ Size - 1) * Dilation\ Factor + 1$. A 3×3 filter with a dilation factor of 2 in horizontal and vertical directions is equivalent to a 5×5 filter having 0s between the elements. The output height and width of a convolutional layer can be computed using the following relation:

$$Output\ Size = \frac{I - (F-1)*DF + 1 + 2P}{S} + 1 \qquad (2)$$

where DF represents the Dilation Factor. This calculation needs to be done separately for the x- and y-direction if they are not the same. The output size needs to be an integer value and MATLAB discards the remaining part if it is not an integer.

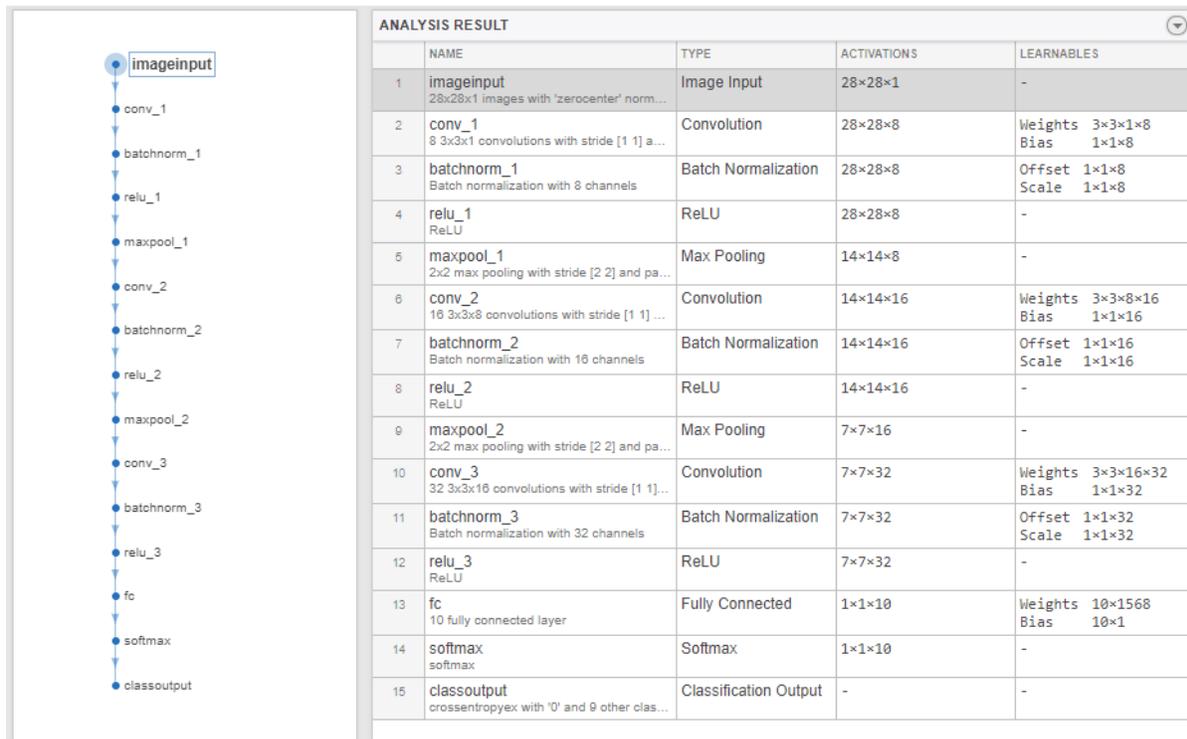
The total number of neurons in a convolutional layer is $(h * w * c + 1) * Number\ of\ Filters$, where h and w are the height and width of the filter, c is the number of channels and 1 is the bias. A convolutional layer with five filters and a filter size of 3×3 for colored images has a total number of neurons equal to $(3 \times 3 \times 3 + 1) \times 5 = 140$. A Convolutional Neural Network (CNN) can have one or more layers depending on the size and complexity of the data. A small network with one or two layers is reasonable for small grayscale datasets whereas a complex architecture of layers is required for a dataset having millions of images. Considering the datasets used, we choose a series of 15-layer Convolutional Neural Network (CNN) architecture. It is an architecture of a deep network with all layers connected sequentially. Since we have categorical responses, softmax and classification layers are used at the end. A snapshot of this architecture when run on the Digits dataset in MATLAB is shown in Fig. 1. Also, the parameters used for such architecture are shown in Table II.


Fig. 1. 15-Layer CNN Architecture on Digits Dataset.

TABLE II.   PARAMETERS OF THE CNN USED

Parameter	Value
InitialLearnRate	0.01
MaxEpochs	6
MiniBatchSize	100

The padding and stride are considered the same in both directions in all experiments. The output size needs an integer value to cover the whole image. If it does not cover the whole image, then the MATLAB software ignores the remaining part along the right and bottom edges in the convolution. The objective of the experiments is to see the effect of this coverage on accuracies while changing the padding size and stride values. The dilation factor is set as one in all experiments. For example, suppose the image size is 32×32 and the filter of 5×5 is used in the convolution. If the padding value is two and the stride is 2 in each direction, then the output size is calculated as.

$$\left(32 - \left((5-1) * 1 + 1\right) + 2 * 2\right)/2 + 1 = (32 - 5 + 4)/2 + 1 = 16.5$$

In this case, the output size will become 16×16 and some of the zero paddings are discarded from the right and bottom of the image.

V.   IMPLEMENTATION OF MODEL 1

The initial weights are saved so that the same weights should be used for the implementation of both strategies. Also, this is to ensure that the comparison should be fair and should be affected by only cropping or padding and not by any other factors. Moreover, neither regularization nor momentum of any form was used for the same reason of fair comparison. The details of the CNN architecture employed for Model 1 in our implementation are provided in Table III.

TABLE III.   MODEL 1 ARCHITECTURE

Layer Type	Conv1	Pool1	Conv2	Pool2	FLC
Size of Filter	9×9	2×2	3×3	3×3	80×10
Depth of Filter	1	10	10	20	N/A
Number of Filters	10	N/A	20	N/A	N/A
Stride	1	2	1	3	N/A
Zero Padding	0	0	0	0	N/A
Input volume size: $28 \times 28 \times 1 \times 50$			Pooling type: mean		

To simplify the study, hyper-parameters of the last pooling layer are selected to investigate the impact of padding and cropping (this analysis can be applied to any other layer too). By using Eq. (1), the pre-calculated output sizes of every layer are integer values except for pool2 which is a float number 2.66. To see more details, let us run the CNN and see what the output size in the forward and backward pass will be and this is summarized in Table IV.

TABLE IV.   OUTPUT AND GRADIENT SIZES FOR MODEL 1

Forward Pass					
Output size	$20 \times 20 \times 10 \times 50$	$10 \times 10 \times 10 \times 50$	$8 \times 8 \times 20 \times 50$	$2 \times 2 \times 20 \times 50$	10×50
Layer x	**conv1**	**pool1**	**conv2**	**pool2**	**FLC**
$\dfrac{\partial L}{\partial x}$	$20 \times 20 \times 10 \times 50$	$10 \times 10 \times 10 \times 50$	$8 \times 8 \times 20 \times 50$	$2 \times 2 \times 20 \times 50$	10×50
Backward Pass					

The results of Table IV show the size of outputs at different layers and it can be noted that all sizes are tensors of order four except the first layer. The term $\frac{\partial L}{\partial x}$ evaluates the partial derivative of the loss function with respect to the output x which gives the expression in terms of the local error (δ_x) in that neuron (note that x here is a feature map of neurons). The local error of every neuron is multiplied by its input in order to backpropagate the error influence. This can be summarized as:

$$\frac{\partial L}{\partial W} = \delta_x * In \qquad (1)$$

For output layer $\delta_x = \delta_x \times f'(x)$ (2)

For any hidden layer $\delta_x = \delta_{x+1} * W_{x+1} \times f'(x)$ (3)

where:

$f'(.)$: the derivative of the activation function.

W_{x+1}: the weight matrix of the next layer.

δ_x: local error tensor of the current layer.

δ_{x+1}: local error tensor of next layer.

ln: is the input tensor to layer x.

$\frac{\partial L}{\partial W}$: the partial derivative of the loss with respect to the weights

Eventually, the size of local errors at layer x will be equal to the size of its output while the error is backpropagated through the layers. At this stage, we analyze what happens in the forward and backward pass only at the critical pool2 layer, as illustrated in Fig. 2.

The original sizes of tensors utilized is of order four. However, in Fig. 2, it can be noted that only the first and second dimensions of those tensors are demonstrated as these are the ones that are affected by different implementations.

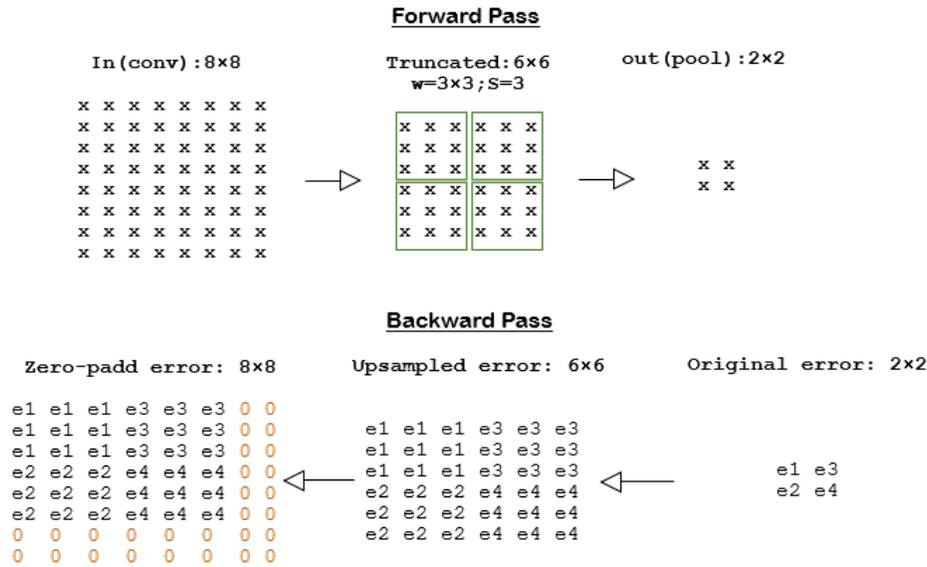
1) Forward pass: During the forward pass, it can be noticed that the sliding 3×3 window with stride 3 on an input of 8×8 (which is the output size of the previous conv layer) can accommodate only the first six rows and columns. Thus, we need to truncate or crop the last two rows and columns to obtain a new input 6×6 for the pool2 layer and this matches the results of pool2 in Table IV.


Fig. 2.   Backward and Forward Pass at Layer 4 for Model 1.

2) Backward pass: For the backward pass, using Eq.(5), it is found that the local error or the local gradient of pool2 layer has a size 2×2 as shown in Table IV. At the same layer, the local error δ_x of conv2 layer (previous layer) will be computed also using Eq. (5). The reason of doing this calculation at pool2 and not at the conv2 layer is the fact that in the forward pass from conv2 to pool2 the only process involves was down-sampling through pooling. Thus, there will be no change in weights or bias. Hence, it is easy to see that the local errors of conv2 can be obtained by up-sampling the local errors of pool2. Using Eq. (5), the local errors of conv2 is achieved by employing up-sampling on local errors of the pool2 layer which is shown in Fig. 2. Now, the *Conv2* local errors are of size 6×6. However, it must be the same size as the size of its output, i.e., 8×8. By employing the padding with zeros it is possible to accomplish the size requirement and this was done via a zero-padded error 8×8 in Fig. 2. In our case, all the weights connected to the right two columns and bottom two rows of conv2 output are not going to be updated because their local errors $\delta_x = 0$ and from Eq. (3) $\frac{\partial L}{\partial W} = 0$. This is due to the fact that these links did not contribute to the final loss as they were cropped in the forward pass. This is a major side effect of cropping inputs in the scenarios when our choice of hyper-parameter stride does not result in an appropriate output size. The next question to be investigated is how this will affect the predictive performance. The answer of this will be found in the ensuing section.

VI. IMPLEMENTATION OF MODEL 2

The architecture of this model will stay the same as the previous one with one change in the FLC weights size which will become 320×10. Table V contains the output sizes in the forward and backward pass (as before) after running CNN model 2. It can be noticed that the vectorized output of pool2

has the dimension $4 \times 4 \times 20 = 320$, which explains why the FLC layer weights were changed in this architecture. Fig. 3 illustrates how the forward and backward passes are implemented.

1) Forward pass: In this second strategy of hyper-parameters implementation, the input padding with four zeros is employed in contrast to the cropping process used in model 1 which results in an input of size 12×12. Hence, this makes the size compatible with the next layer. Eventually, pooling resulted in the output size of 4×4 as shown in Table V.

2) Backward pass: Again as was done in Model 1 implementation, the pool2 local errors are calculated using Eq. (5) which gave a size of 4×4 as shown in Table V. Next, up-sampling was employed to obtain a zero-padded error 12×12 as shown in Fig. 3. One important fact to be noted is that unlike the Model 1 implementation, in this case all weights of the neurons in conv2 are updated using Eq. (3). Hence, this can drastically impact on the predictive performance of model 2.

TABLE V.   OUTPUT AND GRADIENT SIZES FOR MODEL 2

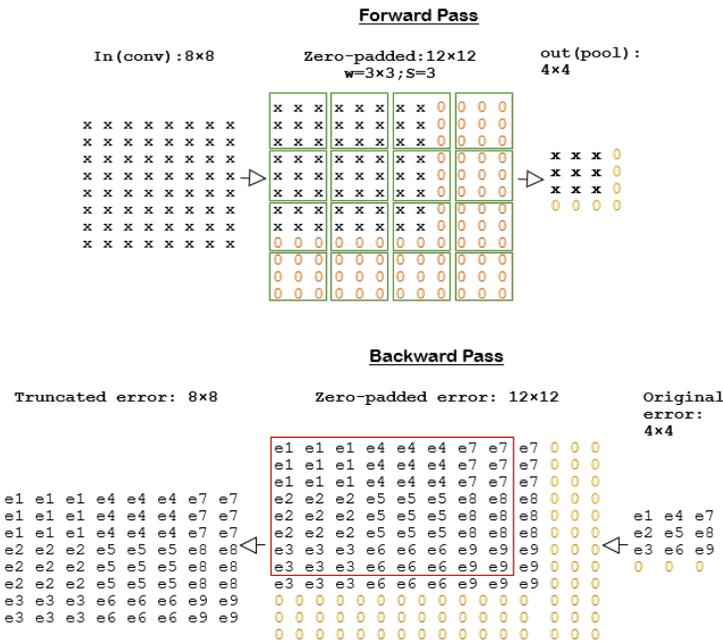
Forward Pass					
Output size	20×20 $\times 10 \times 50$	10×10 $\times 10$ $\times 50$	8×8 $\times 20$ $\times 50$	4×4 $\times 20$ $\times 50$	10×50
Layer x	**conv1**	**pool1**	**conv2**	**pool2**	**FLC**
$\frac{\partial L}{\partial x}$	20×20 $\times 10 \times 50$	10×10 $\times 10$ $\times 50$	8×8 $\times 20$ $\times 50$	4×4 $\times 20$ $\times 50$	10×50
Backward Pass					


Fig. 3. Backward and Forward Pass at Layer 4 for Model 2.

VII. EXPERIMENTS AND RESULTS

In this section, the performance of the implemented Models 1 and 2 is compared in terms of loss, accuracy, and processing time. The objective of the experiments is to see the effect of padding size and stride at layer 10 which is a convolutional layer with the name 'conv3'. Filter size of three is used at the convolution layer. Table VI shows the size of the three layers used for Digits dataset. Here, the size of the convolution layer is calculated using the formula given in Eq. (2).

TABLE VI. SIZE OF LAYERS IN DIGITS DATASET

Image Dimension	Padding dimension	Stride Size	Conv. Layer Filter Size	Actual Output Size
28 x 28	0	1	5 x 5	5
		2	3 x 3	3
		3	2 x 2	2.33
		4	2 x 2	2
	1	1	7 x 7	7
		2	4 x 4	4
		3	3 x 3	3
		4	2 x 2	2.5
	2	1	9 x 9	9
		2	5 x 5	5
		3	3 x 3	3.66
		4	3 x 3	3

The experiments were performed on several datasets to observe the effect of changing padding and stride on all three types/sets of accuracies (training, validation, testing). The padding values from zero to four and stride values from one to four are used for all experiments. It is to be noted that the stride value of one is a trivial case and does not cause a problem but we keep it for comparison purposes. To achieve unbiased results, we first train the architecture with specific parameters such as the same padding size in all layers. After that, we get the weights of all layers out of which we freeze the first nine layers' weights and then see the effects of padding and stride starting from layer 10.

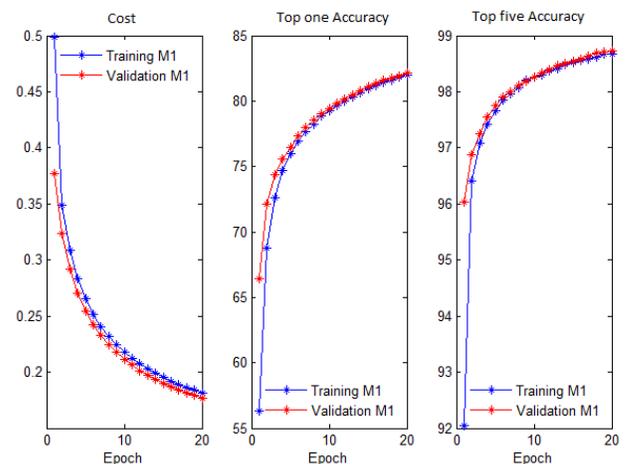
Results of the first experiment reported in Fig. 4 and Fig. 5 for Model 1 and Model 2, respectively, show that the algorithm is approximately converging in 20 epochs for both models. Next, Fig. 6 shows results at the final epoch for the two models. Here, it can be observed that model 1 has achieved a testing accuracy of 82.62% in contrast to 85.580% achieved by the Model 2. The same behavior can also be observed while comparing the training and validation accuracies of the two models. In Fig. 7 it is found that model 2 took almost 2 hours 30 minutes to train in contrast to the 2 hours 38 minutes of training by model 1. Thus, it is concluded that model 2 has a faster speed of convergence than model 1.


Fig. 4. Implementation of Model 1 Performance Measures.
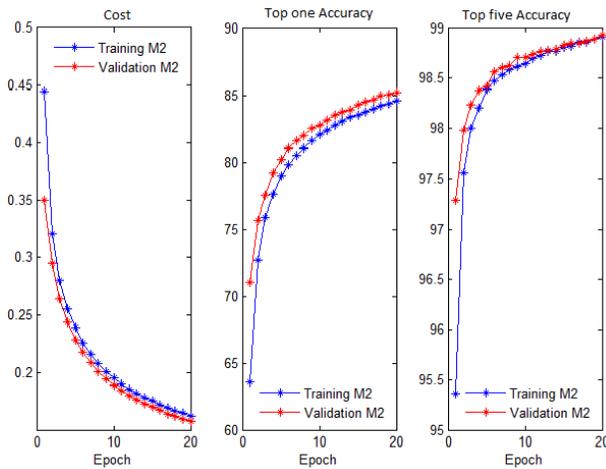

Fig. 5.   Implementation of Model 2 Performance Measures.

value is three, and it is minimum when the stride is 1. Hence, we can say that the minimum the stride, the lesser the difference between training and testing accuracy. This result is intuitive as well because more strides mean more skipping of the bits/values and less learning from the training set, which in turn reduces the testing accuracy. Similar results were observed for other datasets of Merch and CIFAR10 as can be seen in Fig. 11 to 13.

Another important observation from the results in Fig. 4 and Fig. 5 is that validation accuracy is a bit higher than training accuracy, especially in Fig. 5 showing that the trained model are more generalized in training.

In summary, it is observed that model 2 implementation has better classification accuracy, processing time, and generalization than the ones achieved by model 1. This is mainly due to the removal of the 25% conv2 neurons in the backward pass as cropping was employed. In contrast, padding with zeros used in model 2 keeps all the conv2 neurons and hence all conv2 parameters were utilized. Hence, contributions from all the neurons are included which enhances the predictive accuracy of the model.

Next, bar graphs are presented to see the effects of padding and strides in mainly the training and testing accuracies for the datasets used. The training accuracy is higher when the stride value is equal to 1, as shown in Fig. 8. In general, for all stride values, the training accuracy becomes better as the padding increases. The same is observed for testing accuracy in Fig. 9, and although not shown here, the validation accuracy also follows a similar pattern.

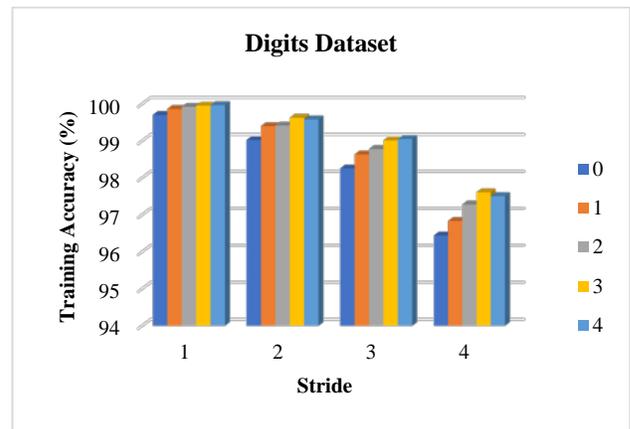
Fig. 7.   Processing Time of Models 1 and 2.


Fig. 8.   Training Accuracy Digits Dataset.

Fig. 6.   Classification Accuracy of Models 1 and 2.

By observing Fig. 10, the difference between the training and testing accuracy is more when the stride value is four for all padding values. The difference reduces when the stride

VIII. CONCLUSION

In this work, we investigated an important issue as to how the performance of a CNN is affected by choice of hyper-parameters in the case when this choice does not fit the input volumes. It was investigated experimentally how the internal implementation of hyper-parameters particularly cropping and padding the input volumes are going to affect the performance measures of CNN. For this purpose, Digits, MNIST, Merch, Flowers, and CIFAR-10 datasets were analyzed and the two models were compared in terms of classification accuracy, processing time, and generalization. It was proved via various experiments that the model employing padding of input volume has higher accuracy with lesser training time in contrast to the model using cropping of input volume. Thus, it is concluded that the fair comparison of the performance for various CNN methods will be obtained when the hyper-parameters are set fairly.

CONFLICT OF INTEREST

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Design of a Speaking Training System for English Speech Education using Speech Recognition Technology

Hengheng He

School of Foreign Languages, Hankou University, Wuhan, Hubei 430212, China

Abstract—A good English speaking training system can provide an aid to the learning of English. This paper briefly introduced the English speaking training system and described the speaking training scoring and pronunciation resonance peak display modules in the system. The speaking training scoring module scored pronunciation with the Long Short-Term Memory (LSTM). The pronunciation resonance peak display module extracted the resonance peak with Fourier transform and visualized it. Finally, the speaking scoring module, the pronunciation resonance peak display module, and the effect of the whole system in improving students' speaking pronunciation was tested. The results showed that the LSTM-based speaking scoring algorithm had highest scoring accuracy than pattern matching and the recurrent neural network (RNN) algorithm, and its accuracy was 95.21% when scoring the LibriSpeech dataset and 90.12% when scoring the local English dataset. The pronunciation resonance peak display module displayed the change of mouth shape before and after training, and the pronunciation after training was closer to the standard pronunciation. The P value in the comparison of the speaking level before and after training with the system was 0.001, i.e., the difference was significant, which indicated that the students' English speaking proficiency significantly improved.

Keywords—English speech; long short-term memory; speaking training; speech recognition

I. INTRODUCTION

In order to ensure that information is communicated as accurately as possible during national exchanges, a common language is needed. English is one of the common languages for international communication [1]. Educational institutions are also paying more and more attention to English teaching, especially spoken English. The biggest role of spoken English is to communicate, and it is difficult to communicate fluently just by reading and writing. The pronunciation quality of oral English will directly affect communication efficiency [2]. In the traditional English teaching mode, classroom teaching is the main focus, and students often learn what the teacher teaches them. The lack of time for oral training in the classroom and the teacher's irregular pronunciation will affect the learning effect of students' oral language [3]. Information technology is gradually integrated into the traditional teaching mode and changes the teacher-oriented structure of the traditional teaching mode. When using information technology to assist oral English training, teachers can still teach relevant speaking knowledge in the classroom, and students can train their speaking independently through the

independent oral English learning system under information technology before or after class [4]. The oral English training system can provide the standard pronunciation of English, collect students' pronunciation, evaluate the pronunciation through the scoring module in the system, and help students adjust their pronunciation [5]. The oral English scoring module is the core of the oral training system; the higher the scoring accuracy, the higher the reference value for the oral training. This paper studied the speaking English training system that adopted the speech recognition technology in order to enhance the students' speaking English level. The LSTM was used to score the students' pronunciation in the speaking scoring module of the speaking training system. The resonance display module used the Fourier transform to extract and visualize the resonance peaks during pronunciation to assist in pronunciation training. The two modules of the speaking training system were tested. The effectiveness of the speaking training system in improving students' speaking skills was tested. The final results showed that the LSTM had higher scoring accuracy than the pattern matching and RNN algorithm, the pronunciation resonance peak display module effectively visualized the resonance peaks of the spoken pronunciation, and the students who used the speaking training system for learning had significantly improved English speaking skills. The research on the English speaking training system and the experimental results of this paper provide an effective reference for improving students' English speaking skills. The limitations of this paper are that only the scoring module and pronunciation visualization module were tested and there were few test subjects in the test of the performance of the speaking training system. The future research direction is to conduct in-depth research on the scoring module and pronunciation visualization module of the training system and to increase the scale of test subjects.

This paper is organized in the order of abstract, introduction, and literature review, introduction of English speaking training system, simulation experiments, discussion, conclusion, and references.

II. LITERATURE REVIEW

Hsieh et al. [6] used a technology acceptance model to investigate the effect of Line on speaking training in a non-native English teaching environment and found that Line had a more positive effect on English speaking instruction than traditional classroom instruction. Reitz et al. [7] embedded the English learning process into a generic 3D cooperative virtual

reality (VR) game and found through example analysis that the designed VR game effectively trained students' English communication skills. Cao et al. [8] proposed a lip movement judgment algorithm based on ultrasonic detection to aid spoken English pronunciation. They performed experiments and found that the system had a speech accuracy of 85%, i.e., it could improve the English speaking trainers to a certain extent.

III. ENGLISH SPEAKING TRAINING EVALUATION SYSTEM

A. The Basic Structure of English Speaking Training System

The basic architecture of the English speaking training system is shown in Fig. 1. The speech acquisition and playback module [9] is equivalent to the ear and mouth of the training system. The acquisition module is responsible for acquiring the audio signal of the spoken language, and the collected audio will be stored in the buffer for later processing. The playback module plays the stored English standard pronunciation to provide a reference for the students [10].

The primary function of the pronunciation resonance peak image display module is to graphically display the standard spoken audio and the student's spoken audio so that students can clearly see the difference between their pronunciation and the standard pronunciation to adjust their pronunciation [11].

The main function of the spoken pronunciation scoring module is to score the pronunciation of the spoken audio signals collected by the audio acquisition module, i.e., to rate the standard level of students' spoken English pronunciation and to make a quantitative analysis of the students' speaking training level. The scores can be used as a feedback incentive for the students' speaking training [12].

B. Speech Recognition-based Spoken Pronunciation Scoring Module

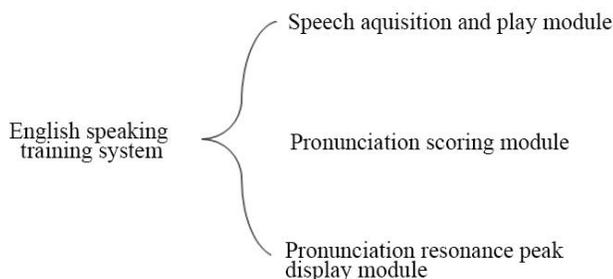
For the whole English speaking training system, the speaking pronunciation scoring module is the core, and its main function is to quantify the students' speaking pronunciation level to give a feedback incentive to the students' speaking training [13]. First, the spoken speech signal is collected using the speech acquisition module; then, features are extracted from the speech signal after preprocessing; finally, the speech is scored according to the features [14]. This paper used LSTM to score the speech collected by the speech acquisition module, and the basic flow is shown in Fig. 2.


Fig. 1. The Basic Architecture Module of English Speaking Training System.
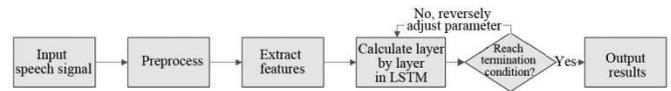

Fig. 2. The Workflow of the Pronunciation Scoring Module.

The flow of spoken pronunciation scoring based on LSTM speech recognition is shown in Fig. 2.

1) The speech signal is collected.

2) Pre-processing such as filtering, windowing, and framing [15] is performed.

3) Features are extracted from the pre-processed pronunciation signal using the Mel-frequency cepstral coefficient [16] to extract audio features.

4) The Mel-frequency cepstral coefficient features of every audio frame are input into the LSTM in order for forward calculation [17]:

$$\begin{cases} i_t = g(\omega_i \cdot [h_{t-1}, x_t] + b_i) \\ \tilde{C}_t = \tanh(\omega_C \cdot [h_{t-1}, x_t] + b_C) \\ C_t = f_t \cdot C_{t-1} + i_t \cdot \tilde{C}_t \\ f_t = g(\omega_f \cdot [h_{t-1}, x_t] + b_f) \\ o_t = g(\omega_o \cdot [h_{t-1}, x_t] + b_o) \\ h_t = o_t \cdot \tanh(C_t) \end{cases} \quad (1)$$

where x_t represents the current input of the cell, h_{t-1} is the last hidden state, C_{t-1} is the last cell state, i_t is the weight that determines the new information to be remembered, $\tilde{C}_t$ is the cell state of the new information added [18], C_t refers to the current cell state after the new information is added, ω_i and ω_t are weights, b_i and b_C are biases [19], f_t is the weight of the information not to be forgotten in C_{t-1}, ω_f is the weight, b_f is the bias, o_t represents the weight that determines the final output information amount, and h_t refers to the final output or the next hidden state [20].

5) Whether the training of the algorithm reaches the termination condition is determined. If the termination condition is reached, the training is finished, and the parameters of the LSTM are fixed [21]. When applied to the actual pronunciation scoring, the extracted features of pronunciation are input into the LSTM in order to get the scoring results. If the termination condition is not reached, the parameters in the LSTM are adjusted reversely using the stochastic gradient descent method [22]. The termination conditions include: (1) the number of algorithm iterations reaches a preset number; (2) the error between the forward calculation result and the expected result converges to the preset threshold.

Fig. 3.   Workflow of the Pronunciation Resonance Peak Image Display Module.

C. Pronunciation Resonance Peak Image Display Module

The pronunciation scoring module in the speaking training system quantifies students' pronunciation level, but this quantification only converts the level of pronunciation into a number, which does not reflect the students' pronunciation process visually [23]. The scoring module can only give a final target, and it is difficult to guide students to correct their pronunciation directly. Therefore, there is a need for a module that can visually assist in pronunciation correction. The pronunciation resonance peak image display module is a module that can visually display the pronunciation process of students.

The human vocal tract and the oral cavity together form a resonance cavity. After the sound wave signal of the vocal cord vibration is filtered by the resonance cavity, the energy will be redistributed in different frequencies. When the mouth shape changes, the resonance cavity will also change; thus, playing a different filtering effect to change the pronunciation. The connection between the mouth shape and the resonance peaks makes it possible to guide the mouth shape and correct the pronunciation based on the changes in the resonance peaks. The workflow of the resonance peak image display module in the speaking training system is shown in Fig. 3.

1) The speech signal is input and pre-processed by filtering, windowing, and framing [24].

2) The spectrum of a single-frame speech signal is obtained by using Fast Fourier Transform (FFT).

3) The maximum resonance peak of a single-frame speech signal is calculated.

4) An image is drawn to reflect the change in students' pronunciation. Time is the horizontal coordinate axis, and the smallest unit of the horizontal coordinate axis is a frame. Frequency is the vertical coordinate axis. The line graphs are plotted in the coordinate chart in the chronological order of the speech signals and the frequency of the maximum resonance peak of every speech signal frame. The difference between students' pronunciation and standard pronunciation can be seen visually when the line graphs of students' pronunciation and standard pronunciation are placed in the same coordinate plane [25].

The combination of pronunciation scores and resonance peak comparison charts can guide students to correct their pronunciation.

IV.   SIMULATION EXPERIMENTS

A. Experimental Data

The LibriSpeech dataset (openslr.org/12/) was used for simulation experiments, which includes 1000 h of audio data. It is a dataset of audiobooks, including texts and speeches. The sampling rate of the audio data in this dataset was 16 kHz.

After subdivision and collation, every audio in the dataset was about 10 s long.

In addition to the above English speech dataset collected from the public dataset, this paper also collected English spoken pronunciation from students to construct a local English speech dataset in order to verify the actual effect of the speaking training system on students' speaking scores. Fifty students, including 25 males and 25 females, participated in the English pronunciation collection. Every student read aloud 15 randomly selected non-repeated sentences from the common oral English sentence database. The read-aloud speech was captured in a recording room using recording software with a sampling rate of 16 kHz. The sentences included:

1) How do you feel?

2) What's the weather like?

3) See you tomorrow.

B. Experimental Projects

1) Scoring module test of the speaking training system: In order to test the scoring performance of the proposed LSTM speech recognition-based speaking training system, the scoring performance of the pattern matching-based and Recurrent Neural Network (RNN) speech recognition-based speaking training system was tested in addition to the accuracy detection experiment.

The scoring algorithm of the pattern matching-based speaking training system used a dynamic time regularization algorithm to calculate the minimum matching distance of extracted features between oral pronunciation and standard pronunciation. The score was calculated based on the minimum matching distance.

The relevant parameters of the speaking training scoring algorithm based on RNN speech recognition are as follows. Thirteen input nodes, 100 hidden nodes, a sigmoid function, and one output node were used. The stochastic gradient descent was used for backward learning. The learning rate was 0.1.

The relevant parameters of the speaking training scoring algorithm based on LSTM speech recognition are as follows. The number of nodes in the LSTM input layer was set as 13. The number of node cells in the hidden layer was set as 100, and there was an input gate, forgetting gate, and output gate in every node cell. The activation function for the node cells was the sigmoid function. The number of nodes in the output layer was set as 1, and the softmax function was used. The stochastic gradient descent method is used to reverse the parameters in the node cells of the hidden layer, the learning rate was set as 0.1, and the maximum number of iterations was set as 1000.

In the process of testing the scoring accuracy of the above three scoring algorithms, the scores calculated by the algorithms were compared with the standard scores. The mean value of manual scoring by 20 experts was used as the standard score. The scoring accuracy of the algorithms is calculated as follows:

$$\begin{cases} R_i = 1 - \dfrac{|S_{i1} - S_{i2}|}{S_{i2}} \\ R = \dfrac{\sum\limits_{i=1}^{n} R_i}{n} \end{cases} \qquad (2)$$

where R_i is the score similarity of the algorithm for the i-th sample, R is the score accuracy of the algorithm, S_{i1} is the score given by the algorithm for the i-th sample, S_{i2} is the expert manual score for the i-th sample, and n is the number of test samples.

2) Testing of the pronunciation resonance peak image display module of the speaking training system: The standard pronunciation of the local English speech dataset was input in the pronunciation resonance peak image display module of the speaking system. Then, the pronunciation of the students' pronunciation of the local English speech dataset before receiving training by the speaking training system and the pronunciation after receiving training by the system were input into the module to output the pronunciation resonance peak comparison graph.

3) Testing of the improvement of students' speaking levels after training by the speaking training system: One hundred students were randomly selected from the School of Foreign Languages of Hankou University and were divided into two groups: a control group and an experimental group. The control group used the traditional teaching method for English speaking training, while the experimental group used the speaking training system in addition to the traditional teaching method for speaking training. The students in both groups were taught to speak for two weeks, and their speaking levels were scored by 20 experts before and after the teaching, using a hundred-mark system.

C. Test Results

To verify the scoring accuracy of the LSTM speech recognition-based speaking training scoring algorithm, the LibriSpeech dataset and the local English speech dataset were used for scoring accuracy testing, and it was also compared with the two speaking training scoring algorithms based on pattern matching and RNN speech recognition. The test results are shown in Fig. 4. For the LibriSpeech dataset, the accuracy of the pattern matching-based scoring algorithm was 79.69%, the accuracy of the RNN speech recognition-based scoring algorithm was 89.65%, and the accuracy of the LSTM speech recognition-based scoring algorithm was 95.21%. The corresponding accuracy for the local English speech dataset was 72.34%, 81.33 %, and 90.12%, respectively. It was seen from the comparison in Fig. 4 that the speaking training scoring algorithm based on LSTM speech recognition had the highest accuracy, followed by the speaking scoring algorithm based on RNN speech recognition, and the speaking training scoring algorithm based on pattern matching had the lowest accuracy when scoring the same speech dataset. In addition,

the accuracy of the three speaking training scoring algorithms was higher when scoring the LibriSpeech dataset.

Due to the space limitation, only a resonance peak graph for comparing a student's pronunciation of an English sentence with the standard pronunciation is shown here, as shown in Fig. 5. Fig. 5 shows the changes in the resonance peak of the students' pronunciation over time. Because of the connection between the resonance peak and the mouth shape, the graph also qualitatively reflected the changes in the student's mouth shape over time. The resonance peak line graph comparison demonstrated that the resonance peak of the student's pronunciation was larger than that of the standard pronunciation, indicating that the student's tongue position was low and the mouth was opened too wide during pronunciation. Therefore, students should raise the tongue position and reduce the mouth shape. After the training, the resonance peak broken line of the student's pronunciation almost coincided with that of the standard pronunciation, indicating that the mouth shape training was effective.

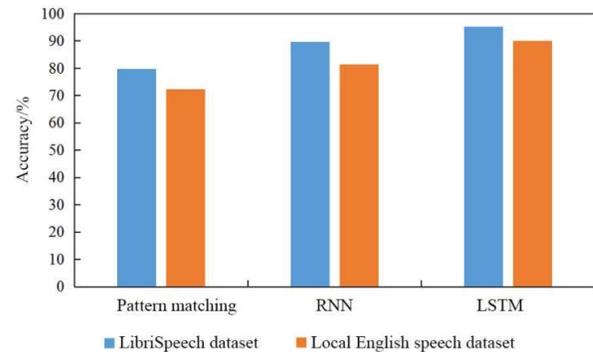
In order to verify the effect of the LSTM speech recognition-based speaking training system in improving pronunciation, 100 students were randomly selected from the Foreign Language Institute of Hankou University and then divided into two groups. The control group was taught traditional speaking, and the experimental group was trained with the speaking training system in addition to traditional speaking teaching. The speaking level of students in both groups was scored by 20 experts before and after receiving the teaching, and the results are shown in Table I.


Fig. 4. Scoring Accuracy of Three Speaking Training Scoring Algorithms for Two Speech Datasets.
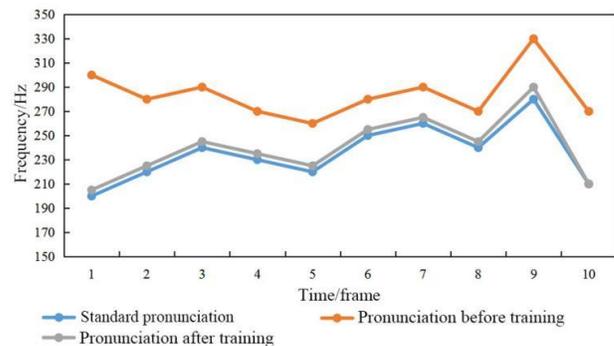

Fig. 5. Comparison of the Resonance Peak between the Student's Pronunciation before and after Training and the Standard Pronunciation.

	Control group	Experimental group	P value
Pre-teaching	75.1 ± 5.2	75.3 ± 6.1	0.126
After teaching	78.6 ± 5.7	92.1 ± 1.5	0.001
P value	0.144	0.001	

It was seen from Table I that there was no significant difference between the speaking level of the control group and the experimental group before conducting the speaking instruction. After the teaching, there was a significant difference between the speaking level of the control and experimental groups, and the speaking level of the experimental group was significantly higher than that of the control group.

It was found from the comparison of the average speaking score of the same group before and after the teaching that the P value of the difference between the average speaking score of the control group before and after the teaching was 0.144, which was greater than 0.05, i.e., the speaking level of the control group was not significantly improved after the teaching; the P value of the difference between the average speaking score of the experimental group before and after the teaching was 0.001, which was less than 0.05, i.e., the speaking level of the experimental group was significantly improved after the teaching.

V.   DISCUSSION

Students need to pronounce English successfully in addition to being able to read and write English correctly in the process of learning English. As English is a language for communication, the level of spoken English is somehow more important than the level of English reading and writing. However, in the process of learning spoken English, a standard pronunciation is needed as a reference. In the traditional teaching of spoken English, the teacher usually pronounces the words, the students follow the teacher's pronunciation, and the teacher corrects the students' pronunciation. In this teaching mode, the students' speaking training effect depends on the teacher's speaking level, and it is impossible for the teacher to teach one-on-one.

With the development of speech recognition technology, it has been gradually applied to various fields, including English speaking training. The English speaking training system built with speech recognition technology can evaluate students' pronunciation by the scoring module and visualize their pronunciation characteristics by the pronunciation resonance peak display module. With these two modules, students can evaluate their own speaking level according to the standard pronunciation given by the system and adjust their pronunciation according to the differences in pronunciation characteristics. The scoring module and pronunciation resonance peak display module were tested in the simulation experiment, and the effect of the speaking training system in improving the students' English speaking level has been studied above.

The results of the accuracy test of the scoring module showed that the accuracy when using the LSTM for

pronunciation evaluation was higher than the pattern matching and the RNN algorithm. The reason is as follows. Although the dynamic time regularization method was used in the pattern matching-based speaking training scoring algorithm to reduce the difficulty of matching due to duration randomness, some information was lost in the process of stretching or compressing the audio, and the standard speech templates in the template library were relied on, so it had better scoring accuracy for the LibriSpeech dataset containing a larger amount of data. The RNN speech recognition-based speaking training scoring algorithm used the RNN to score speech. Compared with pattern matching, the RNN did not require standard templates for scoring but directly scored the pronunciation according to the pattern obtained during training, which was more efficient. Moreover, the activation function in the RNN effectively fit the nonlinear pattern between pronunciation features and scoring, so it was more accurate than pattern matching. Compared with the RNN speech recognition-based algorithm, the LSTM speech recognition-based speaking training scoring algorithm used an activation function that can effectively fit the nonlinear pattern, but the introduced forgetting gate unit avoided the gradient explosion when facing long data, so it had better accuracy when scoring long speech.

The test results of the pronunciation resonance peak display module showed that the module could visualize the resonance peaks of students' spoken pronunciation. The resonance peaks of pronunciation before and after training were compared with those of standard pronunciation, and the results showed that the resonance peaks of pronunciation after training were closer to those of standard pronunciation. Taking the results presented in Fig. 5 as an example, the resonance peaks of the students' pronunciation before training were larger than those of the standard pronunciation, indicating that the tongue position was low and the mouth opened too wide during the pronunciation process. Thus, the tongue position needed to be raised, and the mouth shape should be smaller during the training process. The resonance peaks after training also showed the effectiveness of adjusting the pronunciation.

The results of testing the effectiveness of the speaking training system showed that the experimental group that applied the speaking training system had a significant improvement in their pronunciation after teaching compared to the control group that adopted the traditional teaching mode. The reason is as follows. In the traditional teaching mode, students adjusted their own pronunciation according to the teacher's pronunciation; the pronunciation of the whole class would be affected if the teacher's pronunciation was wrong. Moreover, different students had different pronunciation habits, so it was difficult for the teacher to provide targeted tutoring to students on a one-to-one basis, and the common tutoring would make some students have difficulty in keeping up with the learning pace. When using the speaking training system, the students adjusted their pronunciation independently with the standard pronunciation as the target based on the scoring module and pronunciation visualization module, which was considered targeted training.

VI. CONCLUSION

This paper briefly introduced the English speaking training system and described the scoring algorithm in the speaking training scoring module of the system and the pronunciation resonance peak display module in the system. The pronunciation scoring module and the pronunciation resonance peak display module in the speaking training system were tested. In addition, the speaking level of the students that were trained traditionally and trained by the speaking training system was compared before and after the teaching. The results are as follows. (1) When scoring the same speech dataset, the LSTM-based speaking scoring algorithm was the most accurate, the RNN-based scoring algorithm was the second most accurate, and the pattern matching-based scoring algorithm was the lowest. (2) The three algorithms achieved higher accuracy when scoring the LibriSpeech dataset. (3) The pronunciation resonance peak display module effectively displayed the line graph of the resonance peak of the student's pronunciation over time and visually reflected the difference of the resonance peak between students' pronunciation and standard pronunciation. (4) The difference in the speaking level between the control group and the experimental group before receiving instruction was not significant; the speaking level of the control group improved insignificantly after receiving traditional speaking instruction, and the speaking level of the experimental group improved significantly and was significantly higher than that of the control group after being trained by the speaking training system.

Abstract—The effective loading area decreases because of cracking, leading to a rise in stress and eventual structural failure. Monitoring for cracks is an important part of keeping any pipeline or building in excellent working order. There are several obstacles that make manual inspection and monitoring of subsea pipes challenging. The fundamental objective of this study is to create a relatively inexpensive underwater vehicle that can use an image processing technique to reliably spot cracks on the exteriors of industrial pipes. The tasks involved in this project include the planning, development, and testing of an underwater vehicle that can approach the circular pipes, take pictures, and determine whether there are fractures. In this project, we will utilize the Canny edge detection technique to identify the crack. The system could function in either an online or offline mode. Using a Raspberry Pi and a camera, the paper will discuss the procedures followed to locate the pipe cracks that activate the underwater vehicle. While Python is used for image processing to capture photographs, analyze images, and expose flaws in particular images, the underwater vehicle's movement will be controlled via a connected remote control. When the physical model has been built and tested, the results are recorded, and the system's benefits and shortcomings are discussed.

Keywords—*Crack detection; pipeline; underwater vehicle: image processing; Raspberry Pi; canny edge detection*

I. Introduction

As certain countries start an economic growth period, a subsequent increase in energy demand is anticipated. The infrastructure that supports energy production expands to meet the growing needs of the world's energy consumers. Subsea natural gas production is gaining popularity as a means of accommodating this growth. As a result, there will be an even higher need for resources like human workers, capital, and expertise. These days, robots are being utilized extensively in a wide range of fields [1-6]. Even in the oil and gas industry, robotic assistance is becoming commonplace. By decreasing the need for human intervention while simultaneously boosting operational efficiency and safety, inspection robots are being employed to carry out inspection and maintenance activities on industrial property. Technology advancements in

the field of inspection robotics have made the oil and gas industry more productive, secure, and dependable.

Extraction of petroleum from subterranean sources and transportation to the surface is a complex process that requires a wide range of structures and systems to work together. When conducting such tasks, it is essential to do so while minimizing costs and environmental damage as much as feasible. Transmission of oil and gas across great distances is essential, and subsea pipelines play a key role in this process [7].

From an economic, safety, and environmental perspective, pipelines could be regarded as the most ideal means of transporting petroleum fluids from underwater structures to floating manufacturing plants during exploration and from these sites to land oil refineries. The diameter and length of these pipelines, as well as operating pressures, subsea terrains, undersea conditions, and fluid properties, all have a significant impact on the price of subsea pipelines. The price of building a subsea pipeline varies depending on these factors, from several hundred dollars per kilometer to many millions of dollars per kilometer [7].

Several obstacles make it hard to inspect and monitor underwater pipelines. The area in which a pipeline may be situated for decades is complex and full of potential hazards, and problems can occur at any time during the pipe's lifetime. Damage to the pipeline might be caused by debris that falls from the topside. The pipeline might get caught on ship anchors or dragged by fishing gear that drags the ocean floor. Erosion of the soil beneath the pipeline by ocean currents can lead to free spanning, in which the pipeline is no longer supported anywhere but at its beginning and terminus. Corrosion and erosion can be caused by the inner fluids, which are often acidic and contain abrasive sand particles travelling at high speeds. Cracks in the pipe wall can occur because of such circumstances. Significant damage can be avoided if the crack or fracture is monitored on a regular basis, and the pipe's life can be extended with good treatment. Even seemingly tiny cracks can expand and finally lead to serious structural failure [8, 9]. Therefore, inspection and monitoring

activities must be carried out to ensure that no cracks or defects develop, as this might lead to serious implications for the industry, such as explosions and fires caused by the discharge of toxic gases and liquids.

In consideration of all these issues, it's crucial to constantly check pipelines and install monitoring equipment. Once the system is in place, it might be difficult to inspect the subsea pipeline due to the often-considerable water depths. Many useful inspection technologies cannot be delivered to the pipeline because they rely on costly and potentially risky equipment and methods. It would be impractical to strip away coating layers for routine inspection if the pipeline was multilayered and buried a few thousand feet below the ocean's surface. Pipelines can be inspected internally using inline inspection, but the benefit of doing so must be evaluated against the cost of shutting the pipeline down. In most cases, it would be preferable and more cost-effective to use a less invasive screening inspection or monitoring tool that provides a more comprehensive overview of the pipeline and recommends which regions may require additional attention.

Several studies on remotely operated vehicles (ROVs) for maritime research have recently been published [10-14]. In offshore sectors, such as oil and gas, marine structures, marine sciences, naval security, marine renewable energy, and research reasons, ROVs have been employed for underwater intervention, repair, and maintenance activities. ROVs are used in submarine applications to track mines and are programmed to do high-risk activities by executing algorithms for prediction, diagnosis, and classification. Other research initiatives have concentrated on underwater surveillance, and they are set up to manage continuous tasks with defined goals [10]. ROVs can also be used to capture underwater photographs, for which there are now open research lines [10]. Several detection techniques utilizing image processing with deep learning have previously been deployed by mounting cameras on ROVs to detect fractures in infrastructure such as walls and pipelines, but results can still vary due to ambient factors such as illumination [15]. As a result, researchers are becoming more interested in crack detection investigations to improve detection approaches [16-20]. Despite the tremendous improvements made in the various fields of use and development of ROVs, the wide range of specialties that come into play in obtaining maximum performance makes it a rich topic for research. The accurate sensing of underwater applications is currently a hot issue in academia.

The primary aim of this research is to develop a low-cost underwater vehicle that can accurately detect cracks on industrial pipe surfaces by using a Raspberry Pi as an embedded controller, which can be programmed using open-source software, is inexpensive, has multiprocessing capabilities, and can be programmed in Python. Several parameters, such as the optimal distance and angle between the camera and the object, will be examined in the experimental section. At the end of the paper, two offline and real-time online monitoring systems will be presented and discussed.

II. LITERATURE REVIEW

Multiple mode nonlinear guided waves have already been investigated and published by several academics for the purpose of detecting fatigue cracks in pipes [21]. Guan R et al. provided in-depth analyses of guided wave propagation and interaction with microcrack in a pipe structure using numerical and experimental methods. The simulation model incorporated a third-order elastic constant and a seam crack to account for material nonlinearity and CAN. Piezoelectric transducers and a nonlinear signal collection system were employed in the acquisition of wave nonlinearity experiments. Both theoretical and empirical evidence demonstrated the nonlinearity produced by a 'breathing' fracture, and the identification of several second harmonic waves was distinct from the findings of a previous investigation in a plate structure. In order to quantify nonlinearity in pipe structures, a new nonlinear index has been introduced [21].

Concerns about the stability, longevity, and functionality of a structure are often prompted by the appearance of cracks. The effective loading area decreases as fractures develop and spread, leading to a rise in stress and, finally, structural failure. Nhat-Duc Hoang proposed a model [22] for employing image processing to spot fracture faults on the exterior of structures. When dealing with digital images for fracture analysis, common problems such as low contrast, uneven illumination, and noise pollution during image processing render the conventional Otsu approach useless. Min-Max Gray Level Discrimination is an image enhancement algorithm used in the new model to enhance the Otsu method (M2GLD). The newly developed model can recognize crack objects and assess their attributes like area, perimeter, width, length, and orientation. Experiments indicate that flaws in testing images were appropriately spotted. When used in conjunction with the Otsu technique, the M2GLD can significantly improve performance [22].

Image processing techniques such as Canny edge detection can find lines suggesting fractures within the pipe and split the images to create a new image that only shows the detected fractures, allowing the fractures to be studied. The Canny edge detection method will be used to detect the fracture in this project. The Raspberry Pi will be used to control the system, which will be attached to the underwater vehicle. When compared to the slow and subjective human inspection, the image processing method for detecting cracks and flaws can offer fast and trustworthy results [23-25]. Pipe inspection has traditionally been done visually, and there are a few drawbacks that may be highlighted, including the fact that it is difficult, time-consuming, subjective to the inspector, and only provides a qualitative conclusion [26, 27].

III. METHODOLOGY

The areas of technology and science, as well as the world of computer programming, can all benefit from the use of robots. Developers and researchers are working to make robots useful in as many fields as possible [28-30]. Modern technology has led to a huge increase in the use of image processing tools in the engineering community for a variety of purposes, including measurement, robot navigation, and others. The research community and industry alike can benefit

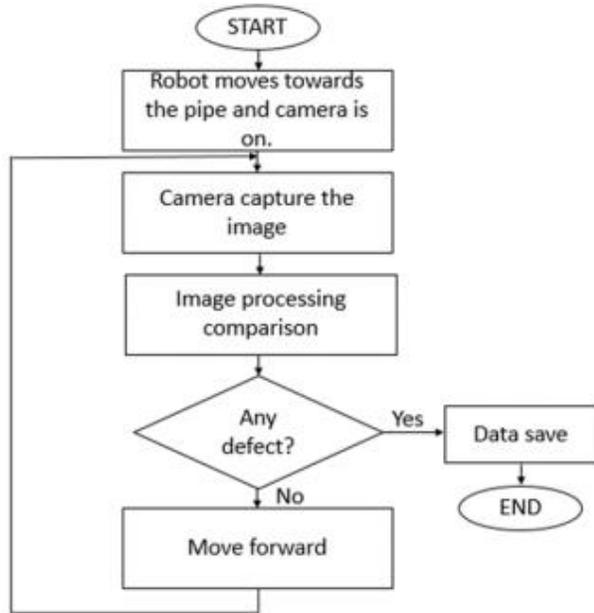
from this technology. Robotics processing steps are shown in Fig. 1, whereas image processing steps are shown in Fig. 2. When the camera is activated, the robot will proceed through the pipe. If a camera spots a crack, it will take a picture and send it to the raspberry pi so it can be analyzed. If a fault or crack is found, it will be identified by a comparison of the two images. If the system detects a fracture, it will take a picture and record the relevant data. If no damage is found, the operation will restart with the camera. To begin the process of crack detection in Fig. 2, a camera image of the structure was first obtained. Prior to data saving, the captured image will be uploaded and processed with the Canny edge technique.


Fig. 1. Process Flow for the Robot.
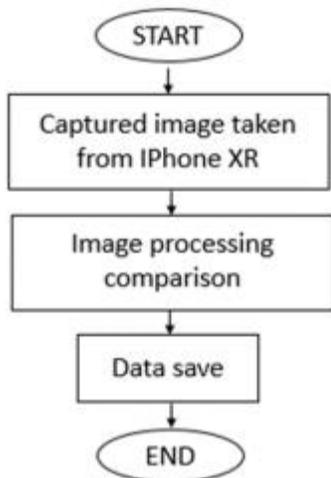

Fig. 2. Image Processing Process Flow.
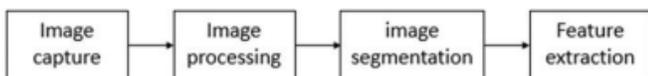

Fig. 3. Process Block Diagram.

Fig. 3 depicts the process block diagram used to identify pipe cracks. Capturing an image is the initial stage of the procedure. The online mode image is captured by the Raspberry Pi V2 NoIR camera, while the offline mode image is captured by the iPhone XR camera. The procedures will thereafter be used both online and offline. There won't be many actions taking place in the image processing phase. At first, the image will shift from its original RGB color mode to a more conventional grayscale. This brings us to our second topic: the logarithmic scale. During this procedure, the image quality improves as the number of pixels is increased by a factor of logarithm. Image smoothing comes last. The term "bilateral filter" or "blurring process" can be used to describe this technique as well. The edge of the break will be maintained during this procedure.

Moving on to the image segmentation stage, where Canny edge detection takes place. Canny edge detection typically has three goals, but the researcher here added a fourth one to boost the overall image quality. The first thing to look at is the image's intensity gradient. Each pixel's gradient vector is computed at this step. Second, the suppression that is less than maximal. To achieve a width of one pixel, the edge must be narrow. Thresholding comes next. First, the morphological operator will be reduced, and then the artificial edge. It serves to patch up the hiccups to make the main crack look more complete. To conclude, we will extract features. SIFT, SURF, and ORB are the three primary methods of feature extraction. The Oriented Fast and Rotated Brief (ORB) format was employed for this study. The object recognition relies on this.

The Raspberry Pi and ultrasonic sensor connection is shown in Fig. 4. The module can be powered by the Pi's 5V and Ground pins. In this project, the Pi's GPIO header's pins 2 and 6 were utilized. The transmission of the ultrasonic pulse is started by pressing the "trigger" input pin on the module. The general-purpose digital input/output (GPIO) uses a 3.3V signal; therefore Pin 16 is directly connected to the trigger (GPIO23). A bit more thought must be given to the module's "echo" output. The output pin is low before the module does its distance measurement (0V). It then maintains this pin high (+5V) for the same amount of time that it took for the pulse to return.

This pin's value must therefore be monitored by the script. The Pi's inputs prefer 3.3V, but the module uses a +5V level for a "high," which is too high. To make sure that the Pi is only exposed to 3.3V in this project, a straightforward voltage divider can be utilized. This is made with two resistors. If R1 and R2 are identical, the voltage is divided in half. 2.5V would be the voltage as a result. If R2 is twice as large as R1, 3.33V will result. The circuit used resistors with resistance values of 470 and 330 ohms.

- Pin 2 is directly connected to the connection for +5V.

- Pin 6 is included into the voltage divider for the Echo pin but connects directly to the GND connection.

- Pin 18 is connected to the voltage divider's center.

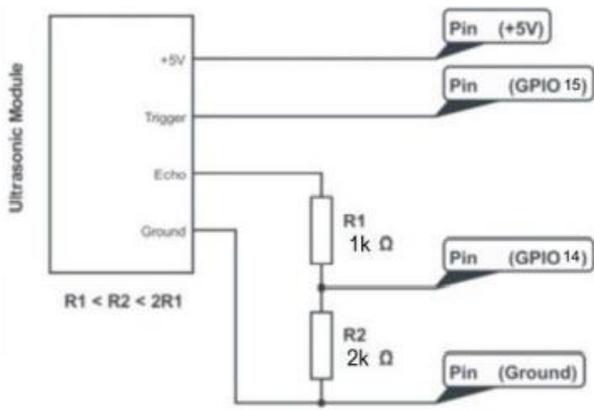
- Pin 16 is used to establish a direct connection to the Trig connector.


Fig. 4. Ultrasonic Sensor Connection.

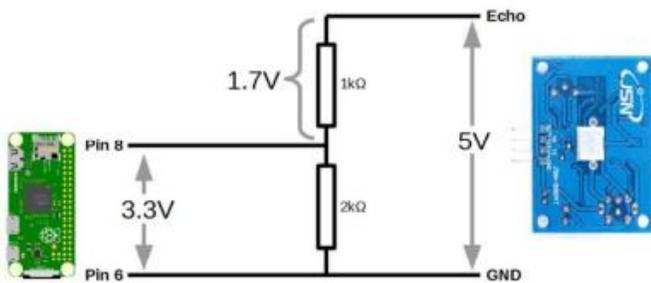
For analyzing digital logic signals, the Raspberry Pi has GPIO pins for general-purpose digital input/output. The GPIO pins will receive the signal from the 'Echo' output pin. The output voltage of the Echo pin is 5V, which is unsafe for use with the Raspberry Pi's GPIO pins, which operate at 3.3V. A voltage divider is used to divide the signal between two connected resistors in a ratio equal to the resistance of the circuit, which is then fed to the Pi to generate the required voltage. As can be seen in Fig. 5, when a 5V signal is supplied from the JSN-SR04T, 1.7V is dropped across the 1k Ohm resistor, and 3.3V is dropped across the 2k Ohm resistor. Fixes and maintenance performed on the prototype of the underwater vehicle are depicted in Fig. 6.


Fig. 5. Voltage Divider.

Fig. 6. Underwater Vehicle Prototype.

A. Canny Edge Detection

The basic method of edge detection has been improved using Canny edge detection. Edge tracking employing hysteresis, smoothing, gradient discovery, non-maximum suppression, and double thresholding are some of the stages that go into obtaining Canny edge detection. To remove camera noise, smoothing will inevitably damage the image. Gaussian filter application triggered the smoothing process. The fundamental idea behind the Gaussian filter was to use a standard deviation using the following equation.

$$B = \frac{1}{159} \begin{bmatrix} 2 & 4 & 5 & 4 & 2 \\ 4 & 9 & 12 & 9 & 4 \\ 5 & 12 & 15 & 12 & 5 \\ 4 & 9 & 12 & 9 & 4 \\ 2 & 4 & 5 & 4 & 2 \end{bmatrix} \tag{1}$$

The standard deviation is a multiplier used to determine how many pixels in a raw image the Gaussian filter will change. This matrix filter is used to convert matrix pixels contained inside a raw image to a raw image. By looking at the region with the most change in intensity, the Canny algorithm seeks to identify the edges of the grayscale image. The gradient of each pixel was handled by the Sobel-operator. Equations following provide illustrations of the x and y gradients.

$$K_{GX} = \begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix} \tag{2}$$

$$K_{GY} = \begin{bmatrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{bmatrix} \tag{3}$$

Finite differences $f(x + 1, y) f(x, y)$ and $f(x, y + 1) f(x, y)$ were used to simplify the finite differences used to calculate the row and column values inside the matrix, where x and y were the raw image's pixel coordinates. The gradient's magnitude is defined in (3) as the angle from Euclidean that Pythagoras' law specifies. The Manhattan distance, which is derived by comparing the distances between the starting and finishing points/blocks, simplifies this calculation (4).

$$|G| = \sqrt{G\frac{2}{x} + G\frac{2}{y}} \tag{4}$$

$$|G| = |G_x| + |G_y| \tag{5}$$

The most obvious limits are shown by the magnitudes of G_y and G_x. But, at times the margins were excessively large, making it difficult to make out exactly where the borders were. To get around this limitation, it is necessary to determine and remember the edges' orientation using the equation below.

$$\theta = \tan^{-1}\left(\frac{|G_y|}{|G_x|}\right) \tag{6}$$

The raw picture was first blurred by smoothing, and then sharpened by using non-maximum suppression. The only part of the gradient picture that was kept was the local maximum. As a second step after non-maximal suppression, we used the improved pixels to label the remaining edge pixels in a

process called double thresholding. Rough surfaces can generate noise and color shifts, which could result in a loss of pixels. We performed a double thresholding method to extract the strongest edge from the image. In this case, only the edge pixels with a value higher than the thresholding value were kept, while the rest were discarded. Weak pixels were those with a threshold value between 0 and 1. In the final stage of edge detection, the strong edge was treated as the real thing. Only edges that were found to have some sort of connection to the real edge were weak. The idea behind it is that noise and other color fluctuations render a clear advantage impossible to achieve. After this point, Canny edge detection will be finished.

IV. RESULT AND DISCUSSION

The system may function both online and offline. Consequently, the user can opt to either upload an existing image or take a new one and process it in real time. Location of the camera used in the experiment is depicted in Fig. 7. Online mode will produce three photos, one from each of the three specified perspectives and distances. The offline option also limits users to uploading and processing just a single image at a time. Fig. 8 through Fig. 16 depicts the original iPhone XR image and the final product after The Canny edge detection was applied. Fig. 17 to 19 demonstrate what happened when we applied the Canny edge detection to data, we got from a Raspberry Pi V2 NoIR camera.

A. Distance of the Camera to the Pipe (cm) and the Angle Taken to the Pipe

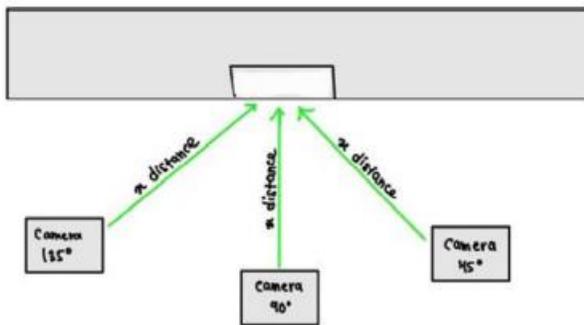
The camera's optimal placement and distance from the pipe were measured. In both online and offline settings, the camera's angle relative to the pipe has been set at 45 degrees, 90 degrees, and 135 degrees, as illustrated in Fig. 7. However, in both online and offline modes, the camera distance to the pipe is fixed at 18cm, 13cm, and 7cm, respectively.


Fig. 7. Camera Angle for Testing.

TABLE I. DETECTION FOR OFFLINE MODE

Angle (°)	Distance of the camera to the pipe (cm)		
	7	13	18
45	Detect	Detect with noise	Detect with noise
90	Detect	Detect	Detect
135	Detect with noise	Detect	Detect with noise

Table I displays the results of the offline testing conducted with the various factors discussed in the introduction. Table I demonstrates that the outcome can be detected across a wide range of parameter settings. However, when testing at 7cm with a camera at an angle of 135 degrees, 13cm with an angle of 45 degrees, 18cm with an angle of 45 degrees, and 135 degrees with an angle of 45 degrees, noise from the raw image is observed. A crack can be detected without any background noise from any distance and any camera angle. Testing in offline mode at a camera distance of 18cm at an angle of 90 degrees revealed that this was the optimal configuration for detecting pipeline cracks.

TABLE II. DETECTION FOR ONLINE MODE

Angle (°)	Distance of the camera to the pipe (cm)		
	7	13	18
45	Detect with noise	Detect with noise	Detect with noise
90	Detect	Detect with noise	Detect with noise
135	Detect with noise	Detect with noise	Detect with noise

Table II displays the outcomes of the tests conducted in the online mode. Based on the testing, a camera positioned at a 90-degree angle and 7 cm away produces the best results. The alternative setting demonstrates that the crack is still detected, although with background noise. The camera on the Raspberry Pi V2 NoIR may have needed bright light to concentrate on the crack, which could explain why this happened.

B. Image Capturing with a Regular Camera for Monitoring in Offline Mode

The offline mode will enable computers input and output data quickly. As a result, relatively slow input devices are no longer required. Instead, the information is kept as files on a fast data storage system. The primary processing computer does not immediately take control of and read the data from its input devices. The data is prepared, kept on a high-speed storage device separate from the computer, and then made available as required. In this mode, the user can select the preferred camera and still apply the same algorithm. From Fig. 8 to Fig. 16, the result may be observed in detail as indicated in Table I.

Distance between the camera and the pipe (7 cm) (45°).

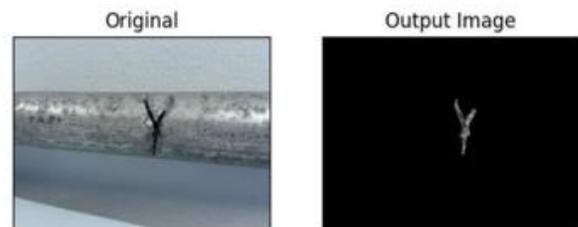
The outcome for a camera to pipe distance of 7 cm and a 45° angle is shown in Fig. 8. The results clearly demonstrate crack detection without any noise.


Fig. 8. Camera to Pipe Distance is 7cm and Angle is 45°.

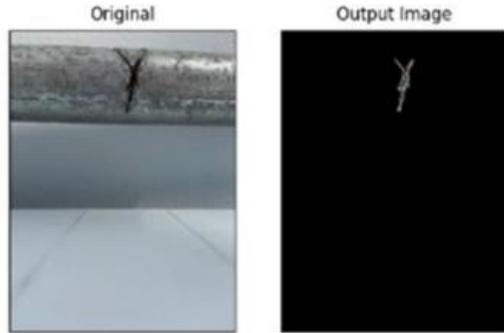
1) Distance between the camera and the pipe (7 cm) (90°): The result is shown in Fig. 9 for a camera-to-pipe distance of 7 cm at a 90° angle. Crack detection is plainly demonstrated by the results.


Fig. 9. Camera to Pipe Distance is 7cm and Angle is 90°.

2) Distance between the camera and the pipe (7 cm) (135°): Fig. 10 depicts the outcome with a camera-to-pipe distance of 7 cm and an angle of 135 degrees. The results indicate the detection of cracks with some background noise.

Fig. 10. Camera to Pipe Distance is 7cm and Angle is 135°.

3) Distance between the camera and the pipe (13 cm) (45°): The outcome for a 13 cm pipe to camera distance with a 45° angle is shown in Fig. 11. The results demonstrate the crack's detection with some noise.

Fig. 11. Camera to Pipe Distance is 13cm and Angle is 45°.

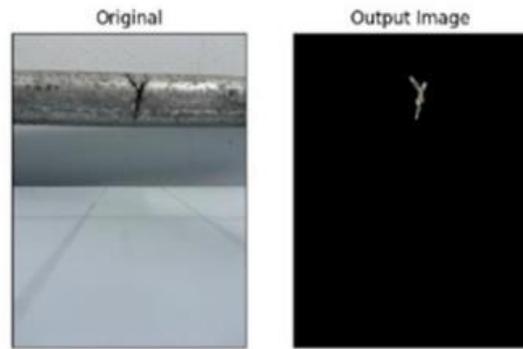
4) Distance between the camera and the pipe (13 cm) (90°): The outcome for a 13 cm camera to pipe distance at a 90° angle is shown in Fig. 12. The outcome demonstrates crack detection.


Fig. 12. Camera to Pipe Distance is 13cm and Angle is 90°.

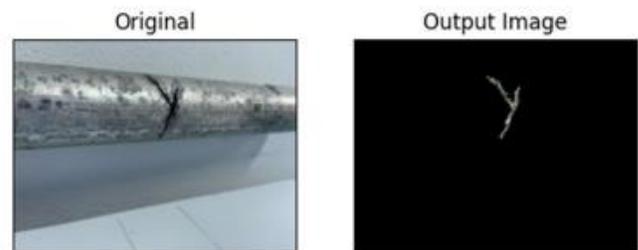
5) Distance between the camera and the pipe (13 cm) (135°): The outcome with a camera to pipe distance of 13 cm and a 135° angle is shown in Fig. 13. The outcome demonstrates crack detection.


Fig. 13. Camera to Pipe Distance is 13cm and Angle is 135°.

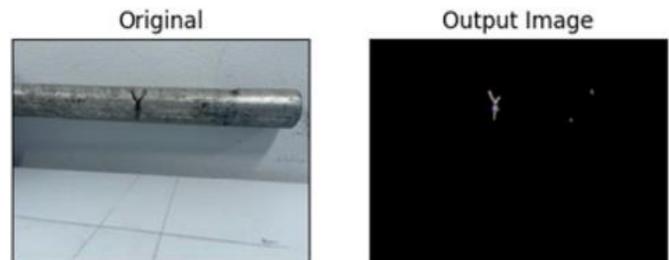
6) Distance between the camera and the pipe (18 cm) (45°): The outcome for a camera to pipe distance of 18 cm and a 45° angle is shown in Fig. 14. The results demonstrate the crack's detection with some noise.


Fig. 14. Camera to Pipe Distance is 18cm and Angle is 45°.

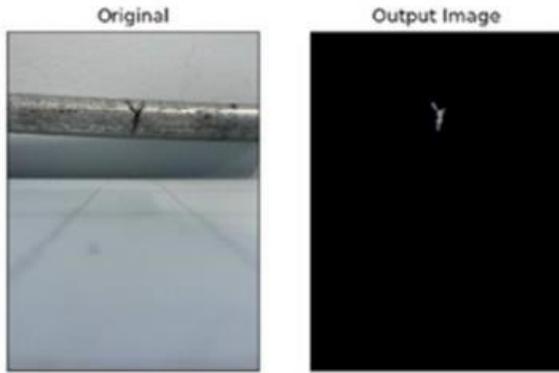
7) Distance between the camera and the pipe (18 cm) (90°): Fig. 15 displays the outcome for an 18 cm camera to pipe distance at a 90° angle. The outcome demonstrates crack detection.


Fig. 15. Camera to Pipe Distance is 18cm and Angle is 90°.

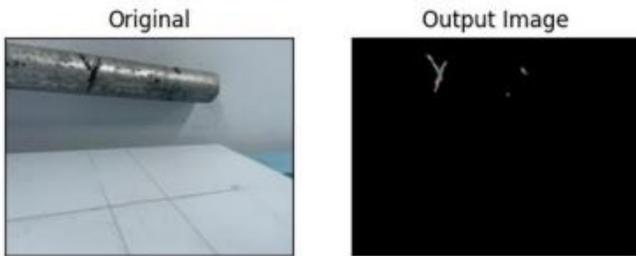
8) Distance between the camera and the pipe (18 cm) (135°): Fig. 16 displays the outcome for an 18 cm camera to pipe distance at a 135° angle. The results demonstrate the crack's detection with some noise.


Fig. 16. Camera to Pipe Distance is 18cm and Angle is 135°.

C. Image Capturing with the Raspberry Pi V2 Module NoIR Camera for Monitoring in Real-Time Online Mode

When a system is connected to a computer and processing data files while using input, output, and storage devices, the process is referred to as real-time "online" processing. The system will take three photographs, giving each image taken a five-second pause period. With the same distance, the three photos have different angles.

The results of an online test for a 7 cm camera distance from the sample are shown in Fig. 17. When the camera is at a 90° angle, feature #2 displays the result without any noise, however testing at 45° and 135° results in some noise in the processed image.

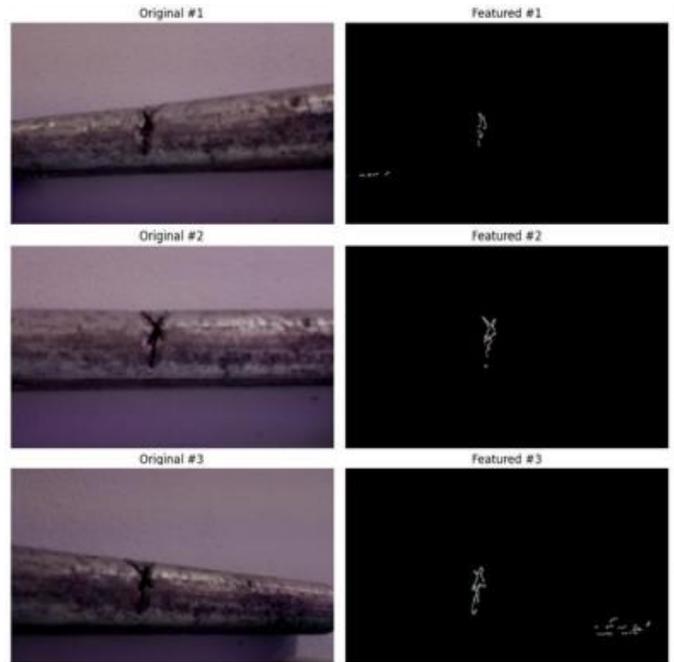
1) Distance between the camera and the pipe (7 cm) (45°), (90°) and (135°): Fig. 18 displays the outcomes of an online test for a 13 cm camera distance from the sample. The crack is visible in the photograph after evaluating it from three different angles, but the results have significant noise. Regarding Fig. 19, the testing is done at an 18 cm camera-to-pipe distance. The crack is still detectable in the results, but there is significantly more noise than at a 13 cm distance. To compare to this chart, use the simplified data from Table II as a guide.


Fig. 17. Camera to Pipe Distance is 7cm and Angle #1 45°, #2 90° and #3 135°.

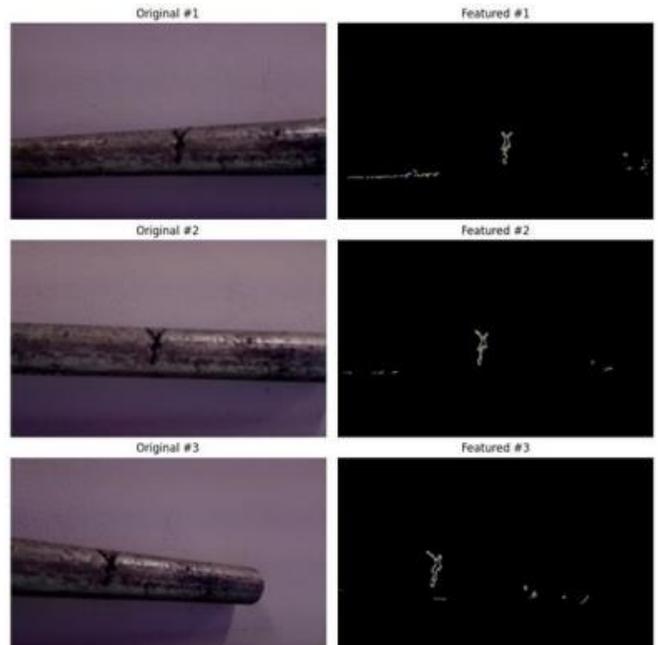
2) Distance between the camera and the pipe (13 cm) (45°), (90°) and (135°)


Fig. 18. Camera to Pipe Distance is 13cm and Angle #1 45°, #2 90° and #3 135°.

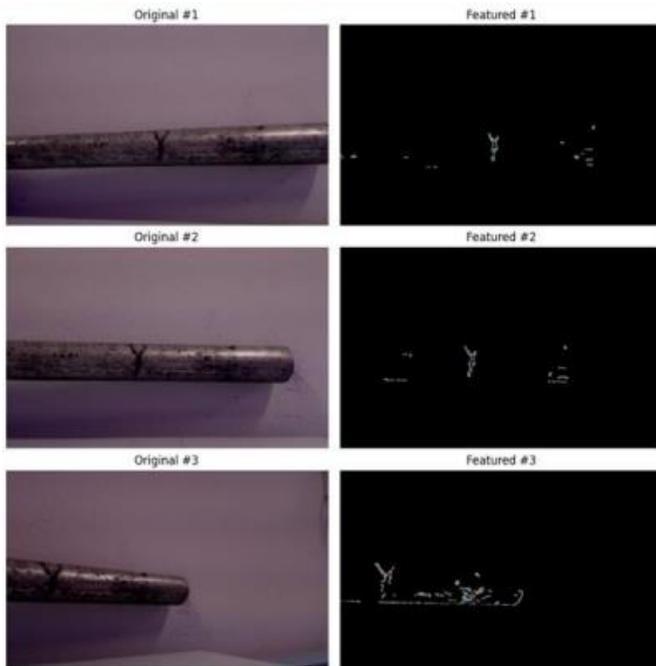
3) Distance between the camera and the pipe (18 cm) (45°), (90°) and (135°)


Fig. 19. Camera to Pipe Distance is 18cm and Angle #1 45°, #2 90° and #3 135°.

V. CONCLUSION

The project's purpose is to help the user detect pipeline faults under water by developing an underwater pipe crack detection system for a low-cost underwater vehicle using a Raspberry Pi and Canny edge detection. Online and offline modes are the two possible techniques. The cracks on the pipe are detected by both modes using the same method, the Canny edge detection.

The primary goal of this project is to use Python on a Raspberry Pi to implement the Canny edge detection crack technique. The algorithm Canny edge detection is employed in coding. Images that are captured online and those that are uploaded offline follow the approach depicted in Fig. 8 to 16. The picture segmentation step three includes the Canny edge detection. Canny edge detection has three fundamental steps, but for this project, one more step is included to make sure that the pipe fracture can be seen clearly. Finding the image's intensity gradient is the first step in the Canny edge detection procedure. Each pixel's gradient vector is computed throughout this process. The second process is called non-maximum suppression. The edge will become narrow thanks to this technique, giving it a one-pixel width. Thresholding is the final step. The artificial edge will be reduced in this stage, and the next step, the morphological operator, will fill in the little gaps to give the main crack more character.

The project's second goal is to create a low-cost underwater vehicle Remotely Operated Vehicle (ROV) prototype that can find cracks in industrial pipelines. Prototypes for vehicles are created with inexpensive but capable materials. The vehicle's mobility, which uses its propulsion system, is one of the precautions. The vehicle's mobility is controlled by the motor or turbine propulsion system. As a result, it is difficult for the user to control.

The project's final goal is to compare the two types of offline and online crack detection methods utilizing image processing. In the system, there are two operating modes: online mode and offline mode. Both modes use the same algorithm but a distinct concept, as is mentioned below. When a user uploads a picture into the system via the online mode, the system analyses the image as described in Fig. 17 through Fig. 19. The system will take three photographs, giving each image taken a five-second pause period. The three photos are at various distances or angles. The user can submit an image into the system for offline mode, and the system will immediately analyze the image. However, only one image may be posted at a time.

The camera utilized for the online approach to find pipe cracks must be improved due to the project's constraints. The camera cannot concentrate on the crack since the Raspberry Pi V2 NoIR camera required the proper lighting. The ultrasonic sensor is up next. It is impossible to determine the precise distance between the camera and the pipe with this ultrasonic sensor. This is due to the UT sensor's high quality. Consequently, it was necessary to purchase a high-quality UT sensor.

Saga University, Saga City, Japan[2]

Abstract—**Method for 1/f fluctuation component extraction from images is proposed. As an application of the proposed method, Kurume Kasuri textile quality evaluation is also proposed. Frequency component analysis is used for 1/f fluctuation component extraction. Also, an attempt is conducted to discriminate the typical Kurume Kasuri textile quality, (1) Relatively smooth edge lines are included in the Kurume Kasuri textile patterns, (2) Relatively non-smooth edge lines are included in the patterns, (3) Between both of patterns (1) and (2) by using template matching method of FLANN of OpenCV. Through experiments, it is found that the proposed method does work for extraction of 1/f fluctuation component and also found that Kurume Kasuri textile quality can be done with the result of 1/f fluctuation component extraction.**

Keywords—*1/f fluctuation component extraction; Kurume Kasuri textile quality; FLANN; OpenCV*

I. INTRODUCTION

Many natural objects in the natural world are known to have fluctuations. Fluctuation is a partly random spatial and temporal fluctuation while following a certain average. 1/f fluctuations can be seen in temporal color changes such as autumn leaves, the rhythm of sea waves, and human heartbeats. Depending on the interpretation of fluctuations, the results are often highly hypothetical or oversimplified. It is considered to be of great significance.

Complex phenomena and shapes in the natural world include unpredictable subtle differences and unpredictable disturbances, and it has been reported that both these complex phenomena and irregular shapes follow the regularity of fluctuations. However, little research has been done on the relationship between color schemes and fluctuations. If there is a color scheme that shows 1/f fluctuation, it can be used in various fields such as interiors, exteriors, and urban planning.

It may say that beautifulness of drawings, textiles and the other images can be explained with 1/f fluctuations. 1/f fluctuation has the effect of suppressing the excitement of the sympathetic nerves and has the effect of making the listening side relaxed, comfortable, and sleepy. 1/f noise is a signal or process with a frequency spectrum such that the power spectral density (power per frequency interval) is inversely proportional to the frequency of the signal. In pink noise, each octave interval (halving or doubling in frequency) carries an equal amount of noise energy.

1/f noise is one of the most common signals in biological systems [1]. The name arises from the pink appearance of visible light with this power spectrum [2]. This is in contrast with white noise which has equal intensity per frequency interval. Within the scientific literature the term 1/f noise is sometimes used loosely to refer to any noise with a power spectral density of the form $S(f) \propto 1/f^{\alpha}$, where f is frequency, and $0 < \alpha < 2$, with exponent α usually close to 1. The canonical case with $\alpha = 1$ is called pink noise [3].

General $1/f^{\alpha}$-like noises occur widely in nature and are a source of considerable interest in many fields. The distinction between the noises with α near one and those with a broad range of α approximately corresponds to a much more basic distinction. The former (narrow sense) generally come from condensed-matter systems in quasi-equilibrium, as discussed below [4]. The latter (broader sense) generally correspond to a wide range of non-equilibrium driven dynamical systems.

Pink noise sources include flicker noise in electronic devices. In their study of fractional Brownian motion [5], Mandelbrot and Van Ness proposed the name fractional noise (sometimes since called fractal noise) to describe $1/f^{\alpha}$ noises for which the exponent α is not an even integer [6], or that are fractional derivatives of Brownian ($1/f^2$) noise.

As for methods of 1/f fluctuation extraction, frequency component analysis is usually used. Namely, (1) extract frequency components from signal sources, first and then, (2) α is calculated from the components. The proposed method allows extraction of frequency components from images in concern using Fast Fourier Transformation: FFT, or Discrete Cosine Transformation: DCT, and also, calculate α from the components. After that, image quality, in terms of textile of the images is evaluated.

As one of the applications of the proposed method, Kurume (Name of the city in Japan) Kasuri textile quality evaluation is conducted. Because humans feel comfortable with the 1/f fluctuation pattern. Therefore, Kurume Kasuri textile quality can be evaluated with the extracted 1/f fluctuation components. Kurume Kasuri is a traditional cotton fabric from the Chikugo region, Japan. By dyeing the cotton yarns first and then weaving them, slight shifts in the pattern occur. Such pattern shifts create a unique "texture" of the fabric, which is one of the main characteristics of Kurume Kasuri. It is also the appealing point of Kurume Kasuri.

There is a problem about the degree in the pattern shift. A moderate amount of pattern shifting brings out a good texture, but if the shifting is too large, the product will not sell, and the fabric has to be sold at a lower price. The problem is that the judgements of the degree of shifting by weavers and dealers are not always the same. In addition, it is necessary to adjust yarns at the stage of weaving Kurume Kasuri, but it is extremely difficult for inexperienced craftsmen (young people) to adjust yarns to achieve a moderate pattern shift. Furthermore, since skilled craftsmen adjust yarns based on their many years of experience and intuition, it is difficult to pass on their tacit knowledge, and there is a shortage of successors. Therefore, a system which can show the acceptable degree of shifting of patterns will help both weavers and dealers for their judgements, and will also improve quality. Furthermore, tacit knowledge can be passed on to younger weavers as explicit knowledge, thus supporting weavers who are suffering from a shortage of successors.

We will use image recognition technology to evaluate the texture (quality) of Kurume Kasuri and build a system to classify whether or not the texture is acceptable as a high-quality (whether or not the pattern shift (or misalignment) is within an acceptable range). By using Artificial Intelligence: AI technology, the team will challenge to make the advanced skills (tacit knowledge) of Kurume Kasuri craftsmen explicit on a computer screen.

In the next section, related research works are described followed by research background and theoretical background. Then, the proposed system is described at first followed by some experiments are described together with conclusion and some discussions.

II. RELATED RESEARCH WORKS

There is the following quality evaluation related papers,

Method for video data compression based on space and time domain seam carving maintaining original quality when it is replayed is proposed [7]. 3D skeleton model derived from Kinect depth sensor camera and its application to walking style quality evaluations is also proposed [8].

Quality flag of GOSAT/FTS products taking into account estimation reliability is proposed and evaluated with actual remote sensing satellite data [9]. Then report on vicarious calibration and image quality valuation of LISA/LISAT (Optical sensor onboard remote sensing satellite) is reported [10] together with methods for vicarious calibration and image quality evaluation of LISA/LISAT [11].

On the other hand, there are the following papers which deal with frequency component analysis,

Polarimetric SAR image classification with high frequency component derived from wavelet multi resolution analysis: MRA is proposed [12]. Meanwhile, hearing aid method by equalizing frequency response of phoneme extracted from human voice is proposed [13].

Incorporating frequency filtering into the tensor singular value decomposition (t-SVD) in robust tensor principal component analysis (RTPCA) is shown to improve the performance of RTPCA [14]. A sensitive frequency component analysis method for cavitation fault using Empirical Mode Decomposition (EMD) method, Fourier Transform and neural network is also proposed [15].

Meanwhile, there are the following papers which deal with noise analysis,

A method of speckle noise reduction for SAR data is proposed [16] together with a new method for SAR speckle noise reduction (Chi Square Filter: CSF) [17]. On the other hand, sensitivity analysis of Fourier Transformation Spectrometer: (FTS) against observation noise on retrievals of carbon dioxide and methane is conducted [18].

Noise suppressing edge enhancement based on Genetic Algorithm (GA) taking into account complexity of target image measured with Fractal dimension is proposed [19]. Meantime, a method for aerosol parameter estimation error analysis is proposed with a consideration of noises included in the measured solar direct and diffuse irradiance [20].

Method of noise reduction in passive remote sensing is proposed for noise and clutter rejection [21]. On the other hand, speckle noise removal of SAR images with Digital Elevation Model: DEM is proposed [22] together with a new method for SAR speckle noise reduction by Chi-Square test filter is proposed and validated with real SAR imagery data [23].

In addition, the higher-order detrending moving-average cross-correlation analysis (DMCA) is proposed to show that physical activity in daily life has a common long-range correlate with heart rate (HR) variability that shows 1/f fluctuation [24].

III. THEORETICAL BACKGROUND AND PROPOSED METHOD

We will evaluate the texture (quality) of Kurume Kasuri, build a system to classify whether it is an appropriate texture (whether the pattern shift is within the acceptable), and verify it.

A. Examples of Fluctuation Pattern of Kurume Kasuri

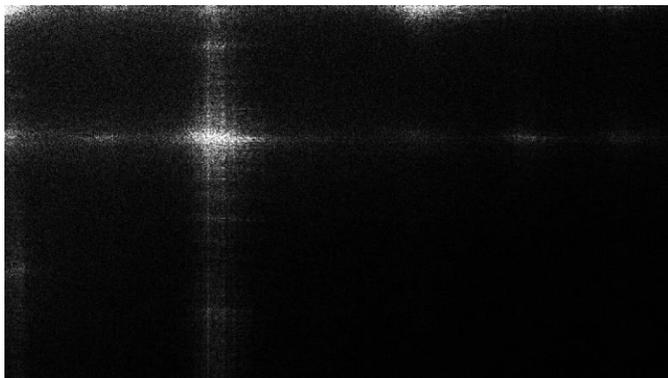
Fig. 1(a) shows one of the examples of the fluctuation patterns of Kurume Kasuri. As shown in Fig. 1, due to the irregular weaving timing of the loom, the Kasuri pattern does not become linear.

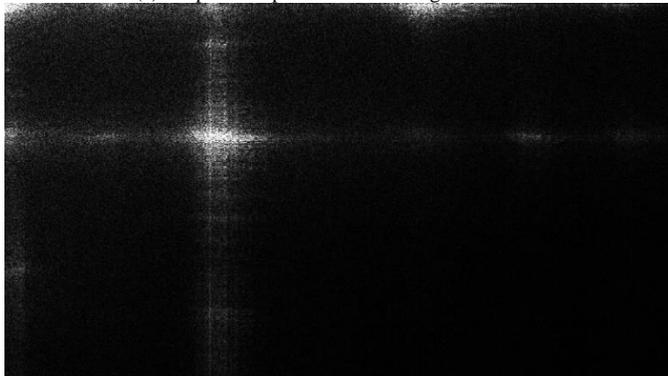
This non-smooth Kasuri pattern has a quaint texture and seems beautiful to the human eye. To put it the other way around, a smooth Kasuri pattern is boring and tasteless to the human eye. For instance, if the pattern edge of the current image in Fig. 1(a) is artificially smoothened, the pattern will be dull and boring as shown in Fig. 1(b).

DCT is applied to these patterns of Fig. 1(a) and (b), then Fig. 2(a) and (b) are obtained. High frequency components of the original pattern are smaller than that of the artificially smoothened edge pattern.

(a) Original Kurume Kasuri Pattern.

(b) Artificially Smoothened.

Fig. 1.   One of the Examples of Kurume Kasuri Pattern and its Artificially Smoothened Pattern.


(a) Amplitude Spectrum of the Original Pattern.


(b) Amplitude Spectrum of the Artificially Smoothened Pattern.

Fig. 2.   Amplitude Spectra of the Original and the Artificially Smoothened Patterns of Kurume Kasuri.

B. Procedure of the Proposed Method

The procedure of the proposed method is as follows:

1) Extraction and accumulation of image data for learning: Only the pattern part is cut out from the image of Kurume Kasuri (Fig. 3) by image processing by OpenCV.

2) Comparison of the number of feature points: Detect the feature points of the image obtained in 1), and compare the number of feature points with the ideal pattern and other features.

3) Comparison with 1/f fluctuation: Frequency analysis is performed on the image obtained in 1), the power spectrum is obtained, and the power spectrum is linearly approximated to obtain the proportional coefficient and the coefficient of determination.

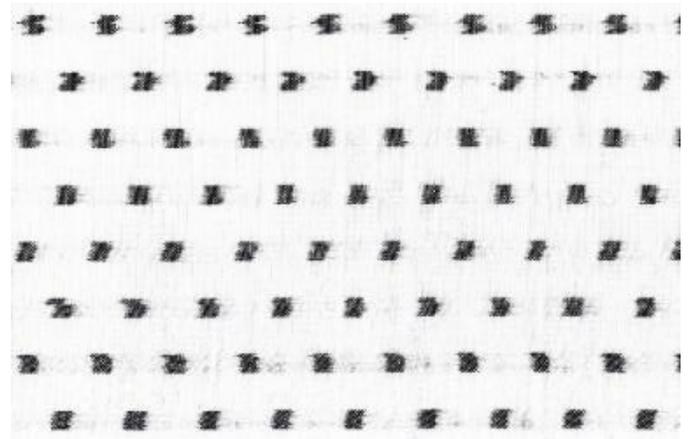
4) Creation of image recognition model: Based on the collected image data for learning and the results obtained in 2) and 3), deep learning is performed based on the evaluation by experts, and an image recognition model is created.


Fig. 3.   Image Example of Kurume Kasuri (Sideways).

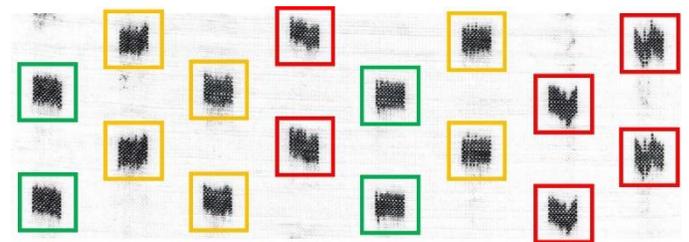
As shown in Fig. 4, there are three types of Kurume Kasuri edge patters, (1) green colored rectangles of relatively smooth edge line patterns, (2) red colored rectangles of relatively non-smooth edge line patters and (3) yellow colored rectangle of the middle patterns between (1) and (2). The pattern type of (1) is boring and tasteless while the pattern type of (3) is quaint texture and seems beautiful. On the other hand, the pattern (2) is that the smooth line fluctuates too much, giving the impression of an unstable pattern.


Fig. 4.   Three Types of Kurume Kasuri Edge Patters, (1) Green: Relatively Smooth Edge Line Patterns, (2) Red: Relatively Non-smooth Edge Line Patters and (3) Yellow: The Middle Patterns between (1) and (2).

In order to extract the rectangle of the outline of the Kurume Kasuri in concern, the following four steps are conducted.

1) Find the outline of the pattern

- Binarization (in black and white)

- Inversion of color (because the background is white)

- Contour extraction

2) Find the circumscribed rectangle based on the contour information

3) Find the center coordinates of the circumscribing rectangle

4) Specify the extraction range

Fig. 5 shows the procedure of the extraction of the rectangle of the outline of the Kurume Kasuri.

(a) Original.   (b) Binarize.   (c) Inverse.   (d) Contour.

(e) Rectangle and Center   (f) Extraction Range.

IV. EXPERIMENTS

A. *Pattern Comparison with Template Matching*

In order to compare the patterns in concern, the ideal pattern selected by the expert (Kurume Kasuri Producer: Orimoto in Japanese) from the obtained images was used as the template image, and the feature points of the template image and other images were compared using Fast Library for Approximate Nearest Neighbors: FLANN (high-speed nearest neighbor search) of OpenCV (Fig. 6).

Namely, the results show that the larger the fluctuation, the larger the number of feature points and the smaller the number of matching feature points. Therefore, it is possible to discriminate among three edge line patterns (1) relatively smooth edge line patterns, (2) relatively non-smooth edge line patters and (3) the middle patterns between (1) and (2).

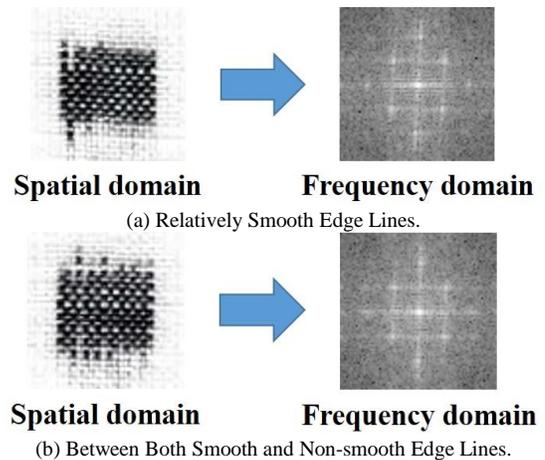
(b) Between Both Smooth and Non-smooth Edge Lines.

Spatial domain   **Frequency domain**

(c) Relatively Non-smooth Edge Lines.


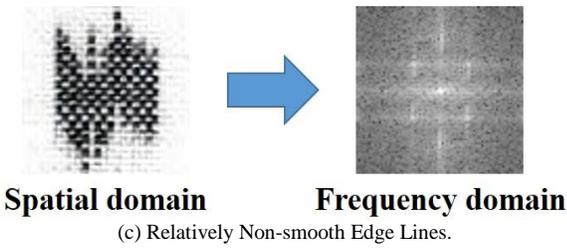


Fig. 7.   Frequency Components of the Typical Three Kurume Kasuri Patterns.

TABLE I.   PROPORTIONAL COEFFICIENTS AND R^2 VALUES OF THE TYPICAL THREE PATTERNS

Types of patterns	Proportional coefficient	R^2	Proportional coefficient	R^2
	Horizontal		Vertical	
(1) Smooth edge lines	-0.584	0.125	-1.850	0.589
(3) Between both	-1.168	0.399	-2.001	0.688
(2) Non-smooth edge lines	-1.885	0.637	-2.365	0.782

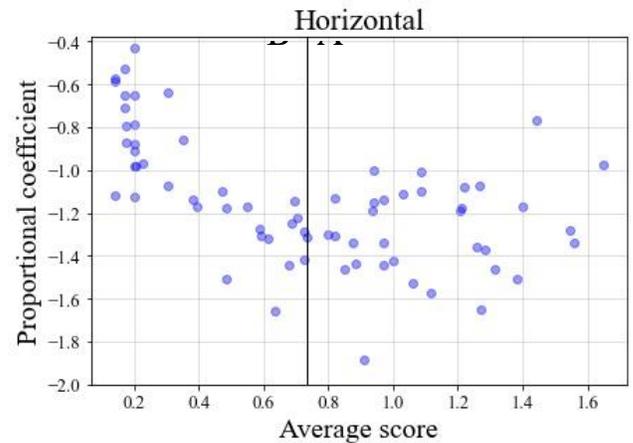
Also, Fig. 8 shows the vertical and horizontal frequency components of the pattern images of Fig. 7. The negative slope (proportional coefficient) did not become one, which is the same as the 1 / f fluctuation, but the larger the fluctuation, the better the accuracy of linear approximation (coefficient of determination), and the larger the negative slope (proportional coefficient). Obtained (Table I).

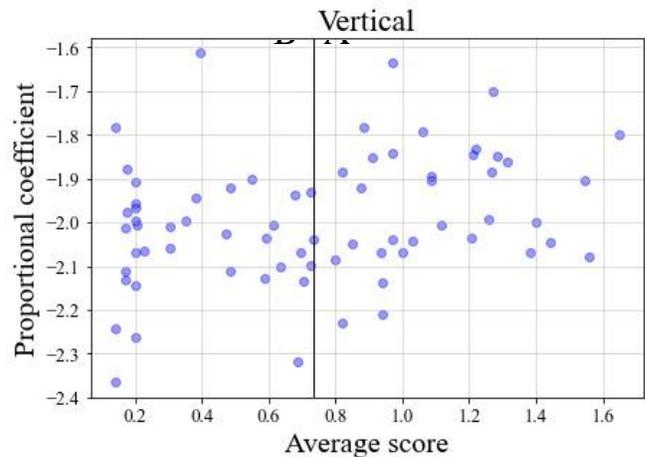
With a negative slope (proportional coefficient) of two as the threshold value, it may be possible to classify anything that exceeds it as excessive fluctuation. It is found that the fluctuation in vertical direction is greater than that of horizontal direction. It is also found that proportional coefficient of two is much comfortable than proportional coefficient of one (the 1/f fluctuation).

(a) Relatively Smooth Edge Lines.

(b) Between Both Smooth and Non-smooth Edge Lines.

(c) Relatively Non-smooth Edge Lines.

Fig. 8.   Amplitude Spectra of the Vertical and Horizontal Directions for the Typical Three Kurume Kasuri Patterns.


(a) Relationship between Average Scores and Horizontal Proportional Coefficients.


(b) Relationship between Average Scores and Vertical Proportional Coefficients.

Fig. 9.   Scatter Plots Showing the Relationship between Average Scores of Evaluations by Orimoto and Proportional Coefficients for each of 70 Patterns.

Finally, we compared proportional coefficients with results of a questionnaire conducted in advance to 35 experts (Kurume Kasuri Producer: Orimoto) in order to check if it is actually possible to classify patterns. Regarding the

questionnaire, each of 70 patterns used in this experiment was evaluated as good (2 pt), acceptable (1 pt), and unacceptable (0 pt). As a result, the average score for the overall Orimoto evaluation was 0.733. Fig. 9 shows the relationship between average scores and proportional coefficients for each pattern, which is classified into Group A and Group B using the average score (0.733) as the threshold.

As for the horizontal, most of the proportional coefficients for group A are less than -1, indicating a negative correlation. As for the vertical, most of the proportional coefficients for group A are more than -2.1, indicating a positive correlation. It is found that pattern shift can be classified by proportional coefficient because t-test was performed at significance level of 5% and found to be significantly different.

V. CONCLUSION

Method for 1/f fluctuation component extraction from images is proposed. As an application of the proposed method, Kurume Kasuri textile quality evaluation is conducted. Frequency component analysis is used for 1/f fluctuation component extraction. Also, an attempt is conducted to discriminate the typical Kurume Kasuri textile quality,

1) Relatively smooth edge lines are included in the Kurume Kasuri textile patterns.

2) Relatively non-smooth edge lines are included in the patterns.

3) Between both of patterns (1) and (2) by using template matching method of FLANN of OpenCV.

Through experiments, it is found that the proposed method does work for extraction of 1/f fluctuation component and is also found that Kurume Kasuri textile quality can be done with the result of 1/f fluctuation component extraction.

This research not only helps improve the quality of Kurume Kasuri, a local traditional craft, but also allows young people to pass on the tacit knowledge of skilled craftsmen as explicit knowledge, supporting Orimoto who is suffering from a shortage of successors.

VI. FUTURE RESEARCH WORKS

In the future, to improve the quality of Kurume Kasuri, we would like to build a model that machine-learn patterns, classifies images to determine if pattern shift is within acceptable limits, and prevents pattern shift outside of acceptable limits.

Image Verification and Emotion Detection using Effective Modelling Techniques

Sumana Maradithaya, Vaishnavi S

Department of Information Science and Engineering

M S Ramaiah Institute of Technology, Bangalore, India

Abstract—The feelings expressed on the face reflect the manner of thinking and provide useful insights of happenings inside the brain. Face Detection enables us to identify a face. Recognizing the facial expressions for different emotions is to familiarize the machine with human like capacity to perceive and identify human feelings, which involves classifying the given input images of the face into one of the seven classes which is achieved by building a multi class classifier. The proposed methodology is based on convolutional neural organizations and works on 48x48 pixel-based grayscale images. The proposed model is tested on various images and gives the best accuracy when compared with existing functionalities. It detects faces in images, recognizes them and identifies emotions and shows improved performance because of data augmentation. The model is experimented with varying depths and pooling layers. The best results are obtained sequential model of six layers of Convolutional Neural Network and softmax activation function applied to last layer. The approach works for real time data taken from videos or photos.

Keywords—*Face detection; face recognition; emotion detection; data augmentation*

I. INTRODUCTION

Facial emotion recognition is a part of nonverbal communication. Recognizing emotions or detecting face from input image is a challenging task. Facial emotion detection is very useful in the research field of robotics, in detecting mental disorders and in marketing division as well. Human face detection has numerous applications in computer vision domain. Facial expression detection and analysis helps in sentiment analysis of humans. The proposed methodology presents a model, which can detect, recognize and understand the emotion of any given input image by creating different pipelines. Output of face detection pipeline is the bounding box faces. Then the output will be fed to face recognition pipeline. Face recognition verifies the given two images and outputs the Boolean value. Using convolutional neural network, model is built to detect seven classes of emotions that is sad, fear, disgust, neutral, angry, surprise and happy. Model is trained using open-source dataset that is FER (Face Emotion Recognition), downloaded from Kaggle. Using image augmentation model performance is improved.

The capability to recognize and differentiate among different faces is a boon for humans. Now with the evolution of technology in machine learning and computer vision, even computers can recognize different faces and are able to distinguish between them. Using face detection and recognition access to security applications can be improved.

Example iPhone does the payments and the processes doesn't require any actual card. The model can also be used in crime detection and other healthcare related applications. Existing functionalities or models focus on analysis of complete facial features, and hence with multiple features it will be very confusing to train the model using convolutional neural network. The proposed model mainly focuses on detecting seven classes of emotions that is happy, sad, anger, disgust, fear, surprise and neutral. The proposed methodology uses face recognition library for detecting the facial locations.

The study [28] indicates the importance of identifying emotions in people, so that any physiological expressions can be detected and handled at an early stage. Facial Detection is nothing but the ability to identify the facial location of any given input image or in any video frame. Bounding box will be the output of the identified face. Face Recognition is nothing but comparing multiple faces to verify whether the face belong to same person. Face recognition is done using by differentiating among the embedding vectors of the face. Detected faces emotion is recognized using the model built based on convolutional neural network.

Face detection can be regarded as object class detection where facial locations can be identified and specify the size of the objects being detected in a specific image or images. With the advent of technology, it is now possible to identify the faces, in image or frame without any constraints like head posture, lightning, illumination, skin color. Face recognition determines whether the given images have face that is positive or negative. To achieve this motive, algorithm applied for the purpose will be trained on large datasets. Once the algorithm is trained, algorithm will be capable of analyzing the images to detect the object that is face in any images. When it comes to face detection, it is very essential for any algorithm used to know the parts of the given image to generate the face prints that are compared with the face prints stored previously to check the match.

The research [29] discusses the need of facial detection and emotion detection during the COVID -19 pandemic times. It further elaborates on the effectiveness of face recognition, face detection and emotion detection in the nonverbal communication.

Section II elaborates on the earlier works done, available methodologies and model building approaches. Section III focuses on the proposed work. Section IV discusses the obtained results. Section V` ` summarizes the proposed work done.

II. LITERATURE SURVEY

The author in [7] has presented a model, which automatically recognizes face and facial emotions and classifies the emotions into eight different classes. This model uses Support vector machine algorithm for classification and the accuracy is almost 94%. This machine learning based model is used to detect real time images along with static images, and it cannot detect multiple faces in a given frame. Initially for face detection, HAAR cascade algorithm is used. Then using the face landmarks, trained dataset along with support vector machine algorithm face detection can be performed.

In [20], the author proposed a smart vision model, which can detect human face and emotions respectively. This model uses deep convolutional network for training the model. Even after applying some of the filters, accuracy achieved in the range of 48% to 80%. The model is used for classifying seven different emotions along with face recognition. Model uses swish activation function which is more efficient in terms of performance and maximum accuracy can be reached. Filters are nothing but parameters and layers in a fully connected neural network. Basically, shallow network (single layer) and modern deep network (8 layers) results are compared and dropout mechanisms are used to avoid overfitting.

The author in [10] proposes a deep learning model for emotion detection. Two different datasets are considered and performance evaluation of the proposed methodology is carried out. Validation accuracy and loss, computationally complex and time per step, learning rate, and detection rate are the factors considered for performance evaluation. Model is trained using convolutional neural network. The accuracy achieved is 79%. In [23], Viola Jones face detection algorithm is used for face detection in the image. The proposed methodology is used for human voice detection based on Mel frequency components. KNN classifier algorithm is used for facial emotion detection. Accuracy achieved is more than 90%. Features or a component of the face is calculated and these features are stored as database. Then face detection and emotion recognition can be done using these features stored in the database.

The authors in [5] proposed face detection model based on auto assistance neural network. Earlier approaches had both patch-based auto assistance neural networks integrated with global local-based auto assistance neural network. Accuracy achieved is 90% for detecting six classes of emotion. Model can be used to detect four classes of emotions in videos. The model can be used for detecting dynamic emotion detection from human videos.

The author in [25], proposes a model which makes use of two algorithms, one is based on colour intensity estimation and the other is based on Viola-Jones algorithm. Model is used to detect emotions based on spotting the micro expressions on the face. Colour intensity-based algorithm is very useful for smaller images and faster as well on coloured images. Viola-Jones algorithm can be used for greyscale images and high-resolution images. Both algorithms considered provide efficient outcomes in recognizing the face

and eyes areas in the image. Model cannot predict entire face with higher accuracy.

The article [12], presents a model, which can be used for facial classification of emotion recognition. When considered face, there will be numerous factors that need to considered, like skin colour, textures, eye position and mouth and so on. The first step in this model is to recognize the skin using elliptical boundary. For facial features detection, an algorithm for extracting geometric and other anthropometric features from face image. Training and testing are done based on the classifiers and the accuracy achieved is 57% for detecting six different classes of emotions.

The author in [24] proposed the facial expression detection model based on Fisher face model. Facial features can be extracted using fisher face and facial expression detection is done using neural networks. The model is very sensitive in terms of illumination, noise and different backgrounds images are not suitable for this model. Accuracy is almost 86.85%.

The emotion detection of facial expression requires an image that is face of the person that needs to be recognized. Speech recognition doesn't require any image or person details. This model can be used in health department, education and customer service. Intelligence service makes use of this method to find the truthfulness of the investigation. The model uses MFCC for various frequency sound processing and it also uses Universal background models which eliminate the overfitting problems along with Gaussian mixture models for normal distribution as discussed in [1].

The authors in [8] propose a model which will capture image and detect the facial emotion based on Viola-Jones algorithm and prepares a list of song based on the emotion recognized. Viola-Jones algorithm is used for face detection and Fisher face features classifier is used for emotion detection. Model is used for detecting the face and based on the face detected, emotion recognition is performed and based on the emotion of the user, and music player is built. Accuracy is less.

One of the greatest challenges faced during face recognition is occlusion detection. This model is used for detecting the missing information in the occluded face. Viola-Jones algorithm is used for face detection and principal component analysis is used for face reconstruction and neural networks are used for face recognition. When considered other algorithms or methods, neural network yields the best result as seen in [19].

The author [22] proposed a model that is an electric wheelchair with emotion detection of the user with impairment. For capturing images, an RPI board with camera is used to record the frames captured in a video stream, along with Raspberry P12 and B model incorporated. This model can recognize the face using the images captured from the streams through sample python scripting, for face detection and sample emotion detection. Only three emotions classes were detected that is anger, fear or danger.

Study [17] elaborates on a model that is built based on hidden markov model, which can detect real time user's emotion. The model can detect six different classes of

emotions. Using hidden markov model, facial expressions can be separated and identified automatically. Model is not suitable for different positions and texture or orientation of the face with respect to images. And the accuracy is very low.

The research [3] proposes a methodology where local histograms are normalized along with their features. These features have orientations that is gradient and give better results for human detection along with densely overlapped grids. A new pedestrian database is introduced by the authors. The impact of different descriptor boundaries for fine-scale angles, fine direction binning, coarse spatial binning, nearby differentiation standardization in covering descriptor blocks is immensely significant for great execution.

The focal point of this investigation is on PC computerized impression of human feeling as discussed in [6]. The investigation was based on utilization of Fisher faces for the acknowledgment of human feeling in facial pictures. Large number of Fisher face models are trained and the overall model is considered in contrast to an autonomous test set. The results obtained are used to construct and test a compound progressive framework that endeavors to decipher human feeling continuously utilizing face discovery and calculations in combination with the look examination technique. Outcomes demonstrate that Fisher faces can be valuable in anticipating feeling dependent on content recovered from facial pictures.

Research [16] manages two particular utilizations of PCA in picture handling. The principal application comprises of picture shading that decrease, while the three shading segments are diminished into one containing a significant part of data. The second utilization of PCA exploits eigenvectors properties for assurance to choose object direction. Different strategies can be utilized for past object identification. Nature of picture division suggests to consequences of the accompanying cycle of item direction assessment dependent on PCA as well. Introduced paper momentarily presents the PCA hypothesis from the start and proceeds with its applications referenced previously. Results are archived for the chosen genuine pictures.

The study [2] features the improvement of an Android stage-based application named XBeats which goes about as a Music Player dealing with Picture Preparing essentials to catch, investigate and present music according to the feeling or temperament of the client utilizing this application. Android application was created utilizing the Android SDK programming and OpenCV programming was utilized to execute facial acknowledgment calculations and falls. The one-of-a-kind part of this task is that it centers around facial acknowledgment on the Android stage dissimilar to that on PC frameworks which utilize normally accessible programming projects for something similar. This article additionally gives correlation between utilization of different arrangement calculations utilized for facial location.

Recent FER frameworks spotlight on two significant issues: overfitting brought about by an absence of adequate preparing information and articulation inconsequential varieties, like light, head posture and personality predisposition. For the best in class in deep FER, the article [14], presents existing novel profound neural organizations and related preparing methodologies that are intended for FER dependent on both static pictures what's more, powerful picture groupings and talk about their benefits and restrictions. Several demonstrations and exploratory correlations on generally utilized benchmarks are likewise summed up. Later stretch out the overview to extra related issues and application situations. At the end, audit the leftover difficulties and comparing open doors in this field just as future headings for the plan of vigorous profound FER frameworks.

In [21], author proposes an emotion recognition framework which can be created by using the advantages of profound learning and various applications like criticism investigation, face opening and so forth can be carried out with great exactness. The primary focal point of this work is to make a Deep Convolutional Neural Network (DCNN) model that groups five unique human facial feelings. The model is prepared, tried and approved utilizing the physically gathered picture dataset.

Research [26] proposes a methodology to examine expressions of the face, dependent on both permanent and transient facial features, in an almost front facing view face picture grouping. The AFA framework perceives fine-grained changes in expressions of the face into action units (AU) of the Facial Action Coding System (FACS), rather than a couple of prototypic articulations. Multistate face and facial segment models are proposed for following and demonstrating the different facial highlights, including lips, eyes, foreheads, cheeks, and wrinkles. During following, point by point parametric depictions of the facial highlights are separated. With these boundaries as the sources of information, a gathering of activity units are perceived whether they happen alone or in blends. The framework has accomplished normal acknowledgment paces of 96.4% for upper face AU and 96.7% for lower face AU.

The authors of [4] have proven that emotional facial expressions are universal. Many other studies signify that different other culture, literate people show up the same expressions for few similar emotions. So by this fact, one can draw the conclusion that facial expressions are universal. And different cultured people have different expressions, but people in all variety of cultures are exposed to one single emotion and almost majority had the same expressions, irrespective of their facial shape, the expression was similar. Dataset was generated by considering three sets of faces using New Guinea. From the hypothesis curve, the results prove that facial expressions for certain emotions are universal.

In speech, emotion recognition is a theme on which little examination has been done to date. In [9], the authors talk about why emotions to be recognized in speech is an intriguing and relevant exploration point and present a framework for feeling acknowledgment utilizing one-class-in-one neural organizations. By utilizing an enormous data set of phonemes adjusted words, our framework is speaker and setting autonomous. Upon testing eight emotions approximately 50% of recognition rate was achieved.

Facial recognition framework is utilized in numerous applications going from HCI, reconnaissance to feelings. The

extension is wide and a great deal should be possible in this field. Highest accuracy is achieved through Neural Network (NN) as a classifier and the blend of Gabor Wavelet (GW) and Local Binary Pattern (LBP) is likewise great with a precision of 91.2 and 90%. The other techniques like Principal Component Analysis and Support Vector Machine's exhibition were low as discussed in [11].

The study [15] primarily considers face recognition with the segments by face parsing (FP). Considering the burden that various pieces of face contain distinctive measure of data for look and the weighted capacity are not the equivalent for various appearances, a thought is proposed to perceive look utilizing segments which are dynamic in demeanor exposure. The face parsing finders are prepared through deep conviction network and tuned by logistic regression. The identifiers initially recognize face, and afterward identify nose, eyes and mouth progressively. A profound engineering pretrained with stacked autoencoder is applied to face recognition with the concentrated highlights of distinguished parts. The parsing segments eliminate the excess data in articulation acknowledgment, and pictures should not be adjusted or some other fake treatment.

The authors in [13] proposed a deep convolutional neural network to arrange the 1.2 million high-goal pictures in the ImageNet challenge that is images are classified into 1000 variety of classes. Based on the testing data, the model accomplished top-1 along with top-5 blunder paces of 37.5% which is more than 17.0%, much better compared to the existing best in class. The neural organization, had 60 million boundaries and 650,000 neurons, which consists of five different convolutional layers, and some of the layers had max-pooling layers, along with three completely associated layers and last layer had 1000-way softmax activation function applied. To make processing quicker, model had non-immersing neurons along with effective GPU execution of the convolution activity. In order to reduce overfitting in the fully associated layers the model had created regularization technique called "dropout" which end up being exceptionally successful.

In the extended cohn-kanade dataset (ck+), [18] the quantity of arrangements is expanded by 22% and the quantity of subjects by 27%. The objective articulation for each succession is completely FACS coded and feeling names have been reconsidered and approved. What's more, non-presented arrangements for a few kinds of grins and their related metadata have been added. The article presents standard outcomes utilizing Active Appearance Models (AAMs) and a straight help vector machine (SVM) classifier utilizing a leave-one-out subject cross-approval for both AU and feeling location for the presented information. The feeling and AU marks, alongside the all-encompassing picture information and followed milestones will be made accessible July 2010.

Essential backpropagation, which is a straightforward strategy currently being broadly utilized in regions like example acknowledgment and deficiency finding, is inspected. The fundamental conditions for backpropagation through time, and applications to regions like example acknowledgment including dynamic frameworks, frameworks

recognizable proof, and control are examined. Further expansions of this strategy, to manage frameworks other than neural organizations, frameworks including concurrent conditions, or genuine intermittent organizations, and other pragmatic issues emerging with the technique are portrayed. Pseudocode is given to explain the calculations. The chain rule for requested subordinates the hypothesis which underlies backpropagation is momentarily talked about. The emphasis is on planning an easier form of backpropagation which can be converted into PC code and applied straight by impartial organization clients as seen in [27].

III. PROPOSED WORK

- To train the model training samples or images are collected using FER Dataset. FER is nothing but Facial Emotion or Expression Recognition. Dataset contains 48x48 pixel-based grayscale facial images. FER Data is used to identify the emotions of the unseen data into one of the seven classes of emotions. The dataset is created by browsing each emotion or expression and their synonyms.

- To detect the face and recognize from the given input images, face-recognition library is used. Given any input, image is converted into grayscale image and data is stored in the form of array using numpy array. Face-recognition library loads the given input image and then encodes the loaded image into feature vector and returns the Boolean value. To detect the emotion, faces being detected are taken as input and return the emotion type.

- Using data augmentation performance of the model is improved. The performance of the model is calculated by plotting the confusion matrix that is by considering the true positive and negative values. The accuracy is nothing but the precision, recall and f1-score.

A. Issues, Controversies, Problem

Improving the automatic facial emotion recognition will help in upgrading the social knowledge in the machines. In the field of computer vision, multiple applications make use of facial emotion recognition system and it is very challenging to identify multiple facial emotion in a given frame or image.

B. Proposed Methodology

Face detection is the key mechanism for emotion detection. Because of mental thinking and physical circumstances, humans tend to change their expression from dusk till dawn. The proposed methodology consists of input image, preprocessing, face detection, face recognition, feature extraction, emotion detection/classification. During face detection, the model automatically finds the face locations from the given input image. These face locations are the output of the face detection that is bounding box face and this achieved using face detection library. Once face is detected using face detection library face recognition is done. Once face is recognized, meaningful features are extracted and face emotions or expressions will be analyzed. Basic facial features are eyebrows, eyes, nose, cheeks and mouth. Facial

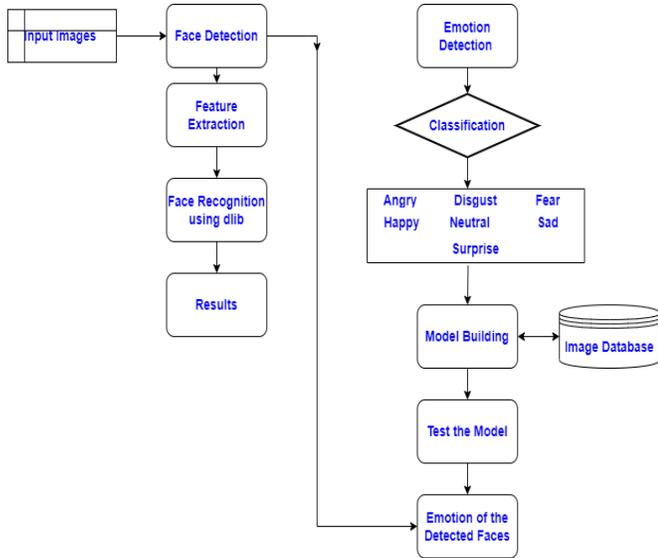
expressions are classified under seven classes, happy, sad, fear, angry, disgust, neutral and surprise.


Fig. 1. Proposed Methodology.

As shown in the Fig. 1, the proposed methodology contains three pipeline stages.

1) Face Detection

2) Face Recognition

3) Emotion Detection

C. Face Detection

Detecting the faces in a given image is the first stage of the pipeline. Face recognition is the python library that is used for facial detection. This python library scans any given input image and outputs the bounding box coordinates of the faces being detected in the given input image. Face detection is special case of object detection technology in which human faces are detected from given input image digitally.

D. Face Recognition

Facial recognition is done using face-recognition library which manipulates the faces from input image. Face-recognition library is built using dlib along with deep learning. Through command line options, facial recognition can be done and that is achieved through dlib's face-recognition library. Facial detection is done using face-recognition library which return bounding box coordinates as output. Then find the required features from given input image and manipulate the features of the face from the given image. That is face recognition. Face landmarks will return person's eyes, chin, nose and mouth. And this is how any makeup related options in the camera works.

Using encoding and based on the images trained or the dataset used, who appears in the image can be recognized using face-recognition library. Using face-recognition library, one can verify any given image and recognize who appears in the image digitally. Create two folders, one with training the model with all the images required. And the other folder which contains all the images present in the training dataset

but in a different angle. Then on unseen data if the input image resembles any of the trained images, then the output will be, the model verifies the image and recognizes the face. Using face-recognition library the proposed model outputs Boolean value if the face matches, then returns true else false.

E. Emotion Detection

Human emotions can be recognized in multiple ways that is through voice, action, facial expressions, and body language and so on. Facial expressions for each emotion are innate and they are not any other part of cultural learning. But making the computer to do so is a challenging task. Facial expressions can be categorized as a form of nonverbal communication. For any given input image face detection and recognition is part of object detection and recognition from any given input images. Humans have tendency to express their emotions through facial expressions at most of the times.

The emotions can be classified into seven different classes apparently. That is happy, sad, anger, disgust, fear, neutral and surprise. The model is built using six layers of convolutional neural network as shown in the below Table I.

TABLE I.   SUMMARIZING LAYERS OF CONVOLUTIONAL NEURAL NETWORK

Layer (type)	Output Shape	Parameters
conv2d (Conv2D)	(None, 46, 46, 32)	320
conv2d_1 (Conv2D)	(None, 44, 44, 64)	18496
max_pooling2d (MaxPooling2D)	(None, 22, 22, 64)	0
conv2d_2 (Conv2D)	(None, 20, 20, 128)	73856
max_pooling2d_1 (MaxPooling2	(None, 10, 10, 128)	0
conv2d_3 (Conv2D)	(None, 8, 8, 128)	147584
max_pooling2d_2 (MaxPooling2	(None, 4, 4, 128)	0
conv2d_4 (Conv2D)	(None, 4, 4, 7)	903
conv2d_5 (Conv2D)	(None, 1, 1, 7)	791
flatten (Flatten)	(None, 7)	0
activation (Activation)	(None, 7)	0

Total params: 241,950
Trainable params: 241,950
Non-trainable params: 0

F. Convolutional Neural Network

Fully connected convolution neural network consists of four inputs that is input layer, and one hidden layer with five neurons and an output neuron in output layer. In fully connected neural network each neuron of the input layer is connected to all the neurons of hidden layer. Then all the computations are performed at hidden layer and the output is presented at the output layer. When any input image is fed into the convolutional layer, apply filters or choose proper parameters along with strides or padding required. Perform the operation that is convolutional on the input. For non-linearity apply Relu Activation function to the convolution operation. Pooling is performed to reduce the dimensionality. Until the error rate is reduced convolution layers are added. Then this flattened output is fed to fully connected convolution layer.

Then model will output based on the activation function used and then object detection and their classification are done.

Artificial Intelligence helps to view the world through computer vision as human does. It is nothing but bridging the gap between humans and computers. It helps in analyzing the world as humans do and perceiving the inputs in the similar fashion how human brain works. Convolutional neural network is a deep learning algorithm which can take input, assign the weights based on the objects in the image and identify these objects or different objects can be identified. Image pre-processing required is very lower when compared to other algorithms available for classification or recognition of objects. Using convolutional neural network, the model can identify any filters applied in the image without any training and they have the ability to learn these filters or characteristics of the image.

To obtain maximum values of the image portion covered by the kernel, max pooling is performed. Max pooling reduces the noise in the input along with the dimensionality reduction. Convolutional neural network will have these layers increased if the input dataset contains more complex images or to capture more low-level detailed information of the image. The output of the final layer can be fed as input for other neural networks, flatten the image which is transposing the row to column vector. Then backpropagation algorithm can be applied to get the network for each training iteration. Then after several series of epochs, model will learn through experience and would provide very accurate results.

G. Data Augmentation

Accuracy prediction for any supervised model largely depends on diversity of data and amount of data available during training. Success of any deep learning model depends on the relationship between deep learning models and the higher amount of data required. Data augmentation is a way of dealing with the problem of limited dataset. Image augmentation is nothing but synthesizing new data from the data available by applying various transformations.

Some of the simple geometric transformations applied on the images are flipping, cropping, scaling, rotating and color casting or pixel transformation that is color space transformations. The proposed model uses geometric transformation because of the positional biases present in the dataset. Color transformation helps in dealing with the problems related to lighting or illumination of the given input image. The proposed model uses keras image data generator augmentation.

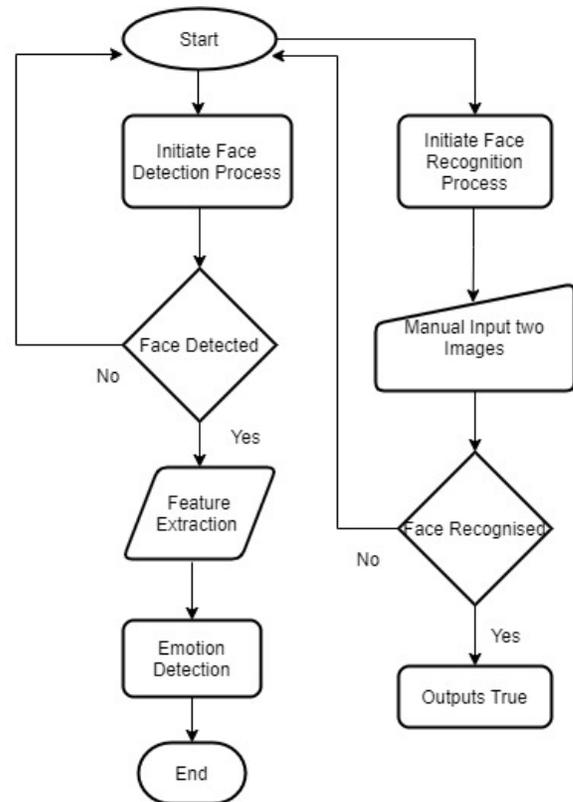
As shown in the above Fig. 2, the workflow of the proposed methodology for any given input image, face detection and face recognition are done using face recognition library which python offers with upgraded version. For emotion detection, there are seven classes of emotions and the faces being detected from the image belongs to which class that needs to be detected. Dataset is downloaded from kaggle that is facial emotion recognition dataset. Once dataset is loaded, divide the number of classes of emotions. The data augmentation is done to improve the performance of the model.


Fig. 2.   Flow Chart of the Proposed Methodology.

IV. RESULTS

Face detection is done using face-recognition library. As shown in the Fig. 3 the output of face detection using dlib's face-recognition library. Given input image has three human faces, and the output is the bounding box coordinates of all the three images present in the input image.

Fig. 3.   Face Detection.

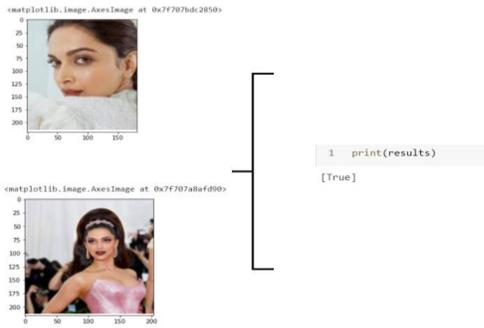
Face recognition is done is using face-recognition library. The output of the face recognition is shown in the below Fig. 4. As shown in Fig. 4, face recognition is nothing but verifying or comparing any given two input images and if two matches then output the Boolean value true or else false. In the below example, took two input images of the same actress and the output was true.


Fig. 4. Face Recognition.

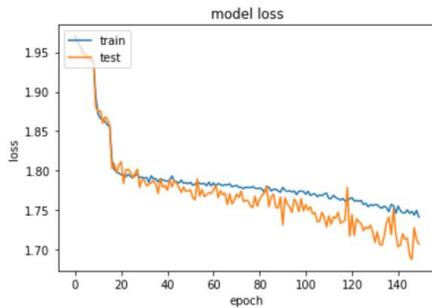
Each time when validation accuracy is increased, model was saved. Calculated model loss for each epoch and plotted graph against the loss occurred vs. validation loss occurred in each epoch as shown in the Fig. 5.


Fig. 5. Model Loss.

Model was trained using facial emotion recognition dataset. There were 28709 training samples which belong to seven different classes of emotions. And 3589 images were considered as validation samples and 3589 images were considered as testing samples. Facial emotion dataset was downloaded through kaggle. There are many open websites and from where image dataset was downloaded. Then image dataset was generated from .csv format into the specific folder. Then the dataset was used for training, validating the model and testing the model on unseen data.

As shown in the below figure, model performance was calculated by plotting confusion matrix for seven different classes of emotions considered for all validations samples considered through validation generator. The accuracy was achieved up to 85% when evaluated the model using confusion matrix as shown in the Fig. 6. Confusion matrix is actual a 2x2 matrix with actual data on one axis and predicted data on the other. Precision and recall are the important terms for performance evaluation, since positive class was considered the most and all other irrelevant or unwanted weeds are not considered while evaluating the performance of the model as shown in Fig. 7.

$$Precision = \frac{True\ Positive}{True\ Positive + False\ Positive} \qquad (1)$$

$$Recall = \frac{True\ Positive}{True\ Positive + False\ Negative} \qquad (2)$$

F1-score is the mean of both precision and recall considered. And it takes both false positive and negatives and performs well on dataset which is imbalanced.

$$F1\ score = \frac{2}{\frac{1}{Precision} + \frac{1}{Recall}} = \frac{2*(Precision*Recall)}{Precision + Recall}$$

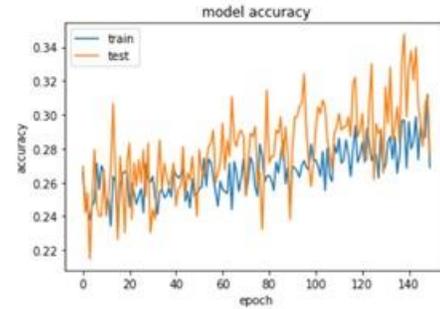
The output of the emotion detection is shown in the Fig. 8. The trained model is loaded and emotion is predicted for each face being detected.


Fig. 6. Model Accuracy.

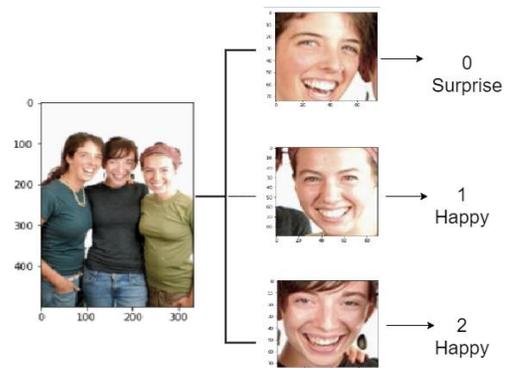
Fig. 7. Performance Evaluation of Model.


Fig. 8. Emotion Detection.

V. CONCLUSION

The proposed model is used for recognizing facial feelings using computer vision along with AI calculations which characterize the given input facial image into eight distinct feelings. On implementation using multiple algorithms and convolutional neural network, CNN outperforms with best

accuracy for image dataset. Model results suggest that computer can have human like capacity to recognize the feelings, at least for applications in which front facing perspectives can be expected utilizing the webcam. Proposed model performs well on classifying the given image into seven different classes of emotions irrespective of number of faces present in the image.

The proposed model consists of six convolutional layers attaining the accuracy of almost 85%. The model uses softmax activation function in the last layer of a fully connected convolutional neural network which makes the model more unique and more efficient in terms of performance. Visualization of the model is done based on the parameters, layers used and results obtained are also shown in terms of graphs and plotted confusion matrix as well for better understanding.

Emotion recognition will be exceptionally valuable soon in the exploration field of advanced mechanics and man-made reasoning for instance if a robot can detect the feelings of any human and that robot can act appropriately without any human aid. This model can be further extended for emotion recognition, can likewise be extended to the identification of different feelings other than these eight all-inclusive feelings.

Big Data Analytics Quality in Enhancing Healthcare Organizational Performance: A Conceptual Model Development

Wan Mohd Haffiz Mohd Nasir, Rusli Abdullah, Yusmadi Yah Jusoh, Salfarina Abdullah
Faculty of Computer Science and Information Technology
Universiti Putra Malaysia (UPM), Serdang, Selangor, Malaysia

Abstract—The advancement of Big Data Analytics (BDA) has aided numerous organizations in effectively and efficiently adopting BDA as a holistic solution. However, BDA quality assessment has not yet been fully addressed, therefore it is necessary to identify essential BDA quality factors to assure the enhancement of organizational performance, particularly in the healthcare sector. Hence, the goals of this study are to recognize and analyse the determining factors of BDA quality as well as to suggest a conceptual model for enhancing the performance of healthcare organizations via BDA quality assessment. The proposed conceptual model is based on a related theoretical model and previous research on BDA quality. The essential BDA quality factors being selected as determinants consist of reliability, completeness, accuracy, timeliness, format, accessibility, usability, maintainability, and portability. The findings of this ongoing study are used to develop a conceptual model that is proposed in line with the ten-research hypothesis and may offer a better assessment quality model to improve the performance of healthcare organizations.

Keywords—Big data analytics; BDA quality factors; BDA quality assessment; organizational performance; healthcare

I. Introduction

Big Data Analytics (BDA) has been used as an end-to-end solution in most organizations, especially healthcare organizations. The use of BDA contributes a significant impact on the enhancement of organizational performance. There are various potential outcomes of BDA for healthcare organizations such as Information & Communication Technology (ICT) infrastructure, operational, managerial, strategic, and organizational benefits [1]. BDA implementation in healthcare organizations affects the efficiency of ICT infrastructure, thus reducing system redundancy and quickly transferring data among healthcare ICT systems and applications [2]. BDA potentially produces some operational outcomes such as enhancing the precision and quality of clinical judgments, processing a substantial amount of health information quickly, and having access to medical data right away for analytics [3]. Likewise, the recent pandemic of Covid-19 has proven BDA as a significant solution in healthcare organizations not just for the analytics part but also for data acquisition for better planning, pandemic, and patient monitoring [4].

The BDA implementation in the healthcare industry may face certain obstacles that have been faced when developing solutions specifically to deal with the Covid-19 pandemic [5]. Information accuracy, security, and privacy are some of the related BDA issues that may affect the performance of healthcare organizations [5][6]. Moreover, healthcare organizations must assess BDA quality to make sure that the related system and application produced by BDA implementation is portable, near real-time information, and easy to maintain to entice consumers to use it in the long run [7]. The effectiveness and efficiency of healthcare organizations can be increased with the right and essential BDA quality factors being fulfilled [8] and this is in line with the finding by Fosso Wamba [9]. The negative implications of poor BDA quality, such as incorrect decision-making, have caused considerable harm to organizations [10][11] especially in healthcare due to life or death decisions depending on having accurate information [12].

In the context of Malaysia's healthcare, Malaysia ranked 47th out of 60 countries left far behind Singapore ranked 9th for access to Universal Healthcare Coverage (UHC) in the recent The Cost of Healthcare Index report [13]. Access to the UHC is a score that represents how much of a country's population has easy access to essential health services and it covers the entire range of high-quality healthcare services, including palliative care, treatment, rehabilitation, and health promotion [14][13]. Achieving UHC is one of the targets the nation of the world set when adopting the Sustainable Development Goals (SDGs) in 2015 [14]. It is showing the urgency for the assessment of BDA quality to overcome BDA quality such as accessibility, usability, and reliability.

Various studies have been conducted on BDA quality; however, the focus is more on "data" quality and does not cater to BDA quality holistically [10][7], and the BDA quality assessment in healthcare is still an understudied research topic. Consequently, the objectives of this paper are to 1) determine the contributing factors to BDA quality; and 2) develop a BDA Quality (BDAQ) conceptual model for enhancing healthcare organizational performance.

The subsequent section will examine the theoretical context, and the third section will glance at the research methodology. The discussion and conclusions of the BDA quality factors are covered in the fourth section, which also suggests a conceptual model for the BDAQ. The study is concluded in the last section by highlighting the contribution of the research and making suggestions for future studies.

II. THEORETICAL BACKGROUND

Several studies have focused on constructing BDAQ models by adopting the Information System Success Model (ISSM) of DeLone and McLean [15] and Wang and Strong [16] while other studies are also incorporating resource-based view theory (RBV) [17]. From the RBV perspective, an organization's competency is dependent on quality to efficiently manage its vital resources and gain a competitive advantage, which can be reflected in enhanced organizational performance [9]. RBV focuses on generating exceptional organizational performance by establishing valuable, rare, unique, and irreplaceable (RIN) resources of superior quality [18]. RBV is in line with the Information System Success Model (ISSM) of DeLone and McLean [15] as both highlight the competencies of in-house information systems to influence organizational performance [9]. To improve healthcare organizational performance, ISSM has been adapted to emphasize data, information, and system quality factors related to outcomes and benefits for the healthcare organization [19].

System and information quality have both been recognized in ISSM as crucial elements of organizational effectiveness [20]. Most previous studies have used ISSM as the main theoretical framework. Wamba [21] in their findings suggests that information quality represents four essential BDA quality factors; completeness, currency, format, and accuracy have a significant positive impact on organizational performance. Chiu [22] had been used ISSM with three groups of quality factors; system quality, service quality, and information quality with a mediating effect on user satisfaction and user continuance intention revealed that the three groups of quality factors positively influenced user satisfaction, and user continuance intention.

Wang and Strong [16] as a theoretical model in another way presented quality factors into four primary categories, namely intrinsic, contextual, representational, and accessibility. The intrinsic category implies datasets having inherent quality, whereas the contextual category emphasizes the requirement of the task that quality be evaluated in context [7], [16]. The representational category highlights quality in terms of its presentation, while the accessibility category reinforces the significance of computer systems that give access to data [7], [16][23]. There are some characteristics for each category that are employed as particular indicators of quality. For instance, the intrinsic category's factors are objectivity and accuracy, while the contextual category's factors are timeliness and relevance. The representational category's factors are interpretability and understandability, while the accessibility category's factors are accessible security and simplicity of use [7]. Ghasemaghaei and Calic [24] used BDA quality factors produced by Wang and Strong [16] to examine the effect of BDA on quality factors and confirmed the critical role of BDA quality in enhancing organizational decision-making.

Current BDA quality models primarily rely on the Information System (IS) theoretical model and are largely based on data and information quality rather than a suitable and comprehensive component of BDA quality factors [7], [25]. Differing from traditional Business Intelligence (BI), BDA, as mentioned earlier, covers end-to-end solutions, a full life cycle, and is inclusive of related BDA systems and applications. Thus, it is very important to leverage broader and holistic theoretical models. To fill this theoretical gap, this study integrates the most common theoretical model in Information System (IS) research with the related Software Engineering (SE) theoretical model which are McCall[26], Boehm[27], Evan & Marciniak, Deutsch & Willis, DROMY's, FURPS+'s, SEI, and ISO/IEC25010 [28]. Table I present the occurrence of quality factor from the ten theoretical models that have been summarized for this study.

III. METHODOLOGY

As shown in Fig. 1, several steps were taken in the creation of the conceptual model for assessing the BDA quality factors. Prior to identifying the pertinent theories, the review process continued with content analysis and was founded on the Systematic Literature Review (SLR) approach [29][30]. 23 publications on the BDA quality in various domains were investigated as part of the review activity, which divided them into two categories: empirical and case study research analysis. A research question like "What are the essential BDA quality factors to consider in constructing BDA Quality (BDAQ) model?" is formulated as the first step in the initial investigation. After further research was conducted using electronic journal databases like Scopus, Science Direct, Emerald, IEEE, Google Scholar, and the snowballing method, 23 pertinent publications were selected. After that, a matrix table was used to examine the pertinent articles (Table II).

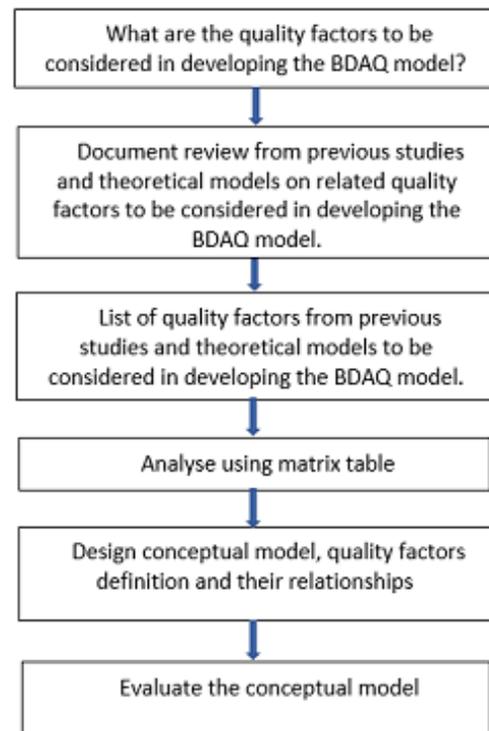
This study selected nine factors from theoretical models and previous research to be considered in the development of the BDAQ model, with the results detailed in the subsequent section (Section IV). In conclusion, the conceptual model and related factors are discussed. Finally, in the conclusion, the BDAQ conceptual model is presented along with the essential BDA quality factors.


Fig. 1. The Workflow of BDAQ Conceptual Model Development.

IV. FINDINGS AND DISCUSSION

The relevant BDA quality factors from the SLR are presented in Table II and include the following; reliability, completeness, accuracy, timeliness, accessibility, and format that affects enhancing organizational performance. Table III presents the integration of quality factors from a related theoretical model and from the previous studies with nine quality factors that have been chosen based on their frequency and suitability in the healthcare context. The frequency of each quality factor was shown in Fig. 2 as a summary frequency of quality factors integrated from related theoretical models and previous studies.

Reliability and completeness were shown to be the two most frequent quality factors highlighted in both theoretical models and previous studies on BDA quality. This is followed by accuracy, timeliness, format, accessibility, usability, and maintainability. Maintainability and portability have been found not been discussed in BDA quality previous studies. However, these two quality factors are the most prominent quality factors found in the related theoretical model as can be seen in Table I. Based on the finding from the theoretical model matrix, this study decided to consider and choose maintainability and portability as part of the nine essential BDA quality factors for the BDAQ conceptual model. Drawing on the ten theoretical models and twenty-three previous studies from the SLR, the BDAQ model is conceptualized and determined by nine quality factors: reliability, completeness, accuracy, timeliness, format, accessibility, usability, maintainability, and portability.

A. Reliability

The definition of reliability by McCall et al. [26] is "the extent to which a program is expected to perform its intended function with the needed precision". The reliability of BDA reinforces the confidence that a BDA platform is interference and disruption-free [37]. Reliable data helps BDA to provide precise decision support and increase the effectiveness of services offered [10], [38]. An overwhelming amount of research studies discovered a relationship between improving organizational performance and reliability as a BDA quality factor [9], [20], [39]–[41]. Hence, it is encouraging to examine reliability as one of the essential BDA quality factors and its relationship with healthcare organizational performance.

Fig. 2. Summary of BDA Quality Factors.

B. Completeness

Completeness is one of the most frequent quality factors from theoretical models and previous studies as shown in Table III. Completeness in this study context refers to that all necessary data and information of BDA are provided and complete either in the stage of data acquisition, data processing, visualization, analytics, related BDA's system and application in the healthcare organization. Failure to assess the completeness of the BDA in healthcare will heavily affect not just decision-making but the confidence of the end-users for the healthcare services [53]. Numerous research demonstrated the significant impact completeness has on improving organizational performance as a primary determinant of BDA quality factors [9], [20], [42], [54]. Therefore, completeness has been selected as one of the essential BDA quality factors of the proposed BDAQ conceptual model.

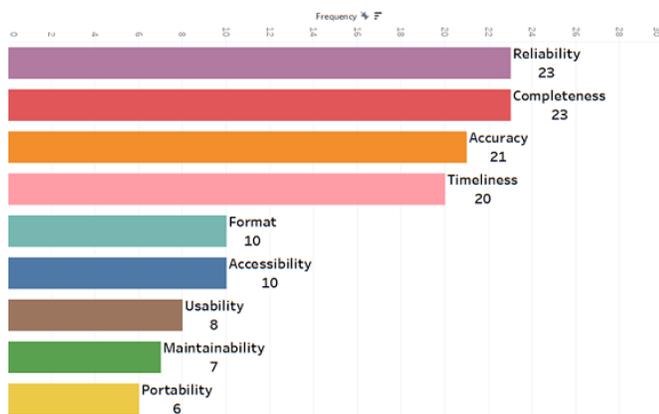
C. Accuracy

According to Wixom and Todd [55], accuracy includes perceived exactness of information, conformance to truth or value in the real world, correctness, validity, and precision [16], [56]. It also checks to see if the data were entered correctly and if the values are accurate [57]. As part of the BDA quality factors, accuracy is important in healthcare because it can affect how decisions are made [58], [59] and have a strong impact on organizational performance based on the experimental case study by Alaoui & Gahi [48]. Inaccurate data may lead to clinical mistrust, the inability to properly interpret data, as well as a higher likelihood of mistakes [60].

D. Timeliness

Making decisions based on old data might result in erroneous insights, hence timeliness has been regarded as an important factor of BDA quality [61]. Timeliness or currency is defined as "the amount to which the age of data is appropriate for the task at hand" and represents the user's perception of the degree to which the information is up to date [55]. In BDA's healthcare applications such as clinical decision support, hospitals, caregivers, etc., the timeliness of data is one of the greatest issues [62]. Since doctors make decisions based on larger amounts of clean, up-to-date data, the process should be less cumbersome, faster, and more precise [62]. Most past empirical studies found timeliness was a significant BDA quality factor and had a significant positive effect in enhancing organizational performance [9], [20], [49], [63]. However, a study by Wook et al. [7] found that timeliness had no significant effect on BDA applications conducted from individual perspectives. Timeliness is one of the essential BDA factors that had been selected for the proposed BDAQ model, thus the significance of timeliness will be analyzed in the actual study and the relationship in enhancing healthcare organizational performance will be examined.

E. Format

The format "represents the user's perspective of how well the information is presented" and the BDA system's presentation of the information [9], [55]. In the area of healthcare, the healthcare information offered by BDA is well-formatted, well-organized, and presented clearly on the screen [55]. Data is obtained and acquired from numerous sources in


both electronic and non-electronic formats, and then it is transformed into the desired format during this essential phase [60], [64]. But data sources come in a wide range of functions, structures, and forms [65] including text, photo, audio, video, web content, GPS data, sensor data, and others, and are geographically scattered [66]. BDA in healthcare is challenging because it must deal with numerous types of unstructured data, in contrast to traditional data analysis where data types are often structured [6][67]. However, BDA is anticipated to work with a combination of unstructured and structured data [6]. Numerous studies have looked at and suggested that format was a significant determinant of BDA quality factors and significantly improved organizational performance [9], [21], [47], [63], [68].

F. Accessibility

Accessibility is the degree to which data is available, easily accessed, and quickly retrieved [16]. The system's accessibility influences the extent to which managers may access a scalable and efficient analytics platform [37]. Wang and Strong [16] emphasize that a system must be accessible without tolerance for privacy and security. Accessibility in the context of BDA in healthcare is not just about data accessibility but BDA's system and application accessibility. Wook et al. [7] selected accessibility as a BDA quality factor because the computer system must ease data access and storage in BDA applications. The efficacy of BDA implementation in healthcare is significantly determined by accessibility [69]. BDA solutions as end-to-end healthcare solutions must be able to generate unconstrained applications of diffused and accessible machine learning algorithms that support healthcare data analytics on Hadoop systems [70]. BDA applications in healthcare either web-based or mobile have now given a big impact on the public in accessing healthcare information. A finding by Wook et al. [7] demonstrated that data accessibility plays a significant role in bridging the digital divide and providing users with effective access to BDA applications. The studies revealed that accessibility has a substantial impact on BDA applications [7].

G. Usability

Usability describes the amount of work needed to understand, use, prepare input, and interpret a program's output [26]. Although modern medical BDA has numerous drawbacks, it is nonetheless a very promising resource for insurers and other academics. Not only for doctors and patients but also for everyone interested in secondary usage, improving BDA quality should be a top focus. There are a variety of steps that could be taken to improve the usability of data and the system of BDA in healthcare, and some of them are through quality assessment [71]. Ensuring high levels of usability to access pertinent data is a frequently mentioned challenge for BDA's system and application in healthcare [72]. Medical practitioners and researchers have used extensive BDA to improve patient care through data science, but their usability in the presence of BDA cannot be guaranteed to justify clinical use enough [72]. Two studies from twenty-three previous studies have usability as a quality factor as shown in Table II. User satisfaction and the success of human interaction with healthcare applications will be achieved when usability is fulfilled [52]. The testing is

typically associated with usability testing to reduce system defects and evaluate user experience [52]. Thus, this study considers usability as one of the essential BDA quality factors to be examined further.

H. Maintainability

Maintainability refers to the efforts required by users and maintenance staff to determine the cause of system failure, and the components or system that need to be fixed or restored [26]. Based on Table III, maintainability is found in seven of ten of the theoretical models. However, maintainability has been not found in any of the twenty-three previous studies on BDA quality. Maintainability has been selected as one of the determinants of BDA quality factors. Assessing maintainability will allow users to customize the setting on BDA's system and application without causing any errors or affecting the system's quality [73]. BDA's system and application in healthcare should be easy to maintain as it will very important to restore the operable condition within a specified time in case of any failure. The enormous amount of data in the healthcare system is expanding exponentially at a breakneck speed [62]. Collective decision-making will be impacted as a result of the genuine obstacles in maintaining BDA storage and processing in healthcare organizations since incomplete healthcare data will be more challenging to incorporate into an analytical platform [62].

I. Portability

The degree to which a system may be deployed or transferred from one hardware, software, or other operational or usage environment to another is referred to as portability [27], [74]. Similar to maintainability, portability has been selected to fill the theoretical gap for this study. The challenges of BDA portability include the simultaneous combination of information derived from many platforms, particularly in the healthcare context, to accommodate all healthcare information [75]. In today's digital era, everyone appears preoccupied with tracking their fitness and health data using the built-in pedometers of their portable and wearable gadgets such as smartphones, smartwatches, fitness dashboards, and tablets [76]. BDA's system and application in healthcare should be effectively adapted for a different software, in evolving hardware, and work independently with other systems [77]. Therefore, portability is selected as one of the essential BDA quality factors that could affect enhancing healthcare organizational performance.

TABLE III. SUMMARY OF BDA QUALITY FACTORS

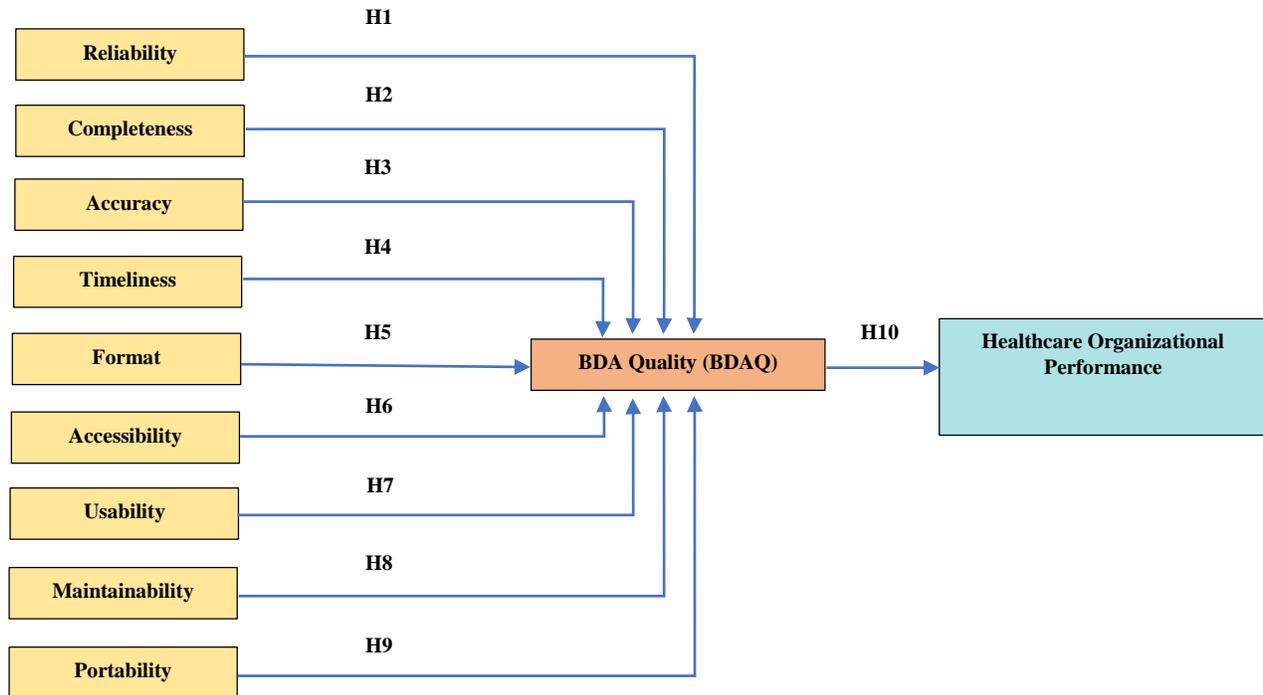
Quality Factors	*Theoretical Models*	*Previous Studies*	*Frequency*
1. Reliability	9	14	23
2. Completeness	7	16	23
3. Accuracy	6	15	21
4. Timeliness	2	18	20
5. Format	1	9	10
6. Accessibility	2	8	10
7. Usability	6	2	8
8. Maintainability	7	0	7
9. Portability	6	0	6


Fig. 3.   BDAQ Conceptual Model in Enhancing Healthcare Organizational Performance.

Fig. 3 illustrated the proposed BDAQ conceptual model with ten hypotheses. BDAQ will be specified as a higher-order or second-order construct that contains nine first-order formative constructs. The study will apply the repeated indicator approach to estimate the scores for the first-order BDAQ constructs [78].

H1: Reliability is significant BDAQ factor in enhancing healthcare organizational performance.

H2: Accuracy is significant BDAQ factor in enhancing healthcare organizational performance.

H3: Completeness is a significant BDAQ factor in enhancing healthcare organizational performance.

H4: Timeliness is a significant BDAQ factor in enhancing healthcare organizational performance.

H5: Format is a significant BDAQ factor in enhancing healthcare organizational performance.

H6: Accessibility is a significant BDAQ factor in enhancing healthcare organizational performance.

H7: Usability is a significant BDAQ factor in enhancing healthcare organizational performance.

H8: Maintainability is a significant BDAQ factor in enhancing healthcare organizational performance.

H9: Portability is a significant BDAQ factor in enhancing healthcare organizational performance.

H10: BDAQ has a significant positive effect on healthcare organizational performance.

V. CONCLUSION

A conceptual model was discovered to be useful in assessing BDA quality. The model may measure and analyze the relationship between reliability, completeness, accuracy, timeliness, format, accessibility, usability, maintainability, and portability as essential BDA quality factors that affect enhancing healthcare organizational performance. The subsequent research activity will involve the creation of a questionnaire-based survey instrument. The proposed conceptual model and surveys will subsequently be validated by an expert from academia, healthcare, and industry. In this regard, a pilot study will be done, which will be followed by the actual study. The model will then be tested using statistical tools, and the resulting insights will enable healthcare organizations to assess the essential BDA quality factors for ensuring that quality compliance is committed and fulfilled when implementing BDA as end-to-end solutions in healthcare organizations. Thus, will improve the efficiency and effectiveness of ICT infrastructure, operational, managerial, and strategic decision-making of healthcare organizations that affect enhance healthcare organizational performance.

Abstract—**Recent Parkinson's disease (PD) research has focused on recognizing vocal defects from people's prolonged vowel phonations or running speech since 90% of Parkinson's patients demonstrate vocal dysfunction in the early stages of the illness. This research provides a hybrid analysis of time and frequency and deep learning techniques for PD signal categorization based on ResNet50. The recommended strategy eliminates manual procedures to perform feature extraction in machine learning. 2D time-frequency graphs give frequency and energy information while retaining PD morphology. The method transforms 1D PD recordings into 2D time-frequency diagrams using hybrid HT/Wigner-Ville distribution (WVD). We obtained 91.04% accuracy in five-fold cross-validation and 86.86% in testing using RESNET50. F1-score achieved 0.89186. The suggested approach is more accurate than state-of-the-art models.**

Keywords—Parkinson's disease; speech impairment; artificial intelligence; RESNET50; deep learning; ht/wigner-ville distribution; 2D time-frequency

I. INTRODUCTION

Parkinson's disease (PD) affects 1% of persons over 60 [1]. Parkinson's disease is the second most prevalent neurological condition [2]. According to European and American epidemiological studies [3], PD affects men 1.5 times more than women. Parkinson's disease causes increasing disability that affects everyday life. Dopamine neurodegeneration induces motor and non-motor symptoms in the midbrain's substantia nigra pars compacta [3].

Early on with Parkinson's, voice problems affect 90% of individuals. Recent PD telemedicine research [4-6] focused on speech problems. These studies employed speech signal processing to evaluate Parkinson's disease. The generated characteristics were used to build reliable decision support systems. Parkinson's disease causes rigidity, resting tremors, bradykinesia, and postural instability [7, 8].

Many research that compares PD and healthy persons utilize a publicly accessible dataset [9] with 195 sound measures from 23 PD patients and eight healthy controls. Another publicly accessible PD telediagnosis dataset [6] utilized in the linked research includes 20 PD and 20 healthy participants' voice recordings. In all datasets, each voice recording contains fundamental vocal frequency, amplitude variation measurements, noise-to-tone component ratio, nonlinear dynamical complexity measures, and nonlinear fundamental frequency variation measures. With these parameters achieved accuracy is less than 85%, which is too less. Using deep learning methods, it can be improved.

The remainder of this research is organized as follows: the research analyzes existing automated speech analysis techniques in Parkinson's disease patients in the section "Related Work." It discusses the 1D to 2D transformation methods and the deep learning classification model in the section "Methodology." The section "Results and Discussion" addresses the employed dataset, classification performance, and statistical analysis results, while the section "Conclusions and Future Study" propose conclusions and future work.

II. RELATED WORK

PD speech analysis research includes recording activities. Sustained vowel phonation is prevalent since it is a regular work [10]. Other research focuses on continuous speech recordings of sentences, reading texts, and spontaneous speech to study prosody [11]. Few papers discussed single-word invention. Early research focused on Parkinson's patients [12]. This study examined spectral and cepstral properties taken from 24 isolated words and five vowels spoken by Colombian Spanish speakers. Scientists used an SVM with a Gaussian kernel to classify Parkinson's patients. They compared each set of attributes individually and all coefficients together. When all utterances and attributes were combined, word and vowel accuracy was 92% and 79%. Despite positive findings, the approach lacked pre-processing.

In [13] mentioned lonely words as a speaking difficulty. The database includes Spanish (50 HC, 50 PD), German (88 PD, 88 HC), and Czech speakers (20 PD, 16 HC). Different languages and feature sets were automatically used to classify HC and PD speakers. Each corpus was modeled using four factors to identify linguistic impairment. Using a radial basis SVM, the authors claimed the latter technique was robust, with 85 to 95% classification accuracy. Both papers used PC-GITA. None studied model generalization on a single dataset. The test models in [13] were optimized, resulting in unduly optimistic findings.

In [14], to explain speech signal non-linearities, the authors proposed isolated word modeling based on Hilbert Spectrum properties. The recommended coefficients, Instantaneous Energy Deviation Coefficients (IEDCC), exceeded the traditional acoustic characteristics when dealing with isolated individual syllables, outperforming them with

accuracy ranging from 81 to 91%. The accuracy was 82%. However, the authors did not give the findings of the combined features. They used 20 Parkinson's patients and 20 healthy controls.

Little et al. [15] reported that each patient made six phonations. A soundproof audiology booth created by an industrial acoustics business caught the phonations. Human sound signals were recorded in a computerized speech laboratory. After recording phonations, they analyzed entropy and conventional and nonstandard measures. A kernel SVM classifier distinguished between healthy and Parkinson's patients. Researchers then used the Little et al. dataset to enhance their classifier. Bhattacharya et al. employed Weka and SVM [16]. Das employed neural networks, DMneural, regression, and decision trees to classify features [17]. Sakar et al. [18] employed SVM and feature selection. Polat identified Parkinson's disease patients using FCMFW and k-NN [19].

Sakar and Kursun [18] suggested an SVM model using mutual knowledge for PD feature selection. Speech characteristics were filtered and sorted using the highest relevance lowest redundancy approach (mRMR). Using the leave-one-individual-out strategy, their test on the UCI dataset obtained 81.53% accuracy and 92.75% using the bootstrap resampling method. It discovered four critical parameters associated with the voice impairment test for Parkinson's disease diagnosis, which additional studies may corroborate.

This paper proposes an approach for analyzing solitary words based on several signal processing and pattern recognition methods. We began with a pre-processing phase, followed by a 1D to 2D time-frequency conversion approach and a classification step. The PD sound series were converted into 2D time-frequency distribution diagrams to display additional information such as time, frequency, and energy. To translate 1D to 2D time-frequency distribution diagrams, a technique combining HT and WVD was presented. The hybrid analysis of the time and frequency flowchart is shown in Fig. 2. The approach first employs the HT to transform the original signal into analytic signals, followed by the analysis of time and frequency using the traditional WVD to generate the relevant time-frequency diagrams.

III. METHODOLOGY

The importance of implementation is to improve the recognition rate.

A. Method Outline

The 1D sound signal was reconstructed as 2D time-frequency diagrams in this work to gather information on the signal's time, frequency, and energy. The suggested method's flowchart is shown in Fig. 1. During data pre-processing, noises like baseline wander (BW) and 50/60 Hz power line noise are initially removed. To convert the 1D time series into 2D time and frequency diagrams, the HT-WVD technique is used. The dataset was randomly partitioned into three sets: training, validation, and testing. 70% of each category was chosen randomly for the training, 10% for the validation, and 20% for the testing.

The validation data is used to validate the performance of the learned deep learning models using a five-fold cross-validation technique. The training data is used to train multiple deep-learning models with a learning rate of 0.001. The ResNet50 was utilized for deep learning to classify the 2D time and frequency diagrams of the PD for classification tasks. The classification outcomes for the test data for the optimal neural network model are shown.

B. Data Pre-processing

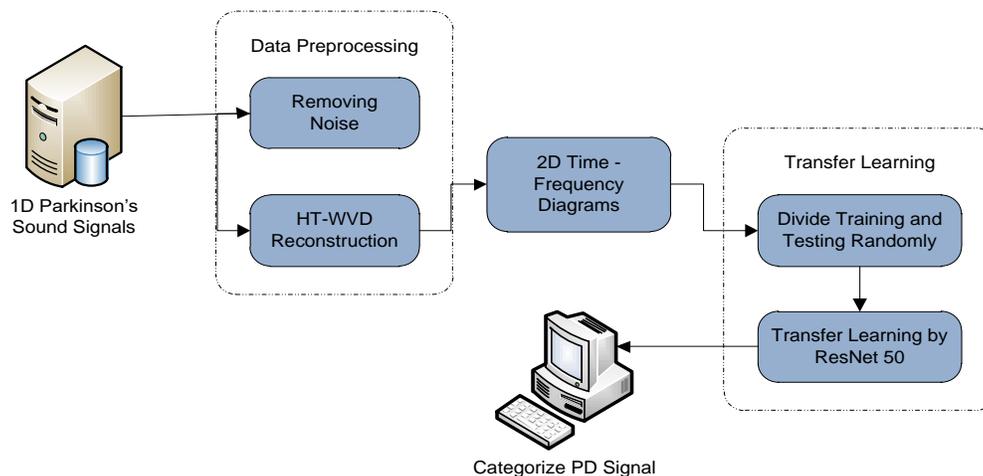
1) Removing noises: Our database of PD recordings comprises familiar sounds such as 50/60 Hz powerline noise and BW. As a result, noise should be deleted from the recordings to ensure accuracy. This research used a median filter approach to remove BW from PD recordings first, followed by a wavelet transform algorithm to remove powerline noise. The PD recordings' baseline curves were retrieved using the median filtering technique. This entails running a median filtering algorithm [20], then subtracting the original PD recordings from the derived baseline maps to generate the new PD recordings without BW. This research employed the wavelet transform to remove additional noise. The Daubechies db5 wavelet is used to create a three-level wavelet decomposition.


Fig. 1. The Proposed Method of Architecture.

2) Hybrid analysis of time and frequency: Because PD sound signals are 1D non-stationary time series, they cannot display the connection between time, frequency, and energy within the time series. Analysis of time and frequency techniques may convert a one-dimensional signal into a two-dimensional density function of time and frequency, revealing how many frequency components are present in the signal and how each component changes over time. Temporal frequency approaches such as the WVD and HT are widely employed for signal analysis [24].

3) One can utilize the bilinear Wigner-Ville distribution to evaluate nonlinear signals and reflect energy distributions in both the time and frequency domains. The definition of WVD is as follows:

$$W(t,f) = \int_{+\infty}^{-\infty} x\left(t + \frac{\tau}{2}\right) x^*\left(t - \frac{\tau}{2}\right) d\tau \qquad (1)$$

4) X* is a complex conjugate, and x(t) is the signal. The study [21] explains every step of the procedure. An actual signal can be transformed into an analytical signal using the HT. The HT is described as follows for a discrete time series x(k):

$$H(k) = xH(k) = FFT\text{-}1(f(k) * h(i)) \qquad (2)$$

where the element-wise product of f and h is calculated using the symbol *. The inverse fast Fourier transform, or FFT-1, is represented by vector f, which is the FFT of the y(k), and h is defined as follows:

$$h = \begin{cases} 0 \ for \ i = (N/2) + 2, \ldots, N \\ l \ for \ i = 1, \ (N/2) + 1 \\ 2 \ for \ i = 2, 3, \ldots, (N/2) \end{cases} \qquad (3)$$

Thus, the analytic signal z(k) of the discrete time series x(k) can be represented as

$$z(k) = x(k) + jxH(k) \qquad (4)$$

5) Where j is the complex imaginary number, i.e., j = (-1)1/2, the HT is detailed in [22].

6) Because the dimensional difference of 1D signals does not affect the energy distribution of 2D time and frequency diagrams, 1D PD signals do not need to be normalized when translated into 2D time-frequency diagrams.

7) Fig. 3 to Fig. 6 shows the signal in the time domain, the signal spectrum, and the signal's spectrogram, which is the 2D time frequency of Parkinson's audio signal for vowels' a' and 'i' for the healthy and Parkinson's disease signal.

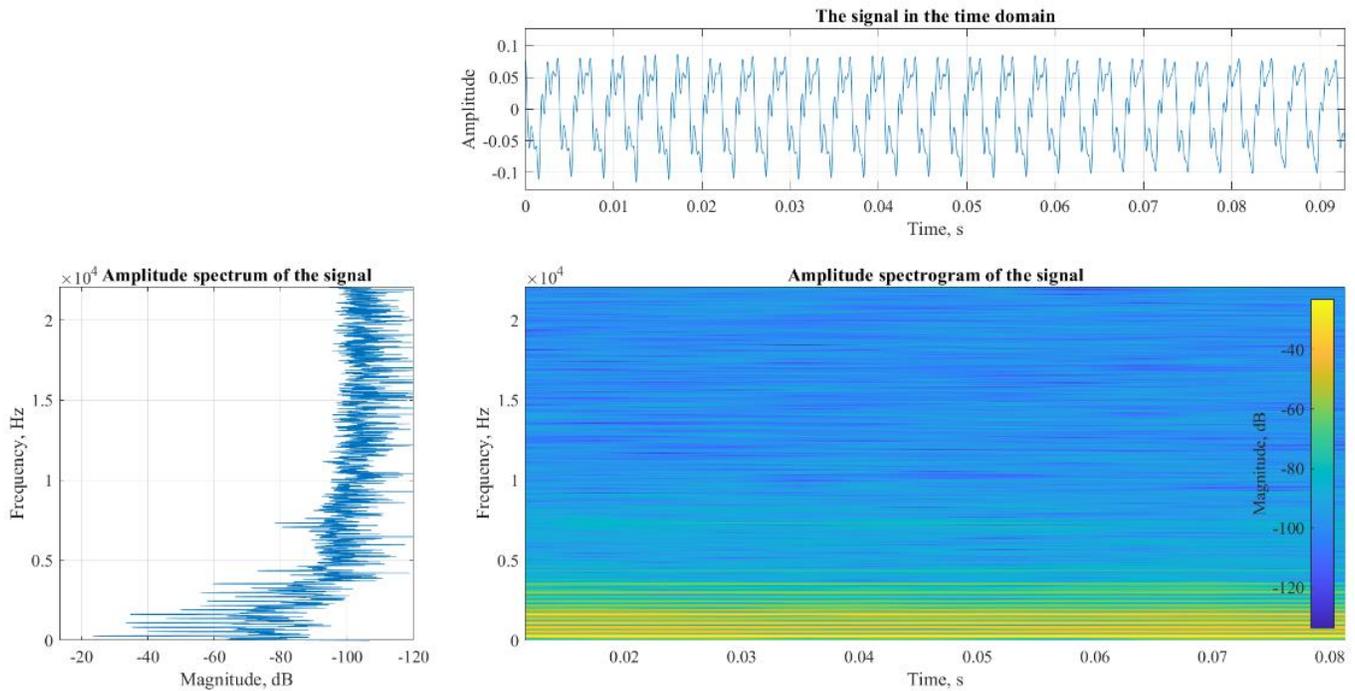

Fig. 5.   2D Time-Frequency Diagrams of HC Signals for Vowels 'A'.
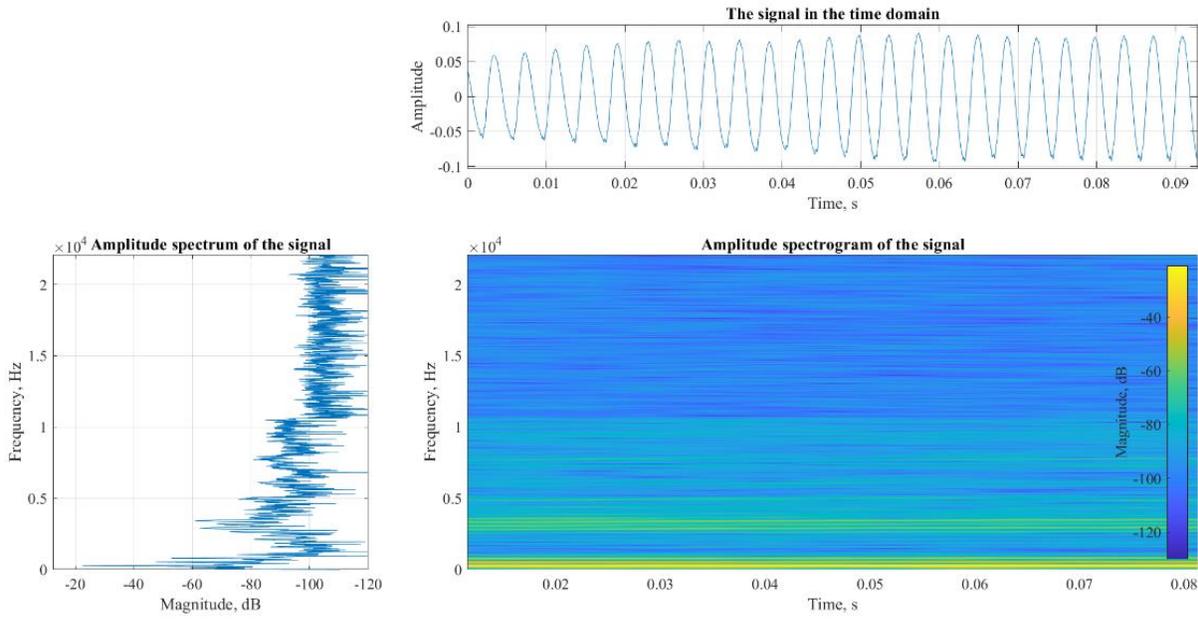

Fig. 6.   2D Time-Frequency Diagrams of HC Signals for Vowels 'I'

C. ResNet50 & Transfer Learning

He et al. [23] presented ResNet at the 2015 ILSVRC competition. ResNet includes a short connection structure that avoids gradient vanishing by immediately bypassing the input information to the output. ResNet is a network-in-network (NIN) architecture comprised of several residual modules stacked on top of one another. These residual units are employed in the construction of deep ResNet architecture. Convolution, pooling, and layering are the residual units. Instead of wholly linked layers, ResNet employs global average pooling.

The ResNet uses residual units to prevent the gradient from disappearing [25]. Let the input and output vectors for the layers be x and y, respectively, and $H(x)$ function as nonlinear stacked layers. It is possible to obtain $H(x) = F(x) + x$ by using the formula $F(x) = H(x) - x$, where F(x) and x represent stacked nonlinear layers. The residual block's typical structure is described in (5).

$$y = F(x, \{Wi\}) + x \tag{5}$$

Wi is the weight in the weight matrix, and F is the residual mapping to be learned.

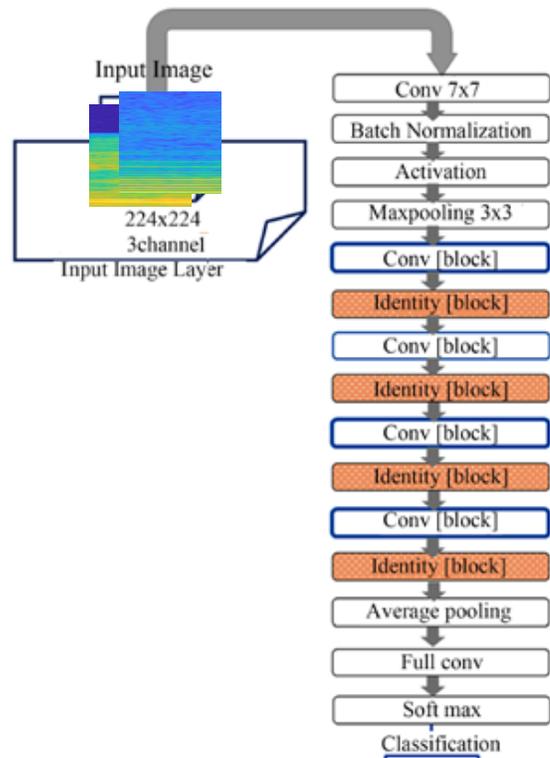
The ImageNet dataset was used to train the conventional pre-trained ResNet50. 2D time and frequency diagrams made from PD recordings were the images to be analyzed in this work; these diagrams differed significantly from the photographs in ImageNet. To enable the modified ResNet50 to classify two PD classes, the last three layers of the pre-trained ResNet50 - the fully connected layer, the Softmax layer, and the classification layer - were altered. We used the same dense layer network after the convolutional layers, as shown in Fig. 7. After the convolutional layer and every block, the rectified linear unit (ReLU) is activated by doing a max-pooling operation. To make the spatial dimension of the activation map half the preceding layer, a max pooling layer with a 2x2 kernel and stride size of two is utilized. The improved ResNet50 was retrained to provide new parameters, and Table I displays the changed ResNet50's structure. The learning rate of deep learning based on ResNet50 was set at 0.001 in this research.


Fig. 7.   ResNet50 Architecture for Proposed Model.

IV. RESULTS AND DISCUSSION

A. Dataset Description

This research gathered speech recordings from 20 people (10 Parkinson's patients and 10 healthy controls). The data for the research was acquired from 188 individuals with the disease (5 men and 5 women) aged 33 to 87 (65.110.9). The control group comprises 10 healthy people (5 men and 5 women) aged 41 to 82 (61.18). The microphone was adjusted to 44.1 KHz throughout the data collection procedure. After the physician's examination, the sustained phonation of the vowels/a/and/i/was gathered from each participant three times. Fig. 8 shows the sample 2D time-frequency diagrams used in the analysis.

B. Experimental Setup

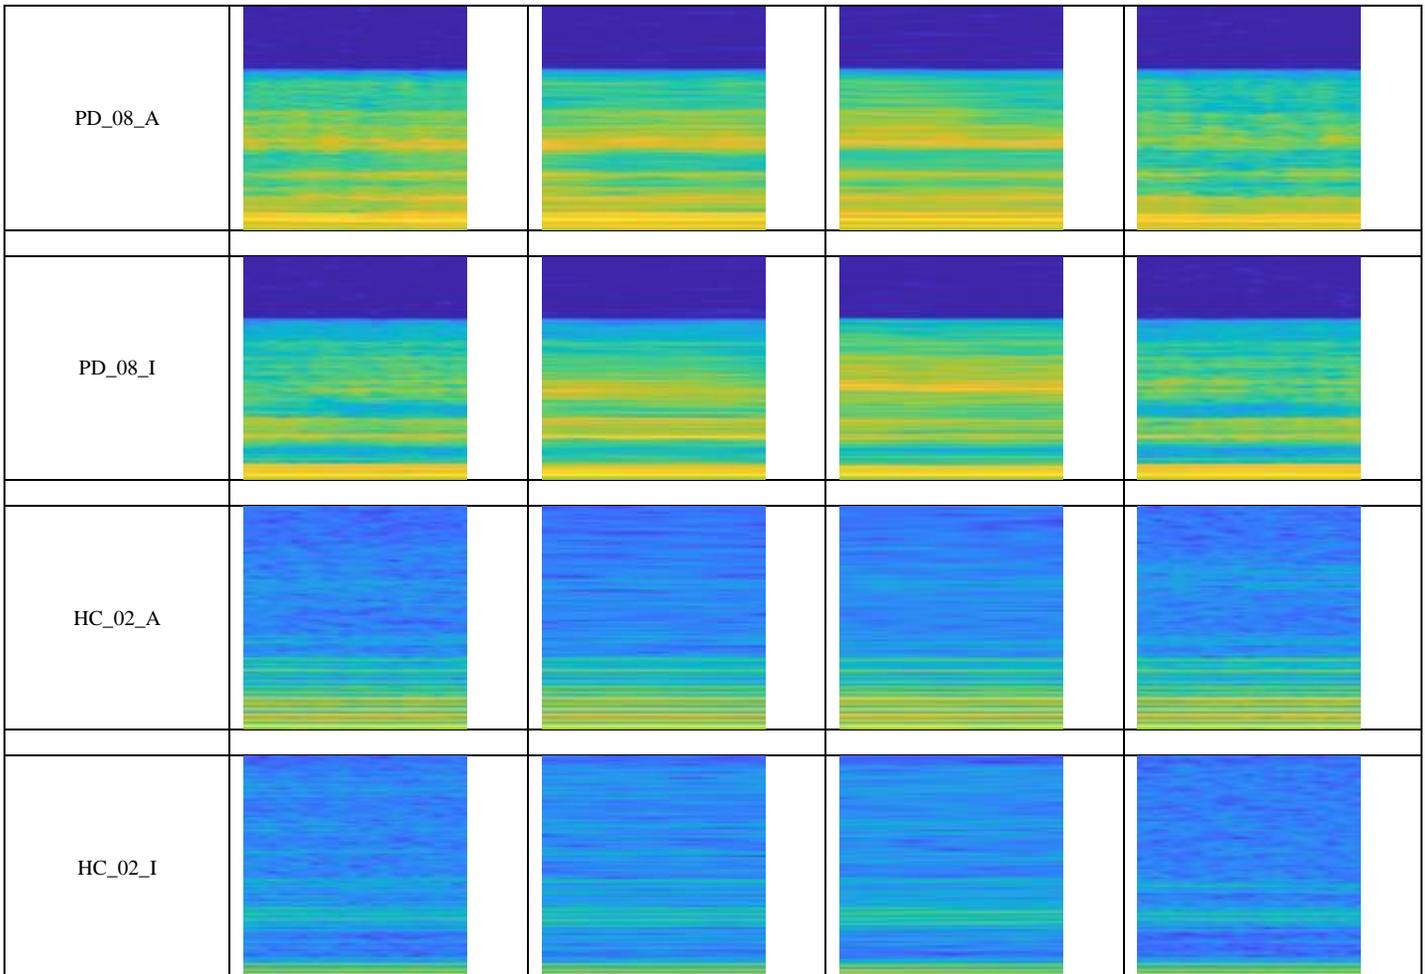
A 64-bit Windows 10 with an Intel Core i7 (2.80 GHz, 2808 MHz, 4 Cores, 8 Logical processors), 16 GB of RAM, an NVIDIA GeForce GTX, and CUDA 9.0 is utilized. The experiments were carried out using the Matlab (R2019a) programming language.


Fig. 8.   Sample 2D Time-Frequency Diagrams used for Analysis.

C. Evaluation Metrics

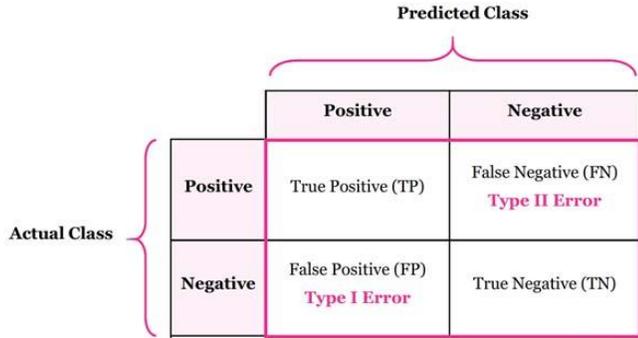
A confusion matrix was utilized in this research to summarize the categorization findings based on the actual and predicted categories. The construction of the confusion matrix is seen in Fig. 9. As a consequence, the numbers on the diagonal display the accurate categorization results, while the other values display the wrong findings.


Fig. 9. Confusion Matrix.

The F1 score was also used in this research to evaluate the performance of the suggested technique. The F1 score may be viewed as a weighted average of precision and recall, with a most incredible score of 1 and the worst score of 0.

$$F1_{Score} = \frac{Tp}{Tp + \frac{1}{2}(Fp + Fn)} \qquad (6)$$

In addition, four statistical indices were produced to assess the performance of the proposed classifier in this work, namely accuracy, Precision, sensitivity, and specificity were defined as follows;

$$Accuracy = \frac{Tp + Tn}{Tp + Fp + Tn + Fn} \qquad (7)$$

$$Precision = \frac{Tp}{Tp + Fp} \qquad (8)$$

$$Sensitivity = \frac{Tp}{Tp + Fn} \qquad (9)$$

$$Specificity = \frac{Tn}{Tn + Fp} \qquad (10)$$

Where the (Tp) is the number of PD signals correctly classified as the PD category, the (Fn) is the number of signals of the PD category incorrectly classified as the HC category. The (Tn) is the number of signals of the HC categories not classified as the PD category. The (Fp) is the number of signals incorrectly classified as the PD category in the HC categories.

D. Classification Results

Table II displays the classification results for the test data using the proposed classifier trained at a learning rate of 0.001. Table II demonstrates that the classifier can get the best results: accuracy 86.86%, precision 89.19%, sensitivity 89.17%, and specificity 84.67%. Moreover, the F1-Score is 89.18%.

Fig. 10 shows the system-generated confusion matrix. Moreover, Fig. 11 shows the receiver operating curve of the system. ROC is the plot of TPR vs. FPR. The Area under the Curve for the PD and HC categories is 93.7%, which is comparatively reasonable.

Table III shows the state-of-the-art results compared with the proposed classification results. From the above comparison, we proved that the proposed method is robust in PD recognition using vowels.

TABLE II. CLASSIFICATION RESULTS

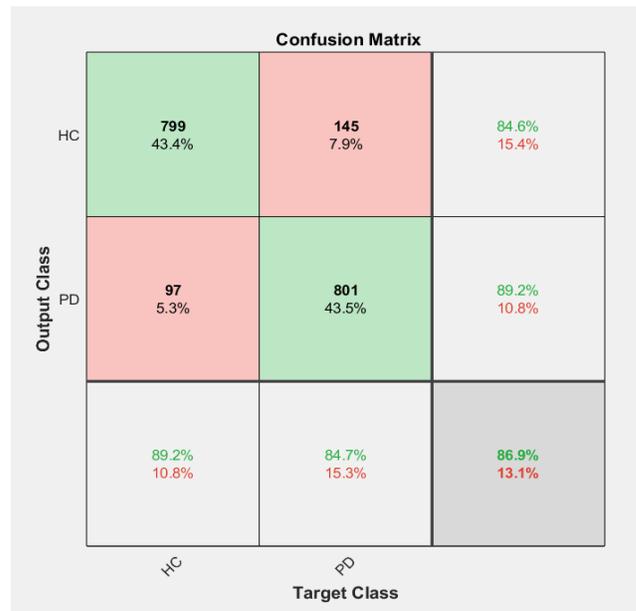
Metrics	Results
Accuracy	86.86
Precision	89.19
Sensitivity	89.17
Specificity	84.67
F1 Score	89.18


Fig. 10. Confusion Matrix shows 86.9% of Accuracy.
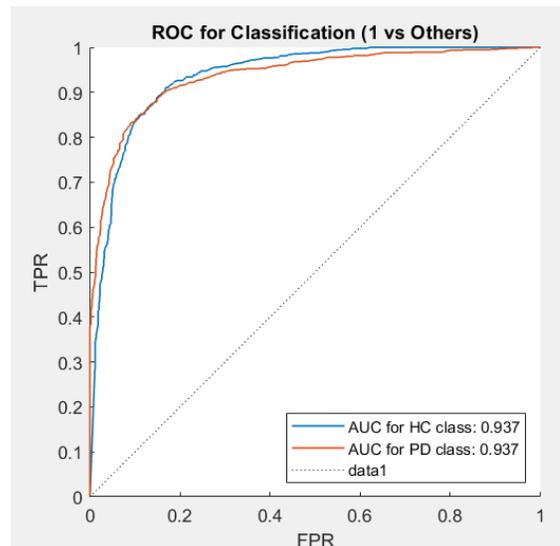

Fig. 11. ROC for PD and HC Categories.

TABLE III. COMPARISON RESULTS WITH PREVIOUS METHODS

Previous Methods	Accuracy (%)
Existing Method (Ref 12)	79.00
Existing Method (Ref 13)	85.00
Existing Method (Ref 14)	82.00
Existing Method (Ref 18)	81.53
Proposed Method	88.86

V. CONCLUSIONS AND FUTURE WORK

The HT-WVD and the deep learning based on ResNet50 are both modules that make up the recommended approach in this study. The HT-WVD removes cross terms to depict the relationship between time, frequency, and energy while keeping time-domain qualities. It directs energy towards the peak (i.e., amplitude and phase within the PD records). In addition, the depth of deep learning based on ResNet50 is adequate to leverage deep neural network performance more extensively than in past studies. Conversely, the suggested technique is more advanced than the existing 1D CNN, and the 2D ResNet model is computationally expensive.

This study proved the feasibility of a speech-based PD classification while proposing new potential approaches for vocal feature analysis. The highest, 86.86% accuracy, was achieved using 5-fold cross-validation. In a clinic, new patients with Parkinson's disease may be identified from healthy persons using the blind test interface. The suggested technique performs well in categorizing PD voice signals compared to earlier research.

Information Systems Department, School of Information Systems
Bina Nusantara University, Jakarta, Indonesia 11480

Abstract—This article focuses on designing a mobile application for ornamental fish auction transactions for fish cultivators in order to increase their sales. This mobile app was created using a prototyping methodology and a four step process. The first is communication, the second is Quick plan and design, the third is construction prototyping, which develops a tender application, and the last stage is development delivery and feedback. Data validation is carried out for users such as farmers, bidders, or buyers in developing the application. The results of this paper propose a mobile auction application that provides auction information and bidding by bidders and sellers. The results show that the application is validated and declared usable and feasible to conduct auctions and bids as needed. This application can increase sales and improve the economic life of ornamental fish farmers in Indonesia.

Keywords—Mobile application; auction; ornamental fish; prototyping model

I. Introduction

The Covid-19 epidemic has not prevented ornamental fish cultivators from countrywide production of ornamental fish products. Freshwater fish, sea fish, and shrimp are included in the category of decorative fish commodities. The expected harvest of this sector commodity is 450 thousand tons between April and June 2020, according to statistics from the Ministry of Maritime Affairs and Fisheries (KKP). Many places, including Aceh, Bengkulu, North Sumatra, South Sumatra, Lampung, Riau Islands, Bangka Belitung Islands, Central Java, East Java, West Java, Bali, West Nusa Tenggara, South Sulawesi, West Sulawesi, Central Sulawesi, Kalimantan, and Maluku, are involved in the harvest [1]. The production of 1.8 billion heads of ornamental fish has been set as the 2020 goal by the Government of the Republic of Indonesia through the KKP. Ornamental fish, as is well known, are one of the trustworthy sources of foreign exchange to promote national economic growth [2], [3]. As its production potential rises, Indonesia is struggling with a major issue, particularly marketing. However, because the information acquired differs from that held by actors in the ornamental fish industry, the government also encounters challenges when making decisions. A more significant sales process is required in many ways with larger manufacturing data. Online auctions are one possibility for utilizing technology to assist farmers in selling.

Online auctions have been conducted since the turn of the century on many websites, including ebay [4]. Online auctions enable participants or customers to sell and bid on goods using internet services [5], [6], [7]. Users may easily connect to one service thanks to this auction without being restricted by location or time by giving thorough descriptions of the goods[4], [8], [9], [10], [11]. The online auction system also makes sure that the information about the commodities auctioned by the auctioneer is safer. Additionally, the price paid will match the auctioneer's desired price. Additionally, it allows the bidder to decide whether to purchase by making an acceptable offer; if the offer is accepted, the bidder wins the item. Additionally, buyers might locate value products that are more appropriate, less expensive, and comfier. Additionally, consumers realize the benefits of using an online auction system to purchase things at lower costs, in a more comfortable environment, and with less financial risk [12], [13]. Because pricing will match the number of bids from customers, online auctions hugely impact selling prices. Users of the online auction system gain advantages from each of these.

This study aims to create a mobile application that functions as an online auction. This system was created using prototyping, allowing simple system adaptation to user needs. Users of the online auction system can access it anytime and anywhere. This system also makes it easy to carry out business transactions according to the agreed price, allowing buyers to easily access information about the commodity to be auctioned.

II. Literature Review

Auctions were originally introduced in ancient Greece. The auction is conducted using a declining pricing method, which starts with the highest price and goes lower to find the lowest bid. Its development is getting faster from auctions in various countries. Auctions are specifically used to sell goods with sellers setting a base price and the following rules a bidder can bid and compete with each other to be able to win bids [14].

Online auctions are services for selling or bidding on goods between auction participants or consumers and sellers via the internet [8]. This auction process is carried out with bidders able to bid, which is acceptable and increases as the

number of bidders' bids. With this online system, auctions can be carried out without geographical, time, or physical meeting restrictions [8].

Internet auctions were created to facilitate market transactions to change how sellers and buyers do business globally [8], [10], [15]. Online use with internet capabilities offers great convenience in providing information about prices, shops, and products being auctioned. Another advantage is that it offers sellers and bidders a unique way of buying and selling transactions happening in real-time.

III. METHODOLOGY

In this study, a mobile application prototype for Indonesian ornamental fish auctions was created using a prototyping methodology.

A. Prototyping Methodology

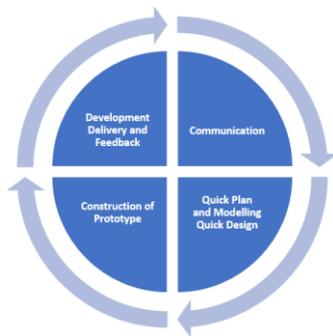
In order to construct an auction application quickly and focus on stakeholders' needs, starting with the communication stage [16]. The prototyping technique is a necessary step. Investigating all application needs and stakeholder requirements is the goal of the communication phase. The second stage, Quick plan and design, is concerned with planning and modeling quickly to reflect design elements that end users utilize, such as the application's interface or appearance. Creating a prototype that meets the needs of stakeholders and the design is the third stage of the construction prototype. The last stage of development, delivery, and feedback, explains how the prototype is provided and assessed to stakeholders to provide feedback. This model's prototyping phase is depicted in Fig. 1.


Fig. 1. Prototyping Methodology.

B. Architecture Application

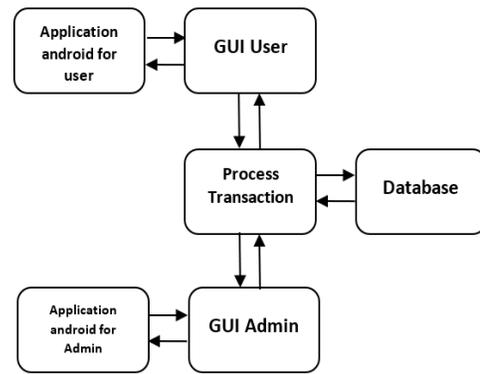
This application architecture clearly explains how the application functions. This architecture illustrates how users and administrators can access the system through the application. The user can complete the auction transaction via a user interface. The database will be involved in the transaction process for the auction. The requested data and data processing, such as entering, editing, deleting, updating, and recording user bidding transactions, will be made available by the database. This Architecture application can be seen in Fig. 2.


Fig. 2. Architecture Application.

C. Mobile Application Evaluation

The International Organization for Uniformity (ISO) evaluation of this mobile application system will give the same standardization between application development and industry needs in software quality measurement [17], [18], [19]. The 1991-first-developed ISO 9126 standard is being used in this investigation. This ISO standard is powerfully adaptable and can be applied to numerous systems. As shown in Fig. 3 are the six standards, and Table I describes the questions of the six standards used for evaluation.

TABLE I. EVALUATION VARIABLES AND INSTRUMENT OF ISO 9126

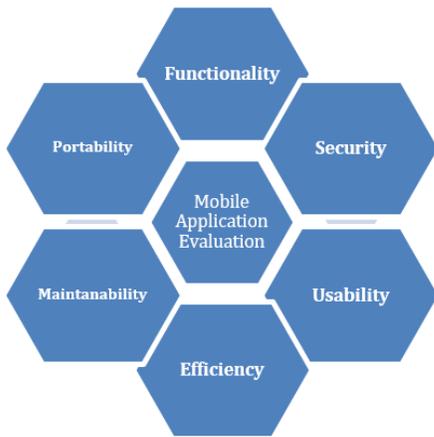
Functionality
Can software complete the tasks?
Has the outcome met expectations?
Will the system talk to other systems?
Can the software prevent unauthorized access?
Reliability
Have the majority of the software flaws been fixed over time?
Does the software have the ability to handle errors?
Can the software be restarted and lost data recovered after a failure?
Usability
Does the user perfectly understand how to utilize the system?
Can the user quickly learn how to utilize the system?
Can the user operate the system easily?
Is the UI appealing?
Efficiency
How rapidly does the system react?
Does the system effectively use its resources?
Maintainability
Is it simple to diagnose faults?
Can you easily modify the software?
Can updates be made without the software ceasing to function?
Easily testable software is this?
Portability
Is it possible to transfer the software to different settings?
Easy installation of the software?
Does the software follow portability requirements?
Is the program capable of readily replacing other software?


Fig. 3.   Six Characteristics of ISO 9126 as a Framework for Evaluating Software Quality.

IV. RESULT AND ANALYSIS

This section discusses the steps of prototyping methodologies for system development and the research findings. These stages include communication, rapid planning and design, prototype construction, development delivery, and feedback. The procedure for a case study on a prototype application is described in this section.

A. Communication Stage

The requirements and stories of the users are identified at this early stage. Users of the application should be made aware of the needs identification process, which includes the sales that sequentially offer information on auctions and bids and ensure that various users can enjoy the same advantages, as shown in Table II.

TABLE II.   REQUIREMENTS

Requirements
The program must contain a page requesting each user's username and password.
The app should feature a primary menu where new users may register themselves and where various jobs will be displayed.
The main menu with a list of tasks should be present in the program.
For applications to hold an auction, a bidding website is required.
A checkout page is a must for the app.
An app's history page is required.

B. Quick Plan and Design Stage

This section discusses the use case, which deals with the various temporal circumstances of each prototyping working sprint. There are two parts to this stage. The first is the Quick Plan, which assesses the requirements for developing prototypes in accordance with user needs. Second, Modeling Quick Design creates design specifications based on a system's needs analysis. The Unified Modeling Language (UML) approach is used in this work.

1) Quick plan: Interviews with relevant users, primarily ornamental fish growers and purchasers generally, are conducted in order to analyze user needs. Furthermore, the

input, process, and output needs are translated from this analysis. Data such as seller and buyer profiles, auction data, history data, payment data, and product data are needed to analyze the input requirements. While the management of the input data is described in the process data. For the information to help users comprehend, the output data is finally in the form of information from the input data processing in the program.

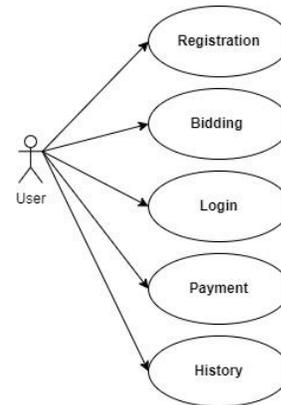
2) Quick design: Analysis of the needs of users is that users can register with the application, users can bid from the bid list, users can log in to use the application, and users can make payments from winning results from bidding. Users can view the history of bids that have been created. Utilizing use case diagrams in UML, this analysis performs needs modeling, as shown in Fig. 4.


Fig. 4.   Usecase Diagram.

3) Construction of prototype: The effort to create the application starts at the prototype construction stage. In order to develop a prototype that actually meets user needs, the work is done in accordance with the information gleaned through the analysis of user needs outcomes. Execution of a design:

a) Design 1: Main Page of the application: A login page allows users to access their own accounts. When there are user users and administrator users, respectively (See Fig. 5(a)). And, to register with a new account in the application, first enter the user identity consisting of name, email address, password, phone number, country, address (see Figure 5b). This is shown in Fig. 6.

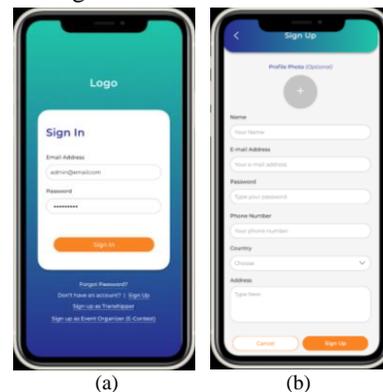
| (a) | (b) |


Fig. 5.   Main Page of the Application.

b) Design 2: User Main Page: Main page User user who owns store as auction maker. (a) Main Page The auction owner user in the application consists of a product menu, auction menu, delivery order menu, (b) Auction creation page, (c) View information on Auctions that have been made, (d) View list of auction winners, (e) Confirmation page to the auction winner, (f) Auction detail information list page, (g) Order history page has been made. This is shown in Fig. 6.

c) Design 3: The main page of users who bid on auctions: (a) User main page, which consists of profile menu, my bid, and history, (b) Settings page, which functions to set profile, currency, payment method, notification, and sign out, (c) My Profile page functions to update user's data, (d) My order auction page which displays auction product orders, (e) Order info page displays detailed information on unpaid auction orders, (f) Order info page displays information on auction product orders with the shipping address inputted, (g) page order info provides information that payments have not been made, (h) Checkout page displays information on choosing the payment method, (i) Order info page displays information on payment confirmation, (j) Summary page displays all auction orders that have been paid for and are ready to ship. (k) History page that displays the history of auction orders. This is shown in Fig. 7.

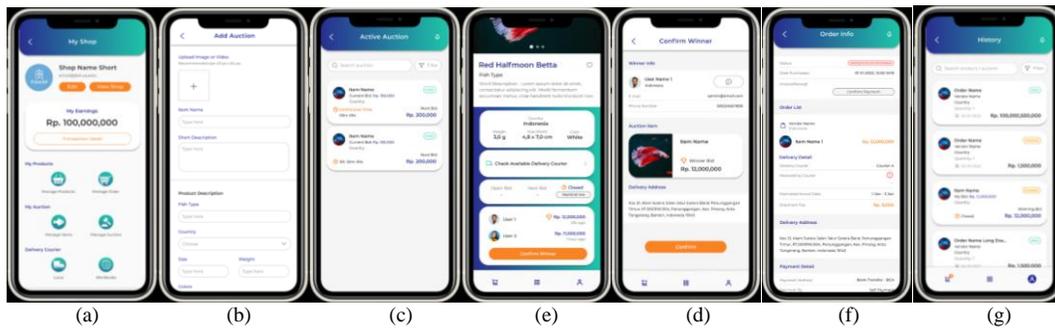
d) Communication stage: At this last stage, the finished application is given to the user to see whether the system is running well, and researchers get feedback from users through the evaluation of the application. This evaluation uses a forum group discussion for users. From the Mobile application evaluation results, the researcher decided to provide a solution, as seen in Table III.


Fig. 6. The User Main Page.
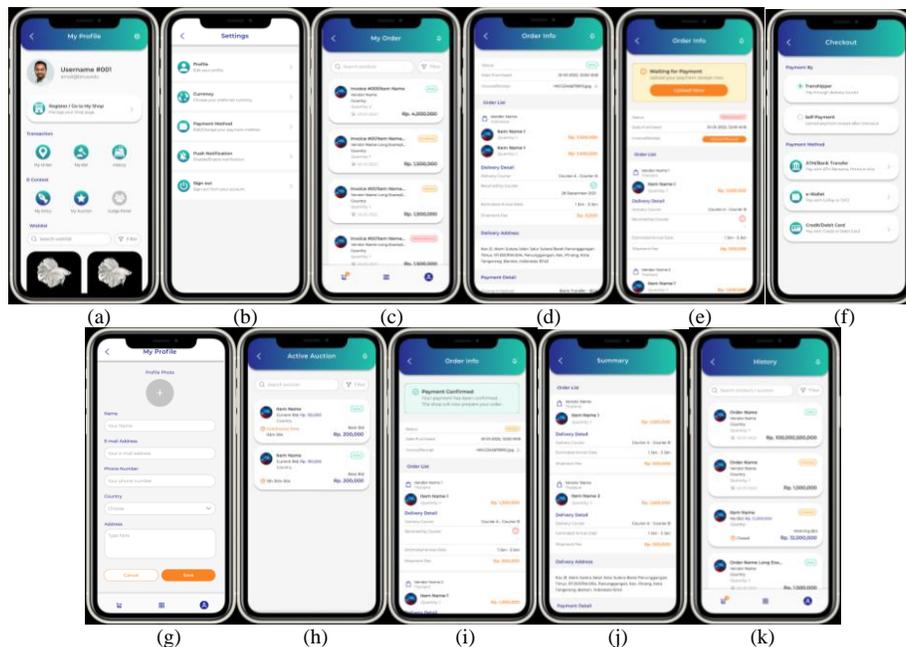

Fig. 7. The Main Page of Users who Bid on Auctions.

TABLE III.   REVIEWER COMMENTS AND SOLUTIONS FOR IMPROVING THE MOBILE APP

Comments from users	Solution
Content of Auction	
Incomplete organizing of the auction	To provide more thorough information, auction materials can be updated with fresh sources.
The instruction's scope supports the purpose	-
The auction documentation is simple to follow	-
New sources can be added to the materials used in auctions.	-
Access and Links	
The application does not provide a search feature.	The application is unable to find an object. It will be investigated more in the future.
Functionality	
The outcome is as expected.	This system can be more interactive
The interactivity access in the display is adequate.	
The program prevents illegal users from logging in.	-
Reliability	
The majority of the software's flaws may not have been fixed over time.	- The program is not set up to deal with the error
The application's ability to handle faults is uncertain.	- The application isn't built to deal with errors.
The application's ability to recover lost data after failure is uncertain.	- The software is not intended to recover lost data following a failure.
Usability	
The system's use is simple for the user to understand.	The user interface might use some improvement.
The system's user interface is simple to understand.	-
The user uses the system with little effort.	-
Efficiency	
The application has a quick response time.	The system is unable to use resources effectively.
Does the system make efficient use of its resources?	-
Maintainability	
Any signs do not show a defect application.	The software is difficult to modify because a skilled coder for multimedia was required.
It is uncertain whether the program can be changed easily.	Changes are performed, and the software is unable to continue operating.
Is it certain that the application will continue to work if changes are made?	Any signs do not show a defect application.
The program should be improved to detect errors in further study.	It is uncertain whether the program can be changed easily.
Portability	
The application cannot be loaded on an iPhone.	It will eventually be produced in an IOS version for iPhone users.
Installation of the software is simple.	
Not sure if the app can easily replace another piece of software?	

The project's completion with the provisions that were envisaged at the outset is the process's last stage. This phase explains how the functionality of the application's design and function has been correctly assessed in light of the proposal. The table will provide the traits and features from the previous stage and describe what first-time mobile app users do.

V. DISCUSSION

The development of this ornamental fish auction application has the following system: Every user who wants to participate in this auction system must register on the application. After registration, the user can log in to use the features in the application, among others, as a seller who makes auction information or as a user participating in auctions. After participating in the auction and winning, the user can see the list of winning auctions on the shopping list. Then make a payment by providing the identity of the address and selecting the sender service provided. After the payment is complete, the sale will process the delivery according to the delivery service chosen and the address of the auction winner. The auction winner can track the delivery process carried out by the seller so that it can create a sense of trust in the application or seller. After the auction recipient gets the auction product (ornamental fish) can confirm receipt on the application and provide feedback to the seller.

The development of this application has received a good response from users of the processes that occur in the system. This is because it has been by the needs required of the user.

In addition, the user provides a view of the need for continuous development from the application side, among others. First, the application can provide complete information content than the product being auctioned or other products that will be auctioned next in terms of application content. From the application access side, it is expected to provide reasonable access, for example, by providing a search feature. In terms of functionality, users hope to get a more interactive and faster system from each of the features provided. From reliability, users wish to reduce errors when accessing applications due to slow responses and can recover lost data. In terms of usability, the user is quite satisfied with the appearance but still needs to improve some application features. In terms of efficiency, the user needs efficiency from using data that is too large to reduce excessive internet usage. In terms of maintainability, the user hopes that the application user interface will not have too many defects, so it is necessary to develop an interface that is easier to use and can be accessed easily. In terms of portability, users find it very easy to install the devices used and hope that it can be developed with various devices so that it can be used more.

VI. Conclusion

The result of the application for ornamental fish auctions provides easy support for transactions for ornamental fish farmers and hobbyists. On the other hand, the application helps in processing a very wide range of transactions regardless of space and time because the application can be accessed anywhere and anytime by the user. The results received by the author are that the application platform can increase the income of ornamental fish farmers with a wide market reach and can foster consumer confidence to make transactions with clear data validation from the seller/auction maker.

In addition, the application is developed by giving priority to auctions only so that it can give focus to users to make transactions with the applicable auction procedures. This auction procedure is very easy to learn because it only bids on the auction information provided. If you win, it will be further informed to the winner of the sale that made the auction. Then, you must agree to take the next step to process the shipping address, and the payment has been completed through the auction process.

Moreover, in-depth research on the auction system, especially for ornamental fish, is very rare, so it provides opportunities for fish farmers to be more advanced in their transactions, get to know buyers, or get more income.

This research is developing by approaching the prototyping method, feeling the advantages at this stage. The stages carried out are appropriate, correct, and supportive in the development process to get applications that suit user needs. In addition, this stage can be seen clearly from application development to evaluation so that the application is appropriate in accordance with user needs. The development process can identify problems that are applied.

On the other hand, it should be noted that this prototype method has several limitations. It does not clearly explain the team members working on it, and the work is not scheduled in detail according to the originally planned time. So this note is estimated to be a top priority in development, so it needs to adjust the focus of the completion time of each application module later. Future work needs to be re-examined regarding adding features for efficient and effective payment methods with various banking services such as credit cards, various FinTechs, and enabling cryptocurrencies. And can also feature live-streaming auctions between sellers and buyers.

Abstract—**Social media data represents the fuel for advanced analytics concerning people's behaviors, physiological and health status. These analytics include identifying users' depression levels via Twitter and then recommend remedies. Remedies come in the form of suggesting some accounts to follow, displaying motivational quotes, or even recommending a visit to a psychiatrist. This paper proposes a remedy recommendation system which exploits case-based reasoning (CBR) with random forest. The system recommends the appropriate remedy for a person. The main contribution of this work is the creation of an automated, data-driven, and scalable adaptation module without human interference. The results of every stage of the system were verified by certified psychiatrist. Another contribution of this work is setting the weights in case similarity measurement by the features' importance, extracted from the depression identification system. CBR retrieval accuracy (exact hit) reached 82% while the automatic adaptation accuracy (exact remedy) reached 88%. The adaptation presented an error-tolerance advantage which enhances the overall accuracy.**

Keywords—Case-based reasoning (CBR); depression; remedy; adaptation; similarity; twitter

I. INTRODUCTION

Depression is among the most critical mental illness that put more than 300 million people lives on risk, and affect patient and his family quality of life. Depression is highly common nowadays and recorded an increased number of cases due to economic factors, global pandemics, and social isolation. Early detection, with an appropriate remedy recommendation is the key to minimize the emotional and financial burden of the depression. However, the increased usage of social network platforms has brought up the essential need to modern analysis techniques on the enormous amount of data available. Twitter, as one the most important and commonly used social network platforms, has a great impact around the world in seconds. More than 500 million tweets are shared per day, bringing up more information and emotions to be diffused among the large number of users. Negative emotion spreads through the network, raising mental illness,

especially depression. As a result, techniques from different fields have been used to analyze and process social network data to diagnose and suggest the appropriate treatments to mitigate such situations [1, 2]. This work exploits Case bases reasoning approach to detect depression in Twitter users. As a result, this study proposes an automatic adaptive case-based reasoning system for early depression detection on social network and automatic remedy recommendation.

Case-based reasoning (CBR) retrieves, analyzes, and stores new knowledge, making it available for solving problems [3]. CBR were used in medical assistant systems for diagnosing and treatment formulation [4 - 9]. Similarly, machine learning is a significant technique for classifying and predicting illnesses through patterns found in the training dataset [10].

This work extends the previous work in the identification of depression levels (tended to be depressed, depressed, deeply depressed) [11, 12] by adding a remedy recommendation system. It uses a hybrid system of CBR and the Random Forest algorithm (RF-CBR), where Random Forest (RF) outcomes feed the CBR to find treatment for users who are depressed. This study aims to recommend the best remedy to depressed Twitter users, when they are in their early stages of illness, or else recommend the visit to a psychiatrist. The most critical stage in the CBR system is the similarity calculation to find the best fit for the new case from the knowledge base. Researchers have used various techniques to reach for the best similarities the match in the CBR model. For example, [13] and [14] used correlations, while [13] used fuzzy logic to calculate the similarity of users to diagnose depression. On the other hand, [14] showed that a combination of RF with the CBR had the best results and highest accuracy among other techniques. As a result, this study used feature importance measurements for calculating similarity through the integration of RF and CBR (RFCBR).

The main challenge of CBR is the adaptation task, which depends on the domain and application characteristics [7]. Most CBR systems are built as retrieval-only systems, especially CBR in the medical and healthcare domain, as they

leave it to human experts [15, 16]. The adaptation task is often left out due to the complexity of the domain or the difficulty in acquiring the knowledge needed [7, 17]. Some studies have attempted to adopt and explore automatic and semi-automatic adaptation strategies, such as [16, 18-22], but they have all required human interference to complete and/or assess a system's performance. The integration of CBR with other methodologies has been used to overcome the adaptation problem [11]. For this, most CBR systems use either human experts or are rule-based for the adaptation task, while this study is data-driven, which, to our knowledge, is novel and has not been introduced for depression treatment.

The proposed work enhanced the previous research by developing an automatic system called Remedy Recommender Model (RRM) entailing RF and CBR for detecting users' depression levels and in consequent of those outcomes recommends the best remedy. The experiments depend on ground truth data prepared by psychiatrists. They studied the cases in the knowledge base and gave recommendations of remedies accordingly. Three feature importance measurements are used each in a separate experiment to identify the features' weights, namely, overall, permutation, and tree interpreter feature importance measures. The results of this study correspond to [12], showing the best results from retrievals and adaptation using the tree interpreter feature importance measurement.

The rest of the article is organized as follows. Section II illustrates the previous work in both CBR and healthcare. Section III elaborates on the background, while Section IV drafts the proposed approach and solution. Section V discusses the experimental results in addition to comparative analysis with other authors. Finally, Section VI concludes and positions the findings and insights.

II. RELATED WORK

CBR has been used in healthcare for diagnostics and treatment. CASEY is one of the earliest medical expert systems that used CBR for heart failure diagnosis. The system searches for similar cases, finds the differences between a current and a similar case, and transfers the diagnosis of the similar case to the current case. The system uses rule-based domain theory if modification attempts fail or if no similar cases are found [7]. Additionally, Nasiri et al. [9] introduced the DePict CLASS, a cased-based learning assistant system that recommends information retrieved from dementia research based on the ICF framework of the WHO. The system detects and predicts the disease using image classification and text information. Caregivers and domain experts use and update the DePicT CLASS for dementia that is used by caregivers and patients' relatives to find answers in dealing with their problems [9]. Moreover, Mulyana et al. [23] developed a case-based reasoning system for diagnosing types of schizophrenic disorders and mood disorders with their treatment. Medical records of patients with mental disorders were obtained from a mental hospital in Yogyakarta and were used to construct the knowledge base of the system. The system selects the case with the highest similarity to the new problem and recommends its treatment to the new case [23].

To increase the accuracy of the similarity measurements in CBR, the authors in [24 - 26] introduced fuzzy logic with CBR. For example, Ahmed et al. [6] reached an accuracy of 88% in the diagnosis and treatment of stress. Houeland et al. [27] also introduced the random decision tree (RDT), which proved that the hybrid combination outperformed the base algorithms in similarity measures. Similarity was calculated using proximities that were computed using an RF algorithm.

Furthermore, Asim et al. [15] compared the nearest-neighbor and artificial neural network to RF and found that RF contributed to the efficiency of the CBR system they used to identify influential bloggers. They reached an accuracy of 89% when using Gini impurity as weights in the similarity measure of the CBR system. Hseih et al. [28] also compared different classifiers and ensemble classifiers as the best for use with CBR to find Internet-addicted users and were able to reach 89.9% accuracy. In addition, Gu et al. [29] used CBR with a genetic algorithm to diagnose breast cancer, achieving 0.927 accuracy.

In the mental illness sector, several studies used CBR to help diagnose or treat mental illnesses. Mulyana et al. [30] used CBR to diagnose mood disorders, achieving 89.3% accuracy using Modified Tcersky to increase similarity retrieval accuracy. On the other hand, other studies used CBR with different techniques. Kwon et al. [31] used crowd knowledge with CBR to diagnose depression and stress. Furthermore, Rahim et al. [32] used the help of specialists and built an expert system with CBR to diagnose physiological disorders. Table I summarizes some CBR systems in different domains.

TABLE I.   COMPARISON OF CBR SYSTEMS IN DIVERSE DOMAINS

Author/ Domain	Techniques	Results	Similarity	Adaptation
Asim [15] (blogger influence)	RF + ANN + C4.0 + NN	f-measure (85% before adaptation, 91% after adaptation)	Gini entropy	Yes
Mulyana [23] (mental disorder)	CBR	Accuracy: 99%	NA	No
Hsieh [28] (internet addiction)	Ensemble classifier + CBR	Accuracy: 89.9%	Weight of classifier	No
Gu [29] (breast cancer)	CBR	Accuracy: 0.927	Genetic algorithms for weights	No
Mulyana [30] (mood disorder)	CBR	Accuracy: 89.3%	Modifies Tversky Similarity	No
Kwon [31] (depression & stress)	Crowd knowledge + CBR	Accuracy: 92.5%	NA	No
Rahim [32] (phycological disorder)	CBR + expert system	Accuracy: 75%	NA	No

As previously mentioned, most studies have used human experts for adaptation tasks or ignored them. Eknog et al. [14] and Nasisri et al. [9] used experts to perform the adaptation task. On the other hand, Asim et al.'s [15] adaptation was automatic in its use of similarity equations but with no change in the results.

The present study reveals the gap in the treatment of depression and other mental illnesses is that most of the studies did not utilize adaptation or created adaptation with human assistance.

III. BACKGROUND

A. Case-based Reasoning

CBR is found to be a good model because it assimilates problem solving, understand, and learn, and integrate all of them with memory processes. It also amends old solutions to meet new requirements [13]. Thus, in the past few decades, has befitted the medical domain as intelligent computer-aided decision support systems [6, 13]. CBR system depends on reusing previous knowledge to solve new problem through defining the similarities between them. Later, before applying the solution (remedy) CBR revises them then retains applicable solutions (remedies) for further reuses [33 - 36]. These steps of the 4R processes demonstrate the R4 model developed by Aamodt and Plaza [13, 37].

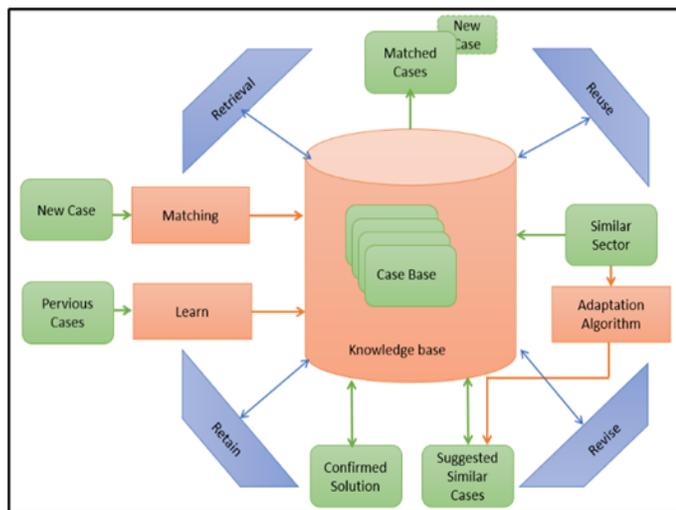
Based on the CBR cycle (Fig. 1), the RETRIEVE process in this article starts with identifying similar cases in the knowledge base using the features' importance and the score of each case. Similarity calculations help find the most similar case with the most similar treatment. A case that has the highest level of similarity will be suggested as the most alike treatment for the case, and this is called the REUSE process. Next, the case will enter the REVISE process, where an adaptation algorithm will be applied to identify if this is the most suitable treatment or if there is another case with better treatment. Finally, after finding the most similar case and recommending the most similar treatment, the RETAIN process can save the case in the knowledge base as a new case.


Fig. 1. The CBR Cycle.

B. CBR in Healthcare

CBR's ability to solve problems and its efficiency in the recommendation process has attracted researchers in the healthcare domain [4 - 9]. CBR systems are increasingly used in healthcare due to its utility for the thought process of a physician [13, 38]. Automatic establishment of a facility-adapted knowledge base is highly beneficial to CBR systems in healthcare [39], which is of great significance in medical decision making [13].

CBR has also been used for developing intellectual computer-aided decision support systems in the medical domain in the past few years because of the continuously changing nature of the medical knowledge base and the presence of more than one solution [6, 13, 40].

IV. PROPOSED SYSTEM (RRM)

RRM used for depression detection starts with retrieval of similar cases in the knowledge base which is an important and critical phase to reach an optimal solution for the desired case. The similarity – as first step in the CBR cycle - depends on the features weights to get the most similar cases according features similarities of both cases. The most similar cases will be used to enter the CBR's REUSE stage. Later, adaptation phase is performed in the REVISE stage which is important to recommend the most suitable treatment for depression in its early stages. Finally, the recommended new case will be retained in the knowledge base. This study uses data from [11], data collected consisted of Twitter users who were depressed and non-depressed. A total of 500 users were collected with more than 1M tweets, and 334 users were classified as depressed. The data consisted of user accounts' information and tweets.

The data has been used for running RF to classify users as depressed and non-depressed users and find importance of each feature and the score of each case obtained from the RF probabilities [12]. Importance of features is used as weights for the similarity calculation to retrieve from the training set the most similar case to the case in the test set. Only depressed users' data is used in this study since they are targeted to recommend the best remedy for them. these results based on generating 10 random splits of data to 50% knowledge base and 50% unseen cases. The target is to neutralize the system to any cases temporal order to the system.

Data is trained using 10-fold cross validation to avoid over fitting and then tested on held-out test data. Fig. 2 summarizes the RRM phases. Novelty of this work appears in both retrieval and adaptation phase where the recommended solution for depressed users is proposed.

A. Retrieval Phase

Retrieval of similar cases utilizes Algorithm 1 using local and global similarity equations [33, 34]. The algorithm starts with calculating local similarity of features for the new case and old cases in the knowledge base:

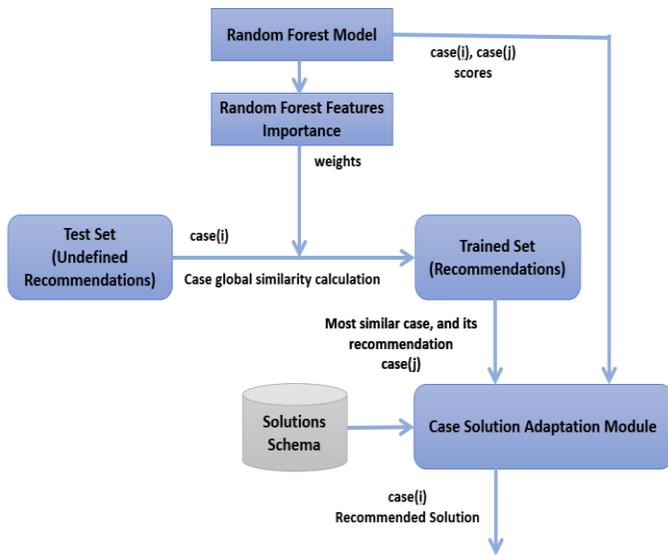
$$sim\ (f_x, f_y) = 1 - \frac{|f_x - f_y|}{f_{max} - f_{min}} \qquad (1)$$


Fig. 2. The RRM System.

where f_x is the feature's value for the new case, f_y is the feature's value for the *y*-th old case, and $f_{max} - f_{min}$ includes the minimum and maximum values for all the old cases included in the database.

Next, the global similarity is calculated, which is the weighted sum of the local similarities of all features used in the analysis. Global similarity is calculated using the following equation:

$$similarity(x, y) = \frac{\sum_{f=1}^{n} w_f \times sim(x_f, y_f)}{\sum_{i=1}^{n} w_f} \qquad (2)$$

Where w_f is the weight of the f-th feature, $similarity(x, y)$ is global similarity between the case x from the training set and the new case y, and $sim(x_f, y_f)$ is the local similarity for the f-th feature between case x and the new case y.

Importance of the features concluded from the RF is used as the weight for each feature. Finding the most similar case is important for the accuracy of the adaptation phase.

To illustrate how algorithm 1 is implemented, this study provides an example from the cases used in this study. This will use a new case and a small case base, containing just two cases and four features as shown in Table II. Importance, minimum, and maximum values of each feature are also shown in Table II. The new case Ci will be compared to the cases stores in the training case repository. The goal is to find the most similar case to the new case to be able to recommend the same remedy. In other words, the remedy used for the case in the repository will be recommended the same remedy. In other words, the remedy used for the case in the repository will be recommended to the new case. Similarity calculations aims to find cases that are analogous in a way their remedy can be reciprocally reused.

Algorithm 1 starts with calculating local similarity for the new case Ci and the two cases using equation (1). Local similarity between C1 and Ci for the (Retweets feature) is:

Algorithm 1: Get_Most_Similar_case (C$_i$, TC)

Input:
C$_i$: input case
TC: training cases in case repository
Output: The most similar case

1:	MaxSim=0
2:	For all training cases *TC*:
3:	For all features in features space:
4:	• Calculate Feature_Local_Sim (case of **C$_i$** and case of TC) //using equation (1)
	End for
5:	• Calculate New_sim = GlobalSim (Feature_Local_Sim of **C$_i$**, Feature_Local_Sim of TC) //using equation (2)
	End for
6:	MaxSim=max (MaxSim, new_sim)
7:	Return the most similar case with MaxSim

TABLE II.   FEATURES' COMPARISON OF NEW CASE AND CASES IN REPOSITORY CORRESPONDING TO THEIR MAXIMUM AND MINIMUM VALUES

Features	C$_1$	C$_2$	New case C$_i$	Importance of features	Maximum Value	Minimum Value
Retweets	26	70	100	0.9	200	0
Hashtags	10	72	20	0.8	123	5
Depress	30	10	56	0.5	350	4
Hate	14	40	20	0.7	120	0

$$\text{Sim}(C_i, C_1) = 1 - \frac{|26-100|}{200-0} = 0.63 \qquad (3)$$

Similarly, local similarity for all features are calculated for the Ci with C1 and C2:

Sim (Ci, C1) = {retweets 0.63, hashtags 0.91, depress 0.92, hate 0.95}

Sim (Ci, C2) = {retweets 0.85, hashtags 0.56, depress 0.87, hate 0.83}

The second step in the retrieval phase is calculating global similarity. Equation 2 is applied to find similarity between cases and the new case. This is done by taking weighted sums of local similarities with the importance of features as weights. Global similarity is calculated as follows in Eq. 4 and 5:

$$\text{Similarity}(C_i, C_1) = \frac{1}{2.9} \times (0.9 \times 0.63 + 0.8 \times 0.91 + 0.5 \times 0.92 + 0.7 \times 0.95) = 0.834 \qquad (4)$$

$$\text{Similarity}(C_i, C_2) = \frac{1}{2.9} \times (0.9 \times 0.85 + 0.8 \times 0.56 + 0.5 \times 0.87 + 0.7 \times 0.83) = 0.769 \qquad (5)$$

Therefore, C1 were chosen to reuse and continue to adaptation phase. C$_i$ is more similar to C$_1$ than C$_2$.

B. Adaptation Phase

Adaptation phase depends on the knowledge base which has three sectors of remedies for different depression levels. Levels of depression are for users who tend to be depressed, depressed users, and users with advanced depression where a doctor consultation is a must. Cases' scores, Sc = {Sc1, Sc2,…Scn} are calculated and retrieved for RF model and saved in the knowledge base with appropriate recommended remedies R = {R1, R2,…Rn}, for each case.

Algorithm 2 illustrates the adaptation phase. For each new case C_i, score Sc_i, and remedy R_i, first, similarity is calculated with the cases in the training set to find the most similar case, C_j. Later, all mean score for remedies in the same sector are calculated. KNN is applied to find the nearest mean score which determines the nearest remedy appropriate for C_i.

In order to illustrate Algorithm 2, this study introduced an example from the study cases. Cases used were introduced in illustrating algorithm 1 above. After applying Algorithm 1, C1 was found to be closer to Ci. As a result, case C1 remedy will be first recommended for new case Ci but adaptation phase will try to reach a better remedy for Ci.

Algorithm 2: RRM Adaptation Pseudo code

Input:

TC: training cases in case repository (knowledge base)

C$_i$: input case

Sc$_i$: Depression classification score of case C_i

CSR: table with columns case, score and remedy

Output: remedy R_i

1: Case C_j = Get_Most_Similar_Case (C_i, TC) // ***using Algorithm 1***
2: RemedySector rs of C_i is the RemedySector of C_j
3: For every remedy r from rs:
4:     -   Obtain Sc(score) from CSR where remedy is r
5:     -   ScoreMean[r,m] where m is the mean of scores of table Sc
6: closeScore = minimum distance between input Sc_i and Scores in ScoreMean
7: R_i is a remedy r obtained from ScoreMean[r, m] where m is closeScore
8: Return remedy R_i

For Algorithm 2, score of new case Ci - derived from the RF result- is used as an input for the algorithm implementation where score Sci is equal to 0.74. Also, CSR containing scores and remedies for repository cases is given in Table III. Since C1 is most similar to new case Ci, remedy of C1 will be used to define the sector. Using classification of sectors in Fig. 3 remedy of C1 is R8 meaning that C1 and R8 is in depressed sector. For each remedy in the depressed case sector, the cases will be retrieved, and the mean score will be calculated. In other words, mean score for cases with remedy in [R6, R7, R8, R9, R10] will be calculated. From Table III, Mean scores of R6= (Sc2 +Sc7)/2= 0.69+0.75/2=0.72. Mean score of R8= (Sc1 +Sc3)/2= 0.785, mean scores of R9 = 0.82, and for R10 = 0.88.

To find best remedy for Ci, Algorithm 2 will apply KNN and find closest mean score to Sci and choose the corresponding remedy for Ci. Since mean score of R6 is the nearest neighbor to score Sci = 0.74 of input case Ci. Sci, Algorithm 2 will return R6 as a better remedy recommended for input case Ci.

TABLE III.   CSR CONTAINS SCORES AND REMEDIES FOR EACH CASE

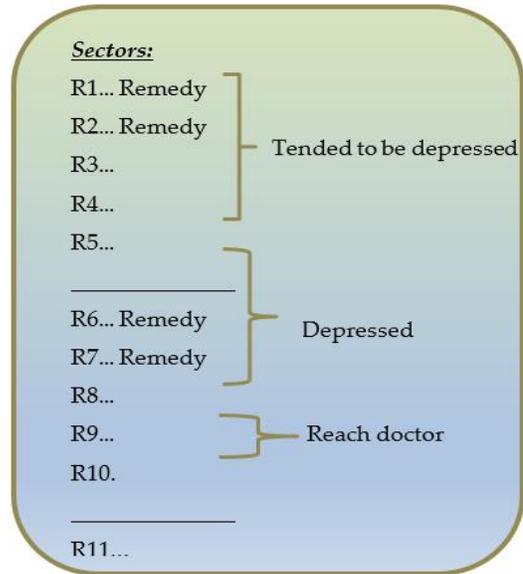
Cases	Score	Remedy
1	0.85	R8
2	0.69	R6
3	0.72	R8
4	0.74	R1
5	0.32	R2
6	0.88	R10
7	0.75	R6
8	0.41	R3
9	0.82	R9


Fig. 3. Classification of Depression Sectors.

V. EXPERIMENTS AND RESULTS

Data used for this experiment has 133 depressed users and 66 not depressed. In an attempt to have ground reality, data for validation of the RRM system results, for each depressed user best recommended solution is assigned with the help of psychologists. This helped to identify how many correct retrievals of similar cases and number of successful adaptations of best solution to each depressed user.

Depending on the score of each case obtained from classification step using RF, the system categorizes the cases to one of the following sectors: tend to be depressed cases, depressed, and deeply depressed as shown in Table IV. Results proved that depression has the exponential distribution of contagious diseases shown in Fig. 4.

TABLE IV. PERCENTAGE OF EACH DEPRESSION LEVEL ACCORDING TO THE SCORES OF CASES

Level	Percentage to data
Tend to be depressed	62%
Depressed	30%
Deeply depressed	8%

A. Retrieval Phase Results

The implementation of CBR starts with applying the similarity equation to find the similarity of the new case to cases in the training set. As explained in the proposed system section retrieval phase is applied to find the most similar cases to the desired case. The results of the implementation showed the accuracy of retrieving similar cases from the knowledge base.

Retrieval experiments employ three different importance feature measures to determine the feature weights used in the similarity equation namely overall, permutation, and tree interpreter feature importance measures. Evaluation measures are applied independently for each experiment. Applying tree interpreter feature importance was able to retrieve successfully 54 users which revealed highest accuracy, 82% as shown in Table V. Precision, recall, and the f-measure revealed tree interpreter is the highest among the other importance criteria reaching 0.766, 0.349, and 0.480, respectively. Overall and permutation feature importance criteria had a smaller number of correct retrievals where the accuracy was 73% and 67%, respectively. Also, precision, recall, and the f-measure indicated that overall and the permutation are less accurate than tree interpreter. Overall results were 0.62, 0.343, and 0.442, respectively while the permutation results were 0.706, 0.343, and 0.472, respectively. Results of retrieval are summarized in Fig. 5.

B. Adaptation Phase Results

Completing the CBR cycle for the experiment, the adaptation phase results are conducted for each cycle and results are recorded according to the type of feature importance measurement used. Tree interpreter feature importance measurement has outperformed other feature importance measurements resulting accuracy of 88% with 58 successful user adaptations as shown in Table VI. Overall and Permutation feature importance criteria had lower result, 76% and 71% were their accuracy results, respectively. Precision, recall, and the f-measure indicated that tree interpreter had higher results than the other measures, reaching 0.762, 0.358, and 0.511, respectively, while overall and permutation reached precision of 0.671 and 0.7401, recall 0.456 and 0.3128, and f-measure 0.543 and 0.439 respectively. Fig. 6 illustrates the adaptation results.

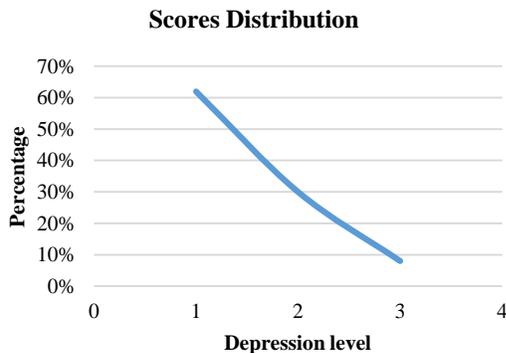
Scores Distribution


Fig. 4. Exponential Distribution of Depression Levels.

TABLE V. RETRIEVAL PHASE RESULT FOR DIFFERENT IMPORTANCE CRITERIA

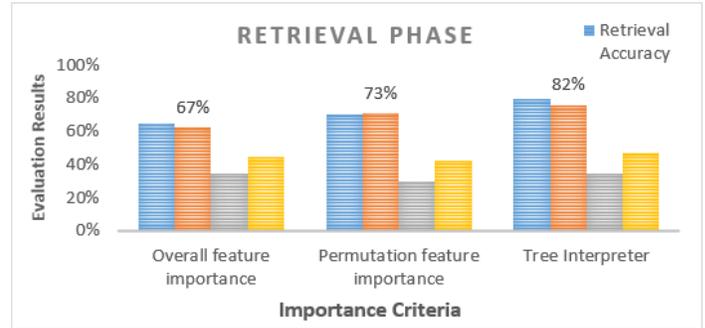
Feature Importance Criteria	Retrieval Accuracy	Precision	Recall	F Measure
Overall	67%	0.61189	0.328456	0.427457
Permutation	73%	0.71192	0.30867	0.43063
Tree Interpreter	82%	0.76611	0.34986	0.480356


Fig. 5. Statistical Illustration of Retrieval Phase Results.

TABLE VI. ADAPTATION PHASE RESULTS FOR DIFFERENT IMPORTANCE CRITERIA

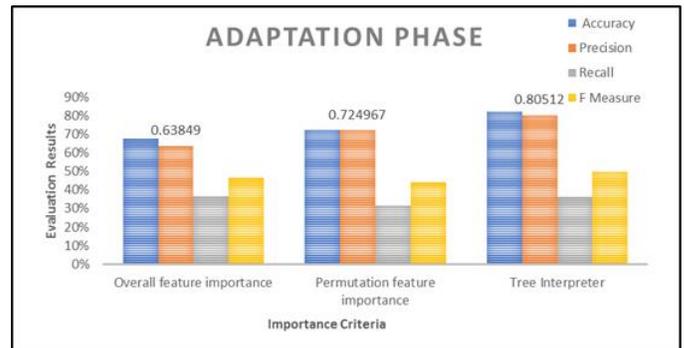
Feature Importance Criteria	Retrieval Accuracy	Precision	Recall	F Measure
Overall	71%	0.6713	0.4561	0.543161
Permutation	76%	0.7401	0.3128	0.439744
Tree Interpreter	88%	0.7624	0.38519	0.511801


Fig. 6. Statistical Illustration of Adaptation Phase Results.

Results of retrieval and adaptation showed that tree interpreter feature importance results outcomes correspond to the results of [12].

VI. COMPARATIVE STUDY

This comparison has been considered to guarantee the effectiveness of the proposed RRM. Other studies used different data sets and labels and aim to propose objective and non-biased results and analysis, this comparative study will apply the same data to different techniques. As mentioned earlier, different studies have used correlations [14 - 15] and

fuzzy logic [16] to find similarities between cases in the retrieval phase. As a result, those techniques were implemented on this research's data and proved that tree interpreter is best used for feature weights in the similarity equation and the adaptation task.

As shown in Fig. 7 and Fig. 8, this tree interpreter in this study (TI) reached accuracy of 88% while the accuracy of fuzzy logic (Fl) and correlation (Cr) are 71% and 68%, respectively. Also, the precision, recall, and f-measure results in Table VII and Table VIII proved that tree interpreter outperforms fuzzy logic and correlation assessments.

TABLE VII.   COMPARISON OF RETRIEVAL STUDY RESULTS

Importance Criteria	Retrieval Accuracy	Precision	Recall	f-Measure
Tree Interpreter	82%	0.76611	0.34986	0.480356
Correlation	68%	0.5124	0.367341	0.427911
Fuzzy Logic	72%	0.691529	0.30156	0.419977

TABLE VIII.   COMPARISON OF ADAPTATION STUDY RESULTS

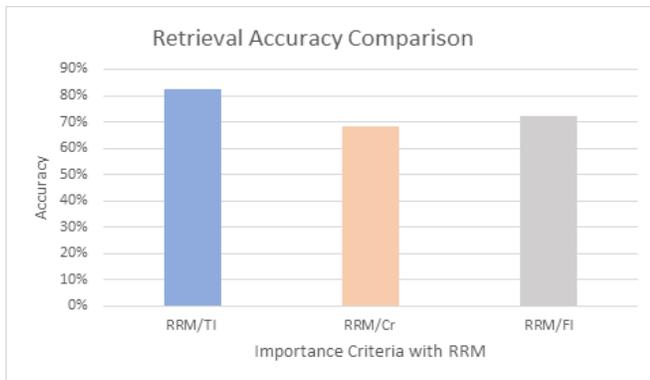
Importance Criteria	Adaptation Accuracy	Precision	Recall	f-Measure
Tree Interpreter	88%	0.7624	0.38519	0.511801
Correlation	77%	0.5841	0.38911	0.467071
Fuzzy Logic	78%	0.7518	0.3671	0.493316


Fig. 7. Comparison of Retrieval Phase Study Accuracy Results.
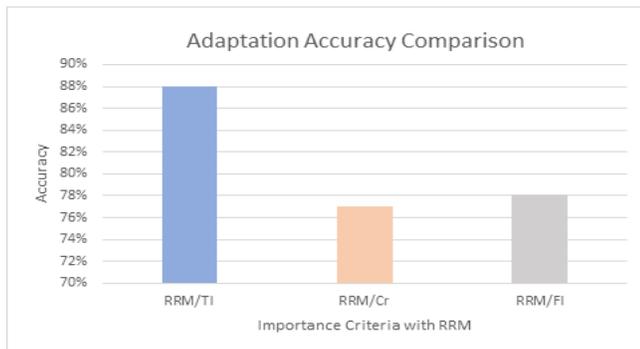

Fig. 8. Comparison of Adaptation Phase Study Accuracy Results.

Reference	Accuracy (%)				
	SVM	Random Forest	KNN	multimodal analysis	CBR
Bohang Chen et al. [42]	74.18	-	-		
Gonzalo A Ruz et al. [43]	81.2	72.5	-		
Priyanka Arora et al. [44]	79.7	84.6	-		
Akshi Kumara et al. [45]	-	81.04	-		
Shakeel Ahmed et al. [46]	-	-	72.0		
Safa, R., et al [47]	-	-	-	83%	
Proposed hybrid RF and CBR system	-	-	-	-	82

The proposed hybrid random forest and Case-based reasoning model showed comparable retrieval accuracy compared to other studies [40 - 47] aimed to depression detection using artificial intelligence and machine learning techniques as shown in Table IX.

VII.   CONCLUSION

This research concludes the best techniques and results for introducing a more accurate retrieved criteria and remedy recommender for depressed user of Twitter. The hybrid system of RF and CBR is a good technique for memory processing, but there were challenges found by previous studies in various fields that CBR system is built as a system for the retrieval of data only. The adaptation task in CBR system is left out, therefore, human interference is needed to complete system performance. To overthrow this dilemma, an automatic system – Remedy Recommendation using (RRM) was developed. This system detects the level of depression for each user and recommends the best solution. As explained in this study, the proposed system is applied to find the most similar cases and recommend remedies accordingly through applying adaptation phase to find best remedy recommended for each user. The system's successful hits exceeded 85% in its optimal hyper parameters configuration. RRM has proven that remedy recommendation done without the interference of human is possible. The main novelty of this work derives from introducing an adaptation task for depression treatment. RRM can be generalized to any type of illness to recommend the best solution using data from different social media platforms. In future work, this study aims to enrich the dataset with raw data collected from other social media platforms, such as Facebook or Snapchat.

Sichuan, 618000, China

Abstract—**Regular and symmetry shapes occurred in natural and manufactured objects. Detecting these shapes are essential and still tricky task in computer vision. This paper proposes a novel hierarchical shape detection (HiSD) method, which consists of circularity and roundness detection, and regularity and symmetry detection phases. The first phase recognizes the circular and elliptical shapes using aspect ratio and roundness measurements. The second phase, the main phase in the HiSD, recognizes the regular and symmetry shapes using density distribution measurement (DDM) and the proposed sampling point-line distance distribution (SPLDD) algorithm. The proposed method presets effective with low computation cost shape detection approach which is not sensitive to specific category of objects. It enables to detect different types of objects involving the arbitrary, regular, and symmetry shapes. Experimental results show that the proposed method performs well compared to the existing state-of-the-art algorithms.**

Keywords—Shape recognition; hierarchical shape detection; sampling point-line distance distribution; regular and symmetry shape detection

I. INTRODUCTION

Regular and symmetry shapes occurred in the outdoor urban scenes, indoor built environments, and manufactured objects [1, 2, 24]. Detecting regular and symmetry shapes is essential in computer vision and pattern recognition communities. Regular and symmetry shape detection are broadly used in urban scene recognition [3, 4, 23], vehicle recognition [5, 6], face analysis [7, 8], image reconstruction [9], and driver assistance systems [10]. Moreover, the regular and symmetry shape features are considered salient features that guide eye movements and can thus mainly be used for visual attention detection [11].

Various methods have been developed for regular and symmetry shape detection. However, existing research works suffer from high complexity and it leads to deduct its applicability on real time shape detection applications [22]. As shown in literature, more existing methods focused on regular shapes detection which are limited to detect specific shapes such as circles or polygons. Moreover, these methods cannot detect symmetric shapes and differentiation from regular shapes.

Although many research works investigated regular shapes, the detection of polygon-based shapes has been studied less,

and little progress has been made in recent years [3]. Barnes and Loy [4] presented a posteriori probability approach that defined the continuous log-likelihood of the probability density function for the appearance of regular polygons. Liu and Wang [3] introduced point-line distance distribution (PLDD) to compute each pixel's shape energy for detecting arbitrary triangles, regular polygons, and circles. Among the existing shape detection methods, the PLDD method [3] presented a better performance in terms of accuracy than other existing methods. However, the PLDD method suffers several drawbacks. The main drawback of the PLDD method is the lack of ability to identify symmetry and parallelogram format shapes [3].

Referring to existing drawbacks of current shape detection methods, developing an efficient with low complexity visual shape detection method is required to cover various shapes detection consisting regular and symmetry and other shapes. Therefore, this study presents a novel shape detection method to deal with the challenges, to detect different types of shapes, including the arbitrary, regular, and symmetry shapes with effective performance and low complexity.

The main contributions of this study are as follows, 1) a novel shape detection method developed which is not sensitive to specific category of objects. It enables to detect different types of objects involving the arbitrary, regular, and symmetry shapes, 2) the proposed method is not based on high complexity and computation cost approaches which is applicable in real time applications, 3) the experiments and comparative analyses are performed using different shapes and noise conditions to validate the effectiveness of the proposed method.

The rest of this paper organizes as follows: related methods and the existing shape detection methods are briefly reviewed in Section II. The proposed shape detection method is described in Section III. Section IV presents the experimental results and performance evaluation. Finally, Section V presents the conclusion of the paper. Hierarchical Shape Detection (HiSD) Method.

II. RELATED WORKS

This section discusses existing research works on shape detection methods. The standard and symmetry shape detection methods are categorized into deterministic-based and

*Corresponding Author.

stochastic-based approaches [3]. For the deterministic-based approaches, Hough transform-based methods are commonly applied to infer the center locations, followed by employing edge information obtained by an edge detector [12]. However, the Hough transform-based methods require large storage space and high computational complexity, which results in low processing efficiency. Furthermore, template matching [13] and least square-based methods have been proposed [14] for the discriminative-based approach. For the stochastic-based methods, Dehmeshki and Ye [15] proposed a Genetic Algorithm (GA)-based method for shape recognition that effectively detects regular shapes. However, the GA-based method cannot differentiate the regular and symmetry shapes. Furthermore, other stochastic-based methods have been proposed based on the random sample consensus technique [16] and simulated annealing [17].

III. THE PROPOSED METHOD

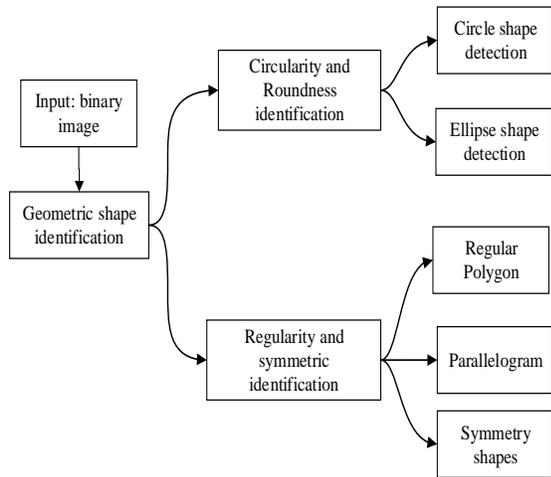
The proposed shape detection method in this study consists of two main processes, which are hierarchically structured, as shown in Fig. 1. The first process calculates the roundness and circularity of the shape to identify whether the shape is a circle, ellipse, or not circular. The second and main process aims to detect the regularity and symmetry of the shapes.


Fig. 1. The Hierarchical Shape Detection Method.

A. Circularity and Roundness Identification

Aspect ratio (*AR*) and roundness factors are used to detect the circularity of the shape. The *AR* is defined as the ratio of length over breadth [18]. *AR* can be calculated through Equation (1) as,

$$AR = \frac{L}{B} \tag{1}$$

where *L* and *B* are the length and breadth of the shape, respectively. Moreover, the roundness feature describes the shape's resemblance to a circle. The roundness factor of a shape will approach 1.0, the closer the shape resembles a circle [18]. The roundness factor (*Ro*) can be obtained by Equation (2),

$$Ro = \frac{1}{\pi}\left(\frac{4*EA}{((D))^2}\right) \tag{2}$$

where *EA* is the enclosed area of the shape and *D* is the diameter.

B. Regularity and Symmetry Identification

This section describes a proposed algorithm to distinguish the shape based on regularity, irregularity, symmetric and asymmetric features. The pseudocode of irregularity and symmetric identification is as follows

Input: *a binary component denotes as S.*
1- *Extract a corner point as P_c from S,*
2- *Compute angles as θ_k for each P_c using Equation (4),*
3- *Determine equal P_c points, initialize N_{eq} and detect shape regularity of S and update the S(T) function,*
4- *For each two connected P_c do:*
 a. *Find mean point as P_m,*
 b. *Generate a perpendicular line as BL that cross the P_m,*
 c. *Measuring the density distribution for two side of BL using calculate integral of are mass based Equation (9) and update symmetry status,*
 d. *Access the symmetry status of the using SPLDD and update symmetry status,*
5- *Distinguish the shape using obtained status*

Output: *shape detection results*

1) Corner points extraction: A corner point is an edge point that occurs when the edge direction changes. In this study, features from the accelerated segment test (FAST) corner detector are used to extract the corner points [19]. FAST corner detector uses a circle of 16 pixels to classify whether a candidate point p is a corner, as presented in [19]. Each pixel in the circle is labeled from integer 1 to 16 clockwise. Suppose a set of N contiguous pixels in the circle are all brighter than the intensity of candidate pixel p (denoted by Ip) plus a threshold value t or all darker than the intensity of candidate pixel p minus threshold value t. In that case, p is classified as a corner. In a mathematic demonstration, for each location on the circle x, the pixel at that position relative to p (denoted by p → x) can have one of three states by Equation:

$$S_{p\to x} = \{d, \quad I_{p\to x} < I_p - t \quad (darker) \; d, \quad I_p - t < I_{p\to x} < I_p + t \quad (similar) \; b, \quad I_p + t \le I_{p\to x} \quad (brighter) \tag{3}$$

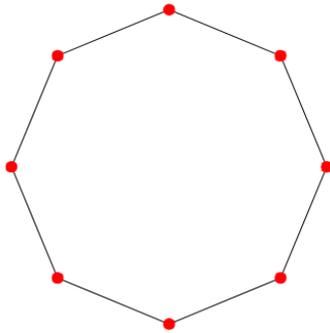
Choosing an *x* and computing $Sp{\to}x$ for all $p \in P$ (the set of all pixels in all training images) partitions *P* into three subsets, *Pd, Ps, and Pb*, where each *p* is assigned to [19]. As an example, a pentagon is used to demonstrate the steps. The FAST corner detector can detect the corners of the pentagon, as shown in Fig. 2.


Fig. 2. Detected Corners of a Pentagon Shape.

2) Corners angles computation: As stated in the shape detection algorithm, the angle for each corner is required to identify. A scalar product-based approach is used for corer angle calculation. In this regard, a 5*5 mask is defined to identify the angle for the corner points. The mask is used for intersection point identification, obtained using corner points and sides on the shape. For this identification, the mask is located on the corner point, and the angle is calculated using the extraction of intersection points between the mask and the sides of the shape, as shown in Fig. 3 (P_c is the corner point and P_i, P_j are the intersection points on the shape sides). The mask contains 0 for all elements in M except M_{33} which is 1.

$$M = [0\,0\,0\,0\,0\,0\,0\,0\,0\,0\,0\,0\,1\,0\,0\,0\,0\,0\,0\,0\,0\,0\,0\,0\,0]$$

Let us define $P_c = (x_c, y_c)$ as a corner point, $P_i = (x_i, y_i)$ and $P_j = (x_j, y_j)$ as intersection points between mask (M) and polygon sides. The angle for corner point can be obtained using the scalar measurement [20],

$$\theta_k = arccos\left(\frac{\overrightarrow{P_iP_c}.\overrightarrow{P_cP_j}}{\|\overrightarrow{P_iP_c}\|\|\overrightarrow{P_cP_j}\|}\right) \qquad (4)$$

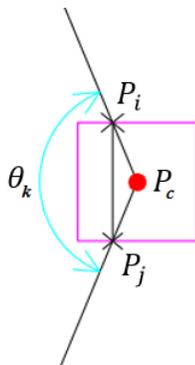
where P_c denotes corner point, P_i and P_j denotes intersection points between mask and polygon sides.


Fig. 3. The Corner Points (P_c) and Intersection Points (P_i, P_j) for Corner Angle Calculation (θ_k).

3) Shape regularity detection: After the corner angle computation, it is required to identify the regularity of the shape. In this regard, a function defines a rule as shown in Equation (5),

$$S(T) = \{(N_{eq} \cong N_T) \text{ and } \left((D(P_{c_i}) \cong D(P_{c_{i+1}})) \forall|u_{i\,N_T}\right) \rightarrow$$
$$S \in Regular \quad (N_{eq} \cong 4) \text{ and } \left(N_{eq} \cong \left[\frac{N_{eq}}{2}\right]\right) \rightarrow S \in$$
$$parallelogram \qquad (5)$$

According the function definition, *S(T)* is defined as the function for determination of shape type. The types of the shape type are regular or parallelogram. This type can be identified using a number of equal angle corners (N_{eq}). As the first statement in *S(T),* If the N_{eq} is approximately equal to total number of corner (N_T) and the distances between corner points are roughly equal, the shape determined as regular shape. Otherwise, if the number of equal angle corners is approximately equal to four and half number of equal angle corners, the shape is determined as a parallelogram.

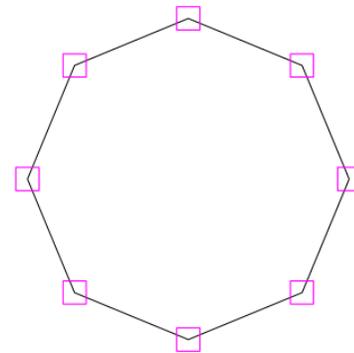
Euclidean distance is used for the distance measurement of corner points. For instance, the Euclidean distance between *i-th* corner points as P_{c_i} and its neighbor as $P_{c_{i+1}}$ is calculated and denotes as $D(P_{c_i})$. Furthermore, a shape is detected as a parallelogram when N_{eq} is equal to a minimum number of $N_T/2$. For example, Fig. 4 shows a regular polygon shape in which the number of equal corners is equivalent to the number of total corners points, and the distances between all the corner points are the same.


Fig. 4. A Regular Polygon with Same Number of Equal Corners and the Distances between the Corner Points.

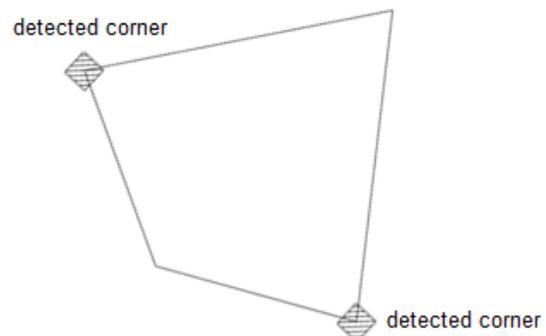
4) Symmetry shape detection: Sometimes the shape is not detected as regular and parallelogram. In this case, the symmetric feature of the shape is checked. Fig. 5 illustrates a non-regular symmetric shape.


Fig. 5. Illustration of a Symmetric Shape.

In the first step, two corresponding corner points are connected through a line, and the mean point of this line is determined P_m. Based on identified P_m, a perpendicular line is drawn and named baseline *(BL)*. Using the *BL*, two correspondence corner points are identified. The length of *BL* is denoted as L_{bl}, which is measured by measuring the longest line connecting the two farthest points from the *S* perimeter. Furthermore, the details of the algorithm are demonstrated in a synthetic symmetry and asymmetry shape as shown in Fig. 6 and Fig. 7.

a) Density Distribution Measurement (DDM)

The *BL* is devised the *S* into two sections (it is called two sides in a shape which is divided in terms of on *BL*). The individual side is defined as a density function as $f(x, y)$. The *DDM* of both sides of the shape is calculated to measure the area side. The *DDM* is based on calculating integral under each space of *BL* sides. A density distribution function using a two-dimensional Cartesian moment m_{pq}, is the order of $p + q$, as $f(x, y)$, can be defined as,

$$m_{pq} = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x^p y^p f(x, y) \, dx \, dy \tag{6}$$

The two-dimensional moment for a $(N \times M)$ discretized image, $g(x, y)$, is:

$$m_{pq} = \sum_{y=0}^{M-1} \sum_{x=0}^{N-1} x^p y^p g(x, y) \tag{7}$$

For a given intensity distribution $g(x, y)$ the image moments is defined. A complete moment set of order n consists of all moments m, such that $p + q \leq n$ and contains $1/2(n+1)$ $(n+2)$ elements. The definition of the zeroth order moment of the distribution, f(x, y),

$$m_{00} = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x, y) \, dx \, dy \tag{8}$$

where m_{00} represents the total mass of the given distribution function or section. The zeroth moment represents the total region area. Therefore, the mass of each side can be measured using zeroth moment. After measuring area mass for each side, the obtained values are compared to identify whether they are close or not. A threshold value defines an acceptable range for the obtained values area mass to distinguish the shape as symmetric.

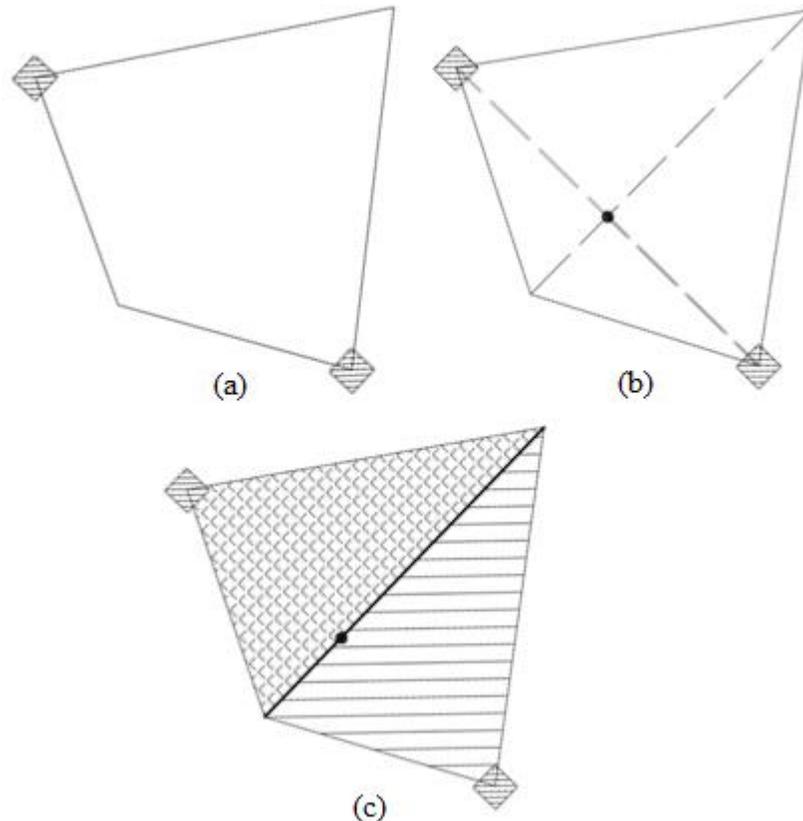
Fig. 6 demonstrates the strategy of regularity and symmetry shape detection shape. As shown in the Fig. 6, the corners of the shape are firstly detected. Secondly, mean metric is calculated using Euclidian distance for each corner pairs as shown in Fig. 6(b). Then a base-line between each corresponding corner points are drawn which intends to divide two are of region for each generated sides of the base-line as shown in Fig. 6(c). Finally, area feature is calculated for each region to check the equality of them. Similar to Fig. 6, the furthest corners of the shape are detected in first step. Then base-line and area region are considered for symmetry measurement and identification.


Fig. 6. Demonstration of Shape Regularity and Symmetric Identification for a Symmetric Shape. (a): Detected Corner, (b): Obtain Mean between Two Corner Points (P_m), (c): Calculate the Area for Region of each Sides.
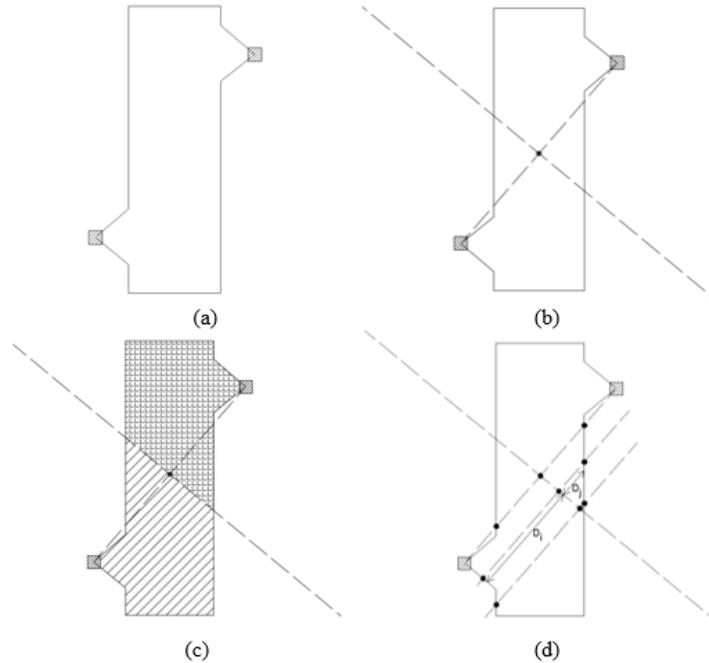

Fig. 7. The Process for Asymmetric Shape Identification.

b) Sampling Point-Line Distance Distribution (SPLDD)

Based on the DDM process, most of the shapes can be detected for symmetry shape identification. However, in some cases like Fig. 7, although the area for two sides of *BL* (the output of the DDM process) are quite similar, they are not symmetric shapes. Meanwhile, using the DDM, they are detected as symmetric shapes though they are not symmetrical.

Our shape detection method considers an algorithm to deal with the *DDM* challenge. The proposed algorithm is adopted from the point line distance distribution (*PLDD*) algorithm [3]. This algorithm is improved with sampling consideration in the *PLDD* algorithm and named Sampling Point-line Distance Distribution (*SPLDD*). The steps of *SPLDD* are as follows: finding the mean point (*Pm*), generating the baseline (*BL*), evaluating the area located on both side of *BL*.

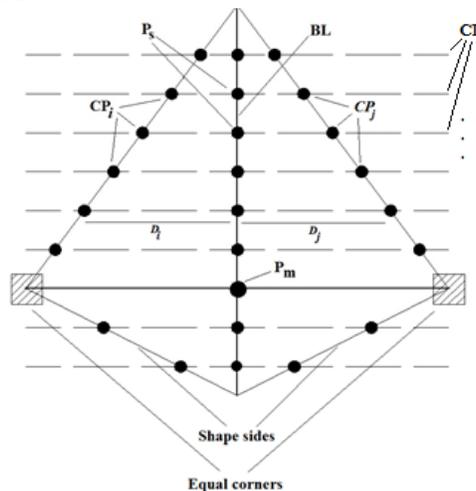
In the *SPLDD* algorithm, as shown in Fig. 8, a set of sample points as P_s are generated on *BL*. In order to generate the P_s points, it is necessary to identify how many P_s are required to allocate on *BL*. For a number of sample points' identification, the length of *BL* (L_{bl}) is considered. Number of P_s denotes as ∂. Different values are tested for ∂ to find the optimum value. In this study, the value of ∂ is identified experimentally, which is $\partial = 10$. Using the value of ∂, the sample points (P_s) are generated. These points are used to draw confluence lines (*CL*). The confluence lines (*CL*) are defined to find the intersection points on *BL*. The *CL* lines touch the sides of the shape *(S)* to find the intersection points around the shape. The intersection points from the *CL* lines are marked as confluences points *(CP)*. Fig. 8 illustrates the details of the proposed *SPLDD* algorithm.


Fig. 8. Graphical Demonstration of *SPLDD* Algorithm.

Since the *CL* lines have an intersection in two opposite sites, two individual points (*CP*) are defined as CP_i (x_i, y_i), CP_j (x_j, y_j). The *CL* lines cross P_s point that defines as P_s (x_s, y_s). The distance between P_s , CP_i and P_s, CP_j (these points are located on a *CL)* are calculated and denoted as D_i and D_j are calculated. This distance measurement uses a Euclidean distance measurement with the following equations,

$$d_i(X) = \sqrt{(x_s - x_i)^2 + (y_s - y_{ij})^2}, \ d_j(Y) =$$

$$\sqrt{(x_s - x_j)^2 + (y_s - y_j)^2} \qquad (9)$$

where the $d(x)$ and $d(y)$ are calculated individually for three points associated with *CL*, however, it is required to perform the distance measurements for all *CP* and *CL*. In this regard, two individual matrices are defined to store all the distance measurements:

$$D(X) = (d_1 (X) \ d_2 (X) \ d_3 (X) \ \vdots \ d_n (X) \,)$$

$$D(Y) = (d_1(Y) \ d_2(Y) \ d_3(Y) \ \vdots \ d_n(Y) \,) \qquad (10)$$

where $d(X)$ and $d(Y)$ contains all the distances between the *CP* and P_s points those are located on the associated *CL*. Using Equation (11), the elements from a matrix are compared to the corresponding distance from another matrix. Consequently, based on the distance comparison, the equal distance of elements is identified, and corresponding points are labeled as True Points (*TP*).

$$\forall \big(d_k (X) \in D(X) \, , d_k (Y) \in D(Y) \big) \qquad (11)$$

$$TP(p_s) = \{ \ p_s \rightarrow true, \qquad d_k (X) \approx d_k (Y), \ p_s \rightarrow false,$$
$$d_k (X) \approx d_k (Y)$$

where the function $TP(p_s)$ contains the true points labeled of p_s points. $d_k (X)$ and $d_k (Y)$ the distance measurements from $d(X)$ and $d(Y)$ matrices. Finally, a number of true points are counted to recognize whether the shape is symmetry or asymmetry. If the number of true points is equal to a defined threshold value, the shape recognizes as symmetry; else, it is asymmetry.

C. Experimental Results and Performance Evaluation

This section presents the experimental results and performance evaluation for the proposed method. For experiments, sample images are firstly generated using addition and applying some image processing operators, including noise and blurring. Secondly, two measurements: the number of correct and false detection variables, are used to measure the performance of the proposed method. Then, the evaluation analysis of the experimental results is presented. The evaluation analysis consists of performance and processing-time measurements.

As mentioned earlier, the sample images are generated based on PLDD experiments [3] for the shape detection experiments. For all the sample images, an image consists of different types of shapes (including regular and symmetry shapes): circles, squares, and regular triangles. Furthermore, for the sample images, Gaussian noise, Pepper & Salt noise, Gaussian blur, and JEPG compression are applied to generate the images for experiments. The generated sample images are organized into different categories-based range of noises scale and compression ratio, as shown in Table I. For example, two generated sample images from Gaussian noise and blur categories are shown in Fig. 9.

TABLE I. GENERATED OF SAMPLE IMAGES UNDER DIFFERENT CATEGORIES

Category	Operator type	Parameter	Range
1	Gaussian noises	Noise variation	0.01–0.04
2	Pepper & Salt noise	Noise density	0.01–0.06
3	Gaussian blur	Scale	0.5 to 3
4	JPEG compressed image	Compression ratio	from 1.33 to 6.02

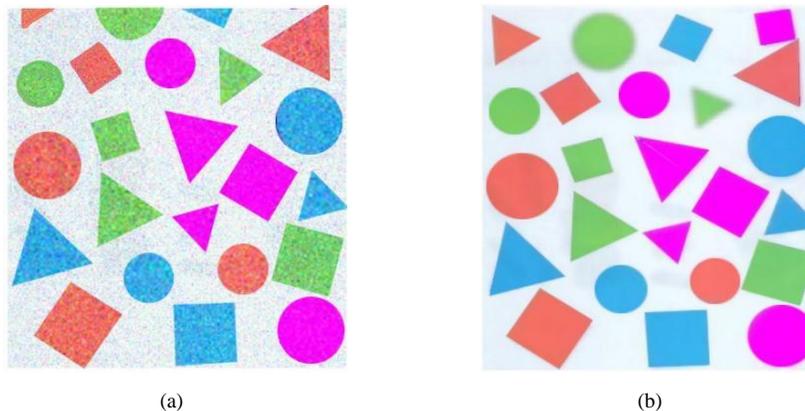
(a)   (b)


Fig. 9. The Images from Dataset for Shape Detection Experiments and Evaluation (a) Gaussian Noise (Variance = 0.01), (b) Gaussian Blur (Scale = 2.5) [3].

D. Performance Evaluation

This section presents the performance evaluation for the proposed shape detection method. As presented in [3], two measurements are used to evaluate the performance. The measurements are the number of corrected shapes (*CN*) (true detection) and the number of false ones (*FN*) (false detection). The sum of the *CN* and *FN* are calculated using Equations (12) and (12),

$$CN = \sum_{i=1}^{N} N_T$$

$$FN = \sum_{i=1}^{N} N_F \qquad (12)$$

$$Acc = \sum_{i=1}^{N} \frac{CN}{CN+FN}, \qquad (13)$$

where N_T and N_F are represented for true and false measurements. The *Acc* denotes accuracy measurement. The measurements are applied in the dataset containing the generated sample images considering defined noise categories, as shown in Table I. Then, the obtained results from the proposed method are compared to other methods, including the PLDD [3] and radial symmetry nature and direction-discriminated voting (RSNDV) [21] method, as shown in Table II.

As shown in Table II and Table III, in the noises categories, including Gaussian and Pepper & Salt noises, all methods, with increasing noises, the performance would be decreased due to decrease true detection and increased false detection. Based on the comparison, the proposed method achieved higher performance than other methods. The PLDD method also presented better performance when compared to the RSNDV method. The poor performance is because the method uses contour points for shape detection. The RSNDV method may miss some corner points that lead to false detection of shapes.

As shown in Table IV, in contrast to other categories, for both CN and FN measurements, the RSNDV method is the prior method compared to the proposed and PLDD methods. The reason for this can be using the voting approach and contour points features for shape detection in the RSNDV method. Using these features, the shape detector (RSNDV method) can detect shapes more accurately. However, in noise categories, the results are not the same with blur cases.

As shown in Table V, the proposed method roughly achieved better performance than other methods. In high ratio compression, the RSNDV method achieved higher performance in a number of correct shape detection; meanwhile, the PLDD and our proposed method archived promising results in lower compression ratio. However, with a lower compression ratio, our proposed method presented a better performance in false detection. Furthermore, the average processing time for the categories is calculated, and a comparison between our proposed method and other methods is illustrated. To calculate the average processing time, Equation (14) is used,

$$T_a = \frac{1}{N}\sum_{i=1}^{N} T_i \qquad (14)$$

where T_a indicates the average processing time for each category, an individual category's processing time (for example, the processing time for each Gaussian noise), and the number of experiments for each category. Table VI shows the comparison of average processing time for PLDD [3], RSNDV method, and the proposed method.

The processing time presented in Table VI for PLDD and RNSDV is based on Liu and Wang's [3] work. As shown in Table VI, the processing time is significantly reduced to be helpful in real-time applications. It is achieved by using the new SPLDD method, which is based on a sampling of points between the corner points instead of whole contour information.

TABLE II. PERFORMANCE COMPARISON BASED ON GAUSSIAN NOISE (CATEGORY 1)

Methods		Noise Range						Acc
		0.01	0.02	0.025	0.03	0.035	0.04	
PLDD	CN	24	24	23	21	21	18	0.86

TABLE VI.   COMPARISON OF AVERAGE PROCESSING TIME FOR PLDD, RSNDV METHOD AND THE PROPOSED METHOD (IN TERMS OF SECONDS (S))

8	Gaussian noise	Pepper & Salt	Gaussian blur	JPEG compression
PLDD	24.39	26.73	24.29	25.27
RSNDV	163.68	146.48	70.58	88.77
HiSD	3.21	4.74	3.98	4.43

IV.   CONCLUSION

This paper presented a shape detection method based on hierarchical and sampling point line distance distribution algorithms. The fundamental concepts of different shapes are first defined. The existing shape detection methods are reviewed, and the recent and relevant study is addressed. Based on the literature review, the PLDD method has shown promising results in arbitrary and regular shape detection. However, this method suffers from some challenges, such as a lack of efficiency in shape detection in different types, including rotationally convex symmetry, ellipse, and parallelogram. Therefore, this study proposed a new shape detection method called hierarchical shape detection (HiSD) to detect the shapes in hierarchical processes. In HiSD, a new algorithm with consideration of sampling point line distance distribution (SPLDD) algorithm was proposed to deal with PLDD challenges. The proposed shape detection method is not sensitive to specific category of objects. It enables to detect different types of objects involving the arbitrary, regular, and symmetry shapes. Furthermore, the proposed method is not based on high complexity and computation cost approaches which is applicable in real time applications. The experiments and comparative analyses are performed using different shapes and noise conditions to validate the effectiveness of the proposed method. The experimental results showed that the proposed shape detection method enables detection of different types of shapes, including circle, eclipse, regular, and symmetry shapes in different noise condition scenarios. For future works, this proposed method can be extended for irregular shape detection as they typically exist in real environment. Moreover, the proposed system can be implemented in real-time shape detection to extend the application of current research work.

Abstract—The quality of computer vision systems to detect abnormalities in various medical imaging processes, such as dual-energy X-ray absorptiometry, magnetic resonance imaging (MRI), ultrasonography, and computed tomography, has significantly improved as a result of recent developments in the field of deep learning. There is discussion of current techniques and algorithms for identifying, categorizing, and detecting DFU. On the small datasets, a variety of techniques based on traditional machine learning and image processing are utilized to find the DFU. These literary works have kept their datasets and algorithms private. Therefore, the need for end-to-end automated systems that can identify DFU of all grades and stages is critical. The study's goals were to create new CNN-based automatic segmentation techniques to separate surrounding skin from DFU on full foot images because surrounding skin serves as a critical visual cue for evaluating the progression of DFU as well as to create reliable and portable deep learning techniques for localizing DFU that can be applied to mobile devices for remote monitoring. The second goal was to examine the various diabetic foot diseases in accordance with well-known medical categorization schemes. According to a computer vision viewpoint, the authors looked at the various DFU circumstances including site, infection, neuropathy, bacterial infection, area, and depth. Machine learning techniques have been utilized in this study to identify key DFU situations as ischemia and bacterial infection.

Keywords—Magnetic resonance imaging (MRI); diabetic foot ulcers (DFU); convolutional neural networks; ischemia& machine learning algorithms & dual-energy x-ray absorptiometry

I. INTRODUCTION

Hyperglycemia (high blood sugar levels) is a chronic illness that causes diabetes. Diabetes can cause serious, life-threatening consequences such renal failure, cardiovascular disease, blindness, and lower limb amputation, which is frequently followed by DFU [6]. According to the World Health Organization's worldwide report on diabetes in 2020, there were 522 million people living with DM in 2018, up from 108 million in 1980. Global incidence among people over the age of 18 increased from 4.7% in 1980 to 8.5% in 2014. According to estimates, there will be 600 million individuals living with DM globally by the end of 2035. According to this estimate, only 20% of these individuals will come from industrialized nations, with the remainder coming from poorer

nations due to low awareness and a lack of healthcare resources [9]. A diabetic patient has a 15%–25% probability of developing DFU at some point, and if necessary precautions are not followed, that might lead to lower limb amputation [8] [10] [15]. However a more recent research [11] [12] suggests higher rates of up to 34%. It has been noted that more than one million patients suffer on average each year [30]. Several significant duties are carried out during the early diagnosis for the evaluation of DFU by monitoring the course of the condition and the number of time-consuming steps made in its treatment and management for each individual case:

1) The examination of the patient's medical history is performed.

2) A specialist in wound or diabetic foot studies the DFU in depth [13] and.

3) Additional tests, such as MRI, CT scans, X-rays, etc., may be helpful in developing the treatment plan.

Leg swelling is a common issue for DFU sufferers, and depending on the specific instance, it may also be itchy and unpleasant. The DFU often has erratic architecture and ambiguous exterior limits. Different phases, such as callus development, redness, blisters, and important tissue types including slough, scaly skin, granulation, and bleeding, all have an impact on the aesthetic appearance of DFU and the skin around it. Clinicians now monitor patients in healthcare settings mostly by visual inspection in order to identify critical problems including infection, area, depth, ischemia, neuropathy, and placement. The likelihood of an infection spreading by DFU is always increased. Therefore, patients must frequently attend healthcare facilities for DFU examination, adding to the cost burden on both patients and healthcare facilities.

The body of existing material on DFU assessment by adaptation of computerized algorithms is still in its infancy. There aren't many computerized approaches for the evaluation of diabetic foot diseases since this way of DFU analysis applying computerized methods is still a relatively new subject. Instead, simple image processing and conventional machine learning are used. The study of computer vision has advanced quickly in recent years, especially with regard to challenging and crucial problems such comprehending pictures from many

domains as spectral, non-medical items, anomalies in medical imaging, and face feature detection [16][19]. Particularly in the area of medical imaging, computer vision algorithms have made significant strides.

The quality of these computer vision systems in detecting abnormalities in different medical imaging, such as "Magnetic Resonance Imaging" (MRI), ultrasonography, dual-energy, X-ray absorptiometry, and computed tomography [26] has been significantly improved by the recent advancement in the field of deep learning. Recent advancements in computer vision and deep learning have made it possible for us to offer complete solutions for DFU recognition. Over a five-year period, a sizable dataset of DFU was gathered from several patients with varying backgrounds at the chosen hospitals in Bengaluru.

End-to-end algorithms, which have the potential to be used to adapt these algorithms to real-world contexts [7] [24] [25] are a major driving force behind the rapidly expanding study fields of medical imaging and computer vision. The capacity of algorithms to detect DFU of various stages and grades has been the main focus of DFU recognition research. Additionally, algorithms must be strong enough to identify DFU in patients with a range of ethical backgrounds. Then, by identifying crucial factors including site, area, depth, infection, and ischemia, a deeper understanding of DFU [18] might be offered. Therefore, creating reliable computer vision algorithms that could analyze the DFU with more accuracy and high precision has the potential to bring about a paradigm change in the treatment of diabetes patients' feet, which would be a cost-efficient, easy, and remote healthcare option.

II.   STATEMENT OF THE PROBLEM

Research in this topic is sparse and frequently exploratory rather than task-focused because it is still in its infancy. The current approaches and techniques for identifying, classifying, and detecting DFU are addressed. On the small datasets, a variety of techniques based on traditional machine learning and image processing are utilized to find the DFU. These literary works never released the datasets and algorithms they used. Therefore, end-to-end automated systems that can identify DFU at all stages and grades are required. It is important to note that no publicly accessible DFU databases are available for study [2] [4]. Modern computer identification methods and medical imaging are mostly dependent on deep learning models at this time. Neural networks are used in deep learning models to somewhat mimic how the human brain operates. Consequently, a sizable collection of DFU photos and professional annotations are required for training the deep learning models. Expert physicians are needed to do these annotations in order to provide ground truth, which makes them expensive. These visual expert annotations in the current DFU dataset are done out by podiatrists who are skilled in DFU. In addition, there may be additional contributing elements, such as the patient's ethnic background and the lighting circumstances.

III.   OBJECTIVES OF THE STUDY

1) To create novel CNN-based automated segmentation techniques to separate surrounding skin from DFU on complete foot pictures since surrounding skin serves as a crucial visual gauge for DFU development.

2) To create reliable and portable deep learning techniques for DFU localization that can be used in mobile devices for remote monitoring.

3) To examine the various diabetic foot diseases in accordance with widely used medical categorization schemes.

IV.   EXPECTED OUTCOME OF THIS STUDY

1) In complete foot photos, experts accurately outlined the DFU and the surrounding skin region. For the first time, the surrounding skin is segmented, which is a crucial sign for physicians evaluating the development of DFU. For the semantic segmentation [22] of DFU and the skin around it, we suggested using two-tier transfer learning segmentation techniques.

2) The huge DFU dataset of 1775 pictures and the Foot Snap dataset are used to evaluate cutting-edge deep learning localization techniques. For remote DFU monitoring, we adapted the durable and lightweight models to portable devices like the Nvidia Jetson TX2 and a Smartphone Android application.

3) According to a computer vision viewpoint, the authors looked at the various DFU circumstances including site, infection, neuropathy, bacterial infection, area, and depth. The identification of crucial DFU circumstances including ischemia and bacterial infection has been done in this research using machine learning methods.

V.   RESEARCH METHODOLOGY

The medical facilities for patients are becoming a major worry, especially for industrialized nations, because to the limited healthcare settings accessible, the growing global population, and the financial strain. The use of computerized telemedicine systems is frequently suggested as a potential remedy for this issue. When it comes to the creation of cutting-edge healthcare systems, the spread of "Information and Communication Technologies" (ICT) brings both opportunities and difficulties. Before establishing an efficient recognition system using DFU pictures, there may be a number of problems for any computerized DFU recognition algorithm that need to be overcome. Several research difficulties are identified based on a study of the current literature that are high levels of similarity within classes between healthy skin and abnormal classes (DFU) in the foot area [1] changes within classes based on the classification of DFU [3] lighting conditions; and ethnicity of the patient.

Another obstacle to accurate diagnosis of DFU is the variations in the visual appearance of the DFU and the skin around it, such as callus development, redness, and blisters, substantial tissue types including slough, granulation, bleeding, and scaly skin depending on the various phases. Because of this, using computer vision algorithms to analyze and recognize DFUs might be exceedingly difficult. It is a difficult annotation work for podiatrists to create ground facts for the segmentation of DFU and the skin around it since these

structures typically have ill-defined outside limits and highly irregular features.

The medical categorization systems say that there are currently no technical ways for identifying the result of DFU. Even for medical professionals, it can be challenging to identify and analyze DFU from a picture. Computer vision algorithms to detect DFU are increasing, but they still have a long way to go before they are as well-established as analysis according to medical categorization systems.

VI. METHODOLOGY

The suggested approach provides feature descriptors, classifiers, and Natural Data-Augmentation utilized in conventional machine learning. This also includes a brief summary of the experimental conditions and deep learning methodologies. To forecast the fate of DFU, the DFU are categorized medically according to many parameters, including size, area, neuropathy, ischemia, and infection. These systems now rely on the clinician's observations and clinical judgments.

These findings will explain why each goal was set and how it was accomplished. With the advancement of computer vision, particularly deep learning techniques, the diagnosis and detection of DFU by a computerized method has become an active study field. In this study, we studied the application of deep learning as well as traditional machine learning for the identification and analysis of DFU. With the help of a traditional machine learning approach, we managed to attain a respectable performance. However, this strategy is highly sluggish for DFU identification jobs because of the several intermediary stages. To identify DFU on the whole foot photos with high accuracy using deep learning, we employed various architectures to train end-to-end models on the DFU dataset with various hyper-parameter values. These techniques have a fast inference rate and can localize and segment numerous DFU. The DFU patch image its region identification of foot ulcer [17] is shown in Fig. 2(a) and Fig. 2(b).

VII. APPLICATION OF CONVOLUTIONAL NEURAL NETWORKS

Deep learning techniques are utilized to perform binary classification to categorize, namely (1) infection and non-infection; (2) ischemia and non-ischemia classes in DFU patches, in order to compare with the traditional characteristics. Modern CNN models like Inception-V3, ResNet50, and InceptionResNetV2 were fine-tuned (transfer learning from pre-trained models) for this purpose.

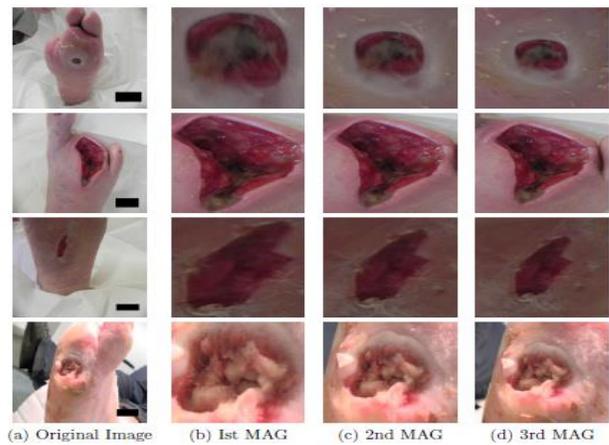
A revised version of the original Inception architecture, called Inception-V3, was created by the Google team and includes additional capabilities including enhanced normalization and the decomposition of larger convolution kernels[23][27][28] into a number of smaller convolution kernels. In this network, the earliest layers of the design employ depth-wise separable convolutions to speed up the calculations involved in down sampling the input pictures. In order to increase convergence during training, they also devised a batch normalization layer that may reduce internal covariate shift and address the gradient vanishing problem [31].


Fig. 1. Representation of Original Image of Various Types of Diabetic Foot Ulcer.
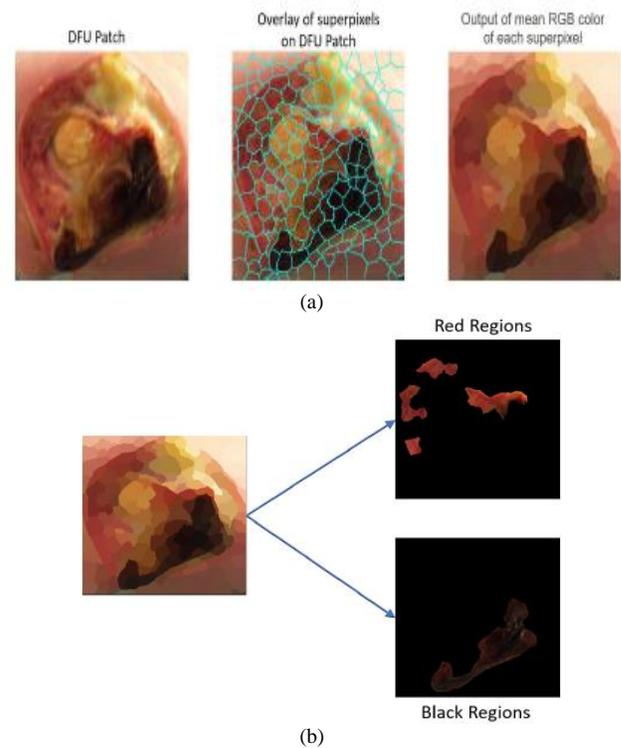

Fig. 2. (a) DFU Patch Image of Diabetic Foot Ulcer, (b) Representation of DFU Patch Image its Region Identification of Diabetic Foot Ulcer.

ResNet50 is a slimmer iteration of ResNet101, which took first place in the ILSVRC classification challenge. The fundamental principle of ResNet is to provide a short-cut link between layers in order to maximize representation from both the initial and subsequent layers during network training. Inception ResNetV2 is an extremely deep network that combines the advantages of residual and inception learning, networks for learning, as their name indicates. It is modeled after the InceptionV3 architecture and uses the remaining connections between the layers to train deeper neural networks [5] which must result in improved performance. On several typical datasets, it produced new, cutting-edge accuracy outcomes.

VIII. RESULTS AND DISCUSSION

We used the five-fold cross-validation approach and divided the datasets for infection and ischemia into three parts: training, validation, and testing [14]. Therefore, we utilized about 6909 patches, 987 patches, and 1974 patches in the training, validation, and testing sets for the ischemia dataset using the suggested approaches, but for the infection dataset, we used 4124 patches, 589 patches, and 1179 patches from the 1459 original foot photos. As previously noted, for the classification job, we employed both TML models and CNNs models, and the input for CML, InceptionV3, Alex Net, and ResNet50 was 256 x 256 RGB photos. The dataset for InceptionResNetV2 was scaled to 299 x 299 pixels.

As our assessment measures, we list Accuracy, Sensitivity, Precision, Specificity, F-Measure, and MCC in Tables I and II. Sensitivity and specificity are regarded as trustworthy assessment measures for classifier completeness in medical imaging [20] [21].

When comparing the results, the TML and CNN approaches outperformed the other methods in the binary classification of ischemia over infection. The average accuracy of all the models in the ischemia dataset is 82.1%, which is much better than the average accuracy in the infection dataset, which is 64.6%. With an average MCC Score for ischemia classification of 64.8% being higher than the infection

classification of 30.1%, MCC score is thought to be a realistic performance metric for the various machine learning algorithms for classification. CNNs fared better than TML models (85.2%) when their performances were compared (compared to 79% for TML models). The accuracy of CNNs (67%) outperformed TML (62.1%) in the infection classification task by a margin of 4.9%. ResNet50 earned the greatest overall score in the ischemia categorization.

1) Discussion and analysis of experiments for the restricted number of medical professionals and healthcare facilities, analysis of DFU situations using automated technologies is crucial. This study performs the preliminary experiment of binary categorization of ischemia and infection of DFU. The primary goal of this experiment is to determine the ischemia and infection situations when computer vision algorithms are most likely to make errors. Few instances of correctly and erroneously identified cases in both binary categories of ischemia and infection are presented in Fig. 1(a), (b), (c), and (d).

Regarding the incorrectly categorized instances, (1) infection and non-infection; (2) ischemia and non-ischemia cases in the DFU have significant intra-class differences and significant inter-class similarities, making it challenging for classifiers to forecast the correct class.

TABLE I. THE PERFORMANCE METRICS FOR THE BINARY CATEGORIZATION OF ISCHEMIA BY CNNs AND CONVENTIONAL MACHINE LEARNING ARE SHOWN IN THE TABLE, WHERE MCC STANDS FOR MATTHEW CORRELATION COEFFICIENT

Other variables that affect how these disorders are classified include the lighting, markings, tattoos, and skin tone as a result of the patient's ethnicity. As seen in Fig. 3(a) and Fig. 3(b) of misclassified non-ischemia is hampered by the illumination and the tattoo, respectively.

The ischemia traits in the incorrectly classified ischemia cases (c) and (d) are, in contrast, too subtle for the algorithm to detect. In Fig. 4, it can be shown that situations illustrated in (a) and (b) where blood is present are mistakenly labeled as non-infections; yet, the situation in (b) represents one of the dataset's unusual instances, namely the existence of ischemia and non-infection. The visual signs of illness in cases of misclassified infection were too subdued in these circumstances. The existing realities aren't supported by clinical trials or medical records; they're just based on specialists' eye inspections. Furthermore, prior to the recording of these photos, debridement was mocked with DFU images. As a result, the debridement of DFU eliminated the crucial visual markers of infection, such as colored exudates. Therefore, in the future, the sensitivity and specificity of these algorithms might be enhanced by feeding in ground truth from clinical tests like vascular evaluations (ischemia) and blood tests for detecting the existence of any such bacterial infection.

IX.   CONCLUSION

These conclusions will explain why each goal was set and how the result was attained. With the advancement of computer vision, particularly deep learning techniques, the diagnosis and detection of DFU by a computerized method has become an active study field. In this study, we studied the application of deep learning as well as traditional machine learning for the identification and analysis of DFU. With the help of a traditional machine learning approach, we managed to attain a respectable performance. Nevertheless, this strategy is highly sluggish for DFU identification tasks because of the several intermediary phases. To identify DFU on the whole foot photos with high accuracy using deep learning, we employed various architectures to train end-to-end models on the DFU dataset with various hyper-parameter values.

These techniques have a fast inference rate and can localize and segment numerous DFU. Then, to demonstrate how the localization techniques may be quickly moved to a portable device, the Nvidia Jetson TX2, to generate inference remotely, a demonstration was conducted. In order to provide real-time DFU localization [29] these deep learning techniques were finally applied in an Android application. In this work, we

developed mobile systems that can help patients and medical professionals in remote settings with DFU diagnosis and follow-up. Although the various algorithms for classification, segmentation, and localization approaches received extremely excellent accuracy, there were some restrictions on the detection of DFU in some specific situations, such as pre-ulcer circumstances and very tiny DFU with subtle traits. The majority of the DFU photos used in the present DFU dataset were taken at Lancashire Teaching Hospital, where DFU had already progressed to a large degree in most cases. Pre-ulcer and modest DFU were only detected in a very small number of patients. Therefore, additional instances of DFU of these grades are required in the DFU dataset in order to strengthen algorithms' ability to recognize these specific DFU.

Energy Consumption Reduction Strategy and a Load Balancing Mechanism for Cloud Computing in IoT Environment

Tai Zhang, Huigang Li

Hebei Software Institute

Hebei Baoding 071000, China

Abstract—**Modern networks are built to be linked, agile, programmable, and load-efficient in order to overcome the drawbacks of an unbalanced network, such as network congestion, elevated transmission costs, low reliability, and other problems. The many technological devices in our environment have a considerable potential to make the connected world concept a reality. The Internet of Things (IoT) is a research community initiative to bring this idea to life. Cloud computing is crucial to making it happen. The load balancing and scheduling significantly increase the possibility of using resources and provide the grounds for reliability. Even if the intended node is under low or high loading, the load balancing techniques can increase its efficiency. This paper presents a scheduling technique for optimal resource allocation with enhanced particle swarm optimization and virtual machine live migration technique. The proposed technique prevents excessive or low server overloads through optimal allocation and scheduling tasks to physical servers. The proposed strategy was implemented in the cloudsim simulator environment and compared and showed that the proposed method is more effective and is well suited to decreasing execution time and energy consumption. This solution provides grounds to reduce energy consumption in the cloud environment while decreasing execution time. The simulation results showed that the amount of energy consumption compared to particle crowding has decreased by 10% and compared to PSO (Particle Swarm Optimization) scheduling by more than 8%. Also, the execution time has been reduced by 18% compared to particle swarm scheduling and by 8% compared to PSO.**

Keywords—Internet of things; load balancing; cloud computing; virtual machine migration

I. INTRODUCTION

Cloud computing is a computing model based on large computer networks such as the Internet, which provides a new model for the supply, consumption, and delivery of information technology services (including hardware, software, information, and other shared computing resources) using the Internet. Naturally, every change and new concept in the world of technology has its own advantages, problems, and complications [1]. Using cloud computing is not an exception to this rule. Among the advantages of cloud computing, we can mention the lack of time and place restrictions, simple sharing of resources, as well as the reduction of capital and operational costs (the most important advantage), because in fact, cloud computing dynamically provides scalable resources as a service on the Internet and has also put many challenges in

front of experts in this field, among which we can mention things like: resource allocation and load balancing, security, reliability, ownership, data backup and data portability [2, 3, 34]. Meanwhile, resource allocation and load balancing in cloud computing are of great importance. This issue has been discussed in various fields such as operating system, cluster computing and data center management. A resource allocation system in cloud computing can be considered as any mechanism whose purpose is to ensure that the requirements of applications are met [4, 36]. In addition, the resource allocation mechanism must examine the current status of each resource in the cloud environment in order to provide algorithms for better allocation of physical resources or virtual resources and thus reduce operational costs in the cloud environment. It is clear that due to the scale and complexity of these systems, the centralized assignment of tasks to a specific server without considering specific solutions is actually impossible, and also due to the increasing load and volume of requests in advanced data centers and the urgent need to achieve quality. For optimal service, the need for solutions to increase the efficiency of existing servers in the data center is felt. One of the ways to achieve optimal productivity is to use scheduling and load balancing solutions [5, 33]. This technology, with its high potential of cloud computing for storing and processing data remotely, has provided a new computing model. Recently, instead of using domestic resources, many large companies have outsourced them to cloud computing [6]. So users can access their data anywhere in the world, and they do not need high-performance hardware and storage systems because all computing and storage operations are performed by cloud service providers and well-equipped and advanced servers. Meanwhile, the scheduling and resource allocation problem in cloud computing is important because it directly affects the amount of energy consumption and reduction of latency in service provision [7]. A scheduling system in cloud computing can be any mechanism to ensure the provision of application requirements. In addition, the scheduling mechanism should examine the current status of each source in the cloud environment to provide algorithms for better allocation of physical or virtual resources and thus reduce operational costs in the cloud environment. That is because, during the processing, a number of servers might have a high traffic load. During the load distribution among servers with less load, the idle servers can be turned off to reduce energy consumption [8, 35, 26]. In this study, a PSO algorithm is suggested for scheduling and ideal load balancing in the cloud infrastructure

in order to reduce energy usage in cloud computing environments' data centers. The proposed technique prevents server overloads or low load through the optimal assignment of tasks to physical servers. This research is also important from another aspect that with the increase of users and their different requests, the following situations may occur:

- The virtual machine may be performing an operation and not accept another request.

- The request should be made on a new car.

- The request should be applied to a machine that is busy and does not have enough capacity to receive new ones.

- Migration may take place.

Therefore, a solution must be provided to manage these challenges. When the bandwidth of a virtual machine is full, the central cluster sends requests to another machine. At this stage, an algorithm is needed to balance the load and choose the right processing server. Based on this, a solution based on the improved particle community optimization algorithm is presented for efficient scheduling and as a result optimal load balancing in the cloud infrastructure, so that the task execution time can be reduced by broadcasting the requests and in As a result, it helped to manage energy consumption for users. In this research, as an innovation, for the purpose of scheduling, a combined method of particle swarm optimization and virtual machine live migration technique has been used to balance the load using an optimal schedule. The use of combined methods for load balancing has not been much considered in other researches. Also, the goals and contributions of the authors in this research are stated as follows:

- Creating load balance and reducing response time to users' requests.

- Balancing load in cloud network using particle swarm algorithm and task migration.

In the continuation of our paper, it is configured as follows. The next section, which discusses prior works in the area of cloud computing in the IoT context, presents a list of related works. In this section's conclusion, the current works' characteristics are given in table format for different criteria. Section III describes the proposed approach in three parts: problem-solving formulation, H algorithm based on scheduling, and virtual machine migration. The performance evaluation for energy consumption parameters and execution time is given in Section IV. The analysis of the comparison between the suggested approach and the current works is presented as a table in the fifth part. In the last part, the conclusion of the research is given.

II. PREVIOUS WORKS

This section looks at concerns like access control and load balancing for cloud computing networks. Also, the discussion related to the Internet of Things environment is covered. A method based on efficient workload distribution and resource management is suggested in reference [9] employing a cloud computing framework. In this approach, clustering learning techniques are employed to decrease network edge energy consumption as well as processing and communication delays. A similar strategy is presented in reference [10] to build a true edge cloud ecosystem. In the Internet of Things, a capillary computing architecture for orchestrating microservices from edge devices to cloud computing providers is suggested in reference [11]. An Edge-Fog-Cloud environment is described as a distributed cloud for IoT computing in reference [12]. The authors also review a cloud computing offloading strategy for simultaneous localization and mapping of indoor mobile robots in reference [13]. A trust management technique is described in reference [14] to enhance a distinct perspective on the cloud environment and to enable a blockchain-based cloud computing architecture. A safe offloading technique based on machine learning is also suggested in reference [15] for cloud computing, which expands the potential of IoT for applications related to smart cities. A semantic model-based strategy for IoT data description and discovery for IoT-Cloud architecture is presented in reference [16]. They suggested a method for optimizing energy consumption in a set of heterogeneous computing groups to serve various web applications in one of the earliest studies in scheduling and power management [17]. The suggested method decides whether to turn on or off the nodes to reduce total energy consumption while controlling the resources sporadically. In order to reduce power consumption, the request scheduling issue for multi-layer web applications was researched in [18]. It was suggested in [19] to use Power-Aware Tasks Scheduling (EATS) to divide and schedule vast amounts of data in the cloud. This model's primary objective was to improve application efficiency and lower energy usage in subsurface resources. According to [20], the grouped tasks scheduling (GTS) algorithm is used to plan out the tasks in a network of cloud computing services while considering customer needs for service quality. The suggested algorithm creates five groups to split tasks belonging to each group and share characteristics such as user type, task type, job size, and work delay. In order to run task-based efficient programs on distributed operating systems and save energy, a real-time dynamic scheduling system was developed [21]. There is currently no optimal multiprocessor solution for the NP-hard job scheduling problem. Therefore, a polynomial algorithm is suggested in [22] that combines exploratory principles and resource allocation strategies to locate suitable solutions quickly. Table I provides a comparison of the aforementioned techniques. The comparison is based on the purpose, the preferred method, and the result of the work.

III. PROPOSED APPROACH

This section provides the particle swarm optimization algorithm, and the virtual machine lives migration technique to create optimal load balancing in the cloud infrastructure. Using this solution, the execution time of the tasks decreases, and the energy consumption is also reduced. Accordingly, the formulation of the solution is presented below.

A. Formulation of the Solution

Since mapping the workflow of a program to distributed resources can have several goals, the present study is focused on two goals: energy consumption and traffic consumption. The two targets are formulated as follows.

Studies in [23] have demonstrated that a linear relationship between energy consumption and CPU sufficiency can correctly describe the energy consumption of servers. As a result, the following model describes how much energy a physical machine uses in a cloud environment:

$$P_j = \begin{cases} \left(P_j^{busy} - P_j^{idle}\right) \times U_j^p + P_j^{idle}, & U_j^c > 0 \\ 0 & , \text{ otherwise} \end{cases} \quad (1)$$

Where:

P_j: Energy consumption of the physical machine j

P_j^{idle}: The average energy consumption of the physical machine j when it is idle

P_j^{busy}: The average energy consumption of the physical machine j when it is busy

U_j^p: The normalized amount of processor consumed by the physical machine j

$U_j^c > 0$: The physical machine j is on

The main idea behind this kind of modeling is to convert the less-busy physical machines into idle and then turn them off. In this relation, P_j^{busy} and P_j^{idle} are constant values which are 162 and 215 watts for Dell physical machines.

The following equation is used to calculate the network bandwidth consumption and traffic generated by each physical machine:

$$D_j = \sum_{\forall m \epsilon V_j} \lambda(j,m) \sum_{i=1}^{\rho(j,m)} C_i \quad (2)$$

Where:

D_j: The communication between the physical machine j and other physical machines

$\lambda(j,m)$: Traffic load between the physical machine j and other physical machines

V_j: The set of physical machines communicating with the physical machine j

C_i: The weight of communication link between two physical machines at level i

$\rho(j , m)$: The level of communication between the physical machines m and the physical machine j

Moreover, the approach presented in [24] is used to model resource usage. The model is predicated on the idea that the devices' power consumption and processor productivity truly follow a linear relationship. To put it another way, the knowledge about a task's processing time and CPU efficiency is sufficient to determine its power usage. The definition of efficiency for a resource like ri at any given time is as follows:

$$U_i = \sum_{j=1}^{n} u_{i,j}$$

Where n is the number of currently active tasks and uij is the number of resources task tj uses. As a result, the following formula is used to determine the energy consumption (Ej) of the rj resource:

$$E_j = (P_{max} - P_{min}) \times U_i + P_{min} \tag{3}$$

In this case, Pmax is the maximum power consumption (i.e., at 100% efficiency), and Pmin is the minimum energy consumption per minute when the server is active (or at 1% efficiency).

B. Load Balancing Processes

Based on the above strategies, the main steps for load balancing are as follows:

- Calculating the transfer probability for all its neighbors and selecting the largest one as the next destination.

- Moving to a new node and checking if it is a candidate node; if the answer is yes, a migration should be created and initialized. For advanced migration, you have to go back to the first step.

- Retrograde migration returns to the starting point of the corresponding leading ant and in the same direction as the leading migration. During the route, the information related to the pheromone of each node that the backward migration passed through was updated and if it reached the starting point, it deleted the backward migration.

- Calculating the total resources of the candidate nodes and if the nodes need to perform load balancing operations, these steps will be stopped.

- Finally, in the last step, the load balancing operation should be performed using the live migration of the virtual machine.

- These steps for max-min rules also; it is similar except in the step of calculating the transfer probability.

C. Particle Swarm Optimization based Scheduling

Now, based on the relations presented in the previous section using the PSO algorithm for scheduling is discussed. Other evolutionary algorithms and the PSO algorithm are comparable. The population in PSO is the same as the number of particles in the problem space. Initialization of the particles is random. Every particle will have a compatibility value, which will be evaluated by the compatibility function, which ought to be optimized for every generation. This algorithm attempts to identify the best solution by updating generations after first creating a collection of particles at random [25]. In actuality, each particle chooses the best location (pbest) and position from the gbest particles. Each particle's pbest represents its best outcome to date, while its gbest represents its best compatibility with the entire population. Each generation will update the particle positions and velocities using relations (4) and (5), respectively:

$$v[\ ] = v[\ ] + \tag{4}$$

c1 * rand() * (pbest[ ] - position [ ]) +

c2 * rand() * (gbest[ ] - position[ ])

$$position[\ ] = position[\ ] + v[\ ] \tag{5}$$

The first part of equation (4) is the particle's current velocity. In contrast, the second and third portions are the particle's change in velocity and its rotation toward the best individual experience and collective experience, respectively. The initialization of the particle position and velocity in the PSO algorithm is random. The given tasks in this study are the particles, and the size (dimension) of the particles represents the total number of tasks in the workflow. The processing resource indices are the values assigned to each particle dimension. Each particle, then, represents the mapping of a resource to a job. Each particle is assessed using the compatibility function provided in relations (1) and (2). Equation (3) is used to calculate the velocity of particles, while Equation (3) is used to update their location (4). This assessment continues until it reaches a certain number of repetitions.

The PSO-based scheduling algorithm is presented in Fig. 1. For scheduling by PSO algorithm, the initial step is calculating the traffic cost between resources using equation (2) based on the current network load. The algorithm then distributes completed tasks to resources by PSO's mapping. Then, according to the number of accomplished tasks, the list is ready to be updated, including tasks that their father completes. Following that, the energy wastage cost is calculated. These steps continue until all tasks are scheduled in the workflow.

1: Calculate the cost of traffic between resources using equation (2)
2: Compute PSO ({Task})
3: for all "ready" tasks {Task} ∈ T do
4: Assign tasks to resources sby PSO
5: Dispatch all the mapped tasks
6: Update task list
7: Calculate energy wastage cost using equation (1)
8: Compute PSO ({Task})
9: Perform VM Migration for load balancing.

Fig. 1.   PSO Scheduling Algorithm.

D. Virtual Machine Migration

During the execution process of scheduling tasks on processing servers performed with the help of particle swarm optimization, some servers may fail to execute tasks for reasons such as delays in previous processing tasks. They might have additional traffic load due to the delay in processing tasks, or hardware and software errors may cause additional traffic and overload while some servers are idle. In this case, the processing servers are reviewed periodically, and then the following three conditions are used to determine the status of the processing servers:

- If the server processor achieves its maximum productivity, then the server falls into the category of overloaded machines (Poverload).

- Suppose the server processor productivity is lower than the specified average productivity. In that case, it falls into the category of underload servers, which is usually around 10%. (Punder)

- Other servers that do not meet any of the above requirements are included in the normal server (Pnormal).

To make load balancing, the overload servers should migrate to under-load servers, so loads of servers in overload mode are migrated through the virtual machine migration technique onto another server in Punder or normal mode. Other servers with productivity below 10 percent will be candidates for tasks migration, and therefore they are turned off to reduce power consumption.

IV.   ANALYSIS, EVALUATION AND PERFORMANCE

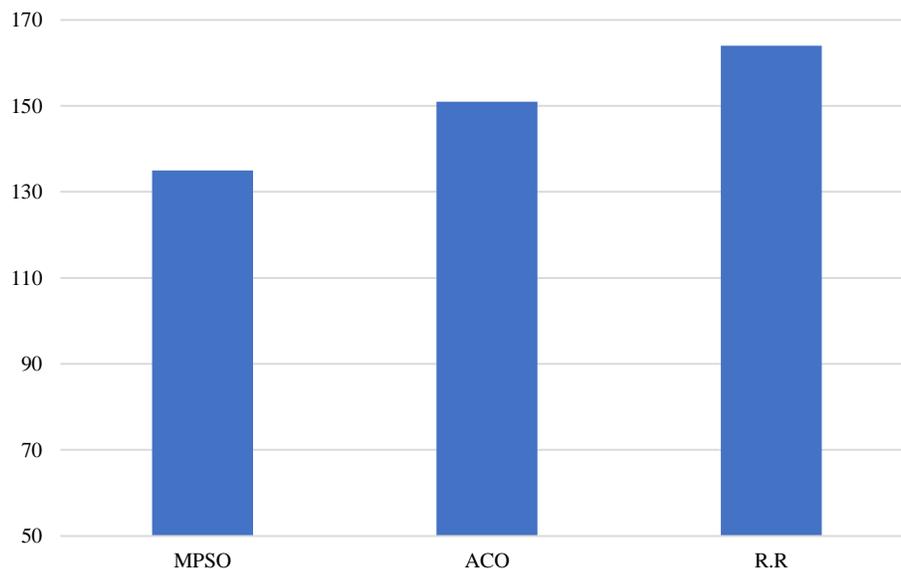
A model that could simulate and evaluate the cloud infrastructure equipment is required to simulate and evaluate the solution. CloudSim is an extendable simulation tool that enables modeling and simulating cloud computing systems and preparing applications. In reality, this program makes it possible to do integrated modeling, simulation, and assessment of cloud infrastructure and associated services [26]. In order to simulate data centers, 800 hosts have also been defined. A class called a server that expands the Power Model SpecPower class, a subclass of the Power Model class in CloudSim, must be developed in order to establish any virtual server in the software. The CoMon project, a monitoring infrastructure for PlanetLab, has tested real traced data, which has been used to generate the workload. The Round-Robin and ant colony optimization methods are compared to the strategy. The power consumption, execution time, and SLA criteria are taken into account to evaluate the suggested algorithm's effectiveness compared to other methods. Finally, the evaluation results are shown in Fig. 2 to 6.


Fig. 2.   Energy Consumption (kw/h).
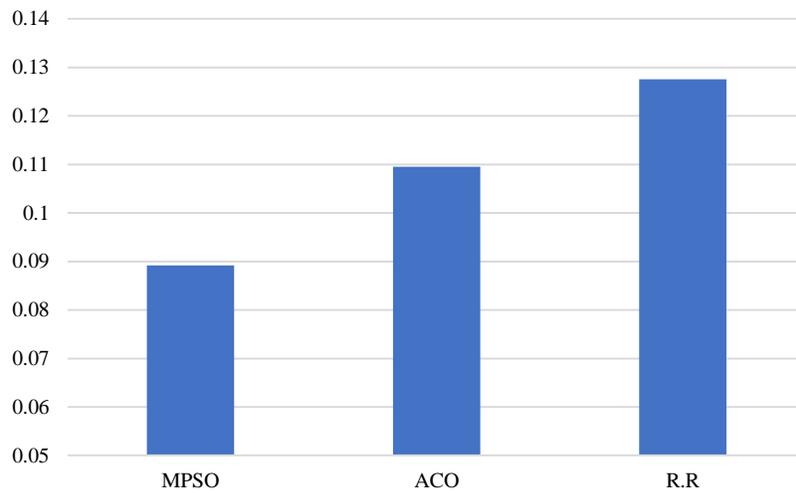

Fig. 3.   Execution Time (Second).
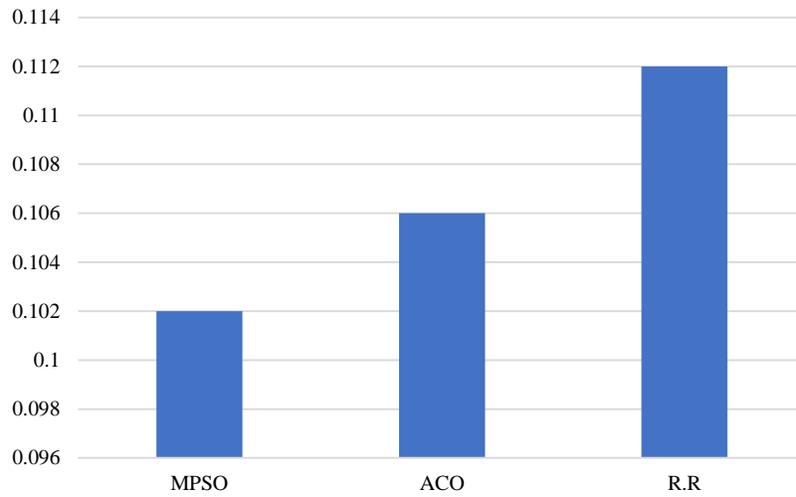

Fig. 4.   Service Level Agreement (%SLA).
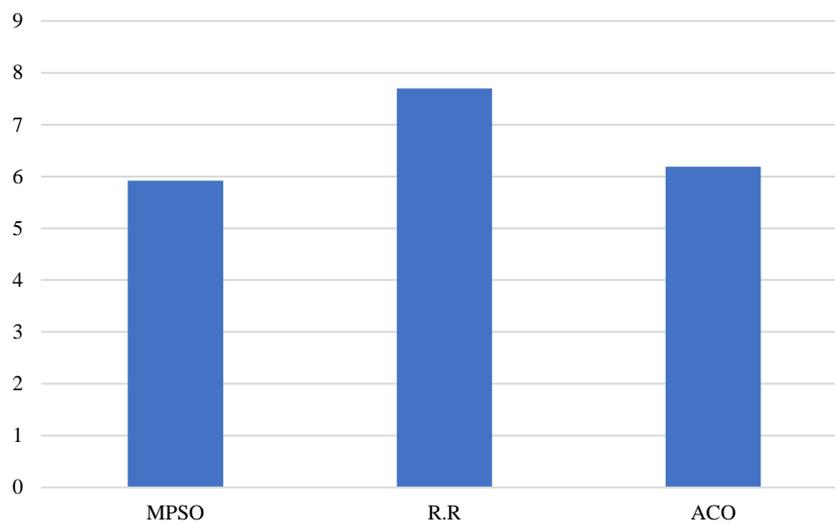

Fig. 5.   Service Level Agreement Degradation due to Migration (%SLA).
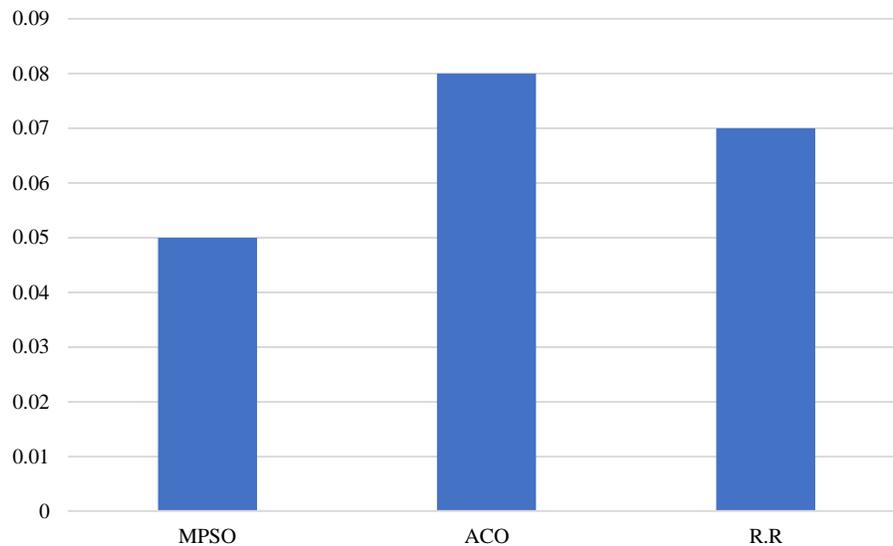

Fig. 6.   Execution Time - VM Reallocation Mean.

According to Fig. 2, the energy consumption in the proposed solution is greatly reduced compared to the other two solutions due to appropriate scheduling and balanced load distribution between processing servers and turning the idle servers off. Accordingly, the scheduling is reduced by 10 and 17% compared to the Ant Colony optimization and Round Robin algorithms. Given the number of resources and energy consumption in each schedule, this reduced energy consumption was predictable.

In addition to reducing energy consumption, reducing demand execution time is also very important in cloud infrastructure. In fact, it is another goal of this research. Accordingly, the execution time in the solution has been reduced to an appropriate level, as shown in Fig. 3. The proposed solution has reduced the execution time by 18 and 28% more than the R.R and ant colony optimization, respectively. This is due to load balancing in the cloud infrastructure by utilizing PSO-based scheduling and the task execution predictor. Moreover, the use of the virtual machine live migration technique allows transferring the processing load to free or idle servers, and the execution time is reduced significantly.

In Fig. 4, the service level agreement violations have been shown. The Service Level Agreement (SLA) is the basis for determining the expected level of service. The service quality parameters in the service level agreement specify the extent to which the provided quality is appropriate. Customers need this contract to ensure the quality level of their services. In fact, the primary purpose of this agreement is to define an official basis for the terms of provided service, such as efficiency or availability. According to the figure, using the load balancing produced by the optimal scheduling, the proposed strategy has provided the servers with higher reliability than the other two strategies, creating better availability in the cloud infrastructure. In other words, the violation percentage of this solution is lower than the service level agreement compared to the other two solutions.

According to Fig. 5, the proposed solution has the least SLA degradation due to migration because all migrations are optimized and adapted to the needs of the infrastructure resulting in the lowest reduction in quality of service. In fact, the service quality parameters in the service level contract determine how appropriate the quality of the provided service is. Customers ensure the quality of the provided service through this contract. As seen in the figure, thanks to the load balancing created by optimizing the timing, the proposed solution has made the servers more reliable than the other two solutions. It thus has higher availability in the cloud infrastructure compared to other solutions. In other words, the percentage of violations of this solution is less than the service level agreement compared to the other two solutions.

Since virtual machine migration can affect runtime, Fig. 6 shows the VM reallocation mean time required for virtual machine reallocation. As it can be seen, the proposed solution in this parameter is also more efficient than other methods. In other words, since this solution examines the status of server resources and allocates them accordingly, it creates the least delay in executing user requests.

V.   COMPARATIVE ANALYSIS

Table II describes the comparative analysis of the suggested method with related research. The comparison is based on features of already published literature, including load balancing, resource management, and energy usage reduction. Almost all publications emphasize the significance of load balancing, except [23, 27] and certain works that allude to resource management, including [19, 20, 22, 23, 25]. Almost all of these studies have not covered the idea of lowering energy usage and scheduling. The references [20, 21, 24, 25] have used edge computing methodologies. They also employ cloud computing in many aspects of their work.

TABLE II. COMPARING THE SUGGESTED APPROACH WITH THE CURRENT APPROACHES

Also, this paper presents a scheduling technique for optimal resource allocation with particle swarm optimization and virtual machine live migration technique. The proposed technique avoids server overload or underload through optimal allocation and scheduling of tasks to physical servers. The proposed strategy was implemented and compared in the cloudsim simulator environment and showed that the proposed method is more effective and suitable for reducing execution time and energy consumption. This solution provides the basis for reducing energy consumption in the cloud environment and at the same time reducing execution time. Compared to the previous test, due to the increase of ants, it is clearly visible that the virtual machine migration is increasing compared to the previous state which has caused the execution time to decrease. In fact, by applying suitable and optimal migrations, additional load has been transferred from high traffic servers to low traffic servers. As can be seen from Table III, although the amount of energy consumption has increased with the increase in the number of ants, but at the same time, the amount of energy consumption has decreased by approximately 12% compared to the MPSO (Multi_Objective Particle Swarm Optimization) method and 9% compared to Round Robin. Also, by placing Optimum methods and reduction of additional overhead, execution time has also been optimized compared to all three other methods. As compared to the R.R. method, it has reached 27%.

TABLE III. THE DEGREE OF OPTIMALITY OF THE PROPOSED SOLUTION COMPARED TO OTHER SOLUTIONS (100 ANTS)

	PSO	R.R	Random
energy consumption	12%	11%	5%
Virtual machine migration	12%	13%	17%
execution time	5%	29%	16%

VI. CONCLUSIONS

Due to the scale and complexity of the cloud infrastructure, the centralized assignment of tasks to a specific server without considering any specific solutions is impossible. Also, considering the increasing workload and volume of requests in advanced data centers and the urgent need to achieve optimal service quality, solutions should be developed to increase the productivity of existing servers in the data center. One method to achieve optimal productivity is the use of scheduling technics. Load balancing is needed to manage the service providers' resources properly. This study uses a solution based on a swarm particle optimization algorithm and the virtual machine lives migration technique for load balancing. The proposed technique prevents server overloads or low load through the optimal assignment of tasks to physical servers. Finally, it was shown with the help of ClodSim software and in the simulation environment that this method significantly increases the efficiency. For this purpose, the proposed solution was evaluated in two cases with the number of ants 50 and 100. In the first test (number of 50 ants), the solution was compared with the three algorithms ACO, Round Robin and MPSO and it was shown that the proposed solution was able to execute the desired requests in less time than the two algorithms ACO and Round Robin. Efficiency can be provided with the help of the correct migrations that the solution has provided, and the machines that have had a heavy load have been transferred from them to another machine that has a lower load, and on the other hand, the machines that have no load have also been transferred, found correctly and by turning them off, the amount of energy consumption is also reduced; so that compared to the ACO algorithm, the energy consumption has decreased by almost 10% and compared to the round robin algorithm by 13%, but compared to the MPSO, the optimization in terms of energy consumption has not been achieved. In the second experiment, the number of ants increased to 100 ants and in comparison, it was shown that although the reduction of energy consumption is less than the first case, but with optimal virtual machine migrations, the execution time for all three algorithms is between 12 to 27% decreased. This indicates that the solution is optimal compared to other methods.

In the future, the continuation of this research can be extended to the execution time based on demand resource

allocation, because the proposed method does not meet the resource requirements during the execution of requests.

Abstract—Augmented Reality (AR) has led to several technologies being at the forefront of innovation and change in every sector and industry. Accelerated advances in Computer Vision (CV), AR, and object detection refined the process of analyzing and comprehending the environment. Object detection has recently drawn a lot of attention as one of the most fundamental and difficult computer vision topics. The traditional object detection techniques are fully computer-based and typically need massive Graphics Processing Unit (GPU) power, while they aren't usually real-time. However, an AR application required real-time superimposed digital data to enable users to improve their field of view. This paper provides a comprehensive review of most of the recent lightweight object detection algorithms that are suitable to be used in AR applications. Four sources including Web of Science, Scopus, IEEE Xplore, and ScienceDirect were included in this review study. A total of ten papers were discussed and analyzed from four perspectives: accuracy, speed, small object detection, and model size. Several interesting challenges are discussed as recommendations for future work in the object detection field.

Keywords—Augmented reality (AR); object detection; computer vision (CV); non-graphics processing unit (Non-GPU); real time

I. INTRODUCTION

As opposed to virtual reality (VR), the term augmented reality (AR) refers to a virtual interface, either in 2D or 3D, that enhances human vision by superimposing additional information (digital content) over the actual surroundings, which results in complete immersion in the imaginary reality[1]. As we can always see and feel the real world around us, it is not possible to get immersed in the virtual world.

AR relies on a device that captures the real world and inverts live animations, virtual objects, texts, data, or sounds observed by the user on a smartphone, tablet, computer, a pair of glasses, or any other on-screen display system [2]. In AR, the virtual information and the real world are synched using geo-localization and embedded sensors (gyroscope, accelerometer) that position the user and adjust the display according to his environment and movements.

Think about driving at night on a mountainous, curved route; also imagine a thick fog covering this area right now. The fog completely hides the trees on either side of the road. Considering how crowded it is, it is challenging to even see the traffic signs from a distance of two to three feet. The fog reflects the headlights' illumination, making driving risky, but stopping could be much riskier. In essence, there is no way to win, Similar cases to this have resulted in numerous multicar accidents. Now imagine being able to view the road's layout on a windshield, displaying the distance between you and the vehicles in front of you, your current speed, exit points, and intersections simply by pushing a button. Even though it's never fully safe to drive in fog, this display can provide the driver access to important information that could help avoid an accident [3].

Again, imagine a new faculty member entering a very large academic library; this new member turns on the camera on his/her cellphone and carefully scans the entire area. Imagine the new member having information about the room he/she is standing on the phone screen. Perhaps the location of the reference books, stacks, and current journals, or where to find help, is recorded by the camera. Imagine a scenario where a new faculty member may have virtual arrows pointing to the book's location., he/she is looking for on display to guide him/her in finding the location of the book. The use of AR makes both scenarios possible [3].

As a method of human-computer interaction, AR merely projects virtual data onto real objects [4]. The accurate superimposition of virtual data onto real objects depends on the detection of real objects and the knowledge of their precise coordinates. Several researchers discussed and elaborated on different challenges faced by AR technology. The following are the main challenges faced by AR technology.

A. Display

One of the main challenges with AR display technology is to create an extensive field of view, high resolution [4], see-through display in a socially suitable shape element. The study by [5] listed some of the challenges in optics and displays that must be addressed, which include offering enough brightness

and sharp display, having a high resolution and extensive area of view, addressing eyestrain, and being in a sunglass-like shape element. Several crucial subjects consist of addressing the AR vergence accommodation challenges, displaying photorealistic content material, and new shape elements which includes contact lenses.

B. Interaction Techniques

This is another challenge which is allowing humans to control AR content material as effortlessly as they do with items within the actual world. One approach that has been explored is utilizing actual gadgets to interact with AR in a method known as Tangible AR [6]. Free-hand gestures are supported by current AR systems; however this will be improved in addition to voice recognition and enabling mixed speech and gesture input in multi-modal interfaces. Future studies might use a variety of different approaches using eye tracking, whole-body input, and various non-verbal indications. Ultimately, [7] recommended more studies on the interaction methods that are not feasible inside the actual world.

C. Social and Ethical Issues

In the long term, the meaningful social and ethical concerns in AR technology are a complicated issue that must be addressed, for instance, identity hacking. However [8] mentioned the privacy implications of seeing individual information in public spaces; the study came up with lists of questionable ethical uses of AR which include deception, surveillance, and behavior modification.

D. Object Detection Techniques

For AR applications like assembly guidance, real-time, scalable object detection is a crucial task. Real-time object detection from RGB images has already been addressed by several Deep Neural Network (DNN) models. Although the majority of current AR and mixed reality (MR) systems can comprehend the 3D geometry of their surroundings, they are unable to recognize and categorize complex items in the real world. Deep Convolutional Neural Networks (CNN) can allow these features; however, it is still challenging to run big networks on mobile devices. It is extremely difficult to offload object detection to the edge or cloud due to the strict requirements for low end-to-end latency and excellent detection accuracy. In [9] proposes an object detector to boost embedded devices' ability to identify objects.

Augmented reality simply displays digital information onto real-world objects as a technique for human-computer interaction. In the era of augmented reality, virtual things created by computers can precisely and instantly overlay physical ones. Predicting bounding boxes and categorizing objects are both steps in the process of object detection which is a key area of computer vision today. Robust detection of objects from natural features of AR is still a complex problem and usually demands high computational time.

DL-based object detection has received significant research interest in current years. For higher picture knowledge techniques, it is vital not only to pay attention to classifying different pictures but to attempt to exactly estimate which objects are present within the pictures and their places (known as object detection) [10]. Many studies have been reported on object recognition using CNN in the field of computer vision.

However, end-to-end DL object identification methods based on regression methods, such as the Single Shot multi-box Detector (SSD) series and the YOLO series, have been successful in detecting objects in real time using GPU-based computers. It is exceedingly difficult to achieve accurate and real-time detection using non-GPU-based PCs and portable devices with low computing capacity because of the high computational needs of many systems. Several researchers discussed that a lot of object detection models have higher computing time which makes their object detection models take a long time to provide the outcomes. The following are the survey's contributions:

1) A comprehensive survey was conducted on the current object detection models for embedded devices published from 2018 to 2022.

2) We summarized numerous object detection methods for mobile and embedded devices.

3) The employment of algorithms to identify their unique and constrained features. We also looked at how these techniques handle problems that arise during the object detection process, as well as the advantages and disadvantages of these techniques for object detection models.

4) Discussion on the current open problems to help direct future studies on improving and enhancing the performance of object detection techniques. The development of the model was done after reviewing many earlier studies from related domains.

There are eight sections in this paper; the introduction and scope of this study are presented in Section I, and the review of the structure of the AR system is presented in Section II. In Section III some applications of object detection were discussed. The most important challenges in the object detection field are presented in Section IV. Previous research on similar topics, the outcome of the analysis, and the limitations and conclusions of such studies are in Sections V, VI, VII, and VIII respectively.

II. AR System

Specific software and hardware are required for the various AR systems, however, the software utilized uses the real-world coordinates via cameras and tracking hardware; the purpose is to convert this location data into an XML file, in software the so-called ARML (Augmented Reality Markup Language) used. The ARML functional blocks establish the relationship between the actual and virtual worlds by identifying the relationship between them; this enables use of virtual items in the real world. These virtual items are controlled by the user's actions that they take [11]. Most devices utilized in AR applications are IoT devices that fall into one of three categories:

- Sensors: Sensors gather information from the real world and send it to an AR app. for example, a mobile device's built-in camera gathers information about a user's environment. Data is processed by the software, which subsequently shows the user predefined content.

With information from cameras or 3D models, the scene's composition is achievable. The tracking device could be (RFID, wireless sensors, accelerometers, GPS, gyroscopes, solid-state compasses, and digital cameras) [11] and have several settings and ranges; they enhance the AR system's tracking accuracy.

- Input devices: These tools let users engage with AR systems. The AR Interface works as a medium between the AR system and these components. The Ikea application's UI could be a good example. The user could move the furniture items in his house by using signs that the program will then interpret as orders [11]. The types of inputs include speaking, blinking, touching, and gesturing, among others. Input devices examples: microphones, touch displays, gesture controllers, styluses, and pointers [12].

- Output devices: Users can interact with the AR system using these tools. Whenever these tools are used for a particular purpose, they are often worn on the user's forehead. HMDs, monitors, and wearable technology are some examples of these devices [13].

Offering a solution in real-time is one of an AR system's main characteristics. The user experience is not the only benefit of AR technology. t offers excellent economic opportunities for service providers and companies [13]. As AR has been more widely used, it allows more e-production of wireless networks, sensors, high-end cameras, cellphones, and other devices, but there are several factors to take into account while designing an AR system and the architecture that supports it. Such as the high quality and how immersive AR is, also the monitoring and rendering slowness [11]. There are some limitations related to the AR systems such as:

A. Hardware Limitations

A variety of smart devices are used to create AR systems. From the least powerful to the most powerful devices that work across multiple environments. Therefore, one of the key goals is to lower these devices' energy consumption to increase their efficiency[14]. In addition to the energy consumption, the cost of the AR devices may easily cost thousands of dollars which makes them unreachable to everyone except the most committed pioneers or early adopters.

B. Software Limitations

The most efficient hardware is useless if it doesn't come with incredible software. Although the architecture of such AR systems has advanced significantly, the software component for such a complex system still has certain challenges to overcome and objectives to achieve [11]. The flexible operating system has to be coded, sized, and powered more efficiently. The following are some examples of operating systems that can be used in the context of AR (FreeRTOS, OpenWSN, and TynyOS). Additionally, there are dedicated browsers for AR, including Mozilla's "Firefox Reality." And several more devices are still under development. Therefore, it is clear that it is needed to design suitable toolkits having the support of various devices and applications across numerous platforms.

C. Lack of Privacy

The perceived risk associated with AR is one of the key privacy concerns. A person's privacy is at risk since AR technology can monitor what they are doing and collects a ton of data about them and their activities.

D. Devices Compatibility

In AR systems, there should be no issues with communication between objects and devices, the compatibility of such devices is one of the main issues with an AR system's design [15]. To address this issue, we should focus on "We must improve semantic exchange between objects and devices and between devices with each other. The semantic web may be used to do this, which can improve the quality of digital content seen via the user interface."

E. User Intervention

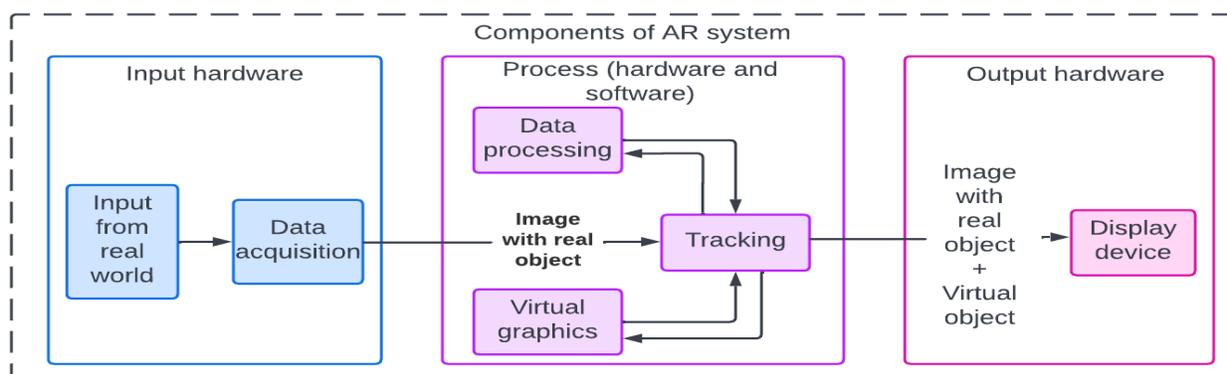
The dependency of AR apps on the user and their activity is another issue. Any IoT device must be independent and sensitive [11]. Its role needs to be less obvious to the user so that consumers may have a system that is much more robust, even when there are problems [15]. Fig. 1 presents the components of AR system.


Fig. 1. AR System Components.

III. APPLICATIONS OF OBJECT DETECTION

This section will discuss some recent significant detection applications, such as the detection of pedestrians, faces, traffic signs and light, and texts.

A. Pedestrian Detection

Nowadays, pedestrian detection has received extensive research, which is closely related to pedestrian tracking person re-identification. Before the recent development in DCNN algorithms, some studies combined boosted decision forests with hand-crafted features to develop pedestrian detection methods. also, to address the deformation and occlusion, part-based methods and explicit handling of occlusion are problematic [16].

B. Face Detection

Face detection is vital for numerous face applications and behaves as an essential face recognition pre-processing step. One of the initial computer vision technologies that has successfully supported object detection is face detection, and many of its amazing principles are still having a big impact on object detecting technology today. Face detection is currently used in all parts of life, for digital cameras' "smile" detection, "face swiping" in online retail, face makeup, etc. [16].

C. Text Detection

The issues with text detection in video and images have attracted more notice recently, as shown by the appearance of recent" Robust Reading" competitions in 2003, 2005, 2011, and 2013. There are several main causes for this trend, including a rising number of applications. Text is one of the most artistic methods of communication and can be integrated into documents or scenes as a technique of connecting information. The same problems with computer vision and pattern recognition are connected to text identification in photographs caused by low quality or worse, despite the fact that many studies consider OCR technology (Optical Character Recognition) to be a settled subject. Text detection field still has a big space for search [17].

D. Traffic Sign and Traffic Light Detection

With the advancement of autonomous vehicle technologies, the detection of traffic signs and lights has received a lot of attention nowadays [16]. Even though the computer vision community has mostly highlighted, Traffic Light Recognition has now made a name for itself as a standard basis for pedestrian and general object detection, until 2010, the majority of traffic sign/light detection technologies, except a very small number of works, did not adhere to this paradigm.

IV. CHALLENGES OF OBJECT DETECTION

Finding and identifying various instances of videos and pictures is made easier with the use of a type of computer vision technology called object detection. The most typical object detection problems that data scientists should be aware of are listed below:

A. Small Object Detection

Small objects are typically difficult to detect because of their noisy depiction and low resolution. Currently used object identification pipelines often find small objects by learning the representations of every object at different scales. Typically, such ad hoc systems only provide performance improvements sufficient to offset their computing costs. Numerous real-world applications, such as pedestrian detection and traffic sign identification for improved autonomous driving, frequently involve small objects. However, the detection of small objects is more difficult than that of regular objects, and effective solutions are yet to be established [18]. Even though some of these problems with small object detection have received some attention, most of the proposed methods erroneously increase the feature dimension or enrich the data to improve the effectiveness of small object detection [19].

B. Object Detection Model Size

The present CNN frameworks are deepening and becoming more complex, despite the fact that the accuracy of such network architectures may match or exceed that of human vision, they frequently need extremely high amounts of computer power [20]. Fast object detection techniques have advanced significantly; however, it is still difficult to apply CNN architectures on non-GPU or mobile devices. The usage of CNN-based technologies has brought rise to major research topics in real-time and lightweight network models [21] [22] for object detection in mobile devices. This is driven by the rapid advancement in mobile and embedded intelligent gadgets with low power consumption and limited computing power, such as AR glasses and small intelligent unmanned aerial vehicles (UAVs).

C. Speed

Deep neural network-based methods have frequently performed better than other methods in object detection evaluations. There are two categories of these models - those with Regional Proposal Network (RPN layer) and those without RPN; those with the RPN layer are normally the faster R-CNN & R-FCN. YOLO and SSD are the models without it. YOLO and SSD are also called single-shot detection models. In general, the models with Region Proposal Network are more accurate while the models without Region Proposal Network and SSD are faster. The size of the model could affect the speed of detection so the pruning of model layers will speed up the model [23] [24]. The best models are the models that balance accuracy and speed.

D. Viewpoint Variation

Deep CNNs are only capable of modeling 2D transformation fields using the existing methods for encoding spatial invariance. This fact does not consider that objects in a 2D space are a projection of the ones in 3D and hence, have a limited power to severely shift object viewpoints is not taken into consideration by this [25]. Recently, CNN-based joint object recognition and viewpoint estimate has drawn attention as a potential solution for viewpoint variations. Before predicting the relative stiff transformation between each picture's 2D coordinate and the camera point in 3D space, must first identify the location and kind of objects in an image viewpoint. Estimation, and category classification problems are intrinsically incongruent.

E. Deformation

Sometimes interesting items may be flexible and distorted in unusual ways. Although a person can be detected by an object detector in a different situations, because of his twisted orientations, it will be difficult for the object detector to identify the same person.

The most advanced item detection technology currently available uses Deformable Parts Models (DPM). They do not appear to be the best at representing deformations. The deformations of objects are frequently continuous and not limited to large parts. Variations in popular and efficient object detectors are due to changes in appearance and deformations[26].

F. Occlusion

In real-world images and videos, occlusion is a frequent issue that presents a significant challenge for object detection. For instance, 70% of pedestrians in the Caltech Pedestrian Dataset, are obscured in at least one video sequence frame, and 19% are obscured in every frame. Almost 50% of these pedestrian occlusions were classified as heavy [27]. According to Dollar et al., even with minor occlusion, the performance of typical approaches to detect objects decreases significantly, and with heavy occlusion, it falls even further. Therefore, better performances are provided by object detectors that can learn and infer visible patterns by focus on fix the occlusion issue [28].

G. Shadow and Illumination Conditions

The alteration of illumination is a typical issue with object detection processes. Some techniques are offered to reduce the effect of changes in illumination and shadow caused by moving objects; an example of such techniques is the Moving Object Detection and Shadow Removing under Changing Illumination Condition model. The shadow causes several problems with object localization, segmentation, recognition, and tracking. The shadow may also result in the objects merging, it can cause the shapes of the objects to change, might even result in things going missing and lead to the foreground being confused for the background. It is equally challenging to capture clear moving objects when illumination changes because of the chances of mistaking some background pixels for foreground pixels. The effectiveness of subsequent procedures (such as tracking, recognition, classification, and activity analysis) that require precise moving object detection and accurate acquisition of its exact shape, therefore there is great impact by removing shadows and controlling illumination fluctuations [29, 30].

III. Previous Work

Numerous theoretical and empirical research has covered and elaborated on AR. This study focuses on approaches and procedures that can be utilized to enhance deep learning AR models. The following are previous studies about AR that were conducted by various studies:

In [31], Trident-YOLO, an upgraded version of the YOLOv4-tiny network with better accuracy and real-time speed was suggested. The most significant improvements made by this model are to the set of tools indicated by Alexey and the suggestions of CSP-RFBs and CSP-SPPs, which are appropriate for thin object detection networks. In order to increase the accuracy and recall of lightweight object detection, the network topology was redesigned, and a trident feature pyramid network (Trident-FPN) was suggested by the authors. This Trident-FPN produces a multi-scale feature map of the model while only slightly increasing the computational cost in terms of floating-point operations per second (FLOPs).

The study of [32] introduced the TRC-YOLO, TRC-YOLO proposed the pruning of the YOLOv4-tiny convolution kernel and the addition of an expansive convolution layer to the residual network model to produce an hourglass-shaped Cross-Stage partial Present (CSP) structure. The introduction of TRC-YOLO enhanced the mAP and real-time speed while minimizing the model size which was achieved by minimizing the number of YOLOv4-tiny model parameters. The CSP Res Net module was then enhanced and integrated to boost the model's capacity for feature extraction. In order to obtain higher quality feature images and to enable the model to concentrate on important feature areas and channels, the RFBs module was included to this model.

A mobile inverted bottleneck module is used as the foundation of the feasible and lightweight object detection model presented by [33]; the model was based on deep CNN. Additionally, an improved spatial pyramid pooling was used to concatenate the multi-scale local region characteristics to increase the network's receptive field. The testing results on the aerial picture datasets VEDAI and VisDrone show that the enhanced YOLOv4-tiny model performs significantly better than the original YOLOv4-tiny model. For the VEDAI and VisDrone datasets, the suggested model outperformed the results with mAP of 53.11 percent and 24.73 percent, respectively.

The study by [34] suggests embedded YOLO to enhance the efficiency of low-level features; the study initially suggested a new backbone network topology called the ASU-SPP network but later developed a more straightforward version of the neck network module PANet-Tiny to make computations simpler. Finally, depth-wise separable convolution was employed in the detecting head module to minimize the number of convolution stacks. The embedded YOLO model was compared with the conventional lightweight model after being verified by the COCO test dataset and online tests; it was discovered that the mAP performance was preserved.

In [21], a newly developed lightweight CSL-Module was presented; the new approach showed a comparative performance with previous approaches of a similar nature but due to limited computing resources, two additional components (CSL-Bone and CSL-FPN) were proposed to achieve superior performance with fewer FLOPs. However, achieving low computation cost depends on how the redundant features are generated as the CSL-Module can lower computation costs considerably. Research done at MS-COCO demonstrates that the suggested CSL-Module can approximate the fitting ability of Convolution-3x3.

A real-time object detection approach for non-GPU systems was proposed by [35] in order to help users of low-

configuration computers. Real-time object detection on CPU-based computers is now possible thanks to the optimization of YOLO with OpenCV for CPU-based computing. On some non-GPU machines, the CPU-based YOLO model can detect objects from videos with an accuracy of 80–99 percent and frame rates between 10.12 and 16.29. Comparison with other GPU-based frameworks showed that the proposed model is suitable for CPU-based applications because CPU Based YOLO obtains 31.05 percent mAP.

A study by [35] suggested a brand-new, DL-based lightweight object detection technique. Based on YOLOv4, the study proposed YOLOv4-tiny is proposed to simplify the network topology and minimize parameters, making it appropriate for development on mobile and embedded devices. The proposed approach achieved faster object detection compared to YOLOv4-tiny and YOLOv3-tiny as evidenced by the simulation results; it also achieved an almost similar mean value of average precision as the YOLOv4-tiny. The authors also proposed two identical ResBlock-D modules for the replacement of two CSPBlock modules in the YOLOv4-tiny network to reduce the object detection process. An auxiliary network block that employs two 3x3 convolutions networks, spatial attention, concatenate operation, and channel attention was also proposed for the global feature extraction in order to balance the object detection time and accuracy.

Mixed YOLOv3-LITE was developed by [22] as a mobile and non-GPU compatible lightweight real-time object detection network. The proposed approach supplements the ResBlocks and parallel high-to-low resolution subnetworks that are YOLO-LITE-based. The detector was developed using narrower and shallower convolutional layers compared to those in YOLOv3; this reduces the required level of computation and number of parameters to be trained, hereby improving the network operation speed. These considerations were aimed at solving the problems of limited computing power and excess power consumption in mobile and embedded smart devices.

In [23], a real-time object detection paradigm was developed for mobile devices like laptops or phones without a GPU. The study YOLOLITE to provide a smaller, quicker, and more effective model based on the original YOLOV2 algorithm; the introduction of YOLOLITE increased the accessibility of real-time object identification to a variety of devices. With its success in bringing object detection to non-GPU machines, YOLO-LITE demonstrates the enormous potential of shallow networks for lightweight real-time object detection networks. For such a modest system, running at 21 FPS on a non-GPU computer is quite encouraging, and it demonstrates why batch normalization must be queried for smaller shallow networks. It showcased the capability of shallow networks in fast non-GPU object detection devices. It also proves that shallow networks do not necessarily require batch normalization but reduce the network's overall performance. To sum up, the YOLO-LITE detector is composed of several parts:

1) Input: Image, Patches, Image Pyramid

2) Backbone: Darknet-53

3) Heads: Dense Prediction: one-stage.

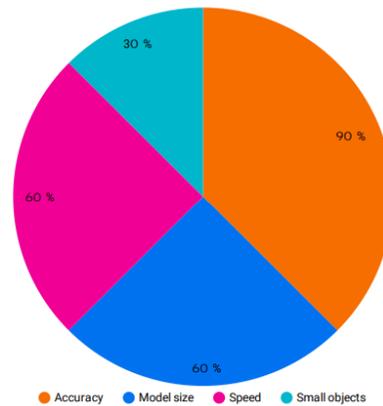
A YOLObile framework that relies on compression-compilation co-design was designed in [36] to enable real-time object recognition on mobile devices. The study proposed a brand-new block-punched pruning approach for any kernel size. Furthermore, advanced compiler-assisted optimizations in conjunction with a GPU-CPU collaborative strategy was also suggested to increase computational efficiency on mobile devices. According to experimental findings, the pruning strategy successfully compressed YOLOv4 at a 14 rate with 49.0 mAP. On the Samsung Galaxy S20, a 17 FPS inference performance was reached using the proposed YOLObile framework with the GPU-CPU collaboration strategy. The proposed YOLObile also includes a mobile GPU-CPU collaborative computation strategy to increase the computational effectiveness of DNNs on mobile gadgets. The evaluation shows that the proposed YOLObile framework achieved high hardware parallelism and excellent accuracy. Fig. 2 summarized the percentage of previous work studies that focus on improve each attribute.


Fig. 2. Applied Approaches.

V. OUTCOME AND FINDINGS

The main finding of this paper is that CNNs object detection models are through an advanced transformation in the field of computer vision. The development of object detection models to be appropriate even for mobile and devices without GPU, which offers customized models and small-scale proof-of-concept studies, is what highlights this transformation. These models' studies provide a foundation for large-scale scientific research issues that employ CNNs. As a result of this tendency, CNNs object detection models will eventually be able to compile a worldwide, digital inventory of everything in order to study object dynamics and their effects on human activity. This study analyzes 10 articles to give a thorough overview of the convolutional neural network (CNN) for object detection in general. Another finding is that always there is a trade-off between speed and accuracy. When focus on increasing accuracy this will make the model more complex which will slow the model down.

TABLE I.   SUMMARY OF PREVIOUS WORK

Reference	Method	Summary	Evaluation Metrics	Dataset Used	Limitations
[31]	Trident-YOLO	Introduce an object detection network that is designed for mobile devices with limited computing power	FPS mAP BFLOPs	PASCAL VOC MS COCO	There is still room for improvement in the detection of complex scenes.
[32]	TRC-YOLO	Proposed a lightweight object detection model based on yolov4-tiny.	FPS mAP	PASCAL VOC MS COCO	Model speed needs to be higher
[33]	Automated object detection on aerial images for limited capacity embedded device	Feasible and lightweight object detection model based on deep CNN	FPS mAP input size F1-score IoU FLOPs	VisDrone VEDAI	The model was based on yolov4 tiny and slower than yolov4 tiny.
[34]	Embedded YOLO	Proposed an ultralightweight target detection network model	FPS mAP parameters Size Latency	MS-COCO	The model's map needs to improve.
[21]	CSLYOLO	Proposed a new lightweight convolution method CSL-Module and proposed two components CSL-Bone and CSL-FPN, both of which achieve better performance with fewer flops.	FPS mAP Params FLOPs	MS-COCO	The model's running speed needs to improve
[42]	CPU Based YOLO	Optimized YOLO with OpenCV to enable real-time object detection on CPU-based devices.	FPS mAP	COCO	Model speed needs to be higher
[24]	YOLOv4-tiny	Proposed Yolov4-tiny based on Yolov4 to reduce the network structure and ensure suitability with mobile and embedded devices.	FPS mAP	MS COCO	Still not implementable for non-GPU devices
[22]	Mixed YOLOv3-LITE	Proposed "an efficient lightweight object detection network that uses a shallow-layer, narrow-channel, and multi-scale feature image parallel fusion" structure	FPS mAP Params GFLOPs Precision Recall F1	PASCAL VOC 2007 & 2012	Need to improve the map
[23]	YOLO-LITE	The proposed detector model runs at "about 21 FPS on a non-GPU computer and 10 FPS after implemented onto a website with only 7 layers and 482 million" FLOPS.	FPS mAP Layers FLOPS Loss	PASCAL VOC 2007 and 2012 COCO 2014	Need to improve the map
[36]	YOLObile	Proposed yolobile framework, a real-time object detection on mobile devices via compression-compilation co-design.	Input Size Backbone Weights FLOPs mAP FPS	COCO dataset	Need to improve detection speed

A. Applied Approaches

The approaches utilized to address the difficulties and resolve the object detection problems are covered in depth in Section V. Tables I and II summarized each of the publications reviewed and how they addressed the difficulties faced by the researchers. As seen in Table II and Fig. 1, most research focus on improving accuracy (90 percent), handling speed (60 percent) have received far more attention than any other problems.

B. Investigated Datasets

Datasets are significant motivators for specific applications and crucial for the development of deep-learning algorithms. The number of case studies and datasets considered has proven to be challenging. It is advantageous and necessary to use a number of datasets, each of which supports a range of parameters and a predetermined composition problem, in order to assess the efficiency of the suggested algorithms. There are many object detection datasets that are readily available in the research domain: COCO [37] [23] [24] [35, 36] http://cocodataset.org/ and PASCAL VOC [23] [38-41] http://host.robots.ox.ac. uk/pascal/VOC/., cifar-10 [42-46]

https://www.cs.toronto.edu/~kriz/cifar.html, bdd100k dataset [47-51] https://www.bdd100k.com/, LISA Traffic Sign Detection Dataset[52-56], KITTI [49, 57-60] http://www.cvlibs.net/datasets/kitti/, SUN-RGB-D [61-65]https://rgbd.cs.princeton.edu/,nuScenes[66-70] https://www.nuscenes.org/, Visual genome [71-75] https://visualgenome.org/ , MPII [76-80] http://human-pose.mpi-inf.mpg.de/ , and imagine [81-85] https://image-net.org/index.php. Some researchers have rarely relied on datasets that are generated synthetically.

VI. LIMITATIONS OF OBJECT DETECTION IN APPLIED APPROACHES

This section discusses a variety of essential object detection techniques as well as object detection issues and constraints. The main problems with object detection systems are their speed, accuracy, difficulty in detecting small objects, and model size. Numerous algorithms have been developed to address these issues, but none of them are completely successful. The enumerated algorithms provide the following solutions to the problems.

- Accuracy

A common metric used to assess the accuracy of object detection models is Mean Average Precision (mAP). The mAP is calculated by comparing the ground-truth bounding box to the detected box; higher mAP scores imply that the associated models have higher detection accuracies. The accuracy metric is the most important factor to assess any object detector. The new models used improved techniques in Neck part like (FPN, PANet, and SPP) and the Residual Blocks in Backbone part also using advanced Head part like head in YOLOv4 to increase the accuracy of bounding boxes position. All these techniques and more are utilized to improve the accuracy of detectors like [23, 24, 36].

- Speed

Beside the accuracy factor, detector speed should be taken in account. The effectiveness of any intelligent system and AR gadgets depends on an effective and quick object detection algorithm. Without real-time detection the model will be useless in field of autonomous vehicles and many other fields. To tackle this issue many researchers suggested new features for example (simple the network structure, reduce parameters, and using simple parts instead of complex ones) in YOLOv4-

tiny the author used FPN without using SPP which used in YOLOv4, additionally YOLO-LIE model minimize YOLOv2 by using less number of backbone layers. However, A constant trade-off always exists between speed and accuracy in larger models [23, 36].

- Small object detection

The detection of small objects is a difficult computer vision task and has been widely used in defense, military, transportation, industry, etc. to improve understanding of small object detection. Object detection has recently made tremendous strides but despite these advancements, there is still significant variation in performance between the detection of large and small objects. To solve the issue of small object detection, some models have been developed, such as those developed in [21, 22, 36] in [21] CSL-YOLO model, because of the huge number of small objects in MS-COCO dataset the author improved new version of feature pyramid network called (CSL-FPN) in this Network Before K-means, a scale limit like Eq. (3) has been included so that the distribution of anchors produced is more in line with the scale of each output layer. In the results, using CSL-FPN has increase the accuracy of detect small objects. However, small objects detection still needs more studies and it's an open issue need more efforts to be improved.

- Model size

Object detection model size has many effects on the speed and accuracy, the trade-off between accuracy in larger models and speed in lightweight versions is continual. The simple network structure and fewer parameters make it ideal for mobile and embedded devices. On other hand the complex structure and more parameters may be caused to improve model accuracy. Modern object detection techniques used in cars now rely significantly on the sensor output from costly radars & depth sensors that make them unsuitable for usage in everyday situations. However, this increase in accuracy may not be useful to address the problem in many real-world applications that demand real-time. performance carried out on a platform with restricted computational resources [22-24, 35]. Simplicity of detector is an open issue due to need of lightweight models in mobile and non-GPU devices. In Table II we can see the summary of improved attributes for 10 studies.

TABLE II. IMPROVED ATTRIBUTES

Author	Year	Method	Speed	Accuracy	Model Size	Small objects

VII. CONCLUSION

The study focused on CNN-based light object detection in the field of AR, and it introduces the CNN's structure, the CNN-based object detection framework, and several techniques for enhancing detection performance. Surveys on the application domains, model components, experience metrics, used datasets, and model performance of lightweight object detection models were also conducted; the challenging problems in the field of AR were also highlighted. Nevertheless, there are still several technical and application-related issues in AR. The performance of CNN in terms of real-time, accuracy, and adaptability was better than that of the traditional approaches, but there is still much potential for improvement. Enhancing the object detection algorithm's structure can minimize the loss of feature information while fully leveraging the relationships between the object and the context. Numerous studies have already been done to address non-GPU and embedded devices. Although the improved methods performed better than the conventional methods, the accuracy still needs to be improved to handle a complex environment. A well-established method specifically for addressing the issue of small object detection is yet to be achieved, however, improvisation in small object methods allows for the achievement of acceptable accuracy values, though it is vulnerable to additional processing time. New methods can be developed in the future by leveraging the strength of the recent trends for improved performance. The current methodologies, for instance, can be improved by hybridizing non-GPU approaches and small object detection with GPU-based approaches.

Abstract—Recently, acquiring the Random Access Memory (RAM) full memory and access data is gaining significant interest in digital forensics. However, a security feature on the Windows operating system - Virtual Secure Mode (VSM) - presents challenges to the acquisition process by causing a system crash known as a Blue Screen of Death (BSoD). The crash is likely to occur when memory acquisition tools are being used. Subsequently, it disrupts the goal of memory acquisition since the system must be restarted, and the RAM content is no longer available. This study analyzes the implications of VSM on memory acquisition tools as well as examines to what extent its impact on the acquisition process. Two memory acquisition tools, namely FTK Imager and Belkasoft RAM Capturer, were used to conduct the acquisition process. Static and dynamic code analyses were performed by using reverse engineering techniques that are disassembler and debugger. The results were compared based on the percentage of unreadable memory between active and inactive VSM. Static analysis showed that there is no difference between all applications' functions for both active and inactive VSM. Further Bugcheck analysis of the MEMORY.DMP is pointed to the ad_driver.sys module in FTK Imager that causes the system to crash. The percentage of unreadable memory while running on active VSM and inactive VSM for Belkasoft is about 0.6% and 0.0021%, respectively. These results are significant as a reference to digital investigators as consistent with the importance of RAM dump in live forensics.

Keywords—Live forensics; memory acquisition; virtualization; virtual secure mode

I. INTRODUCTION

As defined by the Digital Forensics Research Workshop (DFRWS), digital forensics is the use of scientifically derived and proven methods to preserve, collect, validate, analyze, and present admissible digital data that meet the court requirements [1]. Digital data originated from electronic devices that have data storage capability, including smartphones, digital cameras, and even printers. There are two types of digital data, namely: (i) volatile data – data that will be lost when there is no electrical power on the devices, and (ii) non-volatile data – data that is still stored in the device's storage media even though the power is turned off. RAM forensics or memory forensics involves collecting and examining volatile data. It becomes a priority to undertake the live acquisition if an electronic device is on, considering the data will be lost when the device is turned off. Furthermore, some cyber security incidents require RAM forensics such as malware attacks, due to its behavior

that could leave no trail on non-volatile memory [2]. As an example, a study [3] was able to identify Advanced Encryption Standard (AES) keys in the memory of a ransomware process by examining memory dumps using live forensics tools. It further indicates that artifacts from memory forensics are not limited to evidence collection, yet they could be utilized to minimize the impact of cyber incidents.

While there has been significant development in advanced computing architecture, it poses challenges to memory forensics practices. For example, the use of a recent security feature known as Virtual Secure Mode (VSM), which was started from Windows 10 and Windows Server 2016 operating system, complicates the acquisition of volatile data in memory. It has been highlighted in [4] that the use of some acquisition tools (e.g., Magnet RAM Capturer, FTK Imager) to undertake live forensics causes the system to crash. Subsequently, the volatile data (i.e., the initial object of the acquisition) is no longer available since the operating system will restart the system [4], [5]. However, much work remains to be done in the technical analysis such as what happens to the system when the VSM feature is active that affects the tools during the memory acquisition process. This motivates the direction of this study to carry out further investigations on the VSM environment.

It has been noted that not all memory acquisition tools can complete the acquisition process during an active VSM environment. Therefore, this study aims to conduct a technical analysis of the VSM effects on the live memory acquisition process using two cases. The first case is a successful memory acquisition by using the Belkasoft RAM Capturer tool, and the second case is an unsuccessful memory acquisition by using the FTK Imager tool. Reverse engineering techniques are applied to analyze the behavior of the system. The main methods used are static and dynamic code analysis using IDA disassembler and Windbg debugger. Additionally, event analysis is conducted by examining event logs collected by the operating system to facilitate our understanding of the impact.

While previous works have been studying VSM and identifying the BSoD for live forensic tools, our study may become the initial research investigating the impact of VSM on live forensics. The results are discussed with technical data produced from reverse engineering techniques. Static analysis results can be used to understand the tools' program code that could directly lead to crash events. The dynamic analysis could demonstrate the tools' behavior in their running state that

may (or may not) cause the impact, and how they interact with the operating system as the manager of the computer system including memory. We contribute to the underlying methodology that applies static, dynamic, and event analysis in examining the behavior of VSM and how it impacts the running memory acquisition tools.

The remaining of this paper is organized as follows: Section II discusses the related work, Section III describes the materials and methods employed in this study, Section IV discusses the results, Section V presents the conclusion, and Section VI highlights the limitations and future work.

II. RELATED WORK

Collecting, and preserving the data of Random Access Memory (RAM) for forensic analysis is considered critical in live forensics. It contains many valuable forensic interest artifacts, including processes running on the computer. Examples of the content's use are to examine security incidents and get data from encrypted containers when it is being opened. The importance of memory forensic acquisition has attracted significant interest in recent years. Arfeen et al. [6] developed a framework for memory acquisition periodically to analyze process behavior while it is running and reside in memory to help ransomware detection. Prakoso et al. [7] examined how Metasploit attacks on Windows 10 can be analyzed using live forensics techniques on the volatile memory. The study used three well-known RAM acquisition tools, namely: FTK Imager, Dumpit, and Magnet RAM Capture. Volatility was used as the analysis tool. The results showed that RAM's live forensics can obtain key artifacts including the attacker's IP address and evidence of malware. Kazim et al. [8] identified chat artifacts of an instant messaging tool including master encryption keys that are encrypted by Bitlocker and Truecrypt, from memory dumps of Windows 7 computers. The memory dump was been analyzed using analysis tools such as Volatility and Rekall [9], [10]. The results confirm the necessity of deploying mechanisms to collect RAM from local and remote systems to support the RAM acquisition, for incident responder teams.

Choosing the appropriate tools for the acquisition and analysis of memory forensics depends upon the compatibility between digital devices and operating systems, which may pose challenges to investigators [11]. Therefore, many existing studies have attempted to understand the strengths and weaknesses of memory acquisition tools. A study in [12] compared four tools, namely Windows Memory Reader, Belkasoft's Live Ram Capturer, ProDiscover, and FTK Imager, to examine their performance in capturing memory including their ease of use. Another study in [13] showed the differences in processing time, memory usage, registry key, and DLL for FTK Imager, Belkasoft RAM Capturer, Memoryze, DumpIt, and Magnet RAM Capturer. Similarly, [14] also examined how the combination of Belkasoft RAM Capturer, FTK Imager, and Winhex can be utilized to obtain data for the Line app in Windows 8.1. Prakoso et al. [7] identified that FTK Imager, Dumpit, and Magnet RAM Capture, have the same performance in acquiring the targeted artifact of a Metasploit attack in Windows 10 based on their acquisition results comparison.

With the important role of memory acquisition and analysis in digital forensics, it indicates that any issues that may hinder these processes shall be examined, including VSM. VSM is a Windows 10 technology for creating and managing a secure operating system environment [15]. The secure environment is designed to be a place for the execution of critical security functions, protecting it from attacks directed against the operating system. VSM uses virtualization as its base [16].Virtualization on a machine run by an emulator, commonly known as a hypervisor. Microsoft gives a particular name to its hypervisor system which is Hyper-V, while the virtual machine is known as a partition (e.g., Partition A and Partition B). Hyper-V virtualizes hardware resources for each partition and manages these virtual resources, including virtual memory and CPU.

Details architecture of a Windows environment that supports VSM shows that Hyper-V occupies the root partition [16]. The partition houses two environment modes, namely: (i) kernel, and (ii) user. Each environment operates on a separate domain, called the Virtual Trust Level (VTL). VTL enforces isolation in three aspects. First is memory access in which each VTL has a set of memory access protections that prevent an allocated VTL's memory from being accessed by entities in another VTL. Second is the virtual processor state, where each VTL has a set of private virtual processor registers associated with it. Third, interrupt in which each VTL has a separate interrupt system to prevent interference from entities operating in other VTLs during sending and processing of interrupts.

A study on Windows 10 reported that Hyper-V implements two VTLs: VTL 0 and VTL 1[16]. VTL 0 hosts a traditional Windows environment. Users running in VTL 0 are referred to as normal environment users, while the running kernels are known as normal kernels. VTL 1, on the other hand, is the place for the Windows environment to perform security-critical functionality. The environment is referred to as a safe environment. VTL-based memory access protection enforced by Hyper-V can be further referred to in [16]. The study shows the memory region's contents that are part of the memory dump of a VSM-enabled Windows environment mapped to the lsaIso.exe trustlet. The question mark character ('?') indicates unreadable memory because it cannot be accessed beyond the isolation limits implemented by VTL 1, where lsaIso.exe operates. A report in [4] discussed the effect of VSM that causes BSoD on several tools including Magnet RAM Capture v1.1.1 and FTK Imager Lite v3.1.1, however other tools such as Belkasoft RAM Capturer and Passmark osforensics v 5.1.1001 were not included.

There are existing studies that have demonstrated static code analysis and dynamic code analysis. For example, a study by Hirst [17] showed an acquisition test on no-quiescent virtual machines that utilized dynamic code analysis. Another study in [18] identified memory acquisition challenges that misuse two architectural features, which are physical address layout and secure container. The authors acknowledged them as a new class of anti-memory forensic techniques. Significantly, these studies provided key guidance on the methods that can be referred to conduct testing and observation.

Yehuda et al. [19] proposed a hypervisor-based memory acquisition tool by extending the Volatility framework and implementing it in ARM64-bit kernels. The authors showed how their proposed tool can reduce the processor's consumption, maintain the coherent state of the memory dump, and generate fewer tradeoffs for network and disk acquisition. The tool successfully conducts memory acquisition without facing any difficulties caused by security and privilege levels in Linux OS and ARM processors, called Trust Zone which divides accesses into secure and non-secure ones.

Nevertheless, the study on technical analysis of the VSM effect on the live memory acquisition process is still limited. There have been significant studies of VSM architecture on Windows 10, including the details of VSM initialization activity performed by the Windows loader during the boot process, and the communication interface on VSM [16], [20]. However, the explanation still lacks the technical impacts of VSM on the memory acquisition process. In this study, therefore, we attempt to examine the memory acquisition in Windows-based OS, especially in Windows 10 that enabled the VSM feature in Intel machines to manage virtual trust levels for kernel and user processes.

III. RESEARCH METHOD

This study applied reverse engineering as it is a widely recognized technique in digital forensics to process and interpret data [21], [22]. The methods used to analyze the impact of VSM on the memory acquisition tool are static and dynamic code analysis using the IDA disassembler and windbg debugger tools.

Event analysis is conducted using the operating system's event logs for further correlation with the findings from the static and dynamic code analysis. The complete research stages are presented in Fig. 1. The hardware and software specifications used in this research are presented in Tables I and II, respectively.

Experiments in this study are conducted in two environments, (1) VSM-enabled, and (2) non-VSM-enabled. VSM feature is enabled through the BIOS by setting the "Intel Virtualization Technology" option to "Enabled." The BIOS used in this study is from the American Megatrends vendor, version 309, with VBIOS Version 1054.I021x441UAR.002.

TABLE III.   EXPERIMENTS AND ANALYSIS STEPS

Static Code Analysis		
No		*Steps*
1		VSM feature setting [Active/Non-Active]
	a	Disassembling executable files of memory acquisition apps (.exe) [FTK Imager/Belkasoft RAM Capturer] by using IDA PRO
	b	Running the diffting plugin to compare the apps' functions in VSM vs. non-VSM environments by using Diaphora on IDA PRO
2		Save the results
Note: 4 (four) files were produced: Assembly codes for: • FTK Imager • Belkasoft RAM Capturer SQLite files for: • FTK Imager • Belkasoft RAM Capturer		
Event Log Analysis		
No		Steps
1		Acquiring memory by using FTK Imager and Belkasoft RAM Capturer in active VSM and non-active VSM environments
2		Opening Event Viewer
3		Copying event log:
	a	Event Application
	b	Event Security
	c	Event System
Note: 3 (three) files were produced: Application, Security dan System event logs		
Dynamic Code Analysis		
No		Steps
1		Choosing the target executable files
2		Preparing the required symbols
3		Starting the debugging

IV. RESULTS AND DISCUSSION

This section presents the results of experiments and discusses the memory acquisition, static code, event log, and dynamic code analyses that have been carried out.

A. Memory Acquisition Analysis

It has been observed that the FTK Imager has successfully acquired a memory dump in a non-VSM-enabled. On the other hand, no memory dump was generated when VSM was active because the system experienced a Blue Screen of Death (BSoD). Meanwhile, Belkasoft RAM Capturer managed to acquire memory dump in both VSM environments. Therefore, this section will analyze the differences in the results of memory acquisition from the FTK Imager application in a non-enabled- VSM environment (non-VSM), and Belkasoft RAM Capturer in both VSM environments.

All three memory dumps generated by the memory acquisition applications have the same size according to the measured memory capacity of 21.4 GB (23,068,672,000 bytes). Here, we will focus on the contents of the memory dump, which has the value "?????????????????...??????" as a mark of memory locations that are not readable by applications (see Fig. 2).

The data shows that the unreadable memory space of active VSM is larger than non-VSM (the sign … refers to the other 65 rows that are not displayed). It indicates that VSM enforces more limitations on physical memory access than non-VSM. The limitation can be correlated with the implementation of memory access protection for each VTL, especially for VTL1 which runs in a safe environment [16].

By calculating the portion of memory with the value "?????????????????...??????" (see Fig. 2), there are 122 MB of memory size for Belkasoft in VSM-enabled mode. It is about 0.6% of the memory size. Meanwhile, Belkasoft and FTK Imager in non-VSM mode are 0.4 MB and 0.5 MB, respectively. It is only about 0.0021% and 0.0025% of the memory size. The comparison of the unreadable memory percentage between VSM-enabled and non-VSM-enabled is significant, as consistent with the importance of memory data for a live forensic investigation.

B. Static Code Analysis

The analysis compares the differences between an active VSM state and when VSM is not active. In this section, the experiment results are grouped based on two types of memory acquisition applications tested, namely FTK Imager and Belkasoft RAM Capturer. The assembly codes are derived from the machine code from the disassembler process using IDA PRO.

A python IDA plugin called Diaphora is used to generate an SQLite file that lists the functions identified from the assembly code generated by IDA PRO. The main purpose of using Diaphora is to examine differences in the functions of the FTK Imager application for active and inactive VSM conditions and the Belkasoft RAM Capturer application.

Fig. 2.   Memory Sectors that are Unreadable by FTK Imager and Belkasoft RAM Capturer.

Diaphora succeeded in recognizing 32483 functions from the assembly code of the FTK Imager application. The results were compared in terms of names, order of contents, hash values, and relative virtual address (RVA) values of all these functions. It is identified that all functions of these assembly codes are equal when run in both enabled VSM and non-enabled VSM. The number of files with the status of "100% equal", "Perfect match, same name," "Same order and hash," and "Same RVA and hash" are 21760, 3, 6507, and 4213 files, respectively. Likewise, for the 38 functions that have been recognized from the Belkasoft RAM Capturer application, all of them are also identified to be the same. It has been observed that 15 files with the status of "100% equal", 3 files with the status of "Perfect match, same name," six files with the status of "Same order and hash," and 14 files with the status of "Same RVA and hash".

Based on these findings, it can be deduced that FTK Imager and Belkasoft RAM Capturer applications do not have different functions in their static code for both environments (i.e., VSM is enabled and non-enabled). This further indicates that the VSM environment does not affect the overall running characteristics of the application.

C. Event Log Analysis

Windows operating system generates three event logs which are Application, System, and Security logs. In this study, we focused on observing events from Application and System

logs because they contain key information when the system crashes and restarts.

We identified the records of events associated with FTK Imager application crashes during the memory acquisition process, and when VSM is enabled from the event Application log. Detailed information is presented in Fig. 3. It describes the error name called BlueScreen and informs that this crash event has the data stored in the MEMORY.DMP file.

We observed more information from the System log events. Fig. 4 reports an event with an "error" status. This status is captured from the second experiment scenario; when the VSM is not activated. Detailed information can be found in the General field, stating that the VSM feature is not activated and the Hypervisor as a virtualization emulator fails to run. This information confirms the environment in which we did not activate the VSM. While this setting can be checked from the BIOS configuration, this "error" status notified us that this virtualization-based enablement policy should be mandatory in Windows 10. This situation may lead to anti-forensics, where the implementation of security control prevents digital forensic tools to operate.

The captured information about the error when the FTK Imager is running on the active VSM is presented in Fig. 5.

It is likely indicating the cause of the blue screen and the record of the crash event that forced the system to reboot. The operating system provides the information in their Bugcheck error in Event Viewer. Bugcheck error will record the BSoD event, and its basic error code to identify what caused the BSoD. The fourth row in this Bugcheck provides information that the system is rebooted and IsolatedUserMode is active.

Fig. 3.   Selected Significant Events of FTK Imager in Non-Active VSM.

Fig. 4.   Selected Significant Events of FTK Imager in Non-Active VSM.

Fig. 5.   Selected Significant Events of FTK Imager in Active VSM.

We have the same observation about the active IsolatedUserMode when Belkasoft RAM Capturer runs in active VSM (see Fig. 6). Other key points in Fig. 5 are shown in rows 5 and 6. These two rows indicate a Hypervisor failure to handle CVE-2018-3646. Further examination of Common Vulnerabilities and Exposure (CVE) suggests that the vulnerability is related to the possibility of unauthorized disclosure of information [23]. A possible explanation for this failure could be associated with the existence of a memory space isolation system that caused the memory acquisition tools unable to access the information.

An additional analysis of the MEMORY.DMP file was undertaken to obtain further information on the "Bugcheck" event. We used the Windbg application and ran the command !analyze -v (see Fig. 7). The Bugcheck analysis was carried out on the MEMORY.DMP file supports that the crash is related to the FTK Imager application. The associated module is ad_driver, and the image name is ad_driver.sys. The file directory is located at C:\Users\[UserName]\AppData\Local\Temp. This is consistent with the information on the BSoD screen, which indicates an error has occurred in the driver.sys. Furthermore, Windbg provides more information about this error by indicating that the driver.sys in question is related to ad_driver.

D. Dynamic Code Analysis

Dynamic code analysis examines the application's behavior while the operating system executes it. Interaction from the user will affect the direction of execution. The dynamic code analysis is performed on the FTK Imager application with an active VSM environment. The aim is to observe the application's behavior related to the BSoD error.

Fig. 7.   Summary of Bugcheck Analysis Results.

The analysis commenced by selecting the "Start debugging" menu in the Windbg Preview application and selecting the executable file from the FTK Imager application. The debugger downloaded the symbol file "ProfUISad64.pdb" to perform the debugging process. The following commands are typed on the "Command" page to control the process:

- To load symbols:

    - .symfix
    - .reload

- To run the FTK Imager application:

    - g

As a result of executing those commands, we identified that the last module before the system crash was C:\Windows\system32\mssprxy.dll. The module is recorded from the debugger as a module that is loaded before the user clicks the "Capture Memory" button. This is an unexpected finding because the information from the event log analysis suggests the module that caused the crash is ad_driver.sys. Therefore, other scenarios in dynamic code analysis shall be considered to find the very last module loaded by the operating system before the crash happens.

V.   CONCLUSION

This study aims to conduct a technical analysis of the effects of VSM on the memory acquisition process. Two cases were observed that are: (1) a successful acquisition process by using the Belkasoft RAM Capturer, and (2) an unsuccessful acquisition process by using the FTK Imager. The static analysis results of the two applications did not show any differences in the program code when the application machine code disassembler was carried out, both when VSM was enabled and non-enabled. It is concluded that the VSM environment does not affect the program modules of the application.

Meanwhile, Application event analysis comprises logs of system crashes and is stored in the MEMORY.DMP file. Bugcheck analysis of the dump file shows the cause of the system experiencing BSoD when it executes the ad_driver.sys module. Furthermore, results from dynamic analysis explained the behavior of the FTK Imager application just before the BSoD occurs, and it is identified that the application accesses the C:\Windows\system32\mssprxy.dll module.

VI.   FUTURE WORK

This study highlights the impact of VSM on the memory acquisition process that causes the loss of memory artifacts when the process is halted and the system restarts. However, this study is limited to two memory acquisition tools running on the Windows operating system, which respond differently to the activation of the VSM feature. More importantly, the difference opens more directions for future work. Investigating the impact on other tools and operating systems would present more significant results to be compared. Testing environments should involve different scenarios in dynamic code analysis and conduct an in-depth analysis of the ad_driver.sys module content. This is to seek further understanding of how the module causes the system crashes.

Abstract—The creation and generation of schedules that are free of conflicts manually every academic semester present higher education institutions with a duty that is laborious and demanding of their resources. The course timetabling optimization, as an education timetabling problem, is a popular example of an NP-hard combinatorial problem. Numerous attempts have been made over the course of the past few decades to find a solution to this problem, but no one has yet developed a foolproof approach that can examine all alternatives to find the best method. The promising swarm-based optimization algorithm called Whale Optimization Algorithm was heuristically enhanced in the present study and is called HEWOA. It was designed as a solution to the course timetabling problem discussed in the current study. HEWOA was able to generate an efficient timetable for the large dataset of 1700 events for an average time of 14.92 seconds only, with an average generation of 7.2 and a best time of 8.38 seconds. These results reveal that the performance of HEWOA was better than that of various hybrids of the Genetic Algorithm that was compared in the present study.

Keywords—*Heuristics; mutation; optimization; swarm; timetabling; whale optimization algorithm*

I. INTRODUCTION

The application of automated procedures to a time-consuming and resource-intensive task often leads to increased efficiency and productivity, as well as time and cost savings. Among these processes are the preparation and creation of academic schedules. Timetabling problem was solved manually through trial and error, but this was not the greatest option. At present, scientific methods are used to address the problem [1], [2]. Timetabling problems, better known as the university course timetabling problem (UCTTP), are known to be NP-hard, meaning the problem cannot be solved exactly in polynomial time as its size and complexity increase exponentially [3]. It involves allocating non-overlapping classes to given resources such as classrooms and teachers in space-time [4]. The number of courses, the average number of lectures per day, the desired free timeslots each day, and the targeted off-days in a week are a few of the constraints that influence the design of the educational timetable [1], [5]. In the scheduling problem, there are two types of constraints: hard constraints and soft constraints. Hard constraints are rules or restrictions that cannot be broken. Soft constraints are requirements that, if not violated, can improve the effectiveness of the timetable. A timetable is considered efficient if it is able to solve the problem while adhering to all of the hard constraints specified [6].

The process of scheduling classes is often carried out with the assistance of specialized models that are adapted to meet the requirements of the particular educational establishment in question. A significant amount of work devoted to scheduling makes use of streamlined models to investigate and evaluate the performance of various scheduling strategies. The vast majority of research on course scheduling focuses on modeling and computational results, with very little attention paid to actual implementation in the real world [7].

Several strategies have been used to solve course timetabling using benchmark and real-world datasets. This problem was solved over decades using optimization approaches. Heuristic approaches helped resolve timetabling's complex behavior and model [8]. Evolutionary methods are frequently used in solving course timetabling; however, these existing methods were not able to quickly tests all alternatives to find the best solution [8]–[10]. Recently, various research has employed the Whale Optimization Algorithm (WOA), which is appreciated as a simple, flexible, and competitive swarm-based metaheuristic algorithm [11][12][13]. Despite its potential, it has inherent flaws that must be addressed before it can effectively address optimization issues such as course timetabling. WOA, like most metaheuristic algorithms, struggles to have a balanced local and global search.

The present study is an application and enhancement of the algorithm used in the previous work of WOA [14] in solving course timetabling. In this work, WOA was integrated with heuristic mutation to improve further the performance of WOA in solving optimization problems such as timetabling. The aim of the present work is to introduce HEWOA as a heuristically enhanced variant of the WOA, which is used in solving course timetabling problems. A literature review is presented in the next section of this paper, which contains a discussion on timetabling, solutions for solving UCTTP, and WOA. The third section presents the particulars of the methodology, which includes the problem definition, the architecture, and the HEWOA. Section IV presented the observations, results, and discussions on the experiments conducted in solving the timetabling problem. Finally, the conclusion of this study is presented in Section V.

II. LITERATURE REVIEW

A. Timetabling

The process of allocating resources to discrete objects in space-time to achieve desired goals within a given set of constraints is called timetabling. Timetabling encompasses many research-intensive fields. In education timetabling, the timetabling for the course and examination is the most studied. It is challenging to execute a course scheduling solution with the same approach to a problem because each institution has unique characteristics and constraints or limitations [15]. Universities and colleges in the Philippines use a manual procedure to schedule classes, increasing work for program heads and making it difficult to analyze every timetable combination [16]. In each country, accrediting government and private agencies require state universities and colleges to adhere to specific policies and criteria for scheduling classes. One of the recommendations suggests limiting the number of preparations for each faculty member to no more than four distinct subjects so that they have just enough work to do during the semester. The quality of instruction may degrade if faculty members teach more subject courses than the university deems optimal [17], which also leads to student's poor academic performance[18]. This case is often violated in actual practice. There are also cases of an unbalanced allocation of workloads among faculty members, in which some have more than four preparations while others have fewer than four.

More research is encouraged in solving UCTTP as it is unique across institutions due to policies and regulations. A general solution that could solve all the concerns in UCTTP does not exist [9]. Apart from being effective, optimization algorithms should consider simplicity and adaptability to a range of varying real-world UCTTP [10]. Thus, adapting the implementation of state-of-the-art methods on real-world UCTTP is still open to be explored by researchers.

B. Solutions in Solving UCTTP

Over the past decade, several works have shown substantial advancements in timetabling techniques and algorithms. These methods were created to address either benchmark datasets or real-world datasets [9]. In terms of the quantity and hard and soft constraints, benchmark and real-world UCTTPs differ. Creation solutions for benchmark datasets are often generalized and intended for comparing algorithms. The benchmark datasets utilized in international timetabling competitions, such as Socha[19], ITC-02[20], and ITC-07 [21], are the most popular testbeds among researchers in comparing algorithms. Real-world UCTTP, on the other hand, emphasizes the applicability of solutions in academic institutions. Due to varied legislation, educational systems, and cultures, even real-world UCTTP vary in terms of their criteria [10].

Metaheuristic methods promise precise and optimal timetable scheduling solutions and are popular for timetabling and other optimization challenges. They are simple to implement, faster than the standard mathematical-based optimization process, and achieve optimal results [11]. Evolutionary methods like Genetic algorithms, ant colony, local search, simulated annealing, and tabu search are frequently used in course scheduling; however, none of these was considered the best [8], [9]. Hybrid techniques or combining two or more algorithms are also prevalent and have produced more high-quality outcomes than other techniques, as proven in prior studies [22]–[24]. Hybrid methods are appropriate for maximizing the benefits of separate techniques. Single solution-based meta-heuristics and population-based meta-heuristics are the most popular approaches for the benchmark UCTTP, while in the case of real-world or actual datasets such as the one used in this work, the most popular methods used include single solution-based meta-heuristic, Operations Research, population-based meta-heuristic, hyper-heuristic and hybrid approaches [9].

C. Whale Optimization Algorithm

The Whale Optimization Algorithm (WOA) is a swarm-based optimization algorithm that is inspired by the hunting behavior of humpback whales[13]. WOA is among the most promising and competitive optimization techniques [11], [25]. The whales, while encircling the prey, create specific bubbles along a circular path. The bubble-net attacking technique assists in exploitation. The prey for the search state of WOA represents the exploration phase. For exploitation, the whale position is updated using either spiral movement or shrinking encirclement. For exploration, the humpback whale finds the best solution and updates its position according to other whales. Having this inspiration, WOA is composed of three operators: encircling prey, bubble-net attacking method, and search prey.

The following are the relevant equations implemented by WOA on its operations. Eq. 1-4 captures the procedures for the encircling prey.

$$\vec{D} = |\vec{C}.\vec{X}^*(t) - \vec{X}(t)| \tag{1}$$

$$\vec{X}(t + 1) = \vec{X}^*(t) - \vec{A}.\vec{D} \tag{2}$$

$$\vec{A} = 2\vec{a}.\vec{r} - \vec{a} \tag{3}$$

$$\vec{C} = 2.\vec{r} \tag{4}$$

where t indicates the current iteration, $\vec{A}$ and $\vec{C}$ are coefficient vectors, and $X*$ is the position vector of the best solution obtained so far. $\vec{X}$ is the position vector, $|\ |$ is the absolute value, and is an element-by-element multiplication, and $\vec{r}$ is a random vector in [0, 1]. It should be noted that $X*$ should be updated in each iteration if there is a better solution. The vectors $\vec{A}$ and $\vec{C}$ are calculated as shown in Eq. 3 and 4, respectively.

Bubble-net attacking method:

$$\vec{X}(t + 1) = \vec{D}'.e^{bl}.\cos(2\pi l) + \vec{X}^*(t) \tag{5}$$

$$f(x) = \begin{cases} \vec{X}^*(t) - \vec{A}.\vec{D}, & \text{if } p < 0.5 \\ \vec{D}'.e^{bl}.\cos(2\pi l) + \vec{X}^*(t), & \text{if } p \geq 0.5 \end{cases} \tag{6}$$

Where p represents a constant for explaining the shape of the logarithmic spiral and l is a random number uniformly distributed in the range of [-1, 1].

and Search for prey:

$$\vec{D} = |\vec{C}.\vec{X}_{rand} - \vec{X}| \tag{7}$$

$$\vec{X}(t+1) = \vec{X}_{rand} - \vec{A}.\vec{D} \qquad (8)$$

where $\vec{X}_{rand}$ is nominated arbitrarily from whales in the current iteration.

Many recent research has employed the Whale Optimization Algorithm (WOA), which is appreciated as a simple, flexible, and competitive swarm-based metaheuristic algorithm [11][12][13]. Whale bubble-net hunting inspired WOA's algorithm. Its effectiveness and adaptability attract researchers from many fields. It is used in electrical, computer, aeronautical, and construction engineering [26]. Despite WOA's promising features, it has some unavoidable flaws, including being designed for continuous search space [13], requiring too many parameters tuning [27], having no theoretical convergent property [28], and having a probability distribution that changes with iterations [12]. It may also prematurely converge, trapping it in local optima [29], [30]. WOA, like most metaheuristic algorithms, struggles to balance local and global searches. The present study is an application and enhancement of the algorithm used in the previous work of WOA [14] in solving course timetabling. In this work, WOA was integrated with heuristic mutation.

III. METHODOLOGY

A. Problem Definition

In the allocation of schedules to resources, the course timetabling problem must fulfill both hard and soft restrictions. This section presents the problem description and objective functions to be used in the implementation of the timetable. This study's constraints and objective functions are similar to the previous work [14] but were implemented with a different algorithm to enhance WOA.

- Timetable Guidelines

The number of courses, the average number of lectures per day, the desired free timeslots each day, and the desired off-days in a week are a few of the variables that influence the design of an educational timetable. Each course in a curriculum is a class which could be a lecture, a lab, or both. Each of these classes is allocated a teacher and a classroom at a time that should not conflict with other classes scheduled for that day. Classrooms are utilized either for lecture classes or laboratory work. The mathematical formulation must fulfill all the relevant variables in order to produce a timetable that is both efficient and feasible. The following variables have been taken into consideration throughout this study. Let:

- E be the set of scheduled classes for a teacher and students with specified courses and classrooms,

- S be the set of students grouped through blocks in a program,

- T be the set of teachers wherein each teacher can handle many courses with a maximum of 4 unique subjects to handle,

- C is the set of courses wherein each lecture unit in a course is equivalent to one hour, whereas each laboratory unit is equivalent to three hours of class;

- R be the set of rooms, either lecture or laboratory, that will be assigned to classes, and;

- K is the set of period slots in a day from 7:30 in the morning to 7:30 in the evening, wherein the days of the week are paired as Monday-Thursday, Tuesday-Friday, and Wednesday-Saturday.

- Constraints

The constraints in course timetabling problems are classified as soft and hard. Soft constraints are optional, while hard constraints must be satisfied completely [9], [13]. For this work, the minimum requirements set as policies by the Accrediting Agency of Chartered Colleges and Universities in the Philippines and the Commission on Higher Education for state universities such as Bicol University are also taken into account in these constraints. Table I presents the constraints considered in this study which were identified as the most common constraints being used in solving course timetabling [9].

TABLE I. THE CONSTRAINTS

Code	Type	Description
H1	Hard	No teacher may be assigned to the same group of students in two separate classes.
H2	Hard	A teacher should handle only one course in one classroom at each time slot.
H3	Hard	Exactly only one class is assigned per timeslot per day in a classroom.
H4	Hard	The size of the classroom should be considered.
H5	Hard	For all required courses for a group of students must be given a scheduled
H6	Hard	All the teaching periods required in the curriculum must be given a schedule
H7	Hard	An uninterrupted period of time required for a class should be assigned precisely on a given day.
S1	Soft	At least one timeslot in a day should be vacant for a group of students
S2	Soft	The maximum number of straight classroom teaching hours is three in a schedule
S3	Soft	The total number of teaching hours in a day should not exceed 6 hours.

- Objective Functions

The degree to which the timetable can satisfy the constraints effectively will determine how much each solution will cost. In each generation of the candidate solution, a time slot is allotted to a pair of student and faculty groups associated with a classroom and a course. This is done with the goal of satisfying all hard requirements while keeping the expense of satisfying soft constraints to a minimum. The problem may also be expressed using the formulation that follows. Let X be the set of all possible solutions, $HC = \{h_1 \dots h_6\}$ the set of hard constraints, $SC = \{s_1 \dots s_5\}$ the set of soft constraints and $x \subseteq X$ the set of all candidate solutions.

The goal of this procedure is to find the most efficient timetable with the least cost, as presented in Eq. 1 by the penalty charged per violation of a hard constraint:

$$hp(x) = \sum_{t \in T} f_1(x,t) + \sum_{t \in T} f_2(x,t) + \sum_{r \in R} f_3(x,r) + \sum_{r \in R} f_4(x,r) + \sum_{s \in S} f_5(x,s) + \sum_{s \in S} f_6(x,s) + \sum_{s \in S} f_7(x,s) \quad (9)$$

TABLE II. THE OBJECTIVE FUNCTIONS FOR THE HARD CONSTRAINTS

Function	Penalty instance	Purpose
$f_1(x,t)$	Two or more classes are assigned to one teacher to handle	Ensures no conflict in faculty loading
$f_2(x,t)$	More than one teacher is assigned to a class	Ensures that only one teacher is assigned to a class
$f_3(x,r)$	One classroom is assigned with multiple classes.	Ensures no conflict in the classroom assignment
$f_4(x,r)$	If the classroom size is not considered.	Ensures that the classroom can accommodate the class size
$f_5(x,s)$	a course for a block of students has no schedule assigned	Ensures that all courses enrolled by the students are assigned a schedule
$f_6(x,s)$	The number of required hours on the curriculum is not satisfied.	Ensures that the required hours offered in the curriculum are equal to the scheduled classes
$f_7(x,s)$	More than a total of six hours of teaching load for a teacher	Ensures that there is a balance distribution of workload within a week

The penalty function for hard constraints is represented by Equation 9, and the value of the objective function for each solution can be determined as follows when soft constraints are also considered:

$$f(x) = \left(\sum_{s \in S} f_8(x,s) + \sum_{t \in T} f_9(x,t) + \sum_{t \in T} f_{10}(x,t) \right) + (hp(x) \times W) \quad (10)$$

The function $f(x)$ shown in Eq. 10 represents the sum of all penalties from hard and soft constraints. The function examines each solution for possible violations on the constraints wherein a value of one (1) will be given had there been violations; otherwise, zero (0). It can be observed that there is a variable W that is applied to the hard constraints $hp(x)$, where a value of three (3) will be multiplied by the counted violations on hard constraints. This was done so that the objective function would give more weight to violations on hard constraints.

TABLE III. THE OBJECTIVE FUNCTIONS FOR THE SOFT CONSTRAINTS

Function	Penalty instance	Purpose
$f_8(x,s)$	There is no vacant period for a day to a group of students	Ensures that students have at least one vacant period daily
$f_9(x,s)$	The total teaching hours for a course totaled to more than 3 hours	Ensures that the schedules are not straight and that having such would be tiresome both for the students and teachers.
$f_{10}(x,s)$	the total teaching hours to be handled by a teacher is more than 6 hours	Ensures that the schedules are distributed throughout the week.

B. Architecture

The courses and classes to be included in the scheduling were collected from various colleges at Bicol University. The lecture and laboratory rooms available for utilization and faculty members teaching these courses were also identified.

These raw data were used in the generation of the timetable. Various sizes of datasets were considered for the experimentations to test the algorithms: 400, 800, 1200, and 1700 as the largest dataset.

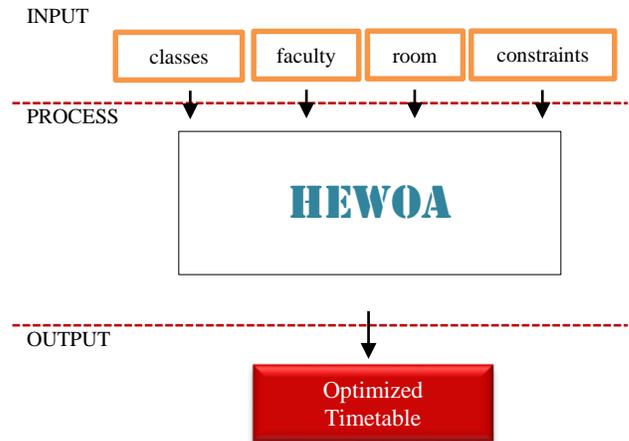
Shown in Fig. 1 is the framework of the method for generating an optimized and fairly distributed timetable. The classes to be scheduled, faculty schedule, room availability, and specified constraints serve as the inputs. These data will be processed using HEWOA as objective functions. A penalty will be applied to violations of constraints, and the process will be repeated through generations until the cost approaches zero to produce an efficient and optimized timetable.


Fig. 1. Framework of the Study.

C. The Heuristically Enhanced Whale Optimization Algorithm

In this work, preliminary results implemented in solving course timetabling using WOA indicate that updating the entire solution using these traditional procedures of WOA has a greater likelihood of destroying rather than improving it. This is because the whale operator is designed to update all values using the same parameter values, and the event number is large. Additionally, the more constraints applied to a problem, the more complicated the search process becomes. A solution emerged during the experimentation: when the first procedure (encircling prey) was not used, the performance of WOA was improved. This is due to the nature of the equation, which has a high probability of destroying the solution. Moreover, the heuristic mutation operator is integrated into the process to enhance further WOA's exploration and exploitation capability.

Fig. 2 now depicts the pseudocode of HEWOA, taking into account the aforementioned modifications to the method as well as the section where the heuristic mutation seen in Fig. 3 will be implemented. It is shown that the encircling procedure was removed from the process.

Instead of updating the position of the current search whale using the encircling prey process, remove it, retaining the Bubble-net attacking method for the exploitation phase and searching for prey for the exploration phase.

```
Initialize the whales population Xᵢ(i = 1, 2,...,n)
Calculate the fitness of each search agent
X*=the best search agent
  while (t < maximum number of iterations)
    for each search agent
    Update a, A, C, l, and p
      if1 (p<0.5)
        if2(|A| < 1)
          • Select a random search agent (Xrand)
          • Update the position of the current search
            agent by the Eq. 8
      else if1 (p ≥ 0.5)
        Update the position of the current search by
        the Eq. 5
      end if1
      Update the position of the current search
      agent using Heuristic Mutation (Fig. 4)
    end for
    Check if any search agent goes beyond the search
    space and amend it Calculate the fitness of each
    search agent Update X* if there is a better
    solution
    t=t+1
  end while
return X*
```

Fig. 2.   The HEWOA Pseudocode.

Accordingly, in WOAs encircling prey section, search agents update to the best agent. It is easy to trap the algorithm in a local solution, causing premature convergence [31]. Consequently, updating the position of the current search agent using heuristic mutation is integrated to further improve the algorithm's exploitation and exploration capability. In this work, the heuristic mutation focuses on invalid classes and repairs them using random pairs of room and period.

- The Encoding Method

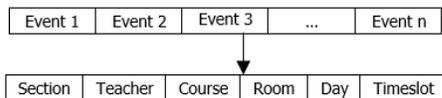
The genetic operator avoids illegal offspring by encoding all events in each candidate solution in the same index, as shown in Fig. 3.


Fig. 3.   The Representation of the Solution.

The subset of solutions in the current generation is a 3-dimension array containing scheduled events. Each of these events contains the codes of other constraints such as student section, teacher, course, room, day, and timeslot. This data structure is similar to the one used in the work of [32]. In addition, prioritizing constraints are applied, and the events of the teacher who has the highest workload and the events of the section of students who have the most classes that need to be scheduled are attached to the solution first.

- Fitness Function

The whale's fitness is the weighted sum of penalty cost based on Equations 9 and 10. Every constraint violation incurs a penalty of 1. However, the cost for hard constraints is multiplied by the weight value W such that the algorithm prioritizes these constraints while finding and ranking all candidate solutions. In addition, the impact of soft constraints will highlight the superior solution since it meets preferences. In other words, a solution with the same cost in hard constraints will be differentiated by the number of violations on soft constraints.

- Heuristic Mutation

Mutation modifies genes to create new individuals. The heuristic mutation is designed to produce better offspring wherein a set of chromosomes is transformed from a parent by exchanging some genes (neighborhood) [33]. In Fig. 4, the operator gets all invalid gene indexes and then mutates them.

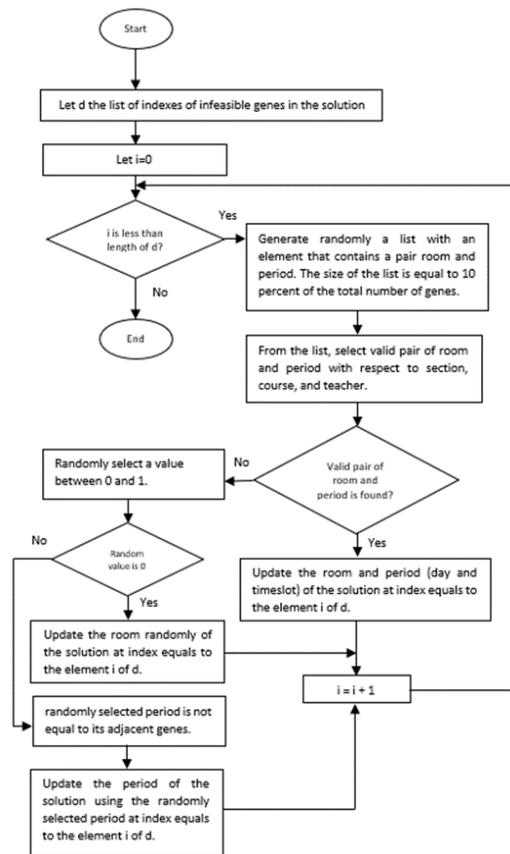
The operator does not implement mutation probability parameters in mutating invalid genes since it generates ten percent random genes or classes. The operator selects one of these randomly generated genes that fulfill stringent criteria. If no valid gene is found, the room or periods are altered at random (day and timeslots). It guarantees that randomly selected times are distinct from nearby occurrences in order to ensure diversity. Additionally, the rate of ten percent random genes or classes can be decreased or increased during the configuration or before running the algorithm.


Fig. 4.   Heuristic Mutation Applied to WOA.

IV.   RESULTS AND DISCUSSION

Using real-world data, the efficiency of HEWOA was evaluated. These are actual datasets that include the courses to be scheduled for the various programs offered by Bicol University, Legazpi City, Albay, Philippines, as well as the rooms being utilized for the conduct of classes and the assigned faculty that will handle the class. The HEWOA uses a population of 10 whales and will stop generating solutions if all hard constraints are satisfied by any whale or when it reaches an iteration of 1000.

TABLE IV.   PERFORMANCE OF THE HEWOA COMPARED TO OTHER
METHODS

Methods	Events	Average Generation	Best Time	Average Time	SD
GA Using Heuristic Mutation	400	3.4	0.590s	1.061s	0.353
	800	5.2	2.370s	**3.455s**	0.650
	1200	8.0	6.430s	8.554s	1.402
	1700	15.5	16.670s	21.670s	4.247
GA Using Invalid Genes Focused Random Resetting Mutation	400	4.1	1.280s	1.595s	0.198
	800	7.0	5.145s	7.608s	1.475
	1200	14.0	16.670s	23.015s	3.979
	1700	33.9	55.700s	81.355s	16.402
HEWOA	400	**2.4**	**0.458s**	**0.74s**	0.160
	800	**4.1**	**2.009s**	3.514s	0.812
	1200	**5.8**	**5.299s**	**8.362s**	1.964
	1700	**7.2**	**8.384s**	**14.942s**	4.671
EWOA [14]	117	-	-	3s	-
	195	-	-	15s	-
	304	-	-	270s	-
Guided GA [34]	878	136.5	-	-	-
	1140	409.5	-	-	-
Parallel GA and Local Search [35]	166	900	-	-	-
Greedy and Genetic Fusion Algorithm [36]	300	900	-	-	-

Table IV shows the various sizes of events or the number of classes used to test the various techniques. As part of the execution of the generating schedules in the timetable, the objective functions (Eq. 9) are executed, which assess penalties (Tables II and III) for schedules that violate the constraints stated in Table I. These costs determine the fitness function. Initial generations or runs would incur corresponding penalties, which would gradually decrease until they approached zero, at which point there would be no violations.

The performance of the HEWOA was compared to other competitive methods that solved course timetabling: GA using heuristic mutation; GA using invalid genes focused on random resetting mutation; guided GA [34], parallel GA and local search [35]; and greedy and genetic fusion algorithm [36]. The result in Table IV of their performances in terms of total execution time is based on ten (10) runs per method. In terms of average generation, HEWOA was able to perform better compared to other work which uses Hybrid GA as the base method. In terms of execution time, HEWOA was also able to perform better except on a dataset with 800 classes.

Fig. 5, 6, and 7 illustrate the pace at which the indicated techniques are approaching closer to zero, which is defined as the state in which no more penalties are incurred on the constraints. The research indicates that HEWOA is the approach with the fastest pace among these solutions, followed by GA with heuristic mutation. The least performing method is the GA when random resetting mutation is applied to infeasible genes.

An example of manually generated faculty workloads that shows unoptimized class schedules and loading is shown in Fig. 8. It can be observed in the workload that on Tuesday and Friday, the faculty had teaching hours of more than 6 hours. Thus, violating soft constraint 3, the total number of teaching hours per day should not exceed 6 hours. The same scenario can be repeated with other faculty since that method of plotting schedules is manual, which is prone to errors, especially when the schedulers are adjusting or transferring loads from one faculty to another.

Table V shows an example of faculty workloads generated by HEWOA. It can be seen that the workloads are equally distributed in the week, although the schedules do not show the consultation hours. It is also noted that that days are paired, like Monday-Thursday and Tuesday-Friday. In each timeslot, the total hour is one and a half hours, and the other one and a half hours are to be lectured on a corresponding pair day.

On room utilization, plotting classes manually can result in an inefficient room allocation. These would result in more classroom usage; it could increase the cost of maintenance and energy. In this work, the utilization of classrooms and laboratories is optimized since the HEWOA can produce timetables with fewer rooms compared to classrooms. For example, when we retrieved the schedules in one semester with 1700 classes, the classrooms and laboratories utilized were more than 120 compared to schedules generated by HEWOA and GA, which only used 91.

A. Implications

Population-based metaheuristics such as Genetic Algorithms, Particle Swarm Optimization, and Ant Colony Optimization are superior to other methods in solution space exploration. Still, these approaches require a higher processing time necessary to generate solutions of high quality [37]. A good quality solution means no violations of the specified constraints whose purpose is explained and presented in Tables II and III. It was observed in the presented results in Table IV and Fig. 5, 6, and 7 that HEWOA was able to generate good-quality solutions that require lesser computational time. HEWOA is a multi-objective implementation of WOA and can be used for other similar solutions.

The typical technique of timetabling is inefficient, manual, and not very robust against changes [10]. As a result, the number of course conflicts is considerable, which reduces the effectiveness of the instruction [38], [39]. The utilization of an intelligent approach for UCTTP has been the subject of much research and widespread debate worldwide. Using the method in the present work would aid in developing efficient software for course scheduling in academic institutions.

V. CONCLUSION

This paper introduces HEWOA, a heuristically enhanced Whale Optimization Algorithm designed to solve UCTTP. The results of the experiments on various sizes of real-world data indicate that both GA and HEWOA could generate a feasible and efficient timetable that could satisfy all the identified constraints set by educational institutions. Generating class schedules using GA and HEWOA can optimize classroom and laboratory utilization which could help decrease the cost of maintenance and energy. Optimized classroom and laboratory utilization could also help increase the number of students since there would be more available resources for classes. Faculty workloads also can be improved using automated scheduling; thus, it helps satisfy soft constraints and enhance the quality of schedules.

Moreover, it is observed that HEWOA outperformed Hybrid GAs [34] and other methods [35], [36] in terms of execution time and average solution generation for the majority of utilized event sizes.

Lastly, future work would include testing the performance of this method using benchmark UCTTP, which provides different constraints than the real-world data used in this study.

Abstract—The development of new technology has the potential to disrupt and transform an existing system as well as information technology. This study aims to build a proposed model in order to transform an old system into a Blockchain-based system. The smallholder oil palm supply chain currently uses a traditional information system and technology, hence its integrity, transparency, and security are vulnerable. To solve this problem, frontier technology is needed, such as a blockchain, which has trust, transparency, and traceable characteristics to improve performance and quality. The method used in this study was digital transformation in the context of operational processes and technology. In addition, the As-Is To-Be model was used as a mechanism to develop a transformation model for the smallholder oil palm supply chain system. Specifically, the As-Is model was implemented in identifying and analyzing the information system and technology in an already existing system, while the To-Be was used to determine the blockchain potential and characteristics. This becomes the proposed model for the transformation of the old system into a Blockchain technology-based. Also, a prospective and mechanism for system transformation were produced in the aspect of transactions, data, and architecture, as well as the flow of change strategies needed in the transformation of the blockchain-based smallholder oil palm supply chain system.

Keywords—*Transformation model; smallholder oil palm supply chain; blockchain; smart contract*

I. INTRODUCTION

The oil palm industry is one of the leading sectors in Indonesia as indicated by its plantation area and productivity. Also, the oil palm supply chain, specifically the FFB management, has been extensively studied from different perspectives.

It has been observed that the smallholder oil palm agroindustry supply chain has a variety of chain models, with many actors and regulations [1]. The independent actors in the oil palm agroindustry supply chain, such as traders are more concerned with the profit element. Therefore, formal supply chain institutions, such as cooperatives need to improve their roles and functions in order to play an active role, which brings benefits and improves the welfare of an independent oil palm smallholder [2][3].

Currently, an information system is used for processing transactions in the smallholder oil palm supply chain environment. This developed system is still centralized, thereby allowing data vulnerability occurrence. Also, the role of users who still interact a lot with the system leads to input errors and other results that are not desired. This simply means data security is not guaranteed, and it is vulnerable to being exploited by other parties. Another problem with a centralized system is that it has a mechanism controlled only by one entity. This implies that the entity can fully control the activities and data contained in the system. Consequently, data are easily manipulated by system owners or hackers, thereby reducing the trust and data transparency in the operation of a product, as well as tracing an asset's provenance [4]. It has been discovered that the digital contract in the existing system was only an agreement between the oil palm mill and the cooperative but the contractual clauses contained therein are often not observed. This leads to manipulation and non-transparency in the running system. In addition, the centralized system poses a high operational challenge in securing the servers and data from hackers. It involves the cost of maintaining data authenticity due to a large amount of manual work and paperwork involved in the business processes [5].

These problems encourage the development of blockchain-based smart contract technology, as an alternative solution to eliminate and reduce challenges in data transactions and a centralized system. The smart contract's implementation reduces human intervention, supports transactions, and increases trust between entities [6]. Meanwhile, blockchain technology adoption targets several domains, such as supply chain, healthcare system, electronic voting, proof of location, distributed cloud storage, and even human resources management and recruitment [7]. According to [8]–[10] blockchain is managed by a distributed peer-to-peer system in a decentralized infrastructure secured by a cryptographic hashing mechanism and with the support of a smart contract and consensus system, which is effective in collaboration between organizations and individuals.

The transformation of a system becomes important when a new technology emerges and has the potential to improve the existing system's performance [11]. This study aims to develop a technological transformation model needed by an existing system to be blockchain technology-based. Subsequently, the following questions were answered

1) What model and technology is used in the current supply chain system for smallholder oil palm?

2) What is the desired model when blockchain is used for the proposed system?

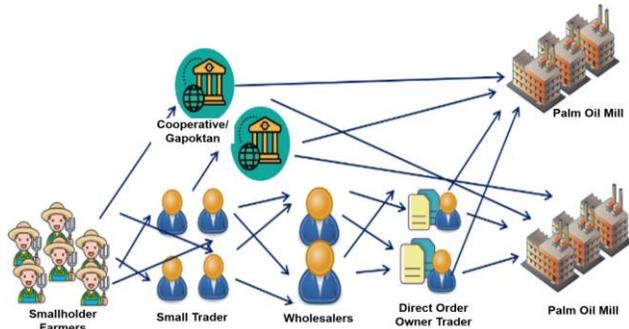
3) Which system and technology transformation mechanisms are required?

Since the existing smallholder oil palm supply chain system is digital-based, the approach selected is a partial blockchain technology adoption mechanism model [12]. In this scenario, the transformation is performed by considering the presence of an information technology/information system existing previously and focusing on the transformation of technology and system architecture. This current study provides an overview of the system transformation mechanism from "traditional" digital solutions (As-Is) to model a system by applying "frontier" digital solutions (To-Be) technology - blockchain-based system.

This article is structured as follows, Section I discusses the problem background in the current system, potential solutions with blockchain technology, as well as the objectives and contributions. Section II entails the literature reviews, namely smallholder oil palm supply chain, blockchain technology, smart contract, and types of blockchain platforms. Furthermore, Section III describes the proposed methodology used in conducting the study phases. Section IV contains the results and discussion, starting with the existing system analysis, the proposed transformation model, and how it can be achieved, as well as discussions related to similar studies and future developments. Finally, the conclusions of the study results are presented in Section V.

II. LITERATURE REVIEW

A. Smallholder Oil Palm Supply Chain

The smallholder oil palm supply chain in Indonesia varies in different regions. However, one similarity between the many flows is that they always involve intermediaries, called middlemen. An example of an existing supply chain is shown in Fig. 1, in which the FFB is harvested from farmers' plantations and is then collected by cooperatives/farmer groups. Furthermore, the FFB is picked up by small agents, who distribute them to large agents, then to Delivery Order (DO) holders, before arriving at PKS. This supply chain is both long and also detrimental to farmers because every party takes profit along the process. This reduces the impact on prices and the profits that independent smallholders are able to earn [13].


Smallholder oil palm farmers do not have a great ability to obtain capital and assistance due to a lack of knowledge as well as access to information and capital that can ensure their sustainability [14]. To increase their prosperity and capacity, standardization and a good plantation management program need to be implemented [15]. Also, institutions capable of uniting smallholder oil palm farmers need to be developed. This can be encouraged through the existence of the farmers' groups (Gapoktan), as well as cooperatives that become facilitators in regulating and supporting smallholders [16]. As reported in [17][18], the ease of obtaining certification for smallholder oil palm farmers needs to be supported by the existing supply chain ecosystem in order to provide quality assurance and products produced.

B. Blockchain Technology

Blockchain is a ledger system, such as a master ledger, in which every transaction that has ever existed is recorded in the form of a decentralized database network. All existing transaction data are recorded in a block entity with each connected to a pre-existing block like a chain [19].

The use of blockchain technology is capable of transforming the conventional supply chain ecosystem with its benefits. In a Blockchain-based supply chain, there are several participants in the network working and interacting together. Each participant sends transactions specifically according to their task in the network [20][21]. In China, a traceability model for agricultural products was developed with blockchain technology and IoT using RFID [22]. As reported, this blockchain technology is capable of developing supply chain business models by reengineering the traditional supply chain to become blockchain-based [23]. Meanwhile, the implementation of blockchain-based logistics operations produces a system that provides a faster and more accurate traceability model [24].

Blockchain has an indelible data structure formed by a series of data blocks that are connected linearly in a time sequence [25]. Information is stored in each block and encrypted with asymmetric cryptographic algorithms to ensure the security of data access and transmission. In the system, each data block records and updates the node data as well as the transaction information according to the defined consensus algorithm of the distributed nodes. The validity of the data is verifiable for all blocks using a hash algorithm [26]. Fig. 2 shows a simple blockchain architecture consisting of a set of blocks containing transactions with a header, transaction, and hash component [27].

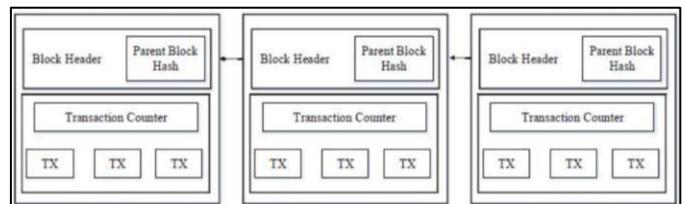
Fig. 1. Smallholder Oil Palm Supply Chain Flow.


Fig. 2. Blockchain Architecture [27].

C. Smart Contract

It is believed that blockchain combined with smart contract technology has great potential to facilitate a business process [28]. A smart contract is considered a computerized transaction protocol that executes a series of contract clauses introduced in the nineties, while blockchain was the first technology to officially support its implementation [29]. In the literature, a smart contract and blockchain are inseparable terms that together form the second generation of blockchain technology [30][31]. The smart contract execution on the blockchain can be implemented in both public and private blockchain environments with conditioned functionality [32][33].

As described in [34], a smart contract is built with the specific purpose of executing a complete set of instructions on the blockchain. Furthermore, it is a computer program containing contractual agreements between entities generated by the user and extracted from the environment (blockchain) [35]. The purpose of a smart contract is to make the agreement efficient, secure, and increase trust between entities [36].

A smart contract is a working mechanism that involves digital assets and two or more parties. Some or all parties input assets, which are automatically redistributed among users according to a formula and on certain unknown data at the time of contract is initiated [37]. Based on the mechanism, a smart contract has five developmental stages, namely 1) negotiation, 2) development, 3) deployment, 4) maintenance, and 5) learning and self-destruction [38]. Also, a smart contract is capable of reducing human intervention in business process flows in the system environment [39], and can audit automatically in order to quickly and efficiently complete the work expected of users [40].

D. Types of Blockchain Platforms

In the development of a system, two types of blockchain platforms can be used. The first is a public blockchain, which emphasizes the importance of anonymity and decentralization, such as the Ethereum blockchain. The second is a private / consortium blockchain which has the characteristics of being more focused on efficiency and centralized to some extent, like the Hyperledger Fabric blockchain [41].

It is important to note that Ethereum was launched in 2015 with a programmable Blockchain. Due to this capability, Blockchain can be used to build decentralized applications according to user needs. As stated in [42], the characteristics of the Ethereum Blockchain are stateful and Turing Completeness, hence it is possible to store data other than transactions and create complex programs. In addition, the blockchain on Ethereum is a public ledger used to record transactions, which means all data from the initial launch of Ethereum are recorded in 23 Blockchains [43]. Since the ledger is publicly accessible, Ethereum connects each ledger block using a hash algorithm. Based on this mechanism, changing one transaction data requires replacing the hash of the next blocks. Ethereum is generally viewed as a transaction-based state machine [44][45] and a stateful Blockchain, as assets are stored in blocks, not just transactions. It was observed that there are three Merkle Patricia Trees, being a modification of the Merkle Tree on

Bitcoin for transactions, accounts, and receipts, thereby leading to three roots stored in the block header. Another study found that there is more data on an Ethereum block than on Bitcoin, which supports the process of creating decentralized applications using the Ethereum Blockchain [46].

Meanwhile, Hyperledger Fabric is an open-source technology of a distributed ledger platform, which is blockchain-enabled [47]. Furthermore, it is a technology developed by the Linux Foundation which is modular for industrial use. Hyperledger Fabric has a smart contract called chain code [48], written with general-purpose programming languages such as Java, Go, and Node.js. It also uses a different approach to a smart contract in general, namely execute-order-validate [49]. Transactions are first executed on a smart contract, then it is ordered via a certain consensus protocol and finally validated with an endorsement policy before being written to the ledger [50]. Hyperledger Fabric has the following main components, such as assets, shared ledger, chain code, peer nodes, channels, organizations, membership service provider (MSP), and ordering services [51][52].

III. PROPOSED METHODOLOGY

This study aims to develop an existing system and transform it into a blockchain technology-based model. The approach used was the As-Is To-Be Model [53], in which the current system is the reference (As-*Is model*) for the development of a new blockchain-based model (*To-Be model*). This is achieved by developing a transformation model that bridges changes from the existing system to the new form. A limitation of digital transformation within the framework of technological transformation was provided, which includes network and communication, hardware and software, and data technologies [54]. Furthermore, the transformation vision approach is at the operational process level and relates to the study conducted by MIT and Capgemini Consulting [55] used to support technological change in the smallholder oil palm supply chain system. Fig. 3 shows the stages of the study performed.

In the first stage, analysis and evaluation of the existing system were conducted. It includes the activities for analyzing the transaction process contained in the existing system. It is important to mention that transaction includes activities or business processes performed by each actor in the current system. The existing system architecture as well as the data contained in the running system was then analyzed based on the model and database used. This architecture is a program structure or computer system consisting of software components, its externally visible characteristics, and its relationship.

In the second stage, a literature review discussing blockchain technology in relation to the transaction mechanism occurring in the blockchain environment, data processed and stored, as well as the architecture supporting the development of a Blockchain-based system was conducted. The final stage involves the development of a transformation model from the old system to a Blockchain technology-based model. This transformation model includes the transaction, the data, and the architecture.

Fig. 3.   Study Flow.

Fig. 4.   Scope of Study Results.

Fig. 5.   Existing System Smallholder Oil Palm Supply Chain.

IV. RESULT AND DISCUSSION

This section entails the results of the study conducted, which include the discussion of the analysis and current system evaluation, the proposed transformation model, and its change strategy. Fig. 4 shows the discussion flow of the results, with the current system used as an As-Is model, which provides an overview of the operating conditions of transactions, as well as data and system architecture. Meanwhile, the To-Be model was proposed for a new system transformation using Blockchain technology. To produce the To-Be model, a transformation strategy is needed, which is described using a flowchart. Specifically, the transformation employed includes changes to the transaction mechanism, data, and technology architecture as part of the operational processes in the smallholder oil palm supply chain system to achieve the objectives.

A. Existing System of Smallholders Oil Palm Supply Chain

The current oil palm supply chain uses a compact mechanism, specifically for the smallholder, which includes only three actors, namely small farmers, cooperatives/farmer groups, and finally the oil palm mill. This aims to reduce the length of the existing supply chain, as well as to utilize institutions, such as cooperation and better welfare for smallholder oil palm farmers.

Fig. 5 shows the current smallholder supply chain work system, in which the flow of information in the system occurs in all supply chain actors, while the FFB products flow from upstream to downstream. In this supply chain, information system and technology was used to support operational transactions conducted by the actors, from procurement requests to FFB product fulfilment.

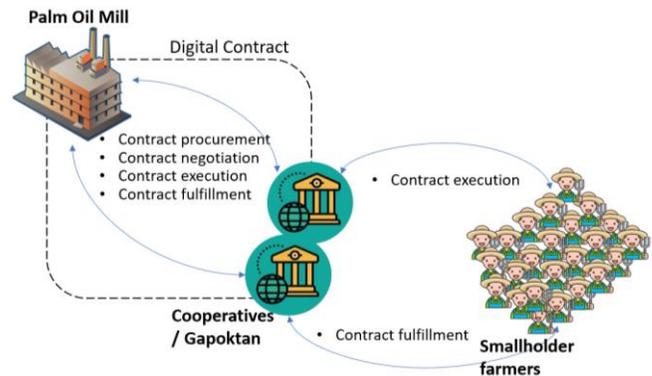
The current information system starts with a digital contract mechanism. Conceptually, a digital contract is a form of an agreement made electronically through the interaction between the offered party and the electronic system. In the current system, two digital contracts were used to initiate operations as well as the demand and supply transactions for fresh fruit bunches (FFB) from an oil palm mill to cooperatives, and also from cooperatives to smallholders. Fig. 6 shows the interaction of the digital contract in the current smallholder oil palm supply chain.


Fig. 6.   Interaction of Digital Contract of Existing System Smallholder Oil Palm Supply Chain.

Meanwhile, Fig. 7 shows the current FFB business process. The activities occurring indicated that the contract initiation process was performed by an oil palm mill, offering the purchase of FFB to cooperatives. Furthermore, the cooperative party that gets a contract offer from the oil palm mill evaluates the approval. When there is a mutual agreement from the negotiations between the oil palm mill and the cooperatives, then a digital contract is created and stored in the system. The next stage is to provide a Direct Order (DO)

as a work letter and implement the digital contract. The DO was given by oil palm mill to cooperatives, and cooperatives pass the DO on to smallholder oil palm farmers who are members. It is important to note that the smallholder oil palm farmers act as suppliers who are obliged to fulfill the DO by entering FFB production data simultaneously. Meanwhile, the cooperatives serve as 1) collectors, 2) distributors, and 3) sellers. This implies that the task of cooperatives is at the center of the current information system because the transactions they conducted are the most compared to other actors in the supply chain system. As a collector, the Cooperative monitors the FFB sent by independent smallholders and collects it into a large batch of FFB ready to be sent to the oil palm mill. Also, as a distributor, the Cooperative has a role to provide transportation tools to pick up and carry the FFB products, but as a seller, they are to ensure that the price obtained still meets the standard price and the mutually agreed contract. The Oil palm mill as a consumer is expected to check the suitability of the FFB products provided by the Cooperative and pay in accordance with the agreement.

Fig. 7. Process Business of the Current Smallholder Oil Palm Supply Chain System.

Table I shows operational transactions performed by farmers which includes farmers' biodata, data on how their plantations and oil palm plantations are managed, and other supporting data. The next transaction is regarding the sale and purchase of FFB, including its fulfilment transaction based on the DO provided by the Cooperative, such as the sales process to the Cooperative as well as information on the farmers' performance level from profiles and the performed transaction records.

Meanwhile, Table II shows the transactions made by Cooperatives, being the intermediary that connects the oil palm farmers with coconut mills. The transaction starts with 1) the recording of the cooperative profile and supporting data in the system. 2) Contract creation and Direct Order (DO) for FFB request transactions. 3) Purchasing the FFB from farmers and selling it to an oil palm mill. The next operation is as a

distributor that transports the FFB from a smallholder to oil palm mill. The process of receiving payments both from an oil palm mill and a farmer is performed by the cooperative. Based on the Cooperative's transactions and profile results, their work performance is explained as follows.

TABLE I. SMALLHOLDER FARMER TRANSACTIONS

No	Actors	Identity Process	Transactions
1	Farmer	Profile	Member Data
2	Farmer	Profile	Farm
3	Farmer	Profile	Land Process
4	Farmer	Profile	Supporting data
5	Farmer	Operational	Transaction fulfillment
6	Farmer	Operational	Sales
7	Farmer	Operational	History DO
8	Farmer	Operational	Performance

TABLE II. COOPERATIVE TRANSACTIONS

No	Actors	Identity Process	Transactions
1	Cooperative	Profile	Member Data
2	Cooperative	Profile	Supporting data
3	Cooperative	Operational	Transactions History
4	Cooperative	Operational	procurement
5	Cooperative	Operational	fulfillment
6	Cooperative	Operational	Delivery
7	Cooperative	Operational	Transactions (procurement and fulfillment)
8	Cooperative	Operational	Payment
9	Cooperative	Operational	Contract History
10	Cooperative	Operational	History DO
11	Cooperative	Operational	Performance

The next operational transaction takes place at the oil palm mill as shown in Table III. It starts with the initiation of contracts between the oil palm mill and cooperatives, then continues with the making of DO and registration of FFB suppliers. The sale and purchase transaction was performed with the cooperative, a partner based on the agreed contract and DO. The FFB payment process was conducted by the oil palm mill at a mutually agreed time.

TABLE III. OIL PALM MILL TRANSACTIONS

No	Actors	Identity Process	Transactions
1	Oil Palm Mill	Profile	Member Data
2	Oil Palm Mill	Profile	Supporting data

4	Oil Palm Mill	Operational	Purchase
5	Oil Palm Mill	Operational	Payment
6	Oil Palm Mill	Operational	Contract History
7	Oil Palm Mill	Operational	DO History
8	Oil Palm Mill	Operational	Supplier
9	Oil Palm Mill	Operational	Performance

The government, such as the provincial or district plantation agency acts as an external actor that regulates, configures the system, processes the FFB reference price data, and monitors smallholder oil palm supply chain transactions in their area as shown in Table IV.

TABLE IV. AGENCY TRANSACTIONS

No	Actors	Identity Process	Transactions
1	Agency	Operational	FFB-Province Reference Price Data
2	Agency	Operational	System Configuration

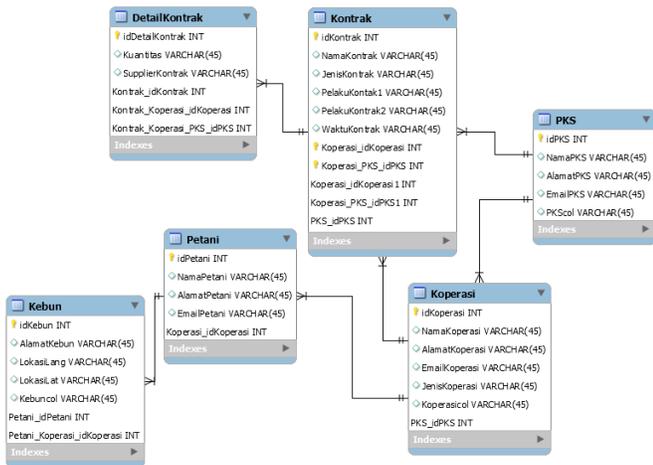
According to Fig. 8, a database was developed to store profile data, manage FFB transaction data, and calculate the performance of each actor in the smallholder oil palm supply chain. The model in the current system includes six interconnected table entities for storing the data used in the digital contract creation and the transaction executed by oil palm mill, cooperatives, and smallholders. Subsequently, the table entails oil palm mill, cooperatives, contracts, contract details, smallholders, and supporting data in the form of plantation profiles.


Fig. 8. Existing Database Scheme.

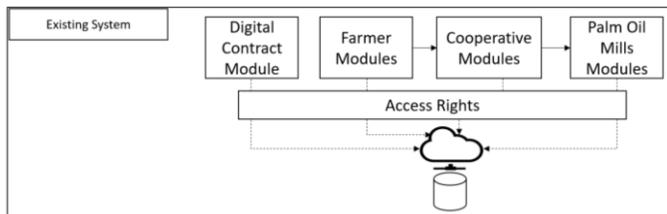
The web-based technology was employed in the current system architecture for it to be accessible by all supply chain actors. The system was developed using platform-based web technology with a centralized database model on a server. In accessing the system, supply chain actors were required to register in order to obtain access rights to perform transactions according to their privileges. Fig. 9 shows the current system architecture.


Fig. 9. Digital Contract Table Relation Schema.

B. Proposed Blockchain-Based Smallholders Oil Palm Supply Chain System Transformation Model

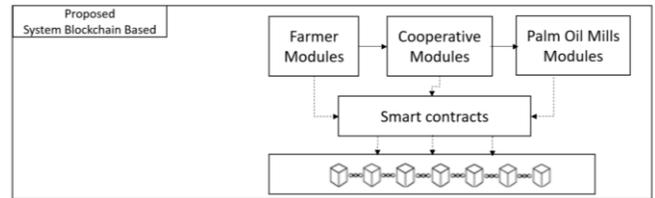
A blockchain technology-based system was the system model developed in the smallholder oil palm supply chain. Fig. 10 shows the logical changes made to the proposed system by adding smart contract technology and a blockchain network. A smart contract is generally used to automate manual work performed by users, as well as increase the accuracy and compliance with data entered in the system. Meanwhile, the use of the blockchain network serves as a data guarantor in a more secure, difficult-to-manipulate, and immutable environment.


Fig. 10. Logic Model of Proposed System Smallholder Oil Palm Supply Chain.

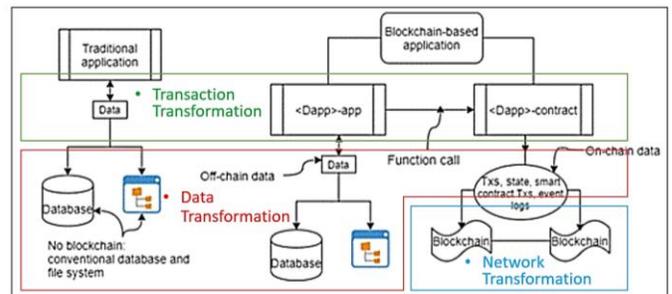
Fig. 11 shows the differences between traditional application development and those that are blockchain-based. This difference affected the application development on the user side, the database model, and the network architecture used. Consequently, the changes caused a system transformation from a traditional model to one that is blockchain-based. The first transformation was the transformation of the designed application to manage transactions (transaction transformation) by changing the traditional concept into Decentralized applications (DApps) used to transact in the blockchain system. The second was the transformation of a traditional database system into a blockchain-based data model, both on-chain and off-chain data (data transformation). Meanwhile, the third was the blockchain network transformation used to store and disseminate transaction records to all nodes in a blockchain-based system (network/architecture transformation).


Fig. 11. Proposed Transformation Model of Smallholder Oil Palm Supply Chain Blockchain-based.

1) Transaction transformation model: It is important to reiterate that the first transformation conducted was to change the current system transactions into those executable in the blockchain environment. This mechanism is shown in Fig. 12 and it begins with identifying the transaction process for each supply chain actor, followed by determining whether the

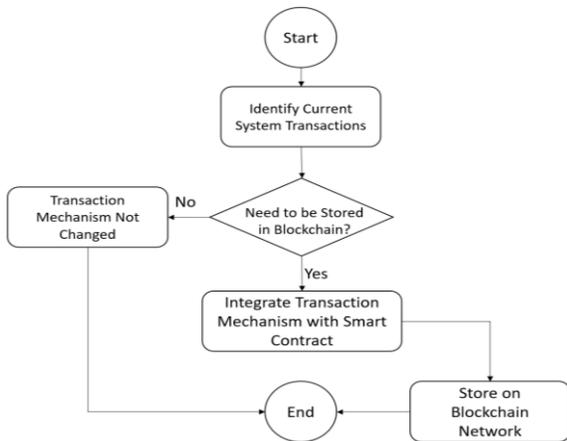
transaction needs to be stored on the blockchain environment or not. When the transaction requires a secure, transparent data environment, and traceability requirements, it was added/modified by adding a smart contract in the system development environment.


Fig. 12. Blockchain-based Smallholder Oil Palm Supply Chain Transaction Transformation Strategy.

The identification and analysis of transactions existing in the current system consist of actors in the supply chain, namely farmers, cooperatives, oil palm mill, and related agencies, such as admins. There are two process identities, namely the identity for storing profile data and that of operational data. Meanwhile, the business processes are operational data that can be executed by any user based on their access rights. Table V shows the results of the identification and analysis of actors, transactions, and recommendations for the proposed smart contract.

The proposed smart contract architecture model stores data related to the profile of each smallholder oil palm supply chain actor, such as farmer profiles, cooperatives, and oil palm mills. The profile data of supply chain actors are in the form of identity data of actors and other supporting data according to their roles. Meanwhile, smart contract transactions are designed to store transactional data occurring in smallholder oil palm supply chain activities, ranging from the main contract, DO manufacturing, FFB sourcing transactions, FFB fulfilment transactions, performance reviews, and payment mechanisms. The proposed smart contract architecture is shown in Fig. 13.

Fig. 14 shows a sequence diagram for the transaction of profiles of actors in the FFB supply chain, namely farmers, cooperatives, and oil palm mills. This helps in describing a scenario or a series of steps taken in response to an event to produce a certain output, including the changes that occurred.

It is important to reiterate that a smart contract is an executable code running on the blockchain to facilitate, execute, and enforce agreement terms. A smart contract's principal goal was to automatically execute the terms of the agreement once the specified conditions are met [56]. An illustration of the smart contract code is shown in Fig. 15, which described the transactions and actions performed.

TABLE V. PROPOSED SMART CONTRACT ON BLOCKCHAIN-BASED SMALLHOLDER OIL PALM SUPPLY CHAIN SYSTEM

2) Data transformation model: Data transformation is part of the development of the current system into a blockchain-based model. Also, data changes and adjustments are needed in determining the data to be stored in the internal database environment and those to be stored on the blockchain network. Fig. 16 shows the mechanism for adapting the existing data in the current system into a blockchain-based model.

The databases managed by centralized authorities typically store multiple copies of data for secure server management. A copy of the data is very important because those stored are prone to corruption. The decentralized nature of blockchain

has a major influence on the changes in how each industry implement digital transaction system. Furthermore, blockchain allows anyone who accesses it to work independently and eliminates any need for centralized control. For example, a server-based database acts as a centralized processing unit, thereby allowing the database to work dynamically from small to large scale. The client and server communicate with each other over a secure connection. It was observed that blockchain is based on distributed ledger technology and the network is enabled with a secure, peer-to-peer cryptographic protocol. Meanwhile, it shows another way of working, in which the accessor can only read and write. It is important to note that the data stored on a blockchain cannot be deleted or replaced. This is because its nature is fixed and it supports immutability, hence the inputted data is not disturbed or manipulated.

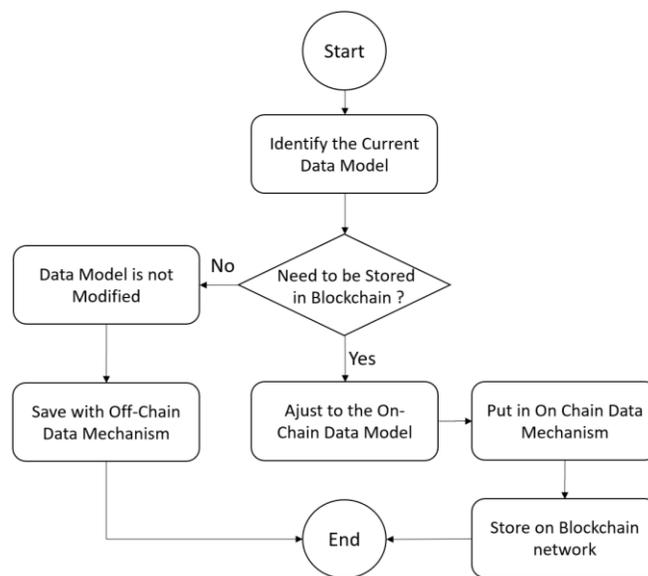
Fig. 17 shows the transformation of the proposed data model from a centralized to a decentralized database. The decentralized data model on the blockchain network is facilitated by the existence of an on-chain transaction mechanism stored in the blockchain network environment. It also involves an off-chain transaction mechanism, which is a data model stored outside the blockchain network. The proposed model uses a NoSQL database type to facilitate the development of a blockchain-based system, as shown in Fig. 18.


Fig. 16. Blockchain-based Smallholder Oil Palm Supply Chain Data Transformation Strategy.
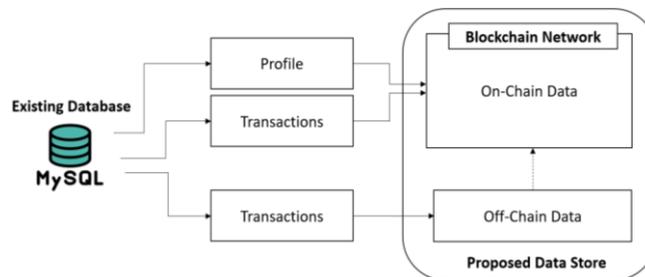

Fig. 17. Proposed Decentralized Data Model Transformation.

Fig. 18. Example of a NoSQL-based Data Model.

The data format used in database development, which is stored in a No-SQL and the process of sending it to the blockchain network with json formatted APIs is shown in Fig. 19.

Fig. 19. On-chain and off-chain Data Models in Smallholder Oil Palm Supply Chain.

3) Network architecture transformation model: Network transformation is the evolution of the current model to a blockchain-based system. Specifically, the current system works with a centralized network, while the blockchain network is decentralized and distributed.

Fig. 20 shows the mechanism for developing a blockchain network architecture on a smallholder oil palm supply chain system. In addition, the stages of change include 1) an analysis of the web platform technology used in the current system, 2) the development towards a web platform that supports blockchain, namely by building a blockchain network, 3) the deployment of a smart contract on a blockchain network, and 4) end-user application development.

The network architecture in the smallholder oil palm supply chain is shown in Fig. 21. Starting from an end-user, applications interact with a smart contract to perform operations on the blockchain network. Consequently, the blockchain stores these records immutably and return the changes in response to the client application.

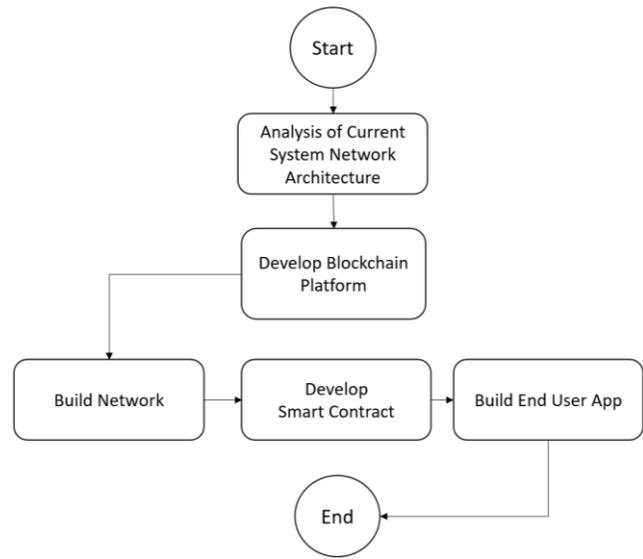
A smart contract works by updating the ledger in the blockchain network, which represents the immutable data on all transactions and manages a world state denoting the current data state. Furthermore, it is capable of executing the state stored in the state DB and requesting transaction records contained in the blockchain. Client applications interact with a smart contract to perform operations on the blockchain network. This causes the blockchain to store these records immutably and return the changes in response to the client application.


Fig. 20. Blockchain-based Smallholder Oil Palm Supply Chain Network Architecture Transformation Strategy.
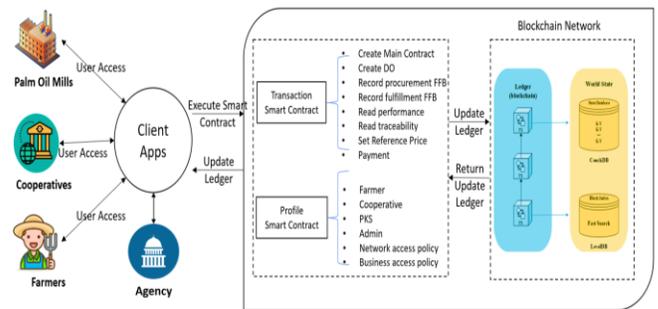

Fig. 21. Proposed Network Architecture in Smallholder Oil Palm Supply Chain.

This is consistent with the study in [57], that the development of a smart contract started from the re-engineering of existing business processes. According to [58], the smart contract's function is applied as an automation mechanism and data integrity guard. This means the smart contract has the ability as a secure data storage mechanism, particularly for access to a smallholder oil palm supply chain [59]. However, this study was only completed at the transformation model stage, hence it is necessary to conduct a maturity assessment of the digital transformation model [60]. It also needs to be developed towards a physical model in the form of developing a prototype system, in which the data, transactions, APIs used, and the blockchain platform was tested [61].

V. CONCLUSION

This study has led to a transformation model from the current smallholder oil palm supply chain to a blockchain-smart contract-based system. The system transformation produced consisted of elements of transaction, data, and

network architecture transformations. The results were obtained by taking a digital transformation approach, particularly at the technological level, and focusing on the operational processes. The proposed system model was derived from the partial integration mechanism for the adoption of blockchain technology. This is because the current system uses an information technology/information system in its working process. The results represented the As-Is To-Be model in developing the system transformation. Specifically, the current system was used as an As-Is model, which was analyzed and evaluated, while the To-Be was the result of analysis and collaboration with blockchain technology, serving as the solution. Furthermore, a flow of transformation strategies in transactions, data, and network architecture was produced. The transaction transformation was based on business processes and those occurring within the smallholder oil palm supply chain. This transaction is analyzed in order to get a picture of the parts that are still being conducted manually by the user, have low accuracy, and lack integrity. Based on the investigation results, a form of change and adjustment of transactions was obtained using the smart contract mechanism. Regarding the data transformation, the results were achieved through the analysis performed on the current system model, which was developed with data in accordance with blockchain technology. The evaluation results showed that some data in the smallholder oil palm supply chain need to be included in the blockchain in order to maintain its security, integrity, and transparency. Consequently, the direction in this section was to apply on-chain and off-chain data storage mechanisms. The last transformation was the network architecture, in which the current system employs an architectural model and the network used was centralized, while blockchain technology was distributed and decentralized. This indicates the need to develop a network that is able to distribute records/ledgers to all nodes and user applications. It is important to mention that these applications are developed based on Dapps capable of working in a blockchain environment with smart contract by utilizing APIs as a medium for connecting data to be stored in the network. This study's results were practically useful as a guide, direction, and strategy for developing the existing model for it to be transformed into a new system based on blockchain-smart contract technology. In the future, studies have to be directed toward the development of physical models and prototypes of the blockchain-smart contract-based smallholder oil palm supply chain system. This can be implemented using a suitable platform with a smart contract model and executed on a blockchain-based prototype environment.

Abstract—**Ultrasound imaging technology is one of the most important clinical imaging modalities due to its safety, low cost, in addition to its versatile applications. The main technical problem in this technology is its noisy appearance due to the presence of speckle, which makes reading imaging more difficult. In this study, a new method of speckle reduction in medical ultrasound images is proposed based on adaptive shifting of the contrast sensitivity function of human vision using a bias field map estimated from the original image. The aim of this work is to have an effective image enhancement strategy that reduces speckle while preserving diagnostically useful image features and allowing practical implementation in real-time for medical ultrasound imaging applications. The new method is used to improve the visual perception of image quality of ultrasound images by adding a local brightness bias to the areas with speckle noise. This allows the variations in image pixels due to speckle noise to be better perceived by the human observer because of the visual perception model. The performance of the proposed method is objectively assessed using quantitative image quality metrics and compared to previous methods. Furthermore, given that image quality perception is subjective, the level of added bias is controlled by a single parameter that accommodates the different needs for different users and applications. This method has potential to offer better viewing conditions of ultrasound images, which translates to higher diagnostic accuracy.**

Keywords—Contrast sensitivity function; image quality metrics; speckle reduction; ultrasound imaging

I. INTRODUCTION

Ultrasound imaging technology is one of the most important clinical imaging modalities due to its safety, low cost, in addition to its versatile soft tissue imaging applications that include abdominal imaging, echocardiography, and obstetrics and gynaecology [1]. Given that this technology relies on sending low intensity acoustic waves into the body and receiving the reflected and scattered echoes to reconstruct a cross sectional image of the body, it is inherently safe and can be considered as the safest imaging modality available today. This is evident by being the only imaging modality allowed for use on pregnant women to follow up the growth of the fetus and assess its biophysical profile in addition to detecting any anomalies present. Another advantage of ultrasound imaging technology is its availability in a wide range of forms including basic hand-held or portable units that cost a few thousand dollars to sophisticated dedicated echocardiography systems that cost hundreds of thousands of dollars. This allows ultrasound imaging to be popular for use in rural and low-income communities as well as in large,

specialized hospitals. Future direction in this technology indicates that it will likely become as essential to medical practice as the stethoscope and it is predicted that general practitioners will soon have small ultrasound units in their clinical practice.

Despite the many advantages of ultrasound imaging technology, it has a clear shortcoming in the quality of its image as compared to other modalities such as x-rays, magnetic resonance imaging or computed tomography. Ultrasound images generally look very noisy to the viewer and requires some training to correlate the anatomy to the acquired ultrasound images. This is mainly due to the presence of speckle that sometimes obscure pathological changes in the body and hence may cause errors in the diagnosis. Therefore, the problem of speckle reduction in ultrasound images has been the focus of research of many academic and industrial research groups since the early beginnings of ultrasound imaging and is expected to remain so given its impact on this technology [2].

Speckle noise is an unavoidable direct result of the physics of ultrasound imaging. Ultrasound imaging is done by sending an ultrasonic pulse through the body from an ultrasonic transducer arranged in 1D or 2D array form. This ultrasonic pulse propagates through the tissues and interact with its different components yielding reflected waves from specular reflectors and scattering from point reflectors [1]. The difference between specular and point reflectors is mainly in size whereas specular reflectors are larger than the wavelength of ultrasound waves while scatterers are significantly smaller than this wavelength. This wavelength is a fraction of a millimeter in the usual range of ultrasound imaging frequencies in the 2-15 MHz. Therefore, tissue interfaces and major blood vessels behave like specular reflectors while blood capillaries and cells within the extracellular space act as scatterers [3][4]. So, in a tissue like the liver, hepatocytes scatter ultrasound waves independently and the backscattered part is what is received by the ultrasound transducer. Given that such scattering depends on the ultrasound transducer frequency and orientation as well as the complex 3D structure of the tissue, the received scattered waves from the many cells involved interfere and produce a pattern of partial constructive and destructive interference points that show as random noise in the image. The difference between speckle noise and true random noise is that random noise change with time and hence can be reduced by simple averaging. On the other hand, speckle noise pattern remains the same as long as the imaging

*Corresponding Author

conditions remain the same (i.e., probe orientation, frequency, and tissue being imaged). Therefore, it does not improve with averaging and other more sophisticated methods be utilized to reduce its effect on image quality [5][6].

II. LITERATURE REVIEW

Several approaches have been proposed to address the problem of speckle reduction. Such approaches can be broadly classified as acquisition and post-processing methods. The acquisition methods try to reduce speckle through the acquisition of multiple versions of the same slice with each acquired with different beamforming (e.g., using steering, different focal point, different frequency, etc.). Then, since the speckle pattern is different when beamforming changes, using simple averaging of these acquisitions will result in an image with reduced speckle [1][7][8]. Despite the intuitiveness of the approach and apparent simplicity, it practically requires reprogramming of the acquisition protocols of different applications, which adds significant cost in addition to being a cumbersome constraint in some applications that require high frame rate and/or special ordering of acquisitions such as in 3D and 4D imaging.

On the other hand, the second approach based on preprocessing was the focus of virtually all research groups working on this problem since the 1980s until today. Its basic premise is to start from the reconstructed image and apply different filters to improve the speckle pattern. Hence, it requires only a computer and access to the frame buffer of the ultrasound imaging system to perform its job. Moreover, with the advent of modern computing platforms and massively parallel processing hardware such graphics processing units (GPUs) that all became well within budget for ultrasound imaging systems, this approach seems like the logical starting point for practical purposes. From the technical point of view, post-processing methods can be categorized into linear, nonlinear, diffusion-based, and wavelet-based filtering methods [2]. The linear filters include such techniques as First-Order Statistics Filtering, Local Statistics Filtering with Higher Moments, and Homogeneous Mask Area Filtering [9][10][11]. The nonlinear filtering methods include Median Filtering, Linear Scaling Filter, Geometric Filtering, and Homomorphic Filtering [12][13][14][15]. The diffusion-based methods include several variants of Anisotropic Diffusion Filtering [16][17][18][19][20]. The wavelet-based methods mainly work using wavelet shrinkage using different wavelet families and levels of composition [21][22][23][24]. Hybrids between the above methods were also introduced [25][26][27].

Despite the relative success achieved by the present methods in reducing speckle in ultrasound images, there remains several problems that hinder the practicality of their use in clinical ultrasound. First, there is a gap between what the quality of the processed image means to researchers and clinicians. That is, the outcome of these methods may look smoother and hence better to the researchers but to the contrary such appearance may hide some features in the image that are important to the clinical sonographers. So, there is a need to develop better quality metrics that more accurately reflect the clinical view of the image quality [28]. Second, the focus only on reconstructed images may be the easiest way to

address the speckle reduction problem but it certainly is not the optimal one. If a better solution to this problem is to be achieved, the different aspects of image formation must all be taken into consideration and optimized together to get the best results. This includes optimizing acquisition, beamforming, dynamic range compression, detection, sampling, quantization, scan conversion, and image reconstruction algorithms. Third, even though parallel processing has been around for a while now, very few reconstruction algorithms have been designed to work on parallel processing platforms. This is a clear disadvantage because they will not run in real-time and/or pose a scheduling problem in the processing chain in ultrasound imaging systems especially in complex, time-critical applications such as 4D imaging.

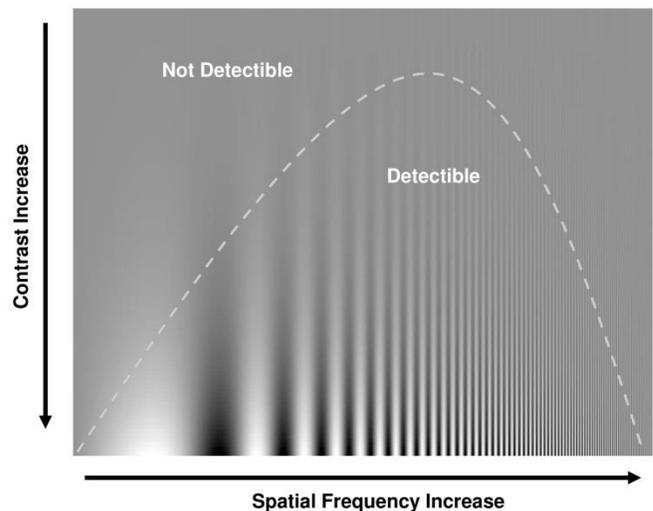
One of the important aspects of ultrasound image quality is how it is perceived by a human sonographer. In particular, the psychophysiological aspects of human vision have a profound effect on such things as contrast sensitivity and details resolution that influence diagnostic quality [28]. In [29], Campbell and Robson presented the concept of contrast sensitivity function (CSF) that define the effects of contrast and spatial frequency content on the visual detectability by a human observer. In Fig. 1, this effect is illustrated using a simulated grating with different spatial frequency and contrast simulated based on algorithms in [30]. As can be observed, the variations in the grating are not detectible above the CSF superimposed on the grating as a dashed line. This suggests that reducing the contrast for high spatial frequency image details can reduce their detectability by a human user. In the context of speckle reduction, the goal is to make their less detectible by the sonographer. Given that the speckle noise has high spatial frequency content, this suggests that reducing their contrast would reduce their visibility by a human sonographer.


Fig. 1. The Campbell-Robson Contrast Sensitivity Function Chart where Visual Detection of Variation Depends on Both Contrast and Spatial Frequency as Outlined by the Separation with the Dashed Line.

In this work, a new method of speckle reduction in medical ultrasound imaging is developed whereby a user-controlled image display method adds a bias field map estimated from the original image that reduces speckle visibility. The new method relies on the contrast sensitivity function of the human visual perception to push the high spatial frequency content in speckle out of the visual detectability zone. This strategy does not affect the speckle pattern itself or change its statistical independence but rather allows the user to control how it is displayed to match subjective needs. The new method is experimentally verified using real ultrasound imaging data collected from a research system and compared to previous speckle reduction methods using quantitative image quality metrics.

III. Methodology

The speckle pattern in ultrasound images is characterized by a pseudo-random pattern with high contrast and high spatial frequency content due to its origin from the interference of many back-scattered waves. As a result, unlike random noise, it contains information about underlying tissue and may contribute diagnostic information in some cases. On the other hand, in many cases, the speckle pattern reduces the perceived ultrasound image quality and hence control over its visibility in the image is needed. In this work, it is proposed to take advantage of the characteristics of the contrast sensitivity function of the human visual system to develop a method that allows the visibility of speckle to be controlled by the user through appropriate contrast modification. This approach recognizes the importance of speckle as containing diagnostic information and addresses the subjective nature of image quality perception. According to this approach, reducing the contrast of speckle can improve image quality by reducing their visual detectability. The contrast is defined as the ratio of the maximum intensity to the average intensity. In order to verify this concept, a preliminary experiment was conducted where a speckle pattern from a real ultrasound imaging experiment was displayed along with the same pattern with different uniform intensity bias added to it. As this bias intensity increases, the contrast becomes lower according to its definition. In Fig. 2, the image to the left is the original

speckle pattern while the other images show the same pattern with an increasing constant bias intensity added to the original as one moves to the right. As can be observed, the coarse visual appearance of the original speckle pattern gets finer as the bias intensity increases. Even though this confirms the validity of the concept, it is still not practical to just add a constant bias to the whole image because it may affect the contrast sensitivity of other areas of the image not containing speckle. A more suitable approach is to design a spatially-variant bias map that estimates a smooth local brightness level in different parts of the image. In this work, using a simple image denoising technique such as 2D median filtering with a large kernel as the bias field is proposed. This allows the differentiation of speckle from specular reflectors in the image. The weighted averaging of this bias map and the original image would result in a variable degree of speckle visibility depending on how the weight is selected and allows the user to select the level of speckle suppression subjectively. Given that, the weighted average may have dynamic range compared to the original, a simple adjustment of the dynamic range is done to maintain the appropriate display quality. A block diagram of the new method is shown in Fig. 3. The method accepts an original image in the form of a reconstructed image or as raw data collected by the imaging system. The original image is fed into two processing blocks. The first uses one of the present image-denoising filters for bias map estimation. In this work, a 2D median filter was used with a kernel size of nine to result in a fairly constant bias within the speckle pattern areas while varying with major interfaces to maintain contrast. It is conceptually possible to use other techniques to estimate that local bias field that serves as a local estimate of average intensity in the neighborhood. Then, the output from the image denoising filter and original image are used to obtain the final image using a weighted average. The weight used is selected by the user depending on the subjective desired outcome and application and applied to the original image. In order to ensure that the resultant image is displayed properly on the imaging system monitor, the dynamic range of the final image is adjusted to fit the dynamic range of the monitors (for example, 8-bit gray scale).

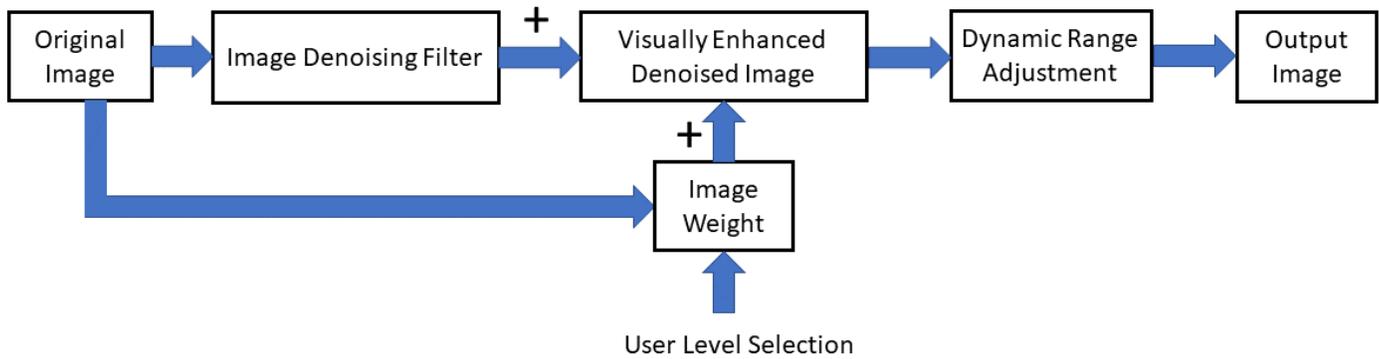

Fig. 3. Diagram Showing the Steps of the Porposed Technique Whereby Intensity Bias Map is Estimated using a Simple Image Denoising Filter and then used to Reduce Speckle Visibility in the Original Image.

IV. EXPERIMENTAL VERIFICATION

The ultrasound imaging data were collected using a Digison Digital Ultrasound Research system (Mashreq Company, Egypt). The system was equipped with a custom research interface to control image acquisition with ability to access and save raw radiofrequency sampled data for each collected image line. In order to make sure that the images are representative of different applications, the images were collected using several ultrasound array probes including convex array abdominal probe, small parts linear probe and a tight convex array endo-cavity probe. The imaging experiments were done for different clinical applications on human volunteers, as well as on a quality control tissue-mimicking phantom (Multi-Tissue Ultrasound Phantom CIRS Model 040GSE, CIRS Inc., U.S.A.). In each imaging experiment, a specific region was imaged using a specific imaging probe and a total of 10 images were collected for each application. The total number of imaging experiments done was 26 with a total number of images of 260. The research interface allowed the collection of raw image data at a sampling rate of 50 M Samples/s at 16 bits of quantization. Signal processing using filter-based Hilbert transformation for peak detection then resampling to obtain a total of 512 data samples per line (or stick). The number of image lines was 128 and this 512×128 array represents the stick data. The application of the new technique was done on the stick data using a bias field estimation from a 2D median filter with kernel size of nine and the weighting factor used to combine the bias field and original image was takes as 0.5. The dynamic range modification was done using simple window/level operation to ensure that the histogram of the combined image extends over the available display dynamic range of 8-bits. The image quality of output images is estimated using two quantitative image quality metrics of structural similarity index (SSIN) [31], and universal quality metric [32]. Given that each application may have different image characteristics, the image quality metrics from the 10 images collected for each of the 26 different imaging experiments were averaged to provide more reliable comparisons.

The final image reconstruction was subsequently performed using scan conversion and/or interpolation according to the array geometry and dimensions to display the image in the correct spatial format. All processing was done on Matlab 2022b (MathWorks, Inc.) using an educational license available through King Abdulaziz University. The computing platform consists of a personal computer with 11th generation Intel® Core™ i7-11700F running at 2.50 GHz clock and using a 64-bit Windows 11 Home Edition, with 32 GB of RAM.

V. RESULTS AND DISCUSSION

The output image results from the new technique as compared to the original images and four representative techniques covering the current approaches in speckle reduction as applied to sample applications are shown in Fig. 4. The previous techniques considered are wavelet denoising [21][23], relaxed median (RMedian) denoising [14][15], speckle reducing anisotropic diffusion (SRAD) [17][16][18], and local statistics based filtering (Lee) [9][10]. In each of these techniques, the original technique is implemented with the implementation details suggested in the most recent variant. As can be observed, the new technique shows finer speckle pattern and less blurring as compared to present techniques. This is particularly evident in the linear array example at the bottom of the page where the texture is significantly smoother compared to other techniques without having a blurring problem as found with the techniques based on wavelet denoising and lee filter.

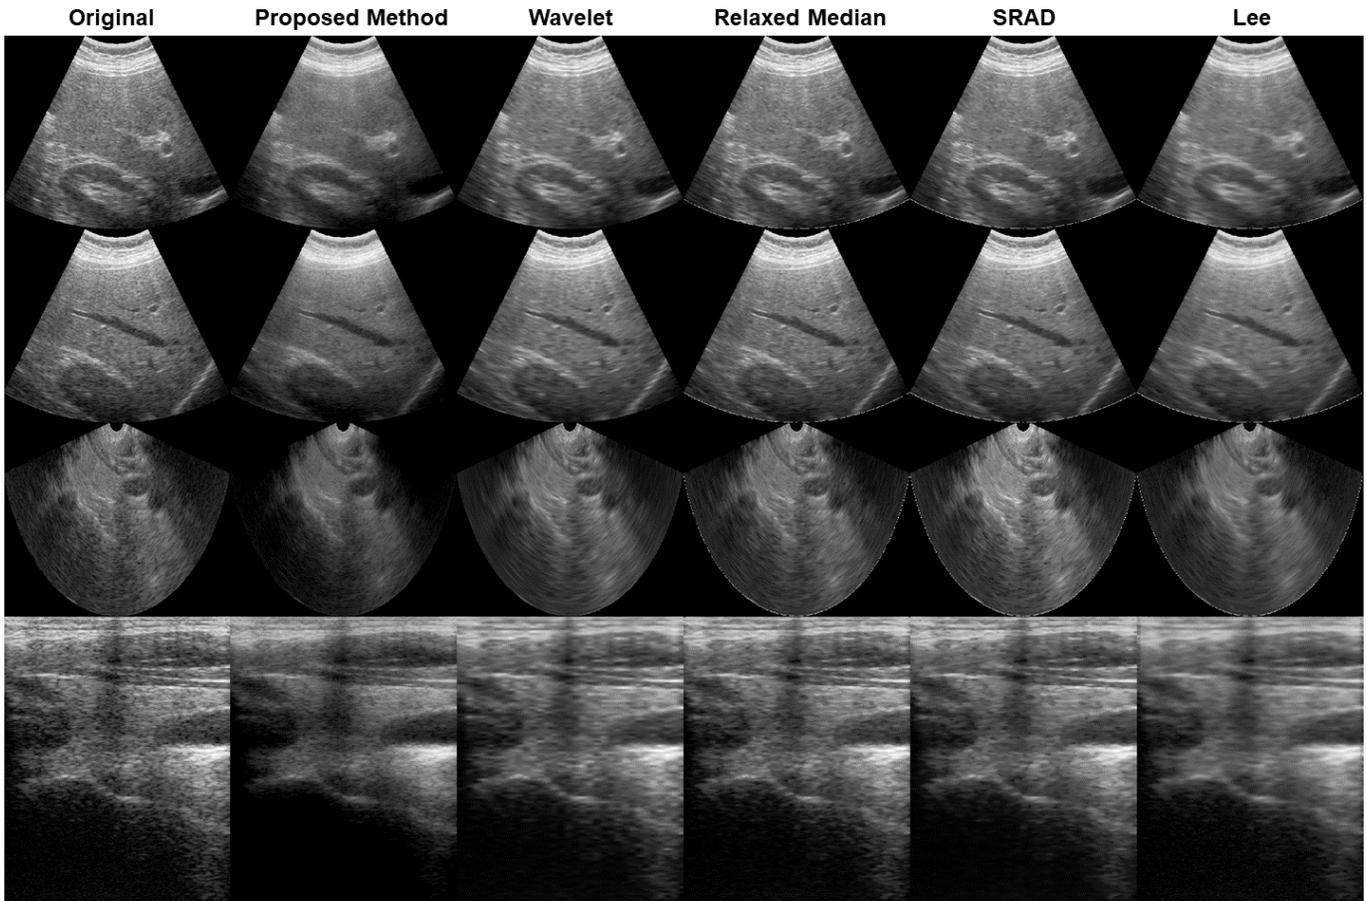
The performance of different techniques was quantitatively assessed using the structural similarity index and universal quality image quality metrics for each imaging experiment. The results are shown in Fig. 5. Each point on these plots represents the average of the respective image quality metric computed over the 10 images collected in each experiment. As can be observed, the proposed method had better metrics in the majority of experiments followed by SRAD and RMedian techniques.


Fig. 4.   Fig. 4. Diagram Showing the Output Image Results from the Porposed Technique as Compared to the Original Images and Four Previous Techniques. As Can Be Observed, the Proposed Method Offers Finer, Less Detectible Speckle Pattern Without Image Blurring.
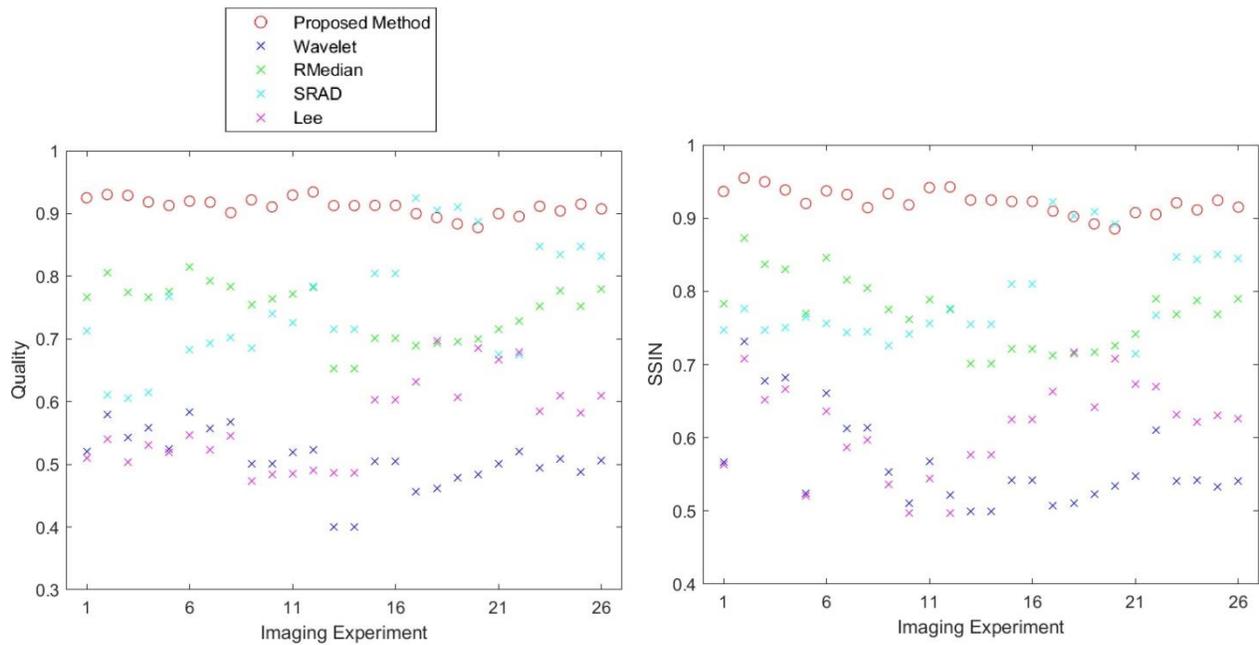

Fig. 5.   The Performance Comparison of Different Techniques as Evaluated by Two Quantitative Image Quality Metrics for Each Imaging Experiment.
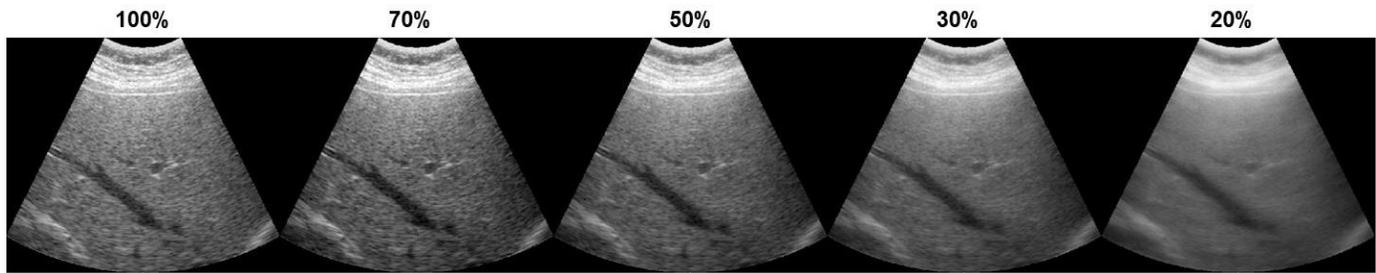

Fig. 6.   Diagram Showing the Output Image for Different user Level Selections Starting from the Original Image (No Intensity Bias) on the Left With Higher Contribution of Bias Intensity From the Left to the Right Images.

To demonstrate the value of user level selection over the speckle visibility in the output image, the output image from the same experiment using levels of 100% (original image without adding intensity bias field), 70%, 50% (used in generating previous results), 30% and 20% are provided in Fig. 6. As can be seen, the level of speckle visibility decreases as one moves to a lower level of original image contribution to the weighted average. This comes at the expense of possible blurring depending on how the bias field is generated. Therefore, a selection of a level around 50% seems to strike a balance between the two requirements of reduced speckle and blurring. This allows the sonographer to adjust the level to what he peceives as the optimal image quality for improved diagnosis.

The challenge facing the broad adoption of the new methodology are mainly due to the way the implementation in real clinical settings. Usually, the sonographer looks at the real-time images on the monitor of the ultrasound imaging system to make the diagnosis while doing the scan. If the implementation is not done on the ultrasound imaging system itself, an external computer must be connected to the system to acquire the images, process them in real-time and then display them on a medical grade monitor. The computational complexity of the new method is essentially $O(N^2)$, which is of the same order as the image reconstruction process itself and does not pose any problems in real-time processing on modern computing platforms. The main problem in the external processing option lies in how the extensive measurements and calculations packages usually offered on ultrasound imaging systems can be accessed and used during the scan. Since asking the sonographer to use an external computer to control and display ultrasound images on an external monitor and use the built-in ultrasound imaging for measurements and calculations might be inconvenient to the doctor, the implementation as an integrated original equipment manufacturer module might be the best alternative.

VI. CONCLUSIONS

A new method of speckle reduction in medical ultrasound images based on adaptive shifting on the contrast sensitivity function of human vision is proposed. The new method offers an effective image enhancement strategy that reduces speckle while preserving diagnostically useful image features and allowing practical implementation in real-time for medical ultrasound imaging applications. The new method is used to improve the visual perception of image quality of ultrasound images by adding a local contrast bias to the areas with speckle noise. This allows the variations in image pixels due to speckle noise to be better perceived by the human observer as a result of the visual perception model. Furthermore, given that image quality perception is subjective, the level of added bias is controlled by a single parameter that accommodate the different needs for different users and applications. The new method is experimentally verified using real ultrasound imaging data from 26 imaging experiments with 10 images in each. The results are evaluated qualitatively by comparing appearance of images and quantitatively using two image quality metrics. The results demonstrate the performance of the proposed method and indicate its potential to offer better viewing conditions of ultrasound images, which translates to higher diagnostic accuracy.

Multi-level Video Captioning based on Label Classification using Machine Learning Techniques

J. Vaishnavi, Dr. V. Narmatha

Department of Computer and Information Science
Faculty of Science, Annamalai University, Annamalai Nagar, India

Abstract—Video captioning is the heuristic and most essential task in the current world to save time by converting long and highly content-rich videos into simple and readable reports in text form. It is narrating the events happening in videos in natural language sentences. It makes the way to many more interesting tasks by the use of labels, tags, and terms such as video content retrieval, video search, video tagging, etc. Video captioning is currently being attempted by many researchers using some exciting Deep learning techniques. But this approach is to find the best of machine learning for the process of captioning videos in a different way. The novel part of the proposed approach is classifying videos by using the labels existing in video frames that belong to the various categories and producing consecutive Multi-Level captions that describe the entire video in a round-robin way. Informative features are extracted from the video frames such as Gray Level Co-occurrence Matrix (GLCM) features, Hu moments, and Statistical features to provide optimal results. This model is designed with two superior and optimal classifiers such as Support Vector Machine (SVM) and Naive Bayes separately. The models are demonstrated with the prevailing standard dataset Microsoft Research Video Description corpus (MSVD) and evaluated by the benchmark classification metrics such as Accuracy, Precision, Recall, and F1-Score.

Keywords—*Video captioning; label classification; Hu moments; GLCM; statistical features; SVM; Naive Bayes*

I. INTRODUCTION

Video is the most used and needed multimedia which is preferred over images and text. Social media influences and increased the usage of videos. It plays an essential role in the everyday lives of people. Video is the combination of audio and scenes which narrates with a lively touch. Hearing-impaired people suffer to extract the complete information from the video. Video captioning is the current attention-seeking computer vision [1] task which is focused on by many budding researchers. Video captioning solves the issue by narrating the video in human-understandable language. It conquers almost every field, especially from education to entertainment. The vast application of video captioning is increasing every day with prime applications such as content summarization, human-robot interaction, reports, tagging, classification, video indexing, and video surveillance [2].

Video captioning is the process of describing the frames of the input video with natural sentences. It is also a task with some complexity such as, it must capture every frame of the input video and extracting the essential features by which the frames are classified with labels to provide accurate captions.

The video captioning task has more different views and possibilities to generate captions. Machine learning techniques contribute to various methods in this field. Here is the attempt to attain the best of machine learning classifiers to classify the frames along with captions based on the labels which are categorized into different categories. Firstly, videos are converted into frames and the input frames are resized by 200×200 as constant. Some essential edge, shape and texture features are extracted from processed frames. Two standard multi-class machine learning classifiers are utilized to classify the frames with appropriate captions.

The proposed model is designed to generate the captions for the videos with less time complexity and high accuracy and also to create captions for each input video frame with particular timestamps. It will be utilized in the crime branch and hearing-impaired people will learn about the happenings of the video fruitfully. Video captioning is approached by various researchers in various methods which include different techniques and cost-effective machines. But this approach is to provide a different dimension of view towards video captioning. The proposed approach is introduced to overcome the issue of utilizing cost-effective resources like GPU (Graphical Processing Unit). The proposed method is constructed with superior machine learning techniques for both feature extraction and classification and the comparative results are analyzed to declare the best model.

The article is constructed based on the following sections. Section II discusses the related works of video captioning. The proposed method is clearly explained with the needed equation and structure in Section III. The preprocessing step is discussed in sub-section IIIC. The elaborate information about the utilized benchmark dataset is given in Section IV. Section V shows the comparative study of two standard classifiers with their computed results. The article is concluded in Section VI.

II. RELATED STUDY

The field of video captioning is evolved with different techniques which various researchers develop. Still, it is considered a challenging task due to its complexities. It includes some sub-tasks such as event detection, localization, object classification, etc. The model discussed the event detection from the high-content sports video. The events are detected by using audio-visual features and classified from the multiple genres of sports video with the employment of the standard Machine learning classifier such as the Support vector machine. Video captioning is performed by utilizing

the template-based techniques [3, 4, 5] for the generation of captions for the videos in the earlier stages.

Dynamic captioning model is introduced to show the variation of the speech signal based on the volume of the audio. It positions the caption which indicates the speaker for a better understanding of hard-of-hearing people. It explores various techniques for the betterment of the model to provide satisfactory captioning, especially for hearing impaired people such as face detection and recognition, speech–text correspondences and visual alignment, etc. The model is tested in real-time with 20 video clips of 60 hearing-impaired people. Video captioning is the extension of an image captioning task. Image captioning is the task of illustrating the content of the image. Graph-based automatic captioning of the image is proposed in which is superior to other methods such as LDA, HAM, and EM with the advantages of not defining the parameters but initializing values for only two constant parameters. This model is demonstrated with the dataset Corel image database. Video is the most preferred media by people when compared to other media. It has various choices. More types of videos are available nowadays effortlessly. The need for an automatic choice selection of videos is essential to avoid wasting energy and conserve time. To overcome the issue, the preferred choice of video for the viewers is automated by the model proposed by the researchers. It is modeled by extracting the fused features of visuals and closed captions with the Hidden Markov model.

In the era of video captioning, traditional machine learning techniques are utilized in the foremost phase of video captioning evolution such as the Hidden Markov model and post-action grammar techniques [6] with various features such as hand-crafted features and object-centric features [7], etc. Videos are captioned easily by initially classifying them where it belongs to and categorized based on the content of the video [8, 9] and activities [10] that exist in the video. Visual features [11, 12, 13] are considered one of the essential features extracted to generate captions for the video. The embedding spaces are constructed between the input videos and the natural language sentences [14, 15].

Visual grounding [16, 22] is also one of the major video-related tasks which utilize visual reasoning. Hidden features [17] are extracted by using pos sequence features. A gated fusion network [18] is utilized for captioning videos. Image captioning techniques are highly functional in advanced techniques in the current time which motivate many tasks such as video captioning [19]. The superior models are designed with an attention mechanism [20] to caption the videos for boosting the performance and also by utilizing convolutions in both encoding and decoding phases. One of the major differences between image captioning and video captioning is extracting the temporal information [21] which is essential to generating captions for videos. Various features are extracted for captioning videos such as visual, object, spatial, etc. Audio features [23] are also extracted for captioning as multi-model features [24] along with speech features. Additional memory modules [25] are exploited to evade coherent captions for the video. Videos are pre-processed to generate appropriate captions in which temporal segmentation [26] in a video between various events is essential in video captioning tasks.

The memory attended recurrent network (MARN) model [27] aims to match the visuals and term that describes the visual. Visual reasoning is adopted in [28] Reasoning module network (RMN) for location and time. Transformers are utilized for the caption generation process. An accelerated masked transformer [29] is utilized in the decoding phase which generates captions especially with localizing tasks. The videos are categorized based on domains designed as domain-specific decoders [30]. Image captioning is also the one of the cause of video captioning. It makes the video captioning processes easier. Image captioning process is taken as the subsidiary content for video captioning process to enlarge the diversity [31]. Activity net captions and Microsoft coco image datasets are utilized for the captioning process which actually enlarges the diversity.

III. PROPOSED APPROACH

In the Proposed Model, the videos are categorized into various categories which are based on labels and generate Multi-Level natural language sentences based on the extracted features. The Multi-Level captions are generated as it describes the content of the video with 7 to 10 sentences successively. The videos are illustrated in a nutshell that truly meets the need of the model as saves time than spending more watching and understanding videos. The process of providing captions in this model consists of two vital parts Feature extraction and classification. The essential features are extracted such as Gray Level Co-occurrence Matrix (GLCM) features, Hu moments, and statistical features to detect and classify the frames. Two foremost and appropriate classifiers which work better in classifying images and videos are employed in this model such as Support Vector Machine (SVM) and Naive Bayes. Preprocessing of video frames is performed for the enrichment of informative frames to generate appropriate captions for the videos. Fig. 1 shows some of the video frames from the MSVD dataset.

Fig. 1. Frames of different Categories of MSVD Dataset. (A). A Man Sits with Two Dogs, (B). A Girl Walks on the Parade, (C). A Car on the Road, (D). A Man is Talking with Children and an Old Lady, (E). A Man is Driving a Vehicle, (F) A Dog is Sitting Near a Bag.

A. Feature Extraction

1) GLCM Features: Gray Level Co-occurrence Matrix (GLCM) shows the various combinations of pixels based on the brightness values as gray level values in an image. GLCM also has another name "Gray Tone Spatial Dependency Matrix". GLCM matrix is performed based on the orders of the texture calculations. Normalize GLCM is needed to get the value one as the sum of its elements. An element in GLCM

after normalization defines the probability of pair of pixels which explores the gray values of spatial relationship in the image. The following steps are involved to create a Normalized GLCM Matrix. Fig. 2 shows the extracted features for the further classification.

a) Arrange and quantize the specific parameters (make the intensities of the pixels arranged in a needed number of gray levels) in an image data.

b) Create the square matrix of GLCM with specific order N×N, where N denotes the Number of Levels.

c) A symmetric matrix is introduced here with GLCM Matrix.

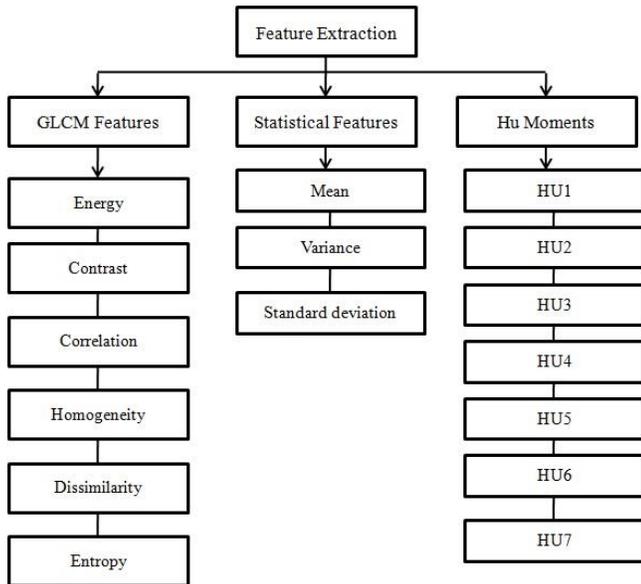
d) Dividing each element to normalize GLCM Matrix by the sum of all elements.


Fig. 2.   Features Extracted for Classification.

Here, six different GLCM features are extracted for the betterment of predicting exact captions for the input videos such as Energy (Angular second moment), Contrast, Correlation, Dissimilarity, Entropy, and Homogeneity.

2) Energy: It is the sum value of the squared elements in the matrix of the occurrence of gray. It is also named Angular Second Moment (ASM) and Uniformity. It ranges the values from zero to one. The constant image has one as the energy value. Eq. (1) explains the calculation of the energy.

$$Energy = \sum_{x,y=0}^{N-1} R(x,y)^2 \qquad (1)$$

3) Contrast: It mainly considers the intensity between the pixels that existed in the entire image. Here frames are considered images. So, the intensity between one pixel and the nearby pixel is calculated to get the contrast value. It is also named variance and inertia. The intensity contrast is measured for the entire pixels with the neighboring pixel of an image. The contrast value ranges from zero as per the constant image has the value zero as its contrast, the range of contrast value is

from zero to (size (GLCM, 1) -1) two. Contrast is calculated using Eq. (2).

$$Contrast = \sum_x \sum_y |x-y|^2 R(x,y) \qquad (2)$$

4) Correlation: Correlation is the estimation of how each pixel is related to the other pixel. It calculates the relation between the neighborhood pixels in the entire image. It values one for the positivity-related pixel and -1 for the negatively related pixel of an image and the value zero is assigned for a constant image. Correlation ranges the values between -1 and +1. By using Eq. (3), correlation is calculated.

$$Correlation = \sum_x \sum_y \frac{((x-\mu_x)(y-\mu_y)R(x,y))}{\sigma_x \sigma_y} \qquad (3)$$

5) Homogeneity: Homogeneity is the evaluation of similarity and nearness of the distribution of various elements in the Gray Level Co-occurrence matrix to its diagonals. It calculates the similarity between pixels of an image. It compares a pixel with the neighbor one. It ranges the values between zero and one. The diagonal of GLCM has one as the homogeneity value. Homogeneity is calculated between two pixels are calculated by using the Eq. (4).

$$Homogeneity = \sum_x \sum_y \frac{1}{1+|x-y|^2} R(x,y) \qquad (4)$$

6) Entropy: It is the average image information that calculates the amount of randomness in an image. It is measured based on the position of the pixel in a region (x, y). The Entropy of an image is computed by measuring the Entropy of the pixel values inside the two-dimensional region centered at each pixel position (x, y). By using equation (6), entropy is calculated. Table I shows the values of various GLCM features for sample frames. By using Eq. (5), entropy is calculated.

$$Entropy = \sum_x \sum_y R(x,y) \log R(x,y) \qquad (5)$$

7) Dissimilarity: It concentrated on the interesting region of the frame. It requires calculating the mean absolute difference and distance between two pixels of an image. It is the calculation of local intensity variation between two pixels which is nearby one another. The larger value means the higher differences; meanwhile smaller value resembles less difference between two pixels of the region. Dissimilarity is calculated by using the Eq. (6).

$$Dissimilarity = \sum_x \sum_y |x-y| R(x,y) \qquad (6)$$

TABLE I.   THE GLCM VALUES FOR SAMPLE FRAMES

Frames	Contrast	Correlation	Energy	Homogeneity	Entropy	Dissimilarity
1	3.59	9.74	4.21	7.89	1.56	1.10
2	5.79	8.05	4.18	8.24	2.87	2.81
3	2.35	9.21	3.49	9.17	1.17	1.35
4	8.14	8.03	7.59	9.13	6.62	8.14
5	4.73	8.57	3.16	8.28	1.59	3.22

8) Hu Moments: Hu moments are specially for shape matching. Hu moments are the essential features to detect the object from an image or frame which is existed in any direction or orientation. It makes the model identify the object or anything that existed despite any direction. Image moments are the weighted sum of the pixel of intensities in an image. These moments take into account the fundamental measures of objects such as area, centroid, orientation, and other needed properties. The central moment of an image gives the information that is constant to translation in an image. It needs to be invariant to translation, rotation, and scale. Hu moments are able to get seven values despite any transformation of an image based on the central moments. Central moments are calculated by the equation (7).

$$\mu_{xy} = \sum_i \sum_y (i - \bar{i})^x (j - \bar{j})^y I(i,j) \tag{7}$$

Here comes, Hu moments that characterize the existence in a frame. It detects the object through its shape. The strong point of Hu moments is stated that it traces the outline or edges of an object by using the shape feature vector to detect its shape. The difference between two different shapes of the object is measured by using the similarity metric. In seven moments, six moments are computed depending on the constant measures of scale, translation, reflection, and rotation. The seventh moment measures the changes in the image reflection. The seven Hu moments are calculated by the equations (8 - 14), Table II shows the values of Hu moments features for sample frames.

$$Hu_1 = H_{02} + H_{20} \tag{8}$$

$$Hu_2 = (H_{20} - H_{02})^2 + 4(H_{11})^2 \tag{9}$$

$$Hu_3 = (H_{30} - 3H_{12})^2 + 3(H_{03} - 3H_{21})^2 \tag{10}$$

$$Hu_4 = (H_{03} + H_{21})^2 + (H_{30} + H_{12})^2 \tag{11}$$

$$Hu_5 = (H_{30} - 3H_{12})(H_{30} + H_{12})[(H_{30} + H_{12})^2 - 3(H_{03} + H_{21})^2] + (3H_{21} - H_{03})(H_{03} + H_{21})[3(H_{30} + H_{12})^2 - (H_{03} + H_{21})^2] \tag{12}$$

$$Hu_6 = (H_{20} - H_{02})[(H_{30} + H_{12})^2 - 7(H_{03} + H_{21})^2] + 4H_{11}(H_{30} + H_{12})(H_{03} + H_{21}) \tag{13}$$

$$Hu_7 = (3H_{21} - H_{03})(H_{30} + H_{12})[(H_{30} + H_{12})^2 - 3(H_{03} - H_{21})^2] + (H_{30} - 3H_{12})(H_{03} + H_{21})[3(H_{30} + H_{12})^2 - (H_{03} + H_{21})^2] \tag{14}$$

9) Statistical features: Statistical features are one of the vital features which are needed to extract the content of an image for classification. It classifies based on the orders. Some of the most utilized statistical features by existing researchers are mean, median, standard deviation and variance, etc. A statistical feature depends on the texture of an image or frame. Intensity distribution information of an image is provided as the textual feature. The probability of intensity level distribution in histograms is utilized for the statistical feature calculation. Mean, Variance and standard deviation are the statistical features that are extracted from the input video frames for further purposes. Mean is the measure of the

average intensity value in an image that represents the brightness of an image based on the results of the mean calculation. The image is bright if it has a high mean value otherwise the image will have a low mean value. Variance is the measure of the difference between every pixel point and the mean value, and it is estimated by determining the difference between each pixel point and the mean value and squaring the differences and then dividing the square sums by the data points. All disparities from the mean in all directions are calculated by variance. Standard deviation is the measure of the contrast of intensity values in gray. The high contrast has resulted in a high value and the low contrast has resulted in a low standard deviation value. Table III shows the values of statistical features for sample frames.

TABLE II.   THE HU MOMENT VALUES FOR SAMPLE FRAMES

Frames	HU1	HU2	HU3	HU4	HU5	HU6	HU7
1	1.25	3.54	2.02	5.00	-6.13	-6.78	2.13
2	2.75	2.03	1.85	6.97	1.69	3.52	-2.63
3	2.14	1.42	1.72	2.03	-2.14	6.55	3.04
4	6.97	1.96	5.98	2.14	-6.12	1.23	1.17
5	3.72	5.89	1.53	3.56	1.96	4.56	-1.06

TABLE III.   THE STATISTICAL VALUES FOR SAMPLE FRAMES

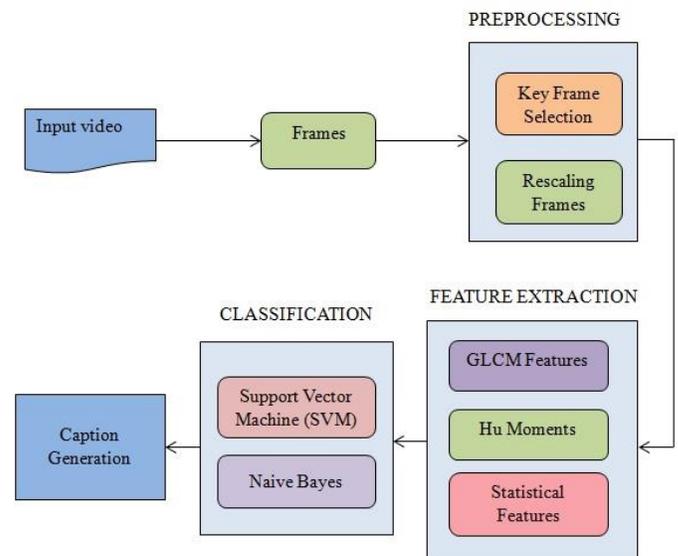
Frames	Mean	Variance	Standard deviation
1	1.00	2.15	4.85
2	6.15	1.56	4.02
3	1.11	3.58	5.99
4	2.44	0.83	0.83
5	9.47	1.74	4.01


Fig. 3.   Overall Architecture of the Model.

B. Classification

1) Support vector machine: Support Vector Machine (SVM) is the standard Machine learning classifier that is abundantly used for many image-related tasks which also gives high accuracy for the most classification tasks. It is a type of supervised model that splits data as training and testing. The training part is taken to learn the logic of the frames and the testing part is utilized to check whether the learned phase matches the actual frame. It works better in high-dimensional spaces. Fig. 3 explains the overall architecture of the model proposed.

2) Naïve Bayes: Naive Bayes is the most utilized multi-class classifier that can decide in less time compared to other classifiers. Probability of the existing object influences more in classifying video frames. It is the probabilistic classifier that works better in the high dimensional space. It classifies the input video frames into various categories which are categorized based on the actions. Finally, the input video is classified with the particular appropriate captions.

C. Preprocessing

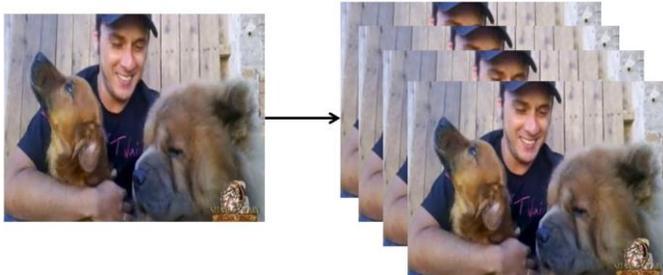
Preprocessing is the foremost step that simplifies the process by reducing the computational cost of processing the entire frames of a single video. It makes the model simpler and more comfortable for the further process of generating captions. Videos are converted into various numbers of frames. Fig. 4 shows the conversion of video into frames.


Fig. 4. Conversion of Video Into Frames.

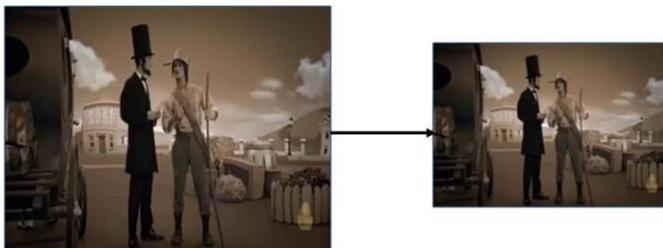
Videos are collected from the MSVD dataset with an average duration of 10 to 25 seconds. The numbers of frames are varied for every video based on the events happening and the duration of the video. The sizes of the frames are different for extracting features. It can reduce the accuracy of predicting sentences for a particular video. To overcome the issue, the Rescaling process is acquired by changing the size of every frame of input videos to a constant size of 200×200.


Fig. 5. Rescaling of Video Frames Into Standard Size.

The size and also the number of frames are made constant. The 50 constant key frames are extracted from every video frame. This step boosted the model by speeding up the learning process. Rescaling of video frames into standard size of 200x200 is shown in Fig. 5.

IV. DATASET

The Microsoft Research Video Corpus (MSVD) dataset is the benchmark video dataset with multi-lingual captions which attracts the researchers to demonstrate their attempts at video-related tasks. MSVD Dataset is collected by AMT (Amazon Mechanical Turk) workers during the summer of 2010. It is a collection of 1970 short random YouTube video clips of a duration of 10 to 25 seconds. Each video consists of seven to ten ground truth sentences that describe the contents of the videos simultaneously. In the sum of 20000 parallel descriptions are collected for video clips with 16000 exclusive vocabularies. The data has the split as per the ratio of 80:20 for training and testing.

V. PERFORMANCE COMPARISON

The performance of two standard techniques such as Naive Bayes and Support vector machine are evaluated using the metrics Accuracy, Precision, Recall, and F1 – score. Table IV shows the evaluation of Naive Bayes with performance metrics. Accuracy for Naive Bayes is 76.99 %. Prediction, Recall, and F1–score are scored as 72.52%, 69.89%, and 68.13% respectively. Fig. 6 shows the performances of the Naive Bayes classifier.

Table V shows the performance evaluation of the Support vector machine classifier with 80.12% accuracy, 73.85% for precision, 71.56% for recall, and 70.95 F1–score. Fig. 7 is the chart that represents the performance evaluation of the Support vector machine.

TABLE IV. PERFORMANCE EVALUATION OF NAIVE BAYES

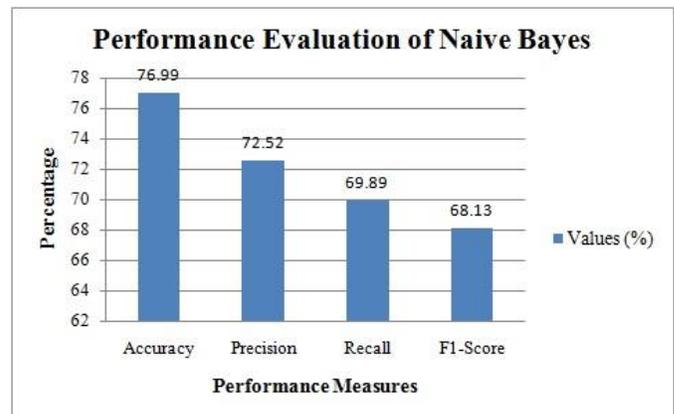
Performance Metrics	Values (%)
Accuracy	76.99
Precision	72.52
Recall	69.89
F1-Score	68.13


Fig. 6. Performance Evaluation of Naive Bayes.

TABLE V.   PERFORMANCE EVALUATION OF SUPPORT VECTOR MACHINE

Performance Metrics	Values (%)
Accuracy	80.12
Precision	73.85
Recall	71.56
F1-Score	70.95

a girl applied eye makeup to a guy   a woman is applying makeup

Fig. 9.   The Result of Two Models. Fig (a). The Result of Naive Bayes, Fig (b). The Result of the Support Vector Machine.

The comparison of the performances of two classifiers such as the Support vector machine and Naive Bayes is clearly shown in Fig. 8. The chart depicts the performances of two classifiers which shows that the support vector machine outperforms Naive Bayes classifier. The results of the two models are shown in Fig. 9. The result of SVM (i.e. (A)) describes the video more precisely than Naive Bayes (i.e. (B)).

VI. CONCLUSION

Video Captioning is a fascinating task that made many researchers make an impact in the field in a unique way. This attempt is to show the different approaches to caption videos with machine learning techniques. The proposed architecture is designed based on classifying video frames with labels that are categorized into different categories and generating Multi-Level captions that explain the happenings of the videos consecutively. The model is structured with two major parts, Feature Extraction and Classification. The feature extraction part involves extracting the essential features to provide exact results such as some Gray Level Co-occurrence Matrix features, Hu moments, and statistical features. The classification process has experimented with two standard classifiers separately which show the comparative performance for classifying videos. The comparative results show that the Support Vector Machine (SVM) overperforms the Naive Bayes classifier. It also shows that the SVM is the appropriate classifier for classifying frames by using labels for other video-related tasks. It also provides the route to some other interesting video-related tasks by labels and tags. The proposed model is examined with the MSVD benchmark dataset and the classification performance is evaluated using Accuracy, Precision, Recall, and F1-Score.

Students' Perspective on Sustaining Education and Promoting Humanising Education through e-Learning

A Qualitative Focus Group Study

Aidrina Sofiadin
Department of Information Systems
International Islamic University Malaysia, Kuala Lumpur, Malaysia

Abstract—The COVID-19 pandemic has shifted the education sector towards an e-learning approach to sustain education. Sustaining student education through e-learning significantly impacts student learning experiences and outcomes, which can be influenced by e-learning infrastructure, e-learning materials, and learning engagement. The concept of humanising education refers to the learning process that reflects students' moralities and values. Focus group discussion is a practical approach to assess students' perspectives on sustaining and humanising their education through e-learning. This qualitative focus group study aimed to discuss the e-learning factors that will sustain education and promote humanising education in the virtual learning environment. Thirty students from Information Technology (IT) and business fields have participated and provided a different view on sustaining education through e-learning. Thematic analysis was used to analyse the focus group data. Five themes were identified: (1) e-learning technologies and infrastructure; (2) e-learning principles: pedagogy and materials; (3) health and wellness; (4) equality; and (5) engagement: communication and collaboration. The analysis enlightened the e-learning design for sustainable e-learning. In addition, this paper outlines how the findings support sustainable development goals.

Keywords—Education; sustainability; humanizing education; sustainable e-learning

I. Introduction

The COVID-19 pandemic has shifted students learning into the online environment to sustain education. Despite of this, the pandemic has exposed education inequalities among students due to lack of access to devices and Internet connection. Consequently, the pandemic has affected the world 2030 agenda for sustainable development in 2015 that intend to improve public health, education, and economic growth while reducing inequality and poverty [1].

In 2021, the Sustainable Development Goals (SDG) report indicated that most of the progression of the goals had been affected due to the pandemic [2]. This is not limited to education only, but also caused lingering threat to food systems, public health, global workforce, and economy [2,3]. Continuous threats were later reported in the SDG report 2022 [4]. Moreover, the pandemic has prolonged health effect among everyone around the globe due to lung and heart scarring. Since many have lost their loved ones due to the COVID-19 pandemic, the health and well-being among the society are worrisome. E-learning has become the main drive to support student's education as it is believed to reduce the

transmission of COVID-19. To sustain education through e-learning, SDG [1] on (1) SDG#3: Good Health and Well-being; (2) SDG#4: Quality education; (3) SDG#9: Industry, Innovation, and Infrastructure; and (4) SDG#10: Reduced inequalities need to be considered.

Even though e-learning helps students to continue their studies throughout the pandemic, there is an alarming increase in mental illness among students. Since the COVID-19 outbreak, a high percentage of depression and anxiety among the Malaysian population aged above 18 years was reported in 2020 [5]. This finding was supported by [6], which indicates the high percentage of depression, anxiety, and stress among higher education students in Malaysia. The research aims to discover students' perspectives on sustaining their education and promoting humanising education through online learning environment. The research findings indicated that the five themes provide insights on designing online education that cater the student's learning ability as a human being and a learning environment that nurture good health and well-being. The outcomes from this research will support the development on SDG#3: Good Health and Well-being and SDG#4: Quality Education through e-learning. This study is organized as follows: literature review, methods, results and discussions, and conclusion.

II. Literature Review

E-learning has been introduced for decades before the COVID-19 pandemic outbreak. Many educational institutions have adopted e-learning; however, e-learning was mainly used as an education resource repository where students can obtain learning materials. Indeed, the COVID-19 pandemic has pressured education institutions to fully migrate to online learning to sustain learners' education. Many studies were conducted on e-learning during the pandemic. However, there are challenges among students, instructors, and institutions to migrate to e-learning. Furthermore, the new norm of online education has also led to health issues such as mental health, depression, and physical health.

Since the pandemic, a huge number of studies have been conducted on students' perspectives on e-learning during the COVID-19 outbreak, see Table I. Many methods such as online survey, literature review, structural equation modelling, and qualitative phenomenological approach were used to identify the impact of e-learning on its stakeholders during the pandemic. Based on these findings, most are concerned with

how e-learning impacts the students' health, education structure, e-learning policies, and teaching and learning styles.

TABLE I.   THE LIST OF PREVIOUS STUDIES ON STUDENTS' PERSPECTIVES ON E-LEARNING DURING THE PANDEMIC

Methods	Findings
Online survey	The status of mental health among university students was greatly affected during the pandemic. Most students have a good perception of e-learning [6].
Literature review	The COVID-19 global lockdown has changed the accessibility and structure of education [7].
Questionnaire survey	Faculty members have a positive attitude toward e-learning for disabled students as e-learning promotes education interaction during the pandemic [8].
Structural equation modelling	Factors of E-learning quality during the COVID-19 pandemic are assurance, reliability, responsiveness, and content [9].
Structural equation modelling	Teachers' online instructional innovation and creativity improve students' engagement [10].
Qualitative phenomenological approach	Inconsistency and awareness in e-learning policy directions on e-learning during the COVID-19 pandemic needs to be acknowledged [11].
Survey	Usability, interaction, and quality would motivate students to use the e-learning system during the COVID-19 pandemic [12].
Systematic Literature Review (SLR)	Network infrastructure, hardware requirements, implementation complexity, and training requirements are the factors for online exam endorsement [13].
Systematic Literature Review (SLR)	Attention is needed on Information and Communication Technology (ICT)-based teaching methods for learning Islamic education. Policymakers should develop better policies for Information Technology (IT) awareness and acceptance [14].
Online survey	The impact of the COVID-19 lockdown on students' mental health due to self-isolation using e-learning [15].

The findings on Table I indicate the need for support systems that enrich student wellness. Furthermore, wellness among students in aspects of physical, social, spiritual, emotional, and intellectual health need to be neglected. A report indicates that 76% of students and 73% of staff highlighted that sustaining their well-being is the main challenge [16]. Some universities have implemented health education programs to support students' academics by promoting and maintaining a healthy and positive lifestyle [17, 18, 19]. At the same time, wellness among university staff was considered by many universities such as Curtin University [19], International Islamic University Malaysia [20], Monash University Malaysia [21], and The University of Texas of Austin [22], to name a few, which provide services and support for their staff well-being.

Table II shows the findings on students' wellness and education development during the pandemic [23, 24, 16, 25, 26]. The statistics of negative impact on students are alarming. Consequently, these issues are detaining the development of the SDG especially on promoting quality education and good health and wellbeing. Based on SDG report in 2022 [4], the global learning crisis has worsened due to severe education system interruptions caused by the COVID-19 pandemic. Many countries have invested huge amount of money to recover the education services and facilities and focus on improving the education as many education institutions are re-

open. However, the report indicates that there is a lack of psychosocial support for students in which only 20 per cent of countries provide support for student's mental health and psychosocial. Not only among students, but also among young people around the world due to limited access to mental health care service. The report suggested that it is crucial to include mental health support as part of the post pandemic plans. Therefore, this significant measure is essential for the education institutions to consider due to rapid increase of depression and anxiety issues among students.

Eisenberg, Lipson, Heinze, Zhou, Talaski and Patterson	2020	The Healthy Minds Study: Fall 2020 Data Report	79% depression, 68% anxiety, 11% eating disorder, 42% feel loneliness in some of the time, and 13% on suicidality ideation.
Salesforce.org	2020	Connected Student Report: Insights into Global Higher Education Trends from over 2,000 Students and Staff.	Financial anxiety and mental health among students
Baldwin, Towler, Oliver II and Datta	2017	An examination of college student wellness	Emotional wellness (stress issue) is the top challenge, followed by Physical wellness (health behavior)
Curtin University	2016	Curtin Wellbeing Surveys	28.8% depression or anxiety 27.5% suicidal thoughts

Thus, to reduce the gaps between mental performance and mental health, there is a need of a support system that tackles both education and wellness to achieve sustainable education. In addition, the introduction of humanizing education concept can become the inspiration to improve students learning and health. Since the use of e-learning continues along with traditional learning, e-learning may have the potential to promote humanize education while improving students' well-being.

III. METHODS

This study aims to investigate how e-learning can sustain education and promote humanized education through focus groups discussion to assess students' perspectives on sustaining their education and promoting humanising education through e-learning. This study used a qualitative research approach to acquire student perspectives. Qualitative methods [27] have been widely used to identify students' needs and perspectives. Thirty students were selected and participated in the focus group discussion. The participants are from various areas of study such as Law, Business, Education, Health Science, and Engineering. The participants from different disciplinary were selected to obtain a different view on sustaining education through e-learning. The participants

were divided into six groups, where each group consisted of five members. The allocation of the group members was done randomly. The participants' demographic data were collected, and descriptive statistics were used to describe the participants' demographic data. However, this paper will focus on the qualitative data obtained from the focus group. Qualitative method was adopted due advised by Hasselblad and Olsson [28] on their publication that qualitative data is necessary to access user opinions on using technology. Thus, to analyse the qualitative data, qualitative coding was applied to increase the analysis validity, fair contribution of opinions among the participants, and transparency on reviewing data analysis.

Semi-structured interviews were implemented since it enables flexibility in achieving the research questions and explore the participants' perspectives [29] on e-learning potential in sustaining education and promoting humanizing education. Table III presents a set of open-ended questions for a semi-structured interview that was developed to facilitate the focus group discussions. Discussions were conducted online via Microsoft Teams and Nearpod for an online collaboration board for 45 minutes. The focus group started with a general question on the use of e-learning during the pandemic and later to a more focused one, covering e-learning accessibility, materials, activities, and impact. During the focus group discussions, participants' opinions were based on their own words and thoughts. The participants were informed that the data from the focus group discussions would be used for research and publication.

Thematic analysis was used to analyse the qualitative data to report themes. This analysis was used due to its practical data analysis approach for the qualitative method [4,30]. Recorded online focus group discussions were transcribed, and data from the Nearpod was generated. Along the focus group discussion, mind map was produced for each interview session to track the topics and sub-topics that were highlighted. These mind maps which represent the themes and highlighted issues, later assisted the data analysis. The use of this mind maps practice in qualitative data analysis was supported by Fearnley [31] that indicates the use of mind map in qualitative data analysis, will provide transparent and broader view of contents discussed in interviews.

TABLE III.   THE OPEN-ENDED QUESTIONS WERE PREPARED PRIOR TO THE FOCUS GROUP DISCUSSIONS

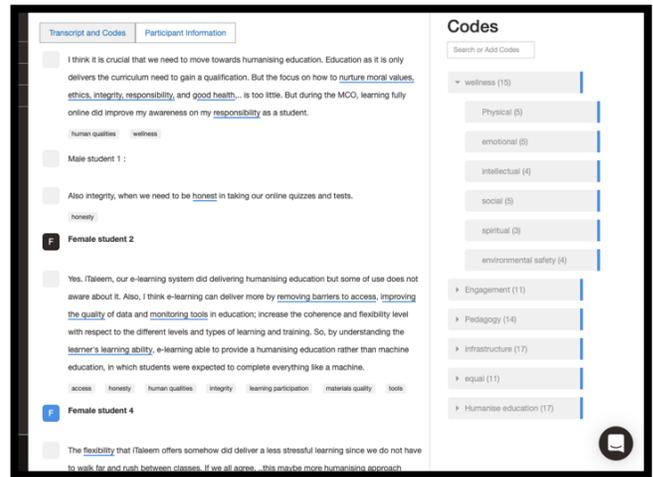
No.	Main questions
1.	What are your perspectives on learning in an online learning environment?
2.	What were your expectations of e-learning and the use of mixed reality?
3.	Did you aware of e-learning limitations?
4.	How can e-learning help you to sustain your education?
5.	What are your perspectives on humanising education?
6.	How can e-learning help you to experience humanistic education?


Fig. 1.   Screenshot of Qualitative Coding Process using Delve Qualitative Analysis Tool.

The transcripts were uploaded to Delve qualitative analysis tool and codes were identified. Fig. 1 shown above is an example of one of the transcripts that was analyzed using Delve. A combination of deductive and inductive coding approaches was used where the data analysis started with the inductive coding with codes were developed from the themes categories and the data. To increase the data validity and reduce potential biases, the second round of analysis was conducted using deductive coding in which the analysis start using the codes generated in the first round of analysis. The transcriptions were read again to assign excerpts to codes. Then, inductive coding applied with new codes. These new codes were later categorized into the themes.

IV. RESULTS AND DISCUSSION

Results were taken from the six focus groups. There were 30 participants between the ages of 20 to 25 years. Among the 30 participants, 13 were males, and 17 were female students. They are from five areas of study: Law, Business, Education, Health Science, and Engineering. Based on the focus group discussions, this research found that many students prefer online education as it offers more flexibility, time-consumption, interactive activities, and e-learning materials.

The participants' satisfaction level is high on the flexibility offered by e-learning since students can access their learning activities anytime, anywhere. Participants believe that e-learning reduces their transportation time to a physical class. E-learning allows students instantly access their online class without spending time driving or walking to class. In comparison with learning activities in class, e-learning activities are more attractive. The use of an online collaboration board, forum, and quiz, allow students to re-access the exercises again. Participants believe that they participated more in online class activities than in physical class activities. Some participants have more confidence in learning in an online environment since they cannot see people they believe will look down on them. Since e-learning provides a repository for learning materials, students have more access to attractive materials such as videos, audio on case studies, and reading materials. However, they are not

satisfied with the social environment because of their inability to feel the student life on campus.

The qualitative data analysis from the focus groups identified five main themes pertaining to sustaining education through e-learning: 1) e-learning technologies and infrastructure, (2) e-learning principles, (3) health and wellness, (4) equality, and (5) engagement. Table IV outlines the main themes and sub-themes.

Main Themes	Sub-themes
E-learning technologies and infrastructure	Network and connectivity, tools, hardware, software, service, immersive technologies, and emerging technologies.
E-learning principles	Pedagogy and materials quality
Health and wellness	Physical, emotional, intellectual, social, spiritual, and environmental safety.
Equality	An inclusive learning environment, equal learning participation, accommodating of different learning styles and disabilities, and fair use of technology.
Engagement	Communication, collaboration, and social interaction

A. E-learning Technologies and Infrastructure

E-learning infrastructure is essential to ensure online learning takes place without any interruptions. The potential loss of internet connection or poor internet connection may create barriers for students to perform online learning. The second concern raised by students was the support service.

"..removing barriers to access, improving the quality of data and monitoring tools in education; increase the coherence and flexibility level with respect to the different levels and types of learning and training. So, by understanding the learner's learning ability, e-learning able to provide a humanising education rather than machine education, in which students were expected to complete everything like a machine." (Male student).

Most students from the focus groups expressed their online learning environment as an interactive way to learn. Some of the students noted that the variety type of learning materials and activities have made e-learning more engaging compared to face-to-face learning. Even though some of them confessed that e-learning have lack of communication and social engagement, a few of the students disagreed and remarked that e-learning provide wider social connectivity.

"I communicate with more people via e-learning and I am more engaged with my group assignment discussion by using e-learning chat…. I think my connectivity will be limited if I only meet people in my classes." (Female student).

A few students pointed out that the use of immersive technology could extend students' learning experience and discover a real-world situation beyond the classroom. This could enrich human sense and quality. Furthermore, VR is believed to provide higher learning opportunity on international exposure due to VR ability to simulate real-life learning environment that are beyond the classroom. This finding tally with Ignatius [32] perspective on how digitalisation should be integrated together with basic human skills and values to re-humanising education.

"Mixed reality can provide more learning exposure on international business practice and technology development and implementation." (Female student).

"The use of virtual reality or augmented reality can increase learning outcome since it allows students to do some tasks beyond the classroom." (Male student).

Interestingly, a few students proposed AI as a coach in e-learning that will provide advice on students' learning progress and recommend healthy learning styles.

"I wish e-learning can help me to advise me to become a better person. It can teach or guide me to become ethical person by give me some information what good or bad practice are. Maybe the use of AI technology in e-learning will help me to increase my human values." (Female student).

Students wanted e-learning as a system that would take care of their education and health at the same time. They believe e-learning should be a system where they can continuously learn even after graduation. E-learning should be a technology that allows them to learn how to improve their knowledge, skills, moral values, and health. A student suggested that the use of AI may assist on learning to be an ethical person rather than just academic matters. Students also pointed out that the e-learning tools should be easy to use and do not require a lot of internet data, which may lead to crashes during online learning activities. Further advantages of VR and AI will be discussed specifically in the following themes.

B. E-learning Principles

Overall, the course syllabus, assessments, and learning outcomes are the same when conducting an online or physical approach. However, the evaluation methods, such as instructions and rules, need to be communicated to the students. A proper lesson plan needs to be shared with the students. Interestingly, a student pointed out that students should prepare their own study plan to organise their studies between online classes. The e-learning materials should be in good quality, attractive and easy to access. Nimehchisalem [33] also discovered that education could be humanised by ensuring the classroom materials were developed with both a human approach and a discovery approach, in which the curriculum can cater to a learner's needs.

"Make sure the content in e-learning is more attractive and easier to access to all students. It is also important to consist of ethical values to ensure students are aware of ethical practice in business and developing technology." (Male student).

"… the project or assignment should not be based on the textbooks or any other reading material. Our learning activities or exercises should promote creative thinking towards a better world. I think if we aim for better world that create harmony relationship between people and environment, then maybe that what it means by humanizing education……. so, e-learning can deliver this by provide some online learning interactivity that promote creative thinking towards making better future and provide some case study on climate change

crisis so that we are aware of the climate change impact in our future." (Female student).

Some participants were worried about the massive number of materials available in e-learning as it consumed more time to study than the indicated student learning time (SLT) in the course outline. Thus, this leads to health issues that lead to stress, anxiety, fatigue, headache, and eye strain. Students believe that awareness of ethics and values is important for them to learn in humanising education. In direction of humanizing education through e-learning, a few students suggested that e-learning content should correspond to promoting moral values and sustainable practices. Awareness and knowledge on best practices, ethics, morality, and values need to be delivered through e-learning activities and materials as a guide toward humanized future leaders.

"…to promote humanizing education, we should not look at education is a way to get more money in the future. It should be look as a way to make our planet and environment better. For example, most people think that business and entrepreneurship are about making a lot of money and be rich. It should create thinking on how business will help our economy become more stable and provide better service and product to our community to improve life and our environment. So, I think e-learning can provide some awareness on this since it can deliver a variety of digital information to the student.".

This may increase the quality of education for all that supports the fourth SDG. The finding also indicates that moral values need to be added as part of education quality criteria, which is supporting Balakrishanan [34], Juhary [35], and Khilji [36] statements.

C. Health and Wellness

Due to online learning during the COVID-19 lockdown, mental health has become a significant concern. Students had substantial concerns about their health in terms of physical and mental. The tremendous amount of time spent online learning has led to physical health problems such as eye strain, back pain, and headaches. The vast amount of learning tasks has caused mental health issues such as stress, depression, and anxiety.

"Be more concern with the student's mental and physical health and help them to keep motivated to sustain the quality of the education. Lectures can play a role as an online motivator." (Female student).

"e-learning can integrate the use of AR or VR to allow active learning that involve movements rather than just sitting on a chair that are causing back pains and bad body posture."

A participant pointed out that the lecturer could play a role in motivating the students through the learning process. It should be noted that the SLT should be revised for the online learning approach as it involves high contact with the computer screen and less body movement. In addition, a student suggested that e-learning should not only consist academic achievements but also the summary of achievements of soft skills and wellness criteria, that will reflect humanise

education. One student added that students need to be treated and educated as human to humanizing education.

"We are not a robot or a business product… to create humanizing education we need to be treated as human who have limitation in performing tasks and remembering things. We do not have the energy to learn the whole day. We go to class during daylight and do our homework at night."

Due to the increasing of mental illness among students [16], the findings from the focus group discussions recognized a few factors that cause a decline in the student's health, namely feeling isolated, lack of social activity, screen time, and learning materials. Thus, to ensure the students to perform better learning achievement and to support the recommendation by the United Nations in the Sustainable Development Goals 2022 Report [4], there is a need to redesign the e-learning materials, activities, and infrastructure as an alternative to provide health and psychosocial support to overcome the health and wellness issues among students.

D. Equitable

Since e-learning was used before the pandemic, some students have accessed e-learning using their personal computers or university computers. Equal access to e-learning is important for students to be able to access all the e-learning materials without any problem. For instance, as pointed out by a participant:

"Looking at the pandemic impact on our education, e-learning has saved us in sustaining our education…..I also believe e-learning provide equality education to both female and male, or even young and old learners." (Male student).

"Basic education like learn to use software and hardware need to be free and accessible for everyone. Like Finland, their education is free and there is no exam or grades that make them compete."

Due to the COVID-19 lockdown and strict movement control order, some students do not have access to e-learning as they do not afford to buy their own personal computer. This is an issue for those students to sustain their education during the pandemic. Some participants suggested government funds and donation programmes provide a personal computer to those unfortunate ones to sustain their education. The post-pandemic has led to an unstable economy, affecting many educational budgets. Thus, to sustain education on international exposure, the use of virtual reality could provide an opportunity for students to learn abroad virtually.

"The use of virtual reality and augmented reality can reduce education difference among students since this mixed reality will allow all students to have the opportunity to discover about other countries' development by virtually travelling there. This will reduce unfairness for some students who were unable to travel abroad to discover new things." (Female student).

E-learning provides a platform that can allow everyone to have opportunity to learn and have an enduring education throughout a lifetime. However, e-learning need to be accessible and provide free basic education to public. This will ensure that no one gets left behind regardless their location

and lifestyle status. The emerging technology such as VR could provide balance the number of students who obtain international exposure during their learning experience.

E. Engagement

An online learning environment may provide flexibility in communication and collaboration. Participants agreed that online activities such as collaboration boards, forums, and quizzes are more attractive and easier to re-access for revision. Some students highlighted that the online activities engaged their social and emotional learning as they are more confident learning online.

"The relationship between students and teachers should be established to promote learning engagement. For example, teachers should give personal feedback on online assessment rather than just computer-generated feedback." (Female student).

"Like Pokemon Go, the use of augmented reality has changed the game experience and increased gamers engagement since it is more attractive. So, I think mixed reality will promote better learning engagement since the learning experience will be beyond the classroom." (Male student).

The use of virtual and augmented reality in education was believed could sustain student learning and promote humanising education. To support this finding, the use of virtual experience needs to be reviewed together with human processes, experiences, and ethics, as suggested by Trkman and Cerne [37]. Furthermore, the use of chat in e-learning improves interactions between the students and lecturers as it provides fast feedback and response. However, this interaction may increase students' engagement if the lecturer responds promptly to the chat or instant messaging. Students were worried about their interaction more with their devices than people, and they are concerned if their learning process does not lead them towards a humanising education. Losing social interaction in campus life was the primary concern expressed by students during the focus group discussions since this may lead to an educational environment without soul. This relates to Razak [38] statement on the importance of education with soul in humanistic education. Instead, online learning during the pandemic feels like a factory production of learners. Students were given tasks without knowing their challenges learning online during the pandemic. Some students highlighted the need to be in a campus environment to enhance their social networks and improve their mental and physical health, which supports their learning engagement.

V. Conclusion

This study identified five themes, namely e-learning technologies and infrastructure, e-learning principles, health and wellness, equality, and engagement that could sustain students' education and promote humanistic education using e-learning. Furthermore, the concept of humanizing education can relate to the student's ability to sustain their education. For students to sustain their education through e-learning, the design of the online learning course should consider students' health, learning time, learning styles, engagement, and emerging technologies that can assist in delivering education

with soul. The e-learning system needs to be publicly accessible to deliver essential education to everyone.

Furthermore, a participant indicates that a sustainable education can be achieved if equal access to quality education is provided. Thus, an e-learning infrastructure should provide a good network, sufficient learning tools and a support system to ensure students can access their learning without interruption. Also, the university needs to ensure that students have a compatible device to access e-learning. The e-learning courses should be designed to meet different student's backgrounds.

The use of mixed reality is able to promote the concept of humanising education. The e-learning materials need to be attractive and interactive to sustain the education quality. In order to make education humanised, e-learning materials and content need to be designed based on students' personal learning styles. As a result, these five themes supported the SDGs, hence, sustaining education and promoting a humanising education. Overall, students in this study appear to have high acceptance and satisfaction levels in using e-learning. Also, they believe that e-learning has fulfilled their learning needs to sustain their education during the pandemic. This study suggests future studies on improvements in quality assurance on online learning to ensure balance between intellectual, emotional, spiritual, and physical aspects. Future research could focus on developing a support system that look after students' mental health and motivate their lifelong learning to ensure sustainable and humanistic education. The findings in this paper could lead to new education support systems that considers both mental and mind performance and health. Consequently, this will lead to the development of sustainable, healthy, and prosperous communities.

Diagnosis of Carcinoma from Histopathology Images using DA-Deep Convnets Model

K. Abinaya, B. Sivakumar*

Department of Computing Technologies
SRM Institute of Science and Technology, Kattankulathur, Chennai, Tamilnadu

Abstract—Cancer is a major origin of mortality around the globe, responsible for roughly high morbidity and mortality in 2020, or almost one per six deaths. Cervical, lung, and breast are the most common types of cancers. Cervical is the fourth highest common in women worldwide. Cervical would then kill approximately 4,280 women. Infections that cause, such as human papillomavirus (HPV) and hepatitis, account for approximately 30% of cases in low- and lower-middle-income countries. Many cancers are curable if detected as early as possible. In this proposed work, developed the DA-Deep convnets model (Data augmentation with a deep, Convolutional Neural Network) for the detection of cervical cancer from biopsy images. Deep Convolutional Neural Network presents one of the most applied DL approaches in medical imaging. Today, enhancements in image analysis and processing, particularly medical imaging, have become a major factor in the improvement of various systems in areas such as medical prognosis, treatment, and diagnosis. Based on our proposed model we achieved 99.2% accuracy in detecting the input image has cancer or not.

Keywords—*Cancer; cervical cancer; convolutional neural network; deep learning*

I. INTRODUCTION

The American Society's estimates for cervical in the US in 2022[16]: "There will be approximately 14,100 new cases of invasive cervical given a diagnosis." Oncology encompasses a wide range of diseases that can affect different parts of the body, collectively known as cancer. There are also terms like cancer and neoplasms in use. The term "metastasis" refers to the spread of cancer cells beyond the normal boundaries of the body. Diagnosing for a person looks to the doctor when they found some abnormal manifestation in the body. After that, the doctor checks that person's manifestation and medical history. Based on the symptoms the doctor will suggest a health check test. Some people may not have the manifestation too. They are able to detect only through medical checks like a biopsy, or CT scan. Sometimes doctors will find after the screening test only such as Pap test or mammography.

A. Types of Cervical Cancer

A lab microscope is used to classify cervical s and pre-cancers. Squamous cell carcinomas and adenocarcinomas are the most common types of cervical [18].

1) In most cases of cervical (up to 9 out of 10), squamous cells are present. They arise from ectocervical cells. The most common site of squamous cell carcinoma is the transformation zone.

2) Adenocarcinomas is one of the majority of cervical cancers, it is generated from the glandular cells Adens. Cervical adenocarcinoma evolves from endocervical mucus-producing gland cells.

3) Adenosquamous or mixed carcinomas are identified when both features are detected in the cervical.

B. Standard Screening Tests for Cervical

1) The HPV Test: By taking the sample piece of the DNA (Deoxyribonucleic Acid) from the cervix the doctor is able to identify, this procedure is referred to as the HPV (Human Papilloma Virus) test. HPV will not detect cancer. It will determine only the presence of HPV that cause cervical. When the person has HPV type 16 and 18 there is a possible cervical risk. In the test, doctor will collect the cell from the cervix and look at the changes caused by the HPV. Visual Inspection with Acetic Acid (VIA) is another method for detecting precancerous cervical lesions. A pathologist applies acetic acid (diluted vinegar) to the cervix to see if there are any changes in the cells. Women are given the results of the VIA test right away. In a Cone biopsy, the doctor will detach a cone-shaped piece of tissue from the cervix, called conization. The tissue includes the transformation zone where cervical pre-s and s are most likely to start also sometimes it will completely remove the early cancerous too. Few general concepts are explained in less technical terms to help you better understand how doctors decide if cancer is presently using the Shape and size of the cells, Nucleus shape, and size.

Based on the above-mentioned, the pathologist identifies cancer from the biopsy images using microscopy manually through the more number of slices in tissue after the progress. So, when they are diagnosed with the biopsy images, they may have an error as a manual error. So, the result may come from those having cancer who don't have it and vice versa. So, in the proposed work, the automatic identification of cancer through the deep convolutional neural network is suggested. For getting more accuracy in the proposed model, generate the input with data augmentation.

II. RELATED WORK

A survey was made about cervical cancer by the American society as more new cases were found as well as more number of death due to cervical cancer. In most cases, cervical cancer

---

*Corresponding Author.

is prevented using the HPV vaccination based on the screening test. When diagnose earlier as possible it will be managed effectively. If cancer is found at later stages with suitable/relevant treatment and palliative therapy then it is possible to control it.

S. N. Eldin et al. [1] proposed the diagnosis of the breast using the biopsy images using the best three models of deep learning techniques such as Resnet50 & 101, Densenet 169 model, without doing the preprocessing of the images and with preprocessing the input images. Also in this work, they tell about the various preprocessing techniques based on the performance of the models. D. Bardou et al. [2] work regarding the classification of breasts automatically using machine learning and deep learning approaches. Classification is based on the benign or malignant with subclasses. They used two approaches for the classification extracting the feature using two coding models using SVM in the machine learning model and the second approach using the Convolutional Neural Network model in deep learning techniques. In this work, they generated the images using data augmentation techniques to increase the accuracy of the result. E. CENGİL et al. [3] detect lung cancer using the 3D Convolutional Neural Network model with the implementation of TensorFlow. Here the identification of the cancer is based on the CT images; also here they classified lung cancer as benign stage and malignant stage. Here they used only the less number of a dataset for detection and classification. Y. Li et al. [4] proposed work for the identification of gastric cancer as well as its classification. Here they did the pre-processing technique as cropping because of the large size of images in the given dataset so that the deep learning model can learn and train properly using the given dataset. Here they classify lung cancer based on the patch-based classification and the slice-based classification. Van Eekelen L et al. [5] here worked for the segmentation of the major cell and the tissue types in the bone marrow trephine biopsy images. Along with the input they have biopsy images for the different wide range of persons. Based on the given input they detect and segment using VGG 16 model. They also get the result from the pathologist and compare that result with the automatic detection of cancer using the deep learning model and give the accuracy compared with the pathologist data.

Koh J et al. [6] here worked on the detection of breasts using CT–images using the deep learning model. In this proposed work they also analyze their result with the internal and the external dataset. X. Dong et al. [7] proposed lung cancer detection and segmentation using the CT images with the help of Hybridized Fully Convolutional Neural Network deep learning model with the help of mathematical calculation. Here they performed the data augmentation during the training process. Identify the size using the pyramid structure and the texture classifier used to detect the normal and abnormal cells from the given set of images. Here they use the method to reduce the false-positive results. 2D feature maps are included for better feature extraction. Singla C, et al. [8], Mammogram screening plays an important screening for

the detection of breast cancer. It has a very poor-quality image so it is very difficult for them to identify cancer from the given input. So, to enhance the image for the training they did the image enhancement with the help of the filters. They use the filters such as High PSNR and low MSE values. R. Roslidar et al., [9] in this work, detect breast cancer using Thermography images. Based on the thermograms screening model, doctors are able to detect cancer by observing the temperature distribution in the breast. Here they detect and classify cancer using a deep learning model. Actually to identify breast cancer with large tissue and early detection, can go for the thermography screening technique. So based on the temperature distribution only it is able to find out. It is very difficult for the pathologist to find out manually. So, to overcome these problems they used automatic detection using the deep learning model. To achieve a better result, they use the image enhancement model as a pre-processing method such as mean subtraction, and local contrast normalization. They also did the resizing such as width and height modified images. For the segmentation part, they use the ROI segmentation. L. Wei et al., [10] in this proposed work, classify using the dermoscopy images with the help of a deep learning model. Detection of lightweight skin cancer based on the image pre-processing, training, and fusion of an image. To overcome the overfitting problem in training progress for given input they did the data augmentation method. In pre-processing steps, they construct the positive pair and also construct the negative pair. Here for the segmentation, they use the Mobile net-V1 architecture. They loaded the input images with preprocessing, and in the training process they took 50 epochs. This paper also showed, the with and without discriminator model process accuracy.

1) S. Sharanyaa et al., [11, 12] based on the deep learning model in this paper, they identify early gastric. It is identified using endoscopy and CT scans with lightweight techniques. Before training, the noise part images are removed as pre-processing and the feature extraction is done by the color threshold algorithm. Here they also said about the part of the images having a greater number of the red color band in the given images. They proposed the Deep color net model for the identification of cancer. Find the maximum correlation between the pixels from the images using a test vector. They also highlighted the more spread area using the higher match score. Some pre-processing is also done such as resizing and the RGB image to grayscale conversion. Feature extraction and feature mapping are also done here for pre-processing the data.

Based on the survey of the paper the early detection of cervical cancer is much needed in the world nowadays. Because if it is found early, it can avoid the most last stage of cancer and also reduce the death rate. Due to manual detection sometimes it may get errors. Also it takes more time to detect cancer. So to overcome these problems it's better to get the automatic detection in the medical field with the use of a deep learning model as the convolutional neural network.

III. MATERIALS AND METHODS

In this section, here discussed the data set pre-processing of the images for accurate results. Also, the method used for automatic detection of cervical cancer is Convolutional Neural Network algorithm.

A. Data Set

In the proposed work, the data was collected from the Kaggle dataset. The dataset contains both normal biopsy images as well as cancer biopsy images. In the deep learning model, it needs to train both the normal and the images then it can ably learn by the Convolutional process during the training process. This dataset is again divided for training, testing, and validation processes. It contains the dataset in png format as an image format. So Convolutional Neural Network can learn the feature from the images by feature extraction in the convolution process. The data was in the zipped file format after that it will unzip the file for the data pre-processing for further steps.

B. Data Pre-processing

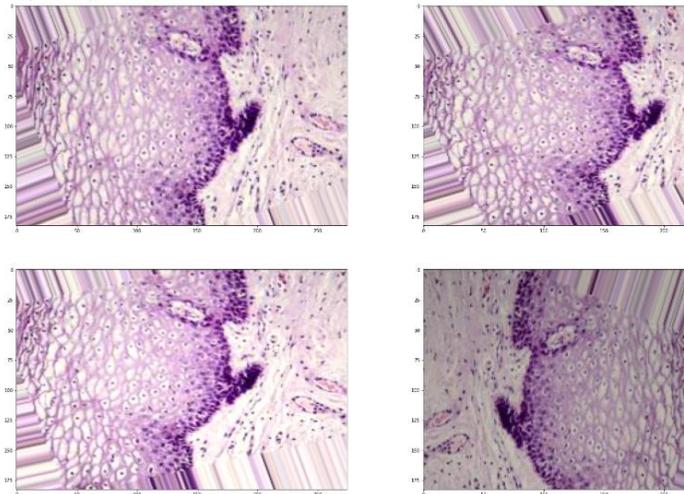
1) Data augmentation: Data augmentation was used to create additional images in the proposed work, and the Google Colab platform's Image data generator was used to put this idea into action. It is possible to bring the image data generator into Collab by way of the Keras preprocessing. The image has been rotated by 40 degrees, out of a possible 360 degrees. Every flipped picture will find its permanent home in the 3D model. The image has become distorted on all sides. Width shift = 0.2, Horizontal shift = true, Fill mode = nearest allows you to make an object in another image appear narrower or larger than it did in the original. The image has been flipped both horizontally and vertically. When an image is flipped, the pixels are rearranged, but the image's original qualities remain unchanged. Some photographs' vertical inversion is meaningless, but it has uses in cosmology and photography studies of microscopic objects. This is shown in Fig.1 along with the corresponding collab python code. Given algorithm 1 explains about the augmentation process.


Fig. 1. Input Images with Data Augmentation.

Algorithm 1 Data Augmentation
Input: Normal and Cancer Images
Output: Augmented Images
for i to n images in dataset do
R[i]=>Rotate range from 0 to 30
R[i]=>Zoom range from 0 to 0.2
R[i]=>width shift range as 0.2
R[i]=>Height shift range as 0.2
End for

2) Image training and validation: The dataset is split 80:20 so that the model can be trained and validated on separate data sets, avoiding potentially biased data. All of the photos in the folders that have been designated to correspond with the designated class names will have their titles applied to them automatically. DataLoader also brings in the train's annotated pictures and its data tracks. This separates our dataset into two classes: "normal," representing a biopsy from a healthy person, and ",", representing a random sample of data.

C. Proposed Model Architecture

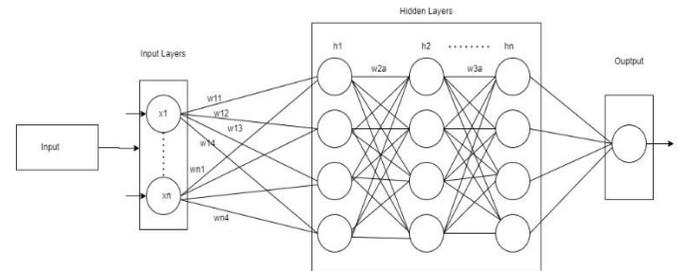
1) Neural network: The goal of deep learning algorithms is to produce results that are competitive with human judgments by repeatedly analyzing data by a predetermined logical framework. This is achieved by deep learning, which uses a network of interconnected neural processors to create a complex computational model.


Fig. 2. Neural Network Architecture.

The Input layer in Fig. 2 above receives the data from the Output layer and does nothing with it other than pass it on. Weight, activation function, a deep network, and dense layers all work together in the hidden layer to process the input. Also it shows the connections between neurons and their associated weights (w) and hidden layers (h). What do weights mean? The weight assigned to a neuron indicates how strongly it is connected to other neurons in the network. Every neuron's output is computed using this method. Only the first input (with weights) is included in the Eq. (1) below.

$$Output = F\{[(x1 * w11) + (x1 * w12) + (x1 * w13)] + [(xn * wn1) + (xn * wn2) + (xn * wn3) + (xn * wn4)]\} \quad (1)$$

The last hidden layer is then used to produce the output in the output layer. The four neurons in Fig. 2 will be used to generate the desired result. Each neuron in the network will have four weights used in the calculation.

2) Convolutional neural network

a) Convolutional layer: The convolutional layer is the first layer of a Convolutional Neural Network. Filters occupy a small portion of the input image's height and width but extend throughout its depth. It's been programmed to identify a specific class of features in the images, it's being shown. The filter or kernel is iterated through every possible location on the input matrix as part of the convolution layer. If the input image is I by I pixels and the filter is f by f, then the dimensions of the convolved output can be determined using below Eq. (2),

$$Dimension\ of\ the\ convolved\ ouput =$$
$$[size\ of\ the\ input\ image - filter\ size + 1] *$$
$$of\ [\ size\ of\ the\ input\ image - filter\ size + 1\ ] \quad (2)$$

The Eq. (3) for determining padding is as follows:

$$Output\ size = [i + 2p - f + 1] * [i + 2p - f + 1] \quad (3)$$

The input image's padded size is determined by the Eq. (4) provided,

$$Size\ of\ padded\ input\ image = \ (i + 2p) * (\ i + 2p) \quad (4)$$

Convolutional layer output can be obtained by performing the below Eq. (5),

$$Output\ for\ convolutional\ Layer = \frac{i - f + 2p}{s} + 1 \quad (5)$$

i represents the input image dimension i x i, f represents the filter size f, p represents the padding value, s represents stride value. After the convolutional layer, the output size is calculated to be 3x3, which is the result of the operations of padding, stride, and convolution.

The Eq.(6) used to determine how many pooling layers should be used.

$$Dimension\ of\ pooling\ Layer = \frac{input - filter}{stride} + 1 \quad (6)$$

Consider input as 4 x 4, Filter value as 2, Stride value as 2. Finally it calculates the input, weight, and bias value to predict the output using Eq. (7),

$$Ouput = ReLu[(i1 * w1) + (i2 * w2) + (in * wn) + Bias \quad (7)$$

i-represent the input layer, w-represent the weight, b-represent the bias value

ReLu is the activation function.

b) Dropout: As a workaround, a dropout layer is implemented. In order to reduce the training time and overall size of the model, this layer prunes the neural network of some of its neurons. The neural network has a dropout threshold of 0.3, at which point 30% of the nodes are removed at random.

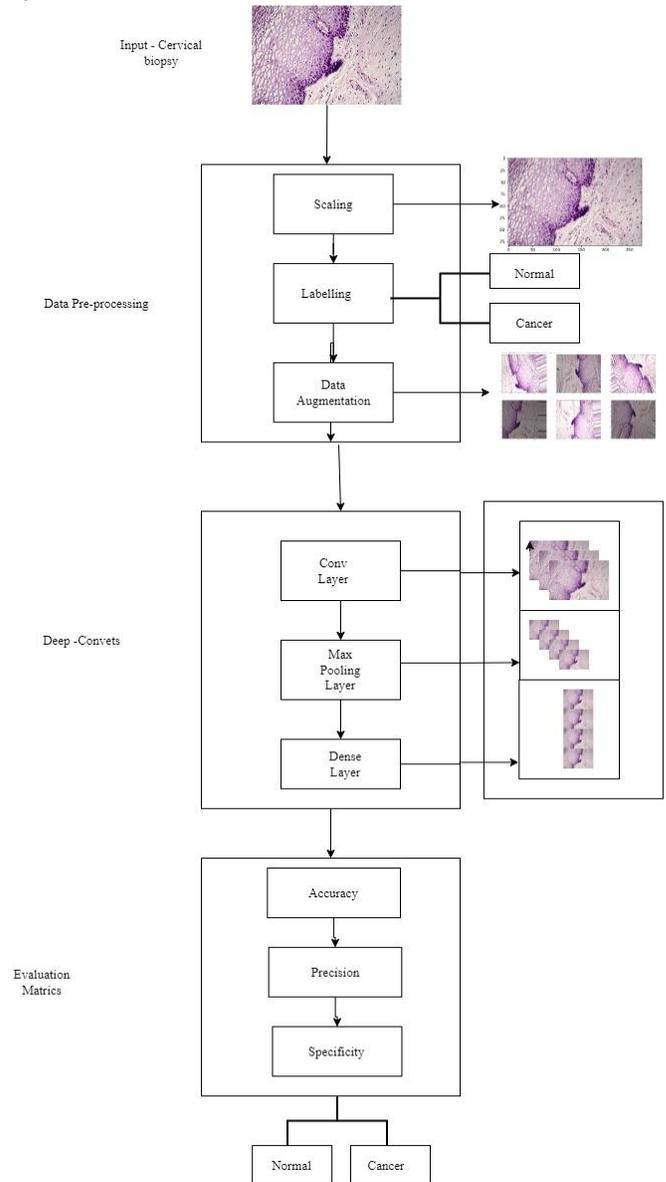
c) Assertion of Activation: The model's final and most crucial parameter, the activation function is essential to any convolutional neural network. It merely chooses which bits of data should be sent forward and which ones should be left floating around indefinitely. Based on this, let's use Adam as an optimizer with a learning rate of 0.001. Consequently, our model's process is depicted in Fig. 3. It is based on all of the aforementioned layers, and it processes the operations and gives the output by training the images through all of the layers.


Fig. 3. Block Diagram of the Proposed DA-Deep Convents Architecture.

IV. RESULT AND DISCUSSION

Using the Kaggle dataset, the proposed DA-Convent model was implemented in Google Colab. We also compared unaltered images to those that had data superimposed on them. Data augmentation for the input images, while it takes more time, will result in higher precision than the raw input data.

Fig. 4(a) and Fig. 4(b) show the training and validation of accuracy and loss value. Here for data augmentation, consider a number of the epochs as four to validate the accuracy and the loss function for the given set of images.

(a)

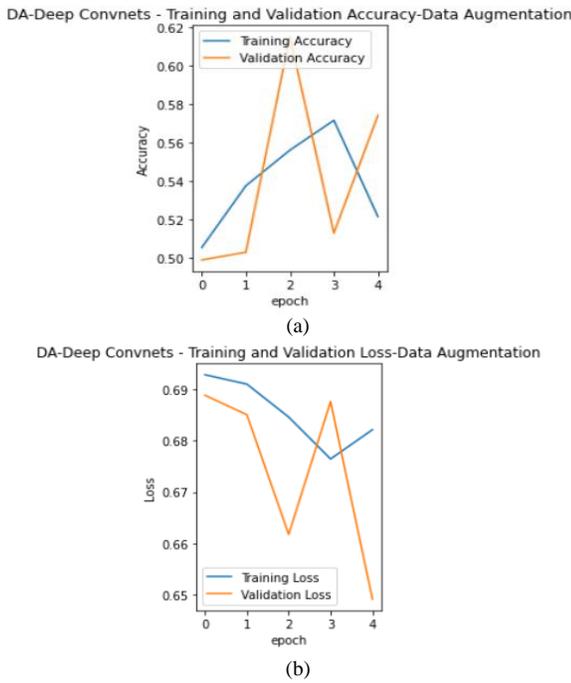
(b)


Fig. 4. (a) Traning and Validation Accuracy for Data Augmentation (b). Traning and Validation loss for Data Augmentation

A comparison of the results obtained with and without data augmentation, as well as an explanation of how the data is changing, will be provided as an output. Therapeutic identification methods include measures like precision, recall, f-score, and accuracy. A confusion matrix can also be used to assess the quality of the model. The Confusion Matrix displays how the classification component becomes confused while making predictions. The confusion matrix displays four categories: the expected classes from the original problem as columns, and the actual classes as rows. The following Eq. (8), (9) and (10) is used to determine the accuracy and loss value of the DA-Deep Convnets model.

True Positive: Normal cell, detect as Normal cell.

True Negative: Really cancer cell, detect as cancer cell.

False Positive: Normal cell, detect as cancer cell.

False Negative: Really cancer cell, detect as normal cell.

$$Accuracy = \frac{Number\ of\ classes\ correctly\ classified}{total\ number\ of\ classes\ taken} = \frac{TP+TN}{TP+TN+FP+FN} \tag{8}$$

$$Precision\ for\ Positive\ class = \frac{True\ Positive}{Number\ of\ cases\ predicted\ as\ positive} = \frac{TP}{TP+FP} \tag{9}$$

$$Precision\ for\ Negative\ class = \frac{True\ Negative}{Number\ of\ cases\ predicted\ as\ Negative} = \frac{TN}{TN+FN} \tag{10}$$

Based on the above equation, here calculated the performance for the given set of images and achieved more accuracy compared to the previous one. During the training process, here achieve more accuracy as well as reduce the loss function, as shown in Fig. 5(a) and Fig. 5(b).

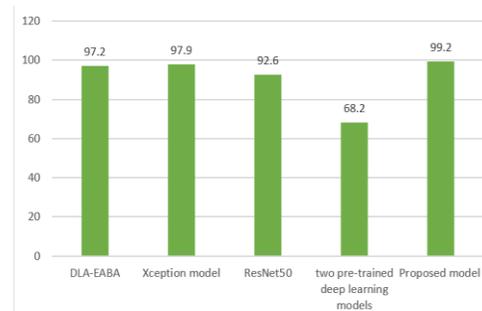

Fig. 6. Comparative Experiment Results of Proposed Architecture with different Models for Accuracy.

Fig. 6 shows the various comparative analysis with different models with the proposed model with reference [13, 14, 15, 17].

V. CONCLUSION AND FUTURE WORK

In the proposed work, an intelligent health care design is developed for the detection of cervical cancer using the biopsy image. Currently, the incidence of cervical cancer is at an all-time high. One of the most important aspects of a patient's recovery is a timely diagnosis. One of the most popular visual recognition tasks is using Convolutional Neural Networks. Every day, CNN's position in the medical section grows stronger. In proposed DA-Deep Convnets model to create a

more reliable model to assist dermatologists in accurately identifying cervical cancer. Accuracy in categorization and the top two was achieved through the use of data augmentation. With the help of data augmentation and the convolutional neural network, accuracy was achieved by 99.2%. In future work, we plan to do the classification and segmentation of cervical cancer for a more accurate process with more number of classifications.

KMIT-Pathology: Digital Pathology AI Platform for Cancer Biomarkers Identification on Whole Slide Images

Digital Pathology AI Platform for Cancer Biomarker Identification

Dr. Rajasekaran Subramanian[1], Dr. R. Devika Rubi[2], Dr. Rohit Tapadia[3], Rochan Singh[4]

Associate Professor, Dept of Computer Science and Engineering, Keshav Memorial Institute of Technology, Hyderabad, India[1, 2]

Research Intern, Dept of Computer Science and Engineering, Keshav Memorial Institute of Technology, Hyderabad, India[4]

Abstract—**Analysis and identification of cancer imaging bio markers on biopsy tissues are done through optical microscope. Digital tissue scanners and Deep learning models automate this task and produce unbiased diagnostics. The digital tissue scanner is called as virtual microscopy which digitize the glass slide tissues and the digitized images are called as Whole Slide Images (WSI). They are multi-layered (level) images having high resolution, huge in size and stored as a pyramidal tiff file. As normal web browsers are unable to handle WSI, a special web imaging platform is needed to obtain, store, visualize and process WSI. This platform must provide basic facilities for uploading, viewing and annotating WSI which are the inputs to the deep learning models. The integration of deep learning models with the platform and the WSI database provides a complete solution to cancer diagnostics and detection. This paper proposes two AI deep learning models for the diagnostics and the detection of cancer imaging bio markers on breast cancer and prostate cancer WSI. Efficientnet deep learning model is used to detect ISUP (International Society of Urologic Pathologists) grading for prostate cancer which is trained and tested by 5000 prostate WSI and produces 80% accuracy with 0.6898 quadratic weighted kappa (QWK) score. R2Unet model is used to identify tubule structures for breast cancer which is a morphological component to grade breast cancer. The model is trained and tested by 17432 WSI tiles and generates f1 metric accuracy as 0.9961 with mean_io_u 0.8612. The paper also shows the complete execution of these two Deep learning models (from uploading WSI to visualize the AI detected results) on the newly developed WSI imaging web platform.**

Keywords—*AI for cancer prediction and diagnostics; deep learning for WSI analysis; tubule prediction on breast cancer; ISUP grading for prostate cancer; WSI imaging platform*

I. INTRODUCTION

Optical microscope is the fundamental device for analysing, diagnosing and identifying disease bio markers on the tissue slides. It helps to identify morphological and cell artifacts of the disease. The heavy workload and continuous diagnosis through naked eye on microscope by pathologist may lead to a biased analysis for the disease. Digital scanners remove all these limitations and introduce a new research field called Digital pathology. Digital scanners capture high resolution images of the glass slide tissues and produce Whole Slide Images (WSI) by scanning the conventional glass tissue slides which are the most usable imaging modality by the pathologists worldwide. WSI system, also called as virtual microscopy, consists of two parts namely a scanner (hardware) and a virtual slide viewer (software). Scanner scans the conventional glass slide into digital image (file) and virtual slide viewer helps to view and analyse these digital images.

The digital WSI files are larger than any other healthcare digital images such as radiology images. These files are multi gigabyte in size (about 1600 megapixels) and requires a storage space about 4.6 GB [1]. They are stored in various types of image formats used by whole-slide imaging equipment sellers, out of which the common ones are TIFF, OME-TIFF, JPEG, NDPI or SVS. All these vendor specific formats are handled in the WSI platform by Open Slide [2] and Bio-Formats which are C and java-based software tools developed by Carnegie Mellon University and OME Consortium [3] respectively. The main processes related to WSI are obtaining, storing, visualizing and processing the digitized WSI. As these files are constructed as a multi-layered pyramid structure which provides a microscopy visual effect to the users to view and navigate (pan and zoom) slides on the computer screen.

Deep learning is used to improve diagnostic accuracy in digital pathology. Various pathologists from different locations can collaborate on the web based WSI platform. The whole slide images can be visualized in the web browser and the pathologists can annotate (mark) the affected (cancer) region on the WSI with the help of annotation tools. These annotations can then be used as inputs for training deep learning models to detect and analyse the cancer regions.

Currently, there are a lot of WSI viewers available in the market. A few examples are Digital slide Archive (DSA) which has an inbuilt WSI viewer [4], Orbit image analysis which is a WSI viewer/analysis tool [5], Orthanc WSI is a web viewer [6], OpenSeadragon AJAX image viewer [7] is a web image viewer for reading and viewing WSI, SlideRunner is an open-source cell annotations and visualization tool [8] and QUPATH is a desktop application for WSI data analysis [9].

This paper proposes two AI deep learning models for Tubule structure detection in Breast Cancer and ISUP Grading detection in Prostate Cancer using a newly developed web imaging platform called as KMIT-Pathology. It also describes the important features of the WSI imaging platform such as obtaining/storing WSI, WSI/Tiles retrieval, annotations, visualizations, images analysis and AI predictions.

This paper is organized as follows; Section II discusses the related works. Section III describes the proposed web platform and deep learning models for cancer diagnostics and detection. Section IV presents the Results. Section V gives the Conclusion, Limitations and Further enhancement of cancer detection, deep learning models and the web-based imaging platform for WSI.

II. RELATED WORKS

The authors Tiago Marques Godinho [10] proposed an architecture to integrate digital pathology workflows with a universal Picture Archive and Communications Systems (PACS) using solely DICOM standard data formats and communications. They suggested that storing a WSI using tiled organization shown in Fig. 1 (Middle) is an efficient way than storing it in a single frame organization shown in Fig. 1 (Left). In single frame organization the entire image pixels are stored sequential array where as in tiled organization the entire image is stored as a series of rectangular regions which makes easy to directly access any 2D sub regions of the image.

Image pyramid organization shown in Fig. 1 (Right) helps to perform panning and zooming vision of WSI. Pyramid organization contains various zoom level tiled images of same WSI at various layers of the pyramid. The top layer of the pyramid contains the lowest resolution of the WSI called thumb nail whereas the bottom layer contains highest resolution tiled images of WSI. This structure felicitates the zooming/panning visualization of WSI. Pyramid organization is the accepted visualization standard for WSI by DICOM [11].

David A Gutman et al. [4] developed an open-source web-based platform called Digital Slide Archive (DSA) for digital pathology. DSA allows users to manage large collections of pathology images. DSA has an image viewer which can be used to view the pathology images. DSA represents the WSI (whole slide image) data in a pyramid structure that contains several images at different resolutions. Partitioning of WSI into tiles is done by the DSA for efficient image analysis and visualization which makes DSA scalable. They also discussed several image analysis algorithms and pipelines for WSI images.

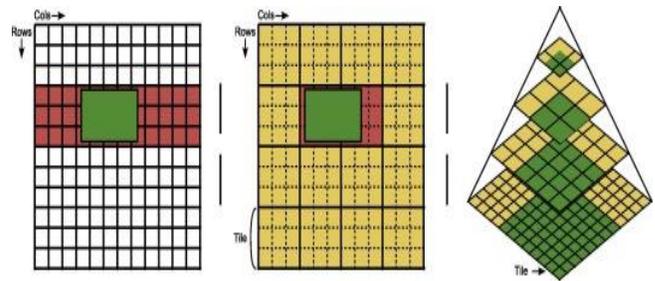
OpenSeadragon (OSD) a JavaScript based open-source web viewer uses deep zoom images (DZI) developed by Microsoft to save pyramidal file for WSI. This helps OSD to extract/display querying image tiles rather than downloading the entire WSI. OSD provides efficient zoom and navigation on WSI through DZI file format and the different file formats of the various vendors are handled by open slide, a C based library developed by Carnegie Mellon University.


Fig. 1. Storage Structure of WSI (Single Frame Structure, Tiled Structure and Pyramidal Structure of WSI).

Slide Runner [8] is a python based open source WSI tool for massive cell annotation and visualization developed at Pattern Recognition Lab, Fried rich-Alexander-Universität Endanger-Nürnberg and the Institute of Veterinary Pathology, Freie University Berlin. It can perform various cell annotations such as centre of the cell, boundary of the cell, single cell annotation and multi cell annotations by a single click. It uses open slide to manage vendor formats of WSI and provide plugins for various image processing operations such as threshold, segmentation and normalization.

QuPath is a java-based desktop software for WSI imaging analysis. It provides annotation, segmentation and classification for individual nuclei or cells. It performs cellular map and morphological feature extraction of the entire tissue section. It uses ImageJ and open CV libraries for image processing operations. Users can create their custom workflow by using scripting functionalities and add their extensions along with the existing QuPath tools. Neofytos Dimitriou et al. [12] discuss the various deep neural networks training models for WSI and emphasize the different methodologies involved in these network models. They also discuss various image formats of WSI and the lack of a universal image format. They give the insights for better performance of deep learning training by using patches of WSI than the entire WSI.

Famke Aeffner et al. [13] gives a brief introduction for modern digital pathology concepts which includes digitization of glass slides, software tools and the complement between computational image analysis and GUI for displaying the WSI. They also discuss in detail about the importance of a pathologist's role in image analysis and emerging role of AI in digital pathology. The authors, Laura Barisoni et al. [14] describe the evolution of digital pathology and computational image analysis which brings a lot of new changes in the pathology ecosystem. They also talk about the use of computer vision and AI techniques in the conversion of digital pathology images into mine able data, extraction of image information, developing techniques to diagnostic diseases and help to accurately identify patients at risk.

Breast cancer is the most leading cancer in the world. Histological grading is used to evaluate the behaviour and prognosis of breast cancer on H&E images. It quantifies the tumour architecture and the cytology deviation of the breast cancer tissue against the normal. Nottingham Grading system is a globally accepted breast cancer grading system in which Tubule identification is one of the morphological components to grade breast cancer classification [15]. The authors, Xiao

Jian Tan et al. [16] used independent data set and support vector machine to classify tubule and non-tubule. They used three parameters spatial angle, distribution and harmonic mean to measure the amount of tubule and non-tubule formation and they got the classification accuracy as 98%.

Ajay Basavanhally et al. [17] used O'Callaghan neighbourhood method to identify tubule on H&E breast tissue. They involved not only low-level attributes for training but also include the spatial distances of lumen, cytoplasm and nuclei to detect tubule. They used colour convolution method to detect nuclei. Colour gradient based active contour model and hierarchical neighbourhood algorithm are used to detect lumen areas in tubule which produced 80% classification accuracy.

Prostate cancer is the deadliest cancer affects and destroys the stroma and normal arrangements of prostate glands. International Society of Urologic Pathologists (ISUP) grades the morphological /cytological patterns of the cells in prostate cancer tissues. Gleason Scoring System (GSS) is a part of ISUP grading which helps ISUP to find major and minor patterns of the cells. These major and minor patterns decide the value of ISUP which ultimately decides the grade of the prostate cancer. Yuchen Li et al. [18] combined different neural networks such as multi scale parallel branch convolution neural network (MP B-CNN) and DeepLabv architecture to identify Gleason grading and pattern segmentation for prostate cancer. The system used 1211 WSI for training and testing and produce mean IOU as 77.29 with quadratic weighted kappa (QWK) as 0.77.

III. PROCEDURE AND APPROACH

The WSI imaging platforms QuPath, Slide Runner and Digital Slide Archive (DSA) provide facilities for Data Annotations, Images uploading, retrieval and visualizations. QuPath is a desktop-oriented platform. All these platforms provide tools to perform WSI image processing techniques. There exists a gap in digital pathology which handles WSI images and require a web-based platform. This platform should perform an end-to-end operation such as images uploading, retrieval, annotations, visualizations with AI predictions.

The proposed KMIT-Pathology platform is designed to fill-in this identified gap by performing above listed end-to-end operations. This section describes the various features of KMIT-Pathology platform such as Description of pyramidal data structure of WSI, Annotations and visualization of WSI. This section also discusses about the deep learning models to identify tubule on breast cancer and to find ISUP grading for prostate cancer.

A. WSI Visualization and Annotations

KMIT-Pathology uses pyramidal structure files of WSI which are stored as .tiff and .SVS formats. Pyramidal images are stored with different levels of resolutions. The base level is having full resolution and as it goes up the resolution of levels decreases [19]. The thumbnail (the top most level) is a very low-resolution version of the image. Fig. 2 represents pyramidal image having various levels with different resolutions. SVS files are the digital slide images produced by

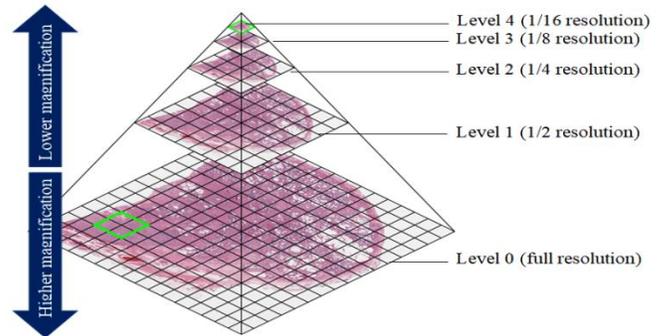
Aperio digital pathology slide scanner [20]. SVS image format is essentially based upon the Tiled TIFF format, it also stores the tiles in pyramidal form. It has all the essential features of TIFF format with few additional features such as storing the thumbnail image and new non-standard compression tags (33003 and 33005) [21].


Fig. 2.   Pyramidal Image with different Levels of Resolution.
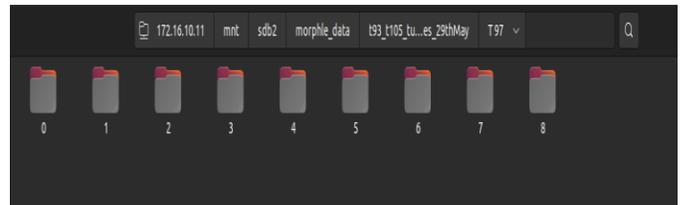

Fig. 3.   Pyramidal Tiff (Level Wise Folders) of WSI.

Morphle continum 240 scanner generates pyramidal TIFF files as a list of sequential folders (level wise resolution) with each folder containing a number of tiles belonging to the resolution of the respective levels as shown in Fig. 3.

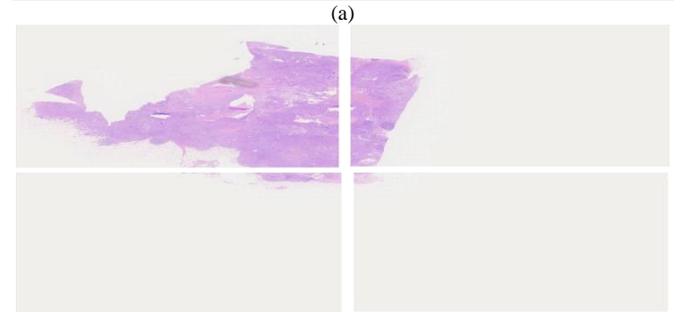
(a)

(b)

(c)

(d)

(e)

(f)


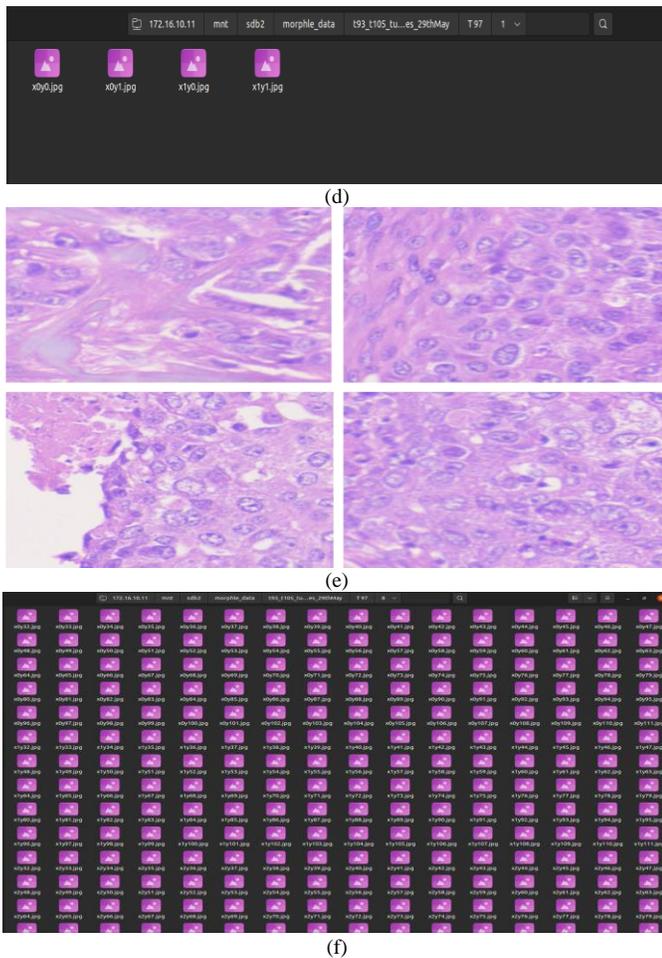


Fig. 4. (a) Level 0 Resolution Image, Level 0 Low Resolution Image is shown in Fig. 4 (a), Fig 4(b). Level 1 Resolution Image, Level 1 Low Resolution Images are Shown in Fig. 4 (b), Fig 4 (c). Level 0 Images Folder, Level 0 Low Resolution Images Folder is Shown in Fig. 4(c), Fig 4 (d). Level 1 Images Folder, Level 1 Low Resolution Images Folders are Shown in Fig. 4(d), Fig 4 (e). Level 8 High Resolution Images, Level 8 High Resolution Images are Shown in Fig. 4(e), Fig 4 (f). Level 8 Images Folders, Level 8 High Resolution Images' Folders are Shown in Fig. 4 (f).

KMIT-Pathology uses zero to eight folders to view various zoom levels from 0x to 80x. Level zero (Folder 0) is the thumbnail of WSI and level eight contains high resolution tiles of WSI. Each level contains twice the number of tiles than the previous level. Level zero consists of one image, level one contains four images and level eight consists of thousands of tiled images which are shown in Fig. 4(a) to Fig. 4(f). OpenSlide is used for zooming and panning operations (for visualization) on tiles which are present in various levels of WSI as shown in Fig. 4(a) to Fig. 4(f). Visualization of a WSI (at Zoom level 1) on KMIT-Pathology platform is shown in Fig. 5.

Annotations on WSI done by pathologist shows the diseased region (ground truth) and deep learning models learns the features of the diseased regions from ground truth and identifying (or predicting) the diseased region on any new image, if it exists. Even though WSI can be visualized at various zoom levels (resolution), the annotations performed at any level will be reflected only at the base level (high

resolution level). So, KMIT-Pathology provides facilities to annotate on base level tiles as well as on whole WSI. For example, as mitosis annotations (Fig 6(a)) requires base level annotations whereas tubule annotations (Fig. 6(b)) depend on structures which can be performed on whole WSI at any level.

KMIT-Pathology provides drawing tools needed for annotations and having a provision to download the .json files of the annotations which are later used by deep learning models for prediction.

B. Deep Learning Models

KMIT-Pathology performs WSI image analysis, primarily for Cancer detection and diagnostics. This section discusses about two deep learning models to identify tubule on Breast Cancer WSI images and ISUP grading for Prostate cancer using WSI images.

1) Tubules identification on breast cancer WSI using KMIT-Pathology platform: Histological grading is used to evaluate the behaviour and prognosis of breast cancer on H&E images. Histological grading provides the degree of differentiation in the morphological assessment of breast cancer. Nottingham grading system (NGS) was globally accepted as a histological guide for breast cancer grading classification. Identification of tubule is one of the major components in NGS system [22]. Tubules are a special type of Breast Carcinoma which are composed of tubular structures. They have an open lumina, lined by a single layer of epithelial cells. 2 - 6 % of malignant tumours are Tubular [23]. They define the aggressiveness of cancer and become disorganized as they progress. In Benign cases, the tubules that are almost round and mostly identical, but in malignant cases they are highly random and identifying boundaries is difficult for experts as well.

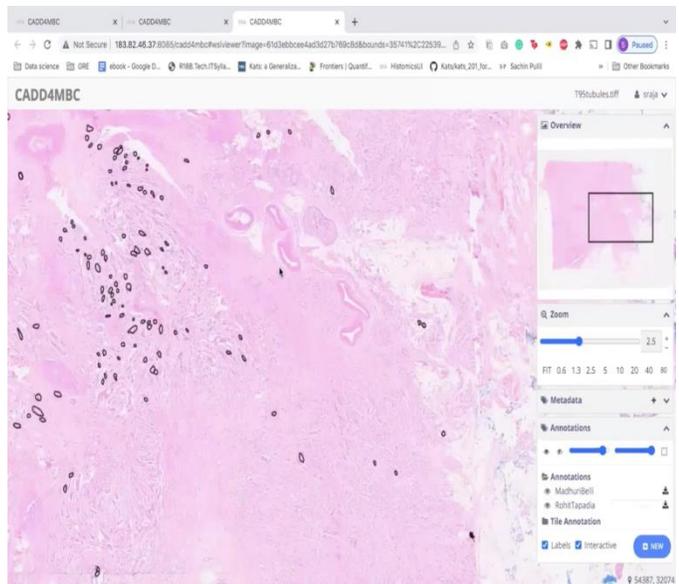
Deep learning model R2Unet is used for training and testing to identify tubule on breast WSI. There are around 50 breast cancer WSI of size varies from 8 GB to 12 GB are collected and annotated by three pathologists on WSI using KMIT-Pathology web platform. The annotations are cropped from WSI and the mask are created to run deep learning models.


Fig. 7. Tubule Identification on Breast Cancer WSI using R2Unet.

The model uses 140000 tiles of size 256*256 of magnification 40x for training and testing and the model got accuracy of F1 score 0.9295. The tubule identification on breast cancer WSI is shown in Fig. 7.

2) ISUP grade prediction for prostate cancer using KMIT-Pathology: Prostate cancer is the second largest cancer which causes more death in men worldwide. Lack of expert pathologist delays the diagnosis and creates human biased decisions in analysis and the diagnosis of the cancer. AI driven computer aided diagnosis (CAD) system automatically predict ISUP grading for prostate cancer and also helps the pathologist for early prediction and diagnosis.AI driven KMIT-ISUP grade prediction model for prostate cancer [24] uses EfficientNet to predict Gleason scores. ISUP grade depends on the Gleason Scoring (GS) system. GS system defines the structural growth pattern of cancer cells in the tissue. ISUP grading is calculated with respect to the combined score of GS majority and minority scores.

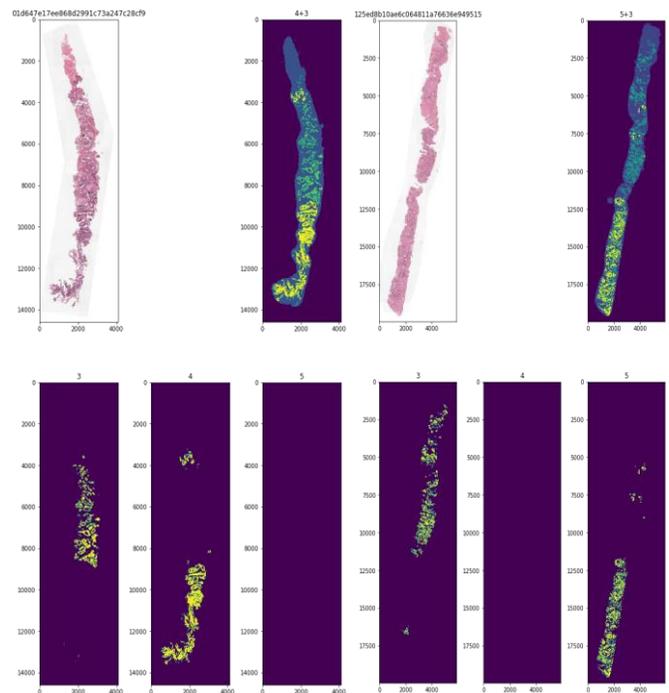
KMIT-ISUP grade identification deep learning model predicts GS score and the respective ISUP grade. KMIT-ISUP model uses Prostate Cancer Grade Assessment (PANDA) challenge dataset provided by Radboud University Medical Center and Karolinska Institute [PANDA Challenge, 21]. The model uses 5000 WSI and the respective semantic masks for various Gleason scores.


Fig. 8. Sample Prostate WSIs and the Masks with Gleason Score Labels.
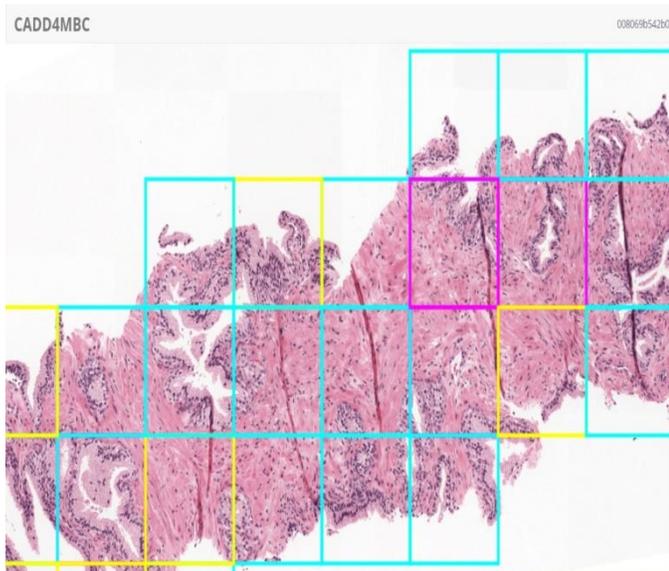

Fig. 9. Prostate WSI with Gleason Score Identification.

The WSI images and the masks are divided into 92783 patches of size 224x224 for training and testing and the model produces 80% of accuracy for ISUP grading prediction. Sample prostate WSIs and the semantic masks for ISUP 3 (4+3) and ISUP 4 (5+3) are shown in Fig. 8. The majority and the minority Gleason score (GS) for ISUP grade 3 is GS 4 and GS 3 whereas for ISUP grade 4 the majority and the minority Gleason scores (GS) are GS5 and GS3. The mask for GS3, GS4 and GS5 are generated using the mask of whole WSI which are also shown in Fig 8. Deep learning predictions for Gleason scores of prostate WSI patches and the color representation for the various GS are shown in Fig. 9. Gleason scores of the patches of WSI are sorted and the two topmost scores (majority and minority patterns) are considered to calculate ISUP grade of the WSI.

IV. RESULTS

KMIT-Pathology imaging platform is an End-to-End digitized pathology imaging platform having various necessary features like WSI data storage in Pyramidal structure with respective folders structures, Pathology Annotations tools for both complete WSI image and for Image-tiles, visualization of AI-Predictions. The deep learning models for Breast Cancer and Prostate Cancer, which are detailed in this publication are developed using KMIT-Pathology platform. Thus, proposed KMIT-Pathology imaging platform has been effectively showcased by using its various features like WSI Images storage and retrieval, Images Annotations, AI-Predictions visualizations etc.

This paper also discusses about the implementation of two AI deep learning models viz. 1) to identify Tubule on Breast Cancer WSI 2) ISUP grading on Prostate cancer by using KMIT-Pathology platform. Tubule deep learning model R2Unet uses 140000 tiles of size 256*256 of magnification 40x for training and testing to identify tubule and the model got accuracy of F1 score 0.9295. The deep learning model EfficientNet is used to predict Gleason scores of the prostate cancer which uses 92783 tiles of size 224x224 for training and testing and the model produces 80% of accuracy for ISUP grading prediction.

Both the deep learning model used KMIT-Pathology for Image/WSI uploading, retrieval, storage, image annotations, AI based cancer bio-markers identification and visualizations of the AI results.

The other imaging platforms like QuPath, OpenSeaDragon Slide Runner and Digital Slide Archive (DSA) provide facilities for Data Storage, Annotations and Visualization. Whereas, KMIT-Pathology includes all the above-mentioned features, along with AI-Deep Learning Models to identify Cancer Biomarkers on WSI images.

V. CONCLUSION AND THE FUTURE ENHANCEMENT

The invention of digital scanners gives a new era to pathology labs and opens a new research area called Digital pathology. Digital scanners capture high resolution images of the glass slide tissues. These virtual microscopy images need to be stored, visualized, analyzed and produce AI driven predictions. Various people located in different places like lab technicians, pathologists and AI engineers are needed to collaborate to perform these operations. So, they need a common web platform to interact with each other. KMIT-Pathology is a web-based platform for WSI image analysis. This platform provides facilities to perform upload, annotate and visualize WSI images. The integration of AI models with the web-based platform helps to identify cancer imaging biomarkers.

This paper also demonstrates the usage of KMIT-Pathology platform for End-to-End Cancer Bio-markers identification for Breast Cancer and Prostate Cancer WSI images.

Abstract—The most exciting thing about computer visualization is to detect a Real time object application system. This is abundantly used in many areas. With the more increase of development of deep learning such as self-driving cars, robots, safety tracking, and guiding visually impaired people, many algorithms have improved to find the relationship between video analysis and images analysis. Entire algorithms behave uniquely in the network architecture, and they have the same goal of detecting numerous objects in a composite image. It is very important to use our technology to train visually impaired people whenever they need them, as they are visually impaired and limit the movement of people in unknown places. This paper offers an application system that will identify all the possible day-to-day objects of our surroundings, and on the other side, it promotes speech feedback to the person about the sudden as well as far objects around them. This project was advanced using two different algorithms: Yolo and Yolo-v3, tested to the same criteria to measure its accuracy and performance. The SSD_MobileNet model is used in Yolo Tensor Flow and the Darknet model is used in Yolo_v3. Speech feedback: A Python library incorporated to convert statements to speech-to-speech. Both algorithms are analyzed using a web camera in a variety of circumstances to measure the correctness of the algorithm in every aspect.

Keywords—Tensor flow; SSD; Yolo; Yolo_v3; gifts; deep learning

I. INTRODUCTION

Human optical coordination is extremely precise and can handle multitasking even with unconscious notice. If you have a large amount of data, you need a more perfect system to appropriately detect and identify multiple objects at once. You can use better algorithms to train your computer to recognize multiple objects in an image with high precision. Object recognition is the utmost difficult application of computer visualization because this requires a comprehensive understanding of the image. This system was developed using a laptop, webcam, and Bluetooth headphones. TensorFlow is used to develop intelligent object detection algorithms. Models of IoT, embedded, and mobile devices are run by using tensor flow lite. It consists of low latency and low binary size, making it easy to design devices at the edge of your network. This advances potential, connectivity, and confidentiality. An unlimited length of speeches can be read by using google translate text to speech API which is a python library interface of google text to speech (gtts).

1) Deep-Learning: Deep learning comes under a branch of machine learning, a multi-tiered semantic network. These try to mimic the behavior of the human brain, permitting it to learn from the vast amount of data, even distant beyond its capabilities [1]. Single-layer semantic networks can provide limited estimates, but additional hidden layers help improve placement and accuracy.

2) Tensor flow lite: A version of TensorFlow is tensor flow lite. Tensor flow lite is used because it can run TensorFlow models on IoT, embedded, and mobile devices. TensorFlow Lite has low latency and a small binary size, which makes it easy to design devices on the network. It advances expectancy, confidentiality, and connectivity. Google Text-to-Speech (gtts), a Python library interface that uses the Google-Translate Text to Speech API. This can read language objects of infinite length. The system accurately detects objects up to 12-13 feet away.

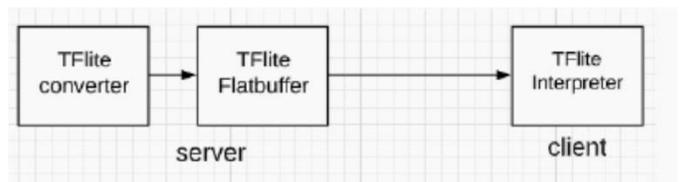
3) Tensor flow framework: It is an open-source Machine learning framework used by many applications developed by Google using Google datasets. TensorFlow develops datasets for many applications, has a flexible architecture that is written in Python or C++, and has various available frameworks such as Keras, Theano,Caffe, and Torch. Among these, Tensor Flow provides robust machine learning and easy model building. TensorFlow Lite is used for embedded mobile IoT models. Tensor flow lite has two important components as listed below:


Fig. 1. Tensor Flow Components.

- Interpreter
- Converter

The interpreter is one which makes calculations based on the input data which have been given, and the Converter creates a flat buffer file (see Fig. 1). This file is given by the client's device. This uses the TensorFlow Lite Interpreter file internally. TensorFlow lite supports APIs in numerous languages such as Objective-C, C ++ and Python Java, Swift. Model optimization tools of tensor flow lite reduce the size of the model and improve performance by not losing its accuracy. TensorFlow Lite features an effective flat buffer model format optimized for small size and portability. Flat Buffer is an effective cross-platform serialization library for Rust, C #, Java, JavaScript C ++, and Typescript. Storage-efficient Flat Buffer trains algorithms to accelerate datasets, classify the data, and predict results precisely. When the input data is entered into the model, the weights are adjusted until the model fits properly. To avoid over fitting in the model cross-validation process is done.

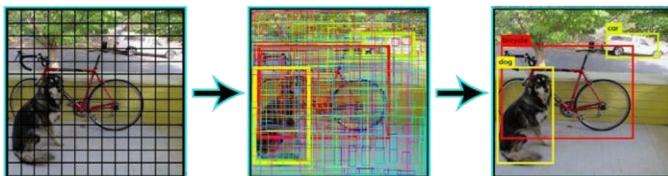
4) Yolo V3: Yolo v3 You Look Only Once is the algorithm proposed by Redmond compared to the method used in the detection algorithms before YOLO V3. This is also useful for discovery bind boxes and class dividers that instantly capture the potential of a class (see Fig. 2). YOLO V3 takes a very different approach to object detection, providing up-to-date results that are superior to other real-time, large margin detection algorithms. Each of these N grids is responsible for content ingestion and retrieval. In parallel, these grids predict binding box bindings in terms of cell bindings [11]. This process handles both cell detection and detection from a single image. This saves a lot of computational effort because multiple cells predict the same by predicting different merge boxes. Duplicate forecasts are generated.


Fig. 2. Working of Yolo V3.

5) CNN: Convolution Neural Network is a concept of deep-learning algorithm that can capture an image and assign a value (readable weight and bias) to the various elements /elements in the image and be able to distinguish one from the other. The pre-processing required for a convolution network is very low when compared to other partition Algorithms. Earlier times, filters were used to be made by hand with adequate training convolution networks that can read these filters and symbols.

The organization of the paper starts with the literature survey, where total 12 papers were analyzed with merits and demits. Methodology is explained with system architecture and use case diagram, followed by results and discussion.

II. LITERATURE SURVEY

Literature review aimed to look at various learning procedures and see if they could be applied to our use case. In [1], it has been proposed that humans use their eyes and mind to see and perceive the playing field and surrounding objects. In blind people, these talents are misplaced or impaired to varying degrees. Their eyes cannot perform the duty of sight. This paper is about designing and implementing a portable utility that helps people accurately determine their distance from them without seeing their environment. The proposed device is equipped with a CNN-based real-time data acquisition technology known as YOLO (You Look Only Once) and a separate digital camera on a Raspberry Pi board. The system additionally measures inference space and logically promises these statistics to the visually impaired. In [2], a geometry-based approach evaluates the entire 3D model. This way there is no need to isolate (or split) the object of interest. This system does not need to isolate the object of interest behind the surrounding. Compared to other methods, the proposed system is tested with real data collected from places such as kitchens or restaurants. The work proposed in this review meets the requirements of high accuracy, execution time, and compliance with the VIP criteria. An analytical data set has been published. In [3], this program does not need to isolate the object of interest behind the surrounding compared to other methods, the proposed system is tested with real data collected from places such as kitchens or restaurants. The work proposed in this review meets the requirements of high accuracy, execution time, and compliance with the VIP criteria. An analytical data set has been published. This system predicts his or her distance for approximate accuracy level. In [4], humans use their eyes and mind to see and perceive the playing field and surrounding objects. In blind people, these talents are misplaced or impaired to varying degrees. Their eyes cannot perform the duty of sight. This article is about designing and implementing a portable utility that helps people accurately determine their distance from them without seeing their environment. The proposed device is equipped with a CNN-based real-time data acquisition technology known as YOLO and a separate digital camera on a Raspberry Pi board. The gadget additionally measures inference space and logically promises these statistics to the visually impaired. In [5], in most cases, ongoing support is needed in almost all situations, especially in daily work. Other issues include difficulty recognizing people and detecting obstacles. To calculate this avoidance, this combines many of the available technologies and is integrated into one device with many features that you can use, for blind people. It takes less time to train the model. In [6], its functionality is easily compromised by creating complex training that incorporates many small image elements with more quality content object finders and scene separators, standard acquisition properties, and other modifications, improving acquisition function. Briefly review specific activities, including key discovery, facial recognition, and pedestrian detection. In [7], here the system gathers all information on motionless cameras to detect moving objects in digital videos. The system is developed based on the visual flow rate and usage as well as the combination. Object limitations are set using blob analysis; to obtain the audios, a

central filter is used and the objects which are needed are removed using thresholding algorithms for natural operation. The accuracy is less than 65%. For this purpose, they suggest that 3D counterparts that are not specific to the most widely used 2D point detectors are insufficient, and suggest another option to support these points of interest, developing a data-based awareness algorithm with a spatial window temporarily. It supports only the static data set and performance is less than 65% K-Means. An algorithm with auto encoders is used. In [9], the experimental data, they achieved higher error rates of 1 and 5 of 37.5% and 17.0%, which is much better than the prior art. Some of these are surveyed by a completely linked layer with a maximum level of integration and a final 1000 Softmax. This used unsaturated neurons to speed up training and more efficient GPUs for convolutional performance. In the experimental data, they achieved higher error rates of 1 and 5 of 37.5% and 17.0%, which is much better than the prior art. A top-five test score of 15.3%, compared to 26.2% obtained by the top runners-up. In [10] this work, they introduced the Regional Proposal Network (RPN) which shares the features of complete image conversion and acquisition network that allows most cost-effective regional proposals. Regional Proposal Network is an entirely synchronized network that predicts object parameters and resistance scores in each area. RPN trained completely to produce high-quality regional proposals, which is used from

Fast R-CNN for recognition. The RPN shows the integrated network where it is headed. Accuracy is high but large number of datasets need to be trained, so it consumes more time and space and computation power. The code has been made public. In [11], test results show the 7-bounds of conversion, the system can provide excellent real-time performance. This shows a 7 layer YOLO with an 11x11 grid cell that can accurately detect small people and vehicles. This provides accuracy and real-time performance and can only identify the person and car. In [12-15], use background-for-back classification methods to extract motion content and produce embedded videos. Then obtained directional vectors based on silhouette computations. They also used the flexible aspect of human movement to make smooth decisions over time and minimize errors in job perception. Our monocular method tolerates moderate viewing changes and can be used for both advanced and side views for most functions. This method does not do any small sample but instead is effective for all small windows. This improves the overall accuracy of the entire detector, it is not supported for other compound scoring functions. By using kernels, and by using this approach they demonstrated the great benefits of working on the three datasets which are publicly available. Surprisingly, they showed that a single solid HOG filter can exceed the modern partially crippled component. The detailed analysis of existing work is depicted in Table I.

TABLE I. THE DETAILED ANALYSIS OF EXISTING WORK

Reference paper No.	Special Features	Merits	Demerits	Conclusion and Future Work
[1]	The proposed MedGlasses system includes a couple of wearable glasses, (AI)- primarily based intelligence drug tablet box, a cellular tool app, and a cloud-primarily based facts control platform. The results shown that recognition accuracy of 95.1% can be achieved.	The improves the safety of medication for the visually impaired people	1.It is limited to only medicines. 2.It is not suitable for other objects.	This system efficiently moderates the problem of drug connections that are caused by taking wrong drugs, hence it decreases the cost of medical management and provides visually impaired patients with a safe medicinal facility.
[2]	This proposes a different framework for the detection of the objects in our daily activities and this system provides its related information which existing such as size, and security path for grasping on a surface. It contains pipelines which are the combinations of a series of point cloud representation and table plane detection, objects detection, and the full model estimation through a robust system.	It has met the requirements Of high precision, performing time, and correctness.	It requires an enormous amount of data to train. Accuracy is not up to the mark	In this framework, they considered the advantages of deep learning (e.g. RCNN, YOLO) that it can be an efficient method for exploration tasks, and the geometry-based approach Model This approach does not require separation or segmentation of the object of interest from the background.
[3]	The proposed system used YOLO methodology and a system with a single camera which is attached to a Raspberry Pi board also estimates the distance of the object and detects it and later sends this data to the blind person the method of audio feedback.	It gives accuracy above 98.8%.	We need large pieces of data to train the model.	This system concluded that it can detect the objects with its distance the accuracy of 98.8%
[4]	This application was developed using the features of the Python and OpenCV libraries, and this eventually ported to the Raspberry Pi3 Model and B+ platform. It has high Processing as well as includes the Extended identification of far distance objects accurately	It consumes less time to train the model.	1.It is expensive. 2.Its processing speed is very less.	This proposed system addresses various optimum distances and objects with less value of image source measurement
[5]	This is a voice assistance system to guide visually blind people in their daily activities. The device used is the various combination of technologies and consolidates all of these into a solitary multipurpose device that is used by the blind people	It consumes less time to train the model.	It is expensive. Its processing speed is very less.	This system discusses the different systems and algorithms for training models to achieve the accuracy of the detection.
[6]	This model behaves differently in network construction, learning strategies, optimization features, etc. it also	Improves the detection	specifies the object. It is not suitable to	It concludes several detection tasks including salient object detection, face

	provides an overview of the deep learning-based object detection environment.	performance further.	detect all the objects.	recognization, traffic signal recognization, etc.
[7]	Here the system gathers all information on motionless cameras to detect moving objects in digital videos. The system is developed based on the visual flow rate and usage as well as the combination. To obtain the audios, a central filter is used and the objects which are needed are removed using thresholding algorithms for natural operation.	Applied many algorithms to detect the object and trained using many algorithms	This is used to detect and track moving objects but accuracy is less than 65%.	It is concluded that the proposed system will accurately detect and track the correct moving objects in moving video.
[8]	In this work it has been developed an allowance of ideas of spatiotemporal case Due to this reason, it showed the direct 3D counterparts to frequently used 2D interest point detection	K-Means Algorithm with autoencoders	It supports only the static data set and performance is less than 65%.	Devised the recognition algorithm related to spatiotemporal data It resulted in recognization based on the variety of the dataset with a large amount of data
[9]	In the experimental data, they achieved higher error rates of 1 and 5 of 37.5% and 17.0%, which is much better than the prior art. Some of these are surveyed by a completely linked layer with a maximum level of integration and a final 1000 Softmax.	achieved in between the top 5 error rates of 37.5% and 17.0%	It needs more amount of data and it consumes more time to train the model.	Used the ILSVRC-2012 competition and achieved a winning top-5 test error rate of 15.3%, compared to 26.2% achieved by the other system error rate.
[10]	used Region Proposal Network which shares full-image convolutional features with the detection network, so it enables nearly cost-free region proposals. The RPN is trained end-tend to create high-quality region proposals, which are used by Fast R-CNN for the detection of an object	Precisely identifies the object that is needed	Accuracy is a high but large number of datasets needed.	Simple, useful, and the code can be freely available Code is open-source with public availability.
[11]	This system used the methodology of YOLO and seven layers of convulsion network(CNN) The various size of grid cells are used for the processing of the object detection.	This system can provide excellent detection accuracy and real-time object detection	Trained only for less dataset.	The visual quality assessment using real-world images that shows the 7layer of YOLO with 11x11 grid cells correctly detects people and small vehicles
[12]	This system does not perform any of the sub-functions but it minimizes all of the MMOD which are used to progress any object identification method which is straightforward in the parameters, such as HOG or bag of visual word models.	MMOD optimizes the accuracy of the entire object detectors.	It does not support any complex functions, that uses the kernel	This approach shows significant performance improvement on three public datasets. Surprisingly it shows, that a single hard HOG filter can perform a deformable part model.

III. METHODOLOGY

A. Modules

1) Image Capturing: Proposed System consists of a camera, placed in the classroom to capture all the students. From these captured image frames, using the opencv and system will detect the student's face in the captured image using Haar cascade face detection technique. 2. Training phase: In the training phase we are applying CNN algorithm.3. Object recognition: i) Find object location: Object localization from the input video stream can be identified. Image classification from object detection, which goes through a ConvNet that results in a vector of features fed to a softmax to classify the object. Neural network have a few more output units that encompass a bounding box. In particular, we add four more numbers, which identify the x and y coordinates of the upper left corner and the height and width of the box (bx, by, bh, bw). ii) Find object movement: The Python's built in deque datatype to efficiently store the past N points the object has been detected and tracked at. Libraries imutils also used by collection of OpenCV and Python convenience functions. By checking the X, Y co-ordinate values and tracking them,

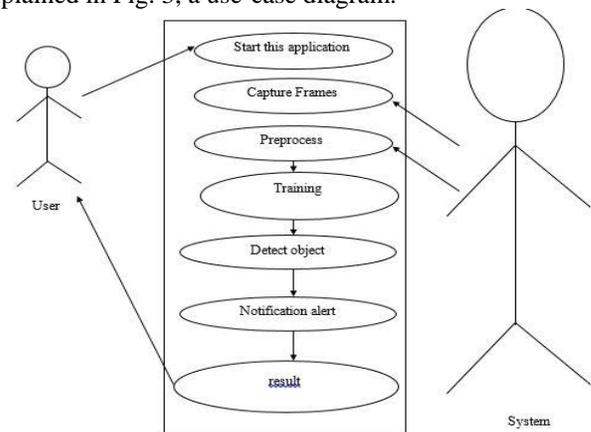
the object movement can be detected. This process is further explained in Fig. 3, a use-case diagram.


Fig. 3. Use-case Diagram.

2) System architecture: The architecture of Object detection system for blind people is described in Fig. 4. In this system input is real-time object through a camera, the captured image is stored for pre-processing, then the object is identified

through the captured image, Then the calculation of distance of the objects from the person and generates the audio signal for the identified objects, transfers the audio signal in the form of audio feedback. When user starts the application, the system captures the frame, the object capture within the frame undergoes for pre-processing in the system. After preprocessing, the system is trained to detect object, the object within the frame is detected, if multiple object is found within the frame, then the distance between those objects are also detected. The notification alert of those detected object is sent as a result to the user. So, the user can be aware of any obstacles in their path. By using this application even the blind people live their lives independently.

Fig. 6.   Multiple Object Detection.

Fig. 7.   The Graph of Model Accuracy.

The above Fig. 7 shows the graph of model accuracy in which x-axis is represented as epoch involved in training and y-axis is represented as accuracy. The graph shows the accuracy for 200 epoch in this dataset that has been divided as train and validation data. This graph shows the overall model accuracy of our implementation, that as the epoch increases accuracy increases.

Fig. 4.   System Architecture.

IV.   RESULTS AND DISCUSSIONS

In the above Fig. 5(a) shows that the person is captured in a frame the system detects the object within the frame then it sends audio feedback as person and also even in the form of text in the figure the person is moved to right so the system sends the audio and text feedback has person is move to right. The object is captured within the frame of 0.8769 pixel. Similarly in the Fig. 5(b) the object known as cat is captured within the frame of 0.6921 pixel and in the Fig. 5(c) the object dog is captured within the frame of 0.8645 pixel.

When multiple objects are detected within the frame the frame is clustered for each object then the system calculates the distance between the each object. In the above Fig. 6, objects such as person, cat and cell phone are captured within the frame. The system calculates the distance between each object and sends the result in the form of audio and text in console feedback.

Fig. 8.   The Graph of Model Loss.

The above Fig. 8 shows the graph of model loss in which x-axis is represented as epoch involved in training and y-axis is represented as loss. The graph shows the loss for 200 epoch in this dataset has been divided as train and validation data this graph shows the overall model loss of the implementation that as the epoch increases, loss reduced.

Fig. 5.   (a) Person (b) Cat (c) Dog.

V. CONCLUSION

Developed a desktop application using python, the system automatically detects the objects and makes the voice alert to blind people. Object detection is used to search objects in the real world in images of the world, often found in blind scenes. It depends on the location and cameras that are used to detect the object. This architecture is proven and is reliable for blind people. Since the use of tensor flow lite, its response time is quick and even it requires small power, making it suitable for transferable applications. There are many things in the data set, and all of these are basic things that anyone needed in their daily activities. The biggest attraction of this work is that the output signal is in the voice listening format and blind people make use of headphones which makes it easy to guide visually impaired persons, so the overall accuracy rate is 98% which is better than previous implementations. Thus it allows users to become self-reliant without having to seek help.

Abstract—**Interconnected power systems receive power through tie lines. Sudden perturbation in load causes uneven power distribution issues resulting in sudden changes in the voltage and frequency in the given system (tie-line power exchange error). The Load Frequency Controller (LFC) has an ability to stabilize the system for the above mentioned disturbances. In this paper, a novel load frequency controller based on Type-2 Fuzzy Quasi-Decentralized Functional Observer (T2FQFO) is proposed. In the proposed methodology the observer gains are obtained mathematically which guarantees, the stability of the system. The efficacy of the proposed technique has been tested on an IEEE standard testing systems. The results shows the proposed T2FQFO has higher performance when compared with Fuzzy Quasi-Decentralized Functional observer, Quasi- Decentralized Functional observer and classical state observer. And the results say that the peak over shoot and settling time have been improved by 25% (Approx.) by Type-2 Quasi Decentralized Functional Observer ((T2FQFO) than other observers.**

Keywords—Load frequency control; type-2 fuzzy quasi-decentralized functional observer; fuzzy quasi-decentralized functional observers; state observer; type-2 fuzzy controller

I. Introduction

State Estimation and its analysis constitute a fundamental aspect of science and engineering. Information about the internal state of a given system can be retrieved simply by measuring the values of inputs and outputs to the system, under this process. The term system state stands for the internal condition of a system at any given instant of time. Dynamic State Estimation (DSE) [7] refers to analysis of internal characteristics that trigger changes in the given system. These are majorly applicable to most engineering and science disciplines (viz. Electrical, Electronics, Civil, Mechanical, Aerospace, Chemical, etc. [13].).

In Control System, an Observer refers to a sub-system that is employed for estimating the internal state/condition of another system (of which it is a part) solely by analyzing the input and output to the system. This idea was first introduced by D. Luenberger in 1966 [21]. Some of the commonly used observers are state observer, functional observer, sliding observer, bounding observer [4]. The terms Observer and State Observer are almost synonymous and are implemented using computers in industrial applications.

Functional observers on the other hand, work using probabilistic/statistical approaches. They are usually available in reduced forms. For LTI (linear time invariant) systems, [3] such observers can still be designed even if the system becomes sun-observable. The paper primarily discusses the application of the aforesaid technique for power systems where exposure to disturbances like sudden changes in the load, modification in system configuration, loss of transmission lines, generator failures, etc.[16][17] are common phenomena.

In this system, there is every possibility of random values creeping into the measured data set. Nevertheless, the state estimation technique being probabilistic in nature can be carried out with random constituents. Hence, probabilistic or set-membership approaches are preferred for data analysis [9]. The common schemes include Method of Moments Estimation, Minimum Variance Unbiased Estimator (MVUE), Maximum a Posterior (MAP), Maximum Likelihood Estimation (MLE), Bayes Least Squared Error (BLSE), Bayes Estimation, Nonlinear System Identification, Wiener Filter, Kalman Filter, Particle Filter [2][6].

Collection of various sub-systems that facilitate power supply or transfer is referred to as a power system. Multiple units/areas in a power system connected via transmission lines are known as interconnected power systems. State observers may be used to measure the magnitude of the transmitted power, the transmission lines being used are commonly known as tie-lines [5]. All units/areas must have identical line frequencies. Load frequency control (LFC) [18] method prevents deviations of frequency and tie-lines for all areas/units under steady state. The main objective of this paper is a comprehensive study of linear and non-linear dynamic state estimation techniques for fault detection and LFC using PMU's [19]. A modern power system is constituted by various types of generators, transmission networks, measuring devices [8], etc. with properties similar to a general power system.

The paper describes the work (methodology) in Section II, the results obtained and the description in Section III and the conclusion in Section IV below.

A. Literature Review

M. Darouach et al. [1] introduced a simple method to design a full-order observer for linear systems with unknown inputs provided with the necessary and sufficient conditions for the existence of the observer. This method reduces the design procedure of full-order observers with unknown inputs to a standard one where the inputs are known. The existence conditions are given, and it was shown that these conditions are generally adopted for unknown inputs observer problem.

Chuang Liu, Hak-Keung Lam et al. [9] in their paper the authors investigated the stability of a Takagi-Sugano fuzzy model-based (FMB) functional observer control system. If the state-feedback control cannot measure the system state, the fuzzy function observer is designed to estimate the control input instead of directly estimating the system state. A fuzzy function observer can reduce the observer order, which determines a large number of observer gains.

Therefore, we propose a new form of fuzzy function observer that facilitates stability analysis so that the gain of the observer can be obtained numerically while guaranteeing stability. The proposed form also shows using the separation principle to design the fuzzy controller and the fuzzy function observer separately. To design fuzzy controllers with system stability in mind, we use higher derivatives of the Lyapunov function (HODLF) to reduce the conservativeness of the stability condition. HODLF generalizes the commonly used first derivative.

By exploiting the properties of the membership functions and the dynamics of the FMB control system, convex and relaxed stability conditions can be derived. A simulation example is provided to demonstrate the feasibility of the proposed relaxation of the stability constraint and the designed fuzzy function observer controller. Based on the proposed fuzzy function observer, operators can easily achieve stable observer gains. To confirm efficacy and mitigation, LIU et al. designed a fuzzy function observer controller for the nonlinear system 1639 via Holdf.

Further a more advanced techniques can be applied to meet the boundary conditions of the derivation of membership functions. And by extending the technique in discrete-time linear functional observer, the discrete-time fuzzy functional observer can also be investigated.

M. Darouach et al. [13], presented a simple and straightforward method to design full and reduced order observers for linear time-invariant descriptor systems and these are presented in this paper. The approach for the reduced order observer design is based on the generalized Sylvester equation. Sufficient conditions for the existence of the observers are given. An illustrative example is included. The reduced-order observer design method is based on the new resolution method of the constrained generalized Sylvester equation. It was shown that the existence conditions of the observer generalize those adopted in D. N. Shields et al. for the observer design of square descriptors systems problem. An extension to a less restrictive conditions is under study.

K. Rama Sudha et al. [16] have described a method based on the type 2 fuzzy system 'T2FS'. For LFC (Load Frequency Control) in power systems including Superconducting Magnetic Energy Storage Units (SMES) of two-area connected reheat heating systems. Therefore the author proposed a Type 2 (T2) fuzzy approach for load frequency control in a two-section connected reheat power plant, considering the Generation Rate Constraint (GRC), Boiler Dynamics (BD), and SMES. A distinct advantage of this controller is its lack of sensitivity to large load changes and system parameter variations, even in the presence of nonlinearities. The proposed method is tested in a dual-range power system to demonstrate its robust performance under different ranges of load changes. We compare the performance of a type 2 (T2) fuzzy controller with an optimal PID controller (Khamsum's optimal PID) and a fuzzy PI controller (type 1 fuzzy) controller in the presence of GRC, BD, and SMES. Simulation results confirm the high robustness of the proposed small-power-capacity SMES controller against various disturbances and system uncertainties compared with SMES in previous studies.

II. Power System DSE and LFC using Functional Observers

Application of Quasi decentralized functional observer (QDFO) to two area inter-connected linear power system with a single tie-line model has been depicted [11]. Development of Functional Observer (FO) [3] model for highly interconnected power systems have been under taken and is presented. The LFC signal has been generated here using a control signal. The signal needed is acquired directly from the functional observer (FO) instead of forming a control signal out of a linear combination of individual state signals. Tie-line power measurements, voltage magnitudes along with phase angles and current measurements combined with current voltage measurements of the PMU are employed for the Quasi decentralized functional observer. Power system state is primarily analyzed using an estimation algorithm, 'observability' analysis, bad data recognition etc. [7]. The basic idea and its analysis were formulated in this paper, under five corollaries.

A. Corollary -I

It might not be possible to measure all state variables under practical circumstances either due to complications related to data acquisition or cost issues. As a result, for all states of the state vector, a state estimation technique is required to obtain state feedback [19].

Let $\hat{x}(t)$ = estimate of the state vector x(t)

State Observer/Estimator

$$\dot{x} = \alpha x + \beta u \tag{1}$$

$$y = \gamma x \tag{2}$$

Here x serves as the state vector, y is the output (which includes an estimation of the state vector x).

The control signal is represented by 'u'.

Open-loop Observer (L= [0], $\alpha obs=\alpha$)

$$\dot{\hat{x}}(t) = \alpha \hat{x}(t) + \beta u \tag{3}$$

Failure of the observer takes place due to disturbances and modeling error.

Open-Loop Estimation Error

$$\tilde{x}(t) = x(t) - \hat{x}(t) \tag{4}$$

$$\dot{\tilde{x}}(t) = \dot{x}(t) + \hat{\dot{x}}(t) = \alpha\tilde{x}(t) \tag{5}$$

Hence,

$$\tilde{x}(t) = e^{\alpha t}\tilde{x}(0) \tag{6}$$

Error Dynamics:

There is no rectification for modeling imperfections, and state matrix α is unstable and has unbounded error.

$$\dot{x} = \alpha\hat{x} + \beta u + \mathcal{L}(y - \gamma\hat{x}) = \alpha\hat{x} + \beta u + \mathcal{L}y \tag{7}$$

$$\alpha_{obs} = \alpha - \mathcal{L}\gamma \tag{8}$$

Where $\mathcal{L}$ is the observer gain

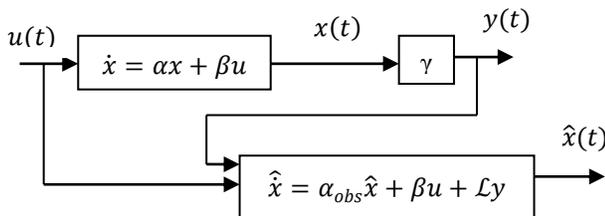
Eigen values are assigned to the matrix $\mathcal{L}$. Appropriate estimation requires the equation to be reduced in terms of an open loop observer as shown in the Fig. 1.


Fig. 1. Block Diagram of Observer.

Theorem1:

The system (γ, α) is observable if and only if the dual system (α^T, γ^T) is controllable [19].

Eigen values could be arbitrarily assigned (stable) by using state feedback provided (α^T, γ^T) is controllable.

$$\dot{x} = \alpha^T x + \gamma^T u \tag{9}$$

$$u = -\mathcal{L}^T x \tag{10}$$

$$\dot{x} = (\alpha^T - \gamma^T\mathcal{L}^T)x \tag{11}$$

$$(\alpha^T - \gamma^T\mathcal{L}^T)^T = \alpha - \mathcal{L}\gamma \tag{12}$$

Similar Eigen values are obtained.

B. *Corollary -II*

In application to the load frequency control, Functional Observability is better than State Observability [20].

Functional observer can be stated as follows.

$$\dot{x}(t) = \alpha x(t) + \beta u(t) \tag{13}$$

$$y(t) = \gamma x(t) \tag{14}$$

$$z(t) = \mathcal{L}x(t) \tag{15}$$

Here $x(t) \in R^n, u(t) \in R^m$ are the state input vectors, $y(t) \in R^p$ is the state output vector and $z(t) \in R^r$ is the vector

to be estimated. $\alpha \in R^{nxn}$, $\beta \in R^{nxm}$, $\gamma \in R^{pxn}$ and $\mathcal{L} \in R^{rxn}$ are matrices of known constants. A functional observer should be a dynamic system that should be able to track z(t) asymptotically. It is theorized to have the following structure:

$$\dot{w}(t) = \eta w(t) + \lambda y(t) + \mu u(t) \tag{16}$$

$$\hat{z}(t) = gw(t) + \text{€}y(t) \tag{17}$$

α, β and γ are the system matrices and η, λ, μ, D and € are the observer matrices and which are defined as:

$\alpha \in R^{nxn}$ $\qquad$ $N \in R^{qxq}$

$\beta \in R^{nxm}$ $\qquad$ $\lambda \in R^{qxp}$

$\gamma \in R^{pxn}$ $\mu \in R^{qxm}$

$\mathcal{L} \in R^{rxn}$ $D \in R^{rxp}$ $\quad$ $\text{€} \in R^{rxp}$

Theorem 2:

If and only if the following conditions are met, the completely observable qth order functional observer of (16) and (17) will estimate Lx(t).

- A stability matrix,η

$$\lambda\gamma = P\alpha - \eta P \tag{18}$$

$$\mu = P\beta \tag{19}$$

$$\mathcal{L} = DP + \text{€}\gamma \tag{20}$$

Observer error in state estimation can be defined as

$$e(t) \triangleq w(t) - Px(t) \tag{21}$$

Derivation and upon substitution of the system and observer equations, we get

$$\dot{e}(t) =$$
$$w(t) + P\dot{x}(t) = \eta w(t) + \lambda\gamma\dot{x}(t) + \mu u(t) - P\alpha x(t) - P\beta u(t) \tag{22}$$

Applying conditions (13) and (14) yields

$$\dot{e}(t) = \eta e(t) \tag{23}$$

The differential solution above is in the form of an exponential function

$$e(t) = e^{\eta t} \tag{24}$$

in which the observer dynamics are controlled by the variable N.

Applying these conditions, we get:

$$\lim_{t\to\infty} e(t) = w(t) - Px(t) \tag{25}$$

Further simplification, leads to the following we get

$$e_z(t) = \hat{z}(t) - \mathcal{L}x(t) = D(w(t) - Px(t)) \tag{26}$$

The above equation should reach zero asymptotically as expected α and η do not share common Eigen values but confirms that P will have a unique solution. Now X(t) and e(t) are easily derived by using above defined conditions.

$$\dot{x}(t) = \alpha x(t) + \beta u(t) = \alpha x(t) - \beta(Dw(t) + \text{€}y(t))$$
$$= (\alpha + \beta\mathcal{L})x(t) + (\beta D)e(t) \tag{27}$$

$$\dot{e}(t) = \eta e(t) \tag{28}$$

This results in a composite system similar to the full-state observer as

$$\begin{bmatrix} \dot{x}(t) \\ \dot{e}(t) \end{bmatrix} = \begin{bmatrix} \alpha + \beta\mathcal{L} & \beta D \\ 0 & \eta \end{bmatrix} \begin{bmatrix} x(t) \\ e(t) \end{bmatrix} \tag{29}$$

Aside from the fact that the control law, $\mathcal{L}x(t)$ is used instead of $-Kx(t)$. Though there is variation in notation, they are similar to each other. Judging the constraints involved, an rth order observer is required to achieve functional state of the system, where the order of the system r is as small as possible. The observer matrices should therefore guarantee the ease of Eigen value assignment and simplicity of the control algorithm so that it can be readily applied.

For order estimation, the matrix ranks are taken into consideration.

$$\text{rank} \begin{bmatrix} L\alpha \\ \gamma\alpha \\ \gamma \\ \mathcal{L} \end{bmatrix} = \text{rank} \begin{bmatrix} \gamma\alpha \\ \gamma \\ \mathcal{L} \end{bmatrix} \tag{30}$$

$$\text{rank} \begin{bmatrix} s\mathcal{L} - L\alpha \\ \gamma \\ \mathcal{L} \end{bmatrix} = \text{rank} \begin{bmatrix} \gamma\alpha \\ \gamma \\ \mathcal{L} \end{bmatrix} \quad s \in \gamma, R(s) \geq 0 \tag{31}$$

The condition is satisfied when the ranks on the LHS and RHS are equal. The author in [15] shows that this condition is equal to the delectability of the pair (F, g), where

$$F = \mathcal{L}\alpha\mathcal{L}^+ - \mathcal{L}\alpha(I - \mathcal{L}^+\mathcal{L}) \begin{bmatrix} \gamma\alpha(I - \mathcal{L}^+\mathcal{L}) \\ \gamma(I - \mathcal{L}^+\mathcal{L}) \end{bmatrix}^+ \begin{bmatrix} \gamma\alpha\mathcal{L}^+ \\ \gamma\mathcal{L}^+ \end{bmatrix} \tag{32}$$

$$g = \left(I - \begin{bmatrix} \gamma\alpha(I - \mathcal{L}^+\mathcal{L}) \\ \gamma(I - \mathcal{L}^+\mathcal{L}) \end{bmatrix} \begin{bmatrix} \gamma\alpha(I - \mathcal{L}^+\mathcal{L}) \\ \gamma(I - \mathcal{L}^+\mathcal{L}) \end{bmatrix}^+ \right) \begin{bmatrix} \gamma\alpha\mathcal{L}^+ \\ \gamma\mathcal{L}^+ \end{bmatrix} \tag{33}$$

Where, $\mathcal{L}+$ denotes the Moore-Penrose generalized inverse of matrix $\mathcal{L}$. Moreover, if matrices λ, μ and E satisfy Theorem 1, a Hurwitz matrix η is given by

$$\eta = F - Zg \tag{34}$$

For F-Zg to be stable, the Matrix Z is obtained by any pole placement method. Matrices E and K are obtained according to the equation,

$$[E \quad K] = \mathcal{L}\overline{\alpha}\Sigma^+ + Z(I - \Sigma\Sigma^+) \tag{35}$$

Where, $\overline{\alpha} = \alpha(I - \mathcal{L}^+\mathcal{L})$, $\overline{\gamma} = \gamma(I - \mathcal{L}^+\mathcal{L})$ and $\Sigma = \begin{bmatrix} C\overline{A} \\ \overline{C} \end{bmatrix}$

Matrix λ, μ are obtained according to

$$\lambda = K + \eta E \tag{36}$$

$$\mu = (\mathcal{L} - E\gamma)\beta \tag{37}$$

All of the required observer parameters can be easily computed using this algorithm, which results in a functional observer of form

$$\dot{w}(t) = \eta w(t) + \lambda y(t) + \mu u(t) \tag{38}$$

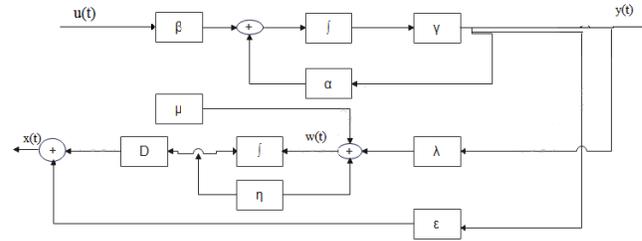
$$\hat{z}(t) = w(t) + Ey(t) \tag{39}$$


Fig. 2. Schematic of a Functional Observer.

C. Corollary –III

Functional Observer based Conventional Controller:

Due to increasing complexity in power distribution network, a simplified assumption that considering all the generators in a given area into one single generation unit, transmission lines and various bus bars are lumped into one single entity might not be appropriate enough for any complex power system network. This paper presents an analysis of a Quasi-decentralized Functional Observer (QDFO) project to control the tie-line power and frequency of multi-area interconnected power system with real time considerations [10]. Also, linear system (two-area) connected with a single tie-line model was considered for the generation of control signals and Quasi-Decentralized Functional Observer(QDFO) is applied to it for the control. Further it is formulated with FO [3] approach for LFC (Load Frequency Control) of highly interconnected power networks. In the process of generation of the LFC signal, it is required to estimate the control signal. It is more rational to estimate the desired signal directly using the functional observer (FO) than estimating all the individual states and then linearly combining those individual state estimates to construct the control signal [4]. And the control signal is generated by a Quasi-Decentralized Functional Observer (QDFO) in this case. PMU measurements of voltage and current magnitudes and phase angles, as well as tie-line power measurements, are used in the Functional Observer (FO) estimate process [2]. The suggested FO-based controllers have less complicated architecture and comparable performance to Full Order observers. Further, the Functional Observability (FO) criterion is less rigorous than the state observability requirement, and the design and analysis of the observer of overall network topology [9] is take into account.

Design Algorithm

1) *L is* Partitioned according to $\mathcal{L} = \begin{bmatrix} \mathcal{L}_1 \\ \mathcal{L}_2 \end{bmatrix} = \begin{bmatrix} g\gamma \\ \mathcal{L}_2 \end{bmatrix}$

2) Checking if condition (26) is met, if yes continue, otherwise a sliding mode functional observer doesn't exist.

3) Calculating *F* using (32) and *G* using (33).

4) Using (34) and any pole placement method obtain *Z* to make *η* Hurwitz.

5) Calculate *E* and *K* using (35)

6) Use (36) to calculate *λ*.

7) Calculate *μ* according to (37).

Design of FO based Controller:

Let ê be the estimate of e.

$$\dot{\hat{e}} = \alpha\hat{e} - \beta\Gamma_c^T\hat{e} + \Gamma_o(e_1 - \hat{e}_1) \qquad (40)$$

Where, $\Gamma_o \equiv [\gamma_1^o, \gamma_2^o, \dots, \gamma_n^o]^T \epsilon R^n$ is the observer gain vector.

Observer error is given as,

$$\tilde{e} = \alpha_o\tilde{e} + \beta(g(x)(u^* - u_{PID} - u_d - u_s) - d) \qquad (41)$$

As (γ, α) is observable, the observer gain vector, Γ_o can be stringently Hurwitz with a symmetric positive definite matrix, P and a positive definite matrix, Q_o.

If $\mathcal{L}(.)$ is taken to be the Laplace transform, the transform function can be written as $\mathcal{L}(\tilde{e}_1)$ by choosing $\mathcal{M}(s)$ such that $\mathcal{M}(s) = s^m + b_1 s^{m-1} + \dots + b_m$, $m < n$ and $\mathcal{M}^{-1}(s)$ is a proper stable transfer function and $\eta(s)\mathcal{M}(s)$ is a proper SPR transfer function. Hence $\mathcal{L}(\tilde{e}_1)$ can be written as:

$$\mathcal{L}(\tilde{e}_1) = \eta(s)\mathcal{M}(s)\mathcal{M}^{-1}(s)\mathcal{L}(g(x)(u^* - u_{PID}) - d) - \eta(s)\mathcal{M}(s)\mathcal{M}^{-1}(s)\mathcal{L}(g(x)u_d) - \eta(s)\mathcal{M}(s)\mathcal{M}^{-1}(s)\mathcal{L}(g(x)u_s) + \eta(s)\mathcal{M}(s)\mathcal{L}(u^* - u_{PID}) - d) - \mathcal{L}(u^* - u_{PID}) \qquad (42)$$

Denote the function φ such that

$$\mathcal{L}(\varphi) = \mathcal{M}(s)^{-1}\mathcal{L}(g(x)(u^* - u_{PID}) - d) - \mathcal{L}(u^* - u_{PID}),$$

Hence the dynamce equation can be written as

$$\tilde{e}_1 = \gamma_m^T\tilde{e} \qquad (43)$$

Where, $B_m = [0,0,\dots,0,0,\dots,b_1,b_2,\dots b_m]^T \epsilon \mathfrak{R}^n$,

$C_m = [1,0,\dots 0]^T \epsilon \mathfrak{R}^n$

For further analysis, there is necessity to assume the following assumptions

Assumption 1: The uncertain non-linear function f(x) for the states is bounded by an upper bound function $f^u(x)$, i.e. $f(x) \leq f^u(x)$. The uncertain non-linear function g(x) related with the input is bounded by $g_l \leq \| g(x) \| \leq g^u$ where both upper and lower boundaries g^u and g_l are positive constants.

Assumption 2: the function φ is bounded by $\| \varphi \| \leq \varepsilon$ where ε is a positive constant.

Defining and differentiating V with respect to t, we get

$$\dot{V} = \frac{1}{2}\Big((\tilde{e}^T\alpha_0^T P\tilde{e} + \tilde{e}^T P\alpha_0\tilde{e}) + (u^* - u_{PID} + \varphi - \tilde{u}_d - \tilde{u}_s)^T\beta_m^T P\tilde{e} + \tilde{e}^T P\beta_m(u^* - u_{PID} + \varphi - \tilde{u}_d - \tilde{u}_s)\Big) \quad (44)$$

But it is given that,

$$\alpha_0^T P + P\alpha_0 = -Q \qquad (45)$$

And $P\beta_m = \gamma_m$ $\qquad (46)$

Where, $Q = Q^T > 0$. Substituting (45), (46) and (43) in (44) we get,

$$V \leq -\frac{1}{2}|\tilde{e}^T Q\tilde{e}| + |e_1||u^* - u_{PID}| + \tilde{e}_1(\varphi - \bar{u}_d) - \tilde{e}_1\bar{u}_s \quad (47)$$

Based on the above assumptions, u_d can be designed such that $\tilde{e}_1(\varphi - \bar{u}_d) \leq 0$.

$$u_d = \begin{cases} \varepsilon + k, & \text{if } \tilde{e}\_1 \geq 0 \text{ and } \varphi > 0 \\ 0 & \text{if } \tilde{e}_1 \geq 0 \text{ and } \varphi < 0 \\ 0, & \text{if } \tilde{e}_1 \geq 0 \text{ and } \varphi > 0 \\ -(\varepsilon + k), & \text{if } \tilde{e}_1 \geq 0 \text{ and } \varphi < 0 \end{cases} \qquad (48)$$

Where, k is a positive constant. Substituting u_d in (47),

$$\dot{V} \leq -\frac{1}{2}|\tilde{e}^T Q\tilde{e}| + |\tilde{e}_1||u^* - u_{PID}| - \tilde{e}_1\tilde{u}_s$$

$$\leq -\frac{1}{2}\lambda_{min}(Q)|\tilde{e}_1|^2 + |\tilde{e}_1||u^* - u_{PID}| - \tilde{e}_1\tilde{u}_s \qquad (49)$$

$$\dot{V} \leq -1/2\,\lambda\_min\,(Q)\,|\tilde{e}\_1|{}^2 + |\tilde{e}\_1|(1/|g\_1|\,(|f^u\,(\acute{x})| + |y\_m^{((n))}| + |\Gamma\_e^T\hat{e}|) + |u\_PID|) - \tilde{e}\_1\,u\_s) \quad (50)$$

$$V_d(K_{PID}) \leq -\frac{1}{2}\lambda_{min}(Q)|\tilde{e}_1|^2 + |\tilde{e}_1|\Big(\frac{1}{|g_1|}\big(|f^u(\hat{x})| + |y_m^{(n)}| + |\Gamma_e^T\hat{e}|\big) + |u_{PID}|\Big) \qquad (51)$$

If K_{PID} estimated by MGA results in $V_d(K_{PID}) < 0$, $\dot{V} < 0$ is satisfied: given that u_s is not applied to the input in (10). Conversely, if $V_d(K_{PID}) > 0$, u_s should be applied leading to the condition $\dot{V} < 0$. For stabilizing the effect caused by u_s being either excluded or included in PID controller, define a gate function.

$$\theta(V_d) = \begin{cases} 0, & \text{if } V_d < 0; \\ \frac{V_d}{V_m}, & \text{if } 0 \leq V_d < V_m \\ 1, & \text{if } V_d \geq V_m \end{cases} \qquad (52)$$

Where, V_m is a positive constant. Now the supervisory control with the gate function becomes

$$u_s \leq \theta(V_d)\text{sgn}(\tilde{e}_1)\Big(\frac{1}{|g_1|}\big(|f^u(\hat{x})| + |y_m^{(n)}| + |\Gamma_e^T\hat{e}|\big) + |u_{PID}|\Big) \qquad (53)$$

D. Corollary IV

In recent years, elements like heuristics, reasoning gained importance due to their ease in more flexible control theories. Fuzzy logic (FL), optimization algorithms like Genetic Algorithm (GA) and Artificial Neural Network (ANN) may be applied for further refinement of this model to facilitate the development of advanced/intelligent controllers. Fuzzy logic (FL) is advantageous in terms of its logical designing and decision making but its drawback lies in the fact that the solution takes a complex form if more number of variables are involved. To estimate the control input specifically when the output y is measurable instead of system state x [15], the author proposed Fuzzy Functional Observer [14]. The T–S fuzzy model (1) is assumed to be as [9]:

$$\dot{x} = \sum_{i=1}^p w_i(y)(\alpha_i x + \beta_i \breve{u}) \qquad (54)$$

$$y = \gamma x \qquad (55)$$

Where, $y \in R^l$ is the output of the system, $\gamma \in R^{l \times n}$ is the output matrix. Now the Fuzzy controller becomes:

$$u = \sum_{j=1}^{p} w_i(y)u_j = \sum_{j=1}^{p} w_i(y)g_j x \qquad (56)$$

Where, $u_j = gG_j x \in R^m$ is the control input in j^{th} rule.

Assuming rank $(\gamma) = l$, rank $(g_j) = m$, i.e., γ and g_j are of full row rank, the following fuzzy functional observer is proposed to estimate the control input u:

$$\dot{z}_j = \sum_{i=1}^{p} w_i(y)\big(\eta_{ij}z_j + \lambda_{ij}y + \mu_{ij}\breve{u}\big) \; \forall j \qquad (57)$$

$$\breve{u}_j = z_j + E_j y \forall j \qquad (58)$$

$$\breve{u} = \sum_{j=1}^{p} w_j(y)\breve{u}_j \qquad (59)$$

Where, $z_j \in R^m, \breve{u}_j \in R^m$, $\breve{u} \in R^m$ are the observer state, estimated control input in j^{th} rule, estimated control input respectively; $\eta_{ij} \in R^{m\times m}$, $\lambda_{ij} \in R^{m\times l}$, $\mu_{ij} \in R^{m\times m}$, $E_j \in R^{m\times l}$ are the observer gains to be designed.

Estimation error

$$e_j = Q_j x - z_j \text{ , where } Q_j = g_j - E_j\gamma \qquad (60)$$

$$\dot{x} = \sum_{i=1}^{p}\sum_{l=1}^{p} h_{il}(\alpha_i x + \beta_i G_l x - \beta_i \sum_{k=1}^{p} w_k e_k) \qquad (61)$$

$$\dot{e}_j = \sum_{i=1}^{p}\sum_{l=1}^{p} h_{il}\Big((\phi_{ij} + \alpha_{ij}g_l)x + \eta_{ij}e_j - \alpha_{ij}\sum_{k=1}^{p} w_k e_k\Big)\forall j \quad (62)$$

Where $h_{il} = w_i w_l$, $\phi_{ij} = Q_j \alpha_i - \eta_{ij}Q_j - J_{ij}\gamma$, $\alpha_{ij} = Q_j \beta_i - \mu_{ij}$

To make the system asymptotically stable, g_j , η_{ij} , λ_{ij}, μ_{ij} and E_j is to be determine.

Now on imposing the constraints, we get

$$\dot{x}_a = \sum_{i=1}^{p}\sum_{l=1}^{p} h_{il}\Gamma_{il}x_a \qquad (63)$$

$$\text{Where,} \Gamma_{il} = \begin{bmatrix} \alpha_i + \beta_i g_l & -\beta_i w_1 & -\beta_i w_2 \\ 0 & \eta_{i1} & 0 \\ 0 & 0 & \eta_{i2} \end{bmatrix}$$

Theorem 3:

The error systems are to be asymptotically stable if there are matrices, $X^T \in R^{m\times m}$, $Y_{ij} \in R^{m\times 2l}$, i,j=1, 2, . . . , p such that it satisfies the following:

$X > 0$

$XF_{ij} - Y_{ij}M_{ij} + F_{ij}^T X - M_{ij}^T Y_{ij}^T < 0 \quad \forall i, j$

$\widetilde{E}_{i_1 j} = \widetilde{E}_{i_2 j} \forall i_1 < i_2, j$

Where,

$$F_{ij} = g_j\alpha_i g_j^+ - g_j\bar{\alpha}_{ij}\Sigma_{ij}^+ \begin{bmatrix} \gamma\alpha_i g_j^+ \\ \gamma g_j^+ \end{bmatrix} \qquad (64)$$

$$\mathcal{M}_{ij} = \big(I - \Sigma_{ij}\Sigma_{ij}^+\big)\begin{bmatrix} \gamma\alpha_i g_j^+ \\ \gamma g_j^+ \end{bmatrix} \qquad (65)$$

$$\bar{\alpha}_{ij} = \alpha_i\big(I - g_j^+ g_j\big) \qquad (66)$$

$$\Sigma_{ij} = \begin{bmatrix} \gamma\bar{\alpha}_{ij} \\ \bar{\gamma}_j \end{bmatrix} \qquad (67)$$

$$\bar{\gamma}_j = \gamma\big(I - g_j^+ g_j\big) \qquad (68)$$

Now the controller gain G_j can determineby

$$\begin{bmatrix} \widetilde{E}_{ij} & \widetilde{K}_{ij} \end{bmatrix} = Xg_j\bar{\alpha}_{ij}\Sigma_{ij}^+ + Y_{ij}\big(I - \Sigma_{ij}\Sigma_{ij}^+\big); \; Z_{ij} = X^{-1}Y_{ij} \qquad (69)$$

Using the equation of constraint, we can have

$$N_{ij} = g_j\alpha_i g_j^+ - E_j\gamma\alpha_i g_j^+ - \big(\lambda_{ij} - \eta_{ij}E_j\big)\gamma g_j^+ \forall i, j$$

$$K_{ij} = \lambda_{ij} - \eta_{ij}E_j \qquad (70)$$

The error system now becomes

$$\dot{e}_j = \sum_{i=1}^{p} w_i\big(F_{ij} - Z_{ij}\mathcal{M}_{ij}\big)e_j \; \forall j \qquad (71)$$

Applying the Lyapunov function, time derivative of $\dot{V}(e_j)$ is obtain as:

$$\dot{V}(e_j) = \sum_{i=1}^{p} w_i e_j^T \big(XF_{ij} - Y_{ij}\mathcal{M}_{ij} + F_{ij}^T X - \mathcal{M}_{ij}^T Y_{ij}^T\big)e_j \qquad (72)$$

Where $Y_{ij} = XZ_{ij}$.

In order to determine the observer gains satisfying the constraints, it is necessary to calculate the following terms from the above equations:

1) η_{ij}
2) E_j and the intermediate variable K_{ij}
3) λ_{ij}
4) μ_{ij}.

Hence observer gains can be obtained.

E. Corollary V

Fuzzy Functional Observer Vs Type-2 Fuzzy Functional Observer:

Type-2 fuzzy systems can model complex uncertainties better than type-1 and it is important to develop type-2 fuzzy systems [12] for enhanced performance. Literature shows that type-2 fuzzy systems gained much importance in recent times. In this paper, T2FFO based on Lyapunov theorem have been modeled to investigate closed-loop stability. Numerous techniques have been presented in this paper for tuning free parameters in the design of optimal type-2 fuzzy systems. Few techniques like instance recursive orthogonal least-squares algorithm, multi-objective genetic optimization [3], steepest descent method, etc. can be employed. Taking the computational cost into account, as the type-reduction part is more, simplified type-2 fuzzy systems have been proposed. Also the direct defuzzification for type-2 fuzzy systems has been proposed and compared with type-reduction. The design of adaptive fuzzy controllers have some challenges like approximation error effects, computational cost, external disturbances and state estimation errors unswervingly on the stability of closed-loop system. Hence a novel robust observer for a class of uncertain nonlinear systems using a new adaptive compensator based indirect adaptive type-2 fuzzy controller [12] is presented to eliminate the disturbances. As it is being employed 3-dimensional type-2 membership functions, the "course of dimensionality" problem can be solved and this controller can be applied to the higher order systems.

Fuzzy systems with normal, orthogonal, consistent and complete triangular membership function in the antecedent. The systems are dynamic and their consequents are in the form of state equation and output equation. The system rules are in the form

$$R^{i_1 \dots i_m} \text{ IF } u(k) \text{ is } \widetilde{U}^{i_1 \dots i_m} \text{ THEN}$$
$$\begin{cases} x^{i_1 \dots i_m}(k+1) = F^{i_1 \dots i_m}.x(k) + G^{i_1 \dots i_m}.u(k) \\ y(k) = C^{i_1 \dots i_m}.x(k) + (x(k), u(k)) \end{cases} \quad (73)$$

With $\widetilde{U}^{i_1 \dots i_m}$ orthogonal triangular type-2 membership functions such that, $\widetilde{U}^{i_1 \dots i_m} = [\widetilde{U}_1^{i_1} \dots \dots \widetilde{U}_m^{i_m}]^T$. The state vector is $x(k) = [x_1(k) \dots \dots x_n(k)]^T$, the fuzzy input vector is $u(k) = [u_1(k) \dots \dots u_m(k)]^T$, and the output vector is $y(k) = [y_1(k) \dots \dots y_p(k)]^T$, $m \le n$, $i_j = 1, \dots, N_j$, $j = 1, \dots, n$. The constant matrices in the consequents are $F^{i_1 \dots i_m} \in \mathbb{R}^{n \times n}$, $G^{i_1 \dots i_m} \in \mathbb{R}^{n \times m}$, $C^{i_1 \dots i_m} \in \mathbb{R}^{p \times n}$ and the uncertainty in output is given by the state vector function and control input

$$D(x(k), u(k)) = [D_1(x(k), u(k)), \dots \dots, D_p(x(k), u(k))]^T \quad (74)$$

Without loss of generality, $D_j, j = 1, \dots, p$, are fuzzy sets with membership functions is assume.

$$\mu_{D_j}(d_j) = \begin{cases} \text{nonzero,} & \underline{S_j}\left(x_j(k)\right) \le d_j \le \overline{S_j}\left(x_j(k)\right), \quad j = 1, \dots \dots, n \\ 0, & \text{elsewhere} \end{cases} \quad (75)$$

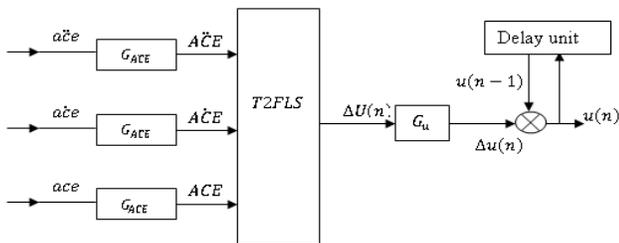
Type-2 Fuzzy PID controller with 3 input Type-2 Fuzzy Logic Controller (T2FLC) structure with coupled rules is shown in Fig. 3.


Fig. 3. Structure of the Interval Type-2 Fuzzy PID Controller.

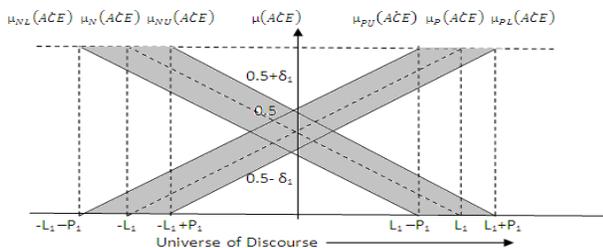
Here ACE, (ACE)˙ and (ACE)¨ are the three input variables which are fuzzified by two interval type-2 fuzzy as positive and negative as shown below in Fig. 2 and represented by and Membership functions for ACE are given as:


Fig. 4. Membership Functions of the Interval Type-2 Fuzzy Sets for the Scaled Input Variables.

TABLE I. CONTROL RULES FOR T2 FUZZY CONTROLLER

	ΔACE			
	N	P	N	N
ΔAĊE	Z	N	P	P
	P	N	N	N

In this paper it is assumed that membership functions of the antecedents of all rules are consistent, triangular, complete and orthogonal (Fig. 4).

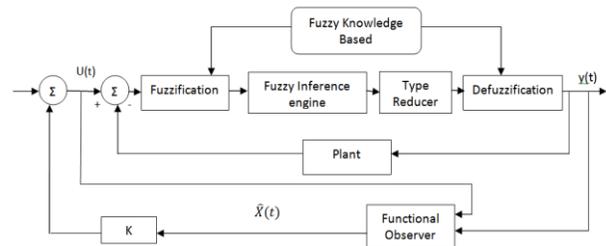
The block diagram of the plant and observer is as shown in Fig. 5 where $u(k)$, $y(k)$ and $\hat{x}(k)$ denotes the plant input, output and state estimate respectively. The system input is a fuzzy variable and the system output is crisp and fuzzy for systems.


Fig. 5. Block Diagram of Plant and Observer.

III. RESULTS AND DISCUSSIONS

Simulation of the proposed technique has been carried out using Matlab / Simulink with an increase in demand of the first area ΔPD_1 and second area ΔPD_2. Testing with wide perturbations in input have been also carried out over both the areas i.e., demand of the first area ΔPD_1 and the second area ΔPD_2. It is apparent from the Fig. 6 – Fig. 12 that the system response is faster in terms of control and frequency deviations using proposed methodology are also nullified as a result. Thus the theorized model provides better control and frequency damping when performance comparison is made with fuzzy functional observer, functional observer, functional observer without controller and Luenberger/state observer, under all operating conditions.

Table I lists down the robustness of performance under various operating conditions numerically. Here the settling time, overshoot and undershoot have been calculated for different operating points. The Simulation results are shown for 10% band of step load change for operating point of Appendix A. According to Table I, the proposed T2FQFO based controller is better compared to the FQFO based controller, Functional Observer based controller, Functional Observer and the Luenberger observer based controller.

A. Result Analysis:

The Peak over Shoot, Undershoot and settling time at different operating points with different observers have been tabulated in the Table II shown below. From the table we can say that, Peak over shoot had been improved by 25.37% (approximately) and the settling time have improved by 8% using Type-2 Quasi Decentralized Functional Observer over Fuzzy Decentralized Functional Observer. Peak over shoot

and the settling time had been improved by 46.77% (approximately) and 28.52% respectively by using Type-2 Quasi Decentralized Functional Observer over Fuzzy Decentralized Functional Observer. Peak over shoot and the settling time had been improved by 58.91% (approximately) and 47.7% respectively by using Type-2 Quasi Decentralized Functional Observer over Quasi Decentralized Functional Observer. Peak over shoot and the settling time had been improved by 53.28% (approximately) and 62.98% respectively by using Type-2 Quasi Decentralized Functional Observer over Full order Luenberger Observer. These parameters are taken at different operating points and these parameters are improving at different operating points. The parameters are more improved at operating point "5".

TABLE II. ΔF_1 (T) RESPONSE PERFORMANCE IN VARIOUS CONTROL STRATEGIES

Operating Point	Controller	Over Shoot (P.U)	Under Shoot (P.U)	Settling time(sec)
1	Type-2 Quasi Decentralized Functional Observer	0.05013	-0.06942	3 . 4 0 1

IV. CONCLUSIONS

In this present paper a novel Type-2 Fuzzy Functional Observer (T2FQFO) as a solution to the as a solution to the problem of load frequency control is proposed and applied to multi-area power system. Testing for disturbance attenuation and precise reference frequency tracking under different load (operating) conditions has been carried out over a typical two area interconnected reheat thermal power system with parameter uncertainties of a wide range. Competence of the proposed observer model is tested by performance comparison with FQFO based control, Functional Observer (With and without conventional controller) and Luenberger observer pertaining to settling time, maximum overshoots/undershoots under a variety of operating situations. Simulation results obtained show robustness pertaining to stability and consistency of performance of the suggested observer modeled herewith. The work may be extended by designing an optimization based design methodology using Genetic Algorithm-Fuzzy controllers or Honey Bee Mating optimization algorithm for tuning Type-2 Fuzzy PI/PID controllers. The LFC design can also be done using certain techniques like Active Disturbance rejection control for Type-2 Fuzzy system. The work may be extended with drawing extra degree of freedom framing as Type-3 Fuzzy. The relationship between the appropriate FOUs for a Type-2 FLC and the uncertainties in the plant parameters is still unsolved. If it is solved, the applications of Type-2 FLCs will be greatly promoted.

EEG-Based Silent Speech Interface and its Challenges: A Survey

Nilam Fitriah, Hasballah Zakaria, Tati Latifah Erawati Rajab*
School of Electrical Engineering and Informatics
Institut Teknologi Bandung
Bandung, Indonesia

Abstract—**People with speech disorders could have social and welfare difficulties. Therefore, the silent speech interface (SSI) is needed to help them communicate. This interface decodes the speech from a human's biosignal. The brain signals contain information from speech production to cover people with numerous speech disorders. Brain signals can be acquired non-invasively by electroencephalograph (EEG) and later transformed into the features for the input of speech pattern recognition. This review discusses the advancement of EEG-based SSI research and its current challenges. It mainly discussed the acquisition protocol, spectral-spatial-temporal characterization of EEG-based imagined speech, classification techniques with leave-one-subject or session-out cross-validation, and related real-world environmental issues. It aims to aid future imagined speech decoding research in exploring the proper methods to overcome the problems.**

Keywords—Imagined speech; silent speech interface; electroencephalograph (EEG); speech recognition

I. INTRODUCTION

Communication is essential in daily human life. People would hardly communicate in noisy circumstances, in quiet environments where no sounds are allowed, in secret conversation, or when they have speech disorders.

Speech disorders could negatively affect a person's social life and welfare. WHO reported that in 2011 there was 3,6% of the world's population experienced extreme difficulty living in their community due to speech disorders [1]. Moreover, they also were hindered from getting a job, as stated by ILO in 2017 for 4,1% of Indonesian citizens [2]. Additionally, research conducted in the United States found that one in 13 adults experience speech disorders annually [3]. In this circumstance, an interface to assist communication becomes more necessary than ever.

One of the interfaces intended to help people with speech impairments to communicate is the silent speech interface (SSI), which converts the biosignal into a speech. Human speech can be categorized into overt speech (with sound), silent articulation (articulator moves but no sound), and covert speech (no sound and movement) [4]. The latter is also called silent speech or imagined speech as our focus of discussion.

The causes of speech disorders can be the absence of

knowledge to speak experienced by deaf people, articulation problems, neurologic dysfunction (e.g., stroke), and paralysis (i.e., tetraplegia, muscular degenerative diseases, locked-in syndrome, or coma patients) [4]. Most causes come from brain disorders [5]. The applicable sensors mainly record brain activity, such as electroencephalograph (EEG) or electro-corticograph (ECoG). While ECoG has a higher Signal-to-Noise Ratio (SNR) than EEG, its invasive electrode placement can have a clinical risk. Moreover, ECoG only covers a specific area, while EEG has a broader coverage than ECoG. Hence, EEG is considered safer than ECoG.

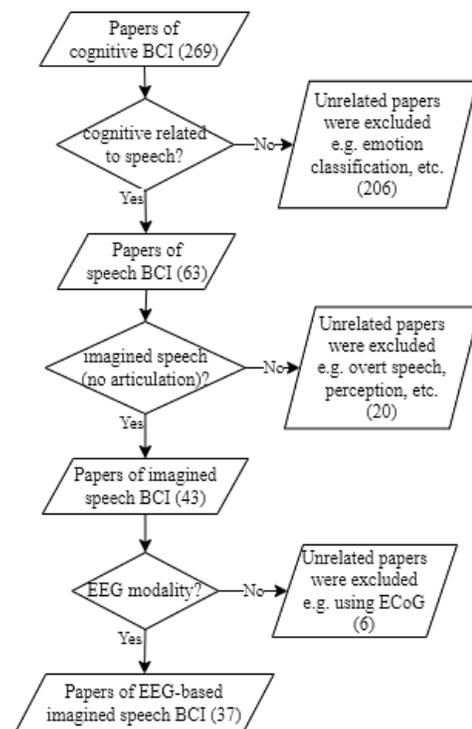
This review aims to present the development of EEG-based speech imagery studies and assist researchers in finding a solution to achieve better accuracy and solve the real problem. It focused on EEG application to decode imagined speech as a pipeline consisting of signal acquisition, signal preprocessing, feature extraction, classification techniques, and the real-world application challenges that were still unnoticed. The process flow of the review is in Fig. 1, and the summary of the discussed references is in Table I.


Fig. 1. Review Processes.

ANN = artificial neural network (NN), AR = autoregression, CNN = convolutional NN, CSP = common spatial pattern, DAE = Deep Autoencoder, DNN = deep NN, DT = decision tree, DTCWT = Double-Tree Complex Wavelet Transform (WT), DTF = direct transfer function, DWT = Discrete WT, ELM = extreme learning, FBCSP = filter bank CSP, FFT = Fast Fourier Transform (FT), HMM = hidden Markov model, kNN = k-nearest neighbour, LDA = linear discriminant analysis, LSTM = long short-term memory, MaxLCor = Maximum Linear Cross-correlation Coefficient, MFCC = Mel Frequency Cepstral Coefficients, NB = naïve Bayes, PDC = partial directed coherence, RF = random forest, RMS = root mean square, RNN = recurrent NN, RVM = relevance vector machine (VM), RWE = relative wavelet energy, SOM = self-organizing map (clustering), STFT = Short Time FT, SVM = support VM, TL = transfer learning.

This paper did not compare the accuracies quantitatively between studies due to the different techniques, datasets, or computation environments. Hence, the comparison would not be apple-to-apple. Discussing techniques and challenges is more worthwhile than the accuracy comparison to find the right solutions. The remainder of this review is organized as follows. Section II discusses the data acquisition process. Section III describes the signal processing used in the reviewed studies. Section IV deals with Spectral, Spatial and Temporal analysis. Section V explains the classification and feature extraction techniques that were categorized further into non-deep learning and deep learning, including the modified validation method. This paper describes the challenges of the application of EEG-based SSI in Section VI. Finally, Section VII draws some conclusions.

II. DATA ACQUISITION

The research subjects were given the cue of speech (vowels or words) shown from the monitor, heard from the earphones, or both (audiovisual cue). If the cue presentation was before the speech imagery, they had to memorize the cue, and this would separate the imagined speech task from the reading/listening task. While in the simultaneous cues, subjects performed the imagined speech task with the reading/listening task at the same time. Besides, the most active brain parts for listening and reading are different, i.e., the listening process involves the temporal lobes, and the reading process involves the occipital lobes. Thus, cue format and presentation regarding the time of imagined speech can affect different active brain areas.

The acquisition protocol of the Arizona State University dataset [26] used only visual cues, as illustrated in Fig. 2. The cue presentation was simultaneous with the imagined speech recording. The subject performed speech imagery at each "beep" sound and continued the same pattern until the visual cue disappeared (7 x T second). They used three short words ("in", "out", and "up") and two long words ("cooperate" and "independent"). For the longer words, T is more than one second. This protocol was applied to 15 subjects (11 males, one left-handed, age 22-32) and the EEG signals recording used 60-channel EEG at 1000 Hz and two-channel electrooculography (EOG) to capture ocular artefacts. They applied Common Spatial Pattern (CSP) to get the most active brain areas. The results showed that brain activity almost entirely focused on the left frontal, middle and parietal sides of the brain, as the location of the motor cortex and Broca and Wernicke's area. Even in the rest state, the brain remains highly active.

The other previous study that used visual cues presented the cues separately from the imagined speech state [23], as shown in Fig. 3, named the KARAONE dataset. The goal was to differentiate between the pronounced speech performed in the cue state and the imagined speech after the cue state. They used seven phonemes; "/iy/", "/uw/", "/piy/", "/tiy/", "/diy/", "/m/", "/n/", and four words from Kent's list [46], i.e. "pat", "pot", "knew", and "gnaw". This protocol was conducted on 12 subjects (8 males, all right-handed, age 27.4±5) and recorded with 62-channel EEG at 1024 Hz. They found that central brain areas in temporal locations had discriminative features.

A different protocol was employed by Coretto et al. [34], as illustrated in Fig. 4. They used both audio and visual cues before subjects performed imagined speech. No specific reason why they decided to use both cue types. They employed five vowels; "/a/", "/e/", "/i/", "/o/", "/u/", and five Spanish words; "arriba" ("up"), "abajo" ("down"), "izquierda" ("left"), "derecha" ("right"), "atrás" ("backward"), and "adelante" ("forward"). This protocol was conducted on 15 subjects (8 males, one left-handed, averaged age 25) and recorded with six-channel EEG at 1024 Hz. Moreover, there was still no further study with spatial analysis to observe which brain parts are more involved in both cues.

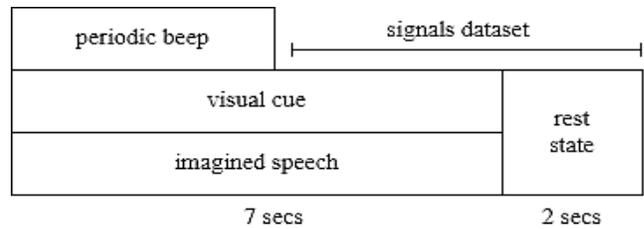
On the other side, a Brain-Computer Interface (BCI) open dataset [47] for the speech imagery study only employed audio cues. They used five common words; "hello", "help me", "stop", "thank you", and "yes" and conducted this protocol on 15 subjects using 64-channel EEG at 256 Hz. The cue presentations were given independently from the imagined speech state, as shown in Fig. 5.


Fig. 2. Arizona State University Dataset's Acquisition Protocol.
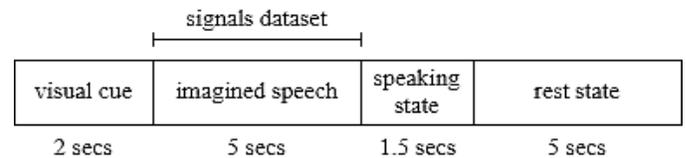

Fig. 3. KARAONE Dataset's Acquisition Protocol.
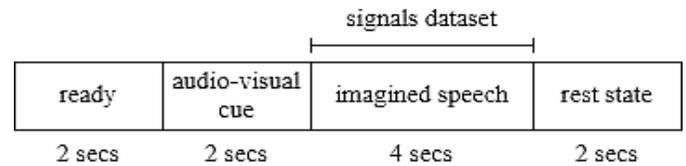

Fig. 4. Coretto Dataset's Acquisition Protocol.
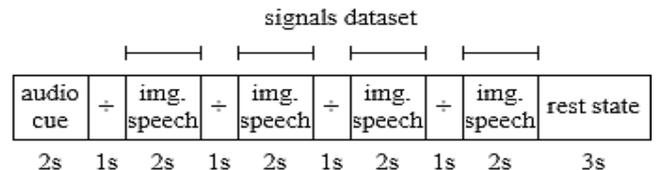

Fig. 5. BCI 2020 Track 3 Dataset's Acquisition Protocol.

Besides the cue format and its presentation timing, the duration of each state is an important issue. In the KARAONE dataset, the length of the imagined speech state was five seconds with no repetition. Meanwhile, Arizona State University's dataset [26] and Coretto's [34] applied repetition

during one imagined speech state using the beep sound. The Arizona State University dataset had seven repetitions in one imagined speech state. Coretto et al. applied repetition only for words, but not vowels, i.e., the subject must complete the task within four seconds of the vowel imagined speech state. BCI dataset [47] also used repetitions, but rather than using the beep sound, it applied a fixation cross shown from the monitor. The purpose of repetition block use was to maintain focus consistency [8]. Moreover, the longer the duration of the imagined speech, the easier for the subject to get sleepy because they performed the imagined speech state in silence.

While performing imagined speech, subjects were asked to refrain from moving articulation, swallowing, moving their eyes, or blinking. These restrictions aim to reduce the muscular and ocular artefacts as the significant artefacts in the EEG signal. These artefacts are generated by the signal from muscle activity surrounding the head, particularly the region near the articulator and eye activity. The range of muscular and ocular signals has intersected with the range of EEG signals [48].

The previous studies used different types of speech, such as vowels [26], phonemes [23], syllables [10], words [6]–[8], [16]–[18], [23], [26], [31], [32], sentences [7], and binary questions [20], [22]. The use of speech parts (vowels, phonemes, and syllables) mainly was to observe the brain when planning to produce the sound of words. Meanwhile, using words or binary questions to observe the brain when planning to respond/send a message earlier than sound production. Thus, the former is more syntactic, whereas the latter is more semantic. The distribution of the speech used in this related research is shown in Fig. 6.

Using syllables or vowels as the cue was for their discriminative sounds or articulator movements. To maintain the number of nasals, plosives, and vowels, Zhao and Rudzicz [23] used phonemes and short words with similar sounds. DaSalla et al. [12] only used the vowels "/a/" and "/u/" because of their articulation differences; "/a/" with an opened mouth regulated by digastricus muscles and "/u/" with rounded lips controlled by orbicularis oris muscles. On the other side, Nguyen et al. [26] utilized vowels to discover the relationships between vowel voices and model accuracies. They reported that different voices had an impact on the performances. Then, the use of the syllables "/ba/" and "/ku/" [9], [10] was mainly to classify the rhythm.

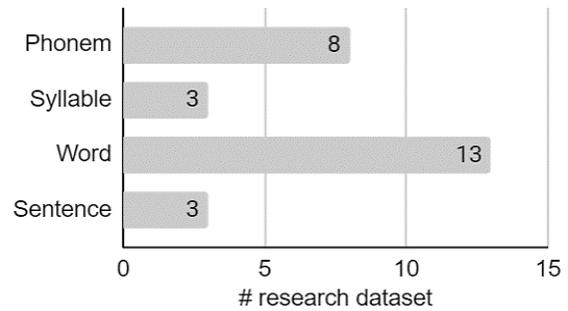
Most SSI studies employed the word cues for several reasons. It represents natural communication, such as asking, responding, or making a statement [18], [32] and semantically differentiates homonyms [6], [16], [17], e.g., "two" and "to". Additionally, employing words with different lengths could help the model to differentiate words (such as "in" and "cooperate") [26] or repetition [8] affected the model and use words as commands for moving the cursor on the monitor ("up"/"down") [31].


Fig. 6. Used Speech Cues.

Wester [7] also applied several words grouped based on their usability; digits (0-9), alpha corpus, phone-related words, MP3 player commands, Graduate Record Examination (GRE) Corpus, and Lecture Corpus. The alpha corpus consists of "alpha", "beta", "theta", "delta", and "echo". The phone-related words covered some phone communication words, such as "yes", "no", "accept", "deny", and "wait". The phrases for MP3 player commands were "start", "back", "next", "louder", and "turn down". GRE Corpus represent the rarely used words like "brittle" or "profundity". Lecture Corpus to examine the sequence of words as a sentence such as "good afternoon, ladies and gentlemen, welcome to the interact centre. My name is …, thank you for your attention, any questions."

The cognitive aspect is vital in the question cue because subjects must first comprehend the question. Then, different questions with the same answer could raise other cognition. For example, the answer to "Are you a scholar?" and "Are you a human?" are assumed to be "yes", but the cognition is different. Furthermore, the brain activity to respond with a "yes" is different from saying a "yes" with no intention. It will need the adaptability of the model to overcome the difference.

The multilanguage issue represents the other chance for SSI study. Many languages have been applied, e.g. English [6], [7], [16], [23], [26], Chinese [18], Hindi [22], Arabic [20], Korean [17], and Spanish [31]. Suppose the model can classify words from one language and their equivalent in another. In that case, this sparks the chance to build a complete set of EEG-based imagined speech datasets, regardless of the source languages of speech.

III. SIGNAL PREPROCESSING

Even though some restrictions, e.g. to move, were applied in the recording protocol, artefacts and noises are still unavoidable in EEG signals acquisition because of the low frequency and voltage, which are easily interfered with muscular/ocular artefacts and other noises. It still becomes a challenging issue for EEG studies in data cleaning without losing significant information/features for later analysis or pattern recognition. The noise removal must be performed before the downsampling step to prevent the downsampled

values from being falsely interpreted as noise. Previous studies used Independent Component Analysis (ICA) [49], [50] or artefact detectors based on the joint use of spatial-temporal features (ADJUST) [51].

If EEG acquisition used a high sampling rate, e.g., 1000Hz, most studies applied the downsampling process to lower the computational complexity. According to the Nyquist theorem and the brain signal frequency range of 0.5-100 Hz [48], 256 Hz covers more than twice the commonly observed maximum frequency. From the 37 reviewed studies, only seven studies used it ([11], [12], [17], [21], [26], [34], [42]). There will be thread off for the downsampling; the smaller the sample size, the lower the needed computation resources, but the more important features lost. Thus, using the original sample size could help observe the discriminative speech recognition features while also considering the available resources.

IV. SPECTRAL, SPATIAL, AND TEMPORAL ANALYSIS

Choosing only certain frequency bands, such as the alpha and beta bands, could decrease the number of features [20] because alpha and beta bands contain discriminative information. Statistic calculation (e.g. maximum value, average, standard deviation, kurtosis, and others) in beta, delta, and theta gave higher accuracy than the other bands in imagined vowel classification [13] with 81.25-98.75% accuracy for classifying the combined task, e.g., features from imagined speech state of "/a/" was combined with rest state, "/a/" and "/u/", and so on. However, the higher gamma band is not discriminative for speech imagery [11], [18], [31], [39] since muscular artefacts produce high gamma activity [52]. Additionally, from the reviewed papers, only a few studies (8 of 37) used it, as shown inFig. 7. Two of them reported that the gamma did not provide discriminative characteristics to decode speech [39] except for a speech with articulation [21].

When observing which frequency bands give the highest accuracy, there are some considerations about physiological activities associated with the specific bands. The high-frequency bands, e.g., beta or gamma, are dominated by muscular artefacts. Even though these waves correspond to the concentration or active attention [53], thus, they could have information for imagined speech recognition. Meanwhile, the low-frequency bands do not correlate with concentration [54]. The alpha waves correspond to relaxed awareness, the theta waves appear when the consciousness moves to drowsiness, and the delta waves are further away from concentration since they relate to deep sleep. Furthermore, low-frequency bands often get interferences with ocular artefacts or lead movements [55]. Since cognitive task, e.g. imagined speech, requires concentration, the role of low-frequency bands that yield higher accuracy than the high ones needs more examination.

EEG spatial analysis can give a better insight into which brain area has essential information for imagined speech recognition; the electrodes can be selected further. When a conversation happens, the most active regions are the auditory cortex, motor cortex, Broca's area, and Wernicke area [56]. Broca's area is in the inferior frontal gyrus, while Wernicke's area is in the superior temporal gyrus, with the arcuate fasciculus connecting both of them to build auditory-motor interaction [57], as illustrated inFig. 8. Some SSI research has

validated this brain region [7], [18], [22], [26]. Furthermore, in early speech production, the auditory potential existed in the superior temporal gyrus (STG) [58], located in the temporal area in both hemispheres.

Most of the reviewed studies reported high accuracy achievement by using the features extracted from frontal lobes (location of the Broca's area) [9], [10], [17], [26], [42] and temporal lobes (location of the Wernicke's area) [17], [21], [39], [42], followed by parietal lobes [9], [17], [26]. The others found that occipital lobes contributed to achieving the highest accuracy, which is obvious since they employed visual cues in their protocols [10], [39].

Suppose the EEG signals were treated as an event-related potential (ERP) during imagined speech production. The signals can be aligned to the onset of imagined speech production and then averaged to focus between the preceding and following onset time [59]. Previous studies have examined it and found that the potential in the left hemisphere arises one-two seconds before speech production [36] and appears a moment before cued speech is produced [60]. One study reported that speech-related ERP reached the peak at 350ms after the cue [12], and the highest significant level (from the paired t-test) existed between 400-600ms after the cue in the frontal area [17]. Moreover, from the five alphabets ("/a/", "/e/", "/i/", "/o/", and "/t/") classification result, data in 100-600ms after the cue gave the highest accuracy of 46.61% (chance level of 20%) [39].

V. CLASSIFICATION AND FEATURE EXTRACTION TECHNIQUES

A. Non-Deep Learning

Most features were the result of the transformation to the frequency domain, as shown inFig. 9, e.g., Fourier, Wavelet, or Hilbert-Huang Transform. Common Spatial Patterns (CSP) and Principal Component Analysis (PCA) are other extraction methods. Filter bank CSP (FBCSP) [61] was the state-of-the-art for feature selection [35] or classification [36], [37], [62].

Since EEG signals are also time-series data, some studies applied auto-regression (AR) [11], [18], [19] or Mel Frequency Cepstral Coefficient (MFCC) [24], [41]. MFCC was more discriminative than the AR coefficient for vowel recognition in DaSalla's dataset [12] by yielding an accuracy of 75% [14] and performed better than statistics and nonlinear features in the KARAONE dataset [23]. MFCC gained an accuracy of 19.69% (chance level of 9.09% for 11 classes), while the accuracy of statistics features was 15.91%, and the accuracy of nonlinear features was 14.67% [24]. Several studies also treated EEG signals as a sequence of words by applying the Bag of Features (BoF) [30], [33]. In text pattern recognition, BoF was often used to represent a word existence using the feature values calculated from its previous words.

The other feature types are connectivity features, which relate to the brain's neural pathways when subjects perform a specific task, such as imagined speech production. They are structural [63], functional [64], and effective connectivity [65]. Structural connectivity refers to the tracts of white matter that physically interconnect brain regions. Functional connectivity refers to the statistical dependence (i.e. correlation) of time-series data between a pair of brain regions influenced by structural connectivity. Meanwhile, effective connectivity refers to a causal model representing the interactions between connected neurons.

Few studies of imagined speech recognition have considered applying functional or effective connectivity features. Qureshi et al. [43] used functional connectivity features fed into an extreme learning machine (ELM) to classify imagined speech of five words. These features were covariance and maximum linear cross-correlation coefficient (MaxLCor), with the same calculation for phase-only time-series data. MaxLCor is one of the spatial connectivity features to measure functional connectivity and extract EEG characteristics by calculating the normalized product of two time-series signals and then measuring their similarities [66]. They reported that covariance features yielded the highest accuracy of 87.90% on binary classification. Pawar et al. [44] also used MaxLCor combined with DWT features to classify imagined speech words [47] and achieved an accuracy of 40.64±2.45% (chance level 20%). Furthermore, Chengaiyan et al. [45] identified vowels and consonants by applying brain connectivity features on each frequency band; coherence [67] as functional connectivity and partial directed coherence (PDC) [68], direct transfer function (DTF) [69], and transfer entropy [70] as effective connectivity. They fed the features into deep learning methods, a Recurrent Neural Network (RNN) and a Deep Belief Network (DBN), where RNN gave lower accuracy of 72% than DBN with an accuracy of 80%.

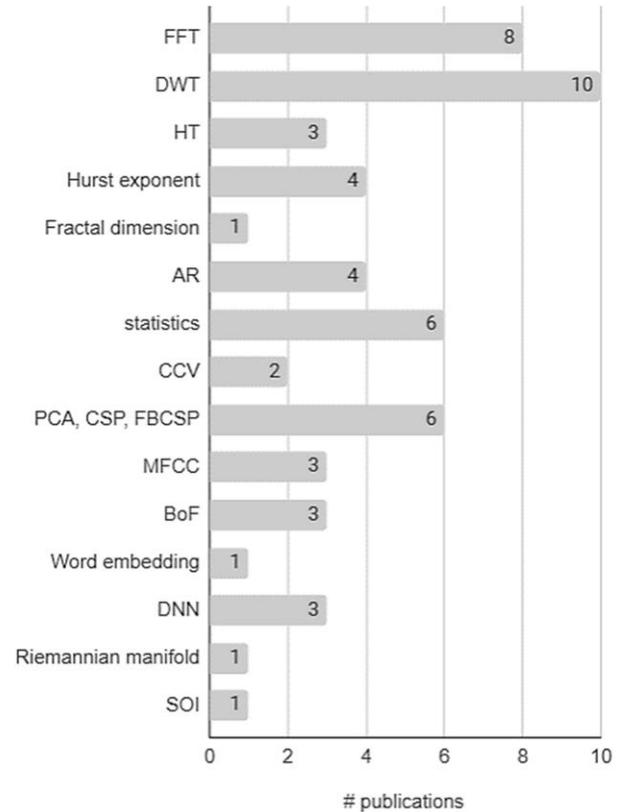
Many different features were classified with Support Vector Machine (SVM) ([17], [18], [20], [39]) or Linear Discriminant Analysis (LDA) ([7], [13], [20]) as shown in Fig. 1, since both are good at separating discriminative values. Meanwhile, the Decision Tree (DT) [16] and its ensemble variant called Random Forest (RF) [31], [32], [34] were used due to their capability to distinguish between the classes and process a large number of features. The RF feed with Wavelet features outperformed SVM in the same dataset [31], [32].


Fig. 9.   Features in EEG-Based SSI.
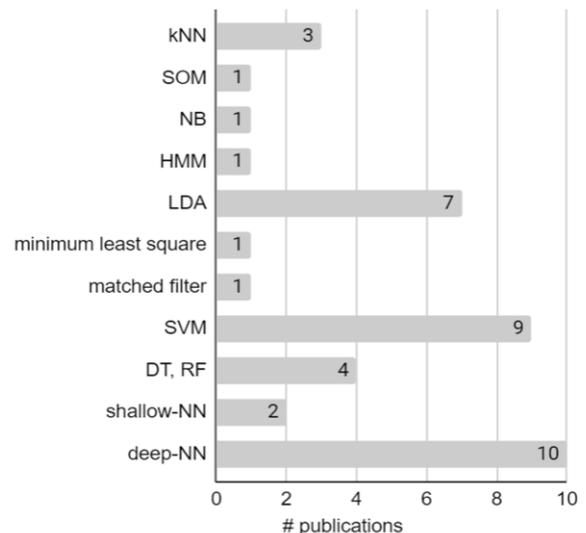

Fig. 10.   Classification Methods in EEG-Based SSI.

Another classification technique formerly used in imagined speech classification was k-Nearest Neighbor (kNN). When combined with MFCC features, it gained higher accuracy than SVM and the Hidden Markov Model (HMM) to identify the vowel of "/a/" and "/u/" from the DaSalla's dataset [12] with kNN's averaged accuracy of 86.89% compared with 75.83% and 70.56% respectively [14]. It also still outperformed SVM in classifying "/a/", "/e/", "/i/", "/o/", and "/u/" in the additional datasets of the same study [14]. Since kNN depends on the centroids for the k classes derived during training and the test dataset was classified based on the majority class of its neighbours, new samples may require k-NN retraining.

The shallow Artificial Neural Network (ANN), in the form of ELM, was also applied due to its architecture of layers and nodes that can achieve good generalization. With only using statistical values of the signals to classify vowels, ELM's accuracy was higher than SVM or LDA, in which ELM's accuracy was 87.07% compared with 51.07% for SVM and 81.98% for LDA [21]. Furthermore, with average power features to classify "yes" and "no", ANN also performed better than SVM and RF, with 92.18% compared with 83.07% and 79.95%, respectively [22].

The ANN's capacity for generalization motivated further research using deep learning (DL). While non-DL techniques depend on the features input, DL uses its layers to learn the data characteristics directly.

B. Deep Learning

Several attempts employed deep learning (DL) to extract features, e.g., Convolutional Neural Network (CNN) to extract spatial features and Recurrent Neural Network (RNN) for temporal characteristics [27]. These feature vectors were concatenated in the form of a channel covariance matrix as the input for Deep Autoencoder (DAE) classifier. Siamese Network increased the distance of different labelled samples and vice versa, which gave higher accuracy ($31.40 \pm 2.73\%$) [38] than the baselines [33], [34], [37], [62] by using the same Coretto's dataset [34].

Although DL has become the common feature and representation learning method, it is also well-known for being data-hungry. A small-size dataset might generate a final model that overfits. Therefore, only a few previous studies have used DL compared with non-DL, e.g., SVM or LDA. Furthermore, it is impossible to cover the whole language corpus, as subjects would feel uncomfortable for more than 30 minutes of EEG recording.

C. Model Evaluation

Although many reported models and their features claimed their highest accuracy, different datasets and experiment environments caused the accuracies to be incomparable since those factors can affect the chosen discriminative features and the model training process. Furthermore, the cognitive variance across subjects [71] needs more consideration since it caused the recognition model's accuracy to be more accurate when it was trained and tested in one specific subject's data but lower accuracy when it was tested to recognize the other's. This problem is called the inter-subject case. Hence, the model's accuracy in most brain signal studies was evaluated by each

person, i.e., the accuracy was calculated for each subject before the whole-averaged accuracy was reported. From the reviewed collected references, the validation was categorized into three versions.

The first type of validation is the usual cross-validation (CV) in machine learning treated subject-wise. The subjects' datasets were gathered into one massive dataset. Then it was split into training, validation, and testing parts with the configurable percentages for each part, e.g., training and validation took 60% and 20%, respectively, for k-fold cross-validation. The remaining 20% for each subject was kept unlabeled for the model to later predict in the testing session. In this type of CV, the training of the model uses the features from all subjects that could make the model achieve very high accuracy because it also learned a part of data whose the same variance as the testing dataset. Still, it became weak when facing the subjects' cognitive variance as an inter-subject problem exists. This case is essential to be solved but still unnoticed by many previous studies.

The second type is leave-one-subject-out cross-validation (LOSO-CV). It is similar to leave-one-out cross-validation (LOOCV) by using one subject's dataset as a validation dataset. This method aimed to measure the robustness of the trained model related to the inter-subject issue. It can prevent the model from peeking at the test dataset variance and overfitting. This method aimed to measure the robustness of the trained model related to the inter-subject issue. It also can be extended to be the leave-N-subject-out CV. Only a few gathered studies, listed in Table I, employed LOSO-CV.

The third type is leave-one-session-out cross-validation (LOSeO-CV) to face the intra-subject problem, i.e., the model's accuracy degrades when recognizing a new recording dataset of the same subjects whose datasets were used for training the model before. This validation type is the modification of LOSO-CV with a different perspective. Even though some studies were aware of the intra-subject problem [7], [15], they did not apply LOSeO-CV since their goal was to get higher accuracy than the baseline with the current data distribution only.

It is essential to note that the comparison of the higher accuracy achieved from the general CV with the lower accuracy gained from LOSO-CV was irrelevant. It is because LOSO-CV aimed to prepare the model to become adaptive to different subjects' data distribution due to the cognitive variance. Besides, the general CV only considers the current data distribution and potentially peeks distribution information from the same subject in the testing dataset. Thus, the model tends to be overfitting.

On the recognition of Arizona State University's dataset [26] in Table II, the researchers could train their model using the general CV on the deep learning model, and they achieved higher accuracy than the baseline (49%), with the highest accuracy being $96,79 \pm 4.19\%$ [28] for vowel recognition only. Another study also used deep learning with the general CV that boosted the accuracy of long-word recognition to 81.65%, higher than the baseline of 66.20%. Although, for short-long word discrimination, a deep learning implementation [29] still did not achieve higher accuracy than the baseline (77.60% of

80.10%). Meanwhile, another research [30] used LOSO-CV while recognizing only the long words. It reported a lower accuracy of 62,99 ± 4.78% than the reported accuracy in Table II. There was still no further observation for short-word classification with higher accuracy than the baseline. Moreover, deep learning also successfully yielded higher accuracy on the KARAONE dataset [23] for multi-class classification (i.e. not a binary classification), as shown in Table III, with an accuracy of 57.15% [25] higher than the baseline (33.3%) [24]. These KARAONE dataset classification studies used the general CV for validation.

Before the development of Coretto's dataset, Torres-Garcia et al. constructed an EEG-based imagined speech dataset [31] with five similar words to Coretto's dataset; Torres-Garcia used "seleccionar" ("select") rather than "adelante" ("forward") and "atrás" ("backward"). The non-deep-learning model achieved the highest accuracy (70.33%) for this dataset, with a general CV for its validation, as shown in Table IV. One deep learning implementation [30] with a transfer learning approach still gained slightly lower accuracy (65.65%) validated by LOSO-CV.

Similar to Arizona State University's dataset, the studies on Coretto's dataset also achieved the highest accuracy by implementing a deep learning model (30% for vowel classification [35] and 62.37% for word classification [36]). It was validated by a general CV, as shown in Table V. Further research validated the deep learning model with LOSO-CV to classify the vowels. It successfully yielded higher accuracy (32.75%) [37] than the baseline (30%) [35] in recognizing vowels. Thus, the model became quite robust since it could still accurately recognize the unseen subject's dataset.

The other reviewed studies used a general CV for validation; DaSalla's EEG-based imagined speech dataset consists of "a" and "u" speech [12], and Dzmura's consists of "ba" and "ku" [9]. There was still no deep learning exploration for DaSalla's dataset. Although, the researchers can achieve higher accuracy than the baseline for binary classification, as shown in Table VI, by using different feature extraction algorithms. Meanwhile, the baseline study of Dzmura's dataset still had the highest accuracy (74.25%) with the spectral feature and matched-filter classification.

From observing several EEG-based imagined speech datasets, some deep-learning studies yielded higher accuracy than the baseline studies validated by general CV, e.g. in Arizona State University's, Torres-Garcia's, Coretto's, and KARAONE datasets. Although, the deep learning models gained lower accuracy with LOSO-CV, e.g. in Arizona State University's dataset, Torres-Garcia's dataset, and Coretto's dataset. Some studies applied the transfer learning approach to build a more robust model with LOSO-CV validation; one successfully gained higher accuracy [37], but the other still got slightly lower accuracy [30]. Nevertheless, the transfer learning approach could have the capability to train the robust model. Additionally, the non-deep-learning models could gain higher accuracy when the informative features fed into them, as in DaSalla's and Dzmura's datasets. The accuracy of the trained models from the same datasets validated with the general CV in Table II-VII can become the benchmark for further studies.

TABLE II. ACCURACY WITH GENERAL CROSS-VALIDATION FOR ARIZONA STATE UNIVERSITY'S DATASET

VI. CURRENT CHALLENGES

A. Laboratory Environment

In the imagined speech decoding research, EEG signals were recorded in a conducive laboratory environment with a proper procedure to minimize the noise and artefacts. When the interface is intended to be practical, e.g., for patients at the hospital or as an in-house assistive tool, it will face a noisier environment and inevitable artefacts.

The previously discussed artefact removal approaches still require validation since they only focused on increasing the accuracy without reexamining the effectiveness of artefact removal. The acquisition should have relaxed restrictions, such

as allowing subjects to swallow or blink during imagined speech production, to validate the result of artefact removal.

B. Related Channels

Much spatial information could be observed using many electrodes, but it will be less convenient, less impractical, and have bigger feature dimensionality. This issue also happens in motor imagery BCI. Several approaches to overcome it are channel selection, spatial filter, and feature selection [32]. Feature selection aimed to select the most discriminative features, spatial filter to extract characteristics from channels employed, and channel selection to choose several channels with similar/better accuracy as the whole channels.

C. Time-Lock

In EEG signals, there is temporal information related to the onset time and spatial features related to the brain area. Spatial and temporal information of overt speech and imagined speech correlated [42]; the spatial pattern is not significantly different, but the temporal one is. It is due to the difficulty in determining the time-lock of the imagined speech, compared with the overt speech whose time-lock is easily detected from the voice. Besides, the time-lock can be different in the different sessions.

D. Intra-Subject and Inter-Subject Problem

One main problem of EEG-based imagined speech studies is the limited speech data. Should the recording cover the whole vocabulary in a language, the subjects will be exhausted, and it will need a very long time. Besides, there are different patterns produced even if a person imagines the same speech, i.e., the inter-subject issue [15], [41], or if he imagines the same speech at a different time, i.e., the intra-subject problem [42]. Thus, the model must be adaptive to recognize new data from new sessions/subjects without training from scratch.

One approach to solving the adaptation issue is transfer learning (TL). Traditional machine learning assumes that the distribution of the present learned data and the future data are the same. In contrast, TL assumes their domain is different, or the future labelling task may differ. Some studies reported that TL did not decrease the accuracy [36], [37]. However, as the accuracy was still poor (35-60%), it needs further observation.

E. Connectivity

The brain works as a neural pathway, and its existing connectivity can contain informative features for cognitive tasks, including speech imagery. Functional connectivity (correlation between brain areas) and effective connectivity (the causal model of brain areas' interaction) become potential characteristics to help identify imagined speech.

F. Subject Limitation

Current SSI studies were limited to healthy subjects. The subjects' brains must be in good condition to record signals. When the study includes brain-impaired participants, the problem-related brain area might affect the data acquired and its recognition accuracy, which needs more profound observation. Additionally, observing subjects with health issues, such as the locked-in syndrome (LIS) patient, was also challenging. The moment the LIS subject began producing the speech could not be identified precisely, although the subject has been instructed to confirm the speech production attempt

[72]. Other health disorders, e.g., Aphasia, Apraxia, Dysarthria, laryngectomy (i.e. removal of the larynx by operation procedure), and tracheostomy, also have specific conditions. For example, the brain activity in speech production for a new laryngectomy patient may differ from a one-year patient.

G. Online Learning

There would be a requirement for online learning where the model training is simultaneous with EEG recording. It could exploit the users' feedback to retrain the model and recognize the pattern more accurately. Moreover, the subjects could also be trained to modify their brain waves to adapt to BCI [73]. Currently, most studies used the offline training (, i.e., outside the recording session). Although few studies performed online learning [7], [20], the performance was low and inconsistent.

VII. CONCLUSIONS

This review discussed the pipeline of EEG-based SSI, which consists of signal acquisition, signal preprocessing, feature extraction, and classification, to see problems that often arise in each step. The acquisition process needs a proper design of subject inclusion, cue format, and speech types according to the purpose of the study, including the challenges that need answers to apply the decoding in the real world while maintaining the high accuracy achieved in a lab environment. These challenges deal with handling noises and artefacts, the trade-off between the number of channels and spatial features and onset time determination to gain discriminative temporal characteristics. Besides, variance shifts due to different recording sessions or users that demand an adaptive model and its validation need consideration. The inclusion of brain-impaired subjects and the potential of online learning could make the interface more applicable. To conclude, this review suggests that it is crucial to start by building the proper pipeline and taking problems in each step into consideration to overcome the challenges. High accuracy is insufficient to make the model applicable in the real world.

Deeply Learned Invariant Features for Component-based Facial Recognition

Adam Hassan[1], Serestina Viriri[2]

Sudan University of Science and Technology, College of Computer Science & Information Technology, Khartoum, Sudan[1]
University of KwaZulu-Natal, School of Mathematics, Statistics & Computer Science, Durban, South Africa[2]

Abstract—**Face recognition underage variation is a challenging problem. It is a difficult task because ageing is an intrinsic variation, not like pose and illumination, which can be controlled. We propose an approach to extract invariant features to improve facial recognition using facial components. Can facial recognition over age progression be improved by resizing independently each individual facial component? The individual facial components: eyes, mouth, and nose were extracted using the Viola-Jones algorithm. Then we utilize the eyes region rectangle with upper coordinates to detect the forehead and lower coordinates with the nose rectangle to detect the cheeks. The proposed work uses Convolutional Neural Network with an ideal input image size for each facial component according to many experiments. We sum up component scores by applying weighted fusion for a final decision. The experiments prove that the nose component provides the highest score contribution among other ones, and the cheeks are the lowest. The experiments were conducted on two different facial databases-MORPH, and FG-NET databases. The proposed work achieves a state-of-the-art accuracy that reaches 100% on the FG-NET dataset and the results obtained on the MORPH dataset outperform the accuracy results of the related works in the literature.**

Keywords—Invariant features; facial components; facial recognition; convolutional neural network; weighted fusion

I. INTRODUCTION

Facial recognition basically is the activity of verifying or identifying a person's identity through facial characteristics. It captures facial features, analyses, and performs patterns comparison to know and determine the identity, or to decide whether the person is the correct one. However, the difficulties that emerge in designing an invariant face recognition system comprise variations in illumination, pose, and age.

One of the most distinguished biometric attributes is facial features, which are the most compatible with Machine Readable Travel Documents [1]. The advantage of facial features is that they can be captured at a distance without permission.

Facial ageing is not a controllable process throughout human life and cannot be avoidable, not like other variations which are flexible to handle during the image acquisition period [2]. Besides, facial ageing images are not free from extrinsic variations such as illumination, pose, and expression which add up to the challenge of finding an appropriate method for age-invariant facial recognition [3]. These

approaches succeeded in finding distinctive features. The approaches are divided mainly into two groups. One of the groups is local appearance-based techniques which are used to extract local features. The whole face is portioned into small patches [4]. The other group is Key-points-based techniques specified to detect points of interest in the full-face image.

A local binary pattern (LBP) is a texture extractor used to extract distinctive features from objects [5]. It is applied in many applications like face recognition [6], texture segmentation, texture classification, and facial expression recognition. Khoi et al. [7] present a fast face recognition model using LBP and its variants based on the content approach. Karaaba et al. [8] proposed multi-HOG that combined different histograms of oriented gradients for robust face recognition.

Prince et al. in [9] used LDA based on probabilistic linear discriminant analysis (PLDA) to maximize discriminability, which is applicable for face recognition with pose variation. Perlibakas et al. [10] used Gabor features to eliminate redundancy to obtain the best descriptors for face recognition, then, used cosine similarity for evaluation.

This paper illustrates subject recognition through the facial components during ageing and relevant variations due to illumination, pose, expressions, resolutions and facial image occultation; thus, face recognition with both intrinsic and extrinsic variation is a challenging process. Moreover, extracting facial components such as the forehead and cheeks is additional work.

Several researchers performed double feature extractors for better representation as a single concatenated vector [2] or separated to vote the robust to increase the accuracy and performance simultaneously [11]. However, features extracted using hand-crafted descriptors do not have sufficient capacity to adequately represent the appearance of the face [12]. The effectiveness of deep learning has been proven to extract highly discriminative features for promising results in the field of facial ageing research [13]. A suitable alternative is to train a convolutional neural network model to identify and extract discriminative features.

The remainder of the paper is organized as follows. Section II gives a brief literature review and related work. Section III describes our methodology and techniques. Section IV discusses the experiments and analysis. Section V draws paper conclusions and future work.

II. Literature Review

Research in recognition based on facial components has seen less attention compared to the attention being given to developing approaches that use global face descriptors. For instance, holistic representations like densely sampled feature extractors such as Local Binary Patterns (LBP) [14] and Scale Invariant Feature Transforms (SIFT) descriptors [15] are heavily used in automated face recognition [16]. In contrast, research concerning facial component-based representations such as features that are extracted from specific facial components is rarely addressed in the literature.

Component-based facial recognition is an alternative to using the full-face approach. A distinguished comparison between the two approaches is found in [17]. The authors proposed a component-based and two others full-face methods. Experiments showed the superiority of the components approach on the whole face with the consideration of the robustness against pose variations.

Wang Lijia et al. [18] used Procrustes analysis, which is insensitive to rotation, translation and scale to align facial components. They used a random measurement matrix to extract components' features and applied the Gradient projection Algorithm for classification. The method proved that component-based approaches matched better than holistic approaches in terms of accuracy rate.

Early research [19] illustrated that the upper face components are more discriminant than other components. Authors in [18] solved the one training sample problem by using a component-based linear discriminant analysis (LDA) method through five facial parts to construct component bunches.

Multi-feature extraction is also used to extract textural and shape from facial components such as eyes, mouth, and nose. The algorithm is flexible enough to be satisfied with the non-occluded facial parts to perform the recognition [20].

Authors in [21] proposed decision-level fusion containing 34 region classifiers decision-level fusion is performed with majority voting.

Boussaad et al. [22] used a pre-trained CNN model on resized components to cope with Alex Net input layer size, then Discriminant Correlation Analysis for fusion and Support Vector Machine for classification.

Component-based methods have proven effective when used to handle age-invariant features. For instance, [22] applied a Discriminant Correlation Analysis (DCA) as a feature-level fusion on separated components features and performed facial classification using a Support Vector Machine (SVM) and obtained a 97.87% as recognition accuracy rate.

This work proposes a component-based approach for age-invariant face recognition using deeply learned features extracted from separated components (eyes, nose, mouth, forehead, and cheeks), then matching score level fusion is performed, and cosine similarity is used for classification.

III. Methodology and Techniques

We propose a methodology to study invariant features for component-based facial recognition during age progression. Fig. 1 illustrates a flow diagram of our proposed methodology that consists of sequential steps. Firstly, facial images are pre-processed through facial component detection, cropping, resizing, and data augmentation. Secondly, the convolutional neural Network CNN extracts discriminative features through the augmented facial components for training the CNN model for validation and gaining the accuracy of testing sets. Thirdly, we fuse the scores obtained by every component for a final overall decision.

A. Facial Datasets

In this work, we use the two freely available datasets MORPH (Album II) [23] and FGNET [24] to perform age-invariant facial recognition. The MORPH dataset consists of 55,134 facial images belonging to 13,617 classes with an age range that extends from 16 to 77 years. The FGNET dataset includes 1002 images of a total number of 82 classes, and its age range begins from 0 to 69 years. The two sets of data that include age variation are also exposed to lighting, expressions, and head position. The Morph dataset contains 9260 images that belong to 754 classes that differ in age. The images are categorized into classes; each contains images of different ages, not exceeding the 5 years age gap. Two separate datasets were created and randomly selected. 70% of images are considered to train the CNN network, while the rest 30% remain for testing.

B. Facial Components Detection

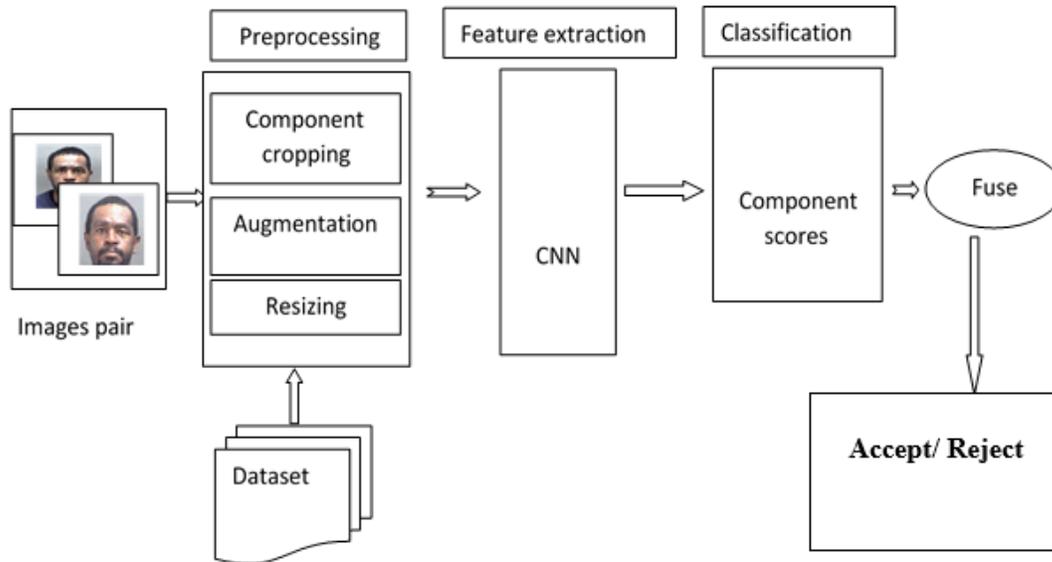
Face alignment is a technique for identifying the geometric structure of the human face. In previous work [11] the angle of inclination of the straight line between the outer corners of the two eyes is used to align the face horizontally. The facial component algorithm using Viola and Jones performs well with optimum execution complexity [25]. However, we use the locations of the eyes, nose, and mouth to detect additional components such as the forehead and cheeks. Fig. 2(a) shows whole face and component detection, and Fig. 2(b) the cropped components analyzed in this work. The three other components are supposed to be discriminating for the facial recognition model of our work.


Fig. 1. Proposed Methodology Framework.

Algorithm 1 describes the other three components depending on Viola and Jones. Many images from the databases used in this work have different pose variations. Therefore, this work employs face alignment as in [11] for correcting horizontal facial images before applying even Viola and Jones detection. We get the benefit from the detected facial components and rectangles boundaries. Specifically, the coordinates of the top left, the width, and the height of the pre-detected components, are crucial to detecting the other components.

Algorithm 1: Components Extraction (forehead, left cheek, and right cheek) – from the Face dataset

---

Input**:** Training set *M*, with *m* classes

nj = number of images in a given class

Bbox: boundary box

for *i* = 1 *to m* **do**

  for *j* = 1 *to nj* **do**

  Bbox (forehead) → Bbox (eyes pair)

  Bbox (left check) → Bbox (eyes pair) + Bbox (nose)

  Bbox (left check) → Bbox (eyes pair) + Bbox (nose)

  end for

 end for

C. Image Pre-processing

Initially, images in the datasets were pre-processed to enhance performance and gain improved accuracy results. Facial components, specifically the eyes, nose, mouth, forehead, and cheeks are detected and cropped using the Viola-Jones algorithm for the first three components and the proposed algorithm illustrated above for the last two facial components. Then the images are translated in different directions, rotated and resided to increase the number of images in the training datasets. Finally, the images are capable enough to be fed to the convolutional neural network with RGB color channels.

D. Feature Extraction and Classification

The convolutional neural network is fed with images after completely being preprocessed. In this work, we propose age-invariant facial recognition using its components and utilizing a Convolutional neural network. CNN is the preferable and most powerful employed algorithm in the area of deep learning [26]. The clear advantage of CNN is that relevant features are automatically identified away from human supervision [27].

1) Convolutional Neural Network: CNN architecture is still an open problem. That, the size of training data determines the best number of layers and filters to avoid over fitting [28].

In this work, extract parts or components of the face like eyes, nose, mouth, forehead, and cheeks instead of a full face to recognize a person. We conduct the work using three convolution layers, two max pooling, and one fully connected layer. The multi-layer neural networks built to recognize discriminant features from the origin pixels of images preceded by suitable pre-processing for the intended purpose. In CNN architectures, the main layers for successful models are convolution layers followed by down-sampling in pooling layers and concluding with fully connected layers.

2) Cosine similarity: Cosine similarity is a suitable choice for metric learning due to its special property of providing similarity between the intervals -1 to +1 [29]. Cosine similarity (CS) between two vectors x and y is defined as the following:

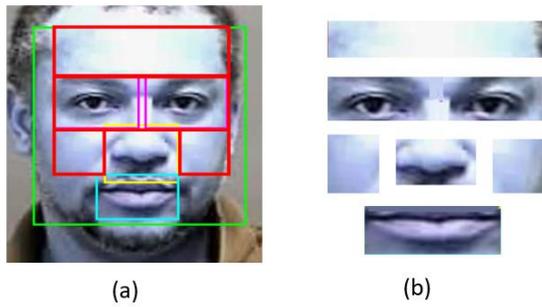
$$\text{CS}(x, y) = \frac{X^T Y}{||x|| \, ||y||} \tag{1}$$


Fig. 2. (a) Facial Components Detection and (b) Facial Components Cropping.

3) Euclidean distance: Euclidean distance [30] is used to evaluate the performance between two feature vectors of pairs. Euclidian distance for two image pairs featuring vectors x and y can be calculated as follows:

$$d(x, y) = \|x - y\| \tag{2}$$

Given two image feature sets, $x = \{x_1, x_2 \dots x_n\}$,

And $y = \{y_1, y_2 \dots y_n\}$, the function defines similarity distance between the two sets adopting the minimum distance as the following.

$$h_{min}(X, Y) = \min d_{(x \epsilon X, y \epsilon Y)}(x,y) \tag{3}$$

Cosine similarity and Euclidean distance measures receive the feature vectors extracted by CNN, then calculate the similarity and distance between two image pair feature vectors as mentioned above. When the result yields less than the threshold, the two faces are regarded as the same identity, otherwise, regarded as different identities.

IV. EXPERIMENTAL RESULTS AND ANALYSIS

MORPH (Album II) [23] is one of the data sets on which we conduct our experiments. The dataset is divided into two main experimental groups: 1) age gap 0-1 which is composed of 2590 images belonging to 494 classes. 2) Age gap 1-5, which includes 5335 images from 942 classes. Then we select randomly seventy per cent of the images in the dataset for the training process and the rest for testing. From both training and testing datasets, six different sub-datasets of eyes, nose, mouth, forehead, left cheek, and right cheek was created. Different CNN networks with the same number of sub-datasets are built. The matched image pairs with the highest similarity are considered as the same identity. To enhance the performance of the networks, we conducted various experiments for each component with different input sizes.

For experimental analysis, accuracy and error rates are calculated. As a result, the most appropriate learning rate and appropriate input image size for each component are adopted using the following equations:

$$Accuracy = \frac{\text{No. of testing samples classified correctly}}{\text{Total no.of testing samples}} \tag{4}$$

$$Error\ rate = \frac{\text{No. of misclassification}}{\text{Total no.of testing samples}} \tag{5}$$

To recognize the image ideally, the input image size plays a crucial role based on the extracted complex features. We notice that image expansion or compression degrades the accuracy. So, many input sizes are chosen to analyze and depending upon performance parameters, an applicable size for all components is recommended.

Learning rate is a hyper-parameter that specifies the adjustment in the weights of the network depending on the loss gradient descent function. It specifies how fast or slow the network will reach the optimal weights. If the learning rate is too high it will skip the optimal solution and if it is too low then, too much iteration will be spent to converge to reach the best values. Thus, utilizing a good learning rate is important.

The experiments involved various input sizes and learning rates and all results were recorded. Generally, six different networks are conducted, one for each component. Each network is trained using only one component and tested using the same component but from other classes not seen during the training phase. All relevant combinations of size and learning rate are carried out and the loss is computed.

For the eyes region component, throughout all various combinations, the size of 64x64 and 0.001 learning rate show the least error of 1.075 and accuracy of 98.925 at the training phase. Thus, it is recommended to use the mentioned size and learning rate for the eye region component for promising results. Fig. 3 illustrates the findings.

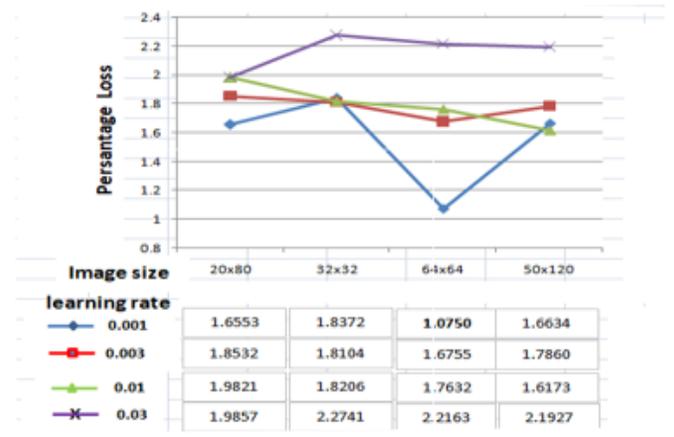
Image size learning rate	20x80	32x32	64x64	50x120
0.001	1.6553	1.8372	1.0750	1.6634
0.003	1.8532	1.8104	1.6755	1.7860
0.01	1.9821	1.8206	1.7632	1.6173
0.03	1.9857	2.2741	2.2163	2.1927


Fig. 3. Percentage Loss Graph for Various Input Image Sizes for Eyes Component.

For the nose component, as depicted in Fig. 4, the size of 32x32 and 0.003 learning rate show the least error of 0.5871% and accuracy of 99.0315. Therefore, the preferable size and learning rate for the component are 32x32 and 0.003 for the trained dataset. Similarly, Fig. 5 shows that the size of 60x80 and 0.001 learning rate for the mouth component produced the least error of 5.7469 and gives the accuracy of 93.9512%.

Two additional components are extracted- forehead and cheeks, using algorithm 1. Following a similar way to find the best image size and learning rate, the goal is to utilize various input sizes and combinations of learning rates. It is noticeable, as shown in Fig. 6 that the size of 40x64 and 0.001 learning rate are the best combination examined that gives the least error rate of 7.1472 and accuracy of 92.8528 for the forehead component.

The other two components are the left and right cheeks which give close results. Fig. 7 and Fig. 8 depicted the results and it's clear to deduce that the best size for both is 32x32 and the combined learning rate is 0.001. The best training accuracy is 90.5167% and 90.4512 for left and right cheek respectively.

A. Training Parameters

This work selects three convolutional layers, two max pooling, one fully connected layer, and a classification layer. All convolution layers are immediately followed by a ReLU (Rectified Linear Unit) activation function. The max-pooling size is 2×2 and stride 2 for down sampling. Images in datasets are RGB color and each component has its applicable resized input image and the best learning rate.

Images in each CNN of the mentioned components are divided into mini-batches. The mini-batch is set to size 100. Each batch is trained and convoluted with a fixed number of generated filters combined with a determined bias and a computed constant value.

In the phase forward pass for each hidden layer neuron, the activation is calculated as:

$$net_h = \sum_{i=1}^{n} w_i * x_i + b \qquad (6)$$

Where net_h represents the total net input for the determinant hidden layer, n is the number of filter weights, w_i is i_{th} filter weight, x is the input neuron, b: bias. Perform the same process for successive layers. Repeat this process for the output layer neurons, using the output from the prior hidden layer neurons as input for the subsequent hidden layer. To get

the total error (E_{total}), squared error function is applied for each output neuron as follows.

$$E \text{ total} = \frac{1}{2}\sum_{i=1}^{n} (T_i - Y_i)^2 \tag{7}$$

Where n is the number of output neurons, T_i is the target output for neuron *i* and, Y_i is the output of the neuron *i* calculated by a forward convolution pass.

The Backwards Pass: the purpose is to update all weights in the network to provide the calculated output to be closer the target output, by minimizing the error for each output neuron and update the whole network**.** Now the crucial role is to know how much the change in each weight will affect the overall error. In other words, the role is to calculate the partial derivative of the total error with respect to each weight. The step describes the partial derivative of E_{total} with respect to w_i . That means to obtain the gradient with respect to w_i. Properly, the following chain rule is applied:

$$\frac{\partial E \text{ total}}{\partial w_i} = \frac{\partial E \text{ total}}{\partial out_{01}} * \frac{\partial out_{01}}{\partial net_{01}} * \frac{\partial net_{01}}{\partial w_i} \tag{8}$$

The final step is minimizing error by subtracting the value multiplied by some learning rate from the current weight. The following is actually what happens to update each weight:

$$w_i^+ = w_{i-} \eta * \frac{\partial e}{\partial w_i} \tag{9}$$

When all weights are updated after a repeated process, we roll into a forward pass using the updated weights. Final activations fed to the fully connected layer transform the learned neurons into a new embedding vector. The distance between the impostor pair is enlarged while the distance between the genuine pair is minimized.

B. Data Augmentation

Data augmentation balances the samples size of training set when some classes have abundant samples while the rest lack appropriate number of samples [26] . Data augmentation is a technique that prevents the network from over fitting through discriminant features of the training images [31]. The input facial component images are translated horizontally and vertically in the range [-30, 30]. Then, we rotate the images and resize them to the ideal input size for each component.

C. Integrating Facial Components

In this work, to verify components of the same type, metric learning to discriminate the similarity is used. Many research works applied Mahalanobis distance learning [32] and Euclidean distance [33] but the drawback of the Mahalanobis distance is the equal adding up of the variance normalized squared distances of the features. However, the key issue of Euclidian norm that it gives the same importance to any direction. So, metric learning that capable with angular distribution to calculate similarity is needed. The best choice is cosine distance to deal with metric learning that provide reliable classification [34].

D. Combining Components Scores

All scores of the facial components are fused at the matching score level. The obtained output matching scores of each of these components are weighted and combined. Fusion at the matching score level is usually preferred, as it is relatively easy to access and combine the scores presented by the different modalities [36]. The adopted matching score in this work is the same as the algorithm specified in [35] but, with a cosine similarity output of each facial component.

E. Score Normalization

Each component is treated independently, and its own score is computed. Then, each component's scores are normalized given a set of n raw component matching scores $\{S_k\}$, k = 1, 2... n. For the sake of this work, n should be 1 up to 6 the number of analysed facial components. The corresponding normalized scores S_k' is given by Min-max normalization as the following:

$$s_k' = \frac{s_k - \min(\{s_k\})}{\max(\{s_k\}) - \min(\{s_k\})} \tag{10}$$

Where min and max are the minimum and maximum seen at learning phase, respectively, of the given set $\{S_k\}$ of component matching scores.

F. Score Weighting

Each component score is given a weighing to achieve an overall fusion. Let s_e' s_n' , s_m', s_f', and s_c' be the normalized scores for a specific class - *i* and t_1, t_2, t_3, t_4, and t_5 are the thresholds of the eyes, nose, mouth, forehead, and cheeks respectively. Then the initial weights of components scores are computed as follows:

$$w_e'^i = \frac{s_e'^i}{t_1 + s_e'^i} \tag{11}$$

$$w_n'^i = \frac{s_n'^i}{t_2 + s_n'^i} \tag{12}$$

$$w_m'^i = \frac{s_m'^i}{t_3 + s_m'^i} \tag{13}$$

$$w_f'^i = \frac{s_f'^i}{t_4 + s_f'^i} \tag{14}$$

$$w_c'^i = \frac{s_c'^i}{t_5 + s_c'^i} \tag{15}$$

The preliminary weights $w_e'^i$, $w_n'^i$, $w_m'^i$, $w_f'^i$, and $w_c'^i$ related to eyes, nose, mouth, forehead, and cheeks respectively. Next, the fusion weights for the ith class are computed respectively, as follows:

$$w_e^i = \frac{w_e'^i}{w_e'^i + w_n'^i + w_m'^i + w_f'^i + w_c'^i} \tag{16}$$

$$w_n^i = \frac{w_n'^i}{w_e'^i + w_n'^i + w_m'^i + w_f'^i + w_c'^i} \tag{17}$$

$$w_m^i = \frac{w_m'^i}{w_e'^i + w_n'^i + w_m'^i + w_f'^i + w_c'^i} \tag{18}$$

$$w_f^i = \frac{w_f'^i}{w_e'^i + w_n'^i + w_m'^i + w_f'^i + w_c'^i} \tag{19}$$

$$w_c^i = \frac{w_c'^i}{w_e'^i + w_n'^i + w_m'^i + w_f'^i + w_c'^i} \tag{20}$$

Then the fusion score is computed as follows:

$$S_{fuse} = w_e^i s_e' + w_n^i s_n' + w_m^i s_m' + w_f^i s_f' + w_c^i s_c' \qquad (21)$$

Cosine similarity between the two facial image pairs is the similarity score between the two faces. Lastly, this score is compared with a threshold to decide whether two faces belong to the same class or not. The threshold *is* selected from the training set so that False Acceptance Rate is equivalent to False Rejection Rate. The decision function defined in Equation (22) verifies the class.

$$Decision\ (S_{fuse}) = \begin{cases} Accept, if > threshold \\ Reiect. otherwise \end{cases} \qquad (22)$$

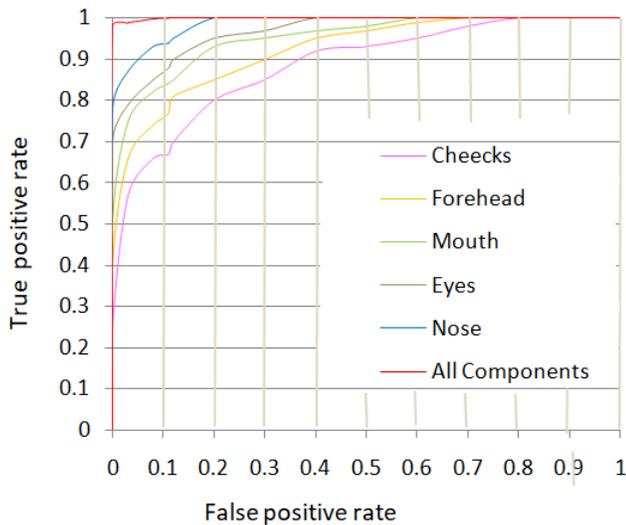
The ROC curve of the experiments on MORPH dataset is depicted in Fig. 9. The curve shows that the cheek component has the lowest accuracy while the nose has the highest contribution that reflects its stability during aging.


Fig. 9.   MORPH Results on 1-5 Year Age Gap Data Set.

The Tables I to IV display per component accuracy performance and detail how the proposed method improves the performance using two-facial component score fusion. Moreover, it is noticeable that the nose component has the highest accuracy, and the cheeks are the lowest. Performance is enhanced when scores of the two components are fused. Eyes and nose combination increases the accuracy for both data subsets. However, the accuracy decreased dramatically when forehead and cheek scores fused. But, when scores of three components or more are fused the accuracy is highly improved. We compared our work with the previous most related works. The comparison results are shown in Table V.

V. CONCLUSIONS AND FUTURE WORK

This paper addressed the challenge of facial recognition on aging subjects using Convolutional Neural Network. Facial components such as eyes, nose, mouse, forehead and cheeks are resized independently, each as ideal input image size. Each subset of the same type classified indecently using cosine similarity. Weighted fusion is utilized to sum up all facial components scores for a final decision. We tested our work using FG-NET and MORPH publicly available datasets. The proposed work achieved a state-of-the art accuracy of 100% on FG-NET dataset and the results obtained on MORPH dataset outperform accuracy results obtained in the literature. Our future work will focus on facial components that give high score contributions and updating the weights of the candidate components to improve overall performance.

Research on the Design of Online Teaching Platform of College Dance Course based on IGA Algorithm

Yunyun Xu

Hunan First Normal University

Cheng Nan Academy

Changsha, 410002, China

Abstract—As a comprehensive art form, dance plays an integral role in developing the overall quality of students. However, with the increasing progress of IT technology, the traditional classroom-based teaching mode of dance course can no longer adapt to the current educational environment. This research designs an e-teaching platform system for college dance lessons based on the IGA algorithm (Improved Genetic Algorithm, IGA). First, it establishes a mathematical model of artificial intelligence questions and then proposes the functional design of an online teaching platform for college dance course based on the IGA algorithm. The feasibility of the proposed online teaching platform system of college dance course based on the IGA algorithm is validated via a number of testes. When the iteration count is 500, the success rate of the IGA algorithm reaches 99%; when the iteration count is 100, the average fitness is 0.929; when the iteration count is 100 times, the moderate calculation value is 0.936. While for the traditional Genetic algorithm (GA), the results are 88.6%, 0.73, and 0.752, respectively. By comparing with the traditional teaching mode based on GA algorithm, the proposed method based on IGA algorithm is obviously superior in many aspects.

Keywords—Online teaching; improved genetic algorithm; college dance course; intelligent test set; simulated annealing

I. Introduction

With the progress of distance internet teaching, scholars in China and foreign countries have been thinking about the reform of traditional classroom-based teaching mode of art courses [1]. Therefore, the establishment of an online teaching platform system of dance course is particularly important for the future development of college dance course teaching [2]. In general, online teaching in colleges and universities in China is still in the early stage. Therefore, it is of great practical significance to propose an online teaching platform for art courses [3]. The genetic algorithm is a computational model that finds the optimal solution or approximate solution by simulating the evolution process. It has the advantages of being able to solve complex, multi-constrained problems and seek global parallel solutions [4]. Genetic algorithm has attracted the focus of many scholars because of its ability to cope with the questions in the platform, initialize the population, and perform genetic evolution to accurately group the questions [5]. However, genetic algorithms can easily fall into a state of premature maturity. In this study, the genetic algorithm is improved to obtain the IGA algorithm and the improved algorithm is used to design a mathematical model of the test problem, so as to enrich and improve the online dance teaching

system in universities. Meanwhile, the current research on online dance teaching in universities in China mainly focuses on the level of online dance teaching promotion, while the innovation of this study lies in detailing the strategies and methods to carry out, which are highly operable and close to the teachers of dance in universities, which will provide new ideas for the construction of online platforms for teaching art courses.

II. Related Work

Genetic Algorithm (GA) is a novel algorithm developed rapidly in recent years. Aiming at the low accuracy of traditional methods in evaluating the quality of university mathematics classes, Yang Yun proposed a genetic algorithm-based quality evaluation method for the reform of university mathematics teaching model. The results revealed that the goodness of fit of the modified genetic algorithm exceeded 90%, and the error was significantly reduced to 0.01-0.04 [6]. In order to improve the search speed and achieve the effect of short-term optimization, Y Zhang et al. summarized various intelligent algorithms used in the current research of related research groups, and proposed a computing method of group parallel evolution. The results showed that the algorithm can prevent the results from falling into the prematurity and has strong convergence in the group experiment [7]. Dong-Jie Li's team proposed a calculation method CGA that combines chaos algorithm and genetic algorithm, in order to overcome the defects that BP neural network is likely to drop into local minimum and converge slowly in the process of gesture action recognition. Simulation results showed that the proposed algorithm can improve real-timeliness and accuracy of gesture recognition. [8]. Hua Wang and Lingwei Wang proposed an improved classical genetic algorithm to address the instability of the traditional computer network system caused by many factors such as the huge system. The simulation experiment results indicated that the algorithm can improve the fluency of the algorithm, thereby improving the availability of the network and reducing the occurrence of error in the network [9]. Aiming at current problem of college English course arrangement in China, J Xu proposed an improved genetic algorithm. Experimental results indicated that the proposed algorithm improved the convergence speed and individual diversity, and prevented the results from easily falling into local optimum. [10].

Online teaching has become more and more important, and there are many ways to improve the existing problems of

online teaching. Wang designed a control system for a web-based distance learning platform. According to the experimental results, the average computing time of resource scheduling consumed by the system is 32.34 ms, which is 12.6% and 23.7% faster than the other two traditional methods, respectively [11]. For the purpose of improving the prediction of professional education evaluation results, Gao et al. proposed a simulated annealing algorithm on the basis of simulated annealing fish swarm algorithm. According to the results, the forecasting system of professional education lesson assessment performance constructed based on simulated annealing algorithm can effectively predict the examination results [12]. To improve the detection of word sequences within the English classroom, Deng Bowen designed an analytical model on the basis of group encoding and modified genetic algorithm. It was demonstrated that the model well achieved subsequent sub-learning target tasks, indicating strong reliability [13]. In order to play the role of virtual reality technology in college dance course teaching, Shi discussed the application of VR technology in dance course education [14]. The MC Tsai's team proposed a computer curriculum design method based on the actual teaching methods of AL and ML, and the results showed that this metheology usefully improved learning outcomes and learning participation of online computer courses [15].

The above research fully shows that genetic algorithm has been widely used in many fields, and there are also many researches on online teaching platforms. However, there are still a variety of problems that need to be solved when combining genetic algorithm with online teaching platform system for university dance course. Therefore, the research will improve GA algorithm to obtain the IGA algorithm, and embed the algorithm into the universities e-dancing teaching platform system.

III. DESIGN METHOD OF ONLINE TEACHING PLATFORM OF COLLEGE DANCE COURSE BASED ON IGA ALGORITHM

A. Research on Artificial Intelligence Test Questions and Establishment of Mathematical Models of Test Questions

The problem research of artificial intelligence group volume refers to the problem of seeking the best answer or near-optimal answer under the restriction of multiple constraints [16]. Combined with previous studies on the reform of online courses in universities, this research assumes that the target test paper must meet the following attributes: Question type (QT), Number of questions (NQ), Difficulty of exam paper (Difficulty of exam paper), DP), knowledge point (KP) and discrimination (Distinction of test papers, DI). Therefore, the mathematical model of the quiz problem involved in this paper can be defined as M.

$$M = \{QT, NQ, DP, KP, DI, EP\} \tag{1}$$

From the above equation, it can be seen that the question of the examination paper is a six-tuple question, and the mathematical model matrix of the test paper is established according to this question as follows.

$$m = \begin{bmatrix} a_{1,1} & \cdots & a_{1,5} \\ \vdots & \ddots & \vdots \\ a_{t,1} & \cdots & a_{t,5} \end{bmatrix} \tag{2}$$

Where t represents the count of questions in the examination paper, $a_{t,1}$, to $a_{t,5}$ represent the t attributes of the first question, respectively.

On the basis of summarizing actual teaching experiences of college dance courses and combined with the mathematical model of the test problem, the constraints required for the test set are set as follows.

Constraints QT, which stipulates that the question types of the test questions must be composed of fixed test question types.

Constraint NQ, which specifies an overall number of questions on the test paper.

Constraints DP, set according to the subject requirements of the candidates, specifies the difficulty level of the examination paper. The difficulty level can be calculated according to the ratio of the difficulty of all test questions to the total score. The formula is as follows.

$$DP = \Sigma_{i=1}^{r} P_i \times C_i / \Sigma_{i=1}^{r} P_i \tag{3}$$

Where r is the total number of item IDs in the test paper, C_i is the difficulty coefficient of the i-th item ID, and P_i represents the actual score of the i-th item ID .

Constraints KP stipulates the knowledge points and scope of the examination paper for the corresponding course, in order to help the teachers to have an accurate understanding of the students' mastery of the knowledge points. In this study, the knowledge point coverage is calculated based on the percentage of knowledge point scores. Assuming that the total number of knowledge points examined in the test paper is d, the formula for calculating the coverage rate of knowledge points is as follows KP_i.

$$KP_i = KS_i / \Sigma_{i=1}^{r} KS_i \tag{4}$$

$$\sum_{i=1}^{d} KP_i = 1 \tag{5}$$

Where KP_i represents the percentage of the score of the i th knowledge point in the mark of the examination paper, and KS_i represents the mark of the i th knowledge point.

Constraints DI, based on which the teacher can master the specific learning status of students. The formula of the discrimination degree DI is calculated as follows.

$$DI = \Sigma_{i=1}^{r} Q_i \times P_i / \Sigma_{i=1}^{r} Q_i \tag{6}$$

Where Q_i represents the discrimination coefficient of the first i question, P_i represents the actual score of the first question, and DI is the overall discrimination.

The choice of the fitness function (FF) directly affects the convergence speed of the IGA algorithm and even determines whether it can find the optimal solution. In this study, the IGA algorithm has satisfied the constraints of the question type QT and the number of test questions NQ at the beginning of the initial population design. Therefore, the remaining constraints affecting FF include the difficulty of the DP test paper, the knowledge points of KP and the discrimination of the DI test paper.

The weight of the above four influences is $W_i\left(i \leq 4\right)$. The difference between the anticipated and realized value of the constraints corresponding to different test papers is expressed as $dv_i\left(i \leq 4\right)$: In conclusion, the f equation for the objective function of present study is as follows.

$$f = \sum_{i=1}^{4} dv_i \times W_i \tag{7}$$

$$\sum_{i=1}^{4} dv_i = 1 \tag{8}$$

It can be concluded that the tinier the value of f, a closer the outcome of individual evolution is to the expectation. Hence, in order to obtain the individual best solution in a group volume, the required objective function f value must be as small as possible. Meanwhile, assuming that the fitness scores reflect the evolution of the individual positively and ensure that the time complexity of calculating the fitness function is small, the calculation formula f of the relationship between the objective function and FF is proposed as follows.

$$g = 1/1 + f \tag{9}$$

Where g represents the FF of the grouping problem.

B. Design Scheme based on IGA Algorithm

The core component of the online teaching platform of college dance course is artificial intelligence. Through previous researches, it is found that the traditional genetic algorithm (GA) has excellent performance in solving multi-constraint combinatorial optimization problems [17-18]. Therefore, the GA algorithm is adopted to address the artificial intelligence quiz problem in this paper. When the GA algorithm realizes the process of intelligent paper grouping, it is often prone to fall into precociousness and has weak local search ability. Therefore, this study improves the GA algorithm to obtain IGA algorithm, and carries out the mat lab simulation experiment to demonstrate the feasibility of the IGA algorithm. The results indicate that the IGA algorithm proposed in this study performs outperforms in terms of test composition.

Chromosome coding is designed by means of piecewise real number coding. Taking the pre-class thinking test paper of the course "Latin Dance in College" as an example, there are five MCQs, three fill-in-the-blank questions, and two short-answer questions in this test paper. The chromosome code of the test paper is shown in Table I.

TABLE I. THE CHROMOSOME CODES OF EXAM PAPERS FOR THE COURSE OF "COLLEGE LATIN DANCE"

Type of question	Topic ID no.
MCQs	3; 16; 72; 26; 42
Fill -in-the-blank questions	86; 28; 34
Short answer questions	2; 48

In the above table, the question type is the chromosome of the test paper, and the question ID number corresponding to each question type is the chromosome code of the test paper.

After the chromosome is encoded, the population will be initialized. To avoid individuals with high level of similarity between topics and the poor quality of the papers, this study will delete the initialized population and the genetic evolution of the offspring, until only one individual remains. Before initialization, it is necessary to calculate individual similarity S_{PQ}, and preset the threshold T of individual similarity. According to previous research, the T value of this study is set to 35%. If the calculation value S_{PQ} is S_{PQ} greater than the set T value, it needs to delete the individual; if the S_{PQ} value is less than the set T value, keep the individual. In this way, it can be ensured that the value between the next generation populations S_{PQ} is less than the set T value, and this method can prevent the algorithm from falling into local convergence in the early stage. In the calculation of the value S_{PQ}, the method of information entropy calculation is adopted, which is expressed as below.

$$H\left(k\right) = -\frac{\sum_{i=1}^{l}\sum_{j=1}^{n} p_{ij} \log p_{ij}}{l} \tag{10}$$

Where k represents the number of individuals; l represents the number of individual genes; n represents the number of alleles available for selection $\{g_1, g_2, \cdots, g_n\}$; p_{ij} represents the j-th allele in each individual P. Therefore, the similarity between S_{PQ} individuals is Q, which can be expressed as follows.

$$S_{PQ} = 1/1 + H\left(2\right) \tag{11}$$

Where $H(2)$ represents the information entropy between P & Q individuals.

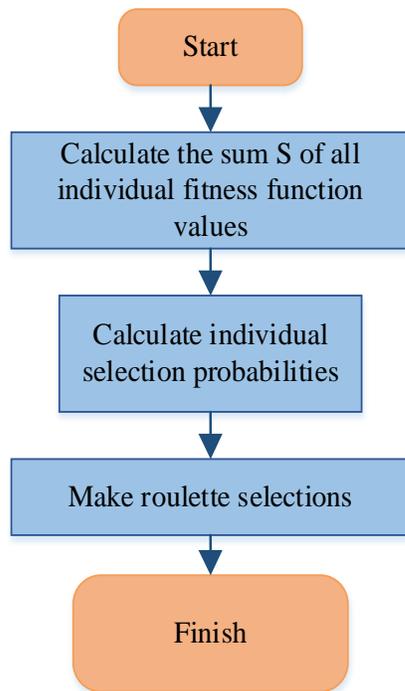
After the design of the initialized population is completed, the selection operator needs to be designed, and the direction of the population genetics mainly depends on the selection operator algorithm. At present, the most commonly used method of selection operator algorithm is the roulette selection method. The approach can determine if the individual is transmittable for the following generation based on the individual fitness value applied in the odds ratio. The benefit of roulette selection method is that the individual with better fitness has a high percentage of being selected for evolution, and those with poor individual fitness have a small percentage of being selected for evolution. The process is illustrated in the chart below.


Fig. 1. Roulette Selection Flow Chart.

The calculation formula of the sum S of the individual fitness function values in Fig. 1 is as follows.

$$F = \sum_{i=1}^{n} f_i \qquad (12)$$

Here, f_i stands for the fitness function value of the i th individual.

The formula for calculating the probability of individual selection is as follows.

$$P_{si} = f_i / F \qquad (13)$$

Although the roulette selection method can make excellent individuals obtain high genetic probability, but there is also the possibility that excellent individuals are not inherited. At present, the selection operator algorithms that are widely used include the optimal individual preservation method and the sorting selection method. This research will combine the advantages of the above methods, and choose the offspring based on the IGA algorithm and combining the roulette selection method and the ranked selection method. The specific process is to use the ranked selection method to set the top 15% of individuals for inheritance, and then use the roulette wheel to select the remaining individuals.

Traditional GA algorithm is prone to fall into precociousness and has weak local search ability [19-20]. To address these drawbacks of the traditional GA algorithm, acceptance probability will be added to the IGA algorithm to perform simulated annealing of the crossover variant operation individuals in the study. The searching capaability of the GA algorithm is improved. The detailed formula is as follows.

$$p = 1, f(old) < f(new) \qquad (14)$$

$$p = \exp\left[-f(old) - f(new)/T_t\right], f(old) \geq f(new) \qquad (15)$$

Where $f(old)$ is the old individual, $f(new)$ is the new individual, and T_t is the temperature at time t. If the new test paper from the group shows that the individual is better, then this individual will be selected for iteration; if the new test paper produced by the group shows the individual is poor, a certain probability P will be selected for subsequent iterations.

The temperature T decreased with time t. The initial temperature is set as T_0, and the specific calculation formula of the temperature drop is as follows.

$$T_{t+1} = \beta T_t \qquad (16)$$

Where β is a constant, which will be set to 0.95 in this study.

Since the IGA algorithm is an evolutionary algorithm, this study sets two conditions for the algorithm. If the result satisfies either one of the conditions, it can be judged to be terminated, and then the result is output, that is, the algorithm is completed. The detailed process is illustrated in Fig. 2.

C. Functional Design of Online Teaching Platform of College Dance Course Based on IGA Algorithm

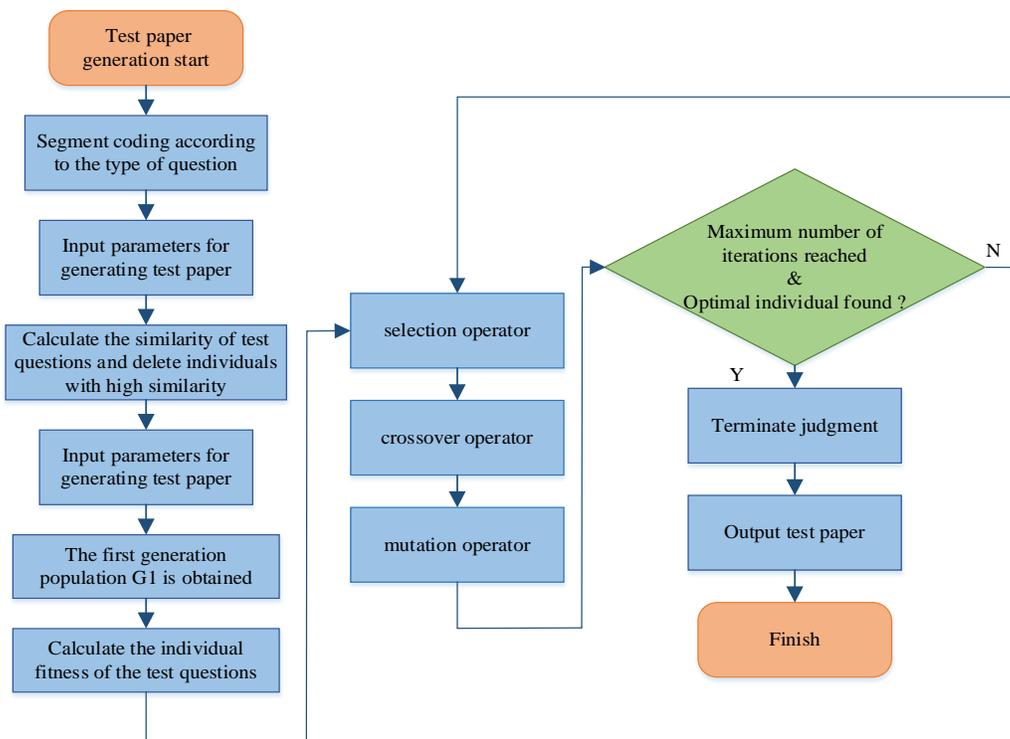
To solve the problems existing in the dance course online teaching platform in colleges and universities, intensive research was conducted, and the results showed that the students' uneven foundation in the subject directly affects their enthusiasm for learning the course. Since this research marks and categorizes the online teaching materials, the students are able to choose course materials at different difficulty levels, and implement hierarchical and classified learning. Based on the requirements of the online teaching platform of college dance course, a functional framework of college dance course online teaching platform based on IGA algorithm is designed, as shown in Fig. 3.


Fig. 2.   Group Volume Flow Chart based on Improved Genetic Algorithm.
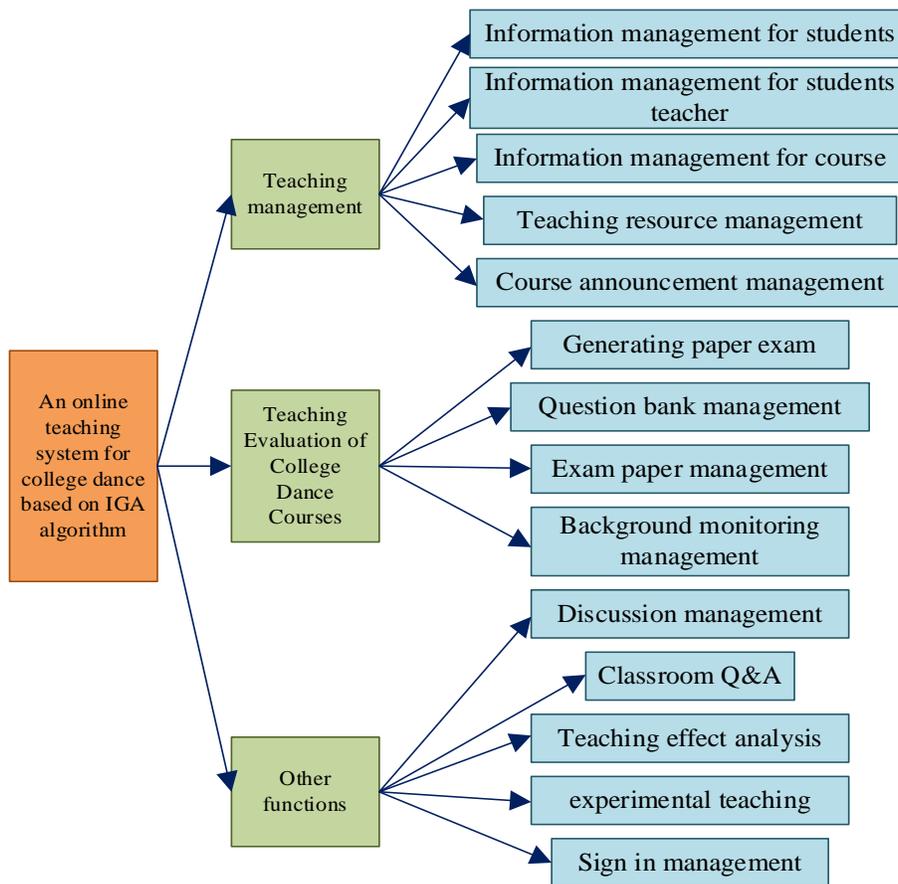

Fig. 3.   Functional Framework of College Dance Course Online Teaching System.

A block diagram of the design of the online dance teaching platform can be seen in Fig. 3 and summarizes the specific needs of the system into three parts.

In the first part, the functional requirements of the management module of the online teaching system include four blocks, namely classroom instructor management, dance teaching resource management, elective student management and background administrator. The specific content is to label and classify the teaching videos and teaching courseware of dance course. Among them, the label attributes are divided by grading settings. For example, teachers can set the first-level labels of the course by themselves, such as course theme, difficulty level of knowledge points, etc. Then, it is subdivided into second-level labels under the first-level label. For instance, the difficulty level of knowledge points is divided into three second-level labels: easy, medium, and difficult. Through the label classification of different teaching resources, the classification results of each label are obtained, so that students who choose this course can accurately select teaching resources from the classified teaching resources according to their own needs.

In the second part, the functional requirements of the evaluation module of the online teaching system of dance course in universities refer to using the IGA algorithm to realize the system artificial intelligence group test and provide the background monitoring. First, the IGA algorithm can effectively solve the optimization problem of artificial intelligence, so as to help teachers conduct targeted pre-class thinking tests for students, unit quizzes in the course, and organize online exams. Second, teachers can monitor students' learning, exams, and sign-in situations through the background.

In the third part, the functional requirements include answering questions in college dance classes, sign-in management, etc. Teachers are able to combine major functions of the dance course online teaching system with the functions of the third part so as to realize the role of supporting teaching.

The IGA algorithm proposed in this study has the following features, its incorporation of acceptance probabilities for simulated annealing of individuals after cross-variance operations, which can effectively reduce the problem of results falling into a local optimum at an early stage, is a major feature of this study to optimise the search capability of traditional GA algorithms.

IGA algorithm-based online teaching platform of college dance course runs on a computer with 2.3GHz, Intel Core i5 processor. The framework design adopts the B/S architecture design mode, the front-end framework adopts Bootstrap, and the back-end framework adopts Springboot. The software is implemented in Java language, combined with Intellij idea 2019, maven3.6.1 and other development tools.

IV. IMPLEMENTATION AND TESTING OF THE ONLINE TEACHING PLATFORM OF COLLEGE DANCE COURSE BASED ON THE IGA ALGORITHM

A. Experiment on the Performance of the Teaching Platform based on IGA Algorithm

The data set used in this experiment is randomly generated by the loop of the randperm function in Matlab. There are 570 test questions in the generated dataset, including 300 theoretical questions, 120 basic movement test questions, 90 work performance questions, and 60 choreography questions. The specific data set is shown in Table II.

According to the test question design and Table II, it can be concluded that the questions ID from 1-300 are theoretical questions, each question is three points; 301-420 questions are basic movement test questions, each question is 10 points; 421-510 questions are work performance questions, each question is 20 points; 511-570 questions are choreography questions, each question is 20 points. The difficulty coefficient of the test questions is randomly generated, including four kinds of difficulty, among which 0.0-0.25 represents easy, 0.26-0.5 represents medium difficulty, 0.51-0.75 represents difficult, and 0.76-1 represents very difficult. The knowledge points of the test questions are set to 10 types. The discrimination coefficient ranges from zero to one. If the discrimination degree of the test question is less than 0.2, it means that the gap between the test questions is small, which cannot reflect the real level of the students.

This study will compare four aspects, including running time, success rate, average fitness, and optimal fitness. Through the comparative analysis, the performance of the IGA algorithm in the paper grouping is studied. After the experiment, the comparison results of the traditional GA algorithm and the IGA algorithm obtained are shown in Fig. 4.

The above picture shows the difference between the genetic algorithm and the IGA algorithm. It can be seen from Fig. 4(a) that in the process of creating papers, the running time of the traditional genetic algorithm increases with the number of iterations. Although the running time of the IGA algorithm also increases with the number of iterations, its growth rate is significantly slower and the overall running time is shorter compared with the traditional genetic algorithm. From Fig. 4(b), it can be seen that the number of iterations is 100, the success rate of the traditional genetic algorithm is about 86.7%, while the success rate of the IGA algorithm is as high as 95.3%. There is no significant change in the success rate between the two algorithms as the number of iterations increases. When the iteration count reaches 500, the success ratio of traditional genetic algorithm is stable at 88.6%, while the success rate of the IGA algorithm is as high as 99%. In short, the success rate of the IGA algorithm is higher.

From Fig. 4(c), it can be seen that the average individual fitness of the IGA algorithm stabilizes at 0.929 when the number of iterations reaches 100, while the average individual fitness of traditional genetic algorithm is only 0.73. The average individual fitness of the traditional genetic algorithm increases significantly with the number of iterations. Comparing the two algorithms, it is clearly seen that the IGA algorithm has higher average individual fitness and requires less iterations.

TABLE II.   EXPERIMENTAL TEST DATA SET TABLE FOR THE IGA ALGORITHM-BASED TEACHING PLATFORM

Question ID	Type	Score	Difficulty _	Knowledge point	Distinction
1	1	3	0.34	6	0.42
2	1	3	0.68	1	0.31
3	1	3	0.91	10	0.67
4	1	3	0.22	5	0.41
5	1	3	0.47	2	0.38
...	...	...	...	...	...
570	4	20	0.86	9	0.49

(a)Test Paper Auto-production runtime comparison chart

(b)Test Paper Auto-production success rate comparison chart

(c)Fitness mean comparison chart

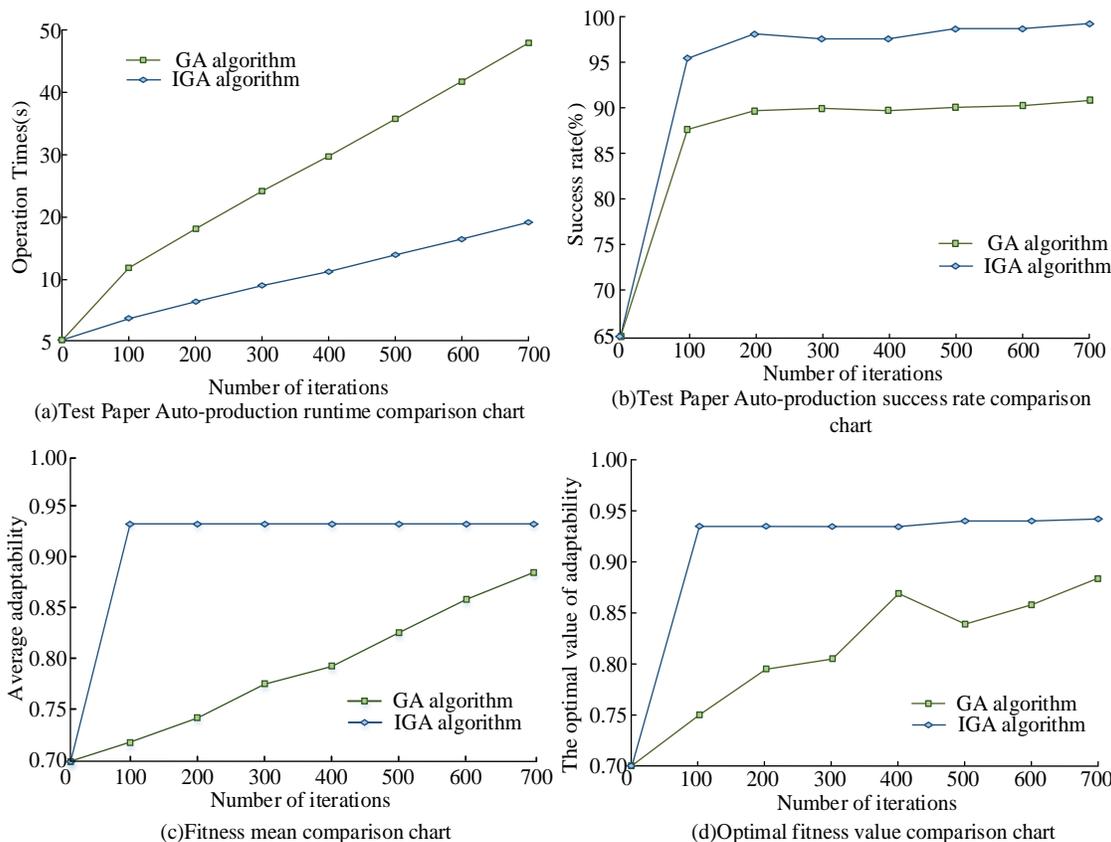
(d)Optimal fitness value comparison chart


Fig. 4.   Comparison between GA Algorithm and IGA Algorithm.

According to the setting of formula (12), when the fitness calculation value is higher, the individual test papers obtained by the grouped papers are better. From Fig. 4(d), we can observe that when the iteration number reaches 100. Optimal value of the individual fitness of the traditional genetic algorithm is about 0.752, while that of the IGA algorithm is about 0.936. The results show that the optimal values of individual fitness for the two algorithms both increase with the iteration number. Comparing the optimal value of individual fitness of the traditional genetic algorithm and the IGA algorithm, the individual value of the individual fitness of the test papers grouped by the IGA algorithm is obviously greater as compared with the GA algorithm, which stabilizes at about 0.94 when the number of iterations is only 100. In short, the IGA algorithm performs better in terms of the best value of individual fitness of test papers.

To sum up, compared with the traditional genetic algorithm, the IGA algorithm proposed in this study has significantly improved the functions in all the above four aspects, indicating that the IGA algorithm can effectively improve the success rate, speed, memory consumption and the ability to produce quality papers in a short period of time in the online teaching platform for university dance.

B. Comparative Experiments on the Performance of the Teaching Platform System under the Conditions of Different Parameter

This study conducted a comparative analysis of the performance of online teaching platform system under the condition of different parameters. Considering the common characteristics of the GA algorithm, the size of the initial population will affect the results of the test. The initial population size was set to five different parameters, including 10, 50, 100, 150 and 200. Then, the comparison of fitness average (favg), the optimal value of the fitness function (Maximum Fitness value, fmax) and group volume uptime of the traditional genetic algorithm and the IGA algorithm are shown in Fig. 5.

(a)Comparison table of average fitness values of
different population sizes

(b)Comparison table of optimal fitness function
values for different population sizes

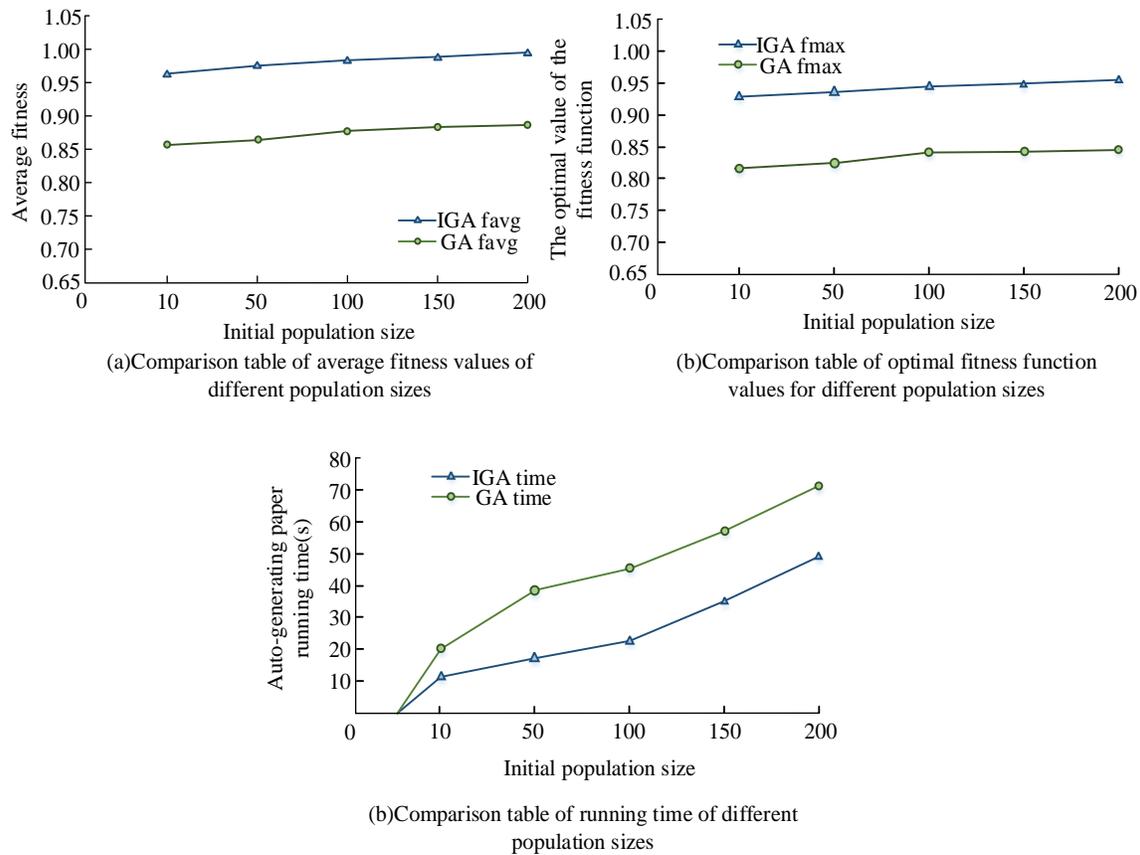
(b)Comparison table of running time of different
population sizes


Fig. 5.   Performance Comparison of Teaching Platform System under Different Parameters.

As can be seen from the above figure, the size of the initial population has various degrees of influence on the three aspects of the algorithm. From Fig. 5(a) and 5(b), it can be seen that while the size of the initial population increases, both favg and fmax increase, indicating that the quality of the groups is better. However, as seen in Fig. 5(c), the time required to create a volume increases significantly as the size of the initial population increases. In summary, when the size of the initial population is at a value of 150, the quality of the rolls is excellent and the time required for the rolls is short, indicating the best value for the initial population.

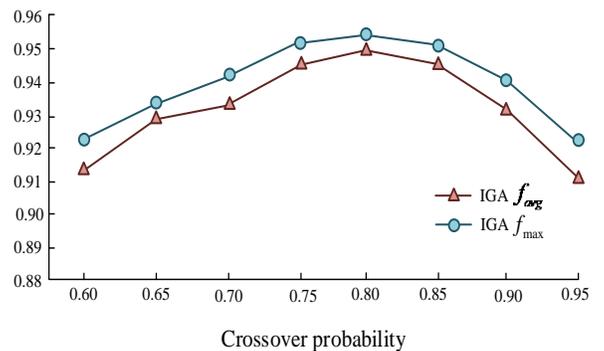
Fig. 6 shows the relationship between the crossover probability (P_c) and the individual fitness of the IGA algorithm. As P_c increases, the value of A shows a trend of rising first and then falling. When the P_c value is 0.8, both IGA f_{avg} and IGA f_{max} reach the maximum value, indicating that when the P_c value is set to 0.8, the quality of the test papers produced by the IGA algorithm is the best.


Fig. 6.   Comparison of Different Cross-Probability Experiments.
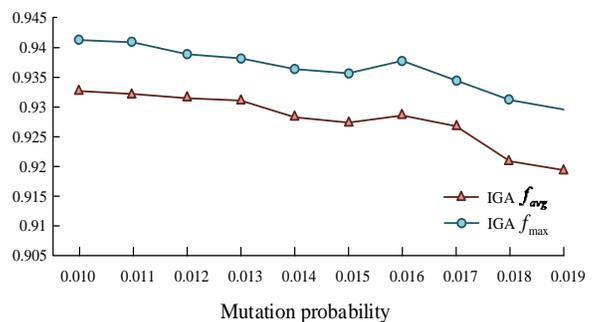

Fig. 7.   Comparison of Mutation Probability.

Fig. 7 shows the relationship between the mutation probability (P_m) and the individual fitness of the IGA algorithm. The results show that the best mark of the individual fitness and the average fitness of the group test P_m show a downward trend as the value increases. When the P_m value is 0.01, both IGA f_{avg} and IGA f_{max} reach the maximum value, indicating that when the P_c value isset to 0.1, the quality of the test paper produced by the IGA algorithm is the best.

In the IGA algorithm proposed in this study, the inclusion of a simulated annealing process allows it to effectively reduce the problem of results falling into a local optimum at an early stage and improve the success rate of the grouped volumes, which is the aim of this study to optimise the search capability of the traditional GA algorithm.

C. Performance Testing of the Online Teaching Platform System

To validate the feasibility of the online teaching system of college dance course based on IGA algorithm in actual operation, the teaching platform system will be functionally tested in this study. The functional test environment of the teaching platform system will run on a computer with 2.3GHz, Intel Core i5 processor. Functional tests will be conducted on the student function block and the teacher function block.

As can be seen from Table III, when the number of system visitors is 50, the response time of the traditional GA-based online teaching platform is 0.812 seconds, with a central processor occupancy of 6.06%. When the number of visitors to the system was 400, the response time of the online teaching platform based on the IGA algorithm was 6.158 seconds, with a central processor occupancy rate of 89.32%.

The system property of university dance online teaching platform based on IGA algorithm can directly reflect whether it meets the design request or not. In the performance testing environment of this experiment, JMeter 5.4.1 software will be used to automate the test in Win10 environment and Fiddle software will be used for script recording. The number of visits to the system is tested, and the specific operation is to simulate the number of concurrent users in the actual running process of the teaching platform. The test results are shown in Table IV.

As can be seen from Table IV, when the number of system visitors is 50, the response time of the online teaching platform based on the IGA algorithm is 0.532 seconds and the CPU occupation rate is 8.12%. When the number of system visitors is 400, the response time of the online teaching platform based on IGA algorithm is 5.52 seconds and the CPU occupancy rate is 68.12%, showing qualified performance in the number of visitors. The comparison with the conventional algorithm in Table III shows a significant improvement in response time, percentage of central processor occupation and balanced response time.

The online teaching platform based on IGA algorithm proposed in this study can meet the requirements of 400 users at the same time, indicating that the system meets the design request.

TABLE III. PERFORMANCE TEST TABLE OF ONLINE TEACHING PLATFORM OF COLLEGE DANCE COURSE BASED ON GA ALGORITHM

Number of concurrent users	response time/s	CPU usage/%	Balanced response time /s
50	0.532	4.06	0.01064
100	1.201	8.21	0.01201
150	1.989	16.42	0.01326
200	2.654	24.52	0.01327
300	3.992	47.31	0.01330
400	5.52	68.12	0.01380

TABLE IV. PERFORMANCE TEST TABLE OF ONLINE TEACHING PLATFORM OF COLLEGE DANCE COURSE BASED ON IGA ALGORITHM

Number of concurrent users	response time/s	CPU usage/%	Balanced response time /s
50	0.532	4.06	0.01064
100	1.201	8.21	0.01201
150	1.989	16.42	0.01326
200	2.654	24.52	0.01327
300	3.992	47.31	0.01330
400	5.52	68.12	0.01380

V. CONCLUSION

This research designs an online teaching platform system for college dance course based on IGA algorithm. In the research, the mathematical model of the intelligent question-making problem is applied, and the constructed model is verified. The results show that the success rate of the online teaching platform system for college dance courses based on IGA algorithm is 99% when the number of iterations is 500 times; when the number of iterations is 100, the average fitness is 0.929; when the number of iterations is 100 times, the moderate calculation value is 0.936. However, for the traditional GA algorithm, the results are 88.6%, 0.73 and 0.752, respectively. By comparing the GA algorithm and the IGA algorithm, the mathematic model of the test-setting problem based on the IGA algorithm is obviously superior to the GA algorithm in all aspects. At the same time, the research shows that the crossover probability and mutation probability are respectively $P_c = 0.8$. When the number of visitors to the

system is 50, the response time of the online teaching platform based on the IGA algorithm is 0.532 seconds, and the CPU occupancy rate is 8.12%. Compared to traditional genetic algorithms, the IGA algorithm proposed in this study shows significant improvements in all four of these areas, indicating that the IGA algorithm can effectively improve the success rate, speed, memory consumption and the ability to produce high quality papers in a short period of time on an online university dance teaching platform. Although the method proposed in the study can provide teachers and students with functions such as personalized teaching, intelligent test detection and teaching evaluation, the system lacks real-time monitoring of students' learning behavior and corresponding data analysis, so the follow-up research will conduct further research on this problem.

Early-Warning Dropout Visualization Tool for Secondary Schools: Using Machine Learning, QR Code, GIS and Mobile Application Techniques

Judith Leo

School of Computational and Communication Science and Engineering (CoCSE)
The Nelson Mandela African Institution of Science and Technology
Arusha, Tanzania

Abstract—Investment in education through the provision of secondary school to the community is geared to develop human capital in Tanzania. However, these investments have been hampered by unacceptable higher rates of school dropouts, which seriously affect female students, since most schools do not have effective mechanisms for quality data management for immediate and effective decision making. Therefore, this study aims to solve the problem of data management from the school level in order to assist higher levels to receive appropriate and effective data on time through the use of emerging technologies such as machine learning, QR codes, and mobile application. To implement this solution, the study has explored the predictors of school dropout using a mixed approach with questionnaires and interview discussion. 600 participants participated in problem identification in the Arusha region. Through the use of design science research methodology, Unified Modeling Language, MYSQL, QR codes and mobile application techniques were integrated with Support Vector Machine to develop the proposed solution. Finally, the evaluation process considered 100 participants, and the results showed that an average of 89% of participants provided positive feedback on the functionalities of the developed tool to prevent dropouts in secondary schools in Africa at large.

Keywords—*Dropout; education; girls; machine learning; students; QR code; mobile application*

I. INTRODUCTION

Yearly in Tanzania, 30% of girls drop out before reaching form four compared to 15% of boys. Overall, more than 70,000 girls were expelled from school due to pregnancy between 2003 and 2015 [1]–[3]. As a result, girls aged between 15-24 years old are 2.5 times more likely to contract HIV/AIDS than their male counterparts [4]–[8]. Additionally, in Tanzania, especially at the village, ward, and district levels, female counterparts are not given their rights because of traditional beliefs, cultural practices, child labor, girls' menstruation periods, a long distance from home to school, poverty, etc.; hence, gender-based violence is still significantly high [9], [10], [19]–[24], [11]–[18]. Furthermore, the variation in completion and dropout rates in Tanzania differs from one region to another; for example, in Arusha, the percentage of dropouts of total students enrolled in 2015 was 8.9% and 2.3%, respectively, making Arusha the leading region in school dropout [25]–[28](BEST, 2016). Moreover, it has been noted that school dropout is more dominant in lower

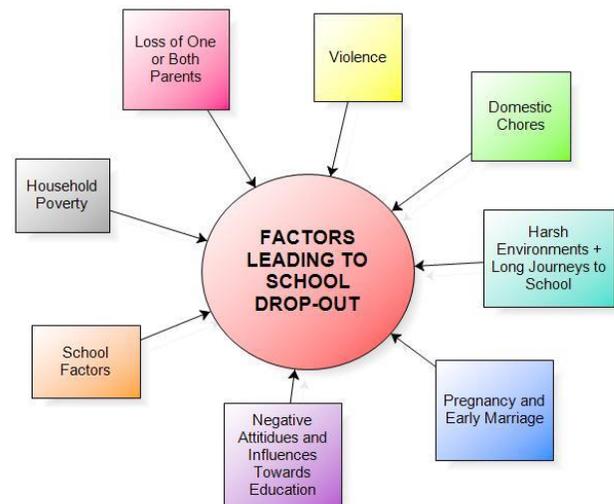
secondary levels than in Ato primary levels. The major factor contributing to this high dropout rate in secondary school is early pregnancy, which in turn makes the victims young women, with a poor economy and a high probability of dropout from HIV/AIDS patients [29][30], as briefly described in Fig. 1. Fig. 1 shows a young adolescent secondary school girl who is faced with many challenges, such as child labor, home chores, cultural practices such as early marriage and girls not supposed to be educated, long distances between the home premises and school, and menstruation issues to mention a few [26], [31]–[37].


Fig. 1. Description of the Challenges that Lead to School Dropout [38].

The government of Tanzania has made efforts to ensure equal opportunities for boys and girls in schools. However, many initiatives have been implemented using the top-down approach, which focus on ensuring that the government uses an electronic-based information system to collect and store data from lower levels, such as schools, wards, and districts [3][39]. The top-down approach has proven to produce poor quality data and delays in data submission and decision making. This is because the lower levels (schools, wards, and district education offices) do not have proper mechanisms for data collection and storage. Additionally, most schools in Tanzania still use manual systems to collect data; for instance,

the class teacher has to document the attendance of more than thirty (30) students twice a day [40]–[42]. The activity of attendance and collection is tedious to the extent that it is not done every day, and sometimes wrong information is captured in the attendance book. Furthermore, there are no effective mechanisms to track and ensure that students enrolled in schools complete their studies, according to [38], [43]–[46]. Moreover, there are poor-quality datasets that can be used to develop demand and data-driven solutions for immediate action, effective planning, campaigns, and policies on matters related to the elimination and reduction of school dropouts [47]–[50]. Therefore, this research study aims to solve the problem of data collection, on-time data submission, effective data visualization, and availability of quality datasets from the lower levels (schools) in order to assist higher levels of receiving appropriate and effective data on time through the use of emerging technologies such as machine learning (ML), QR codes, statistical visualization, and mobile applications, which are cheap to operate, understandable, and sustainable. In connection with the proposed technical solution, the study, with the collaboration of the government of Tanzania through the Ministry of Education, Science and Technology and other related stakeholders such as HakiElimu, also aims to conduct campaigns, workshops, seminars for secondary school students, teachers, parents, and related domains of education sectors on matters related to the elimination and reduction of school dropout.

II. MATERIALS AND METHODS

This section presents the methodologies of the research study, including the study area, participants, sampling procedures, tools, and methods used throughout the research activities. The study followed the design science research methodology (DSRM), which consists of three stages: problem identification, solution development, and validation [51]. The DSRM was chosen because it is an outcome-based method. It also offers iterations through the research stages and provides guidelines for evaluation, with a focus on improving the functional performance of each interface. The study took a total period of three years from 2017 to 2020 to observe the impact (outcome) of the research study based on the initial focus group of participants.

A. Study Area

This study was conducted in six districts of the Arusha region in Tanzania. This is because, according to the literature, the Arusha region has a high school dropout rate, and the region can well represent the situation that is happening in both rural and urban areas based on its existing geographical position in the country and the nature of its people [52]. The region is positioned in such a way that it attracts many tourists; therefore, natives, including their children (local people in the area), tend to depend on tourism activities instead of focusing on acquiring education. In addition, the majority of people in Arusha are Maasai who still practice and seriously follow their culture and customs; hence, most young adolescent girls are not allowed to go to school, practice early marriage, and also have babies at a very young age, to mention a few. This study considered six districts in the Arusha region, namely Meru, Longido, Ngorongoro, Karatu,

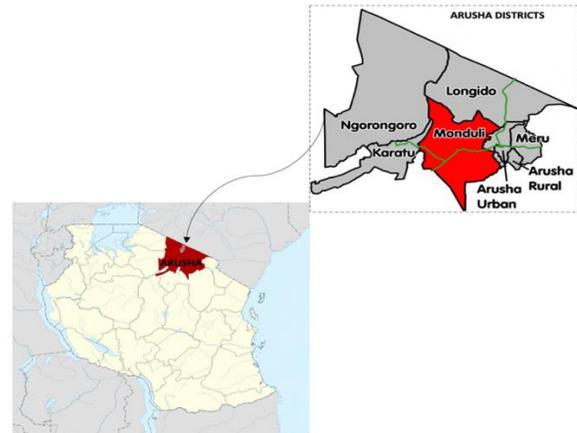
Moduli, and Arusha urban and rural areas, as shown in Fig. 2. The urban and rural areas of Arusha were considered as one district.


Fig. 2. Districts of Arusha Region in Tanzania.

B. Problem Identification Stage

In the problem identification stage, an intensive literature review was conducted on various strategies and mechanisms that have been implemented so far in the area, especially the information and communication technology (ICT), -based solutions, to understand the existing challenges that led to continued secondary school dropout. In the process, a mixed design approach, qualitative and quantitative methods with focus group discussions, and administered questionnaires were conducted, as shown in Fig. 3, in order to receive feedback and constructive comments from the participants. This feedback and comments were used to identify the requirements for the design, development, and validation of the proposed solution Early-warning Dropout Visualization Tool (EDV-Tool).

The study population comprised 600 participants, including teachers, students, parents, education officers, health officers, and policymakers, in the Arusha region. In each district, 100 participants were systematically selected to form the sample. In general, 100 participants in each district were distributed as follows: 20% teachers, 20% students, 20% parents, 20% education officers, 10% health officers, and 10% policymakers, as shown in Table I. The collected data were then coded and analyzed using R programming software to determine the most appearing or mentioned features and functionalities of the proposed solution.

C. Design and Development of EDV-Tool

The rapid application development (RAD) method was followed in the design and development processes of the EDV-Tool. RAD was chosen because it allows short and iterative development cycles with effective results. Five iterations were conducted between development processes. The tool was developed using MySQL, JSON, JavaScript, Java Server Pages, Python (ML), QR codes, mobile apps, and ML techniques.

D. Evaluation of EDV-Tool

The evaluation of the developed EDV-Tool was conducted in the last year of the research study (2020). The evaluation considered only 100 participants from the urban and rural districts of Arusha. This is because the urban and rural districts of Arusha represented both urban and rural features and challenges well based on the nature and responses received during the data collection stage. During the evaluation process, a mixed-design approach of quantitative and qualitative methods was deployed as the study design. Focus group discussions were used in the process to obtain a large amount of feedback and participants. Focus group discussions and interviewer-administered questionnaires focused on understanding the performance of the tool in terms of both functional and nonfunctional features. Focus group discussions were limited to a maximum of 15 participants to ensure equal participation. Audio recorders, mobile phones, and laptops were used to record, transcribe, and code the discussions and interviews. The interfaces and functionalities (requirements) of the tool were then evaluated in four stages: unit, integration, system, and validation tests. During unit testing, each module was tested independently before integration with other modules of the tool. Integration testing was then performed after integrating one module with another. These tests were performed to eliminate any syntax or logical errors and maintain the compatibility of all modules of the

tool. After successfully integrating all modules, a black-box testing methodology was used to verify the functionalities of the tool that were identified during the requirement identification and collection processes. The black-box testing methodology is a type of testing approach in which the tester tests the system without having knowledge of the internal codes. Finally, a validation test was performed by deploying the developed tool to 100 selected participants from the Arusha urban and rural districts. Data from the questionnaires were analyzed statistically using the R programming software.

III. RESULTS

This section briefly presents the results of each stage taken towards the development of the EDV-Tool. The content in this section is presented in four subsections, which include the results of problem identification, design, development (description of EDV-Tool), and evaluation.

A. Results of Problem Identification

The data collection exercise conducted in the Arusha district using focus group discussions and administered questionnaires. Tables I and II briefly describe the selected participants and collected requirements, and Fig. 3 presents the most identified existing predictors of dropout in secondary school.

TABLE I. DESCRIPTION OF THE PARTICIPANTS DEMOGRAPHIC INFORMATION

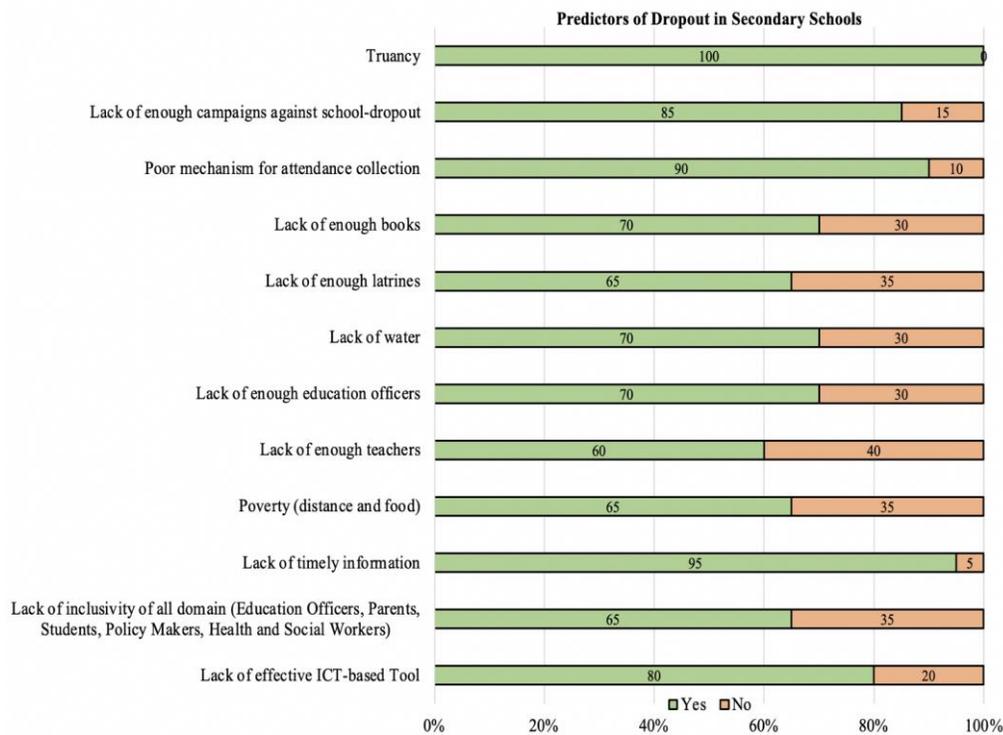
SN	Characteristics of Participants		Total Sample (N=600)	Percentage Distribution(%)	Description
1.	Age in years				
		≤ 20	260	43.33%	-The average age group for the study was 28 years old.
		21-35	240	40%	
		≥ 36	100	16.67%	
2.	Level of Education				
		Primary	60	10%	-Secondary comprised of participants with junior and senior high school levels at a ratio of 2:3 respectively.
		Secondary	200	33.33%	
		Certificate Level	140	23.33%	
		Diploma Level	100	16.67%	-Non-formal education comprised of participants who do not have any kind of education whereby majority were parents.
		University	100	16.67%	
3.	Disctrict				
		Arusha urban & rural	100	16.67%	-In each district, 100 participants were selected for problem identification. Whereas, for evaluation only 100 participants from Arusha urban & rural district were involved.
		Meru	100	16.67%	
		Longido	100	16.67%	
		Karatu	100	16.67%	
		Monduli	100	16.67%	
		Ngorongoro	100	16.67%	
4.	Gender				
		Female	360	60%	-Majority of participants were Female at Female to Male ratio of 3:2.
		Male	240	40%	


Fig. 3.   Predictors of Dropout in Secondary School in Tanzania.

TABLE II.   DESCRIPTION OF FUNCTIONAL AND NON-FUNCTIONAL REQUIREMENTS

Functional Requirements		
SN	**Requirement and its Description**	
1.	Generate visual, excel-format, and map-based reports	
2.	Search records per keywords, location, and image.	
3.	Submit all essential data on time.	
Non-functional Requirements		
SN	**Requirement**	**Description**
1.	Security	The system should be secured at both data access and transmission levels. All users should access data based on their usability levels and uniques credentials (user-names and passwords).
2.	Accessibility	The system should be available at all times and easy to use. The attendance collection module should capture data both when on-line and offline.
3.	Efficiency	The system should be reliable, affordable, and scalable.
4.	Interoperability	The system should be compatible with all browsers and android OS.
5.	Maintainability	The system should be easy to maintaining to the extent that when one service is under maintenance should not hinder other services from operation.

B. Results of EDV-Tool Design

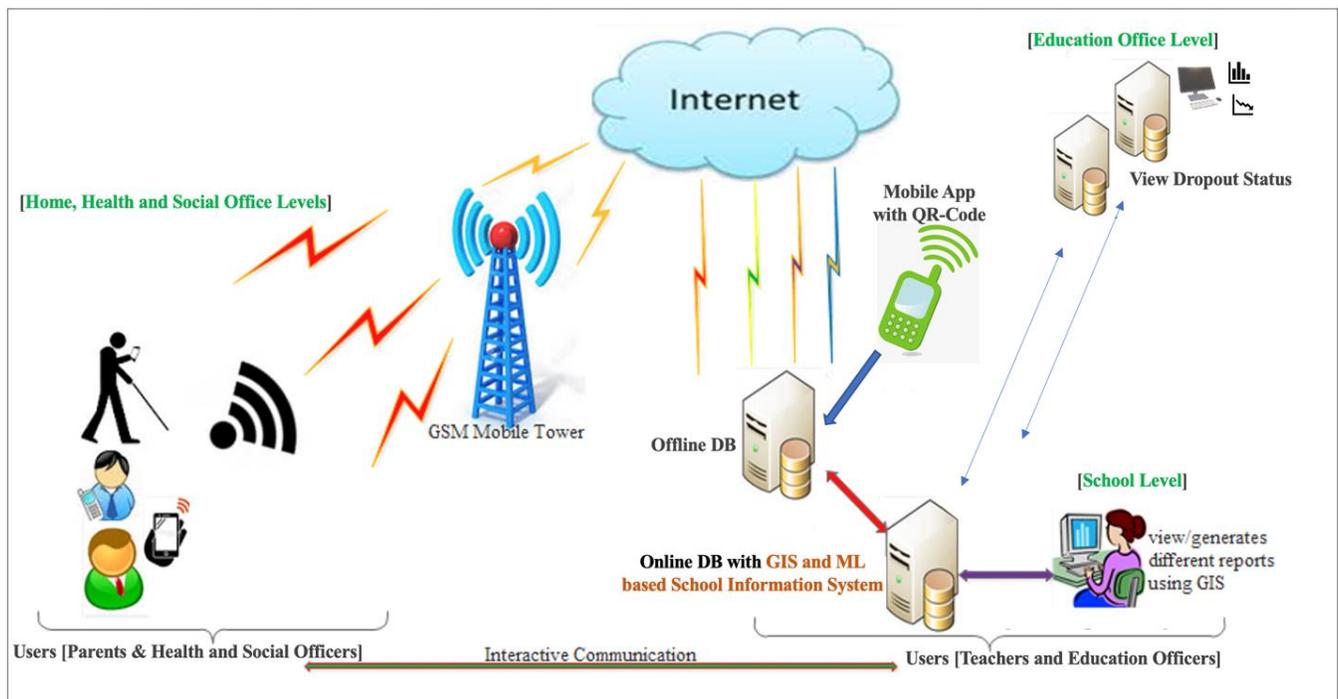
Fig. 4 shows the conceptual framework of the EDV-Tool, which describes the flow of data and main users. In connection with Fig. 4, Table III describes the main users of the EDV-Tool and a brief explanation of their activities in terms of the data that they submitted to and received from the tool. Fig. 5 shows the ML model development approach that was deployed, starting from the users sending the required data to the online database (DB). The dataset was then cleaned and transformed into the appropriate format. Because the data are not well balanced at a ratio of 0.43 (Yes Dropout (30%) and No Dropout (70)), the SMOTE oversampling techniques were used to balance and then, the best features for prediction of the dropout status truancy rate, lack of sufficient teachers, lack of digital system for data collection, lack of sufficient latrines, and water were selected using random forest (RF) techniques. The model was then developed considering three supervised ML algorithms: support vector (SV), extra tree (ET), and XGBoost classifiers. Using sensitivity [0.999, 0.941, 0.892], accuracy [0.732, 0.587, 0.522], and F1-score [0.821, 0.756, 0.744], respectively, the models were validated, and then the Wilcoxon signal ranking was used to select the best model based on the three validation techniques. Finally, the user acceptance procedure was performed using 100 stakeholders from Arusha's urban and rural districts. Based on this approach, the SV classifier was selected as the best model for developing the development of EDV-Tool. Fig. 6 describes the flow of information to enable attendance data from the school level to be captured using either online or offline modes based on the status of Internet connectivity in the area.


Fig. 4.   Conceptual Framework of EDV-Tool.

TABLE III.   DESCRIPTION OF USERS AND THEIR ACTIVITIES IN THE EDV-TOOL

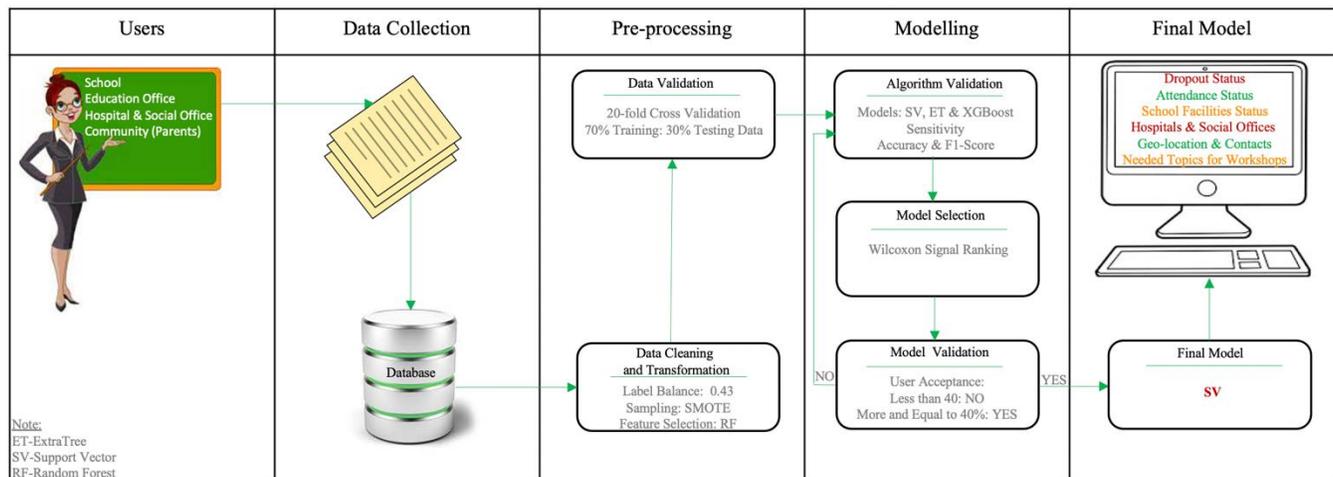
S/N	Name of User	Submitted Data in EDV-Tool	Received Data from EDV-Tool
1.	Teachers	-Feed data into the EDV system -Update pupil status into the system	- System user
2.	Education Officer	-Visualization of system output/information for decision and planning purposes.	- System user - Decision making
3.	Students	-Visualize system information -Help in identifying schools with high-dropout. -Locating pupils affected by dropout.	- System user
4.	Parents	-Key decision maker and planner all matters pertaining education in the district. -Visualize system information	- System user
5.	Hospitals and Social Officers	-Victims of dropout will provide data on the causes of dropout.	- Beneficiaries of project outcomes
6.	Policy Makers and Community	-Receive data for policy making -Get knowledge and information	- Beneficiaries of project outcomes


Fig. 5.   Machine Learning Model Development Approach.
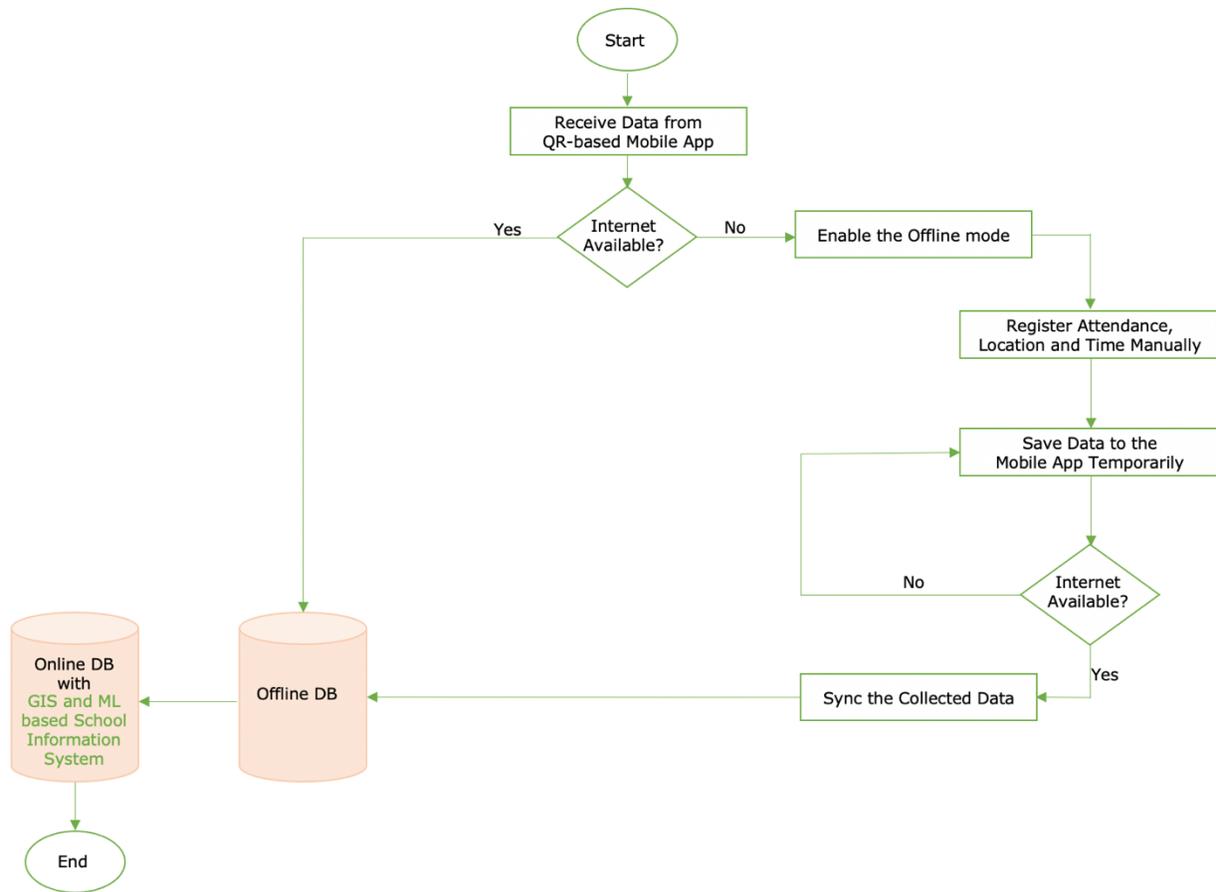

Fig. 6. Flowchart of EDV-Tool Describing Online and Offline Modes.

C. Results of EDV-Tool Development

The EDV-Tool consists of (i) a mobile application that is integrated with the QR code and visualization techniques to facilitate attendance collection from both teachers and students, easy to understand graphical representation of school dropout status, and timely sharing of information to the users; (ii) Geographic Information System (GIS) and ML-based school information system, which is responsible for processing the integrated data from school (teachers and students), and education, health, and social offices and then transforms the data into required formats such as Excel, graphs, and map-based formats; and (iii) a communication subsystem that integrates data between offline and online databases, and sends data to be displayed by the EDV-Tool.

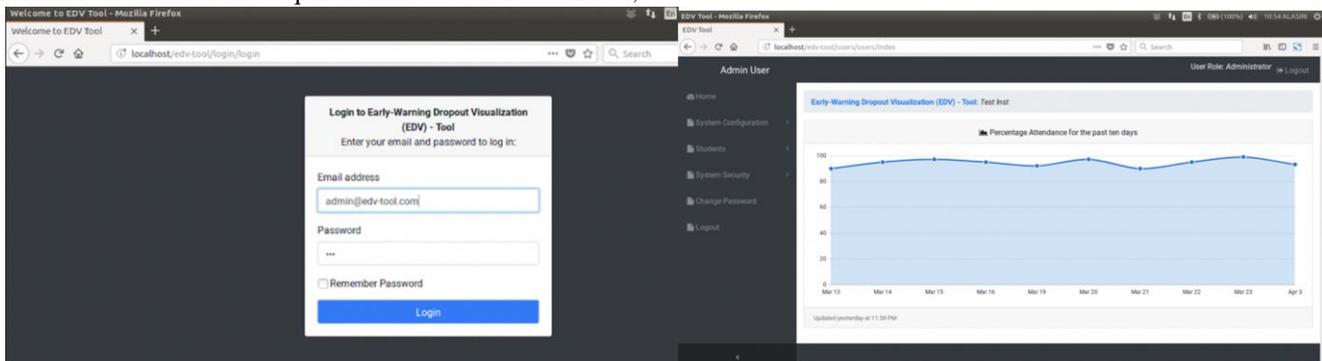
The main features of the developed system are as follows: secured login and report sample interfaces, as shown in Fig. 7. Fig. 8 shows the training on the use of EDV-Tool which was done at Murieth secondary school and the exhibition of the EDV-Tool to "SIKU YA VIJANA KIMATAIFA which was held on 2018 and also, describe the campaigns and seminars which were done to different stakeholders on elimination of the school dropout.


Fig. 7. Interfaces of EDV-Tool Describing the Login Section and Report Sample.

D. Results of EDV-Tool Evaluation

Overall, at an average of 89% of the participants agreed that the system performs well in terms of visual reports, essential data for all domains, easy to search data, security level, accessibility level, effectiveness, interoperability, and maintainability as described in Fig. 9. The remaining 11%.

of the average evaluation results represent the majority of participants who strictly practice cultural activities and do not believe in educating girls in their community. In addition, the analysis results of the 100 participants, as described in Fig. 10, showed that there was a ratio of 45:55 for male to female ratio and 60:40 for participants with education higher than secondary school (O-level) to those with education lower than secondary school.

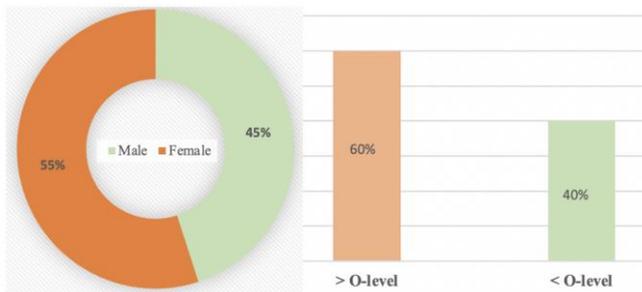
Fig. 8.   Results of Evaluation of EDV-Tool.


Fig. 9.   Description of the Participants in Terms of Gender and Education Levels.

IV.   DISCUSSION

The developed EDV tool is a combination of not only an ICT based system but also integrated measures and strategies such as involvement of all key players of education under one system, planned campaigns, seminars, and workshops to educate, motivate, and encourage students on the importance of education, elimination of bad-cultural practices such as early marriages and pregnancies, and HIV-AIDS education. Therefore, the tool captured all essential requirements collected during the problem identification stage (data collection and literature review), as described in Fig. 3. In addition, the tool enables quality data collection, on-time data submission, and effective data visualization from the low level (e.g., school – village – ward–district) to higher levels (government-Ministry) through the use of emerging technologies such as ML, QR-code, mobile apps, GIS, and visualization techniques that are inexpensive, easy to use, and

sustainable. Furthermore, the tool can be accessed both via mobile devices and the web to monitor the attendance of students and staff, as well as other statistical information regarding school resources or facilities such as number of toilets, availability of tap water or water, number of classrooms, teachers, and students. Hence, through the generated data, the ML techniques enable the tool to predict the students who are at risk of school dropout weekly, and then, the status of dropout and non-dropout is shared with the teachers, parents, and education officers. The tool has proven to provide understandable and early representations of school dropout status, and as a result, the whole scenario assists in the reduction of HIV/AIDS risk behaviors since the students, especially adolescent girls, who are at the risk of dropping out, will be controlled and monitored by sending daily attendance to their parents via SMS and special alerts to the school and education offices. Based on the school dropout status, special meetings with parents can be easily arranged in order to discuss how the students can be assisted, and sometimes special interventions such as campaigns, workshops, and seminars are arranged with the help of other domains such as education officers, social workers, medical experts, policy makers, and the community. Lastly, the tool contains geo-location and contact information of nearby hospitals; therefore, any required action for incidences, such as rape and education on early pregnancies and HIV, can be easily accessed.

Apart from these major contributions towards the prevention of school dropout, other issues were learned during the different processes of tool development and

implementation. These contributions include: (i) It is important to understand the timetable (school examination, marking of the examination, sports day, work deadlines, etc.) of the school before visiting in order to select the best time for data collection, campaigns, evaluation, and other activities related to the study. (ii) Some schools do not even have windows and doors in their classrooms and walls that surround them for security purposes. Such schools find it unusual to be given ICT-based tools and solutions such as the EDV-Tool instead of being supported to build walls and fix-in classrooms with the required doors and windows. (iii) Some schools have the issue of poverty as the major problem that leads to most students not being able to attend classes and courses until the end of the day without going back home for lunch. (iv) Some schools in the Maasai tribe do not cooperate well with female researchers; therefore, planning to visit the schools should involve a male figure who will initiate the communication. Therefore, based on these findings, it is very important to prepare as early as possible measures and strategies to overcome these dynamics and shortcomings, as well as to justify that the intention of the study is still valid and flexible enough to adopt other measures that will come out during the data collection meetings and discussions on the required solutions with stakeholders.

V. CONCLUSION

Efforts to prevent school dropouts in Tanzania entail reducing and eliminating risk factors across all essential domains (i.e., individual, peers, family, school, community, culture, government level, and its associated subdomains) in the education sector. Therefore, the developed and implemented EDV-Tool has taken into consideration these factors by being a combination of school-community-based mechanisms and strategies that have involved key players from schools, communities (parents), education offices (ward, district, and government levels), health, and social offices. In addition, the tool has facilitated the use of open data from TAMISEMI as well as encouraging the flow of information from low levels (schools and communities) to government levels, and on-time access of school dropout status to all essential domains in the education sector and to the highest organ, which is the Ministry of Education, Science and Technology through the linkage with the education officers and schools. In addition, based on the data collected via the EDV-Tool, the schools were able to identify the required number of seminars and select appropriate topics for discussion in terms of seminars, campaigns, and workshops on matters related to the prevention of school dropout and its risk factors. Therefore, through the use of the EDV-Tool mechanism and strategies, all associated dropout risk behaviors such as truancy, HIV-risk behaviors, and bad-cultural practices such as early pregnancies and marriages will be timely identified and special measures will be timely implemented with the involvement of all essential domains. The study recommends the implementation of the EDV-Tool in all schools in Tanzania, especially those in rural areas, to reduce the rate of school dropout and facilitate timely collection and sharing of quality data, which is essential for effective and timely decision making on school dropout issues

at large. Future research should focus on conducting the same study in other regions of Tanzania.

VII. DATA AVAILABILITY STATEMENT

Abstract—**Datasets with a balanced distribution of data are often difficult to find in real life. Although various methods have been developed and proven successful using shallow learning algorithms, handling unbalanced classes using a deep learning approach is still limited. Most of these studies only focus on image data using the Convolution Neural Network (CNN) architecture. In this study, we tried to apply several class handling techniques to three datasets of unbalanced text data. Both use a data-level approach with resampling techniques on word vectors and algorithm-level using Weighted Cross-Entropy Loss (WCEL) to handle cases of imbalanced text classification. With Bidirectional Long-Short Term Memory (BiLSTM) architecture. We tested each method using three datasets with different characteristics and levels of imbalance. Based on the experiments that have been carried out, each technique applied has a different performance on each dataset.**

Keywords—Imbalanced text classification; deep learning; resampling technique; weighted cross-entropy loss

I. INTRODUCTION

Datasets with unbalanced class conditions are usual in real life, for example, in the case of fraud detection[1], cancer diagnosis[2], and spam detection[3]. These are challenges for machine learning models to perform classification tasks because samples are not the same in each class. As a result, the classifier may have high accuracy in the majority class. However, the classifier tends to ignore the minority class, so it has poor performance for detecting the minority class[4]. On the other hand, the minority class sometimes has a more important role because it has beneficial information, for example, when diagnosing cancer where patients are in the minority class. If the learning algorithm cannot detect the minority class properly, it can endanger someone's life.

Although various methods for dealing with class imbalance problems have been developed over the last two decades and have proven successful in various domains, most of them still focus on shallow learning algorithms[5]. Several researchers express similar things, among others: [6], [7], and [8], which states that the handling of unbalanced classes in deep learning has not been studied further. Based on a survey conducted by[5], more than 80% of research related to unbalanced classroom problems in deep learning still focuses on the field of computer vision using the Convolution Neural Network (CNN) architecture. Research by[9] as well, using Convolution Neural Network (CNN) to estimate the accuracy of the head pose angle based on deep learning in image recognition.

There are three approaches used to deal with unbalanced classes: data-level methods, algorithm-level methods, and hybrid methods[10]. Data-level methods are carried out by changing the data distribution in each class or resampling to achieve the desired condition. Resampling is done by reducing data from the majority class (under sampling) or adding data to the minority class (oversampling). Although it has been proven to be effective in overcoming the problem of data imbalance based on the survey conducted, on the other hand, under sampling has the potential to eliminate data that has important information. Oversampling can result in the learning model being overfitted so that the performance of the resulting model may not necessarily improve and increase computational effort [11]. The following method is algorithm-level, namely by making direct modifications to the learning algorithm to reduce bias in the majority class. Finally, the hybrid method is a combination of data-level and algorithm-level methods[8].

II. LITERATURE REVIEW

Handling unbalanced classes using a data-level approach is done by[6], [12], and[13]. Study[6] compared the Random Under Sampling (RUS), Random Oversampling (ROS), and Two-Phase Learning methods using multiclass image datasets trained with various CNN architectures. Overall, ROS has the best performance compared to the other two methods, RUS has poor results, and two-phase learning is considered less effective in dealing with class imbalance cases. The two-phase learning method was also proposed by[12] to classify WHOI-Plankton dataset images with a high level of imbalance. Different from[6], study[12] Instead, it concludes that this approach has been proven to be effective in improving the performance of the minority class while maintaining the performance of the majority class. Still using image dataset and CNN architecture, research[13] gets better performance by implementing the ROS method to handle unbalanced classes.

The algorithm-level approach is carried out by[14], [15], and[16]. Study[14] implemented a cost-sensitive CNN to classify various image datasets. This study also compares cost-sensitive with data-level approaches such as SMOTE and RUS. The proposed method is proven to have the most superior performance. Unfortunately, the performance metric used in this study is only accuracy, in which the evaluation method is not appropriate for measuring the performance of learning models with unbalanced classes[5]. Furthermore, research[15] used a cost-sensitive deep neural network (CSDNN) to predict hospital readmission. This study also compares the proposed

---

*Corresponding Author.

method with shallow learning algorithms such as Decision Tree and Support Vector Machine. The proposed method is proven to get better performance. CNN's cost-sensitive approach was also used in this study[16] for time-series classification with unbalanced data. The proposed method provides superior performance compared to the data-level approach.

The research that applies the hybrid method is[17] by combining SMOTE technique and weighted loss function to classify various image datasets with deep neural network architecture. The proposed method can improve the learning algorithm's performance, but on the other hand, the application of SMOTE also produces noisy data.

In this study, we intend to use the Bidirectional Long-Short Term Memory (BiLSTM) architecture to classify text data with various levels of imbalance. Several techniques to overcome class imbalances will be applied and observed how they affect the learning model's performance.

III. RESEARCH METHOD

A. Data Acquisition

We use three datasets in the form of labeled text with varying levels of imbalance. The level of imbalance is using the imbalance ratio (IR) formulated in Equation 1 by dividing the maximum class size against the minimum class[18].

$$IR(\varsigma) = \frac{\max_i \varsigma_i}{\min_j \varsigma_j} \tag{1}$$

Where:

$\max_i \varsigma_i$=maximum class size, $IR(\varsigma)$=imbalance ratio.

The first dataset we use is the Customer Support Tickets Dataset, which contains complaints about problems from users of an application obtained from the Google Play Store review column. The second dataset is the News Category Dataset, containing news headlines from 2012 to 2018 obtained from HuffPost[19]. Then the last dataset is the Drug Review Dataset which contains patient reviews related to drugs from the disease[20]. This study only used a few categories or classes from the three datasets with details, as shown in Table I.

TABLE I. DETAILS OF THE DATASET

Datasets	Instances	Class	IR (ς)
Cust. Support Tickets	5,150	3	4.99
News Category	50.879	3	15.72
Drug Review	57,463	5	8.52

B. Data Preprocessing

This stage includes the case folding process, data cleaning from special characters, normalization, to data representation. The cleaned text data will be converted into numeric digits by utilizing the Tokenizer library on Keras. Then the digits will be converted into word vectors using the word embedding technique with a dimension of 300. The word embedding technique applied is different based on the language contained in the dataset. The first dataset uses the fastText technique because the Indonesian language training model is available. In

contrast, the second and third datasets use the GloVe technique because an English training model is available.

C. Unbalanced Class Handling

There are two approaches that we will use in this research, namely:

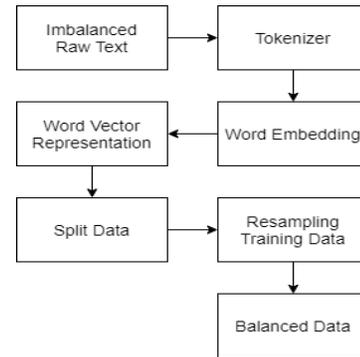
1) Data-Level: In simple terms, Fig. 1 shows the resampling technique in this study. Resampling of training data is 80% training and 20% testing. The resampled data is a word vector from the training dataset.


Fig. 1. Data Balancing Step.

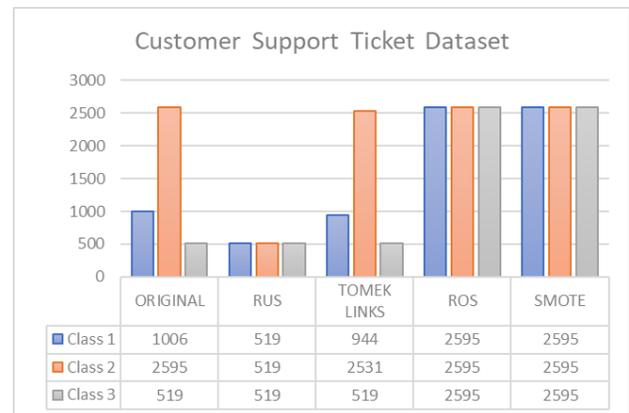
We used RUS and Tomek Links (TL) for undersampling. RUS will delete some instances randomly in the majority class until the desired distribution is reached. In comparison, Tomek Links will delete a pair of closest neighbors but belong to a different class[21]. To perform oversampling, we used ROS and Synthetic Minority Oversampling Technique (SMOTE). ROS will randomly duplicate instances of the minority class, while SMOTE will generate synthetic data by linear interpolation between adjacent minority class samples[22]. The distribution of classes before and after resampling is shown in Fig. 2 for Customer Ticket Dataset, Fig. 3 for News Category Dataset, and Fig. 4 for the Drug Review Dataset.


Fig. 2. Class Distribution before and after Resampling on the Customer Support Ticket Dataset.
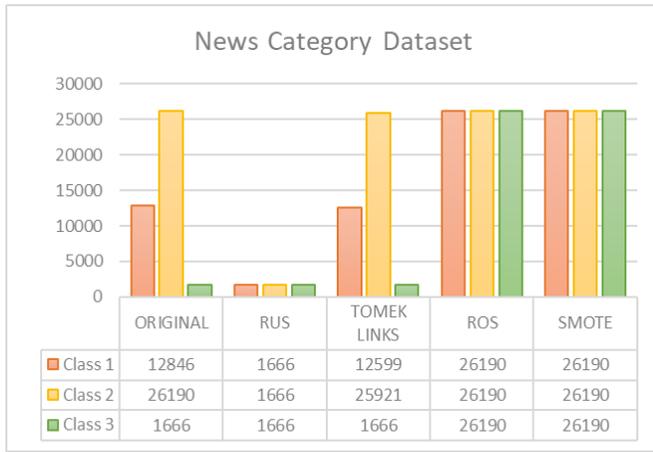

Fig. 3.   Class Distribution before and after Resampling on the News Dataset.
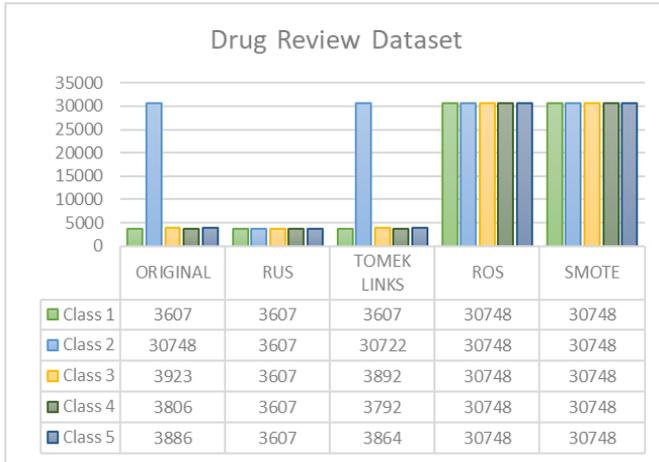

Fig. 4.   Class Distribution before and after Resampling on the Drug Review Dataset.

2) Algorithm-Level: In the algorithm-level approach, we use Weighted Cross-Entropy Loss (WCEL) to increase the sensitivity of the learning model to minority classes. For this reason, significant weight will be applied to the minority class, while the majority class will be given a smaller weight. By applying this weighting, the cross-entropy loss can be formulated in Eq. 2.

$$L(y, o) = - w \sum_{c=1}^{M} y_{o,c} \log(p_{o,c}) \qquad (2)$$

With w is the weight of the calculated class using $w = \frac{Cmax}{Ci}$ where Cmax is the size of the majority class, and Ci is the number of data samples in the class c. Then M Then represent the number of classes, y is a binary (0 or 1) indicator if the class label *c* is the correct classification for the observation o and p is the predicted probability.

D. Build Neural Network

In this study, we use Bidirectional LSTM architecture because, according to[23], the highest accuracy value is when using bidirectional LSTM to perform multiclass text classification tasks. There are 64 neurons in each hidden layer (the more neurons, the more accuracy, but the computation

time will be extended). We trained the network with a batch size of 8 based on[23], that smaller the batch size, the greater the accuracy, and applied a dropout with a probability of 0.6 to reduce the risk of overfitting. The higher the dropout value given, it will reduce overfitting, but if it is too high, it can decrease accuracy, so try n error only to determine the dropout value. The cost function we use is cross-entropy, specifically for applying the algorithm-level method in handling class imbalances. We use different weights for each class through the equations described previously. As a gradient descent optimization algorithm, we use the Adaptive Momentum Estimation (Adam) Optimizer with a learning rate of 0.001.

E. Evaluation

Evaluation with the right measuring tools is needed to compare the performance of several applied approaches. Considering that the minority class has a negligible impact on accuracy, apart from using Overall Accuracy, we also use other performance metrics, namely True Positive Rate (TPR), True Negative Rate (TNR), F1 Score, and Geometric Mean. F1 Score is a combination of Precision which calculates the positive class score classified in a positive class, and Recall, which represents how well the prediction of the positive class to be a single score. Next, by considering sensitivity (another term for Recall) and Specificity, which represents how well the prediction of the negative class is, we use the Geometric Mean (G-Mean) to combine the two into a single score. Since the deep learning algorithm is stochastic, we train five times for each method, then take the average Score of the five training results. The equations for calculating True Positive Rate (TPR) / Sensitivity / Recall / Hit Rate, True Negative Rate (TNR) / Specificity / Selectivity, Overall Accuracy, F1 Score, and G-Mean are as follows.

$$TPR = \frac{TP}{TP+FN} \qquad (3)$$

$$TNR = \frac{TN}{TN+FP} \qquad (4)$$

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \qquad (5)$$

$$F1\ Score = 2 \times \frac{Precision \times Recall}{Precision+Recall} = 2 \times \frac{\frac{TP}{TP+FP} \times \frac{TP}{TP+FN}}{\frac{TP}{TP+FP} + \frac{TP}{TP+FN}} \qquad (6)$$

$$G\text{-Mean} = \sqrt{Sensitivity \times Specificity} = = \sqrt{\frac{TP}{TP+FN} \times \frac{TN}{TN+FP}} \qquad (7)$$

IV.   RESULTS AND DISCUSSION

The results of this study are summarized in Table II. Based on our results, no method consistently provides the most superior performance using three predefined benchmarks. In the Customer Support Ticket Dataset, the highest accuracy was obtained without applying any method, while the highest F1 Score and G-Mean were obtained using WCEL. Furthermore, the highest accuracy was obtained using TL in the News Dataset, while the highest F1 Score and G-Mean were obtained using ROS. Finally, in the Drug Review Dataset, the highest accuracy and F1 Score were obtained without using any method, while the highest G Mean was obtained using WCEL.

TABLE II. COMPARISON OF THE PERFORMANCE IN EACH METHOD

Method	Cust. Support Ticket			News Category			Drug Review		
	Overall Accuracy	F1 Score (Average)	G-Mean (Average)	Overall Accuracy	F1 Score (Average)	G-Mean (Average)	Overall Accuracy	F1 Score (Average)	G-Mean (Average)
None	**0.836**	0.789	0.834	0.892	0.755	0.795	**0.930**	**0.837**	0.904
RUS	0.700	0.656	0.783	0.752	0.658	0.811	0.836	0.672	0.803
TL	0.796	0.722	0.767	**0.900**	0.787	0.825	0.878	0.697	0.801
ROS	0.826	0.784	0.828	0.892	**0.814**	**0.872**	0.916	0.832	0.904
SMOTE	0.810	0.760	0.799	0.896	0.803	0.859	0.904	0.806	0.886
WCEL	0.834	**0.798**	**0.867**	0.864	0.755	0.867	0.926	0.834	**0.906**

Table III shows the comparison of class-level performance for each method for the Customer Support Ticket Dataset. There are three classes/categories: Class 1: Account, Class 2: Customer Service, and Class 3: Transaction. Table IV for the News Category Dataset shows three classes/categories, namely Class 1: Entertainment, Class 2: Politics, Class 3: Tech. Table V the Drug Review Dataset shows five classes/categories, namely Class 1: ADHD, Class 2: Birth Control, Class 3: Tech, Class 4: Insomnia, Class 5: Weight Loss.

TABLE III. COMPARISON OF TPR, TNR, F1 SCORE, AND G-MEAN IN EACH METHOD ON THE NEWS CATEGORY DATASET

Method	True Positive Rate (TPR)			True Negative Rate (TNR)			F1 Score			G-Mean		
	Class 1	Class 2	Class 3	Class 1	Class 2	Class 3	Class 1	Class 2	Class 3	Class 1	Class 2	Class 3
None	0.746	0.892	0.722	**0.934**	0.786	0.958	0.770	0.882	0.714	0.834	0.838	0.830
RUS	0.708	0.648	**0.828**	0.810	0.866	0.864	0.618	0.752	0.598	0.756	0.750	0.844
TL	0.656	**0.896**	0.562	0.920	0.698	0.964	0.686	0.862	0.618	0.776	0.790	0.736
ROS	0.720	0.890	0.740	0.926	0.772	0.962	0.740	0.876	**0.736**	0.814	0.828	0.842
SMOTE	0.710	0.882	0.640	0.914	0.732	**0.972**	0.722	0.864	0.694	0.806	0.804	0.786
WCEL	**0.824**	0.848	0.806	0.908	**0.878**	0.942	**0.780**	**0.884**	0.730	**0.864**	**0.864**	**0.872**

In the Customer Support Ticket Dataset, WCEL has the most superior performance except for the F1 Score in Class 3. However, WCEL's performance is consistently superior to the original data or without applying any method. Although the accuracy produced by WCEL is still less than the original data, the resulting difference is not too far, which is 0.2%.

TABLE IV. COMPARISON OF TRUE POSITIVE RATE (TPR) AND TRUE NEGATVE RATE (TNR) IN EACH METHOD ON THE CUSTOMER TICKET DATASET

Method	True Positive Rate (TPR)			True Negative Rate (TNR)			F1 Score			G-Mean		
	Class 1	Class 2	Class 3	Class 1	Class 2	Class 3	Class 1	Class 2	Class 3	Class 1	Class 2	Class 3
None	0.870	0.934	0.360	0.926	0.848	**0.998**	0.856	0.924	0.484	0.898	0.890	0.598
RUS	0.788	0.736	**0.752**	0.810	0.876	0.922	0.718	0.816	0.440	0.798	0.804	**0.832**
TL	0.856	**0.948**	0.474	**0.944**	0.846	0.994	**0.864**	**0.930**	0.566	0.898	0.894	0.682
ROS	**0.886**	0.910	0.670	0.918	0.892	0.982	0.862	0.922	**0.658**	**0.904**	**0.900**	0.812
SMOTE	0.856	0.930	0.622	0.942	0.862	0.986	**0.864**	0.928	0.616	0.900	0.896	0.780
WCEL	0.864	0.874	0.718	0.918	**0.906**	0.954	0.844	0.908	0.514	0.890	0.886	0.826

In the News Dataset, SMOTE has consistently superior performance over the original data, although it is not superior to other methods. On the other hand, the TL performance is superior to the original data except for the G-Mean Score in Class 2. TL even has the highest accuracy compared to other methods.

In the Drug Review Dataset, the original dataset tends to be superior to the unbalanced class handling method. Although ROS has a reasonably high contribution to Class 4 and Class 5, ROS lowers the performance of Class 1, which is a minority class. In the case of this dataset, it seems that the minority class already has a pretty good performance. In theory, the learning algorithm will have difficulty detecting the minority class.

Based on the results we got, no method has the most superior performance over other methods. Overall, RUS had the worst performance, despite getting the highest G-Mean Score in Class 3 in the News Dataset. ROS and WCEL tend to improve the performance of the minority class, but at the same time, sometimes, these methods also reduce the performance of the majority class. Meanwhile, TL and SMOTE performed exceptionally well on the News Dataset, but not on the other two datasets that we used in this study.

Although the data-level method approach contributes to improving the performance of the minority class in some cases, the weakness of this approach is that it takes a long time to resample, except for RUS and ROS. The comparison of the time required for each data-level method is shown in Fig. 5. SMOTE and TL, which performed well on the News Dataset, took resampling time of more than 1.6 hours for SMOTE and more than 3 hours for TL. With a performance increase of <1%, this seems less applicable to the case of big data, where the amount of data available will be much larger, so the time required for resampling will also be longer.

TABLE V.   COMPARISON OF TPR, TNR, F1 SCORE, AND G-MEAN IN EACH METHOD ON THE DRUG REVIEW DATASET

Method	True Positive Rate (TPR)					True Negative Rate (TNR)					F1 Score					G-Mean				
	Class 1	Class 2	Class 3	Class 4	Class 5	Class 1	Class 2	Class 3	Class 4	Class 5	Class 1	Class 2	Class 3	Class 4	Class 5	Class 1	Class 2	Class 3	Class 4	Class 5

V.   CONCLUSION

This study discusses several testing methods for handling unbalanced classes, including RUS, TL, ROS, and SMOTE for data-level methods and WCEL for algorithm-level methods. We used three labeled text datasets with varying amounts of data and levels of balance. The neural network architecture we use is Bidirectional LSTM. We tested five times for each method. From the research results obtained, no method has the most superior performance because the quality of the data is also very influential on the learning model's performance. Both data-level and algorithm-level approaches can, in some cases, improve minority class performance. However, at the same time, The algorithm-level used in this study sometimes also reduces the performance of the majority class. Meanwhile, in the data-level approach, the resulting increase does not seem proportional to the time required for resampling.

Further research on the handling of unbalanced classes in deep learning is needed to produce consistent performance and be implemented effectively and efficiently.

A New Framework for Accelerating Magnetic Resonance Imaging using Deep Learning along with HPC Parallel Computing Technologies

Hani Moaiteq Aljahdali

Faculty of Computing and Information Technology
King Abdulaziz University, Jeddah, Saudi Arabia

Abstract—**MRI (magnetic resource imaging) has played a vital role in emerging technologies because of its non-invasion principle. MR equipment is traditional procedure being used for imaging biological structures. In medical domain, MRI is a most important tool being used for staging in clinical diagnosis that has ability to furnish rich physiological and functional information and radiation and non-ionizing nature. However, MRI is highly demanding in several clinical applications. In this paper, we have proposed a novel deep learning based method that accelerates MRI using a huge number of MR images. In proposed method, we used supervised learning approach that performs network training of given datasets. It determines the required network parameters that afford an accurate reconstruction of under-sampled acquisitions. We also designed offline based neural network (NN) that was trained to discover the relationship between MR images and K-space. All the experiments were performed over advanced NVIDIA GPUs (Tesla k80 and GTX Titan) based computers. It was observed that the proposed model outperformed and attained <0.2% error rate. With our best knowledge, our method is the best approach that can be considered as leading model in future.**

Keywords—Magnetic resonance imaging (MRI); segmentation; classification; acceleration; deep learning

I. INTRODUCTION

Magnetic resonance imaging (MRI) is a fundamental instrument for clinical determination, illness and furthermore in clinical exploration. Because of its solid ability they give rich useful data and non-radiation and non-ionizing nature [1]. MRI is a non-obtrusive imaging approach for acquiring organic data with high spatial goal. Compared to X-ray computed tomography [9], MRI scan times are longer due to the use of a data acquisition system [1], which is sampled by a Fourier domain [15], also known as k-space. The suggestion for this is in parallel imaging and echo imaging [5], to reduce the time required for MRI scanning. However, in clinical diagnostic procedures, imaging speed should be improved at deterioration in order to minimize active movement and burden placed on patients. MRI is a technique used to detect an error or disease in the brain, heart, knees, etc. MRI deals only with X-rays, but is completely different in the medical and biological fields of science. Every MRI (brain, heart) has same technique but different method. A computer, GPU and Graphics plays [5], an important role in this biological technique. The most important part of this technique is algorithm which tells how the machine behaves and which command applies to which time.

Deep Learning (DL) is the foundation of this strategy since basically everything done by profound learning. DL is a part of AI dependent on the utilization of numerous layers to learn information portrayals [1], and can be applied to both regulated and unaided learning. These various layers permit the machine to get familiar with different level highlights of information to accomplish its ideal capacity.

Deep learning techniques with validated neural networks have been recently incorporated into clinical imaging, where successfully used to demonstrate the effects of dividing parts of the brain, brain tissue, cardiac structures, bone and cartilage on MR images. The purpose of this study has been to develop and test the feasibility of in-depth study methods in MR imaging. The Harmonic phase (HARP) algorithm is a medical imaging image detector that is able to extract and process motion information from a magnetic resonance image (MRI) sequence. CNN based Training and Classification [3, 4, 24- 26], MRI Brain Imaging. These days, CNN plays a major role in the fine-tuning and testing of brain tumors present in Magnetic Resonance Imaging (MRI) imaging. Graphics is also important in MRI to improve image quality.

During the past few years, compressed sensing and later deep learning have remained in forefront of accelerated MRI gaining, leading to large and important improvements in terms of the time efficiency of image acquisition (time efficiency plays an important role to reduce the cost) with a hardly obvious reduction in image quality. The purpose of the study focused on the stage of image restoration and resolution [3, 14], trying to recover high quality MRI scans from reduced sets of their measurements available through partial sampling of the k-space. At the same time, recent studies have also attempted to directly increase the geometry of k-space trajectories, indicating further improvements. This method also improves image quality by reducing the movement. There is another technique like MRI called Fast Magnetic Resonance [2], Imaging (MRI) which is much needed in many medical applications. This method also improves image quality by reducing image movement. The method can reconstruct each image in 0.22ms-0.37ms [2], for real-time applications. Once the desired resolution has been selected the minimum scan time is determined by the need for sufficient data to meet the NY-Quist-Shannon [16], sampling procedure. Compression sensing (CS) vision is fully compatible with MRI scanning sequence design with very little data needed for image reconstruction. Reconstructing and reconstructing MRI images in sample data at high speed in the data acquisition process leads to deep

network-based learning. MRI is associated with the speed of detection that slowly detects the sample information which is not directly collected in the image area, but rather in the k-space because the term contains general spatial information. The speed where k-space can be detected is limited due to physical and hardware constraints. The fast MRI approach is under k-space-for-sample, which can provide a rate proportional to the under-sampling ratio. The challenge for rapid MRI is to find an algorithm that can reconstruct the image from under-sampled data [15].

A. Challenges

Some of the challenges faced are given below:

1) GPU Computation: Computational acceleration in the graphics analysis unit (GPU) can create high-resolution imaging of magnetic resonance imaging (MRI) in clinical settings, thereby improving the quality of MR images over a wide range. Because of the huge size of the dataset, it is unimaginable to expect to stack patches for all subjects in PC memory without a moment's delay. To quantify this, a Python generator is required to pick and deliver fixes independently for each group.

2) Connectivity: Useful network is by and large arranged by assuming chronicles that the transient relationship between two cerebrum districts is driven by low recurrence motions. In this work, we utilized example free planning to distinguish possibilities in the hubs of the mind organization, which are regularly examined with useful availability MRI, and these occasions are displayed to happen in short and long windows that add to estimated network availability [18].

3) Sensitivity: We further investigated the case wherein the sign can show up in one of a few areas and found that CNN spatial affectability relates to IO. Notwithstanding, CNN affectability was far underneath ideal in identifying some complicated surface examples. These estimations recommend that CNNs might have exceptionally huge execution contrasts when distinguishing the presence of spatial examples. The case wherein the sign can show up in one of a few areas and found that CNN spatial affectability compares to IO [27-33]. Nonetheless, CNN affectability was far underneath ideal in distinguishing some complicated surface examples. These estimations recommend that CNNs might have exceptionally huge execution contrasts when distinguishing the presence of spatial examples. These distinctions might majorly affect the exhibition of imaging frameworks intended to recognize low spatial examples [17].

4) Noise Reduction: Noise reduction due to lack of locally changing Russian noise in MR images. With the advent of intensive learning methods, some pre-processor steps have become less important to the performance of previous sections. For example, curvature change and quantitative-based power standardization are often effectively suppressed by z-score estimates, while serious practice-based separation shows another work improvement when applying standardization prior to the process [19].

5) Intensity Normalization: The normalization of noise is toward planning the power of all images on an ideal or reference scale, for example, somewhere in the range of 0 and 4095. Regarding the de-learning system, processing the z-score where one makes a cut is the division of pixels by the normal picture force and the standard deviation of power from all the pixels in a picture, another well-known speculation process [19].

6) Collecting Multiple Types of Data: Another test is that the events for which we have sufficient information, is typically only one sort of information, for example, picture information. In any case, just seeing pictures can tackle specific clinical issues. In case it is an issue of distinguishing an infection from a picture that identifies a disease type characterized from a pathology picture, or an irregularity out of the radiology picture, then, at that point, a solitary information type is likely adequate. In any case, numerous issues require additional information from only one mode. Specifically issues like a clinical forecast; more reference is required with regards to patients given by clinical record information and pathology [20].

7) Scanning Cost: Fast magnetic resonance imaging (MRI) has become very popular for some clinical applications, thereby reducing test costs and improving patient experience. The quality of the film can be improved by minimizing antiquity and time differences. Presumably, when selecting the image view and the appropriate target, the initial test time is usually determined by a precondition to obtain sufficient raw information in accordance with the Nyquist–Shannon test criteria [2].

8) Image Reconstruction: The process of converting the acquired raw data into image is called image reconstruction and on modern MRI devices, it is finished by committed reconstruction software that fills in as a magnet encoding gadget with inclination and radio recurrence equipment. Radio recurrence radiation is transmitted to the patient, where it animates the charge of the tissue and discharges radio recurrence signals from the tissues. The radio recurrence loop is utilized to accomplish the superposition (all out) of all tissue signals [21].

9) Point Spread Function: A significant component of the picture is the point show work, which shows how much neighbors are seeping from one another because of inflexible spatial goal and different impacts. PSF is a picture gotten by replicating a solitary point object. With the fitting point engendering capacity, the picture of the point source must be a picture with a sign of a solitary pixel. Be that as it may, explicit point publicity exercises in MRI digress altogether from this perfect structure. [21].

10) Speed of Detection: MRI is associated with slower detection speed, due to data samples it can be collected directly in the image area, but instead in the k space, which contains standard location data. Here the k-space and image and image are related to deviations, the setting of one domain is limited to another. Samples of raw data are sequentially

available in the k-space and the speed at which the limited k-limited space can be obtained due to visual and hardware constraints. When taking the necessary field view adjustments and MRI predictions, the green details k-space we need to find traditionally are determined by Nyquist's procedure - Shannon's procedure [39].

Leading to existing accelerating MRI, a list of challenges is presented in Table I as follows.

TABLE I.   CHALLENGES TOWARD ACCELERATING MAGNETIC RESONANCE IMAGING

#	Challenges	Description
1	GPU	System required to form quality image to detect disease.
2	Connectivity	Connectivity MRI, and have been shown that these events occur over short and long windows Contribute to measured network connectivity.
3	Sensitivity	CNN sensitivity was far below optimal in detecting some complex texture patterns.
4	Noise Reduction	If noise reduction is not lesser the noise observed in MRI image. However, improvement appears when applying normalization before the intensive learning-based segmentation process.
5	Intensity Normalization	Normalization of power is the way toward planning the force of all pictures to a normal/standard or reference scale.
6	Collecting Multiple Types	Another challenge is that if you have got enough data, it is usually just one type of data, such as image data
7	Scanning Cost	This can likewise conceivably build the picture quality by lessening the movement ancient rarities and difference waste of time
8	Image Reconstruction	Reconstruction networks for multi-coil data, By expanding the deep cascade of CNNs and leveraging data consistency Layer.
9	Point Spread Function	Feature of an image is the point dispersion function.
10	Speed of Detection	Desired field-of-see and spatial goals of MRI pictures are resolved, the k-space crude or raw information.

II. LITERATURE WORK

In this article, we investigated twenty relevant approaches from different research articles that are presented in this section.

Wang, Shanshan, et al., [1], proposed a deep learning method for accelerating magnetic resonance imaging (MRI). MRI is an essential tool in medical diagnostics, diagnostics and in clinical research because of its rich quality and robust dynamic properties it provides anatomical and functional information. Trying a deep learning process at the highest level of data has shown an explosive popularity with many layers of research on the availability of powerful GPUs. It also used the neural network (CNN) to find objects. The resulting off-line neural network was also designed and trained to detect the map relations between the MR images obtained from the full zero and k-space data. Experimental results in MR data have the advantage of efficient and accurate thinking. The CNN network studied the end-to-end mapping between MR images with a sample and zero saturation.

Warach, Steve, et al. [2], the author proposes a Fast Magnetic Resonance Imaging (MRI) is in high demand in many clinical applications to reduce scanning costs and improve the patient's experience and knowledge. This method improves image quality by reducing movement. Once the required resolution is selected, the minimum scan time is determined according to the need for sufficient data in accordance with the sample criteria. Sample data is not stored directly in image space, but is associated with slower acquisition speeds than K-space, because the term contains spatial-frequency information. K-space travel speed is limited due to physical and hardware limitations. The fastest MRI procedure is the under-sample K-space, which provides the acceleration rate with the under-sample ratio. The challenge for Fast MRI is to find an algorithm that can reconstruct an image from under-sampled data and change the name.

Authors said about the accelerated parallel MR image reconstruction in [3], the paper proposes a reconstruction networks for multi-coil data by extending deep cascade of CNNs. There are two articles which one is POCSENSE and the other one is calibration-less. The networks are the extensions of CNN deep cascades (DC-CNN), where the sub-networks and data consistency layers are between them. For parallel imaging, the data layer can be extending two network variants, which can be computed by using such type of algorithms. Authors presented a novel method for studying conflicting transitions from one MRI to another in [5]. Because MRI images are available for diagnostic purposes, when this happens is distributed, this information is zero. Although the data used here include only healthy subjects, future work will include pathological images of tumors. The main strength of magnetic resonance imaging (MRI) is the ability to measure different tissue differences. To evaluate our results, we compare the number of different network depths, input features, and training topics [34-38].

According to [6], Magnetic resonance is one of the most important diagnostic and therapeutic indicators, as well as the degree of physical and physical impairment of magnetic resonance scan acqustism when MRI reconstructs high-resolution imaging based on local K-cell data, the use of existing network data in which Kranselskii - Mann iteration for K-space translate algorithm is used to make a tread pattern for detailed study of low frequency sampling and Gaussian random sample and similarity. The proposed provided the reconstruction results among other CS and parallel imaging algorithm comparison. The KM method uses k-space scaling, which also improves the reconstruction efficiency.

In [7], authors said about the network acquired through read-only transmission using tens of images in the test domain which achieves almost the same performance as the network specially trained for thousands of test images. The networks were well-formed MR images with various experimental domains. Differential diagnosis of soft tissue on MRI has made it a common practice in many diagnostic applications. Due to the diversity and features of natural and MR images, the use of the Image Net test network domain is scheduled to be the end of tens of images. Network training is a distortion of the supervised learning process aimed at obtaining a set of network parameters that reach reconstruction under pre-acquisition. In

which deep architecture is used with many subnetworks. The subnetwork consists of CC and CNN blocks, and each block follows the DC block and in which each CCN block is trained sequentially so that they are recombined to synthesize images of multi-coil nature from ImageNet Can be synthesized from ImageNet under Zero-filled Fourier reconstruction [40-45].

Author investigates about the deep learning electrical properties tomography (EPT) [10], for application to various simulated and in-vivo datasets including pathology to obtain quantitative brain conductivity maps. However, from the results this concludes that networks can be restricted to data that have anatomic geometries and artifacts that are very close to those present in the training data. This emphasizes the importance of completing training information relating to the geometry of the brain and tissue components. In addition, in addition to the accuracy of the standard EPT method, the training dataset must include many types of in-vivo techniques as well.

According to Sandino CM, Dixit N, Cheng JY, and Vasanawala SS [8], aims at the deep neural network of fast dynamic magnetic resonance imaging, which can be accelerated using integrated methods of building architecture, which allows the detection of image quality under sample data. Unfortunately, CS reconstruction takes hours between dynamic MRI scan and image availability for diagnosis in this work. CNN improve rapid reconstruction. Dynamic magnetic resonance imaging the MRI organs, such as the heart and brain, must be continuously scanned over a long period of time to obtain a series of images that illustrate the anatomy and magnitude of movement. Longer scan times accelerate the exploited narrow sensory reconstruction schemes [48-51].

Repetition of dynamic MRI acquisition in space and time can be used to achieve high spatio-temporal resolution while interpreting data.

In [9], authors raise Dynamic cardiac MRI obtained using similar assumptions, in which Fourier data is obtained by multiple recipients in a variety of locations. For the purpose of CNN reconstruction, the Fourier raw data is converted into a photographic background because it is a natural environment above the photographic background because it is a more natural environment for layers of spatial exploitation spaces. It also gives CNN a hot start, as you don't have to study Fourier to convert images. This construction occurs very quickly when raw data is sampled from the Cartesian grid in the Fourier space, as is the case in the examples shown in it. We also wanted to simplify CNN installation by mixing data from multiple accepted pounds into a single installation image. This is done using the total number of non-reconstructed image groups from each recipient.

Qin, Chen, et al., [10], discussed about Neural networks have recently received interest in reconstructing MR detection under the sample. Network performance should be best done through training and testing of data from the same domain. The purpose of this study was to introduce a transfer method to solve the problem of data shortages in training complex high-speed MRI networks [46-48]. Neural networks are trained in thousands of samples from public data of natural images or MR images of the brain. The network was then configured to use only dozens of MR brain images in a separate test domain. A comparative analysis of existing techniques has been presented in Table II as follows.

TABLE II. COMPARATIVE ANALYSIS OF EXISTING DEEP LEARNING STATE-OF-THE-ART TECHNIQUES USED TO ACCELERATE MRI

Ref.	Proposed Model	Characteristics	Used Technology	Limitations
[11]	U-Net	The Refinement Module (R) puts multi-kilogram coil data into a single image, enters U-Net, and reverts back to multi-coil data.	• Sensitivity Map Estimation (SME)	Variational network with the shallow CNNs replaced with U-Nets (VNU
[12]	E2E-VN	The proposed end-to-end (E2E-VN) network model is proposed. E2E-VN demonstrates the importance of reading sensory maps as part of a network.	• SSIM	Adjustment of parameters
[13]	VGG 19	The idea of using small filter filters is popular and therefore deep networks and deep training networks using pre-configured fixed versions	• PROSTATEx	noncancerous tissues with multi-parametric MRI using data
[14]	DenseNet	This energizes include reuse and brings down the quantity of boundaries for a given profundity. Thick Nets are in this way especially appropriate for littler informational indexes.	• CPU,CNN	Expands on the thoughts of ResNet, yet as opposed to including the actuations created by one layer to future layers, they are essentially linked organised.
[15]	ResNet (18,34,50,101, 152, Upto 1001)	Increase the accuracy to maximum	• CPU, but if we go deeper layers up to 1000 then need GPU & TPU	Computational cost increase rapidly
[16-18]	Sigma Net	enhance the learning ability of the CNN by making it deeper	• NVIDIA GTX 580 GPUs	With an increase in depth system is overfitting.
[20-21]	Alex Net	enhance the learning capacity of the CNN by making it deeper	• NVIDIA GTX 580 GPUs	With an increase in depth system is overfitting
[22]	Res Next	Expands on ResNet and Google Net by utilizing beginning modules between skip associations	• Google Net	Quadratic time increases
[23]	NASNet	The control network (standard neural network) proposes a construction that aims to perform at a particular level of work, and by test and error learns to propose an improved models.	• AutoML	NASNet was based on Cifar-10, and has diffident computer requirements, but quiet has a very good facial features

III. PROPOSED METHODOLOGY

In this section we have presented the proposed architecture that shortly explains the algorithm that how the machine works efficient and fast. Our article shortly tells how the imaging works in MRI with help of GPU [48-51]. In this field, if you do have graphics, and not reduce the motion of the imaging, without these things your machine can't work efficiently and it becomes useless. If you have an algorithm but based on the big data and the if you have an another algorithm the work efficiently but in small amount data that reason of time efficient algorithm because both work same but one takes time and other one is easy to implement and time efficient, that's the reason to improve our technology. In this architecture, in offline training use simulate calibration data that is used in MRI for the measurements then use learn dataset parameters and simulate calibration data that's use database and send to data in data base to learn the data that is also a raw MRI data and use model interference that is helpful for images reconstruction and used for MRI scanner that extracts calibration data and to send data to model inference and then image reconstruction; then used graphics for image output to clear the image and improve the patient experience and scanning cost. In our model that is going to propose, adding some important functionality that improves the performance of algorithm and proposed architecture. This section provides material, the source of the brain MR image dataset, and the algorithm used to perform brain MR tissue segmentation. Fig. 1 presents a block diagram of our proposed model. The total number of pieces for all channels is 15, which leads to 200 pieces or 9 slices with a total of 135 images per patient, 1 mm inter-slice gap and 0.78 mm size tone. 0.78 mm × 0.5 mm. The proposed method is applied to real datasets containing 512 × 512 pixel size brain MR images and converted to grayscale before further processing. The following sections discuss algorithm implementation.

In the article, architecture that we compared to our architecture, this architecture works according to their own algorithm. In this architectre, there is a training phase and

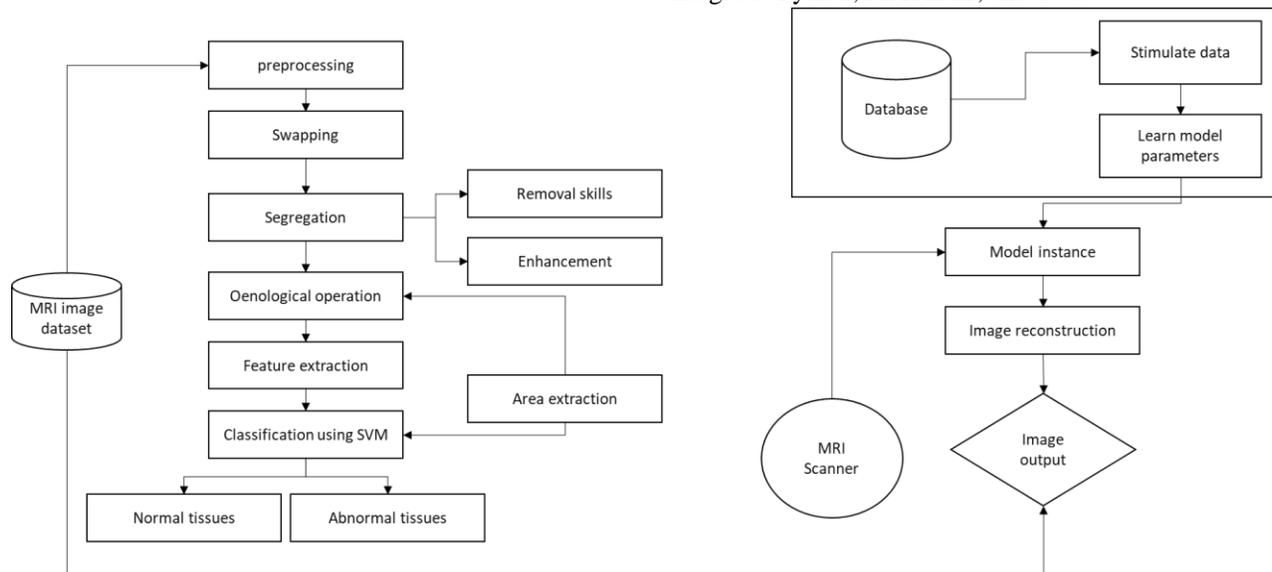
Recon phase. Firstly the machine input CT image and in training phase input the reference mask if the reference or related image or mask is loss the data is in CAE and train the data filtering the image and pseudo CT and PET raw data that is not useful but sometimes that is useful is some-terms but this algorithm is not useful because some errors and this architecture can't reconstruction about the image, time efficiency, scanning cost and reduce motion of image. This Architecture is a stack of two-dimensional axial images. All composite input images were optimized using standard calibration and plotted with a 340 x 340 matrix size using pre-translation as the default Auto encoder (CAE) input. The encoder weight and the disorder wheels weight when initialized using the initialization program are defined and updated using the sliding scale domain with a constant rate of 0.01 to 0.9. The intermittent CAE network estimates growth tissue marks and analyzes them to the file veils produced by CT information. CT reference subtleties affirm that the organization comprehends the connection between MR pictures and reference names. The framework was arranged using multiclass cross-entropy setback as an objective work, where the not really settled in a more modest than ordinary bunch of four pictures in each emphasis. Network preparing is performed on 60000 cycle steps, comparing to 33 hours of preparing information to accomplish preparing changes. Preparing subtleties were changed before every mishap to make irregularity in clump preparing. Other organization boundaries incorporate an expanding number of channels from 64 to 512 from the primary layer to the furthest limit of the implanting organization. The maximum derivation layer utilized a 2 X 2 window with column 2, bringing about a custom picture decrease of 2. The high-goal decoder network test utilized close-up areas, which increment the picture size by 2 things for every layer. When the preparation stage was finished, the design of the CAE network was ready and used to record the bones, air, and delicate tissues of the new MR pictures, which were subsequently handled into pseudo CT pictures. In this Framework the in-depth MRAC framework was developed in an integrated computational environment that integrates Python, MATLAB, and C / C ++.


Fig. 1. Block Diagram of Proposed Method.

A. *Skull Stripping*

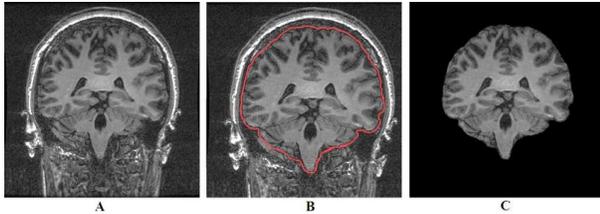
Head trauma is the process of separating brain tissue (cortex and cerebellum) from the nearby region (skull area and no brain). It is also a very important preparatory step that follows further analysis if there are multiple neurological MRI images (such as image registration or tissue fragmentation). Fig. 2 presents the multiple steps of tissue fragmentation.


Fig. 2. Tissue Fragmentation Steps.

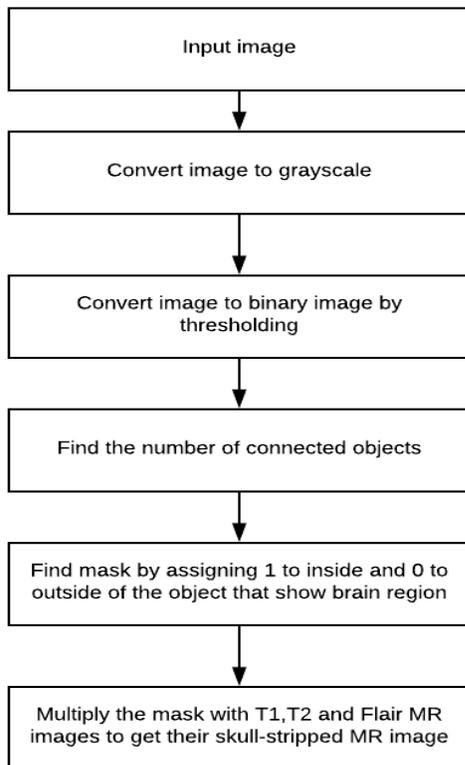
Skull Stripping/Head trauma is an important process in biomedical image analysis, and it is necessary to successfully diagnose brain tumor from MR images. Skull removal is the process of removing all the tissue that is not working in the brain tissue. By removing the skull, you may be able to remove excess tissue such as fat, skin, and skull from the brain. There are a few schemes available for skull scanning; other popular techniques are to disassemble the skull using a contour image, skull dissection is based on segment and morphological function, as well as the ripping of the skull based on the analysis of the histogram or number of divination. Fig. 3 presents the skull stripping algorithm sections. This study uses a skull stripping method based on the threshold function of the skull to remove skull tissue.


Fig. 3. The Phases Followed in Skull Stripping.

IV. EXPERIMENTS AND RESULTS

The data training comprises of north of 500 completely tested MR mind pictures we gathered from a 3T scanner (SIEMENS MAGNETOM TrioTim). The pictures are of an incredible variety counting hub, sagittal, level ones, different ones, for example, T1, T2 and PDweighted pictures and of various sizes. Informed assent was acquired from the imaging subject in consistence with the Institutional Review Board strategy. Undersampled estimations were reflectively gotten utilizing the 1D low-recurrence testing cover and the 2D Poisson circle inspecting veil. The enormous measure of ruined/ground truth subimage matches are then produced with the size of 33×33. At long last we utilize 90% of the subimage matches as the preparation dataset and the rest 10% for approving the preparation interaction.

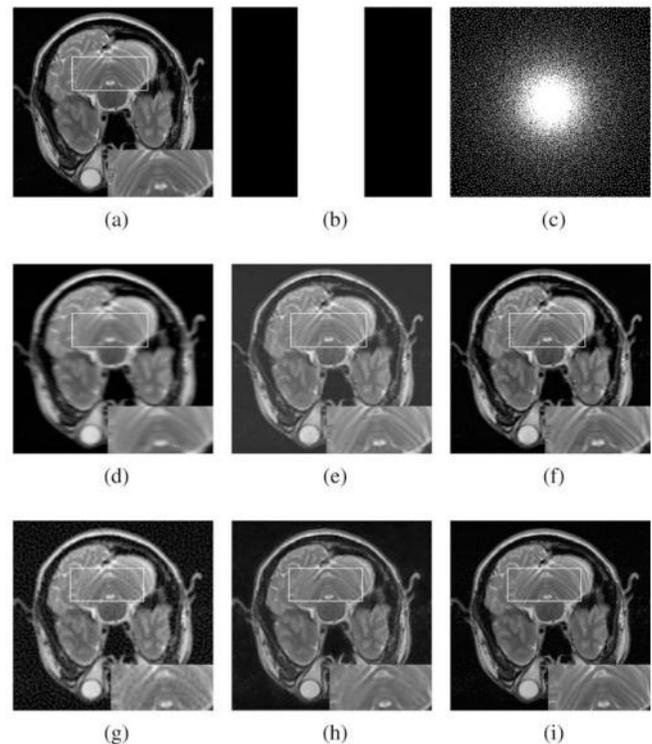
We utilize three layers of convolution for the organization. The boundaries are individually set as n1 = 60, n2 = 30, M1 = 10, M2 = 6 and M3 = 4. The channel loads of each layers are instated by irregular qualities from a Gaussian dispersion with zero mean and standard deviation 0.001. The predisposition are completely introduced as 0. The preparation requires around three days, on a local machine with 16G memory and 24 CPU Intel Xeon processor with 2 Quado 6000 GPUs. Fig. 4 shows a bunch of recreation consequences of a cross-over mind picture.


Fig. 4. Recreation Output of a Transversal Brain Image.

The cerebrum dataset was acquired completely tested with 12-channel head curl and T2-weighted super twist reverberation (TSE) succession (TE = 91.0ms, TR = 5000ms, FOV = 20×20cm, grid = 256×270, cut thickness = 3mm) by means of 3T scanner. Furthermore, the information was then undersampled reflectively with 1D low-recurrence examining

cover at a speed increase component of 3 and the 2D Poisson plate at a speed increase component of 5. We likewise tried the proposed strategy on a sagittal mind picture.

which was procured on a GE 3T scanner (GE Healthcare, Waukesha, WI) with a 32-channel head curl and 3D T1-weighted ruined angle reverberation grouping (TE=minimum full, TR= 7.5ms, FOV=24 × 24 cm, framework = 256 × 256, cut thickness=1.7mm). We can see from the pictures that there are many subtleties and designs caught by the organization. Besides, the picture created by the basic reproduction model is very near the unique picture. As indicated by Fig. 4(f), we can see the distinction picture is clamor like and comprises just the shape data. There are no conspicuous subtleties and designs lost. It exhibits that the proposed network is fit for reestablishing the subtleties and fine designs which are disposed of in the zero-filled MR picture. Moreover, albeit the disconnected preparation requires approximately three days, under similar GPU designs, it takes undeniably under 1 second for each web-based MR recreation case.

V. DISCUSSION AND RECOMMENDATION

All the previous articles that is based on the imaging, time-efficient and reducing cost but there is an error in some type of algorithms, their algorithms is not more efficient, fast and mainly highly graphical imaging to reduce the high type of motion. The challenge of fast MRI is to find an algorithm that can reconstruct and remove the image from the sample data below. The authors argue that, through time propose an analytical learning method for training generator network and stabilize training with rapid integration environment and less parameter input. In the dynamic visual field of MRI imaging such as heart and brain it should be continuously monitored to obtain a series of high-resolution images and over time. Various loss functions used for CNN training appeared in the developed models, which were quantitatively and qualitatively similar to CNN reconstructions. In the article, we want to train GAN's algorithm for other complex tasks such as perceptual loss or reconstruction. The best approach would be to train deep reconstruction in the radiologist network, which shows images in parallel scores provided by the radiologist or radiologists committee. However, this may require a large amount both data and time of radiologists. We have designed and implemented a GPU, Graphics and algorithm based fast magnetic resonance imaging (MRI) that uses deep learning neural network term to improve patient experience, scanning cost, time efficiency, image quality and reduce its motion. The algorithm matters because if the algorithm is faster and best, the machine works efficiently. Our architecture proposes a short overview of algorithm that works fast, time efficient and mainly to detect errors and disease. In imaging, Graphics plays an important role for enhance the patient experience and improve the reliability to detect more problems and disease more efficiently. Compared to CS-state of the art reconstruction techniques, our CNN achieves 150x faster reconstruction speed without any loss of image quality. Our main purpose is to maintain the image quality and its reconstruction. Connectivity as you know connectivity is the main part if your connectivity is not stable you result is in doubtful so build a strong connectivity with an algorithm and its commands. Sensitivity, is used to detect text patterns so it's

a challenge however, we use an algorithm to detect low spatial patterns.

In this study, using MR images of the brain, we isolated brain tissue into normal tissues such as white matter, gray matter, cybrospinal fluid (posterior) and infected tissue. MRI is associated with slower detection speed, due to data samples that can be collected directly in the image area, but rather in the k space, which contains general location data. Here the k-space and the image and the image are related to deviations, adjustments in one domain set limits on another. Samples of raw data are sequentially available in the k-space and the speed at which the k-limited space can be detected is limited by visual and hardware constraints. When the required field view resolution and MRI imaging is taken, the raw k-space data we need to obtain is traditionally determined by Nyquist - Shannon's sampling process. In short, we recommended all the parts in our architecture that how's our algorithm works and output the image this is main concern of GPU. If the algorithm works efficiently your data output gave efficient report to reduce the scanning cost, works on skull skipping and dataset these are the terms to improve the patient experience and also improve the image reconstruction and image quality.

VI. CONCLUSION

This study presented an accelerated magnetic imaging resonance remaking through Deep Learning. We determined that CNN can be utilized to display MR images recreation of 2-D information. Time reconstruction is accelerated by a factor of 150 in comparison to ES-PIRIT. The study experiments showed that there is two factors time scan to accelerate CNN model. In order to reconstruct MR images, several algorithms exploit the redundancy while receiving data from different receivers concurrently. Initially, we collected data from 32 receiver channels that were merged to a single channel by adopting whole-square operation. We observed that to train data over multi-channels, it is a tough and complex process; however, neural network models should be able to learn parallel imaging. The main purpose of this is to maintain the images graphics in very short period of time to maintain or lower the scanning cost with help of creating efficient algorithm. Recent developments documented show great potential for in-depth learning strategies in the field of MR brain image analysis. Even though further developed learning strategies have been utilized for brain MRI as of late. They are primarily emphasizing to move from traditional existing methodologies to mature AI/ML/DL based models. In bioinformatics, the brain MRI analyzing has been a vital challenge in computer based methods because of its complex structure and variations in appearance. MR scale does not match the scale due to differences in cognitive conventions, image retrieval, and the existence of pathology. Therefore, there is a need for familiarity strategies such as in-depth learning that can manage these differences.

Abstract—As a viable technique for next-generation wireless networks, Device-to-Device (D2D) communication has attracted interest because it encourages the usage of point-to-point communications between User Equipment (UE) without passing over base stations (BS). Device-to-device (D2D) communication has been proposed in cellular networks as a supplementary paradigm to primarily increase network connection. This research takes into account a cellular network where users are trying device-to-device (D2D) connection. A D2D pair is composed of two D2D users (DUEs), a transmitter, and a receiver. To improve spectral efficiency, we use the premise that the D2D pairs only employ one communication channel. In order to minimize interference between D2D pairs and increase capacity, a power control is required. In the scenario where only typical cellular channel gains between base stations and DUEs are known and channel gains among DUEs are completely inaccessible, we address the issue of D2D power control. For each individual D2D pair, we use an artificial neural network (ANN) to calculate the transmission power. We show that the maximum aggregate capacity for the D2D pairs may be reached while anticipating the transmission power setting for D2D pairs using cellular channel gains.

Keywords—*Artificial Neural Network (ANN); Base Stations (BS); CUE; Device-to-Device (D2D); DUE; ML; User Equipment (UE)*

I. INTRODUCTION

In general, the allocation of spectral resources and power control are two processes that are not separate from one another. Power control is a way to limit interference between network users while guaranteeing the minimal quality of service requirements. Interference between cellular and D2D users occurs when shared resources are assigned; in this scenario, the transmission power of the D2D user is lowered in accordance with the minimum reference value of the cellular communication. Thus, the network can also establish a maximum transmission value for D2D devices, depending on the impact of the different power levels of the devices on the quality of the cellular links.

Since there is minimal to no chance of interference between D2D and cellular users, the transmit power may frequently be greater when dedicated spectrum resources are allocated to D2D devices rather than shared resources. Thus, the management of spectrum resources can be carried out mainly by the network or by the devices themselves. In dedicated sharing, devices must be aware of the environment and use resources adaptively, trying to cause minimal interference to other users. Leaving resource management in

the hands of the device it results in a less predictable process, but with greater flexibility and less complexity.

Power control is one of the most often used interference avoidance methods [1]. This technique allows an adjustment of maximum D2D transmission power so as not to exceed the predefined SINR limit in cellular communication that is, the transmission power level can be limited by the eNB in order to reduce potential interference to cellular receivers. In addition, the eNB can also control access to shared cellular communications resources and D2D peers, which represents greater efficiency in the use of spectrum [2].

However, this technique is simple, but not efficient, in the sense that by placing the restriction at the D2D power level, it implies that it may affect D2D communication, that is, it results that D2D communication may not always be viable.

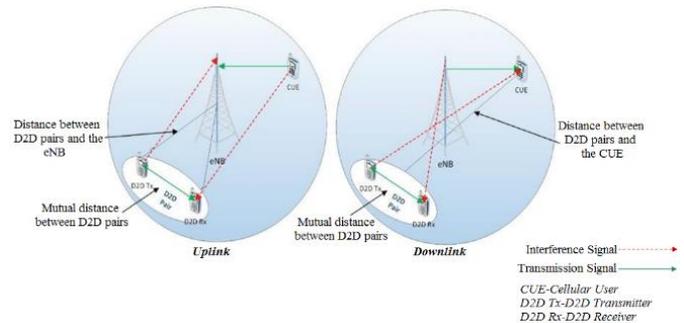
The schematic depiction of the power control strategy is shown in Fig. 1. The distance between the D2D pairs, the distance between the D2D pairs and the eNB, or the distance between the DUE_T pairs and the cellular users (CUE) all have a significant role in how well this strategy works.


Fig. 1. D2D Power Control Technique [3].

The performance of the D2D communication is unaffected by the power reduction if the D2D pairs are close together and remote from the eNB or CUE.

The D2D power reduction can provide a very low probability of D2D communication or even completely preclude communication between the D2D pairs in the opposite scenario, when the distance between the D2D pairs is great while also being reasonably close to the eNB or CUE.

In spite of this, the power management strategy only works well for reducing D2D communication interference in cellular communication when the D2D pairs are near together and at the same time separated from the eNB and/or CUE. The

performance of D2D communication might be harmed by severe regulations that limit the transmission power of D2D users.

II. LITERATURE REVIEW

Machine learning has application in a wide range of fields: image processing, audio, finance, economics, social behaviour analysis, telecommunications network management, the latter being one of the most promising applications of this branch of artificial intelligence [4] [5] [6].

Telecommunications networks are now able to learn from and extract information from data thanks to the discipline of machine learning's growth. The latter is of vital importance for new wireless network standards such as 5G [4] [5] [6].

Until now, the development of machine learning and telecommunications networks have been carried out as different research fields, but the application of ML in 5G networks has demonstrated the present and future potential of this combination of paradigms and technologies. It is now clear that this is the case with mobile edge computing, location-based services, contextual networking, edge caching, network traffic monitoring, and big data analytics [4] [5] [6].

Machine learning is perfect for difficult problems that need a lot of human fine-tuning to solve or for problems for which there is no traditional answer. The above problems can be addressed by replacing conventional software that contains a large number of rules with software (containing ML routines) that is capable of automatically learning from data. Automatic feature extraction, anomaly detection, scenario prediction, environment adaption, information gathering on complicated issues with enormous volumes of data, and pattern discovery are some of the distinctions between machine learning algorithms and conventional cognitive algorithms [4] [5] [6].

Many parameters in wireless and mobile networks are estimated using heuristic techniques because there is no analytical answer or because it is impractical given its complexity and related expenses. In these situations, machine learning algorithms can aid in the resolution by forecasting and estimating variables and functions based on the existing information [4] [5] [6].

Despite the advantages of using ML, this technique has limitations that prevent its widespread use in wireless communications, including the findings' interpretability, the difficulty of locating pertinent data, the needed processing power, the complexity added, and the lengthy training cycles of some algorithms, among others, which cause the cost, time, latency and delay introduced to be incompatible with some real-time applications [4].

Despite the difficulties to be overcome, it can be said that machine learning is already widely used in the modelling of a variety of technical issues of next-generation systems, including large-scale MIMO, low-latency communications, heterogeneous networks made up of femtocells and small cells, vehicular networks, D2D networks, among others [4] [5] [6] [7] [8] [9] [10] [11] [12] [13] [14] [15].

Basically AI is any technique that allows computers to imitate human behaviour; ML are those algorithms that use statistical techniques to allow machines to "learn" through experiences; and Multi-layer neural networks are used in the deep learning subfield of machine learning to carry out algorithm execution [4] [5] [6].

D2D communications were initially found to be beneficial for increasing spectral efficiency and frequency reuse, while reducing communication delays. However, this mode of communication has introduced additional interference due to multiple simultaneous communications on the same frequency bands, which is difficult to control and mitigate. This is especially true when D2D communications take place in Inband and/or Underlay circumstances, i.e., on the same frequency as the cellular network and/or concurrently with cellular communications [16].

Numerous academics have looked at resource distribution challenges in this setting, such as connecting for D2D communications and power and frequency distribution. The performance of D2D and cellular communications in a basic wireless network was examined by the authors of [17] in relation to the effect of the QoS requirement on latency. They developed the best power allocation strategies taking into account statistical QoS provisioning in order to maximise network performance while adhering to QoS limitations.

The authors of [18] described an underlying D2D-based network that allows D2D users to serve as a relay for cellular communications in order to optimize the transfer rates that D2D users may achieve while still meeting the QoS criteria of cellular users. The best power allocation technique for the base station (BS) and the D2D transmitter is found in closed mode when there is a global power restriction. Moreover, the simulation results demonstrate the superiority of using D2D devices as complete relays compared to classical cellular communications.

In order to increase the overall throughput of cellular and D2D users while maintaining the required minimum QoS for WiFi users, the authors of [19] investigated the issue of shared channel and power distribution. They proposed a particle warm optimization (PSO) algorithm, which significantly reduces interference in both licensed and unlicensed bands and improves throughput performance. This work has focused on the derivation of optimal solutions or heuristics that are applied offline, i.e., with the a priori knowledge of the state of the entire system. For online deployments, where device locations and channel conditions are constantly shifting, these techniques would be insufficient. The research has suggested increased learning methodologies as a solution to these problems.

In [20], the authors proposed a Q-learning method that jointly assigns channels and power levels to D2D devices to maximize end-to-end traffic flow in an underlying scenario D2D. They showed that their method outperforms benchmarks in terms of average system capacity. The authors of [21] employed Q-learning with logarithmic regret to minimize total transmission power and associations to SB. Then they extended their proposal to distribute Q-learning to reduce complexity. The results obtained demonstrated the superiority

of their approaches compared to benchmarks, in terms of reduction of transmission energy consumption. Additionally, the authors of [22] looked at the issue of power distribution in D2D underlying networks. The authors suggested a D2D power control based on extreme hierarchical machine learning that, in terms of communication speed and energy efficiency, surpasses both distributed Q-learning and CART decision trees. Finally, in order to maximise the D2D sum throughput, [23] developed a deep reinforcement learning strategy for scheduling D2D connections in a cellular underlay network. The results of the simulation showed that the suggested strategy outperformed the conventional procedures.

D2D communications would offload content and traffic off the cellular network, reduce recovery and content delivery, and enhance the energy efficiency of the cellular network, all of which would considerably improve system performance in caching cellular systems. These benefits have been demonstrated in several recent works.

In [24], the authors proposed to cache content either in the cellular BS or in D2D devices. Next, they studied the co-design of the content caching and delivery policy, given their prior knowledge of user demands. The authors described in [25] the D2D cognitive communications underlying cellular transmissions in order to cache files between devices transparently. On BS and D2D devices, they then assessed the delay and queue length. Additionally, the authors in [26] suggested a caching method that reduces the typical content delivery time in a D2D-supported cellular network. They demonstrated the superiority of their proposed greedy algorithm over the naive popularity-based caching policy. In order to maximize the probability of successful transmission, which gauges the percentage of users meeting their QoS delay criteria, the authors of [27] took use of the collaboration between BS caching and D2D caching. They showed that by using the proposed block coordinate descent algorithm, they can achieve significant performance gains over conventional caching methods.

In contrast, the authors of [26] used a user behaviour learning algorithm that predicts user requests and estimates file popularity. Thus, this information is used to adjust the caching policy between D2D devices, with the aim of minimizing transmission delays for file delivery. Simulations demonstrate that the suggested strategy performs better than both probabilistic and naïve caching. In [28], the authors examined the combined cache placement and resource allocation problem in heterogeneous networks with D2D support. In terms of average content delivery times, they suggested two imperfect heuristic methods that outperform D2D-unsupported systems. Authors of [29] examined content placement in the context of a D2D-assisted Hetnet with the goal of reducing the average content delivery time. For a single content library, the optimal solution is obtained and then used to design a low-complexity heuristic for a larger content library. They demonstrated through simulations the advantages of storing popular data in D2D devices inside the cellular system that had the best connectivity to other D2D devices.

The authors of [30] investigated content caching and delivery in a D2D network. They used a deep-Q network (DQN) method to improve content distribution with respect to delays and energy restrictions, and echo-state networks for predicting user mobility and content popularity. In [31-32], the authors formulated a Multi-Agent Reinforcement Learning (MARL) D2D caching problem, aiming to improve the average latency content delivery rate and cache hit rate, without prior knowledge of content popularity. To solve it, they proposed Q-learning for independent learning devices and joint action learning devices. Through simulations, they found that joint action learning algorithms outperform individual learning algorithms and other basic approaches.

Numerous research have been conducted to improve the spectral efficiency of D2D networks using power regulation as a resource allocation problem [33-40]. A non-convex issue, sum capacity-focused power management over D2D pairs. Because of this, a number of iterative techniques with varied degrees of complexity are provided in the literature. But latency problems might arise with iterative techniques. Deep neural networks (DNN) are being employed as an alternative lately by researchers to regulate instantaneous power in D2D communication [34]. Through supervised [35]–[36] or unsupervised [37]–[40] learning based on offline training, the DNN significantly decreases the complexity of power control. Importantly, power control approaches that combine unsupervised learning and the DNN surpass the presently used iterative strategies in terms of cumulative capacity. For unsupervised learning, a DNN loss function is necessary. Examples include the overall capacity as a function of channel gains among DUEs and DUE transmission powers. The fact that all of the aforementioned approaches, both conventional and DNN-based, typically take into account full information of all the D2D channel gains is a significant disadvantage. By feeding the D2D channel gains into the neural network as an input, machine learning techniques change the transmission powers. Sometimes it is possible to reduce the need that channel state information (CSI) contain all distributed D2D channel gain values. In contrast to the signalling needed for conventional cellular communications, even a partial understanding of the benefits of D2D channels indicates that they come at a significant expense in terms of extra channel estimates and signalling.

This paper's main proposition is a unique power control technique for D2D communication based on artificial neural networks (ANNs) that requires no further understanding of the D2D channel gains. Since the channel quality to all nearby base stations is sent during a shared network operation, there is no signalling overhead. Our suggested ANN's main goal is to establish a connection between D2D and cellular channel gains. In order to increase the total capacity, the transmission power of the D2D pairs is then changed using this relation. It is vital to keep in mind that there is no known explanation for the association between cellular channel gains and the overall D2D pair capacity. Therefore, it is difficult to provide a suitable loss function for an ANN based on unsupervised learning. Because we first identify the targeted DUEs transmission powers that increase the cumulative capacity, we employ a supervised learning technique. The ANN is then

trained to create a mapping between cellular channel gains and the target transmission powers in order to arrive at the correct power setting. The whole training procedure takes place offline, and without any further training during communication, the trained ANN is used for swift power control decisions in the real network.

The remainder of the paper is laid out as follows. The proposed methodology for power control in D2D is presented in Section III. Section IV states the problem under study. Section V talks about power control for D2D pairs using ANN. Section VI discusses the MATLAB based simulation outcome of the research followed by the conclusive remarks in Section VII.

III. PROPOSED METHODOLOGY

A. System Model

We take into account a model with M D2D users (DUEs) and L base stations producing N D2D pairings inside a square area (i.e., $N = M/2$ provided M is an even number). To ensure the viability of the D2D connection, the distance D_{max} between the receiver DUE_R and transmitter DUE_T that make up the D2D pair is restricted. It is expected that the common channel is used by D2D pairs. The various D2D pairs that are using the channel interfere with one another. This definition of the nth D2D pair's capacity reads as follows [33]:

$$C_n = B \log_2 \left[1 + \frac{p_n g_{n,n}}{\sigma_0 B + \sum_{\substack{j=1 \\ j \neq n}}^{j=N} p_j g_{j,n}} \right] \qquad (1)$$

Where,

- σ_0 is symbolized for the noise power spectral density.

- p_j represents the transmission power of the jth DUE_T, and $g_{j,n}$ is the channel gain between the nth DUE_R and the jth DUE_T.

- B is symbolized for channel bandwidth.

- p_n is the symbol for the transmission power of the nth DUE_R.

Since it is challenging to predict D2D channel gains, therefore a channel between any DUE_R and DUE_T ($g_{j,n}$ and $g_{n,n}$) is thought to be unknown.

Since D2D users will continue observe the transmit channels to the server base station (for prediction, decoding, etc.), the channel quality information between each D2D user and neighbouring base stations should be periodically measured and reported to the server base station. The $G_{m,l}$ stands for the equivalent expected channel gain between the lth and the mth DUE.

IV. PROBLEM FORMULATION

To boost the overall capacity of D2D pairs, this study effort aims to optimize the transmission power p_n for every n^{th} D2D pair. Since p_{max} and p_{min} are the maximum and minimum transmission powers, respectively, the binary power

control is assumed resulting in $p_n \in \{p_{min}, p_{max}\}$. To optimize their combined capacity, the D2D pairs' transmission power must be set up as follows:

$$P = \arg\max \sum_{n=1}^{n=N} C_n \qquad (2)$$

$$p_n \in \{p_{min}, p_{max}\}, \forall_n \in \{1, 2, \dots, N\} \qquad (3)$$

Where $P = \{p_1, \dots, p_N\}$ is the vector holding all D2D pair transmission powers, maximizing the total number of D2D pair capacity, and constraint of equation (3) guarantees that each D2D pair's transmission power is set to either maximum or minimum.

Maximizing the cumulative capacity of D2D pairings is the goal of the optimization problem in Eq. (2). But as we can see from Eq. 1, C_n is reliant on the channel gains of D2D pair. We focus on the case when the developers of current systems presuppose full or at least partial knowledge of the channel gains of D2D pairs.

V. POWER CONTROL FOR D2D PAIRS USING ARTIFICIAL NEURAL NETWORKS

Based on biological neural structures, artificial neural networks are arrangements popularly used in machine learning. A Neural Network is made up of neurons, which in turn are organized into layers. Each layer can contain one or multiple neurons, and its position in the neural network dictates which class it belongs to: input layer, hidden layer, or output layer. Input layer and output layer are terms used to describe the first and last layers, respectively. Between the input and output layers, there are several layers, each of which is referred to as a hidden layer.

The cellular channel gains and D2D channel gains are related mathematically, which is the basis of the optimization issue in equation (2). For mobile networks, the relationship between cellular channel gains and D2D channel gains is unknown, and it cannot even be deduced analytically from any known mobile network characteristics. In order to automatically learn this relation and adjust the transmission strength of the D2D pairs in accordance, we advise employing an Artificial Neural Network (ANN). More specifically, the ANN may be thought of as a regulator that manages the transmission power of the D2D pair based only on the information provided by the D2D users to the base stations regarding cellular channel gains.

When using the binary power control, the goal of Eq. (2)'s optimization is to set each D2D pair's transmission power to either $p_n = p_{min}$ or $p_n = p_{max}$. Thus, the challenge of N identical binary classification is how to set the transmission power for N D2D pairs. In order to build the mapping between cellular channel gains and the ideal binary transmission power setting for every n^{th} D2D pair that maximises the cumulative capacity of D2D pairs, we propose the utilization of a fully-connected ANN.

The suggested ANN for binary classification is shown in Fig. 2. An input layer $X = (X_1, X_2, \dots X_n)$, hidden layers $H = (H_1, H_2, \dots H_n)$, and an output layer $Y = (Y_1, Y_2, \dots Y_n)$ make up the proposed ANN. The suggested ANN features an input layer that contains an input vector, and this input layer

aligns the cellular channel gains from the D2D users to the base stations. The term, $Out_{X_0} = P_{1,1}, P_{1,2}, \ldots, P_{C,D}$ with a length of $C \times D$ is a vector representing the cellular channel gains between base stations and D2D users and is produced by the input layer.

$(H_1, H_2, \ldots H_n)$

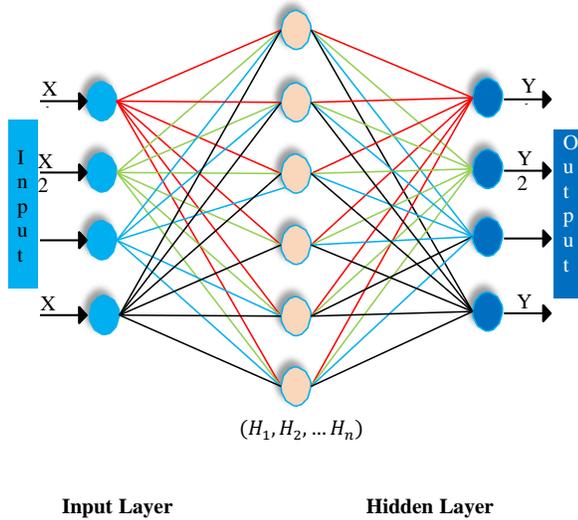
Input Layer   **Hidden Layer**


Fig. 2.   Proposed ANN Architecture for Binary Classification, Matching to a Single D2D Pair's Transmission Power.

Because the value of the sigmoid function is between 0 and 1, the output of the ANN will be $out_Y \in [0,1]$, displays the probability that $p_n = p_{max}$. Consequently, the nth D2D pair's transmission power is set to:

$$p_n = \begin{cases} p_{max} & if\ out_Y > 0.5 \\ p_{min} & otherwise \end{cases} \qquad (4)$$

A basic model of a neuron is described by applying an activation function Φ on a linear combination F of the input data, $X = (X_1, X_2, \ldots X_n)$, with their corresponding weights, $W_1, W_2, \ldots W_d$, and a bias constant b. Thus getting the output Y such that $Y = \Phi(F)$, in which $F = b + \sum_{i=1}^{d} W_i X_i$. This output is then passed along with the other outputs of this layer as input data to the next layer; this chain is perpetuated until the final output is generated by the output layer.

The best-known neuron model is called the sigmoid neuron, whose activation function Φ is the sigmoid function, that is, $\Phi(F) = \frac{1}{1 + e^{-\eta F}}$, and therefore the output Y is calculated as follows:

$$Y = \frac{1}{1 + e^{-\eta \sum_{i=1}^{d} W_i X_i - b}} \qquad (5)$$

The popularity of the sigmoid neuron is due to the ease of obtaining the partial derivative of this function, since the technique used by many to adjust the weights and bias is gradient descent. These adjustments are made by the back-propagation and feed-forward processes.

There is no simple mathematical relationship between the cumulative capacity of the D2D pairs and the cellular channel gains that can be used to calculate the transmission power of the D2D pairs. We therefore provide an offline supervised learning-based technique in which the optimum binary transmission powers are identified following a comprehensive search in order to maximise the sum capacity of D2D pairs. The transmission power of the nth D2D pair is then provided as a targeted class associated with the set of the cellular channel gains as features to the proposed artificial neural network. A single learning sample is comprised of the features and targeted class. From the collected learning samples, testing and training sets are produced.

VI.   Simulation Results

A. Simulation Parameters

TABLE I.   SIMULATION PARAMETERS

The radius of the cell	500 meters
Maximum transmit power of all devices P_{max}	0.2 Watt
Minimum data rate requirement of all D2D pairs	3 bps/Hz
The proportion of CUE's minimum rate requirement to CUE's achievable data rate	0.2
Maximum iterations of Dinkelbach's method	3
Maximum iterations of condensation method	2

B. Simulation Results

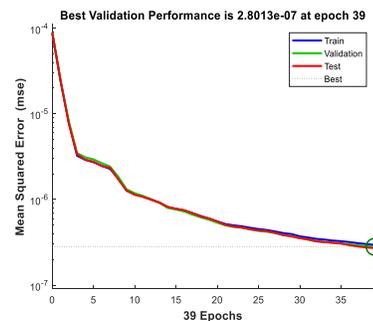
The proposed ANN is trained using samples of cellular channel gains and their associated expected transmission powers from the training set. In order to prevent overfitting, the trained ANN is next assessed on a test set of data using cellular channel gains that were not used during the training. This illustrates the set of samples' classification accuracy. The simulation results of our study are illustrated in Fig. 3 to 6 and Tables I and II.


Fig. 3.   Training and Testing Performance of Proposed Approach.
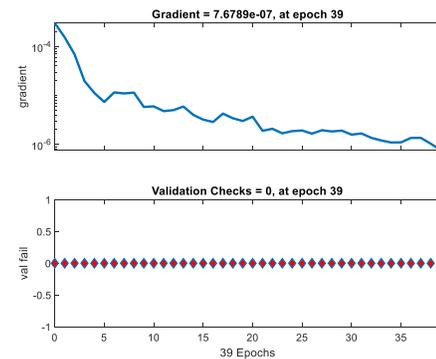

Fig. 4.   Performance Measures of Proposed Classifier.
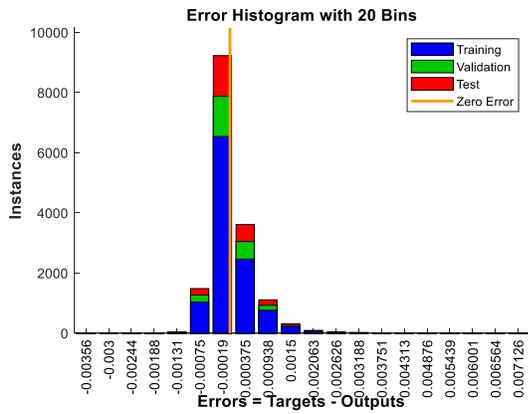

Fig. 5.   Error Histogram Graph.

TABLE II.   PERFORMANCE RESULTS

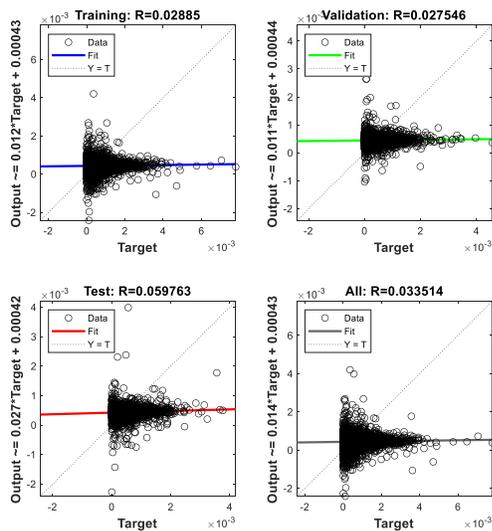
Optimal result obtained by NN (System Efficiency)		63.0430
Throughput		78.9144
Total Power Consumption		1.2518 Watt
Channel Gain of First Cell's CUEs	First CUE	2.6703
	Second CUE	1.9669
Channel Gain of Second Cell's CUEs	First CUE	2.0554
	Second CUE	2.2861
Channel Gain of First Cell's D2D Devices	First Device	1.5199
	Second Device	6.8406
	Third Device	9.6770
	Fourth Device	12.1281
Channel Gain of Second Cell's D2D Devices	First Device	4.3259
	Second Device	13.7552
	Third Device	11.8723
	Fourth Device	9.8168
Classification Accuracy	p_{min}=93.6%	**Total Accuracy = 92.25%**
	p_{max}=90.9%	


Fig. 6.   Final Output.

VII. CONCLUSION

For D2D communication, we have developed a novel power control method in this paper that doesn't require any understanding of the channel gains. In order to determine the transmission power of each D2D pair using an artificial neural network, the suggested method simply utilises the cellular channel gains between D2D users and nearby base stations. The main advantage of the suggested plan over current practises is that the network does not experience any additional signalling overhead. It is only necessary to be aware of the cellular channel gains, which are reported on a regular basis for a variety of objectives connected to conventional communication and handover. The suggested method surpasses the scenario with no power control and achieves a D2D pair sum capacity that is almost ideal with a maximum classification accuracy of 92.25%. Expanding the applicability of the suggested strategy to the estimation of D2D channel gains, which can then be applied to any radio resource management issue, should be the primary focus of future study.

Beijing, 100083, China

Abstract—**With the advent of Internet of Things technology, tremendous changes are taking place. Perhaps what humans never even imagined will come in the near future, and just as the Internet surrounds all aspects of people's daily lives, intelligent objects will autonomously take over all aspects of people's lives. So far, a lot of research and development has been done in the field of Internet of Things, but there are still many challenges in this field. One of the most important challenges is the issue of security in the Internet of Things. Therefore, in this paper, while reviewing the requirements, models and security architectures of the Internet of Things, a framework for security management in the Internet of Things is proposed, which takes into account various aspects and requirements. The proposed framework uses various ideas such as cryptography, encryption, anomaly detection, intrusion detection, and behavior pattern analysis and can be considered as a basis for future research. The purpose of this research is to determine security requirements and provide a method to improve security management in the Internet of Things. Based on the tests, the proposed method is completely 100% resistant against data modification attacks. Against impersonation attacks up to 97% and against denial of service attacks up to 89% resistant detection accuracy.**

Keywords—Internet of Things (IoT); security management; security requirement; security model; security architecture

I. INTRODUCTION

Internet of Things (IoT) is a new concept in the world of technology and communication. The term Internet of Things was first used in 1999 by Kevin Ashton. He described a world in which everything, including inanimate objects, would have a digital identity of their own, allowing computers to organize and manage them. The Internet currently connects all people, but with the IoT, all things are connected. In other words, the Internet of Things is a modern technology in which any entity (human, animal, or objects) can send data through communication networks, either the Internet or intranet [1, 2].

According to Cisco research, the birth of the Internet of Things is estimated between 2008 and 2009. This research also shows that after 2008, the number of devices connected to the Internet is more than the total number of human population and their number is increasing exponentially. Thus, it is predicted that by 2030, the number of devices connected to the Internet will reach more than 30 billion IoT devices in the world [3, 4]. In research communities, the Internet of Things has been defined from different aspects and perspectives; therefore, several definitions have been provided for it. The difference of different views is rooted in the two terms "Internet" and

"things". The first (internet-oriented) perspective moves the IoT perspective to a network-oriented perspective, and the second (object-oriented) perspective shifts the main focus to public objects that must be integrated into a common framework [5]. But in the field of information and communication, the terms "Internet" and "things" when used together, evoke a new concept. From a semantic point of view, the Internet of Things means "a wide global network, based on standard communication protocols, of interconnected objects, each of which can be uniquely addressed" [4]. Right now, the Internet of Things has evolved from a random collection of purpose-built networks. For example, today's cars have multiple networks to control engine performance, safety features, communication systems, etc. Commercial and residential buildings also have different control systems for cooling, heating and air conditioning, telephone service, security and lighting. With the progress and evolution of the Internet of Things, these networks and many other networks will be connected to each other with additional management, analysis and security capabilities. This issue will increase the power of the IoT [2]. The potential possibilities offered by the Internet of Things make it possible to use it in many applications. But currently there is only a small part of its applications in society. Nevertheless, in many different contexts and environments, the use of new applications is likely to improve people's quality of life. As an example, can refer to its various uses at home, when traveling, and also its various uses at work, when sick. These environments are now equipped with various objects that have a basic intelligence. But in most cases, these objects do not have any communication capabilities. Creating the ability to communicate with each other, for these objects, and enriching the information received from the surrounding environment, implies that there are different environments in which a very wide range of applications can be deployed [3]. Many challenges have arisen with the emergence of the Internet of Things. These challenges can be examined from different aspects, including social and technical. As an example, can mention security challenges [5] and legal challenges [6]. In order to accept and spread the Internet of Things, its challenges must be well identified and overcome [7]. One of the limitations of this study is low power and few resources, which is not always possible due to the implementation of complex security algorithms on Internet of Things systems. Security management is one of the basic security challenges in the Internet of Things, and this issue is very important and necessary for the development of this emerging technology.

Despite this issue, the activities carried out so far have not been able to provide a complete and appropriate answer to this issue. Therefore, further research in this regard can contribute to the development of the frontiers of knowledge and finally, provide new horizons for the development and applications of the Internet of Things. Therefore, in this research, an effort will be made to propose a suitable solution for security management, while reviewing the literature on the subject and determining the security requirements of the Internet of Things, which will ultimately lead to improvements in this field and also to improve the level of security in the Internet of Things. Since in this paper focus is on the security challenges of the Internet of Things. In the continuation of this paper, security requirements, security models and security architectures of the Internet of Things are examined first, and then a framework for managing security in the Internet of Things is presented.

- The following questions are raised in this research:

- What are the security requirements of the Internet of Things?

- How to meet the security requirements of the Internet of Things?

- How to provide a method to improve security management in the Internet of Things?

In the following, Paper is configured as follows. In Section II, the requirements of the Internet of Things in different environments are discussed. Sections III and IV deal with security models and architectures in the Internet of Things. In Section V, the framework of the proposed method for managing security in the Internet of Things is presented, and finally, 6 is related to the conclusion.

II. RELATED WORK

Users can ensure that they have a secure, private place with the aid of data security. The centralized administration of data security across several Internet of Things levels is the subject of this study. The compliance standard, identity management, data management, policy engine, and audit reports are the key axes of this paper. Standards for security, hardware security, adherence to certain legislation, and flaws in the IoT layer are not demonstrated in this paper [8]. The Internet of Things has numerous advantages, but it also faces significant difficulties. The most crucial of them is raising an IoT network's vital connections' susceptibility to hacker attacks. There is currently no tested access control technique for designing security frameworks with device authentication. This issue has been resolved in the source [9] of the method of expanding a security framework with powerful and transparent security protection. These issues involve creating new authentication mechanisms, an access control subsystem, and extremely precise risk indicators, as well as looking at the security requirements of three scenarios, including IoT of the body, IoT for the home, and IoT for the hotel. The sample security framework provided provides us with some workable answers to some of the security issues associated with the Internet of Things. In source [10], researchers looked into the traits of seven well-known frameworks in an effort to make choosing a good framework for an industrial application easier. The choice

of a suitable framework is complicated by the growing number of frameworks and platforms that already exist and offer varying degrees of support for the aforementioned needs. It takes effort. The goal of this study is to highlight new developments in existing research and the most recent commercial Internet of Things frameworks, as well as to provide a technical comparison of their traits. An examination of the Internet of Things' current state and security issues is provided by source [11]. (IoT). Connecting people to anything and anywhere is one of the objectives of the IoT framework. Perception, Network, and Application layers make up the three-layer architecture that characterizes the Internet of Things. Therefore, in order to fulfill Internet of Things goals that have a high reliability factor, a variety of security principles must be applied in each layer. Only if the security concerns related to the IoT framework are resolved can its future be assured. Many researchers have attempted to design appropriate countermeasures in order to solve the unique security issues of IoT layers and devices. In order to secure the Internet of Things, this paper presents an overview of security principles, technological and security concerns, possible solutions, and future perspectives. IACS will undergo architectural modifications as a result of the acceptance and deployment of Internet of Things (IoT) technologies, including improved connectivity to industrial systems. The growth of IoT technologies in industrial systems has altered the IACS architecture by adding more connections inside the chips. Industry 4.0 and physical-cyber systems have both been looked at in the paper [12]. This paper defines the IIoT and examines the associated IoT subcategories. In order to count and characterize IIoT devices when examining system design and security threats and vulnerabilities, it offers an analytical framework for IIoT. The conclusion of this research identifies certain gaps in the literature. In [13], a framework for blockchain-based GSD public access control is given, offering users a platform for comprehensive GSD administration. First, users and GSDs issue visual identities based on the World Wide Web Consortium (W3C) Decentralized Identifiers standard (VIDs). Then, they added user and device authentication to the GSD-DIDs protocol. Finally, an integrated access control system for GSD was created based on the decentralization and non-tampering characteristics of blockchain. This system comprises registering, granting, and cancelling access privileges.Using this framework, users can accomplish decentralized, lightweight, and fine-grained GSD access control, according to the findings of the experiments. The research [14] introduces the information security risks the Internet of Energy faces, classifies errors, and studies the information security defenses of distributed energy stations operating in the Internet of Energy environment. This paper analyzes the countermeasures to protect the distributed energy station's information security, analyzes the security framework of the distributed energy station by building the network security framework, and presents the system architecture of the distributed energy station in the Internet of Energy environment in accordance with its network security features. The study [15] employed a systematic literature review (SLR) technique and went through all of the basic literature to look for structures and themes. These approaches were carried out in four steps: eligibility, screening, identification, and so on.

After 568 papers from reliable journals were evaluated, 260 papers and 54 reports were analyzed. Additionally, they used MAXQDA to conduct an analysis in which nodes and themes were first discovered. A qualitative model was created using MAXQDA after classification. The proposed paradigm has literary backing, making it beneficial for IoT consumers, developers, and IT managers. In order to balance security and other services in dense IoT, an ascending authentication framework (AAF) is presented in [16]. Through integrated keying and allocation, the proposed system offers a high level of authentication and user services. A framework that includes service providers and end users defines this procedure. In this authentication, key distribution follows a discrete assignment method while service authentication uses hyperelliptic curve cryptography. Regression learning is used to determine the discontinuity and continuity in authentication in this case. For future service releases, the level of authentication and security redemption is determined by a modification in the distribution function. As a result, the regression sequence is completely altered without the inclusion of any new keys. This lowers failure rates, response latency, service authentication time, and computational complexity. In order to study the use of IoT in diabetes monitoring, critical issues, a systematic literature analysis on the adoption of MHIoT for diabetes management was undertaken in [17] Methodology comprehensive literature review. Despite the larger benefits of MHIoT in such resource-constrained environments, key studies show that underdeveloped countries are falling behind. Findings indicate that the biggest barriers to MHIoT adoption for diabetes control are infrastructure costs, security concerns, and privacy concerns. As healthcare costs decline in a context of limited resources, the opportunities afforded by MHIoT exceed the constraints. To fully reap these benefits and handle problems, more study is needed on infrastructure needs and privacy issues. The paper [18] presents trustworthy algorithms for the Internet of Things' security framework. On actual marketing data for the bank obtained from the Cloud Internet of Things, these algorithms, which include Simple Bayes (NB), Logistic Regression (LR), Random Forest (RF), Support Vector Machine (SVM), ID3, and C4.5, are applied (CIoT). By identifying the key factors influencing success and evaluating the effectiveness of CIoT and SDM algorithms, this study aims to develop an effective framework for improving marketing campaigns for banks. This work is anticipated to boost scientific contributions in researching marketing information capabilities by merging SDM with CIoT. There are eight factors used to calculate how well SDM algorithms perform. Precision, balance precision, accuracy, root mean absolute error, recall, F1-score, and run time. Experimental results demonstrate the success of the suggested framework, which has higher accuracy and good performance. The findings demonstrated the importance of marketing strategies and customer service to a company's success and survival.

III. INTERNET OF THINGS SECURITY REQUIREMENTS

To implement security in any system in the Internet of Things, different areas such as environment, user, software, physical device, information and network should be considered in an integrated manner and in the form of a general solution. In other words, paying attention to each of these areas alone cannot be a guarantee for creating and establishing security in the Internet of Things, but requires an answer that considers all these areas in a comprehensive and integrated manner [19, 28]. To protect communications in IoT, sufficient assurance in terms of confidentiality, integrity, authentication and non-repudiation of information flow must be provided. The security of Internet of Things communication can be considered in the context of communication protocols. Also, this work can be done with external mechanisms and on the other side of communication. Other security requirements must also be considered for the Internet of Things. In particular, by considering the communication between objects, it can be concluded that attacks such as denial of service can target data availability. Therefore, there is a need for mechanisms to protect against such threats that guarantee the proper functioning of IoT communication protocols. Other security requirements of the IoT include privacy, anonymity, responsibility, and trust, which are necessary for the social acceptance of most future applications of the IoT [20, 35, 27]. Security key management is another important security requirement in the field of Internet of Things. In particular, due to the fact that the security keys are accessible to attackers, if an attacker gets hold of these keys, he will be able to recover all the information being sent by the relevant device. In addition to key management, there is a need for appropriate methods for generating, distributing, exchanging, updating and revoking keys. Appropriate encryption protocols and mechanisms should also be used. IoT devices are expected to operate unattended and deploy in unprotected environments. Subsequently, this makes IoT devices easily accessible to attackers and increases the risk of physical attacks on them. Therefore, there is a need for mechanisms to prevent interference and attacks related to hardware elements and embedded chips in IoT devices [21, 36]. Generally, the security requirements in the IoT can be examined and analyzed from different aspects. In this research, based on the studies, a complete list of security requirements in the field of IoT has been prepared and shown in Table I. In addition, each of these requirements are also placed in a special category. This table can be used to develop security models and architectures and propose new frameworks to improve security management in the IoT, which will ultimately lead to the improvement of the security of the IoT.

TABLE I.   SECURITY REQUIREMENTS IN THE FIELD OF IOT

Row	Requirement	Description	Category
1	confidentiality	Protection from unauthorized disclosure of information	Information flows
2	Integrity	Ensuring the correctness or correctness of the information	
3	Authentication	Ensuring that only authorized entities can access information	
4	Access level	Classification of access based on permissions	
5	non-denial	Ensuring that the sender or receiver does not deny sending or receiving information	
6	Privacy	Non-disclosure of sensitive information of people	social
7	Anonymity	The possibility of activity without the need to introduce the real identity	
8	Responsibility	Accepting the legal consequences of people's activities	
9	trust	Accepting people's approval	
10	Management of security keys	Including how to use public and private keys	encryption
11	Protocols	Guidelines and standards to be followed	
12	Security of hardware elements	Protection of hardware elements against various damages	Physical care
13	Embedded chip security	Protection against penetration and modification of embedded chips	

IV.   IoT Security Models

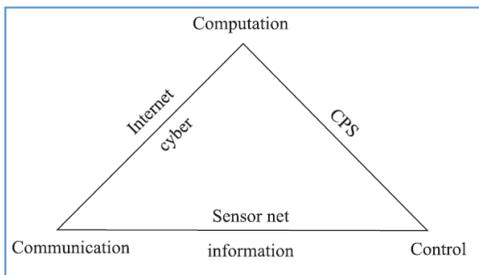
As shown in Fig. 1, in old information systems, there are three components of communication, control and calculation. There is a link between communication and control, which is sometimes called "information" and sometimes called "sensor network", which means collecting information from the control part and then putting it in the communication part. There is another link between communication and calculation, which is called "Internet" in China and "Cyber" in America [22, 29, 37].


Fig. 1.   IoT Model [22,34].

Theoretically, there is no link between control and calculation because control depends on the intervention of people. With the advent of the IoT, the link between control and calculation has also been established, which has made the impact of calculation results on control possible. This link, called CPS, is a real bridge connecting the data layer to the physical layer. In a broad sense, the entire diagram of Fig. 2 is the IoT, which includes cyber. But in a smaller sense, IoT refers to the link between computation and control. With the emergence of this link, it is expected to face a new security challenge called "direct control. Although the control should be done without human intervention, a security control should be used to prevent hackers from interfering. Therefore,

considering this issue, the security model of the IoT according to Fig. 2 requires a security control between calculation and control [22, 33].

In Fig. 3, a model called U2IoT is presented, which is a heterogeneous system, including Unit IoT and Ubiquitous IoT. This model uses social factors for security layers and adds intelligence and adaptability to security requirements. At the core of this model, the IoT Unit is similar to the human neural network, which refers to a primitive cell that provides responses for specific applications. Ubiquitous IoT includes industrial, local, national and public Internet of Things, which is the result of the integration of several IoT Units and is similar to the social organization framework. Specifically, Unit IoT includes IoT networks, sensors, distributed control nodes, management and centralized data center (M&DC), and Ubiquitous IoT also includes industrial data center and management (iM&DC), local data center and management (lM&DC), and National Data and Management Center (nM&DC) [23, 30, 39].

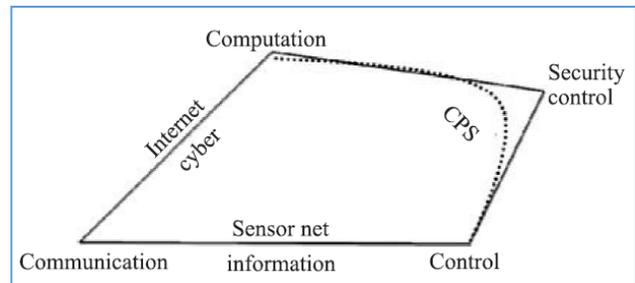
Fig. 4 shows the security layers and requirements of the U2IoT model. In this figure, the x-axis is related to U2IoT, the y-axis is related to security requirements, and the z-axis is related to security layers.


Fig. 2.   IoT Security Model.
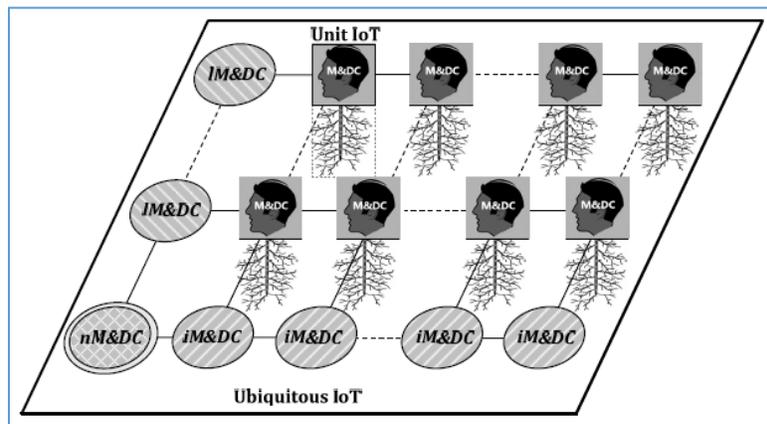

Fig. 3.   U2IoT Security Model [23].
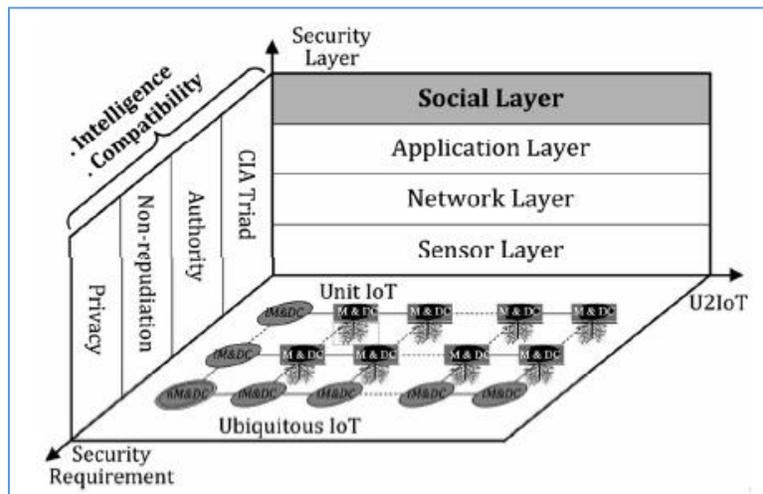

Fig. 4.   Security Layers and Requirements of the U2IoT Model[23].

In this model, security is divided into four layers: sensor, network, application, and social. In the sensor layer, entities are observed to extract information and discover semantic resources. Also, special techniques are used to detect the effective Integrity and adaptation of imprecise information interactions. The network layer includes network interfaces, communication channels, network management, information storage, and intelligent processing. In this layer, centralized, distributed, and hybrid network topologies are used to help monitor and maintain the network configuration in real-time. In this layer, the safe transfer of information is ensured by using algorithms for coding, extracting, integrating, reconstructing, exploring and aggregating data. The main function of this layer is to transfer and process the information obtained from the sensor layer and realize data exchange between high-scale heterogeneous networks.

Application layer provides functionality for specific applications and provides implicit interfaces to the infrastructure to perform testing, monitoring, and auditing applications. Standard protocols and service composition technologies have been applied to realize integration between heterogeneous distributed networks and its applications such as support monitoring, intelligent scheduling, intelligent search, and cloud computing. Such applications must be adapted for

dynamic environments. The social layer includes social features in the U2IoT model. This layer is basically provided for communication between objects and other support networks to establish correlation between cyber characteristics and its corresponding profile in social networks. Corresponding social characteristics are assigned to each entity and hierarchical management and data centers implement general security considerations. In the social layer, various interfaces are available to entities that act on their cyber existence and control their behavior. Meanwhile, in this layer, other social combinations are also considered, such as property control management, social relationship modeling, and entity behavior formulation. The security requirements considered in this model are three CIA (Confidentiality, Integrity and Availability), Authority, Non-repudiation, and Privacy, which bring reliable security along with privacy protection [23].

V.   IoT SECURITY ARCHITECTURES

So far, various security architectures have been proposed for the IoT. The main difference between the presented architectures is related to the number of layers and also the difference in performance of each layer in the IoT architecture. Fig. 5 presents a four-layer architecture including sensing, network, support, and application layers. The sensory layer

collects all the information through the physical equipment and identifies the physical world. The information collected by this layer includes object characteristics, environmental conditions, etc. Physical equipment also includes all types of sensors, including GPS and RFID, which are responsible for collecting data and information. In fact, sensors are the key component of this layer that captures the physical world and displays it in the digital world. The network layer is responsible for the reliable transmission of information from the sensory layer, primary processing, classification and combination of information. In this layer, information transmission is based on several main networks, including the mobile Internet communication network and satellite networks. Also, network infrastructure and communication protocols are also required to exchange

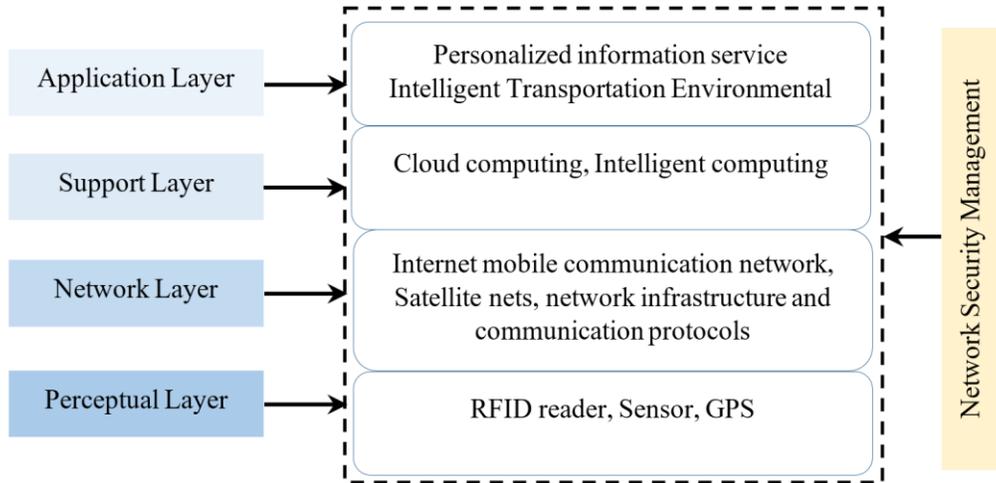
information between devices. The support layer establishes a platform for reliable support of the application layer. On this support platform, all intelligent computing capabilities will be organized through grid network and cloud computing. This layer plays the role of combining the application layer upwards and the network layer downwards. The application layer provides services such as personal information services, smart transfers, and environmental monitoring according to the needs of users. In fact, users will access the Internet of Things through application layer interfaces using televisions, personal computers, mobile devices, and the like. In the presented model, network security management is integrated with all the different layers of the architecture and manages them at different levels [24, 31, 32].


Fig. 5.   Four-Layer Security Architecture of IoT [24].

Fig. 6.   Three-Layer Security Architecture of IoT[25].

Fig. 6 shows a three-layer architecture including the sensing layer, the transmission layer, and the application layer. This architecture has divided each layer into several sub-layers. The sensory layer is divided into two sublayers of sensory nodes and sensory network. The transmission layer is divided into three sublayers: access network, central network, and local network. The application layer is also divided into two application support sub-layers and Internet of Things applications. Each layer in this architecture has its own technical support. These technologies play an irreplaceable role at all levels. These techniques are more or less related to the range of existing issues that cause insecurity, privacy and other data security issues [25].

The IoT must ensure the security of all layers. In addition, the security of the Internet of Things should include the security of the entire system. The sensory layer includes RFID security, wireless sensor network security, RSN security, and anything else related to this layer. The transport layer includes access network security, central network security, and local network security. For example, 3G access network security, Ad-Hoc network security, WiFi security, and GPRS security are related to the access network substrate. Internet security is related to the security of the central network sublayer and local network security is related to the local network sublayer in the transmission layer. The application layer also includes application support and specific applications of the Internet of Things. Security in the support layer includes middleware technology security, service support platform security, cloud computing platform security, information development platform security, and other support platform; security must ensure the security of all layers. In addition, the security of the Internet of Things should include the security of the entire system. The sensory layer includes RFID security, wireless sensor network security, RSN security, and anything else related to this layer. The transport layer includes access network security, central network security, and local network security. For example, 3G access network security, Ad-Hoc network security, WiFi security, and GPRS security are related to the access network substrate. Internet security is related to the security of the central network sublayer and local network security is related to the local network sublayer in the transmission layer. The application layer also includes application support and specific applications of the Internet of Things. Security in the support layer includes middleware technology security, service support platform security, cloud computing platform security, information development platform security, and other support platform security. IoT applications in different industries have different application requirements. For example, smart home security requirements are different from telemedicine security requirements or smart traffic security requirements, and they should be specified according to the type of application of the relevant requirements [25].

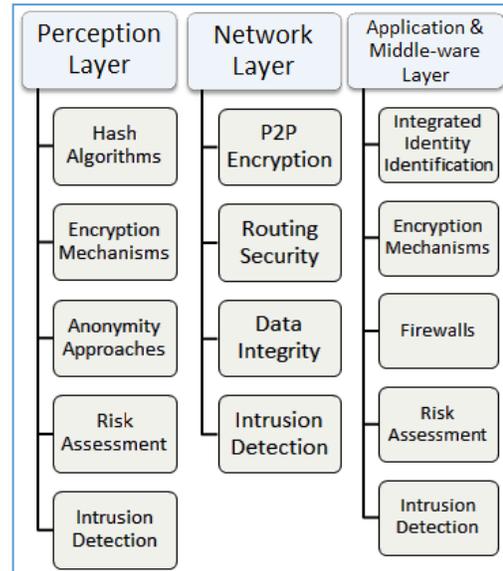
Fig. 7 shows the security architecture in three layers of sense, network and application and middleware. In this form, middleware and application are considered in one layer. In the sense layer, hashing algorithms, encryption mechanisms, anonymity methods, risk assessment and intrusion detection are placed. In the network layer, peer-to-peer encryption, routing security, data integrity and intrusion detection are considered. In the application and middleware layer, integrated identity recognition, cryptographic mechanisms, firewalls, risk assessment, and intrusion detection are placed [26].


Fig. 7. IoT Security Architecture [26].

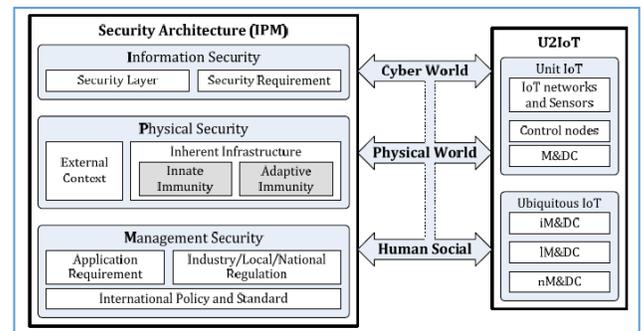
In Fig. 8, a security architecture for the U2IoT model is presented. In this architecture, three parts of information security, physical security and management security are considered. Information security covers security layer and security requirement. Physical security covers external content and core infrastructure, including intrinsic security and adaptive security. Security management includes application requirements, national/local/industry regulations, and international policy and standards. In this architecture, the connection of the U2IoT model with the security architecture at the cyber, physical and social levels is considered [38, 40].


Fig. 8. Security Architecture of the U2IoT Model [23].

VI. THE PROPOSED FRAMEWORK FOR MANAGING SECURITY IN THE INTERNET OF THINGS

In order to create a comprehensive security in the Internet of Things, it is necessary to ensure the security of all the entities of the Internet of Things at different levels from different aspects. For this, it is necessary to first define the different entities of the Internet of Things. Generally, the following entities can be imagined in the Internet of Things:

- Objects: are the main components of the Internet of Things.

- Communication networks: networks that provide communication between objects.

- Internet: establishes the global connection of different communication networks.

- Users: a set of human agents who are the main users of the Internet of Things.

- Applications: Manage objects to meet users' needs.

A. Objects

There are different types of objects, and according to the type of each object, its security requirements will also be different. Generally, objects can be classified into three different categories based on how they interact with their surroundings:

- Sensor: They collect information from the surrounding environment. (example: camera).

- Stimulator: execute commands in their surroundings. (example: door lock).

- Combined: perform both sensor and actuator functions. (example: robot).

It is obvious that the security requirements of a sensor object that only collects information from its environment will have important differences with the security requirements of an actuator object that only executes commands in its environment, and a hybrid object must also meet the security requirements of two types benefited previously. For greater simplicity, a composite object that is both a sensor and a trigger is conceptually divided into two different parts, and security requirements can be entered for each part separately based on its functionality. Therefore, from now on, only the first two types will be considered. A sensor must be able to evaluate and validate the accuracy of its observations, and only if this evaluation and validation is correct, it can encrypt its observations using its private key and propagation the encrypted packet in the communication network for predefined purposes. With this, the requirements of comprehensiveness and confidentiality will be met. Fig. 9 shows the proposed model for sensor security in the Internet of Things.

According to Fig. 9, in the proposed model, two modules of physical care and intrusion detection are also used to increase the security of sensors. The physical guard module ensures the security of the hardware elements and chips embedded in the sensor, and the intrusion detection module is an intrusion detection system embedded in the sensor, which investigates the intrusion of hackers into the sensor. If a sensor has been compromised, it will be notified to other related departments using cryptography. By doing this, other entities can isolate the compromised sensor before any malicious action by the attacker and prevent any further damage. The use of cryptography in sensors has other advantages, for example, any suspicious activity can be reported. Therefore, a secret communication layer is created between different entities and the sensor, which makes other entities aware of the danger

before any serious incident and before they succeed in attacking the sensor. All the entities that need the information of a sensor can decrypt the information sent by the sensor only if they have the public key of that sensor. In addition, the communication network is responsible for checking and authenticating entities that request to use sensor information. In fact, the communication network must guarantee that only authorized entities have access to sensor information. This is done through a predefined protocol. This protocol is defined by each application separately and exclusively. This will satisfy the authentication and access level requirements .The commands that are given to an actuator for execution must also be previously encrypted using special keys, and the actuator must also decrypt the commands using the key it has. In addition, a stimulus must be able to evaluate and verify the correctness of the commands it has received for execution, and only if this evaluation and verification is correct, it can execute the received commands in the external environment. Fig. 10 shows the proposed model for actuator security in the Internet of Things. In this model, as well as the proposed model for the security of sensors, the physical surveillance module and the intrusion detection module are used. Since an actuator, unlike a sensor, cannot send information to other entities, therefore, it cannot inform other entities of the dangers that have happened to it in a normal way, like a sensor. Therefore, an innovative method is used to inform other entities of dangerous conditions and intrusion into a trigger. In this method, a certain behavior is hidden in the execution of the commands of an actuator, and other entities, by observing this hidden behavior in the executive behavior of the actuator, will notice its critical condition and take the necessary measures to minimize possible damages. Although this idea adds a hardware overhead to the system, the resulting advantage is also significant. In other words, for each actuator, one or more sensors, which call monitoring sensors, are assigned to check the behavior of the stimulus, and in case of observing an abnormal behavior or a hidden behavior that is already defined in the intermediate protocol, the necessary notification done and the required security measures will be taken.

It should be noted here that all the explanations that were previously provided about how to manage keys and predefined protocols for sensors are now also true about how to manage keys and define protocols for operators, and repeating it is avoided.

B. Communication Networks

Communication networks are networks that establish communication between objects. In order to establish secure communication between objects, it is necessary to pay attention to logical communication in addition to physical communication. As an example, suppose that in a smart home there are security cameras and electronic alarms in a communication network. Now, is it reasonable that a security camera can issue commands that lead to the opening of the electronic lock on the door or not? Therefore, a communication network should be able to perform certain security controls based on a series of pre-defined protocols and policies, in addition to establishing the ability to exchange information between different objects and creating a secure communication channel. As mentioned earlier, these protocols and policies are

defined by the respective applications. Fig. 11 shows the proposed model for a communication network in the Internet of Things.

As can be seen, in this model, an anomaly detection module is used for network management. This module can detect anomalies based on communication channel activities, as well as pre-defined applications, protocols, and policies, and report them to the network management unit. The network management unit will also prevent unnecessary and suspicious communication if necessary. In this way, a double intelligence will be created in the communication network, which will ultimately improve the security of the Internet of Things.

C. Internet

The Internet, as the main infrastructure of the Internet of Things, establishes the global connection of various communication networks. In this way, access to objects from

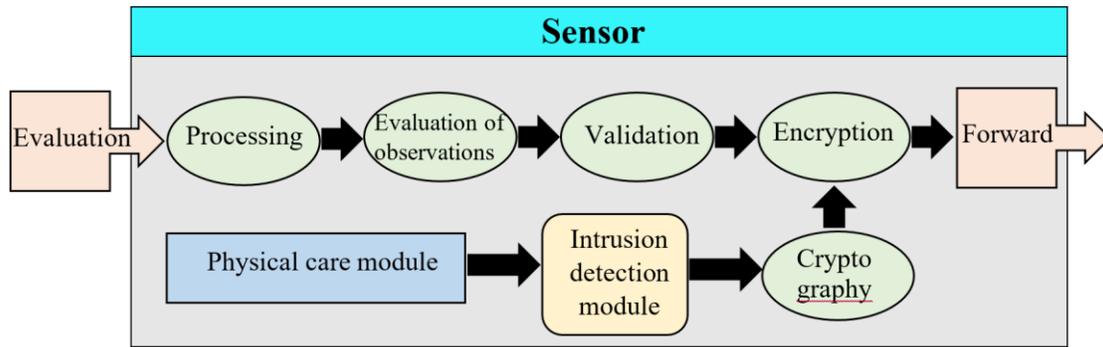
anywhere in the world will be possible. This issue will make the requirement of accessibility, which is one of the main requirements of the Internet of Things, be met. Since the communication of objects in the proposed model has a hierarchical structure, therefore, in the proposed model, there is a very good savings in assigning unique identifiers to objects. In other words, a unique local identifier is assigned to each object in the respective communication network, and a unique global identifier is assigned to each communication network. In this way, by using the sum of two network identifiers and the object, a global unique identifier will be obtained, which makes the addressing of each object unique in the world. In addition, more hierarchical levels can be used for this purpose. In this way, a suitable answer will be created for one of the basic challenges of the Internet of Things, which is related to assigning a unique identifier to each object.


Fig. 9. Proposed Model for the Security of Sensors in the Internet of Things.
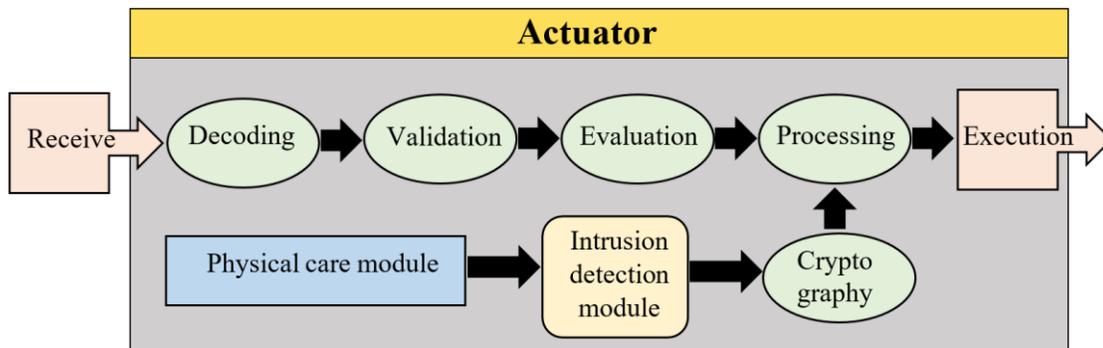

Fig. 10. Proposed Model for the Security of Actuator in the IoT.
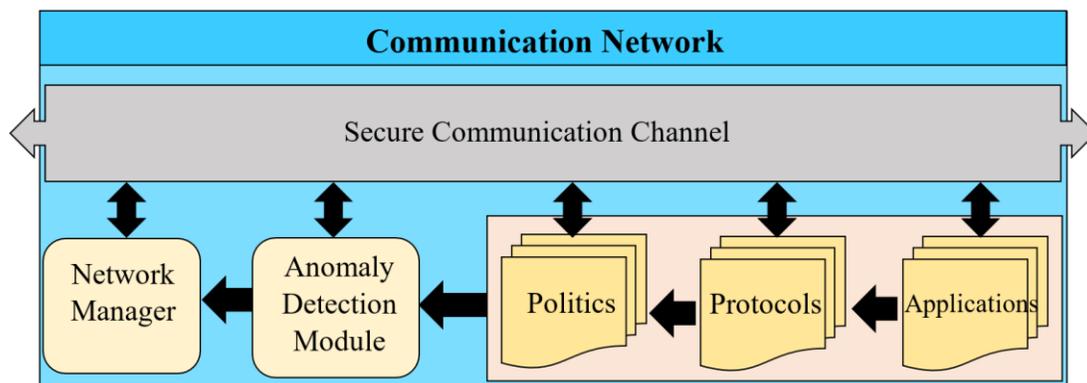

Fig. 11. Proposed Model for Communication Network in IoT.
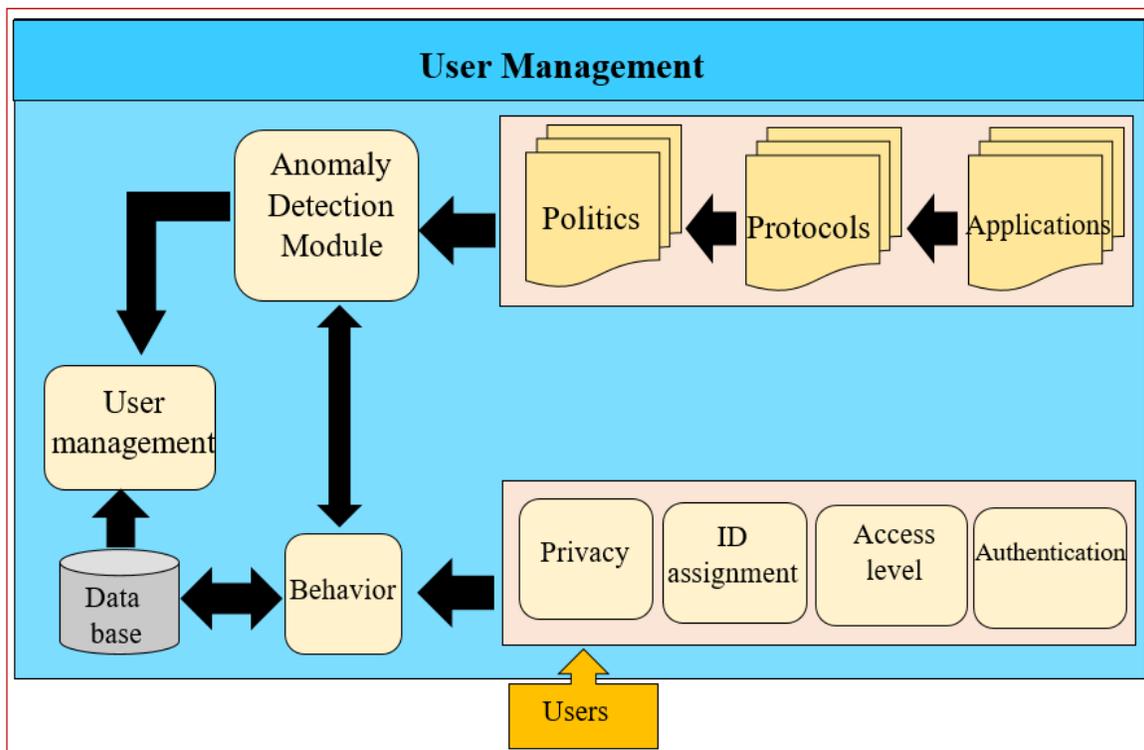

Fig. 12. Proposed Model for Managing Users in the IoT.

D. *Users*

Users are a set of human agents who use the Internet of Things to perform their desired applications. Generally, users can be divided into three different categories:

- Users: there are people who only use the Internet of Things at the user level.

- Managers: There are people who define applications and protocols at the management level.

- Attackers: unauthorized people who put themselves in the place of one of the above two groups and implement their goals.

User management is one of the most sensitive activities that must be done in the Internet of Things. In this regard, there are many security requirements such as authentication, access level determination, privacy, anonymity, responsibility and trust that must be covered. Fig. 12 shows the proposed model for user management. In this form, the components of authentication, access level determination, ID assignment, and privacy work in parallel, and an additional component called "behavior check" examines the behavior of users and stores the necessary information in the behavior database. This information is used along with applications, protocols and policies to detect anomalies in user behavior.

As shown in the Fig.12, the main idea in the proposed model is to use the behavioral characteristics of users to detect anomalies, and finally, by using the obtained information as well as the information in the database, user management operations are performed. This operation can include activating or deactivating users as well as issuing or not issuing access licenses for them.

E. *Applications*

Applications are responsible for managing objects to meet the needs of users. In fact, applications determine how objects should be related to each other and what mission they should perform. Applications also determine what activities different users can perform in the Internet of Things. In fact, applications provide a set of protocols, each of which provides a set of policies that are used in all the models described so far. As an example, consider the application of a smart air conditioning system.

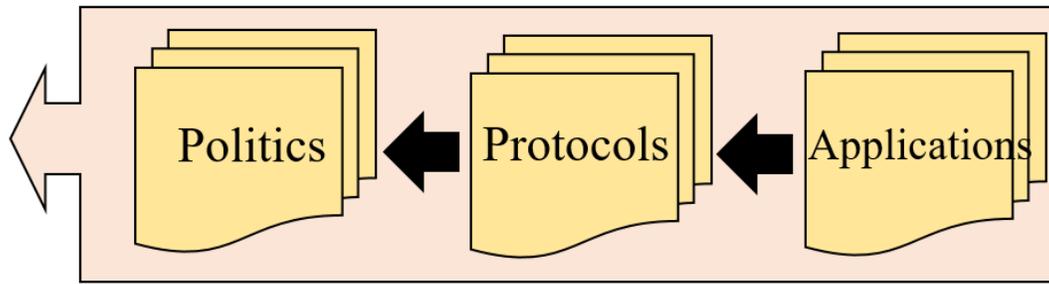
In this application, the temperature and humidity sensors as well as the electronic key actuators of the cooling and heating system are defined as endpoints. The final task of this application is to adjust the temperature of the environment based on the needs of the users. Therefore, it is necessary for users to be able to determine the optimal minimum and maximum temperature. With this explanation, this particular application provides a set of protocols that describe how sensors, actuators, and users communicate. In addition, each of these protocols also provides a set of policies. For example, setting the minimum temperature by the user leads to a protocol that shows how the user interacts with the relevant data and changes it. For this purpose, a set of policies is considered. As an example, assume a policy where the user is allowed to change only one temperature data grade per step. In fact, this policy ensures that there are no drastic changes in sensitive data at once. In addition, such a policy also provides the ability to observe and track user behavior. Fig. 13 shows how applications, protocols and policies interact.


Fig. 13. Proposed Model for the Interaction of Applications, Protocols and Policies in the IoT.

VII. EVALUTION AND RESULTS

To evaluate the proposed method, after simulation, various scenarios are executed and the success or failure of the system in detecting and responding to an attack is measured as a measure of accuracy. Of course, to create diversity in the tests, a random number has been used, which generates identifiers for the objects that are the target of the attack, and the desired scenario is executed on it.

Also, to achieve stable and reliable results, according to the number of sensors and actuators, each experiment with random object ID is repeated 100 times and the average accuracy obtained is shown.

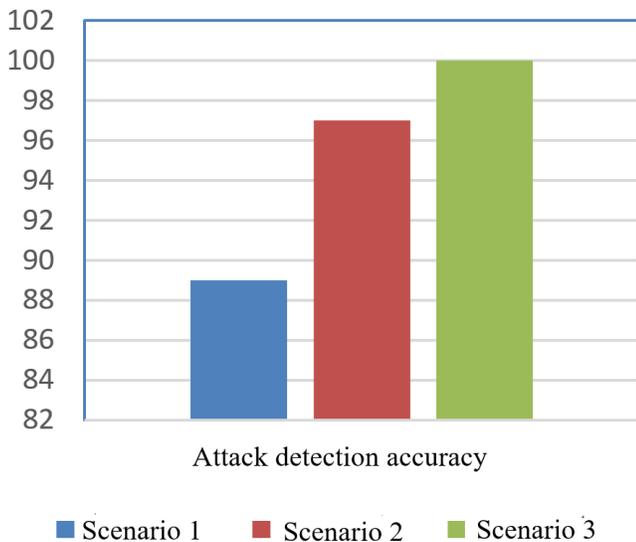
As can be seen from the above graphs (Fig. 14 and Fig.15), in general, the accuracy of the proposed method is significant. The point that should be noted here is that based on the tests, the proposed method is completely (100%) resistant against data modification attacks. It also performs well against impersonation attacks (97%). But against denial of service attacks, it has a lower detection accuracy (89%). This issue also seems quite logical because one of the prominent features of the proposed method is the use of behavioral and cryptographic parameters, which makes the resistance of the proposed method against change and impersonation attacks much higher than other attacks.


Fig. 14. Comparing the attack Detection Accuracy in Different Scenarios by Implementing the Proposed Method.
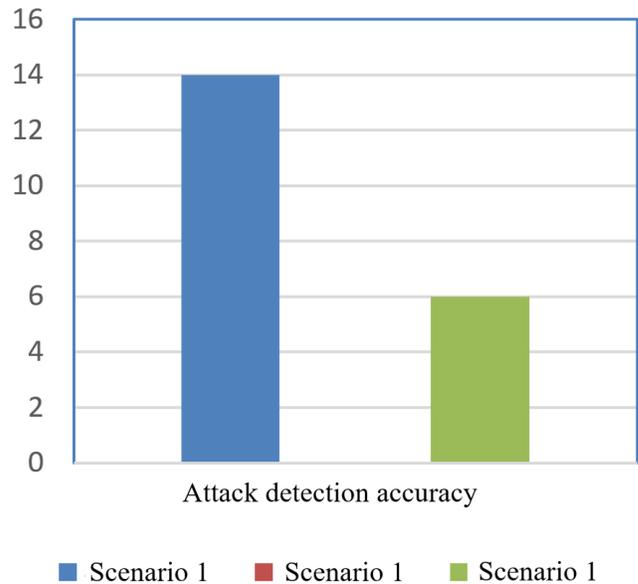

Fig. 15. Comparison of attack Detection Accuracy in Different Scenarios without Implementing the Proposed Method.

Contrary to this issue, if the proposed method is not used and relies only on the application and the centralized control system, the accuracy of attack detection will also be greatly reduced. In this case, the accuracy of detecting denial of service attacks is higher than others (14%), followed by the accuracy of detecting modified attacks (6%) and finally impersonation attacks cannot be detected at all (0%). It should be noted that these results are completely logical considering the way the mentioned system is implemented and its lack of use of impersonation detection mechanisms. Table II compares the mentioned results numerically.

TABLE II. NUMERICAL COMPARISON OF TEST RESULTS

Scenario	Attack detection accuracy without implementing the proposed method	Attack detection accuracy by implementing the proposed method
1	14%	89%
2	0%	97%
3	6%	100%

VIII. CONCLUSION

Until now, various activities have been carried out in line with the existing security challenges for the Internet of Things, but a comprehensive and integrated solution has not been provided for it, and more research is needed in this field. The

main activities carried out in the field of Internet of Things security are related to determining security requirements and providing models and security architecture. Generally, the security requirements in the field of Internet of Things can be placed in different categories, including data and information flows, encryption, social and physical care. Generally, the security models and architectures presented for the Internet of Things consider different levels and apply security issues at different levels separately. Therefore, there is a need to develop new models and architectures that cover all the security aspects of the Internet of Things in an integrated manner. For this purpose, the security requirements of the Internet of Things should be paid attention to from various aspects, and the connection between different levels should be fully seen in the security model of the Internet of Things. Although such work requires multiple activities and an optimal answer cannot be achieved at once. In this Paper, a new framework for managing security in the Internet of Things has been presented, which has presented solutions to improve security in the Internet of Things in a hierarchical manner and at different levels. The main focus of this framework has been relying on solutions for anomaly detection as well as intrusion detection, and in this regard, behavioral characteristics have been used, as well as data encryption of sensors and behavioral activities of actuator. What is specifically paid attention to in this Paper is the issue of notifying other departments by using encryption of the correctness of the operation or the possibility of detection of intrusion into the sensors and actuators, and based on the anomalies reported at the levels of the communication network and also manage users to make the necessary decisions. In other words, in the proposed model, the communication network is in charge of managing the network and it does this by using the protocols and policies specified by the applications and based on the observed anomalies. The user management level also uses the behavioral characteristics of users to detect anomalies and takes the necessary decisions if abnormal behaviors are observed. In other words, at this level, by storing user behaviors, a behavioral database will be created, which will be the main basis for subsequent decisions. This database stores user behaviors like a long-term memory and can be used in various ways. For example, this database can be used to track user activities and distinguish real users from attackers who intend to infiltrate the system.

Novel Strategies Employing Deep Learning Techniques for Classifying Pathological Brain from MR Images

Mitrabinda Khuntia[1], Prabhat Kumar Sahu[2], Swagatika Devi[3]

Dept. of Computer Science and Engineering, ITER, S'O'A University, Bhubaneswar, India[1,2,3]

Abstract—**Brain tumors are the most widespread as well as disturbing sickness, among a very precise expectancy of life almost in their serious structure. As a consequence, therapy planning is a critical component in enhancing the characteristics of the patient's life. Image modalities like computed tomography (CT), magnetic resonance imaging (MRI), along with ultrasound images are commonly used to assess malignancies in the brain, breast, etc. MRI scans, in evidence, are employed in this study to identify the brain tumors. The application of excellent categorization systems on Magnetic Resonance Imaging (MRI) aids in the accurate detection of brain malignancies. The large quantity of data produced through MRI scan, on the other hand, renders physical distribution of tumor and non-tumor in a given time period impossible. It does, however, come with major obstruction. As a consequence, in order to decrease human mortality, a dependable and automated categorizing approach is necessary. The enormous geological and anatomical heterogeneity of the environment surrounding the brain tumor makes automated classification of brain tumor a difficult undertaking. This paper proposes a classification of Convolutional Neural Networks (CNN) for automated brain tumour diagnosis. To study as well as compare the findings, other convolutional neural network designs such as MobileNet V2, ResNet101, and DenseNet121 are used. Small kernels are employed to carry out the more intricate architectural design. This experiment was carried out using Python and Google Colab. The weight of a neuron is characterized as minute.**

Keywords—*Brain tumor; CT; MRI; CNN; MobileNet V2; ResNet101; DenseNet121*

I. INTRODUCTION

The process of changing an input image into an output image or image attributes is known as image processing. The primary goal of all image processing techniques is to make it simpler to visually recognize the image or item under investigation. Methods that incorporate quantitative analysis will augment the traditional visual examination of images. Anatomical segmentation of regions of interest (ROI), such as distinguishing a volume of abnormal tissue from a backdrop of normal tissue, is an important stage in the image processing pipeline. This will enable statistical examination of aspects that are not evident to human vision. Image segmentation is critical in the realm of image processing. Segmentation is vital in medical imaging for feature extraction, image measurements, and image presentation [1]. Image segmentation is the partitioning or segmentation of a digital image into comparable sections with the primary goal of simplifying the image under review into something more understandable and simpler to visually evaluate. Image segmentation techniques are classed as thresholding, region-based, supervised, or unsupervised.

The central nervous system sends sensory information and the activities that go with it all across the body [2]–[4]. Brain is most intricate organism in human body. It serves various roles and controls the operations of the body's other systems. The brain's frontal lobe aids in motor control, problem solving, and decision making. The parietal lobe regulates body posture. Memory and hearing are handled by the temporal lobe, whereas vision is handled by the occipital lobe. The cerebral cortex is a grey substance that surrounds the cerebrum and is made up of several neurons. The cerebellum regulates different voluntary movements in living animals equipped with nervous system. When brain cells grow abnormally and are not effectively managed, a brain tumor can form. A tumor is an abnormal collection of cells that is generated by uncontrolled cell division. It has been discovered that all tumor variations are not malignant. Brain tumors are the world's tenth largest cause of mortality. Cancer, in its most basic sense, refers to malignant tumors rather than benign ones. There are two categories of brain tumours: grades 1 and 2 (low) and grades 3 and 4 (high).

Computer-Aided Diagnosis (CAD) can be extremely beneficial in the investigation, prognosis, along with the remedy of brain tumors. A typical brain tumor CAD system includes three major phases: tumor ROI segmentation, feature extraction, and classification (based on the retrieved features) [5]. The most significant and time-consuming aspect of such a system is brain tumor segmentation, which may be done manually or automatically. The requirement of tracing ROIs is an evident restriction of such systems, which might pose a few issues. First of all, because of the varying nature of brain tumors greatly in shape, size, and location, tracing ROIs may be difficult and frequently not totally automated. This may result in severe segmentation mistakes that aggregate into subsequent phases, resulting in erroneous categorization. Second, tumor-surrounding tissues are thought to be distinct between tumor classifications. Third, relying entirely on ROI characteristics implies full ignorance of tumor location information, which might have a significant impact on categorization.

The aforementioned issues inspire us to offer an alternate technique for classifying brain tumor that fully eliminates the segmentation step. Brain tumour detection is critical in biological applications. The brain tumor grouping continue to help doctors in disease diagnosis. Throughout the classification process, many operations including as preprocessing, feature extraction, and classification are necessary. Preprocessing is a stage in image processing that happens before feature extraction to establish the location of an area or item. This technique

includes filtering, standardizing, and identifying things prior to the extraction stage. The method of obtaining essential numeric values from photographs in order to distinguish them is known as feature extraction.

Brain MRI image is mainly used to diagnose tumors as well as to mimic tumor growth. The data is generally employed in tumor detection and therapeutic methods. An MRI image contains more information than a CT or ultrasound image. An MRI scan can detect anomalies in brain tissue and offer extensive information on brain architecture. MRI may detect a variety of brain diseases, which include abnormalities like cyst and tumor. It can detect white and gray matter of brain. Tumor diagnosis at an early stage is crucial since tumors may be hazardous in many scenarios and, in the worst-case scenario, lead to death. As a result, tumor prediction utilizing automated algorithms may be of great help in tumor identification and is the most secure option.

Convolutional neural networks (CNNs) are a type of deep learning technique which is extensively used in image processing. It is based on basic activities of the human brain [6]. CNNs have several advantages over ordinary machine learning networks, which can be achieved by increasing the number of training data, leading in an efficient and resilient model [7]. CNN is used in image processing techniques such as MRI image segmentation, identification, and classification, together with brain cancer classification and detection. Therefore, we offer a fully automatic CNN-based MRI image segmentation along with classification system for three types of malignancies: meningioma, glioma, and pituitary tumors in this study.

The remainder of the paper is divided into the following subsections. Section II goes over the existing literature on brain MRI classification. Section III describes the convolutional neural network. Section IV elaborates a detailed survey on some popular deep learning based MRI classification techniques. Section V describes analysis of MRI images using CNN architecture. Section VI describes the proposed CNN methodology. Section VII elaborates on the experimental work and compares it to the current state-of-the-art CNN model. Section VIII describes the experimental results. Section IX describes the limitation of the existing CNN architecture. Section X discusses about the experimental results. Finally section XI concludes the research paper.

II. LITERATURE SURVEY

Segmenting the region of interest from an item is one of the most complex and time-consuming processes, and segmenting the tumor from an MRI Brain image is a major one. Several current publications divide brain images into normal (tumorous) and pathological categories (non-tumorous). Al-Baderneh et al. [8] investigated the arrangement of brain MRI applying Artificial Neural Network as well as K-Nearest Neighbour (KNN) including textural characteristics utilizing 181 images of sick brains as well as 94 images of normal brains. The study [9] describes how to use feed-forward back-propagation to classify MRI vision as abnormal or normal. The particular algorithms are supervised (classes are known) and need feature retrieval before classification. Rajesh et al. [10] provide one such strategy, in which they conducted classification using a Feed Forward Neural Network with ternary layers, 50 nodes

in the hidden layer, along with single output node. Provisional investigation can be found in [11] as well as Taie et al. [12] used Support Vector Machine (SVM) to accomplish classification.

Cutting-edge deep learning algorithms are being developed in tandem with these technologies. Many of these works do not employ brain imaging to determine if something is normal or pathological, but they were included since they were done on a variety of other sorts of distribution. Pereira et al. [13] employed CNN to identify gliomas in their article. Deep learning was utilized by Kamnitsas et al. [14] to classify ischemic stroke. The author [15] examined the Adaptive Network-based Fuzzy Inference Approach, a suggested technique for categorizing tumors into five classes (ANFIS). Another study used pre-trained AlexNet to categorize and segment tumors depending on Gray-Level Co-Occurrence Matrix (GLCM) features [16]. SVM [17], CNN [18], other studies include Recurrent Neural Network (RNN) [19], AlexNet transfer learning network of CNN [20], VGG-16, Inception V3 and ResNet50 [21], along with CNN quartet technique.

The authors suggested a strategy for glioma classification that merged SVM and KNN in [22]. The accuracy for multi-classification is 85%, but the accuracy for binary classification is 88%. Ertosun and Rubin [24] advocated using CNN to differentiate between low along with high grade gliomas as well as their grades. They achieved 71% as well as 96% accuracy, respectively. Using axial brain tumor pictures, Paul et al. [23] trained and developed two unique classification algorithms (a fully connected CNN). The CNN architecture's accuracy was 91.43%, with two convolutional layers followed by two fully linked layers. M Malathi, P Sinthia, and colleagues [25] demonstrated completely automatic brain tumour segmentation using a convolutional neural network. Brain tumours and gliomas were the most common and lethal, with little life suspense on its highest level. Manual segmentation was a time-consuming task in medical practise, and its execution was highly dependent on the operator's experience. J. Seetha and S. Selvakumar Raja et al. [26] demonstrated that the massive amount of data generated by MRI impedes manual classification of tumour vs non-tumor at an exacting time. However, it has a few limitations (i.e. precise quantitative measurements were given for a restricted number of images). The classification of brain tumours using convolutional neural networks is described in this paper.

Vipin Y. Borole, Sunil S. Nimbhore, and Dr. Seema S. Kawthekar discuss brain tumours [27]. Because of the structure of the brain, brain tumour recognition is a difficult task for MRI images. A brain tumour is an unusual development of cerebrum cells. X-ray images provide better contrast of various delicate tissues of the human body. X-ray images outperform CT, Ultrasound, and X-beam images. In this, various preprocessing, post-processing, and strategies such as (Filtering, difference improvement, Edge recognition) and post-processing systems such as (Histogram, Threshold, Segmentation, Morphological operation) are accessible in MATLAB for the location of brain tumour images via image handling (IP) apparatus (MRI-Images). Gooya et al. [28] presented GLISTR, a method for segmenting gliomas in multi-modal MR images by registering the images to a probabilistic atlas of healthy individuals. The incorporation of the tumour

growth model into the anatomy of the patient brain was the major contribution. Based on histogram analysis of temporal Magnetic Resonance Image (MRI) data, Manikis et al. [29] proposed a novel framework for assessing tumour changes. The proposed method detects tumour distribution and quantitatively models its growth or shrinkage, potentially assisting clinicians in objectively assessing subtle changes during treatment.

Bauer et al. [30] developed a novel method for converting a healthy brain atlas to MR images of tumour patients. They presented a new method for adapting a general brain atlas to an individual tumour patient image that uses sophisticated models of bio-physio mechanical tumour growth. Roy et al. [31] proposed an investigation into automated brain tumour detection and segmentation from brain MRI. Brain tumour segmentation was an important step in extracting information from complex MRI brain images. Sindhushree K.S et al. [32] created a brain tumour segmentation method and validated it using two-dimensional MRI data. In addition, detected tumours are represented in three dimensions. To detect tumour, high pass filtering, histogram equalisation, thresholding, morphological operations, and segmentation using connected component labelling were used. The extracted two-dimensional tumour images were reconstructed into three-dimensional volumetric data, and the tumour volume was calculated.

Ertosun and Rubin [24] proposed using CNN to distinguish between low and high grade gliomas and their grades. They achieved 71% and 96% accuracy, respectively. Krol et al. [33] used axial brain tumour images to train and develop two distinct classification approaches (a fully connected CNN). The accuracy of the CNN architecture, which consisted of two convolutional layers followed by two fully connected layers, was 91.43%. In the next section, we will go through the various methods for classifying MRI as normal or abnormal.

III. CONVOLUTIONAL NEURAL NETWORKS

Convolution is a convolution layer approach placed on a linear algebra operation which helps in multiplying the filter in the image [34]. CNN is a neural network that analyses information by using a grid topology. The convolution layer, is used as the first panel. It changes the input data without altering initial information. Another frequent sort of layer is the pooling layer, which is used to compute the maximum or average value of the image's pixel coordinates. By generating a feature map, CNN can learn complex features.

A. Brain Imaging Modalities

To assess the brain structure, four basic technologies (CT, PET, DWI, and MRI) are commonly employed for brain malignancies.

1) Computed Tomography (CT): A CT scan is a diagnostic imaging test that produces images of the internal body using X-ray technology. CT scans are utilized to evaluate and diagnose brain abnormalities, they are also used to assist various surgical operations. It creates a 3D image of soft tissues along with bones using X-rays and a computer. CT is a non-invasive, painless technique for your healthcare professional to diagnose issues. CT scans are commonly performed with and without contrast agents to help the radiologist detect any abnormalities.

2) Position Emission Tomography (PET): PET is used to evaluate brain metabolism as well as the distribution of radio labeled chemical agents in the brain. PET detects emissions from metabolically active compounds that have been radioactively labelled and circulated throughout the body. The brain emission data PET scans are computer-processed to provide multidimensional pictures of chemical distribution throughout the brain. PET is a sort of functional imaging which can detect metabolic anomalies such as glucose metabolism, blood flow, oxygen consumption, amino acid metabolism and liquid synthesis. These measures represent the amount of brain activity in distinct brain areas and help us to understand more about how the brain functions. When they initially became available, PET scans outperformed all other metabolic imaging modalities in terms of resolution and completion time (as low as 30 seconds).

3) Diffused Weighted Image (DWI): Diffusion weighted imaging (DWI) is a technique for producing signal contrast based on Brownian motion changes. DWI is a method used to evaluate the human body's molecular function and micro-architecture. DWI is a critical component of today's cutting-edge magnetic resonance imaging and is widely employed in neuro-imaging and cancer research. DWI is a continuously changing technological field, with new applications emerging on a regular basis.

4) Magnetic Resonance Imaging (MRI): MRI is one of the most popular imaging procedures utilized before and after surgery, with the goal of giving critical information for the treatment plan. In the medical industry, MRI is commonly used to identify and see elements in the body's internal structure. It is used to identify differences in biological tissues and is significantly superior to computed tomography (CT). Strong magnets are used in magnetic resonance imaging (MRI) scanners to polarise and excite hydrogen nuclei (one protons) in human tissue, creating a measurable signal that is spatially recorded and translated into body images. The proper interpretation of brain MRI images is vital for gathering important information that can aid in the early identification and diagnosis of illnesses.

B. Contributions

Convolutional Neural Networks (CNNs) have shown to be extremely fruitful in diagnosing a wide range of disorders and are commonly utilized in bio-medical image analysis. Those networks are particularly useful in detecting, classifying, and segmenting brain cancers in MRI datasets. Our approach's primary goals are as follows:

- Using deep learning and convolutional neural networks to detect brain cancers in MRI datasets.

- Experiment findings have shown that enlarging a dataset utilizing rotation, flipping, and translation approaches is quite beneficial for training the VGG architecture.

IV. A DETAILED SURVEY ON SOME POPULAR DEEP LEARNING BASED MRI CLASSIFICATION TECHNIQUES

A. MobileNet V2

MobileNet-V2 is a 53-layer deep convolutional neural network. It enables real-time categorization in devices with

little computing power, such as smart phones. MobileNetV2 has an inverted residual architecture, with narrow bottleneck layers functioning as the residual blocks' input and output. It also uses lightweight convolutions to filter features in the expansion layer. Finally, nonlinearities in thin layers are eliminated. MobileNetV2 enhances the up-to-date execution of mobile models on a variety of tasks along with benchmarks, as well as over a wide range of model sizes. It is a powerful component for obtaining the object recognition and segmentation. MobileNetV2 is a feature extractor with tremendous capability for object segmentation and detection.

Advantages

- Network size has been reduced to 17MB.

- The number of parameters has been reduced to 4.2 million.

- They are faster in performance and excellent for mobile apps.

- A convolutional neural network with a low latency.

- MobileNets employ depth-wise separable convolutions in a simplified design.

- MobileNet employs two simple global hyperparameters to efficiently trade off accuracy for latency.

- MobileNet might be utilized for item identification, fine-grain categorization, face recognition, large-scale geolocation, and other applications.

B. ResNet101

The residual block is the fundamental basic element of ResNet101. As we proceed further into the network with a large number of layers, the computation gets increasingly complicated. These layers are built on top of one another, with each layer attempting to learn an underlying mapping of the desired function. We try to fit a residual mapping instead of these pieces. Another benefit of this extremely deep architecture is that it enables for up to 150 layers of this, which we then stack on a regular basis. We additionally double the number of filters and use stride two to spatially down sample. Finally, only layer 1000 was entirely linked to output classes. The fundamental loss of the present network is that due to the enormous number of parameters, assessing it is fairly expensive [35]. The ResNet101 focuses largely on treating the second non-linearity as an identity mapping, which implies that the result of the addition operation between the identity mapping and the residual mapping should be sent immediately to the next block for processing. Batch Normalization is at the heart of ResNet101. Batch Normalization modifies the input layer to improve network performance. The problem of covariate shift is solved. The Identity Connection is used by ResNet101 to assist avoid the network from experiencing the vanishing gradient problem. Deep Residual Network improves network speed by leveraging bottleneck residual block design.

Advantages

- Networks with several layers (even thousands) may be trained simply without increasing the training error percentages.

- ResNets can help solve the vanishing gradient problem by using identity mapping.

C. DenseNet121

DenseNet121 is a novel category of convolutional neural network in which all previous layers are linked to the current layer. A DenseNet121 is a sort of convolutional neural network that connects all levels directly by using dense connections between layers through Dense blocks. A deep DenseNet121 is defined as a collection of DenseNets (referred to as dense blocks) with extra convolutional and pooling operations performed between each dense block. DenseNet121 connects layers together using dense blocks [36]. DenseNet connects each layer to every other layer. This is incredibly effective.

Advantages

- They address the problem of disappearing gradients.

- They enhance feature dissemination.

- They promote feature reuse; and

- They minimize the number of parameters greatly.

V. ANALYSIS OF MRI IMAGES USING CNN ARCHITECTURE

Classification is important because it arranges images into distinct groups. It is the first step in diagnosing any disease by forecasting an area or region having anomalies. The CNN model has several layers, including the convolution layer, pooling layer, flatten layer, dropout layer, and dense layer. In addition to the layers used in the CNN process, this study includes an activation function based on rule activation. An image in the shape of a number that interweaves the first convolution, with a resolution of 240x240 pixels. Kernels with a size of 3x3 and a thickness of three are used in accordance with the channel of the image data and filters. The model will perform the activation and data pooling functions after receiving the results of the operation. The Pooling layer process reduces the size of the feature map. The convolution process produces a feature map, which is then used for subsequent convolution processes. The next step is to flatten the feature map into vector form in order to perform a fully-connected layer process to produce image classification. This section briefly examines three alternative deep learning architectures (DenseNet121, MobileNet V2, and ResNet101) in addition to the recommended approach. Because of its successful performance in image classification that automatically finds key parts, CNN was employed to carry out the recommended classification strategy for brain MRI images. Fluid Attenuated Inversion Recovery (FLAIR) of MRI is the imaging method used here. It looks like a T2 picture but has a relaxation time (TR) along with longer echo (TE). The present sequencing is the disease perceptive as well as greatly simplifies the distinguishing CSF from an aberration.

VI. PROPOSED MODEL

A. MobileNet V2 Model

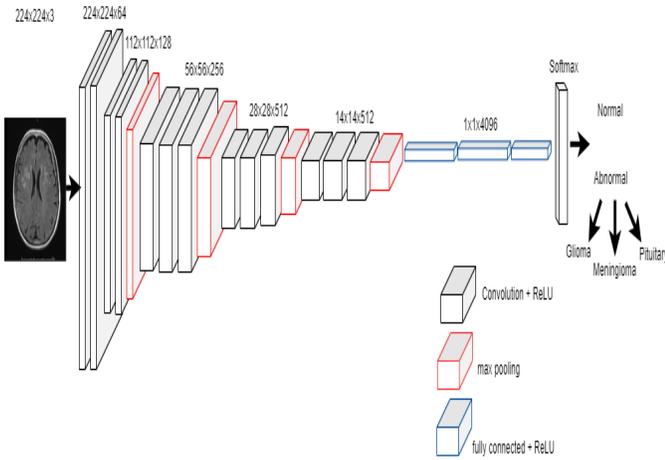
MobileNet-V2 is a fully convolutional network designed for mobile devices. It has an inverted residual framework,


Fig. 1. MobileNet-V2 Model.
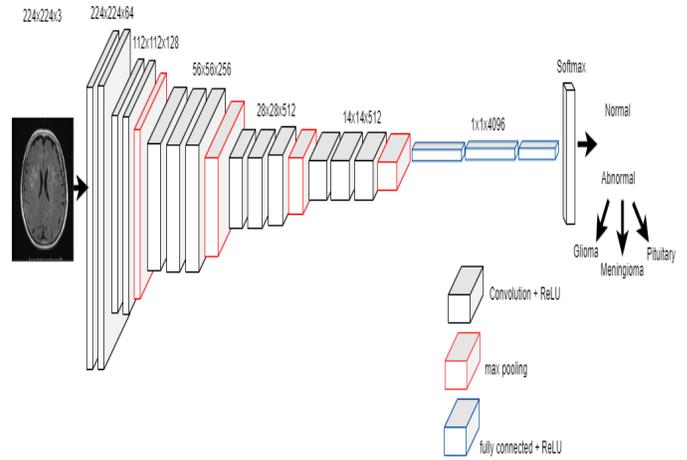

Fig. 2. ResNet Model.

along the congestion layers associated with residual connections. As a source of nonlinearity, the intermediate extension layer filters features with lightweight depth-wise convolutions. The original and improved images come in a variety of range. The first phase is via eliminating the noise from an image by using preprocessing, via median filtering. After that, the images are shrunk to a precise magnitude of 124x124x3 to ensure that they are not at all tiny; that is done to preserve the proportion along with the assists in improved training assuming that the sizes are just the same. The magnitude of 124 was selected since it is the fundamental size of accessible image. The images continue to turn into gray scale for easier understanding of characteristics. The particular images are then transferred to the convolutional layer, the most essential part of a CNN. Fig. 1 shows how the stride varies in each convolutional layer. The MobileNetV2 model has a total parameter count of 2,263,108 and consists of a first fully convolutional layer with 32 filters, followed by 17 residual bottleneck layers and the activation function Relu. It achieves promising accuracy results while using less computing memory and resources. Furthermore, it transforms them into a high speed network for image processing jobs by using dropout, dense followed by softmax activation function. MobileNetV2 is a lightweight convolutional neural network utilized in synchronous functions. First, it has 2,228,996 trainable parameters than classic convolution, which minimizes computing expenses, along with 34,112 parameters are used as non-trainable parameters.

B. ResNet101

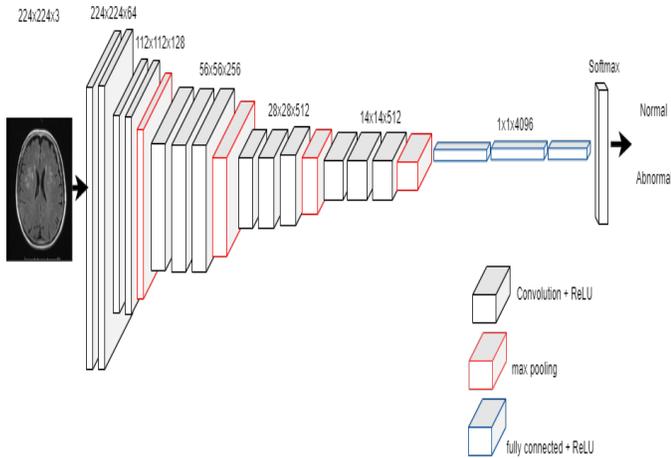
Using ImageNet data, ResNet101 took first state in the ILSVRC 2015 classification test. Because the pre-trained representation is used straight-forwardly for image categorization, transfer learning is adaptive. The images are trimmed such that just the brain area is visible. Preprocessing is the initial stage in removing noise from a image. After median filtering, the images are shrunk to an exact size of 124x124x3 to ensure that they are not too small; this preserves the ratio and aids in better training if the sizes are all the same. Because it is the least accessible, the image size of 124 was chosen. For improved learning of characteristics, the images are turned to gray scale. These images are subsequently transmitted to the

convolutional layer, which is the most crucial aspect of a CNN. Fig. 2 shows how stride varies in each convolutional layer along with pooling layer. The network can accept input images with height and width multiples of 32 and channel width of three. For the purpose of clarity, we'll assume the input size is 224 × 224 x 3. The kernels utilised to conduct the convolution operation in all three levels of the stage 1 block are 64, 64, and 128 correspondingly. Because the convolution operation in the Residual Block is conducted with stride 2, the size of the input is decreased to half in terms of height and width, while the channel width is doubled. As we advance through the stages, the channel width doubles and the input size is cut in half. Each pooling method is repeated for five times. Flattening is an important layer following pooling since we need to turn the whole matrix representing the input images into a single column vector, which is required for processing. The data is subsequently put into the Neural Network for processing. The model is trained and updated using the dataset under consideration for our study to solve two-class problems with outputs of abnormal (class 0) as well as normal (class 1). The ResNet50 model has a total parameter count of 42,666,372 and consists of a first fully convolutional layer with 32 filters, followed by 15 residual bottleneck layers and the activation function Relu. It achieves promising accuracy results while using less computing memory and resources. Furthermore, it transforms them into a high speed network for image processing jobs by using dropout, dense followed by softmax activation function. First, it has 42,561,028 trainable parameters than classic convolution, which minimizes computing expenses, along with 105,344 parameters are used as non-trainable parameters.

C. DenseNet121

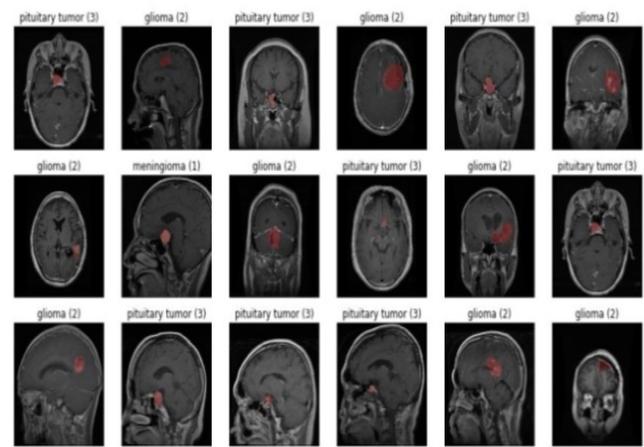
The first step is to use preprocessing to eliminate noise from a image. It is accomplished by the use of median filtering. The median filter is used to eliminate outliers from a picture while preserving the image's information. The photos are scaled to an exact size of 124x124x3 after median filtering to ensure that they are not too tiny; this retains the ratio and assists in better training if the sizes are all the same. The image size of 124 was chosen since it is the least accessible.

Fig. 3. DenseNet Model.

Fig. 4. Dataset of Brain Tumor.


For improved feature learning, the images are transformed to gray scale. These images are subsequently sent to the convolutional layer, which is the most critical aspect of a CNN. Figure 3 shows how the stride varies in each convolutional layer. DenseNet121 employs a first fully convolutional layer with 57 filters, followed by 119 residual bottleneck layers and activation function maximum pooling with 7,047,504 total parameters. The network may accept input images with height, width multiples of 32, and channel width of three. For the sake of clarity, we will take the input size to be 224×224 x 3. The kernels utilised to execute the convolution operation in all three levels of the block of stage 1 are 64, 64, and 128 correspondingly. Because the convolution operation in the Residual Block is conducted with stride 2, the size of the input will be decreased to half in terms of height and breadth, but the channel width will be doubled. As we move through the stages, the channel width doubles and the size of the input is cut in half. Instead of using the Gradient descent (GD) technique, the Adam optimizer was used, which maintains a consistent learning rate for each weight in a network. Dropout, a regularizer, is used in our technique in completely linked layers. For this reason, a rate of 0.5 is specified. As a loss function, the binary cross-entropy loss function (log loss) was used. Finally, ReLU is used in conjunction with the Adam optimizer for classification, where 0.5 is classified as [1 0] (abnormal) and anything else as [0 1] (normal). The DenseNet model has a total parameter count of 7,041,604 and consists of a first fully convolutional layer with 32 filters, followed by 15 residual bottleneck layers and the activation function Relu. It achieves promising accuracy results while using less computing memory and resources. Furthermore, it transforms them into a high speed network for image processing jobs by using dropout, dense followed by softmax activation function. First, it has 6,957,956 trainable parameters than classic convolution, which minimizes computing expenses, along with 83,648 parameters are used as non-trainable parameters.

VII. EXPERIMENTS AND ANALYSIS OF RESULTS

The information came from the open-source Kaggle database. The collection contained X-ray photos of healthy and brain tumour patients. To extract the characteristics, a CNN model is used. Four Conv2D layers, three Maxpooling2D levels, one flatten layer, two dense layers, and a ReLu activation function comprise the model. The ReLU function is used to activate the last thick layer. The primary goal of this research is to evaluate the accuracy of the planned model to that of the pretrained model. The final layers are fully adjustable, with options such as Average Pooling, Flatten, Dense, and Dropout.


A. Dataset Used

Magnetic Resonance Imaging is the most effective tool for detecting brain cancers (MRI). The scans yield massive quantities of data pictures, which the radiologist examines. We propose a classification model in this paper that would allow us to take MRI pictures of the patient as input and calculate whether or not a tumour exists in the brain as output. The dataset of the proposed framework has been taken from the kaggle repository as shown in Fig. 4. The dataset contains 826 brain MRI images of glioma tumor, 822 images of meningioma tumor, 847 images of pituitary tumor, and 395 images with no tumor. As a result, there are 2890 images in total. 80% of the dataset has been used for training where as 20% for testing purposes. X-ray images of both healthy and brain tumor patients were included in the collection. The models learn to recognize images based on the properties extracted from the provided images. To eliminate noise, the dataset was gathered locally and pre-processed with an adaptive histogram equalizer.

B. Tools Used

To carry out the implementation, the Python programming language is employed. Keras and TensorFlow are the libraries utilized. Several Python-based packages are studied in this study to implement our techniques.

C. Preprocessing

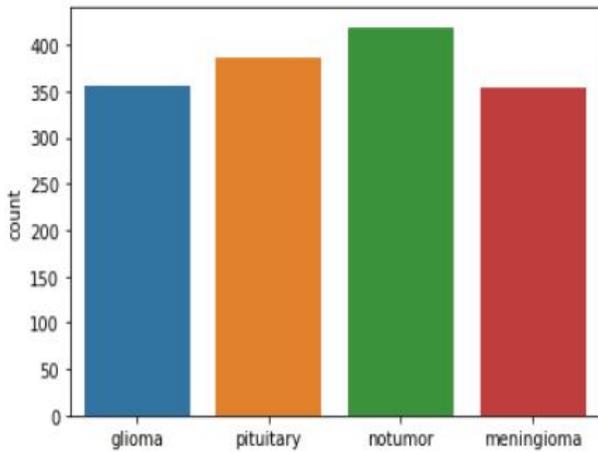
The modified curvature diffusion equation (MCDE) is used to normalize image intensity as additional step in the preprocessing phase. The Wiener filter is used in medical imaging to increase local and spatial information. When the noise level is excessive, it is difficult to recover the edge of


Fig. 5. Testing Simulation Result of Dataset.
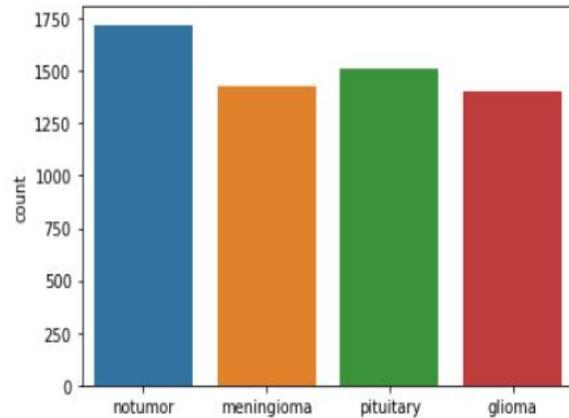

Fig. 6. Training Simulation Result of Dataset.

an image. Because images have distinct variations in intensity, contrast, and size, pre-processing is used to provide smooth training [12]. The wrapping and cropping method will be applied to the input image in the first pre-process. The input image is verified against the edge of the major object in the image during wrapping. Cropping occurs when the biggest edge of an image is set so that the item in the image stays intact. Because the picture sizes in the collection differ, resize the image to (240x240x3) = (image width x image height x number of channels). To aid in learning, normalise pixel values to the 0-1 range. The next step is to make an array out of each photograph in the collection. The image is used as a preprocessed input by MobileNetV2, DenseNet, and ResNet50. Coding is the final stage. The tagged data is converted into a numerical label, which may be understood and evaluated. The dataset is then separated into three sections: 20% for validation, 70% for training, and the remaining for testing.

Fig. 7. Classification Report of MobileNet-V2 Model.

D. Performance Metrics

Researchers evaluate many performance indicators in classification, with accuracy being the most commonly used performance parameter. Accuracy, precision, F1 Score, and support are the parameters used to validate our results.

VIII. EXPERIMENTAL RESULTS

To categorize the images as normal or abnormal, MobileNet V2, DenseNet121, and ResNet101 are used. The implementation is separated into two parts: general categorization into normal or abnormal brain tumors and specific classification into different categorises of the brain tumors. There are two approaches: k fold cross validation with k fold = 5 as well as 8 (arbitrary values), along with the generalisation strategy, which does not use training phase data in the testing phase. Both training as well as testing evidence of the used dataset are represented in Table I.

The graphical representation of result of the testing simulation is shown in Fig. 5 and the result of the training simulation is shown in Fig. 6.

A. Results and Analysis

In MobileNetV2, total parameters 2,263,108 are used. Out of which, 2,228,996 are used as a training parameters and 34,112 are used as a non-training parameters.

Fig. 7 shows the classification results for parameters such as precision, recall, f1-score as well as support for four classes of dataset used along with macro-average accuracy of 97% and weighted-average accuracy of 97%.

Fig. 8 shows the confusion matrix for the four classes of tumor dataset in MobileNet-V2 Model, which shows exponential value as 3.5e+02, that means the accurate values is 350 in decimal for glioma tumor, exponential value as 3.2e+02, that means the accurate values is 320 in decimal for meningioma tumor, exponential value as 4.2e+02, that means the accurate values is 420 in decimal for normal patients and exponential value as 3.8e+02, that means the accurate values is 380 in decimal for pituitary tumor patients.

Fig. 9 shows the graphical representation of the training and validation accuracy/loss for the MobileNet-V2 model. The testing accuracy and loss is almost constant for number of

TABLE I. TESTING-TRAINING SIMULATION RESULT OF THE DATASET

Types of tumor	Testing Simulation result	Training Simulation Result
Glioma tumor	350	1400
Pituitary tumor	375	1500
No tumor	425	1700
meningioma tumor	340	1400

Fig. 15 depicts a graphical depiction of the ResNet101 model's training and validation accuracy/loss. The testing accuracy and loss are practically constant for the number of epochs, but the validation accuracy varies substantially with

the number of epochs, but the validation loss is constant.

IX. LIMITATIONS OF EXISTING MACHINE LEARNING METHODS

The following are the primary difficulties in detecting brain tumors:

- It is still difficult to detect a little quantity of tumour since it might be mistaken for a normal region.

- Some existing techniques are effective in one tumour site but not in another (enhanced or non-enhanced), and vice versa.

X. DISCUSSION

The Table II displays the comparison of loss along with accuracy values for test parameters of different machine learning methods. The following parameters such as precision, recall, F1 score and accuracy have been used to assess the prediction results. Obtained values of precision, recall, F1 score as well as support for classification of ML models are represented

TABLE II. COMPARISON OF LOSS AND ACCURACY VALUES FOR TEST PARAMETERS OF DIFFERENT MACHINE LEARNING METHODS

Machine Learning Methods	Test Loss	Test Accuracy
MobileNet-V2	3.8652	0.30735
DenseNet121	0.25539	0.893838
ResNet101	0.082731	0.971789

in Table III. MobileNet-V2 models are the least suited for the image classification of brain tumors, as the accuracy for both macro-average and weighted-average is 97%. It can be seen that DenseNet model shows best results, which shows the accuracy for both macro-average and weighted-average is 99% due to its improved generalization and embedded ensemble learning feature. Our experimental performance proves the highest for our proposed CNN model with an accuracy of 92% which is more than all other models trained.

Following a thorough examination of existing state-of-the-art approaches, the following challenges have been identified:

- A brain tumor grows rapidly in size. As a consequences, early tumor diagnosis is an extremely important job.

- MRI pictures are inaccurately classified due to magnetic field changes in the coil.

- Another tough procedure is the structured and best feature extraction and selection.

XI. CONCLUSION

Convolutional neural networks are still a hot topic in the field of automated tumor segmentation. It is critical for radiologists to understand convolutional neural networks in order to be prepared to use these technologies in clinical practice in the future. A thorough examination of several CNN designs was conducted along with their limitations when faced with a small dataset. One of the most significant fields of medical imaging is the hunt for a treatment for various forms of brain tumours. To avoid overfitting, this article employs a data augmentation approach prior to classification. To reach a conclusion, we examined three machine learning approaches: MobileNet-V2, DenseNet121, and ResNet101. However, this study demonstrates the significance of supervised learning approaches in the development of CAD systems to reduce the burden on radiologists. A future investigation could include collecting larger brain MR images to generalise the classifier systems. T2-weighted contrast-weighted MRI images were used in this study. The fundamental purpose of this project is to develop a high-accuracy, high-performance, and low-complexity automated brain tumour classification system. As the loss for test parameters is very high for MobileNe-V2 i.e. 3.8652 as compared to DenseNet121 i.e. 0.25539 and ResNet101 i.e. 0.082731, due to lot of errors, so this MobileNet V2 model is going to be modified in our future work.

Abstract— The role of test results in the diagnosis and treatment of patients' diseases at medical facilities cannot be ignored. Patients must have a series of tests that are related to their symptoms. This can be repeated as many times as possible, depending on the type of disease and treatment. Seriously, in the cases where the patients lose their medical test record (i.e., patient's medical history), the diagnosis is difficult due to the lack of information about the medical history as well as the symptoms/complications in the previous treatments. Storing this treatment information in medical centers can address risks related to user failure (e.g., loss of medical test records and wet/fire documents). However, users face a bit of difficulty when they change to other medical centers for medical examination and treatment since the data is stored locally, and difficult to share this with others. Current solutions focus on empowering users (i.e., patients) to share medical information related to disease treatment. However, the main barrier to these approaches is the knowledge of the users. They must embrace some background in terms of the technologies, risks, and rights they may share with treatment facilities. To solve this problem, we propose a Blockchain-based medical test result management system where all information is stored and verified by the stakeholder. The data will be stored decentralized and updated throughout the treatment process. We implement a proof-of-concept based on the Hyperledger Fabric platform. To demonstrate the effectiveness of the proposed system, we conduct evaluation methods based on three main tasks of the system: initializing, accessing, and updating data on six different scenarios (i.e., increasing in size of processing requests). The evaluation based on Hyperledger Caliper helped us to have a deeper analysis of the proposed model.

Keywords—Blood donation; blockchain; hyperledger fabric; blood products supply chain

I. Introduction

The need for health care is extremely urgent for all ages. The diagnosis process has a great influence on the treatment of the patient. To be able to make an accurate diagnosis of the condition, doctors must consider the test results as well as the patient's medical history. This information is usually compiled in a medical test result. Depending on the medical facility, medical test results are provided in the form of paper results or electronic results [1]. One of the biggest difficulties in this traditional process is the long processing time and waiting time, not to mention all the information resulted in the medical test result (i.e., information about the patient's health). In addition, the traditional medical process is not yet capable of reusing the patient's existing test results. Specifically, the current storage methods are only centrally stored in a central or hospital server in the big cities. This situation does not apply to small health facilities in the countryside [2]. For this reason, all resulted information is manually analyzed by the physicians before being resulted in the patient's medical result [3].

This situation is extremely risky for the healthcare system because i) it is easy for patients to lose the medical test results due to natural issues (e.g., flood, fire) or their failure (e.g., lost); ii) it is very difficult to back up those results because of technology and equipment limitations. To this end, the previous approaches that have contributed a lot to these risks are based on centralized personal data methods (i.e., where the user is central and is allowed to share any data with the hospital/ medical facility or third party) [4]. In addition, the methods propose a decentralized management mechanism for users, including hospital or medical center staff (e.g., doctors, nurses) and patients and their family members; [5] in special cases (e.g., emergency [6]). These approaches are based on the assessment that health care is needed and prioritized over privacy issues. However, both groups of approaches have encountered a binding mechanism that the patient must be able to use smart devices (i.e., smartphones). They argue that privacy risks are of great concern and that there must be a reasonable mechanism for healthcare-related issues where medical data is exploited/stored/processed. This argument is completely correct and can be applied to big medical institutions where the facility is available for data storage and processing. However, for the other scope (i.e., small medical centers), not many approaches provide the solution in terms of storage and processing of the medical data [7], [8].

This paper is one of the first attempts to address the above issues related to the storage of medical test results from medical/healthcare centers. We aim for a decentralized storage solution that is not bound by data storage and processing equipment in small and medium medical centers. This study opens up a potential approach where decentralized methods of storing and processing patient personal data (i.e., test results) can be applied. In addition to infrastructure barriers, we also consider issues related to data transparency, where all information stored is verified by stakeholders (e.g., patients, the patient's relatives in the emergency situation, and the doctor). This method gives transparency to all stored data. All of the above solutions lead to a Blockchain-based approach, where all data is verified by the parties involved. Furthermore, the data is stored and processed decentralized.

Blockchain technology is known for its outstanding features of transparency and immutable content. Picha Edwardsson et al. studied the possibility of using blockchain technology

to create a secure, community-facing information verification database with the goal of creating a solution that could improve the reliability of verifying information and monitoring each authenticity verification process for digital content, including images and videos. The paper indicates that blockchain is not yet ready to be directly applied to fact-checking processes in a real-world scenario. The study also shows that the application of blockchain to verify a scenario is entirely possible and highly reliable and transparent [9]. Several approaches address these problems by applying Blockchain techniques in the other environment (e.g., cash-on-delivery [10], [11], [12], healthcare [5], [4], [6], supply chain [13], [14], [15], and others [16], [17], [18]). As for the patient's/patient's ability to use technology, we assume that they have the ability to read information about their personal data usage through their phone whenever there is a phone call. access from outside the system.

Rather than emphasizing the role of patients in our system [19], [20], [21], our proposed model aims to propose a de-centralized store and process system for the patient's medical test results (see more details in Section II). In other words, our system is device-centric instead of user (i.e., patient) or service provider (i.e., app). All processing requests are guaranteed by the parties (i.e., patients and therapists) and stored on a distributed ledger. An important difference from our system is that our proposed model still uses a trusted third party to manage the encryption and decryption of data before and after processing them. Acknowledging that adopting a model of depending on a trusted third party will compromise the security of the entire system (i.e., third party trust level). However, it also brings benefits when the data is secure and has fewer burdens on users as well as the user's background requirements [22]. Responsibility for the protection of personal data is assigned to a security company (i.e., third party). As for the implementation, we exploited the Hyperledger Fabric platform for our proof-of-concept. The related evaluation to prove the effectiveness (i.e., focusing on initialization, query, and update) was analyzed by Hyperledger Caliper.

Stemming from the research problem of ensuring transparency and decentralized storage for patients' medical test results (see details in the related work section), we propose a model for information management about patients. Test results based on Blockchain technology and Smart contract. Therefore, our main contribution revolves around three aspects: (a) building a medical test result management system based on Blockchain and Smart contract; (b) building proof-of-concept on top of Hyperledger Fabric; and (c) assessing the appropriateness of the approach based on an analysis of three main scenarios (i.e., initialize, retrieve, and update) based on the Hyperledger Caliper platform.

The next section presents the state-of-the-art. Sections III and IV present our approach, processing model, and system implementation. Section V builds an environment for evaluating proposed models and makes comments on their strengths and weaknesses as well as future directions in Section VI. Finally, we summarize the study in Section VII.

II. Related Work

There are many approaches that have proposed methods for remote diagnosis and treatment of diseases, which are

data mining and other practical applications based on medical data by exploiting the strengths of the blockchain technology. For example, Chen et al. [23] proposes a model for storing and controlling personal data in a healthcare environment based on Blockchain technology. This system can collect information from IoT devices (i.e., medical devices in real time). To improve the security of the system, the authors build an anonymous data sharing environment and encrypt the patient's personal data before storing them on cloud servers. Similarly, Du et al. [1] and Son et al. [24] used medical centers (i.e., hospitals) to store data and manage access and those hospitals. Specifically, they categorize two types of medical data protection policies: global for all data shared outside of the medical center, and local, which is accessed only by individuals at the medical center. medical (i.e., doctor, nurse). However, one of the major limitations is that through this solution, patients do not have full control over their data as the data and policies are stored in the hospital. Patra et al. [25] proposes a cloud-based model to build an information system at the national level, providing a more convenient solution for patients in rural areas at the lowest cost. Specifically, instead of having to go to health care centers in large companies, they propose a solution to diagnose and treat diseases remotely. Specifically, citizens are encouraged to provide their personal healthcare information, which will be stored in the health cloud and accessed by health professionals and policymakers to provide more medical services. Similarly, Rolim et al. [26] proposes a framework that covers the process from data collection to cloud-based data delivery. Using sensors mounted on medical equipment, data can be collected and stored directly in the cloud, which can be accessed by authorized medical professionals.

Some other approaches build a user-centric (i.e., patient) model, who has full discretion to share their personal data with providers/health care facilities. economic (i.e., in a medical setting). For example, Makubalo et al. [27] has summarized the above approaches in their publication. They argue that the methods of building a user-centric health data sharing system are facing a lot of difficulties due to the limitations of the method of building centralized data system (i.e., data) stored and processed centrally in cloud servers). Yin et al. [28] introduced a patient-centric system built in the cloud with a data collection layer, data management layer, and medical service delivery layer based on medical records of the patient. To protect data privacy, many approaches have adopted attribute-based encryption (ABE), one of the most common encryption schemes used in cloud computing, to define patient data object. Depending on the context, the policy tells to lose (or not) grant the corresponding access rights. For example, Barua et al. [29] proposes an ABE-based access control model based on patience and privacy protection; Chen et al. [30] described a new framework with a cloud-based, privacy-aware Role-Based Access Control model that can be used for control, data traceability, and access allowed access to healthcare data resources. Methods for applying the Access Control model are also introduced for dynamic policies [31], [32] or protection policies for both security and privacy [33].

In addition, Madine et al. [34] has introduced a Smart Contract-based system that provides patients with reliable, traceable and secure control over their medical data (i.e., which is stored non-invasively). concentrate). To increase the security

and privacy of medical data, they used the decentralized storage feature of the interplanetary file system (IPFS) to store and share patient medical data safely. For practical applications, HealthBank has proposed a healthcare system and surrounding ecosystems that allow users (i.e., patients) to manage and control their data.[1] This solution is recommended to be able to comply with strict security and privacy regulations (e.g., GDPR) and to assist users in using their services. In addition, the system also proposes solutions for storing personal data with complex data encryption algorithms, immutability and accountability. Similarly, HealthNautica and Factom Announce Partnership have used blockchain technology to ensure the integrity of patient medical data while providing transparency based on blockchain technology and encryption of sensitive data (e.g., personal information, health status).[2] With the same approach based on Blockchain technology and IPFS, Misbhauddin et al. [35] introduced the MedAccess platform, A Scalable Architecture for Blockchain-based Health Record Management. The platform supports on-chain storage and processing allowing doctors, lab technicians and patients to securely manage medical records. However, these systems face some problems in the processing and storage of personal data. Specifically, Le et al. [12] has argued that not all data collected must be processed on-chain. Instead, Son et al. [14] argues that personal data that is either not directly related to treatment or diagnosis may be stored off-chain (i.e., offchain). Similar to the above approach, to increase the processing capacity for the whole system, Zyskind et al. [36] presented an approach based on in-chain and out-of-chain processing. Onchain processes require all entities of a typical personnel management system, where patient and medical staff information is stored; in contrast, encrypted medical data is stored on a separate centralized storage server to enable faster access and low cost. However, the above methods have major limitations including that any information that is validated must be executed on-chain instead of local processing. This only benefits storage but does not change data handling (i.e., since all information still executes on-chain) [7].

The above approaches have brought many solutions to today's traditional health care systems. However, in developing countries (e.g., Vietnam) where medical equipment and supplies are one of the barriers that directly affect people's health care process. In addition, the above approaches require a certain knowledge of information technology as well as the risks related to security and privacy. It is for the above reasons that a few case studies (i.e., applied to a specific geographical area - country, region) address the upper limits of [37]. In this article, we provide Blockchain-based support for the management of test results in medical centers.

III. The Blockchain-based Medical Test Results Management System

A. Traditional Model

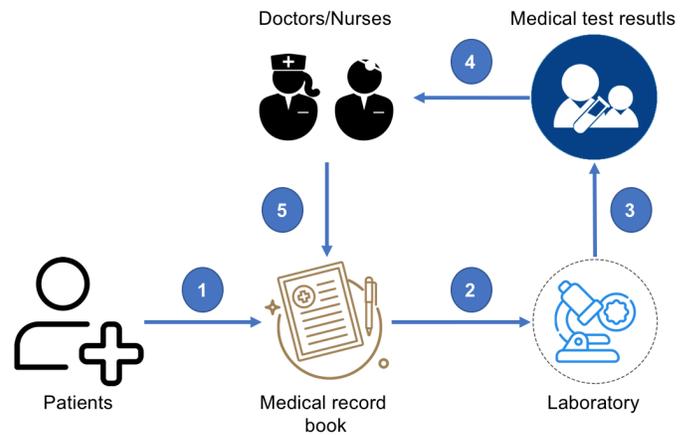
Fig. 1 shows the basic steps of the traditional medical test results management process. This model describes the five main steps, excluding the risks of losing medical test


Fig. 1. The Traditional Process for Medical Test Results Management System.

results. In other words, this process will be repeated for each patient whenever they have a routine checkup or a health-related reason. Specifically, in the first step, the patient registers for a medical test result, which includes basic information about the patient, such as full name, address, phone number, or medical condition. The medical test result number is also the patient number at that hospital. In the second step, the patient brings the medical test result to a specialist at the hospital, called a laboratory (e.g., eye, blood, urine) for sampling. This procedure requires a very long wait time from the patient. The patient then receives information about this form in the third step before forwarding this information to the doctors and nurses for consultation in the fourth step. Finally, the consultation results are updated in the medical test result of the patient in the fifth one.

For the process of storing patient information, the storage of their information is completely manual. Only a few major medical centers in major cities support the storage of medical results on their centralized database. This demonstrates that it is not feasible to share a patient's medical result between different healthcare facilities. It is easy to see that there are many inconveniences for both patients and hospital staff when using the current testing/receiving process, respectively. The first limit comes from the patient, all information stored on the medical test result must be ensured carefully, and the medical test result must not be lost otherwise, all procedures will have to be repeated from the beginning with a new medical test result. Changing the place of treatment/examination is extremely difficult because the patient has to bring the medical test results issued at the previous medical facility to a new one. In addition, the loss of medical test results is extremely risky, besides the reason for having to repeat the entire sampling process, since they relate to the diagnosis process. Regarding the responsibility of physicians (i.e., doctors/nurses), they must reread a patient's entire medical history each time their patient has a follow-up visit. This is similar to the process of examining a new patient.

B. Proposed Model

To solve the above problems, we introduce a model based on Blockchain technology, where all information related to the testing process and the storage of patient's medical test results are updated and shared freely in the healthcare environment. Fig. 2 shows our proposal system based on Blockchain technology and distributed ledger (i.e., Hyperledger). As a first step, the patient initializes a global ID for not only a certain healthcare facility but also for others ones (e.g., the hospital in the same city). Unlike the traditional process, in another word, this ID will identify the user globally, which means that the patient can be examined at another medical facility without affecting the diagnosis process. Specifically, doctors/nurses can retrieve information about a patient's medical history based on their global ID (this will be covered in more detail in the next steps). From the initial global ID, users can generate more than 1 medical test result (i.e., per medical facility or healthcare service). These records store all test results and related patient information (i.e., similar to a medical test result in the paper). The data stored on the medical test result is always updated to Hyperledger (step 3). Users will then go to the respective Laboratories to take samples (step 4) before seeing a doctor in person to receive advice on their health status (step 6). This is the biggest difference between our model compared to the traditional model. Patients do not need to wait a long time at the facility; instead, an appointment is delivered to their device (e.g., smartphone) whenever their result is available. Meanwhile, the remaining steps will be executed independently at the system under the confirmation of the relevant parties. Specifically, after testing, the results are updated to the Hyperledger, and this information includes the user's corresponding medical test results and metadata about the time and location of the test as well as the doctors participating in the consultation. In case the patient goes to another medical facility, the patient's permission (or the patient's family member's/relatives in some special cases) must be obtained before accessing the patient's medical data (i.e., over-privileged permission). After receiving the request from the system, the doctors will enter the diagnostic results into the system (i.e., Hyperledger). The whole process will be confirmed by the stakeholders during the execution. The data will be encrypted when there is no request for access or update from the relevant parties (e.g., patient, nurse, doctor). The next section presents our approach based on Hyperledger Fabric.

IV. IMPLEMENTATION

A. Permission Diagram

Fig. 3 presents the working mechanism of the request authentication process in this paper. Specifically, we built two organizations with corresponding encrypted material certificates, each organization includes two users and two peers. Each peer is responsible for maintaining the version of the ledger so that the network and data can be maintained even if other peers are shut down.

When the user initiates a request and sends it to the service. The back-end service processes the data and sends it to the smart contract API. When receiving the request and the data, the smart contract sends this to the peers in the network for authentication and data interaction purposes. During the

creation, querying or updating data processes, peers check the identity of the request to decide whether to allow access to the data at the distributed ledger. If the identified user of the request is not defined in the data collection, the system denies access and sends a message to the back-end API to notify the user; the system allows access and proceeds with further processing steps.

B. Hyperledger Component

The model in this paper is implemented on the Hyperledger Fabric platform. Fabric is a permissionless blockchain platform that integrates smart contracts, the storage of data to the distributed ledger is controlled through the smart contract APIs, from which the data is simplified and easily traced. Each request that goes through the smart contract is verified with public and private key pairs. In other words, if the user does not exist in the system, the system is better protected from malicious requests outside the system.

The Fabric system in this paper includes two organizations. Each organization consists of two peers to store smart contracts, where each peer registers two users and is authenticated with public and private key pairs. The components of the model are shown in Fig. 4

When user devices access the system to initiate/query or update data for a particular transaction, requests are sent from the client to the services of the existing system. Then, these services send access information to the peers belonging to the organization located in the blockchain network. At this step, the peers conduct verification of that user's key pairs, and if the successful peer authentication process proceeds to send information to the smart contract with the transaction type declared in a smart contract requested by the user, the smart contract will go through the designed features function to access the distributed ledger to initiate/query or update specific data.

C. Our Proposed Model's Diagram

One of the most important parts of the model lies in the validation and interaction with the patient's global ID and their medical data described in Fig. 5 and 6. In particular, the main functions include initializing and querying the patient's global ID and their medical data.

Fig. 5 depicts the process of storing new record data (e.g., patients' global ID and their medical data). In step 1, when the user initializes information about a certain ID, the data is sent to the back-end service of the health center's information management system. In the next step, the back-end APIs (i.e., backend) check, authenticate, and initialize the default values, then pass the parameters to the API inside the smart contract. At this point, a smart contract transfers data and stores transactions to the distributed ledger of the blockchain network. The default values for parameters sent from the request are intended to minimize errors caused by null field data.

Fig. 6 presents the process of retrieving data of a particular (e.g., patients' global ID and their medical data). When the user sends a query request to the system, the service query data checks and confirms whether the parameter ID of their

Fig. 2. The Proposed Model for Blockchain-Based Medical Test Results Management System.

Fig. 3. Permission Diagram.

Fig. 5. Initializing and Storing the new Data.

Fig. 4. Hyperledger Fabric Component.

Fig. 6. Retrieving/Querying Data Process

medical data exists or not. Then, the smart contract's APIs are called and passed into the corresponding parameter. Next, the smart contract's APIs check for the existence of data in the request before querying. In the case that the ID does not exist, the smart contract sends an error notification to the user's device; otherwise, it returns the relevant data/record of the patient corresponding to the requested ID.

V. EVALUATION SCENARIOS

A. Environment Setting

Our paradigm is deployed on the Hyperledger Fabric network maintained inside docker containers. In this section, we measure the performance of chaincode in the two scenarios: initializing (i.e., creating data) and accessing data. The exper-

iments are deployed on Ubuntu 20.01 configuration, core i5 2.7Ghz, and 8GB RAM.

To prove the effectiveness of our model, we also define several experiments by exploiting the Hyperledger Caliper[3] that is used to design the test scenarios and collect all the information regarding the performance.

B. Results

1) Data Creation: In this scenario, the study measures the performance of the data initialization function/data created (e.g., medical record book) performed through smart contracts. The number of requests sent simultaneously from two users[4]. Table I shows the execution results of the data initialization/creation function (e.g., medical record book). The data initialization/creation script is conducted with two users concurrently making 1000 - 6000 requests to the system. We measure the parameters of command success/failure and system latency (i.e., max, min, avg). Based on the execution results in Table I, it can be seen that the number of successful and failed requests is stable (except in the case of 6000 requests). Specifically, the number of failed requests is limited to less than 7,500 (i.e., 7,458 requests - 16.24%). Meanwhile, the lowest case was with only 6.57% (2,953 requests). The highest failed request rate is in the first 1,000/s request, the system is more stable in terms of data creation with only an average of 5K errors per scenario (from 2K requests to 6K). For system-wide latency, we recorded the number of requests with response delays per 1,000 requests/second to 6,000 requests per second. Specifically, the data in Table I demonstrate that the highest latency ranges from 1,626.57 to 1,781.15 seconds. The minimum is less than 8 seconds. The average delay when creating new data is less than 900 seconds. This is acceptable because creating thousands of new records at the same time is very unlikely in medical centers. The results observed in this scenario also demonstrate that the system supports very well with the continuous generation of new profiles.

2) Data Access (Retrieving/Querying): In the second experiment, we consider the data access (e.g., medical record book). We also set up 6 scenarios from 1000 to 6000 requests which access the medical record book from 2 users. Table II shows the execution results of the data access function (e.g., medical record book). Compared with the first task (i.e., data creation), the results of 6 scenarios to evaluate the data accessibility of our proposed blockchain-based system are more balanced. Retrieval of stored data is extremely important. Indeed, considering health data retrieval time directly affects the patient's health care.[5] To solve this problem, we consider the latency of the system (i.e., the maximum/average/minimum time it takes to process the request of data accessed from the system). Specifically, the maximum time to wait for a data retrieval request is 15 seconds (Note: all of our simulation scenarios use single information retrieval/querying data - not concluding. complex access requirements, such as join and group by commands like database management systems on SQL). The minimum wait time is almost instant response

(i.e., with only 0.06 seconds). The average time for each data retrieval request is about 7.35 seconds. Given the number of successful and failed requests, we also collect the number of requests at every 1000 to 6000 requests per second. The number of successful and failed requests is fairly balanced, around 80% of the requests are successful in all 6 scenarios.

3) Data Edit/Update: Finally, we look at the user's ability to update the medical test result's data. This parameter reflects whether a doctor or nurse updates information about a patient's medical record (e.g., new symptoms, diagnoses). In this scenario, we also conduct a review of six different scenarios, each of which will require processing from 1000 to 6000 requests per second. We also measure two parameters, similar to the two scenarios above, the number of successful and failed requests and the overall latency, which is shown in Table III. In terms of time, updating data is more complex than the previous two scenarios (i.e., initialization and access). Specifically, we must determine if user information exists in Hyperledger, then we determine which information needs updating (e.g., symptoms, disease diagnoses). Because of the above requirement, the execution time for the update task is longer. Specifically, the latency of all scenarios ranges from 850 to 950 seconds in the maximum case. The minimum latency ranges from 0.5 seconds to 0.6 seconds, while the average latency required by an application to process ranges from 370 seconds to 400 seconds. Similarly, the number of failed requests was also higher than the success requests in all six scenarios (with an average of about 51%).

VI. Discussion

Comparing all three evaluation scenarios, we find that real-time is acceptable. We also describe why there is a difference between the time lag in the execution of requests from the system depending on the complexity of the query. Specifically, the most prolonged time lag was recorded in data initialization due to updating to Hyperledger. This is different from the traditional way of storing data, where the information is only stored in tables and is done by the system administrator. On the contrary, initiating a medical test result requires confirmation from all relevant parties. In addition, defining constraints in an update request is more complex than in a retrieval request. The update time clearly defines the information the requester wishes to add/update to the existing medical test results. Finally, the fastest execution time is the data retrieval request which offers more promise for a Blockchain-based system than traditional storage systems.

However, Section V provides a marked change in all three data creation, retrieval, and update scenarios regarding the number of success and failed requests. Specifically, in the update scenario, the failure rate of requests is much higher than in the data initialization scenario (with more than 50% compared to less than 20%). A similar method occurs when comparing data retrieval and initialization with more than 20% and less than 20% of failed requests, respectively. This happens because we build a system that simulates the interactions between the parties (e.g., patient, nurse, doctor). In particular, the update and retrieval request must require the data to be initialized before. Otherwise, the request is considered a failure. For the update scenario, the system also requires that the updated information be initialized before being replaced

with new data (e.g., patient information and medical history). Initializing a dummy data system according to the above requirements is extremely difficult because we do it on two separate user groups.

For the system specification, we have not included encryption and decryption times for the data stored on Hyperledger. We assume that a trusted third party will take care of this. In terms of execution time, including the user critical generation time, as well as encryption and decryption, will increase the execution time for the whole system. This is hard to meet on our simulation system. In addition, this proposed model is also the first attempt to build a blockchain-based system that aims to offer a test management model in medical centers in developing countries. We intend many potential research directions to follow after this work. One of the mandatory requirements for health systems is confidentiality (i.e., authentication and authorization). We apply the proposed models based on the dynamic data support the environment of IoT devices [38], [39]. For authorization, a model based on ABAC [32], [31] and supporting dynamic policy [40], [41] is an appropriate choice in the context of the current health system. For encryption requirements, we use a trusted authority that provides a solution to store and protect patient data on Hyperledger [42].

VII. CONCLUSION

In this work, we propose a test process management system based on Blockchain technology. The main contributions of our solution are threefold: (a) building a medical test result management system based on Blockchain and Smart contract; (b) building proof-of-concept on top of Hyperledger Fabric; and (c) assessing the appropriateness of the approach based on an analysis of three main scenarios (i.e., initialize, retrieve, and update) based on the Hyperledger Caliper platform.

Specifically, (**a**) all user-related information as well as test results, diagnoses, and patient medical records are stored on Hyperledger (distributed ledger). All this stored information is authenticated by the relevant parties (i.e., patient, nurse/-doctor). We also offer a traditional test process management system. Thereby, we compared it with our proposed model before implementing proof-of-concept implementation on Hyperleger Fabric platform (i.e., (**b**)). In evaluating the feasibility of the proposed system, we analyze 3 key tasks of a Blockchain-based system (i.e., data initialization, retrieval and update) on six scenarios requiring access from 1,000 to 6,000 requests/second. Comments and future directions are presented in the Discussion section of the paper. Based on the analysis results, we found that our proposed model works stably in the scenario of up to 6,000 incoming requests per second in a simulated environment with limited resources (i.e., (**c**)).

Abstract—**Ever since the medieval era, the preponderance of our concentration has been concentrated upon agriculture, which is typically recognized to be one of the vital aspects of the economy in contemporary society. This focus on agriculture can be traced back to the advent of the industrial revolution. Wheat is still another type of grain that, in the same way as other types of harvests, satisfies the necessity for the essential nutrients that are required for our bodies to perform their functions correctly. On the other hand, the supply of this harvest is being limited by a variety of rather frequent ailments. This is making it difficult to meet demand. The vast majority of people who work in agriculture are illiterate, which hinders them from being able to take appropriate preventative measures whenever they are necessary to do so. As a direct consequence of this factor, there has been a reduction in the total amount of wheat that has been produced. It can be quite difficult to diagnose wheat illnesses in their early stages because there are so many various forms of environmental variables and other factors. This is because there are numerous distinct sorts of agricultural products, illiteracy of agricultural workers, and other factors. In the past, a variety of distinct models have been proposed as potential solutions for identifying illnesses in wheat harvests. This study demonstrates a two-dimensional CNN model that can identify and categorize diseases that affect wheat harvests. To identify significant aspects of the photos, the software employs models that have previously undergone training. The suggested method can then identify and categorize disease-affected wheat crops as distinct from healthy wheat crops by employing the major criteria described above. The reliability of the findings was assessed to be 98.84 percent after the collection of a total of 4800 images for this study. These images included eleven image classes of images depicting diseased crops and one image class of images depicting healthy crops. To offer the suggested model the capability to identify and classify diseases from a variety of angles, the photographs that help compensate for the collection were flipped at a variety of different perspectives. These findings provide evidence that CNN can be applied to increase the precision with which diseases in wheat crops are identified.**

I. Introduction

In addition to terms of its civilization, but also terms of its cuisine, Bangladesh is a very diverse country. Bangladesh is primarily an agricultural nation, with 80% of its inhabitants dependent on the sector for their livelihood. Wheat is an excellent resource for a variety of minerals, including magnesium and selenium. Certain nutrients are essential for maintaining healthy health. Wheat leaves are particularly susceptible to damage from leaf rust. It has a high incidence of fungus illness, latent infection, and other diseases. Wheat diseases focus on leaves and can be diagnosed using Deep Learning and computer vision [1]. Wheat is the main carbohydrate source in most countries. Both wheat protein and wheat starch are readily absorbed by the body [2]. When wheat is combined with a tiny quantity of animal or legume protein, it becomes highly nutritious because it includes minerals, vitamins, and fats (lipids). One of the earliest plants that have been domesticated, wheat has long been a vital food source for many nations. The nutritional content of the wheat grain is very high. The wheat grain contains 14% protein, 14% starch, and other nutrients like fiber, vitamins, minerals, and high-quality amino acids. Wheat was previously essential to global nutrition due to its high nutritional value and excellent storage qualities. For the manufacturing of contemporary food, basic resources derived from wheat are crucial, such as wheat starch and wheat proteins. 20% of our daily caloric intake comes from bread and baked goods, which are essential to a healthy diet [3,4]. We find it fascinating that one of the oldest crops on the planet may employ modern processing techniques to offer a significant solution to fresh problems. In a variety of applications, the natural components of wheat increase quality and lower resource usage in the final product for the consumer. In the developing world, wheat accounts for more than 35% of the calories consumed from cereal, compared to 74% in the rich world and 41% globally. Almost 70% of wheat is utilized for food, whereas just 20% and 2% to 3% of it are used for industrial processing and animal feed, respectively. Between 2001/02 and 2016/17, the world's consumption of wheat increased by 25%. Two-thirds of the globe's wheat is utilized for food, 20% for animal feed, and 3% to 5% for seed,

industry, and other uses. The economy grew rapidly over a shorter time as a result of the transportation of wheat. Wheat might be used to make a variety of novel foods, including muffins, cereal, and bread. The largest producer of wheat in the world, China has produced over 2.4 billion tonnes of wheat in the past 20 years or around 17% of global production. China consumed roughly 148.5 million metric tons of wheat in the marketing year 2021–2022. In that year, the United States consumed close to 31 million metric tons of wheat. Precision agriculture, often known as artificial intelligence systems, is assisting in enhancing the overall quality and accuracy of harvests. AI technology aids in the detection of pests, plant diseases, and undernutrition on farms. Artificial intelligence (AI) sensors can identify and target weeds before deciding which herbicide to use in the area. The condition of a plant can be assessed by looking at its leaves. This effort aims to create a system based on statistical analysis and blob detection that can detect and classify different diseases. Precision agriculture, often known as artificial intelligence (AI) technologies, is assisting in enhancing harvest quality and accuracy. AI technology helps identify plant illnesses, pests, inadequate plant nutrients, etc. Additionally, it enables farmers to keep an eye on the condition of the soil and crops. After rice, wheat is Bangladesh's second-most significant crop for producing staple foods. Since independence, it has become more significant as a crop for food and nutrition security. From about 0.115 million tons in 1971–1972 to 0.73 million tons in 2005–2006, wheat production climbed considerably. Several study articles discuss the various problems associated with diagnosing wheat crop diseases, such as the frequencies of disease groups, the accurateness, and the dataset; however, there are a lot of areas that may be improved. We have attempted to classify all of the different diseases that can harm wheat crops in this article. We have decided to focus on this system due to our desire to aid our farming sector by fixing these challenges so that the rate of production of wheat may be increased. This is why we have chosen to work on this system. As a result, we are concentrating on the challenge of binary image classification, in which a picture of a leaf can either be assigned to a wheat crop that is healthy or one that is infected with a disease. Here, we used 12 classes, 11 of which were for photographs of crops that were sick, and one class was for a healthy wheat crop. The 12 varieties of wheat crops that we have access to for our research are as follows: Barley yellow dwarf, Black chaff, Common root rot, Fusarium head blight, Leaf rust, Powdery mildew, Tan spot, Wheat loose smut, Wheat soil-borne mosaic, Wheat streak mosaic, Karnal bunt with Healthy wheat crops samples. Following is how the rest of the article is organized. Section II of this study's literature review provides details on the previous study. The materials and procedures utilized to assess our strategy are covered in Section III, along with a description of our system, picture pre-processing, the Keras sequential model, and the datasets that were employed. Section IV contains a report on the experimental findings and related discussion. The conclusions are presented in Section V. Limitations were discussed in Section VI, along with suggestions for further study. In this study, a disease detection system for wheat employing a dataset of 4800 pictures and CNN models is described. The Keras-sequential model served as the foundation for the CNN model.

II. LITERATURE REVIEW

With automated wheat disease diagnostic system is what the authors of article [5] set out to demonstrate and verify. They were able to circumvent the challenges and achieve an average output of 97.95percent by employing VGG-FCNVD16. They have made use of the 2017 Wheat Disease Database (WDD2017),. There were four distinct categories of illness. K-means clustering is proposed as an automatic and successful strategy in this study. Image segmentation was utilized by the author [6] to identify diseases on wheat leaves. They have discovered that the accuracy rates are more than 90 percent for three main disorders (powdery mildew, leaf rust, and stripe rust). In [7], author developed a Computer Vision Framework for the Identification and Classification of Wheat Diseases Using Jetson GPU Infrastructure demonstrating that manually identifying and interpreting wheat illnesses requires a significant amount of time and effort. They demonstrated that the VGG19 model was accurate in identifying wheat disease 99.38% of the time. Article [8] offered an ML-based system for automatically identifying brown- and yellow-rust wheat diseases. They provided an efficient ML-based framework for wheat disease detection and classification. The suggested scheme surpassed known ML algorithms with 99.8% accuracy. PRI and ARI at different development stages were computed as all conceivable three-band combinations across such susceptible wavelengths, and their ability to predict yellow rust disease severity was examined by the author [9]. In the article [10], the author used a better deep convolutional architecture to find and classify leaf and spike wheat diseases. The study comes up with a brand-new way to group wheat diseases. A new deep learning system has been made that can appropriately put 10 different wheat diseases into the right category. The paper [11] conducted a thorough assessment of recently published data and addressed WD prediction methods for recognizing and categorizing wheat illnesses. A machine learning-based early detection strategy based on hyperspectral images was reported in [12]. This research initially extracted the normalized difference texture indices (NDTIs) and vegetation indicators to discriminate between wheat with powdery mildew and healthy wheat (VIs). Study [13] used three common diseases and an insect of winter wheat as examples to investigate the applicability of channels' reflectance and many conventional vegetation indicators (VIs) of seven high-resolution satellite sensors. A method for diagnosing five fungal diseases that harm wheat shoots was provided by the author in this article [14]. The dataset's 2414 images of wheat fungal infections were utilized (WFD2020). They discovered a 94.2% accuracy rate. In [15], the author advocated Qt-based applications. Using image processing, the identification rate is 96.2% and the accuracy is 92.3%, approximately similar to human eyesight. This approach identifies, diagnoses, and classifies crop illnesses. It's a field-inspecting agricultural robot. According to the paper, using certain wavelength ranges, reflectance measurements may be employed for disease diagnosis and discrimination in the early stages of infection. This method has been used to identify wheat powdery mildew. Article [16] describes PCR methods for detecting wheat illnesses and DNA regions for fungal identification. PCR-based approaches for detecting wheat pathogens need additional research. For diagnosing wheat leaf illnesses and their severity, Paper[17] proposed an algorithm based on Elliptical-Maximum Margin Criterion (E-

MMC) metric learning. The highest identification accuracy of the proposed method is 94.16%. Paper [18], presented an AI-based algorithm (ANN). After analyzing 300 test photos of wheat leaves, the proposed system successfully detected illness in 97% of instances. Research [19] examined the viability of employing the newly announced Sentinel-2 Multispectral Instrument (MSI) to discern between the several phases of yellow rust infection (healthy, mild, and severe) in winter wheat. In the article [20], Continuous wavelet analysis (CWA) was compared to traditional spectral features to diagnose yellow rust on leaves. Both phases exhibited perfect R2 and RMSE of 0.81 and 0.110. In the paper [21], high, medium, and low LAI values were utilized to identify wheat leaf rust in the canopy. Four machine learning (ML) techniques were developed to measure disease severity (DS) at the canopy scale: support vector regression, boosted regression trees, random forests regression, and Gaussian process regression. Author [22] developed a kernel discriminant technique (SVIKDA) for detecting yellow rust, aphid, and powdery mildew in winter wheat at the leaf and canopy level. The author of this study [23] presented a simple convolutional neural network (CNN) model named SimpleNet for detecting wheat illnesses such as glume blotch and scab in genuine field photos [24]. This research assessed the spectro-optical, photochemical reflectance index's (PRI) precision for assessing the yellow rust disease index (DI) in wheat (Triticum aestivum L.) and its utility in detecting the sickness using hyperspectral pictures. The precision of the earlier study's use of a different model is unclear. Additionally, although it is not ideal, they have used fewer datasets to train the CNN model and other models. The CNN model is currently essential in identifying plant diseases. For greater accuracy, image pre-processing is also desirable. Therefore, a CNN model based on a Keras-sequential model is suggested in this study paper to more reliably identify and categorize wheat illnesses. The following are the article's main factors that contribute:

- The far more recent identification and classification findings from the massive dataset utilizing the Keras-sequential model are given. Compared to previous CNN models, the testing model demonstrated more accuracy.

- During the model's training and testing, samples from 12 diseases that afflicted the class were taken, demonstrating how the CNN model can be useful in identifying wheat diseases.

- To allow the CNN model to recognize and categorize diseases from various angles, images were rotated at various angles.

- A total of 4800 recorded photos were used to create a dataset, demonstrating how using more datasets can improve the training accuracy of the CNN model.

III. Methodology and Design

In this day and age of advanced technology, the early diagnosis and identification of plant diseases are of the utmost importance. If diseases can be diagnosed in their early stages,

then it will be much simpler to administer the appropriate treatment. More importantly, the production of agricultural goods would not be affected in any way by any diseases. Farmers and agro-technologists would benefit more from the disease detection system if it were possible to transform it from a manual system to a machine system. The objective of this study is to create a machine-learning tool that employs a CNN model to identify and diagnose wheat illnesses early on. The proposed classification scheme was developed to identify and classify various diseases that can affect wheat. The model includes the following information:

- The various layers and the layering scheme of the model.

- The number of components for each output data dimension for every tier.

- The number of variables (strength training) for each tier.

- A list of all the design variables.

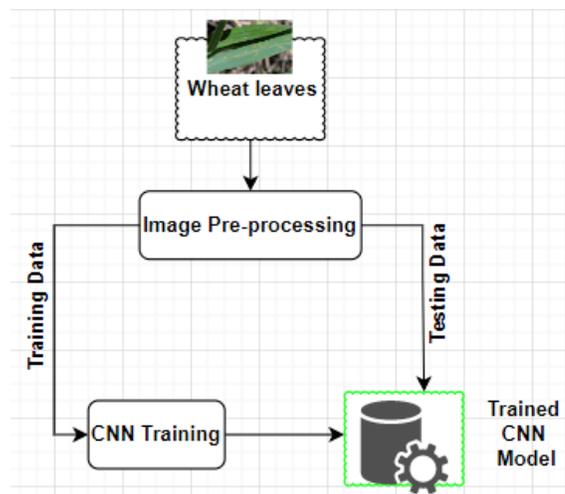
The following modules are included in the system that is being proposed: dataset collecting, image pre-processing, feature extraction, identification, and classification. These modules are currently being redesigned to be the flowchart that is seen below in Fig. 1:


Fig. 1. Overview of the Proposed System.

The proposed system used the following algorithm:

1) Image pre-processing of the collected dataset.
2) Import the appropriate modules.
3) Load photos from the dataset.
4) Convert images to binary images and save them in a pixel array.
5) Image noise reduction
6) Define the input layer and build the model.
7) Encoded the layer as needed.
8) Train the model

TABLE I. NUMBER OF IMAGES TAKEN PER CLASS

Class Name	Number of Images
Barley yellow dwarf	400
Black chaff	400
Common root rot	400
Fusarium head blight	400
Healthy wheat	400
Leaf rust	400
Powdery mildew	400
Tan spot	400
Wheat loose smut	400
Wheat soil-borne mosaic	400
Wheat streak mosaic	400
Karnal bunt	400

9) Determine training accuracy
10) Test the model with various inputs
11) Obtain the model's testing accuracy.

The dataset utilized in the development of this suggested system was compiled using data obtained from a variety of online sources. Kaggle provided a dataset, while Github provided additional datasets, both of which were retrieved. After that, the two datasets were combined, and the result was a dataset consisting of 4,800 photos. This dataset included photographs of various areas of wheat leaves and roots that were impacted by the illness, as well as images of wheat leaves that were disease-free. These are shown in Table I below:

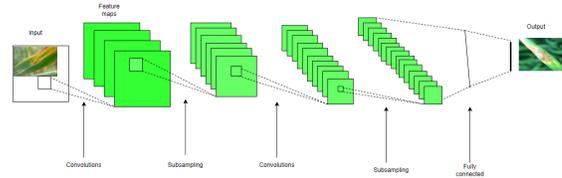
Pre-processing is a term used to describe activities with the lowest quality photographs. both the input and the output are intensity images at this level of abstraction. These famous pictures are of the same type as the original data that the sensor originally acquired, with a matrix of image function values typically used to depict an intensity image. (brightness). Pre-processing is intended to enhance the image. data that reduces unintentional distortions or enhances certain aspects of the image geometric changes of pictures (such as rotation, scaling, and translation) are categorized as pre-processing but are crucial for subsequent processing since similar approaches are employed here. Feature extraction tries to reduce the number of features in a dataset by extracting new ones from existing ones. This new, smaller set of features should then describe the bulk of the data included in the initial shipment of characteristics. In the object-based approach used by Feature Extraction to classify images, an object (also known as a segment) is a group of pixels with common spectral, spatial, and/or textural features. Using standard pixel-based classification approaches, the spectral data contained in each pixel is used to classify photographs. A deep learning model called CNN is used to handle data with a grid pattern, such as photographs. because of the high degree of precision it has, CNNs are utilized for picture categorization and recognition. Yann LeCun, a computer scientist, first proposed it in the late 1990s after becoming intrigued by how humans recognize objects visually. Utilizing CNNs is advantageous since they can create an internal representation of a two-dimensional image. This enables the model to pick up on location and size in different types of data structures, which is crucial when working with photos. Each plant class's diseases are taught to the CNN classifiers. The classifier, which has been trained to categorize various diseases in that plant, is called up using Level 2 results. A pre-trained CNN model called VGG16 is employed for picture classification. It has been fine-tuned to


Fig. 2. Image Classification Process using CNN.

TABLE II. THE MODEL SUMMARY FOR THE PROPOSED SYSTEM

Layer (type)	Output Shape	Param #
sequential (Sequential)	(32, 256, 256, 3)	0
conv2d (Conv2D)	(32, 254, 254, 32)	896
maxpooling2d (MaxPooling2D)	(32, 127, 127, 32)	0
conv2d1 (Conv2D)	(32, 125, 125, 64)	18496
maxpooling2d1 (Max Pooling 2D)	(32, 62, 62, 64)	0
conv2d2 (Conv2D)	(32, 60, 60, 64)	36928
maxpooling2d2 (Max Pooling 2D)	(32, 30, 30, 64)	0
conv2d3 (Conv2D)	(32, 28, 28, 64)	36928
maxpooling2d3 (Max Pooling 2D)	(32, 14, 14, 64)	0
conv2d4 (Conv2D)	(32, 12, 12, 64)	36928
maxpooling2d4 (Max Pooling 2D)	(32, 6, 6, 64)	0
conv2d5 (Conv2D)	(32, 4, 4, 64)	36928
maxpooling2d5 (Max Pooling 2D)	(32, 2, 2, 64)	0
flatten (Flatten)	(32, 256)	0
dense (Dense)	(32, 64)	16448
dense1 (Dense)	(32, 12)	780

easily suit picture classification datasets after being trained on a sizable and diverse dataset. Convolutional Neural Networks have three different kinds of layers: Hidden Convolutional Layer connects each input neuron. CNN's input neurons are partially connected to the buried layer. Pooling shrinks the map. CNN has activation and pooling layers. Last is Fully Connected Tiers. The last pooling or convolutional layer output is flattened and applied. Fig. 2 shows the image classification process using CNN. The model summary for the proposed system is given in Table II.

A variety of APIs is available from Keras-sequential that can be used to define neural networks. Sequential API, Functional API, and Model Sub-classing API are all different names for APIs. Layer by layer can be built up a model using a sequential API. One input layer, one hidden layer, and one output layer make up the Keras-sequential model. Two neurons are joined to form the hidden layer.

IV. EXPERIMENTAL SETUP AND RESULT ANALYSIS

The previous section showed how to use a CNN model to classify and identify wheat illnesses. In this section, the theoretical process that was described in our previous section will be converted to a computational function so that using the digital device for image processing the diseases of wheat can be identified and classified. This experimental phase will be deployed using algorithm construction, deploying the algorithm via computational machine and output evaluation. We will be able to take the necessary measures for additional research and assess a good identical system that will work more accurately and perfectly based on the results of the performance evaluation that we conduct. All of the experimental data, as well as the experimental design and the analysis of the system, are given throughout this section. There are many different

TABLE III. TRAINING AND VALIDATION ACCURACY WITH LOSS

Epoch	Total Steps Per Epoch	Training Accuracy	Training Loss	Validation Accuracy	Validation Loss
1	30	0.9555	0.1023	0.9062	0.3057
50	30	0.9778	0.0628	0.9479	0.1309
100	30	0.9862	0.0403	0.9479	0.1245
150	30	0.9873	0.0333	0.9792	0.1049
200	30	0.9882	0.0118	0.9797	0.0203
250	30	0.9901	0.0099	0.9812	0.0188
300	30	0.9979	0.0021	0.9861	0.0139
350	30	1.0000	0.0000	0.9933	0.0067
400	30	0.9912	0.0088	0.9891	0.0102
450	30	0.9812	0.0188	0.9803	0.0197

Fig. 6. Comparison between Epoch vs Validation Accuracy.

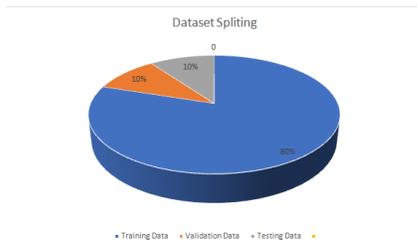
forms of accuracy in the methods used to evaluate systems, and they are all covered here in that they can be of great use in one's subsequent academic endeavors. This research project was performed in the rainy season but this is not the production season of wheat. For this reason, the dataset for this research project was collected from a variety of online resources. Then, 4800 photos of wheat crops with 11 diseases and healthy wheat crop images were mixed. 3840 photos were utilized for preparing the model, 480 for validation, and 480 for testing the system. 32-batches were used. The following graphic in Fig. 3 shows training, validating, and testing dataset ratios:


Fig. 3. Dataset Splitting Ratio for the Proposed System.

Fig. 7. Comparison between Epoch vs Validation Loss.

After pre-processing all the images, the feature vector was created using feature extraction. Then this feature vector was used for training the CNN model. A total number of 500 epochs were moved to the dataset for training and validation testing. There was a total of 30 steps per epoch. Using these feature vectors the model was trained and a validation test was performed for checking the validity of the dataset (Fig. 4to 7). The measurement shows in Table III.

Fig. 4. Comparison between Epoch vs Training Accuracy.

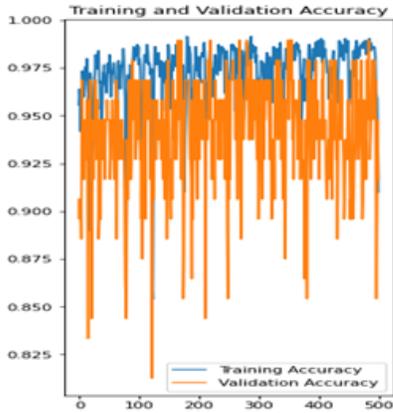
After completing training and validation testing on the dataset using the proposed model these scores were stored for prediction and testing of the system. Following the testing had been completed on the dataset, the F-1 score and recall value were then determined. After performing all the processes it was found that the training accuracy was 100%, the validation accuracy is 99.33%, and the testing accuracy is 98.84%. A comparison between training and validation accuracy is shown below in Fig. 8:


Fig. 8. Training vs. Validation Accuracy.

TABLE IV. RECALL VALUE, F1-SCORE, PRECISION VALUE PER CLASS

Class	Recall	F-1 Score	Precision
0	1.0	0.99	0.98
1	1.0	1.0	0.99
2	0.99	1.0	1.0
3	0.98	1.0	0.99
4	1.0	1.0	1.0
5	0.97	0.97	1.0
6	1.0	0.99	1.0
7	1.0	0.98	1.0
8	0.99	1.0	0.97
9	0.97	0.98	0.97
10	1.0	1.0	1.0
11	0.98	0.99	0.98
Avarage	0.99	0.99	0.99

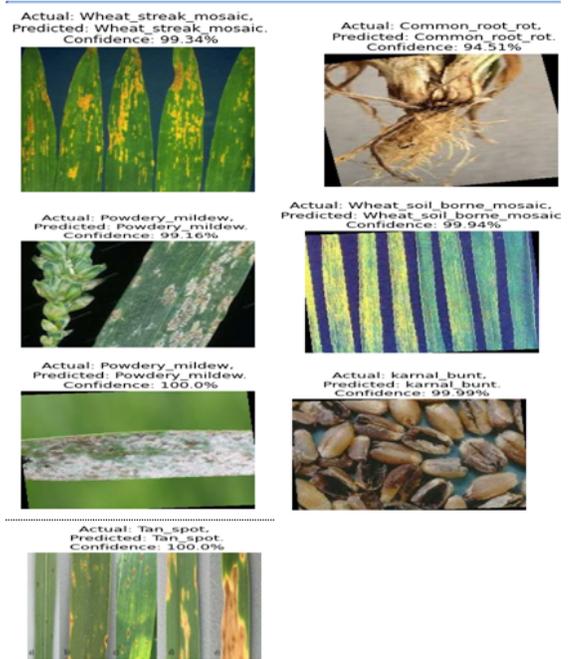
Comparison of training and validation loss is given below in Fig. 9:


Fig. 10. Prediction Result based on Samples.

Following the Recall value, the F-1 Score, and Precision values were obtained after calculating the confusion matrix shown in Table IV.

When compared to the accuracy of the other proposed systems, the accuracy of this system is adequate to be considered satisfactory. Even though the accuracy of the research [24] was measured at 99.8 percent, the authors chose to concentrate their attention on two disease categories, namely, brown and yellow rust disease. The following Table V provides a comparison of the following:

V. CONCLUSION

This study presents a CNN-based paradigm for wheat illnesses. We gathered high-quality images of wheat leaf diseases such as barley yellow dwarf, black chaff, common root rot, fusarium head blight, leaf rust, powdery mildew, tan spot, wheat loose smut, wheat soil-borne mosaic, wheat streak mosaic, and karnal bunt from Bangladeshi agricultural websites to evaluate the proposed system. We also gathered samples

Fig. 9. Comparison of Training and Validation Loss.

Finally, some samples were tested for checking the confidence and testing accuracy of this proposed system. Average confidence for identifying and classifying varied from 93%-100%. The average F-1 score for all classes was 99%. The average recall value and precision value were 0.99 and 0.99. The following Fig. 10 is showing these prediction results based on the proposed system:

TABLE V. COMPARISON BETWEEN THE PROPOSED METHOD AND OTHER PROPOSED METHODS BY OTHER AUTHORS

Model Proposed	Number Of Classes	Dataset	Accuracy
K-Mean Clustering [25]	Three classes including powdery mildew, leaf rust, stripe rust		90%
MTMF + NDVI	Two classes including powdery mildew and leaf rust	Onfield Experiment	88.6%
Machine Learning [26]	Two classes brown- and yellow-rusted disease	1050 samples	99.8%
Photo chemical Reflectance Index + Anthocyanin Reflectance Index [27]	One class including Yellow rust	Onfield Experiment	93.2%
Deep Convolutional neural network [28]	One class including Yellow rust	Onfield Research	85%
Proposed System	Twelve classes include Barley yellow dwarf, Black chaff, Common root rot, Fusarium head blight, Healthy wheat, Leaf rust, Powdery mildew, Tan spot, Wheat loose smut, Wheat soil-borne mosaic, Wheat streak mosaic, and karnal bunt	4800 samples	98.84%

of healthy wheat crops. Techniques such as segmentation and resizing are utilized so that the pre-processing can be precise. The use of distinct feature descriptors allows for the extraction and combination of a wide variety of features, including shape, color, and texture features. Following the completion of the comparative study, the proposed CNN model was found to have higher levels of accuracy. Accuracy, precision, recall, and F1-score were used to evaluate the suggested methodology on unseen data. A comparison between our method and the other methods already in use is carried out as part of the ongoing evaluation process. As a consequence of this, it has been determined that our approach is superior to other methods in terms of the accuracy with which it recognizes and categorizes wheat diseases.

VI. FUTURE WORK

Based on the experiments, the approach has the potential to help farmers and agri-technologists measure wheat disease. As a consequence of this, they would be able to implement necessary precautions for the control and prevention of disease. A software program will also be investigated in greater depth to assist farmers in discovering wheat diseases as quickly as is practically possible. This will help agricultural workers quickly identify wheat illnesses. In addition, the suggested system will be capable to manage additional disease classes, which will allow it to manage a greater number of illness types. Farmers would benefit more from this approach if there were a greater variety of crop diseases included in it. In addition, it was observed that adopting multidimensional CNN could provide more accuracy for detecting disease. Multidimensional CNN can recognize output from a variety of inputs. Furthermore, it would be preferable if such a model could be created to acquire numerous photos and diagnose disease in each of them at the same time.

Abstract—In Benin, after the GCSE (General Certificate of Secondary Education), learners can either enroll in a Technical and Vocational Education and Training (TVET), or further their studies in the general education. Majority of those who take the latter path enroll in Senior High School by choosing the Biology stream or field of study. However, most of them do not have the abilities required to succeed in this field. For instance, for the last edition of the Senior Secondary Education Certificate (French baccalaureate) held in June 2022 in Benin, the Biology field of study had a low success rate of 42%. Therefore, one may consider that there is a problem in the orientation of the students. In recent years, Machine Learning has been used in almost every field to optimize processes or to assist in decision-making. Improving academic performance has always been of general interest. And, good academic performance implies good academic orientation. The goal of this study is to optimally help learners who have just obtained their GCSE to select their field of study. For this purpose, two major elements are predicted: i) Scientific or Literary ability of students, ii) Literature or Mathematics and Physical Sciences (MPS) or Biology stream of learners. More precisely, the average marks in Mathematics, Physics and Chemistry Technology (PCT) and Biology from 6th to 9th grade for 325 students are used. Machine Learning algorithms such as Decision Tree, Random Forest, Linear Support Vector Classifier (SVC), K-Nearest Neighbors (KNN), and Logistic Regression are used to predict learners' ability and the stream. As a result, for learners' ability prediction, we obtained the best accuracy of 99% with the random forest algorithm for a split that reserved around 21% of the dataset for testing. As for the learners' stream prediction, we obtained the best accuracy of 95% with the Linear SVC algorithm for a split that reserved around 20% of the dataset for testing. This study contributes to Educational Data Mining (EDM) by performing academic data exploration using numerous methods. Furthermore, it provides a tool to ease students academic path selection, which may be used by educational institutes to ensure student performance. This paper presents the steps and the outputs of the study, we performed with some recommendations for future research.

Keywords—*Academic path; academic performance; machine learning; educational data mining*

I. INTRODUCTION

The improvement of academic performance has always been a concern for the educational system's actors [1], because the supposed performances in schools no longer satisfy everyone expectations. This situation requires a formula that could invert the trend. The education system is challenged to find a scientific instrument to overcome practices which continue to promote this deleterious situation [2].

According to [3], factors that impact field of study choice include: ability, experience, habit, program, instructor's role, university/school atmosphere and study culture. Authors in [4] also acknowledged that the field of study chosen by a student is in relation with prior knowledge and judgment of his/her own competence. Students often engage with peers and educational institutes through social networking to gather information about the university/school's fields of study or forthcoming courses. Therefore, deciding on a academic path can be stressful for secondary education students. Authors in [5] think that students need group guidance for fields of study and major choices.

If good or bad academic results have brought praise to some schools or tarnished the image of others, it is because of the lack of proper use of the data to direct students in the different fields of study. In fact, in Benin's high schools, students have to further their studies in general education track (Literature, Mathematics and Physical Sciences, Biology) or in Technical and Vocational Education and Training (TVET). Orientation in the TVET is not systematic because students must take an entrance exam before being admitted. Therefore, orientation problem is more acute in general education because it is done at best, on the basis of the marks obtained at the General Certificate of Secondary Education (GCSE). Otherwise, learners are oriented according to their parents' choice.

The use of Artificial Intelligence (AI) in general and more particularly, Machine Learning, in almost all fields, allows nowadays, to predict from the available data, a number of interesting elements for decision-making [6][7]. Thus, it is easy to understand the importance of using Machine Learning to improve the quality of academic performance [8][9]. This study contributes to research in Educational Data Mining (EDM) by developing a prediction model for academic orientations [10][11], in high schools in Benin. The study is articulated in two parts. We predict: (1) learner's aptitude or ability (literary or scientific), (2) learner's fields of study (Literature, Mathematics and Physical Sciences-MPS, Biology).

In the remaining of the paper, we address the background concepts of the performed study. Then, a state-of-the-art analysis is performed. Subsequently, the proposed prediction model' architecture is released, followed by the performance evaluation results. Furthermore, we highlight discussions and give an overview of the application that shows a concrete use of the optimal model. Finally, we summarize contributions and limitations of the proposed model and give the conclusions.

II. BACKGROUND

In this section, we briefly discuss the concept of Educational Data Mining (EDM) and describe the beninese education system.

A. Educational Data Mining

Nowadays, many research activities are interested in data mining, and EDM has become a promising field of research [12], [13]. EDM uses several algorithms to improve educational results and account for educational procedures in future decision-making. EDM can be defined as the techniques for finding the specific types of data coming from the education system and implementing these techniques to better understand students and the system [14] [15]. Some applications of EDM can likely be a recommender system for students and prediction of their performance.

B. The Beninese Education System

After two years in Preschool (optional), students must complete six years in Primary school to achieve and obtain the Primary School Certificate (PSC) [16]. Primary school years are: Year 1 (Introductory Courses - IC), Year 2 (Preparatory Courses - PC), Year 3 (Elementary Courses 1st year - EC1), Year 4 (Elementary Courses 2nd year - EC2), Year 5 (Middle Courses 1st year - MC1) and Year 6 (Middle Courses 2nd year - MC2). Then, it takes seven years to complete Secondary school. Indeed, Secondary school in Benin, is made up of two levels: the first known as General Junior Secondary and the second is divided in General Senior Secondary and TVET. The General Junior Secondary grades are: 6th grade, 7th grade, 8th grade and 9th grade. Thus, at the end of General Junior Secondary school, learners must pass the exam of the GCSE. Afterward, grades of General Senior Secondary or TVET are: 10th grade, 11th grade and 12th. In addition, to completing the 10th grade, learners must enroll in a specific domain of study such as: General Senior Secondary (Literature, MPS or Biology stream for example) and TVET (Mechanical Science and Technology or Electrical Science and Technology stream for example). At the end of the General Senior Secondary or Technical Secondary, learner should take the Senior Secondary Education Certificate, equivalent of the French Baccalaureate. After that, they can enroll in the Tertiary Education in the existing courses and complete the years required to obtain a bachelor degree, a master or a doctorate [17]. Table 1 presents the main subjects taught in three streams, selected for the performed research. Fig. 1 illustrates the Beninese education system.

TABLE I. MAIN SUBJECTS

Stream	Main subjects
Literature stream	French, English, German, Spanish, Philosophy
MPS stream	Math, PCT
Biology stream	Math, PCT, Biology

III. RELATED WORK AND DISCUSSIONS

Hereby, are an overview of existing work and their shortcomings compared to the model proposed in this study.

A. Related Work

In literature, several ML algorithms are used for students academic orientation in high school. Whatever the educational system, at a given moment in his/her academic career, student at junior secondary level is required to make a choice of stream.

Therefore, to better orient learners, many research studies have been undertaken. In [18], authors predicted the performance of students in bachelor's and master's degrees in computer science and telecommunications.

Some models are based on real data. Usually, authors used tools such as a chatbot to collect data [19]. In [20], authors noticed that the increase in data did not significantly improve the obtained results.

Individuals in a database are characterized by a number of variables and all of them are not necessarily relevant for learner orientation. In [21], authors insist on correctly detecting the relevant variables involved in the process and their relationships with each other. In [22], authors used learners' scores to make predictions. In addition to grades, they used the number of absence per subject of the student.

In order to have a maximum prediction accuracy, in [23], authors compared several ML algorithms such as Support Vector Machine (SVM), neural networks, regressions, random forest, k-nearest neighbors, Naive Bayes', decision trees, etc.

Several performance measures exist to determine the degree of reliability of a prediction model. Following the example of [24], in which authors used three performance scores to validate their model (accuracy, Cohen's kappa, and the ROC curve), other authors used only the accuracy to assess the performance of their models. They used data that is not very large in size (a size that varies between 100 and 250 individuals). They obtained an accuracy of 94% with the random forest. In [25], authors were faced with an explosion of data and they obtained the best accuracy of 97% with Bayes' naive.

In addition, the authors of [26] implemented a framework which predicts academic orientation using supervised machine learning. They had a dataset of 350 individuals and compared the performance of decision tree, KNN, SVM and logistic regression by cross-validation and by a split that reserved 30% of the data for testing. Their proposal is mainly based on personality types such as Realistic, Investigative, Artistic, Social, Enterprising, and Conventional. They obtained the best AUC (Area Under Curve ROC) with the decision tree which was 0.8.

B. Discussions

From all above, we can notice three types of categories to classify the models aiming at providing academic or professional guidance for learners. There are the size of the data, the nature of the data and the nature of the prediction.

As far as data size is concerned, we can distinguish models that are based on a huge data size [25] and those based on a relatively small data size [24].

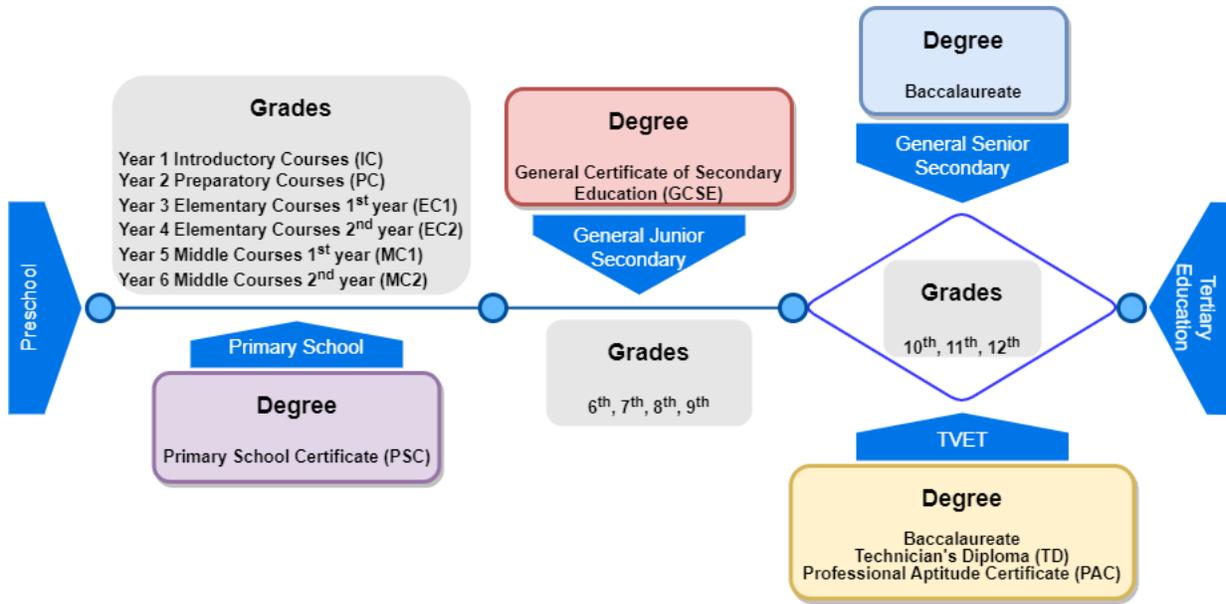
For the nature of data, some models are designed based solely on learners' grades and others are designed based


Fig. 1. The Beninese Education System.

not only on grades but also on learners' social environment variables [22].

Finally, different models are not intended to predict the same things. One set is designed to predict school dropout [21], other to predict the stream or the aptitude/ability in a given track and another to predict a score or the average mark [23].

Based on related work study, we can conclude that for academic orientation prediction, Bayes naive is the most suitable, when dealing with massive data, while random forest is the most suitable when data size is relatively small. It should also be noted that the combination of random forest and regression does not really provide good prediction accuracy.

Unlike previous works, current study focuses at first stage on learners' grades for guidance. Our educational context is different from those found in the literature and not all subjects have an impact on the learners' streams choice. Since a database of learners' digitized grades is not available, we started by collecting these grades using the students' transcripts of records. We trained the models on several ML algorithms with the scope of having maximum accuracy.

IV. OUR PREDICTION MODEL

To achieve academic orientation prediction for Benin's high schools, we propose the architecture illustrated in Fig. 2. Our architecture includes several stages: preprocessing, model creation, model evaluation, and model optimization. However, the first three are compulsory for any prediction model and are described in this section.

A. The Dataset

A learner in the MPS stream, must have a basic knowledge of mathematics and PCT, and a learner in the Biology stream must have a basic knowledge of mathematics and PCT, as well as Biology. We can conclude that these subjects make it possible to distinguish scientific learners from literary learners. Moreover, considering subjects such as French, English, Philosophy, History and Geography, would not be optimal because they are cross-cutting subjects. One can be in Literature, MPS or Biology stream and be excellent in these subjects. In Benin, evaluations are done in secondary schools on a semester or quarterly basis. A semester or quarterly average in a given subject does not reflect the actual performance of learners in that subject over the course of a year. For this purpose, we used available transcripts of records to calculate annual averages in mathematics, PCT and Biology.

The dataset used in this study contains 325 learners' instances with 13 variables. Table II shows a description of all variables of the dataset.

TABLE II. DESCRIPTION OF VARIABLES

Symbol	Meaning
Mm6	Annual average mark of the 6th grade in Mathematics
Mp6	Annual average mark of the 6th grade in PCT
Ms6	Annual average mark of the 6th grade in Biology
Mm5	Annual average mark of the 7th grade in Mathematics
Mp5	Annual average mark of the 7th grade in PCT
Ms5	Annual average mark of the 7th grade in Biology
Mm4	Annual average mark of the 8th grade in Mathematics
Mp4	Annual average mark of the 8th grade in PCT
Ms4	Annual average mark of the 8th grade in Biology
Mm3	Annual average mark of the 9th grade in Mathematics
Mp3	Annual average mark of the 9th grade in PCT
Ms3	Annual average mark of the 9th grade in Biology
S	The stream of the learners

B. Preprocessing

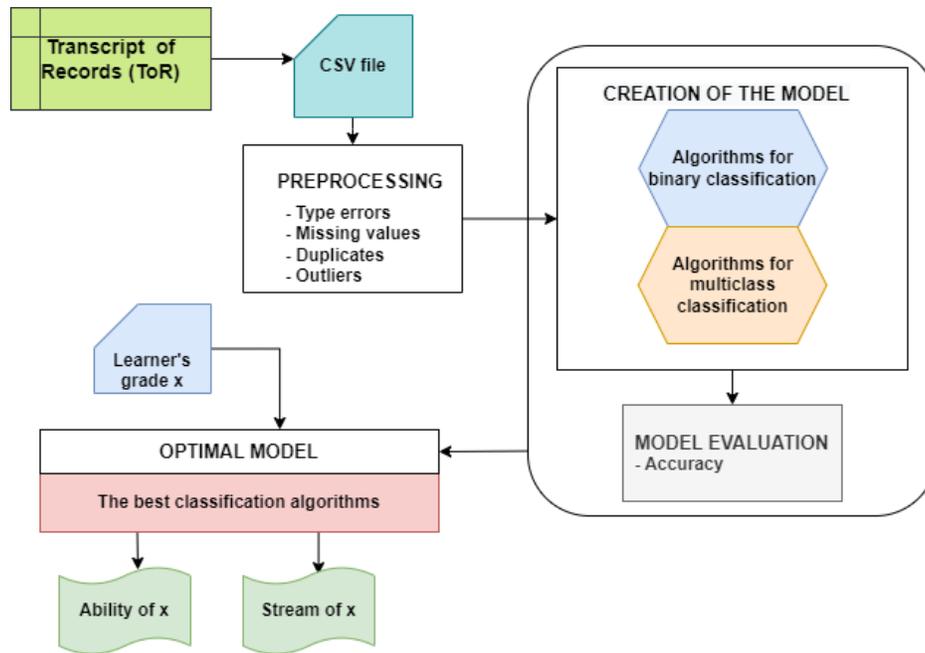
Since the data collection stage has been performed manually, the probability to push up some shortcomings is high.


Fig. 2. Machine Learning-Based Architecture for Academic Orientation.

The most common are:

- Outliers Values
  Generally, the average mark is between 0 and 20. A typo error can lead to enter a value outside this range.

- Duplicates Values
  Two learners may have the same average marks in all considered subjects. Also, the same average marks can be entered twice by mistake.

- Missing Values
  Students may not have average marks in some subjects, for a variety of acceptable and unacceptable reasons.

The preprocessing stage allows us to clean the collected data (the average marks) to deal with missing, duplicates, and outliers values [27]. Then, the exploration of the average marks was done and allowed to notice that all the average marks of the learners will not be relevant for the prediction of their orientation. Indeed, we want to predict the optimal study path for this mass of general education learners who rush to the Biology stream because of the several opportunities it offers. Among this batch of learners who enroll in the Biology stream, some are more likely to take literature and others to choose TVET.

Taking the MPS or Biology stream, requires for learners to have good skills in Mathematics, Physics, Chemistry and Technology (PCT) and Biology. Therefore, we collected learners' yearly average marks in Mathematics, PCT and Biology from the 6th grade to 10th grade and the yearly average of the 10th grade. Fig. 3 provides an overview of the data.

It can occur that some students choose Biology stream and fail, probably because they underperformed or were not proficient. Our concern here is to orient the learners in the best possible way, that is finding the right stream. Then, we proceeded to label the data using the following assumptions:

- If the annual yearly average as well as the yearly averages in PCT, mathematics and Biology in the 10th grade are greater than or equal to 11, this instance is labeled as Biology stream.

- If an average mark of a given instance of data, in the 10th grade is greater than or equal to 14 and the annual average marks in mathematics and PCT in the 10th are greater than or equal to 15, then, the instance is labeled as Mathematics and Physical Sciences (MPS) stream.

- Otherwise, the instance is labeled as Literature stream.

C. Model Design

During this stage, ML algorithms allowed us to create prediction models. For this purpose, we use five Machine Learning algorithms and design two types of models:

- The first category of model is used to predict a learner's literary or scientific aptitude. It also allows the orientation of some learners towards TVET, since scientific aptitudes are compulsory for some streams such as Mechanical Science and Technology or Electrical Science and Technology for example.

- The second category of model predicts Literature, Biology or MPS stream of the learner.

D. Model Evaluation

In the model evaluation stage, we mainly use accuracy metric.

	Mm6	Mp6	Ms6	Mm5	Mp5	Ms5	Mm4	Mp4	Ms4	Mm3	Mp3	Ms3	MS
count	325.000000	325.000000	325.000000	325.000000	325.000000	325.000000	325.000000	325.000000	325.000000	325.000000	325.000000	325.000000	325.000000

Fig. 3. Data Overview.

The accuracy is the metric that is often used to evaluate the performance of a classification model. It is the rate of good prediction. Therefore, the closer the accuracy is to 1, the better the model is performing.

V. PERFORMANCE EVALUATION

This section focuses on presenting the outcomes of the study in terms of model performance. Indeed, performance evaluation is performed in two steps: the first one uses 10 folds cross-validation and the second performs a specific split. The implementation code of the proposed models is available online (https://github.com/Jomamer/StudentAcademicPathSelection).

A. Overview of Labels

Before presenting the outcomes of the performed study, we present here the labels. In the dataset, there are 41% (133 instances) literary learners and 59% (192 instances) scientific learners.

Furthermore, there are 41% (133 instances) of Literature learners, 11% (37 instances) of MPS learners and 48% (192 instances) of Biology learners.

B. Cross-Validation Performances

The model is evaluated by performing a cross-validation of 10 folds.

Fig. 4 shows the mean accuracy and the std (standard deviation) of each algorithm for predicting learners' scientific or literary ability. Random Forest has the highest mean accuracy of 0.94 and the third lowest std of 0.08. It is followed by Linear SVC which gets 0.92 as mean accuracy and the second lowest std of 0.07. Logistic Regression gets the lowest mean accuracy of 0.87 and the highest std of 0.13.

Fig. 5 shows the mean accuracy and the std of each algorithm for predicting learner' Literature, MPS or Biology stream. Linear SVC and Random Forest obtain the best mean accuracy which is 0.90. They have the second and third lowest std of 0.08 and 0.1 respectively. Logistic Regression gets the lowest mean accuracy of 0.71 and the highest std of 0.15.

C. A Specific Split Performances

At this stage, we have booked for the prediction of each element, at least 20% of the dataset for validation.

In order to predict learners' scientific or literary ability, the size used for the test set by this split is 71 (more than 21% of the dataset). Table III presents the performances achieved. Random Forest has the best performance, followed by Linear SVC. KNN and Logistic Regression obtain the lowest performances.

For predicting Literature, MPS or Biology stream of the learners, the size dedicated to the test set, by this split is 66 (more than 20% of the dataset). Table IV presents the performances obtained. Linear SVC has the best accuracy.

TABLE III. A SPECIFIC SPLIT PERFORMANCES FOR ABILITY PREDICTION

Algorithms	Accuracy	Recall	f1_score
Decision Tree	0.97	0.96	0.98
Random Forest	0.99	0.98	0.99
Linear SVC	0.97	0.98	0.98
KNN	0.92	0.87	0.93
Logistic Regression	0.9	0.96	0.92

TABLE IV. A SPECIFIC SPLIT PERFORMANCES FOR STREAM PREDICTION

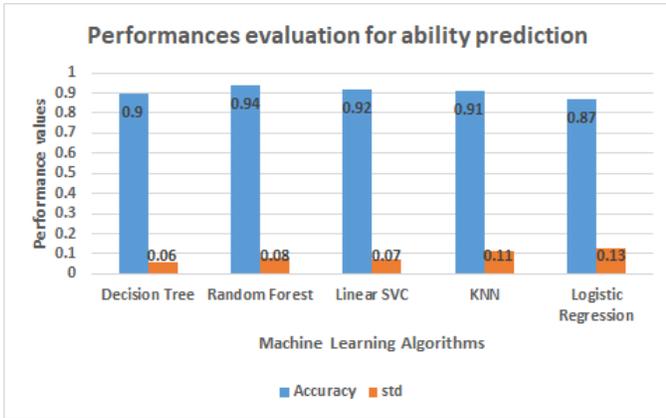
Algorithms	Accuracy
Decision Tree	0.86
Random Forest	0.92
Linear SVC	0.95
KNN	0.94
Logistic Regression	0.82


Fig. 4. Performances for Cross-Validation based Ability Prediction.

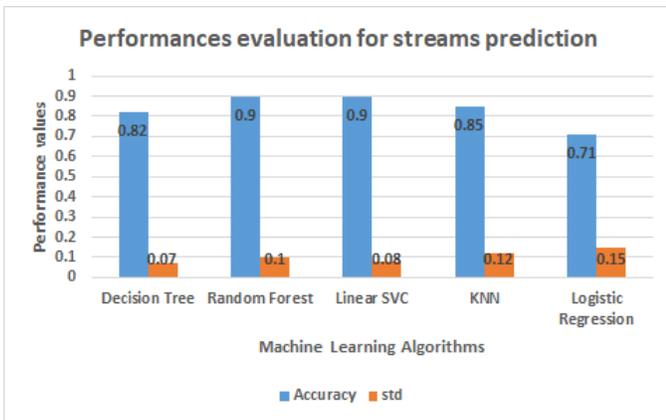
Fig. 6. Confusion Matrix for Ability Prediction.


Fig. 5. Performances for Cross-Validation based Streams Prediction.
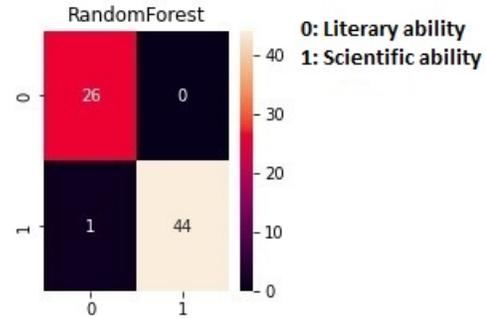

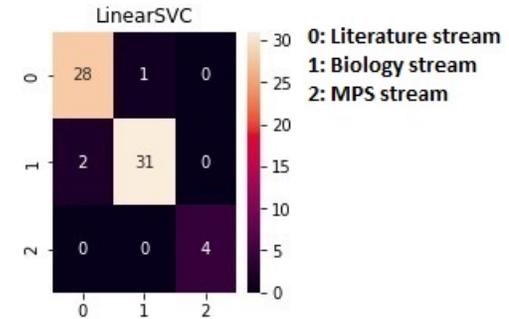

Fig. 7. Confusion Matrix for Stream Prediction.

Fig. 6 and Fig. 7 represent respectively the best confusion matrices for ability prediction and stream prediction. Indeed, Random Forest presents the best confusion matrix for ability prediction. However, it raised one error. In fact, the algorithm predicts a scientific ability for the learner instead of the literary one.

On the other hand, Linear SVC gives the best confusion matrix for Literature, MPS or Biology stream prediction. It correctly predicts the learners in MPS stream. However, it made an error, which is to predict two learners for Biology stream, whereas they are actually in Literature stream. Another prediction error, less serious than the previous one, is the classification of a learner in Literature study rather than Biology stream. This error seems to be less severe because, usually a learner who is able to attend Biology stream can also attend Literature stream.

D. Optimization of the Model

The tuning of algorithm parameters allowed us to reach the optimal model. To achieve it, we used the Gridsearch method to make cross-validation of K parameter of the KNN, the max-depth for the trees decision and the n-estimators for the random forest on the training set. A higher number of trees gives better performance but slows down the code.

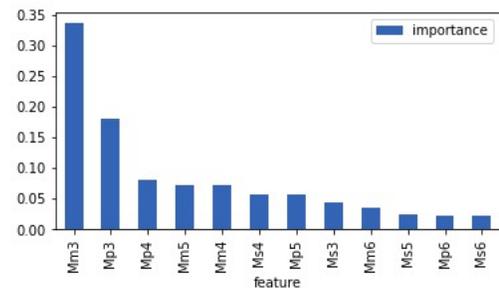
In order to get better results, we tried to monitor the importance of the characteristics with Random Forest for the learners' scientific or literary ability, and the learners' stream. Taking into account the most important features, could improve the results. Fig. 8 gives an overview of the importance of the characteristics with Random Forest for the scientific or literary aptitude of the learners as well as the learners' stream.


Fig. 8. Importance of Characteristics for Learner Ability and Stream with Random Forest.

Overall, the yearly average mark of mathematics and PCT of learner in 9th grade are very important. Average mark of 6th grade are less important. We tried to improve the performance obtained by considering only the characteristics that were having at least a given importance but it was not the case. We can conclude that average mark of the 9th grade are certainly more important but they are not enough to guide the learners.

The optimal model is the one that offers the best performance. Two models are chosen at the end of the evaluation stage:

- a model to predict the scientific or literary ability of learner.

- a model to predict the Literature, MPS or Biology stream of learner.

VI. Discussion

This discussion is conducted along two axes: starting with the prediction of the learners' scientific or literary ability, then approaching the prediction of the Literature, MPS or Biology stream of the learners.

A. Case 1: Predicting Learners' Scientific or Literary Ability

Random Forest has the best mean accuracy of 0.94 and the third lowest std of 0.08. Linear SVC is not far behind with 0.92 for mean accuracy and 0.07 for std. With the specific split, which reserves more than 21% of the dataset for testing, Random Forest presents the best performances, which are 0.99 for accuracy, 0.99 for f1-score and 0.98 for recall. With the confusion matrix obtained, we noticed that, it made only one error. It predicted that a learner is in a scientific stream when in fact he is in literary stream.

From the above, we can deduce that for the prediction of scientific or literary aptitude of learners, Random Forest is the most suitable. Linear SVC can also be used as its performance is very close to the Random Forest one. It even has a lower std than Random Forest in the cross-validation comparison.

B. Case 2: Predicting Learners' Literature, MPS or Biology Stream

Linear SVC and Random Forest had the best mean accuracy of 0.9 and the second and third lowest std of 0.08 and 0.1 respectively. With the specific split, reserving more than 20% of the dataset for testing, Linear SVC has the best accuracy of 0.95. With the confusion matrix obtained, we noticed that it correctly predicts the learners of the MPS stream. However, it makes one error, in the sense that it predicts two learners from the Biology stream, when they are actually from Literature stream. There is also another prediction error that is less serious than the previous one. It predicts that one learner is from Literature stream when he is actually from Biology stream.

After all, we can conclude that for predicting Literature, MPS or Biology stream of the learners, Linear SVC is the most suitable. Random Forest can also be used as its performance is very close to that of Linear SVC. It even obtains the same average accuracy as Linear SVC in the cross-validation comparison. It is true that KNN has the second best accuracy in the specific split comparison, but we do not focus on it, because it has the second lowest performance in the cross-validation comparison.

In general, performance obtained when predicting learners' scientific or literary ability is better than those obtained when predicting learners' streams. This may be related to the fact that, usually, a learner who is able to attend MPS stream can also attend Biology stream. So, if the proposed model predicts the Biology stream for a learner who is actually enrolled in MPS stream, this is not an error.

As a matter of fact, it should be recognized that a learner's average mark does not only depend on the previous performance of the learners. It could rely on many factors such as: i) *How does the teacher explain the lessons?* ii) *Are the classmates much motivated to outperform?* iii) *Did the learner change school?* iv) *Is the teacher proficient with the subject?*

VII. Application of the Optimal Model

A Web page in https://jomamer-orientation-streamlit-app-rl3b0z.streamlitapp.com/ gives an overview of the framework that we designed to allow school's authorities to use the model. As a matter of fact, to make the proposed model usable, we designed a simple ML web application with Python and Streamlit. In particular, Streamlit is a Python package compatible with most of the Python libraries that are used for ML (scikit learn, keras, seaborn, matplotlib, numpy, pandas, tensorflow, etc.). It is an open source application framework in Python language that allows to create web application for data science and machine learning in a short time.

Notebook Jupyter allowed us to pre-test a number of things in order to deduce optimal models for predicting scientific or literary ability of the learners and Literature, MPS or Biology stream of the learners. After importing Streamlit, the useful libraries have been called. Then, we imported the entire dataset and trained the identified optimal models. As a matter of fact, the split allows us to reserve a part of the dataset to evaluate the model performance. In production, it was no longer a question of testing the model, but rather of using it. Therefore, we have used the entire dataset so that the model learns more cases.

Finally, the obtained results are quite satisfactory. Indeed, the strength of the proposed model relies on two predicted indicators which are complementary and play absolutely, a major role in the effectiveness of learner's orientation.

VIII. Contributions and limitations

In this work, we developed a model for predicting academic orientations using ML techniques. To achieve this, we predicted the learners' scientific or literary ability and Literature, MPS or Biology stream. We used mathematics, PCT, and Biology average marks from the 6th grade to the 9th grade and the size of the dataset is 325. Our results are quite satisfactory for both models. The two models, together, allow achieving an optimal orientation for the learners.

However, it is worth to emphasize that in the paper [26] published in June 2022, authors went in the same direction. But, the major difference between both proposed approaches lies in the fact that they based themselves only on personality variables whereas the study performed in this paper is based on learner' average marks. Overall, the obtained performance results are better. It should be noted that both approaches may be complementary and future studies could look at how to combine them for optimal learner guidance about academic path selection.

On the other hand, with respect to the current study, authors of [24] used the same algorithms. Random forest has given an

accuracy of 94%, Decision tree 93% and Logistic regression 85%. They had bootstrapped a dataset of 101 records. One can notice that, the performances we obtained are better. Moreover, our data are real and in addition, we have also used the cross-validation which is recommended when dealing with a small size of data. It should be noted that authors of [24] have also taken into account characteristics such as age, gender and geographical area.

As a limitation, the current size of the dataset, can be underlined. Moreover, academic performance does not depend solely on the average marks obtained by learners. Several variables such as social environment factors could be taken into account.

IX. Conclusions

Everyone, no matter the position, tries to find a way to improve student's academic performances. In this work, we brought our support with a model, using Machine Learning which is very useful in almost every field nowadays. We compared the performance of five ML algorithms using a cross-validation and a specific split to predict learner's scientific or literary ability and the Literature, MPS or Biology stream of the learners. For this purpose, the Mathematics, PCT and Biology average marks from 6th grade to 9th grade of 325 instances of data are used. The best performance is pointed out by Random Forest algorithm with 99% of accuracy. Most probably, a larger data size could allow improving performance results even for the other algorithms.

The main limitation of this study resides on only considering the average marks obtained by the learners to perform the prediction. Thus, other parameters such as social environment factors may improve the performance results. The dataset size may also be increased. It would be interesting to look in these directions for future studies.

Abstract— **YouTube connects people with each other through an online video sharing service platform. With the great development of the entertainment industry, content on YouTube is accessible to many people of different ages. However, verifying the content posted on YouTube is clean or not is a difficult problem. Dirty content is violent, pornographic and vulgar content that causes serious psychological harm to the segment of users under the age of 18, i.e., especially those of an age who are not yet aware of the harmful effects of content. Toxic will bring to the child's behavior. Agree that Google (i.e., YouTube) has developed a YouTube Kid application where the videos are only for children under the age of 13. However, cultural and educational differences between regions strongly influence the choice of children. Select content for children. Therefore, the content restrictions on the YouTube Kid application have not yet met all the requirements of parents around the world. There have been many development directions to identify videos containing malicious content based on deep learning. However, there is no method to build a tool to support parents of children to share and identify videos with objectionable content (e.g., violence, pornography, obscene words) on the YouTube platform. In this research paper, we introduce YVC, a YouTube-verified content platform by applying blockchain's distributed, public validation. This tool helps parents validate YouTube content and issue a report to reduce dirty content on YouTube. To demonstrate the effectiveness of our approach, we implement the proof-of-concept in the three most popular EVM platforms: Ethereum, Fantom, and the Binance smart chain. Compared to the YouTube Kids (i.e., the most common shared video platform for the under 13-year-old kid), our approach is able to capture the video preferences of the parents covering the difference areas/countries.**

Keywords—Blockchain technology; public authentication; Ethereum; Fantom; Binance smart chain platform; social media platform

I. Introduction

With the development of technology, many social media platforms are born and become indispensable parts of people's lives. Among them, the YouTube video-sharing platform is a prominent online presence that provides various types of content for today's society. With a large and wide user base, YouTube has opened a monetization policy for creators, and this policy becomes a potential monetization target not only for large companies but also for individual creators [1].

Dirty content appears to creep inside the content on Youtube in an uncontrollable way. As Hank Green notes, YouTube is "a bridge between creators who are making stuff and advertisers who want to make money. YouTube makes its money through these people but also has to keep both of these

groups happy" [2]. Creators all want their video products to attract many people, the ultimate purpose is to develop media channels and earn profits. To attract more people, dirty content with erotic and violent nature gradually crept into the daily entertainment content.

Other social platforms (e.g., Reddit, Twitter) have done a lot of research regarding the issue of detecting harmful content (i.e., violence, calls to violence, pornography). For example, Tseng et al. [3] and Bellini et al. [4] highlight how forums like Reddit serve as platforms for discussing methods of intimate partner violence. Similarly, abuse, cyberbullying, and online harassment on online platforms such as Twitter was also studied by [5], [6]. For work related to malicious behavior detection on the YouTube platform, Chu et al. [1] exploits the differences used to monetize illegal YouTube content that could potentially harm viewers and other users. Thereby, the authors propose methods to prevent abuse of this service (similar findings are presented in the Related Work section of the article).

YouTube has taken a remedy by censoring and removing violent and pornographic content on the platform. In addition, the age restriction mode for adults and minors is set on the admin rights of the creator. Moreover, YouTube launched [7], a version made entirely for children to prevent children from accidentally being exposed to dirty content that causes psychological effects. However, the measures taken by Youtube have not eliminated the dirty content that is being uploaded every day. A weakness of the age limit when watching videos lies in the admin rights of the creator. If the creator intentionally does not limit the age before giving the product to the user segment older than 18, the content will still be published. open, anyone can enter. Recognizing the advantages and risks of harmful content for children's education and entertainment, Google founded YouTube Kids to serve children under 13 years old. Based on the regulations for child-friendly programs, a number of violations were identified and restricted to television programs. When a child surfs the Internet, the same rules can be automatically detected and filtered. However, content filtering on YouTube for Kids currently relies on metadata attributes, where inappropriate content can pass the [8] filter.

Blockchain technology is known for its outstanding features of transparency and immutable content. Picha Edwardsson et al. studied the possibility of using blockchain technology to create a secure, community-facing information verification database with the goal of creating a solution that could improve the reliability of verifying information and monitoring each authenticity verification process for digital content, including

images and videos. The paper indicates that blockchain is not yet ready to be directly applied to fact-checking processes in a real-world scenario. The study also shows that the application of blockchain to verify a scenario is entirely possible and highly reliable and transparent [9]. Several approaches address these problems by applying Blockchain techniques in the other environment (e.g., cash-on-delivery [10], [11], [12], healthcare [13], [14], [15], supply chain [16], [17], [18], and others [19], [20], [21]).

To solve the problem of verifying dirty content through social media platforms (specifically in the research paper, YouTube). We introduce YouTube verify content system based on blockchain (YVC). YVC's purpose is to verify dirty content on youtube platform and store it on blockchain platform. The purpose of storing data on the blockchain platform is data transparency and community application. With the YVC system, we build three main user groups: Reporter, Verifier and Middleman. YVC system consists of 6 main steps from Reporter report content then to Verifier verifying dirty content and Middleman is responsible for forwarding verified data back to social media platform. Besides, to define the logical constraints in the smart contract to maintain the stable operation of the system, we also design the authorization service for the stakeholders. To design logical constraints on smart contracts, we additionally exploit Solidity language[1]. To evaluate YVC, we implemented a test model on all three of the most popular platforms that currently support EVM, including Ethereum[2], BNB Smart Chain[3] and Fantom[4].

The research problem of this article is to define the YouTube-communication channel based on blockchain and smart contract technologies, which support the parents can detect and share the violation content of the videos before reporting those videos to the Youtube. This approach also define the protocol to verify the voting from the check based on crowdsourcing approach. Therefore, the contribution of this paper is threefold: i) designing the YVC (i.e., Youtube verify content) model to support the user detect the unusual content; ii) implementing the proof-of-concept based on the blockchain and smart contract technologies; and iii) deploying the proof-of-concept on the three most common EVM-supported blockchain platform (i.e., ETH, BNB, Fantom) to select the most suitable platform.

Following this introduction, a state-of-the-art is presented to help understand the limitations and challenges of the current approaches. Then we define the architecture of the blockchain-based YVC system, and we also verify the structure of the smart contract and the database. In the next section, we describe the implementation process including the smart contract, data structure, YVC execution algorithm, and authorization. Section 6 focuses on the evaluation process based on deploying YVC in the three platforms. Finally, suggestions for future research and conclusion are made in the last section.

II. RELATED WORK

Detect illegal activity on YouTube. The YouTube ecosystem has been studied to identify harmful content. Recent works analyzed the metadata and sharing features (i.e. keywords, hashtags) on spam YouTube videos [22], [23]. Another line of work focuses on the automatic classification of harmful activity on YouTube. Fueled by Elsagate, a controversy in which YouTube videos classified as children's content contain inappropriate themes (e.g. Elsa in the Disney movie Frozen performs the action. pique). Papadamou et al. [24] have developed a binary classifier to detect potentially annoying/harmful YouTube videos for toddlers. Similarly, several efforts have identified spam and clickbait videos by studying video metadata, comments, user activity, and video attributes [25], [26], [27]. On the contrary, we provide an overview of malicious content based on user reviews through a user-review sharing system based on blockchain technology. Our system aims to detect malicious behavior based on two aspects (i.e., content sharer and content identifier).

Based on the benefits of the blockchain-based system, more and more information verification systems are built on a blockchain platform for the purpose of transparent verification and community application. As a prime example of the application of blockchain technology in content verification, Ghimire et al propose a new method of video integrity verification method (IVM) using the blockchain technology framework. The study aims to verify data integrity and avoid tampering with video recordings in providing evidence of crime scenes or road accidents. The verification process is done by shredding the videos and comparing them with the hash value of the video previously stored in the blockchain [28].

The integrity verification method (IVM) applied by Ghimire, et al. in the blockchain platform shows that blockchain brings a new transparent and community-oriented approach to content verification in the digital age. In addition, Sathish, et al. developed Aurum [29], a new multimedia streaming platform that hosts user-generated channels with authenticated content through the use of a blockchain-driven creative process. The platform requires public content verification and the goal of community-driven development in which the research paper also mentions that the Aurum system uses effective support protocols to ensure QoS.

Aiming at community authentication and authenticity transparency, Banerjee, Prabal, et al. develop a trusted and fair platform for sharing content without a central moderator. Banerjee, Prabal, et al. have applied blockchain to manage content lists and also use smart contracts to support storage [30]. The system is built on Hyperledger Fabric and the data layer is built on Tahoe-LAFS with the goal of scalability at a lower cost than the Ethereum blockchain platform.

Besides, Zelensky, et al. also have a research paper on analyzing and verifying video data [31]. The problem of data validation to avoid interference and correct the content of violations, banking, remote management, and action confirmation. In which the algorithm will use Swype code using the movement mobile camera to verify the video content. However, the research paper by Zelensky, Aleksandr, et al. still uses a third-party intermediary to verify the content and does not really highlight the characteristics of the blockchain.

Compared with previous approaches, YouTube verified content system (YVC) builds a content authentication system applying blockchain technology on social media platforms (specifically in the research paper, YouTube). In addition, YVC aims at a transparent authentication application for the community, which also reduces the error when third parties approach.

III. YVC Architecture

YouTube verifies content based on the blockchain architecture depicted in Fig. 1. YVC consists of three main elements Reporter, Verifier, and Middleman.

- *Reporter*: The person who reports dirty content to YVC. In the YVC system, the reporter acts as an information provider, the reporter is anonymous on the system and does not need to pay gas fees when providing information.

- *Verifier*: The person who verifies the content on the YVC system. In the YVC system, the verifier acts as a content verifier, and the address information of the verifier will be public on the blockchain. However, personal information will be kept anonymous. Besides, Verifier will bear a small gas fee for verification work.

- *Middleman*: An intermediary who forwards verified and publicized reports to social media platforms (specifically in our research, Youtube).

Platforms applied in the YVC system include Website, Smart Contract, and social media platform.

- *Website*: This is the place where the information is reported and waiting for verification. In the YVC system, the website is the place where the verifier interacts with the smart contract to verify the reported content.

- *Smart Contract*: This is where the verification information of the verifier is stored. In this study, we implement smart contract deployment on the Ethereum blockchain platform and Binance smart chain platform.

- *Social Media Platforms*: These are the social networking platforms where content is stored. In the YVC system, we focus on the Youtube social networking platform.

According to Fig. 1, YVC has six steps. . In the first step, the Reporter is a viewer of the content on social media platforms (Specifically in the research paper, YouTube), if it feels that the content contains vulnerable content, the Reporter will report that content through the website of the YVC system. In the second step, the report information is displayed on the web, now everyone when accessing the website can see the reported content. In the third step, Verifier will verify content to see if the reported content contains objectionable content or not. When the verification is successful, the information about the verified content will be published on the blockchain (specifically in the research we will publish on the Ethereum blockchain platform and Binance smart chain platform). One thing to note is that, in the third step, Verifier will incur a

fee to publish verification information on the blockchain, this fee is called a gas fee. In the fourth step, when the content is successfully verified, the content is also pushed to the database of the YVC system, about the storage structure we will go into details in the following section. In the fifth step, Middleman is the database administrator, Middleman has the role of getting data from the database and reporting back to social media platforms (specifically YouTube). Note that, because the information is publicly published on the blockchain, if Middleman changes the information in the database, the real information is still public and traceable. From there, it can be seen that the application of blockchain helps to reduce the intervention of third parties. In the sixth step, after successfully retrieving data from the database, Middleman reports that data to the social media platform where the reported content originated. In this step, the social media platform based on data reported by Middleman and verified on blockchain to incinerate vulnerable content on their platform. Note that, since the information on the blockchain is public and immutable, social media platforms' reporting disregard for content is minimized.

IV. Implementation

A. Smart Contract Structure

- The address (on blockchain) of verifier (`verifier`).

- The name of channel which includes on the report content (`channelName`).

- The name of video which includes on the report content (`videoName`).

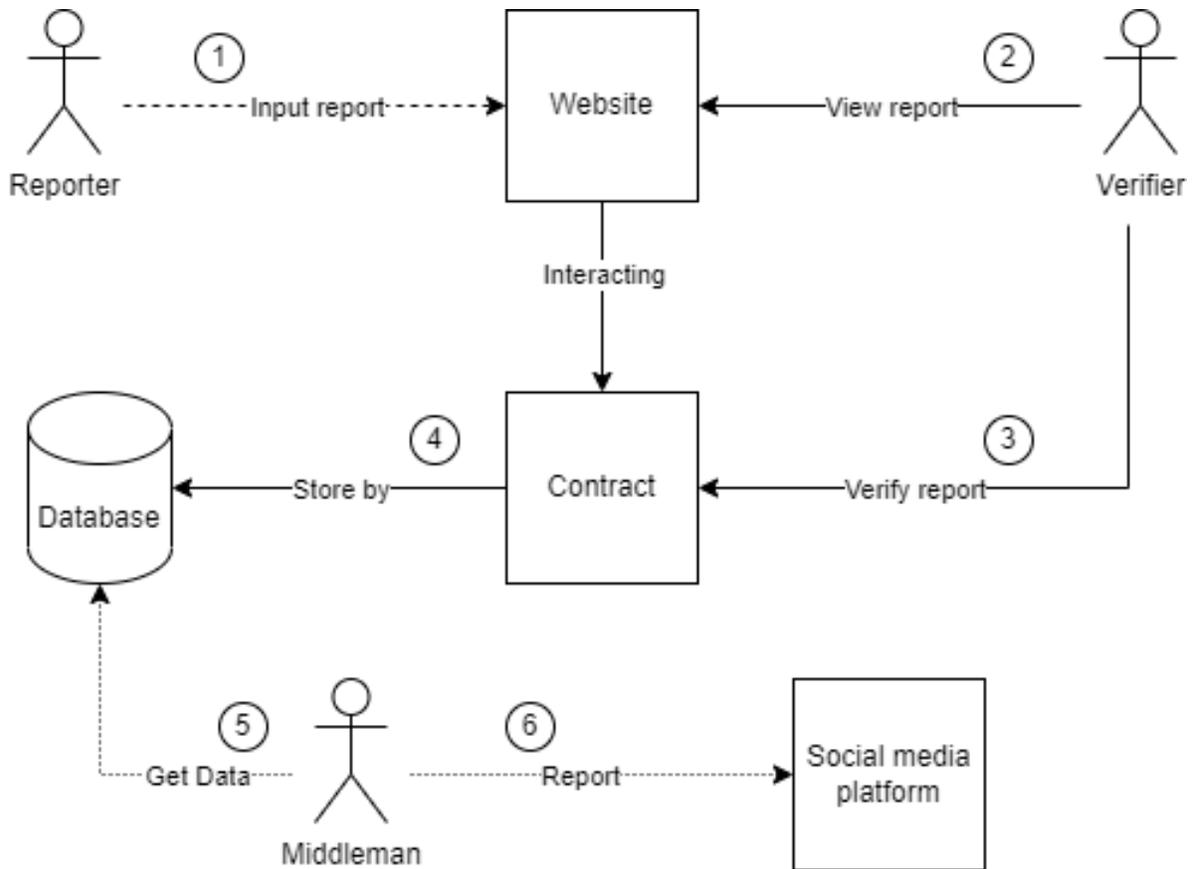
- The link of video on social media flatform which includes on the report content (`linkOfVideo`).

- Duration of the start of the video containing vulnerable content (`startVulnerableDuration`).

- Duration of the end of the video containing vulnerable content (`endVulnerableDuration`).

- The verified information will be stored in the verify content with the declared struct type (`verifyContent`). The information inside the struct will be determined by two data types: boolean for true/false verification and string for storing results.

All information in the Verify field will be stored inside the smart contract (see Fig. 2). This storage will contribute to transparency between Reporter, Verifier, and Middleman. If any changes are made, the changed data will be made public on the blockchain network.

To determine whether the verified information is true or false. Verify the information is a set of variables stored inside (`verifyContent`) with data type struct. The information to verify includes (`channelName`) verified true or false by (`isChannelName`), similar to (`videoName`) will be verified by (`isVideoName`), with (`linkOfVideo`) will be verified by (`isLinkOfVideo`), with (`startVulnerableDuration`) will be verified by (`isStartVulnerableDuration`), with (`endVulnerableDuration`) will be verified verified by (`isEndVulnerableDuration`), and finally verifyResult


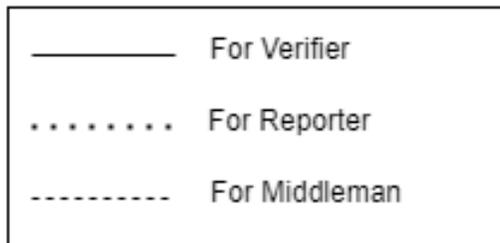


Fig. 1. Youtube Verify Content (YVC) base on Blockchain Architecture.

will save the verification result of the (`verifier`), (`verifyResult`) will be automatically programmed to display the result based on the verification result of the Verifier.

The final result received after verifying content is in the (`verifyResult`) variable. The result will be a set of true or false evaluations of the reported information and a string that evaluates the result (`verifyResult`) based on the evaluation of the (`verifier`).

B. Database Structure

Fig. 3 describes the structure of the database. The list below details the component in the structure.

- The name of channel which includes on the report content (`channelName`).

- The name of video which includes on the report content (`videoName`).

- The link of video on social media flatform which includes on the report content (`linkOfVideo`).

- Duration of the start of the video containing vulnerable content (`startVulnerableDuration`).

- Duration of the end of the video containing vulnerable content (`endVulnerableDuration`).

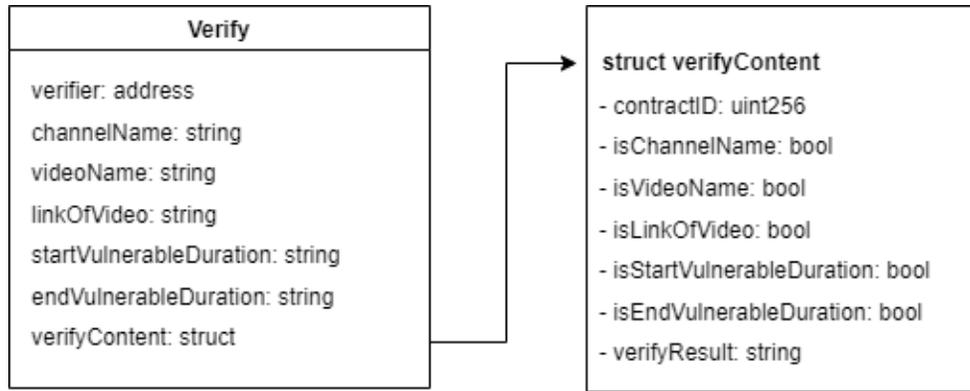
- The address of the contract. Is a blockchain platform where verified content is stored.


Fig. 2. Smart Contract Structure.
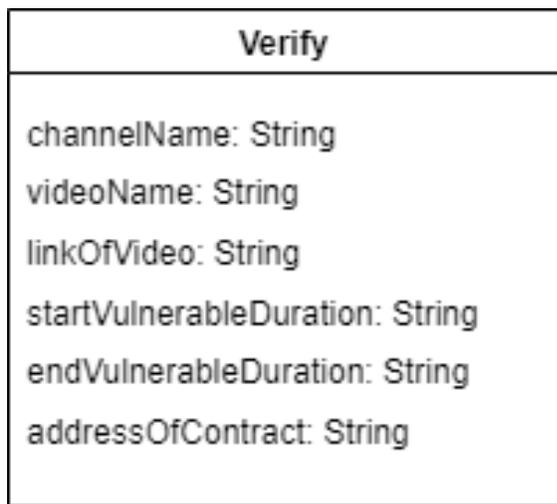

Fig. 3. Database Structure.

(`addressOfContract`).

The database is used to store information about the content present on the blockchain platform, which means that the content has been successfully verified. Information stored inside the database includes (`channelName`), (`videoName`), (`linkOfVideo`), (`startVulnerableDuration`), (`endVulnerableDuration`) and (`addressOfContract`). The storage is to help Middleman manage the database effectively and easily transfer the reported information back to social media platforms (specifically in the research paper, Youtube). Because verified content is publicly available on the blockchain, if there is a change in the database, the information about that verified content will remain unaffected and, more importantly, unchanged. This helps the YVC system to become transparent and limit Middleman's information interference.

The database will not store the evaluation information of the Verifier, but will instead store the address of the evaluated contract on the blockchain. This storage is to streamline the database, and when Middleman reports back to the social media platform, the social media platform side can easily verify the verified contract.

C. Algorithm

Algorithm 1 YVC Execution

1: Input: verifier, channelName, videoName, linkOfVideo, startVulnerableDuration, endVulnerableDuration, verify-Content
2: Output: verifyContent
3: Begin: set isChannelName = false, isVideoName = false, isLinkOfVideo = false, isStartVulnerableDuration = false, isEndVulnerableDuration = false, verifyContent = ""
4: manual update isChannelName
5: manual update isVideoName
6: manual update isLinkOfVideo
7: manual update isStartVulnerableDuration
8: manual update isEndVulnerableDuration
9: **if** isLinkOfVideo == false **then**
10:     update verifyResult = "Due to verifier, link is not correct to verify"
11:     update isStartVulnerableDuration = false
12:     update isEndVulnerableDuration = false
13:     print verifyContent struct
14: **else if** isStartVulnerableDuration == false or isEndVulnerableDuration == false **then**
15:     update verifyResult = "Due to verifier, range of duration vulnerable content is not correct"
16:     print verifyContent struct
17: **else if** isLinkOfVideo == true isStartVulnerableDuration == true isEndVulnerableDuration == true **then**
18:     update verifyResult = "Due to verifier, video contain vulnerable content"
19:     print verifyContent struct
20: **end if**

The algorithm executes sequentially from top to bottom of the YVC framework's execution. First, the system will take input information including the `verifier` as the address when the Verifier conducts content validation. `channel-Name`, `videoName`, `linkOfVideo`, `startVulnerableDuration`, `endVulnerable-Duration` are the information obtained based on the Reporter's report information. `verifyContent` is a variable that stores the Verifier's content verification value. In the next step, the system will automatically set the values to be verified to false and the resulting string is

TABLE I. THE PERMISSION OF THE AUTHORIZED IN YVC

Function/ Method	Verifier	Reporter	Middleman
constructor	Authorized	-	-
setContent	Authorized	-	-
setVerifyContent	Authorized	-	-
getChannelName	Authorized	Authorized	Authorized
getEndVulnerableDuration	Authorized	Authorized	Authorized
getLinkOfVideo	Authorized	Authorized	Authorized
getStartVulnerableDuration	Authorized	Authorized	Authorized
getVerifyContent	Authorized	Authorized	Authorized
getVideoName	Authorized	Authorized	Authorized
verifyContent	Authorized	Authorized	Authorized

empty because Verifier has not started verifying. From lines 4 to 8, Verifier verifies the content to see if the reported content is vulnerable. After Verifier verifies the content, the system will base it on the verified data to give verification results. From lines 9 to 13, if `isLinkOfVideo` is false, the result is returned and stored in the verifyResult variable as "Due to verifier, link is not correct to verify" and the values of `isStartVulnerableDuration` and `isEndVulnerableDuration` are set to false, then the system From lines 14 to 16, if `isStartVulnerableDuration` is false or `isEndVulnerableDuration` is false, the variable that stores the `verifyResult` result will be updated to "Due to verifier, range of duration vulnerable content is" not "correct", then the system prints the `verifyContent` dataset. From lines 17 to 20, if `isLinkOfVideo` is true and `isStartVulnerableDuration` is true and `isEndVulnerableDuration` is true, the variable that stores the `verifyResult` result will be updated as "Due to verifier, the video contains vulnerable content", similarly the system will print the `verifyContent` dataset. and terminate the algorithm.

D. Authorization

The YVC system provides functional authorizations to the stakeholders in the system. The list of functions is described in Table I. The three main user sets inside the system include Verifier, Reporter, and Middleman. When a user joins the system, they will fit into the above user set.

We verify the actor's authority on smart contract by account address (public key) in the Binance smart chain network. The functions and methods in smart contract are described below.

- *constructor*: The function is executed first and executes only once when verifying content on the smart contract. constructor in the YVC system will be used to validate the verifier address when performing a transaction. Therefore, only the verifier can authorize this method

- *setContent*: A function used to confirm the reported content information. This method consists of a set of variables (*channelName, videoName, linkOf- Video, startVulnerableDuration, endVulnerableDuration*) that represent the information of the reported content, respectively. When verifying content, only Verifier can authorize this method.

- *setVerifyContent*: A function used to provide content verification information. This method includes

a set of boundaries (*contractID, isChannelName, isVideoName, isLinkOfVideo, isStartVulnerableDuration, isEndVulnerableDuration, verifyResult*) these variables correspond to the information to be verified. When verifying content, only Verifier can authorize this method.

- *getChannelName*: This is the method used to extract information about the channel name. This information is authorized on all 3 user sets: Verifier, Reporter, and Middleman

- *getEndVulnerableDuration*: A method used to extract information about the end time of the vulnerable video. This information is authorized on all three user sets, Verifier, Reporter, and Middleman.

- *getStartVulnerableDuration*: A method used to extract information about the start time of the vulnerable video. This information is authorized on all three user sets, Verifier, Reporter, and Middleman.

- *getLinkOfVideo*: This is the method used to extract information about the link containing the vulnerable video. This information is authorized on all three user sets, Verifier, Reporter, and Middleman.

- *getVideoName*: This is the method used to extract the information of the video name reported. This information is authorized on all three user sets, Verifier, Reporter, and Middleman.

- *verifyContent*: This is the method used to extract verified content information. This information is authorized on all three user sets, Verifier, Reporter, and Middleman.

V. EVALUATION

A. Environment Setting

We use Solidity language and Remix IDE to program smart contracts because it is pretty popular. When implementing this solution, compiler 0.8.7+commit.e28d00a7 is stable. We also use the default EVM version and don't need optimization. The gas limit is 3000000, just enough to deploy smart contract. We also use the MIT License because we want more people to reuse our solution. Choosing a blockchain network to run smart contracts on is also an issue to be evaluated. We have measured (will be covered in the Experimental section) and decided to use the several platforms, namely, Ethereum, and BNB Smart Chain platforms.

Fantom platform contract deployed: https://testnet.ftmscan.com/address/0x9e307b1de9d4f4d3fcc3682b752f09d135490395;

Ethereum platform contract deployed: https://rinkeby.etherscan.io/address/0x51a75b578a2a64f007a728e50c2fb8b104200078;

BNB smart chain platform contract deployed: https://testnet.bscscan.com/address/0x2ad5ed1473fedf93557621dc420f7d91b39a0626.

TABLE II. THE GAS FOR THE SMART CONTRACT EXECUTION OF THE THREE PLATFORMS, I.E., FANTOM, ETHEREUM, AND BNB CHAIN

Gas for execution	Fantom	Ethereum	BNB Chain
Deploy contract	0.003927833 FTM ($0.0011)	0.00448948 ETH ($6.67)	0.01120938 BNB ($3.12)
call setContent	0.000247230422 FTM ($0.000066)	0.00022971 ETH ($0.34)	0.00773244 BNB ($2.15)
call setVerifyContent	0.000171262102 FTM ($0.000046)	0.00015912 ETH ($0.24)	0.005584608 BNB ($1.55)

B. Results

Reporters have the role of defining and submitting report content to the YVC system. Since this submission has not yet reached the validation stage on the blockchain, the Reporter will not waste gas reporting content. This is similar to Middleman, Middleman acts as the receiver of the authenticated data on the blockchain and transfers that authenticated data to the database which then reports back to the social media platform. Middleman's authentication and data forwarding does not affect smart contracts on the blockchain platform. Therefore, Middleman will not cost gas on the YVC system.

For Verifier, when the verifier verifies content in the YVC system, they will call two methods, *setContent* and *setVerifyContent*. When these two methods are called, the verifier will incur a gas fee for publishing verification on the blockchain. In Table II, we conduct verification to determine the price of each gas fee on blockchains including the Fantom blockchain platform, Ethereum blockchain platform, and Binance smart chain platform.

VI. CONCLUSION

This article introduces a content verification system for social media platforms (namely, YouTube) based on blockchain and a smart contract called YVC (YouTube Verify Content). The main aim of this study is to solve the problem of tightening dirty content that is existing on social media platforms. The highlight of the system is the application of blockchain technology to limit the human impact in changing report information. To evaluate the results of the YVC system, we deployed and analyzed it on three popular platforms, including Fantom, BNB Smart Chain, and Ethereum. Based on the evaluation results, we can confirm that Fantom's Gas is one of the lowest of the three. Regarding possible future directions, we aim to expand to apply the system to verify a lot of dirty content on multiple social media platforms. We will set up verification not only for videos but also for other digital content.

Abstract— This paper provides a novel implementation of blockchain technology, and data is stored in a decentralized distributed ledger to assist information protection in blood supply chain management and prevent data loss or identity theft. The present blood supply is used exclusively from the blood of volunteers (known as donors), making blood and its derivatives one of the significant roles in treating diseases today. In particular, depending on the type of product extracted from the blood (e.g., red blood cells, white blood cells, platelets, plasma). They require different procedures and storage environments (e.g., time, temperature, humidity). However, the current blood management processes are done manually - where all medical staff does all data entry. Additionally, data about the complete blood donation process (e.g., blood donors, blood recipients, blood inventories) is held centrally and is challenging to examine accurately. Therefore, ensuring centralized data security is extremely difficult because of stealing personal information or losing data. In this study, we present the blockchain technology-based blood management process and offer Blood and Product-Chain, a decentralized distributed ledger that stores data to address these restrictions. Specifically, we target two main contributions: i) we design the Blood and Product-Chain model to manage all relevant information about blood and its products based on blockchain technology, and ii) we implement the proof-of-concept of Blood and Product-Chain by Hyperledger Fabric and evaluate this in the two scenarios (i.e., data creation and data access).

Keywords—Blood donation; blockchain; hyperledger fabric; blood products supply chain

I. INTRODUCTION

The rising need for medical supplies and services, particularly blood, due to which it is necessary to improve blood management. Blood has many components, such as red blood cells, white blood cells, platelets, plasma, and other features [1]. Each blood component serves a specific function in the human body; for example, red blood cells help transport oxygen to cells/parts of the body, and a liter of blood can sustain the life of a premature baby for two weeks, and an accidental blood loss trauma sufferer may need 40 or more units of blood to survive. Therefore, blood is an essential medical resource, and blood management is a fundamental problem the human species needs to solve.

However, all blood collected must be analyzed before being transferred to the recipient. One important part of this work is reducing the risk of infection by transmission [2]. Specifically, the common infection mechanism is hepatitis B virus (HBV),

human immunodeficiency virus (HIV), and hepatitis C virus (HCV). Besides, blood is generally collected from volunteers; hence the supply chain for blood and its products is impacted by a lack of donors, a delay in testing, and, most importantly, the short shelf life of perishable blood products [3]. However, reducing these risks necessitates a difficult process and expensive blood supply chain management.

It can be argued that optimizing the blood supply chain management process is the key to solving the current blood shortage problem in medical facilities. The traditional model is depicted in Fig. 1. Specifically, the blood donation center will directly contact donors (i.e., in case of an emergency) or organize events calling for community blood donations. Donors must undergo a health assessment before donating blood. Then, this raw blood is converted into different components such as red blood cells, white blood cells, platelets, and plasma. The amount of blood and its products after censorship will be partially transferred to medical / health care centers (periodically), or the rest will be stored in the warehouse in case of emergency. It is also important to consider how blood is distributed and stored because different blood components have varied usage requirements and lifespans.

Besides, the information of blood, recipients, and donors is stored in a centralized server. Specifically, information about donors is divided into many areas. If those donors are not at their residence address, they cannot participate in the system. Additionally, the information stored is very private for donors and recipients (i.e., it comprises information unrelated to blood illnesses). Risks related to centralized storage include user misconduct and information loss. To solve a series of important issues mentioned above, we applied blockchain and smart contract technology (i.e., Hyperledger Fabric platform).

Blockchain technology is known for its outstanding features of transparency and immutable content. Picha Edwards-son et al. studied the possibility of using blockchain technology to create a secure, community-facing information verification database with the goal of creating a solution that could improve the reliability of verifying information and monitoring each authenticity verification process for digital content, including images and videos. The paper indicates that blockchain is not yet ready to be directly applied to fact-checking processes in a real-world scenario. The study also shows that the application of blockchain to verify a scenario is entirely possible and highly reliable and transparent [4]. Several approaches address

these problems by applying Blockchain techniques in the other environment (e.g., cash-on-delivery [5], [6], [7], healthcare [8], [9], [10], supply chain [11], [12], [13], and others [14], [15], [16]).

Therefore, this paper focuses on building Blood and Product-Chain: the management transportation of blood and its products based on blockchain technology. The main contributions of Blood and Product-Chain are two-fold. i) we design the Blood and Product-Chain model to manage all relevant information about blood and its products based on blockchain technology, ii) we implement the proof-of-concept of Blood and Product-Chain by Hyperledger Fabric and evaluate this in several scenarios.

In this paper, the structure is organized as follows. The next section of the paper presents a literature review of relevant issues. The Blood and Product-Chain overall architecture and implementation are shown in two following sections (III and IV). Section V describes the framework and benefits of the proposed system via evaluation. Finally, Section VI dedicates the conclusions and future research opportunities.

II. Related Work

A. Healthcare Systems based on Blockchain Technology

There are several blockchain-based approaches in terms of healthcare/blood donation management systems. For example, Du et al. [17] and Son et al. [18] used medical centers (i.e., hospitals) to store data and manage access and those hospitals. Specifically, they categorize two types of medical data protection policies: global for all data shared outside of the medical center, and local, which is accessed only by individuals at the medical center. medical (i.e., doctor, nurse). However, one of the major limitations is that through this solution, patients do not have full control over their data as the data and policies are stored in the hospital. Some other approaches build a user-centric (i.e., patient) model, which has full discretion to share their personal data with providers/health care facilities. economic (i.e., in a medical setting). For instance, Makubalo et al. [19] have summarized the above approaches in their publication. They argue that the methods of building a user-centric health data sharing system are facing a lot of difficulties due to the limitations of the method of building centralized data system (i.e., data) stored and processed centrally in cloud servers). Yin et al. [20] introduced a patient-centric system built in the cloud with a data collection layer, data management layer, and medical service delivery layer based on the medical records of the patient. To protect data privacy, many approaches have adopted attribute-based encryption (ABE), one of the most common encryption schemes used in cloud computing, to define patient data object. Depending on the context, the policy tells to lose (or not) grant the corresponding access rights. For example, Barua et al. [21] proposes an ABE-based access control model based on patience and privacy protection; Chen et al. [17] described a new framework with a cloud-based, privacy-aware Role-Based Access Control model that can be used for control, data traceability, and access allowed access to healthcare data resources. Methods for applying the Access Control model are also introduced for dynamic policies [22], [23] or protection policies for both security and privacy [24]. Ateniese [25]

proposed a new framework that makes it possible to re-write or compress the content of any number of blocks in decentralized services exploiting the blockchain technology.

One disadvantage of centralized storage in the above approaches is transparency [26], [27]. To address this issue, Lam et al. [28], [29] demonstrated the implementation of a micro services-oriented software architecture for middleware that collects, stores, and traces data in a centralized manner in order to provide data analysis. However, for the specific requirement (e.g., blood donation w.r.t supply chain), we need a specific model to balance the demand (i.e., blood recipients) and supply (i.e., the time for the next round of donors). To apply these advantages, many studies focus on blockchain-based approaches for the blood supply chain donation issues, which contribute to the improvement of demand and supply requirements.

B. Blood Supply Chain Management Systems based on Blockchain Technology

Trieu [30] proposed the cold chain model for blood donation based on the Hyperledger Fabric platform called BloodChain.[1] They only considered the blood data and ignored its products as well as the other storage requirement for them. The main contribution of the two above papers is only to verify the information of the recipients to the donors. These papers are very soon introduced in the large picture of this problem. Similar to BloodChain, Lakshminarayanan et al. [32] presented a blood supply chain management system based on Hyperledger Fabric to ensure the transparency requirement in terms of blood units between donors and recipients. To detect the location of the donor's blood, on the other hand, Toyoda et al. [33] provided hardware-based approaches (i.e., RFIDs) in combination with the blockchain to track the status of the blood donation. However, there are some limitations to the solutions above. For example, the verification of the system proposed in incomplete due to the lack of evaluation analysis. Furthermore, the monitoring solution proposed in [33] is limited to monitoring blood bags only, and it does not guarantee the traceability of blood components (i.e., red blood cells, platelets, white blood cells, platelets and plasma). Since different blood components have other shelf lives and storage temperatures, the order of the user preference should also be considered.

Moreover, the authors in [34] have proposed a decentralized solution based on an Ethereum-based blockchain for blood transport. In their design, certified blood donation centers (CBDCs) are the only privileged members with the right to create smart contracts to manage the entire system. Donors were recognized through an identifier such as their social security number and password. Besides, Peltoniemi et al. [35] discussed how decentralized blockchain was for plasma tracking and management. In more detail, the system stores donors' information before separating their plasma. They then maintain the origin of the plasma and identify poor blood quality. Another solution based on Hypeledger was proposed by Kim et al. [36] to build a blockchain-based blood supply chain management system. For the GDPR privacy compliance, Campanile et al. [37] presented literature solutions and design

---

[1]Their model is the extended version of [31].

implementation in the context of a traffic management system for the Internet of Vehicles based on the Pseudonymization/Cryptography solution, evaluating its viability, its GDPR compliance and its level of risk. In addition to the fact that this solution is based on a private blockchain, to protect the privacy of donors, it only focuses on tracing information related to the supply chain, but it does not track the identity of the donors as well as the part of a blood unit.

To sum up, none of the above blockchain-based solutions guarantees data privacy while providing a robust system for tracking and managing the donated blood supply chain. In addition, the above methods focus only on managing blood information rather than considering their products (i.e., red blood cells, white blood cells, platelets, and plasma). This is extremely important because each product has different management conditions and usage times. Our proposed solution captures various aspects of the blood donation system such as collection, distribution, request and delivery of blood units. It ensures that all these aspects are captured as decentralized, traceable, accountable, transparent, secure, and auditable. Our solution tracks all necessary stages of the donated blood unit cycle, from donation until consumption.

III. BLOOD AND PRODUCT-CHAIN ARCHITECTURE

To address the limitation of the traditional approach which mentioned in Section II, we first introduce the overall architecture, which provides the overview model. In this model, we provide the key components (i.e., actors) as well as the relationship among them. After that, the relationship and main steps are presented in the detailed model which highlights the Blood and Product-Chain in nine main steps.

A. Overview Model

There are several approaches that provide the traditional model for the blood supply chain (e.g., [38]). In this section, we target the overall architecture of the Blood and Product-Chain model before focusing on the two main processes that store the donor's information in the distributed ledger and use this info to contact the donor candidate for blood donation in the next round.

For the first target, Fig. 1 shows the three actors who have the main role in our proposed system, namely the Doctor/Nurse, recipients, and donors. Whereas, the remaining components represent the medical facilities as well as the blood-collection/protection centers/ways (e.g., blood transporter, blood bank), respectively. All the corresponding data of the facilities or actors are stored and processed in the distributed ledger. This process allows the stakeholders to verify their data before using it. This also increases transparency for the whole system (i.e., accessing and performing blood data/transferring the blood of the donors to the other facilities).[2] Thereby, medical facilities can retrieve and confirm data related to the treatment process.

For the second target, we present the two main blood donation process in Fig. 2 and 3 for the donor's information and

---

[2]Regarding the collected data for each donor, we store the blood type, number of blood donations, and its metadata (e.g., time, location), as well as other personal information in a decentralized approach (i.e., distributed ledger).

contacting process in medical facilities, respectively. The main contribution of this task is that we consider the decentralized system, where a certain facility is allowed to contact the other donors, who donate their blood in another hospital, rather than only their list.

B. Detailed Model

Blood and Product-Chain is presented in Fig. 4 with eight main actors including medical staff (nurses, doctors), recipients, donors, hospitals (i.e., clinic, medical clinic, mobile blood collection unit), hematology hospital, blood bank, blood transporter, and distributed ledger. Blood and Product-Chain focuses on building a Blockchain-based blood supply chain model, where the transport of blood between medical facilities plays an important role and reduces the pressure on the hematology hospital in the blood collection process from donors. Specifically, step 1 collects the treatment history of recipients through the records of nurses and doctors (i.e., medical staff). All this information will be updated to the hospital where the recipients are being treated (Step 2). In the event that the amount of blood and blood products is insufficient during treatment, the hospital will submit a request by updating the current status of blood amount on the distributed ledger. All information about blood volume, blood type and other special requirements are shared with relevant parties in Blood and Product-Chain (Step 3). At this step, the data of medical facilities is also updated. Blood volumes in a medical facility's system can be shared with other facilities to optimize blood availability. To do that, the establishment needs to update the status and send a request to the transporter about the collection and receipt locations of blood and blood products (Steps 4 and 5). After that, the transporter must always update the progress of the shipment on the distributed ledger (Step 6). All information about location, time, and order information can be verified and moderated by the stakeholders. We continue to consider another case where the requested amount of blood and blood products is not available in the system, i.e., the state of blood and blood products is not available. This request is forwarded to the hematology hospital (Step 7). Step 8 describes the procedure for checking the amount of blood and blood products in stock. Step 9 contacts the donors to schedule a blood test and donation if the requested amount of blood is unavailable. The list of donors is gathered from previous blood donation sessions and selected the candidates with the closest addresses.

IV. IMPLEMENTATION

A. Permission Diagram

Fig. 5 presents the working mechanism of the request authentication process in this paper. Specifically, we built two organizations with corresponding encrypted material certificates, each organization includes two users and two peers. Each peer is responsible for maintaining the version of the ledger so that the network and data can be maintained even if other peers are shut down.

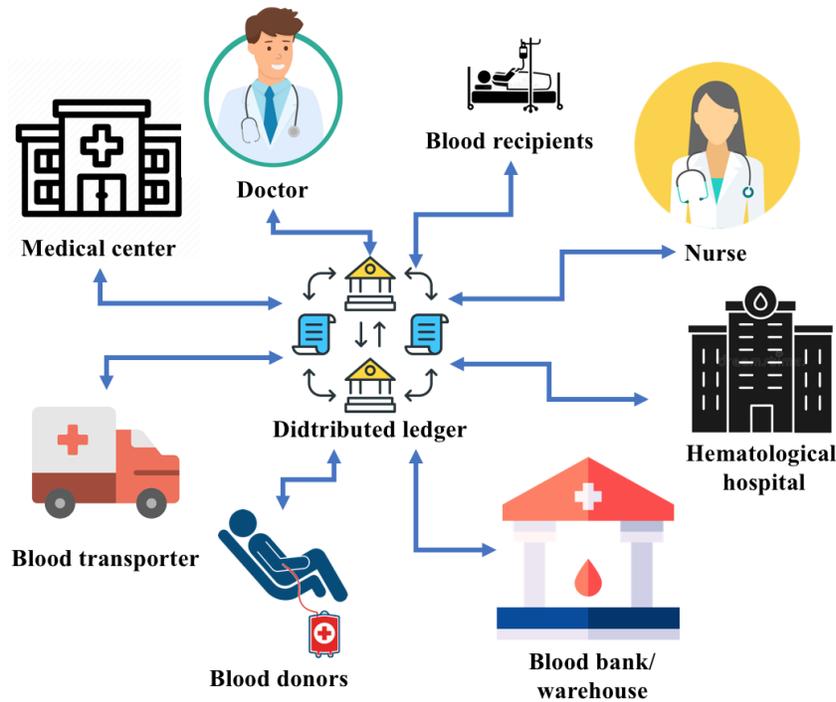
When the user initiates a request and sends it to the service. The back-end service processes the data and sends it to the smart contract API. When receiving the request and the data, the smart contract sends this to the peers in the network


Fig. 1. The Overall Architecture of the Blood&Product-Chain.
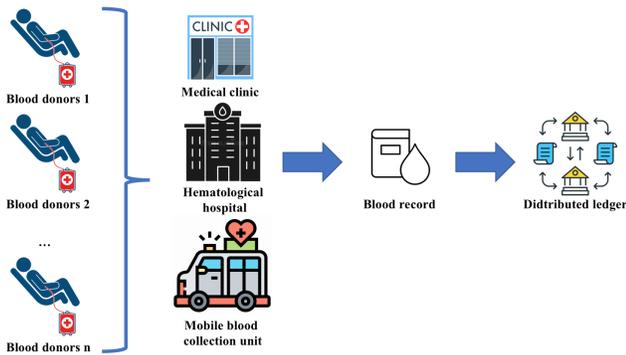

Fig. 2. The Storage Process of the Donor's Information in Distributed Ledger.
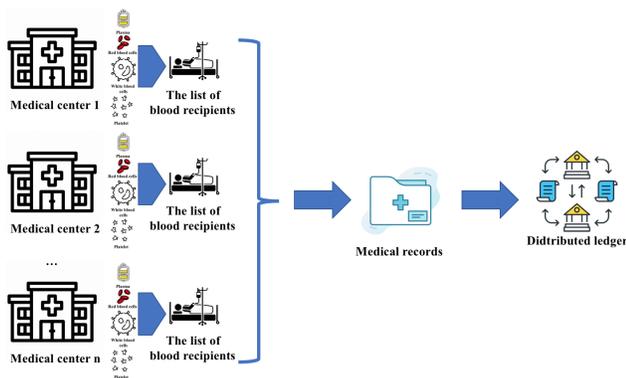

Fig. 3. The Storage Process of the Medical Center's Information in Distributed Ledger.

for authentication and data interaction purposes. During the creation, querying or updating data processes, peers check the identity of the request to decide whether to allow access to the data at the distributed ledger. If the identified user of the request is not defined in the data collection, the system denies access and sends a message to the back-end API to notify the user; the system allows access and proceeds with further processing steps.

B. Hyperledger Component

The model in this paper is implemented on the Hyperledger Fabric platform. Fabric is a permissionless blockchain platform that integrates smart contracts, the storage of data to the distributed ledger is controlled through the smart contract APIs, from which the data is simplified and easily traced. Each request that goes through the smart contract is verified with public and private key pairs. In other words, if the user does not exist in the system, the system is better protected from malicious requests outside the system.

The Fabric system in this paper includes two organizations. Each organization consists of two peers to store smart contracts, where each peer registers two users and is authenticated with public and private key pairs. The components of the model are shown in Fig. 6

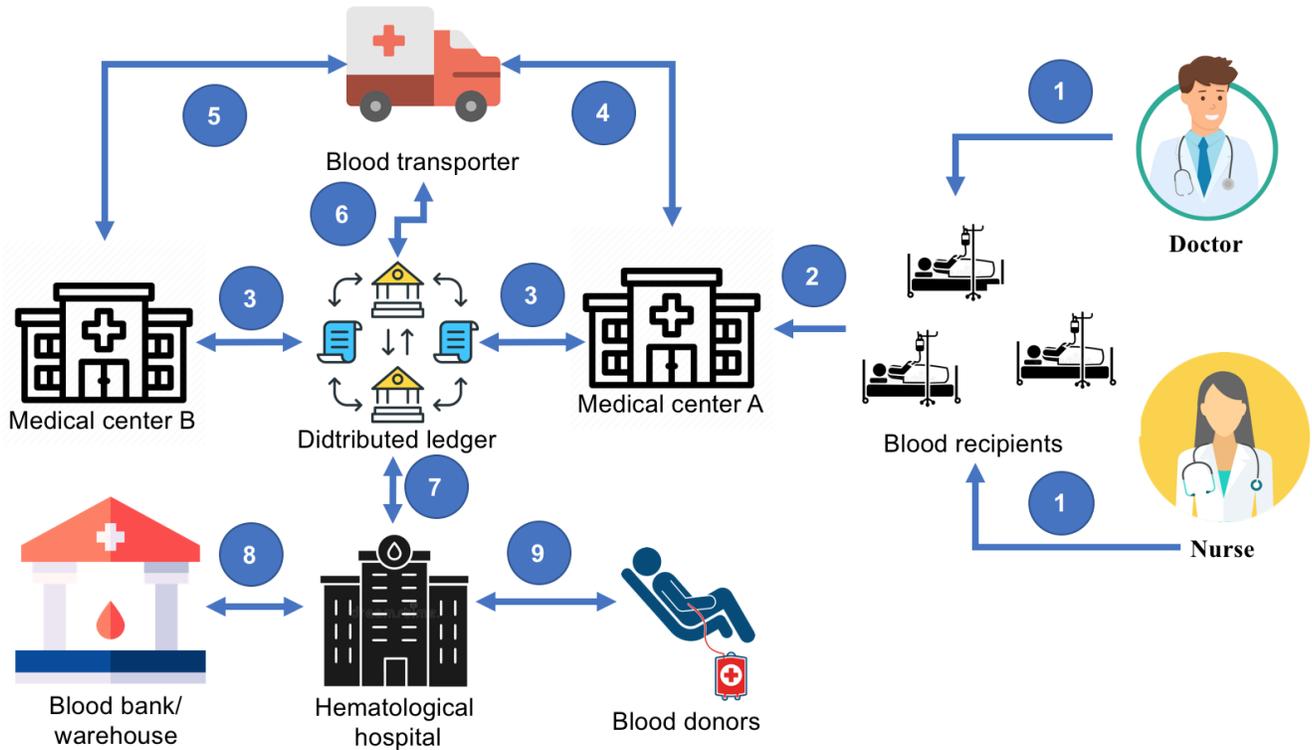
When user devices access the system to initiate/query or update data for a particular transaction, requests are sent from the client to the services of the existing system. Then, these services send access information to the peers belonging to the organization located in the blockchain network. At this step, the peers conduct verification of that user's key pairs, and if the successful peer authentication process proceeds to send information to the smart contract with the transaction


Fig. 4. The Detailed Architecture of the Blood & Product-Chain.
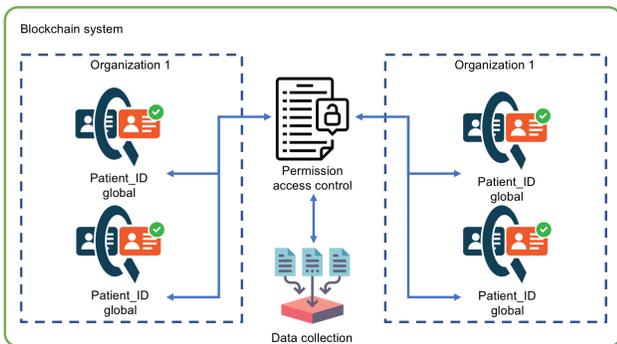

Fig. 5. Permission Diagram.
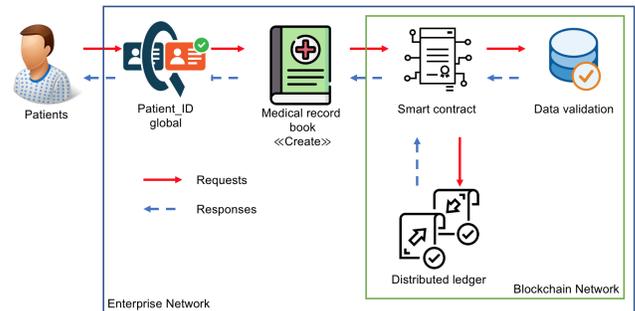

Fig. 7. Initializing and Storing the New Data.
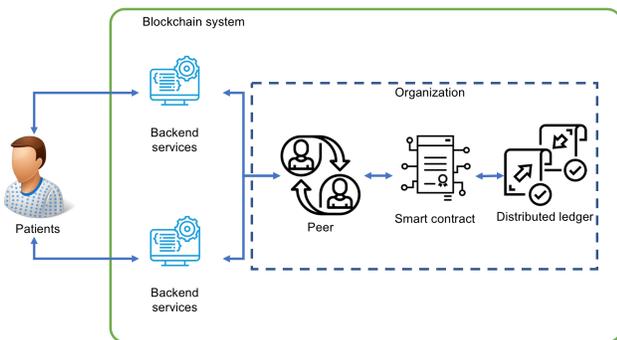

Fig. 6. Hyperledger Fabric Component.

type declared in a smart contract requested by the user, the smart contract will go through the designed features function to access the distributed ledger to initiate/query or update specific data.

C. Blood Pro-Chain Diagram

One of the most important parts of the model lies in the validation and interaction with the blood records described in Fig. 7 and 8. In particular, the main functions include initializing and querying the blood records.

Fig. 7 depicts the process of storing new record data (e.g., blood and its products). In step 1, when the user initializes information of a blood record, the data is sent to the back-end service of the health center's information management system. In the next step, the back-end APIs (i.e., backend) check, authenticate and initialize the default values, then pass

the parameters to the API inside the smart contract. At this point, a smart contract transfers data and stores transactions to the distributed ledger of the blockchain network. The default values for parameters sent from the request are intended to minimize errors caused by null fields data.

Fig. 8 presents the process of retrieving data of a particular (e.g., blood and its products). When the user sends a query request to the system, the service query data checks and confirms whether the parameter ID of the blood record was sent or not. Then, the smart contract's APIs are called and passed into the corresponding parameter. Next, the smart contract's APIs check for the existence of data in the request before querying. In the case that the ID does not exist, the smart contract sends an error notification to the user device; otherwise, it returns the data of the blood record corresponding to the requested ID.

V. EVALUATION SCENARIOS

A. Environment Setting

Our paradigm is deployed on the Hyperledger Fabric network maintained inside docker containers. In this section, we measure the performance of chaincode in the two scenarios: initializing (i.e., creating data) and accessing data. The experiments are deployed on Ubuntu 20.01 configuration, core i5 2.7Ghz, and 8GB RAM.

To prove the effectiveness of our model, we also define several experiments by exploiting the Hyperledger Caliper[3] that is used to design the test scenarios and collect all the information regarding the performance.

B. Results

1) Data Creation: In this scenario, the study measures the performance of the data initialization function/data created (e.g., blood record) performed through smart contracts. The number of requests sent simultaneously from two users[4]. Table I shows the execution results of the data initialization/creation function (e.g., blood record). The data initialization/creation script is conducted with two users concurrently making 1000 - 10000 requests to the system. We measure the parameters of command success/failure, send rate (transaction per second), system latency (i.e., max, min, avg), and throughput (transaction per second) Based on the execution results in Table I, it

---

[3]https://www.hyperledger.org/use/caliper

[4]We set up one organization with two users and two peers

can be seen that the number of successful and failed requests is stable (except in the case of 10000 requests). In the first nine scenarios (1000 - 9000 requests), the number of failed requests ranges from 14861 - 22283, while the number of successful requests is maintained at a much higher rate, from 27970 - 34831 requests. However, in the last scenario, the failure rate is higher than the success rate, 37894 and 23672, respectively. This proves that the system works well with the scenario from 9000 requests (i.e., two users - 2 peers). In addition, we also evaluate the latency of the whole system. Specifically, the maximum delay value ranges from 840.33 to 1366.83 seconds. Besides, the value of send rate ranges from 163.5 to 173.5 (TPS) in the first nine scenarios and the highest in the tenth scenario with 205.2 (TPS). Similarly, throughput measurements ranged from 30.3 to 38.8 (TPS) in the first nine scenarios and reached a maximum value of 54.1 (TPS) in the last one.

2) Data Access (Retrieving/Querying): In the second experiment, we consider the data access (e.g., blood record). We also setup 10 scenarios from 1000 to 10000 requests which access the blood record from two users. Table II shows the execution results of the data access function (e.g., blood record). Compared with the first solution, the results of 10 scenarios to evaluate the data accessibility of Blood & Product-Chain are more balanced. Specifically, the successful data retrieval commands rate accounted for 95% (ranging from 85194 to 111384 requests). The system's latency is also minimal, with a maximum of 8.36 seconds and a minimum of 0.01 seconds. The send rate value achieves very high performance from 289.5 to 388.7 (TPS). Similarly, throughput values range from 289.1 to 387.4 (TPS).

C. Discussion

This is the first attempt to develop a system for the management and storage (i.e., supply chain of blood and its products) of products extracted from blood. Compared to other approaches (see more detail in the related work subject), we aim for adaptability and load-bearing with a large number

of requirements described in scenarios in the data creation and data access sections. Our approach can guarantee a large number of requests (i.e., 10K requests/sec) to initiate and retrieve data.

In future work, we aim to build an authorization mechanism for stakeholders [39], [40]. Specifically, users (e.g., donors) are allowed to design policies to manage their personal data (e.g., what data to share, and with whom). Moreover, this research result is only the first step toward building a system based on blockchain technology in a real environment. We, therefore, aim to implement the proposed model for export in more complex scenarios where healthcare facility processes have multiple roles and execute off-chain (i.e. out of scope for the current version) of medical facilities.

VI. CONCLUSION

The paper applies the benefits of Blockchain technology (i.e. transparency, decentralized storage) to propose Blood and Product-Chain: blood and its products transportation management process is based on the limitations of the traditional system. The paper provides a proof of concept based on the Hyperledger Fabric platform, which stores information about blood and blood products during storage and transport. Information is transparently stored for easy verification during transportation and storage. Detailed assessments of the number of successful, and failed requests, latency, send rate (TPS), as well as throughput (TPS), analyzed based on the Hyperledger Caliper platform, proved the feasibility of our approach.

Abstract—This paper proposes an adaptive software architecture focused on hotel marketing based on immersive virtual reality (VRI) with 360° videos, which includes a component based on Case-Based Reasoning (CBR) to provide experiences that correspond to the analysis of user profiles. For the validation of the system, considering that the use of VR can trigger experiences in several dimensions, affective, attitudinal and behavioral responses, as well as the cognitive load were evaluated using visualizations of 2D photographs contained in hotel websites , which were compared with 360° videos in a VRI environment. To test the hypotheses, a quasi-experimental study was conducted with an independent sample group, in which subjects were randomly assigned to the two types of visualizations. The contribution of the article lies in the incorporation of marketing concepts and approaches in VRI experiences with 360° videos through virtual objects that are used by the software architecture, as well as in the proposed validation of the effectiveness of the proposal.

Keywords—*Immersive virtual reality; adaptive software architecture; case-based reasoning; user profiles*

I. INTRODUCTION

Making visits to tourist resorts, hotels, museums, laboratories, factories, etc. in tourist, hotel and educational environments through virtual tours mediated by 360° immersive virtual reality (IVR) devices can become an important factor for the success of marketing strategies used by hotel, tourist, educational and other organizations.

VR employs virtual scenarios that allow the user to move freely in the virtual environment, while 360° VR offers spherical/panoramic experiences [1]. Immersive 360° video became popular in contemporary applications due to a higher perceived credibility in those scenarios, considering that 360° VR content is based on real-world photos and videos, which can be more representative of the environment the experience is focused on [2], allowing to offer a clearer and more detailed vision of the environment and a more pleasant experience [3]. Wu and Lin [4] consider that VR environment can be directly linked to 360° videos, impacting the perception-sensation of presence.

This work is focused on the proposal of a system model that performs the division of 360° videos, to then make the composition of tours, considering an intelligent component based on Case Base Reasoning (CBR) that adapts and performs the composition of tours according to the specific requirements of each user profile, which will be displayed as 360° virtual reality videos tours.

For the implementation of the CBR component, some data related to potential guests, such as the area of the hotel, the reason for the trip, whether they will travel accompanied, the services they require from the hotel and the priority they give to each of these services, are considered in the inputs for the CBR algorithm, which obtains the cases from a database based on the information of previous guest visits.

Wan, Tsaur, Chiu, and Chiou [5] suggest that when using VR as a resource for promotion, the context and specific details of the objectives should be considered, because results may vary and a one-size-fits-all approach should be avoided, as there are reported differences in the effectiveness and impacts of VR [6]. In this perspective, cognitive load, affective aspects and behavioral outcomes were identified as factors to be considered when comparing visualizations using VR resources with traditional ones [7]. In order to validate the effectiveness of the proposed model, it is investigated whether the visualization of 360° VR video tours can outperform the visualization of 2D photos used by traditional marketing resources, which is still under study.

Several studies were focused on the evaluation of the content and functions of hotel web sites, based on online satisfaction of consumers. For [8], the content of the website and its functions can directly influence the preferences and decisions of customers. Website functionalities represent the completeness of a website and its features [9], considering a list of hotel website functionalities, whose classification establishes four dimensions [10]: general hotel information, referring to the mechanism through which a hotel introduces products and services to potential consumers; reservation information, referring to the functions and information about the hotel room to be reserved, website management and surrounding information, referring to online services and features that help hotels communicate with potential consumers.

Website usability design is used to determine the experience and interaction of consumers on hotel websites [11], [12]. Au Yeung and Law [13] conducted a usability study adopting a heuristic model, which considered the following aspects: navigability, ease of use of the website, the number of languages available [14]. Consumers' online satisfaction is influenced by the ease of navigating web pages for information search and that a good user-friendly system of a website leads to a positive first impression. The users are always looking for the website quality and quality of hotel services [15].

The previous studies were focused on establishing a comprehensive evaluation of websites both of the functionality and the usability criteria to establish the general usefulness performance of a hotel website, being necessary also to explore and evaluate the influence of the adaptability of tours in hotel facilities and services to the requirements of user profiles, as well as the objective of determining the cognitive, affective and attitudinal responses, in the exploration of hotel web sites, in order to demonstrate whether for the visualization of hotel environments and services, the use of 360°VR whose technical knowledge requirements and costs are lower than those of immersive VR applications, can be more powerful in making users feel influenced in relation to booking the hotel and/or or say positive things to other potential users compared to 2D images.

The following is a description of the points discussed in the different sections. Section II reviews the literature, Section III presents the proposed software model and the use of the CBR engine for the proposed model, Section IV establishes the methodology, Section V describes the tests and discusses the results, and finally, Section VI establishes the conclusions and recommendations for future work.

II. REVIEW OF THE LITERATURE

A. Immersive Virtual Reality Technologies (VRI)

A well known definition definition of VR is: "the use of a computer-generated 3D environment in which the user can navigate and interact, resulting in a real-time simulation of one or more of the user's five senses" [16]. As [17] argue, solutions focused on tourism applications can be non-immersive, semi-immersive and fully immersive, and when a solution is more immersive, the more complicated and complex is the implementation of the technology, devices and content.

Significant improvements in VR technologies impacted more frequent use in tourism research and practice [18]. Various authors divide VR applied in tourism into five categories: planning and management, education, marketing, accessibility, heritage conservation, and entertainment. This paper is specifically focused on marketing in tourism and hospitality. Several authors focused on the similarities and differences between VR and augmented reality (AR) [19]. Other authors focused on VR as a visualization technique in which the real environment completely disappears and the client is immersed in a completely digital world [20]. Other authors state that mixed reality (MR) describes the combination of a real environment with digital content, and can vary perceptions of the real environment without complete virtual immersion [21].

From a hardware perspective, a virtual environment represents a "digital space" in which a user's movements are tracked and their environment rendered, and displayed through various senses, according to those movements [22]. A virtual environment makes it possible to replace the real-world environment by allowing users to block out the physical world of stimuli and fully immerse themselves in the virtual world [23]. The emergence of smartphones and online virtual environments allowed marketing experts to engage tourists as active participants in VR applications, where destinations can be experienced from the comfort of their home [24].

VR technologies, properly used in the proposed adaptive model, which have Artificial Intelligence components, provide an immersive interaction, which is focused on the characteristics and interests of users, which should be framed in the concepts of Experiential Marketing and Sensory Marketing, for the adaptation of experiences and virtual objects in a personalized way and according to the experiences offered by a particular hotel and in a particular environment.

B. 360° Videos in Virtual Immersion

The use of 360° videos is relevant from the use of VR technology to create immersive spaces in which the observer mimics, captures through the senses and feels what has been artificially created in the environment. According to [25], immersive videos show more interesting information within the 360° environment than normal videos and are more eye-catching, due to the greater interest of users in those visual contents, since there is a feeling of being present in the explored content; in addition, that information of interest to explore can be obtained, that is why the number of consumers in the entertainment industry using 360° videos is increasing day by day.

The system includes a perceptual component, coupled with the technological component, which generates in the viewer the illusion of being in another place, despite knowing that this is not real, as highlighted in [26]. The narrative receives particular attention because it has been shown that the deliberate manipulation of the narrative structure affects the phenomenon called "transportation" of the reader or viewer, as mentioned in [27]. The "theory of narrative transportation" [28] describes an experience by which the reader or viewer "disappears" in the narrative worlds through the commented theory.

In [29], it is proposed that immersion should generate a sensation similar to when one is immersed in the ocean: of being surrounded by a completely different reality. In [30], an emphasis is placed on the narrative with the proposal that immersion is a different mental process, an integrative mixture of images, feelings and attention, where the participant's attention and capabilities are focused on the events occurring in the narrative. In that direction, the type of narrative required for virtuality must rethink the current narrative structures, as proposed in [31] and [32]. In [26] it is argued that, in order to rethink the narrative structure, it is necessary to manage the space in such a way that, through it, the viewer perceives the sensation of being immersed in the reality proposed in the 360° video; considering the technology on which the narrative is based. A satisfactory answer to the change of narrative structure has not yet been achieved. The research for this topic focuses on improving the production of 360° videos, which is a challenging path to undertake.

In relation to these VR resources, according to [33] several authors, two dimensions are defined as the virtual presence of the observer, the media or technological characteristics of the system (media form) and the content of that system (content factors); the latter includes the objects, actors or events represented in the narrative.

C. User Profiles

Understanding what users want to get from the services they use is important, as it can facilitate the offer of different

personalized content [34], it is important to evaluate the behavior of users and generate personalized profiles, based on the data obtained, resulting in valuable knowledge for the content creator; additionally, it can allow the possibility of including advertisements or interactive advertising, for example, in the form of questionnaires; but this will not be useful only as an advertising campaign, but can also be a means to collect valuable information about a brand or product, and to support decisions in future marketing actions.

D. Case-Based Reasoning (CBR)

The basic concepts of CBR can be presented as follows: a so-called "base case" is generated, which is a problem question that will be compared with previous cases; for this purpose, a similarity function is used to recognize the possibility of adaptation between the new case and the existing cases in the case base. As a result, the most matching case is selected and this solution will be considered as a suggested solution to the new case. The three steps involved in CBR are:

1) Step 1: Build a case base. For greater accuracy, the complete case base will be accessed.

2) Step 2: Implement a similarity function. The implementation of this function will depend on the experience and logic of the developer. This function must be able to recognize the degree of similarity between the new case and the cases stored in the case base.

3) Step 3: Find the most similar cases and choose the best ones, according to the adaptation criteria.

The degree of similarity between attributes is multiplied by a weight factor, which represents how much that attribute influences the search, and then the sum of the similarity of all the attributes is calculated to obtain an overall measure of the similarity of the case [35]. In this way, we can obtain the percentage of similarity with which it is possible to sort the list of cases that have been previously stored, so we can deduce that the system will be constantly learning and improving.

In [36], it is mentioned that the CBR allows a great capacity for learning and adaptation to the context, since it resorts to past experiences to solve similar problems, as well as to generate creative solutions to new problems. Each time a new user enters to consult about tours that he/she wants to visualize, the probability of finding a visual resource that is useful to him/her increases, so that, thanks to this approach, we can prepare our system for future searches that have not been taken into account due to the great amount of variety that may exist in the preferences of the users.

E. Adaptive Systems in Marketing

For adaptive marketing systems, there are several sources of experience, such as Intelligent Learning Environments (ILE), Tutorial Systems (ITS) [37], Pedagogical Agents (PA) [38], and Adaptive e-Learning systems [39], [40], whose characteristics and adaptation techniques can contribute to achieve experiences and present virtual objects in adaptive marketing systems, according to the profiles, characteristics and expectations of potential hotel guests, improving their exploration and learning activities about hotels. In [41], it is mentioned that it is possible to generate first-person experiences related to the facilities and services provided by a hotel, through information exploration techniques and VR.

In [42] it is pointed out that these systems have as an important feature the ability to adapt the interaction process and the virtual objects, which must be flexible to the specific requirements and profiles of the users. The characteristics of the user must be considered for decision making, elements that constitute a key factor for the success of its development and implementation.

This approach was reviewed in several works [43], which recommend adaptations focused on Cognitive Styles (CS), to which it is convenient to adapt virtual experiences and objects, which resemble the contact with the hotel facilities or services. In [44] it is mentioned that the adaptation to the client's knowledge consists of focusing on the adaptation of the objects to be explored and the presentation of contents, according to the client's knowledge on the subject, about the facilities, services, experiences, landscape, environment, etc. The adaptability of marketing systems is one of the important factors to improve their quality and efficiency.

This work is focused on identifying the adaptability parameters of content and virtual objects for each particular hotel customer and then using a CBR for the adaptation of virtual experiences and objects. All these issues and elements explored have allowed the establishment of the proposed model.

Regarding the gaps and limitations of the related works, it was possible to verify that most of them focus on the usability, interactivity and functionality tests of the applications, but few studies analyze the cognitive load, which could influence the results of the tests and analyzes carried out.

III. Software Architecture Proposal

To provide a better experience to users using the proposed immersive application, a CBR engine was used to provide tour recommendations to potential users, based on user preferences and previous stored experiences, either from the user's own queries or from other users with similar profiles. In this way, if a user is interested in a certain service, they will be shown tours that have that service and fit their requirements.

Within the CBR, each case corresponds to an experience or query previously made. These cases are derived from legacy databases, converting organizational resources into exploitable knowledge. Within the proposal, the cases will be stored when a user decides to view one of the tours offered.

The attributes that make up each case, defined on the basis of the data most commonly used by hotel companies are:

- Id: tour identifier in the database, which will be used to show the recommendations to the user.

- Zone: main characteristic of the area where the hotel is located, for example, near the beach or in the city.

- Reason: represents the reason for the user's trip, e.g., vacation, work.

- Services: represents the services the hotel has; essential to show certain images or 360° videos when viewing a tour.

TABLE I. TABLE OF ATTRIBUTE WEIGHTS

Attribute	Weight
Zone	15%
Motive	24%
Services	17%
Company	20%
Priority	24%
TOTAL	100%

- Company: indicates whether the user is traveling alone or with other people (family, friends, partner, etc.).

- Priority: the most important criterion for the user when choosing a hotel, for example, price.

Six parameters are defined for the CBR search function:

- Attribute names: represents the attributes of the case to be taken into account at the time of the search.

- Search values: represents the search case, which will be the basis for searching for those cases that are most similar to it.

- Weights: importance of each attribute in the search, which allows the CBR to prioritize the attributes. These weights were obtained based on the opinions of experts in hotel management, marketing, researchers, and potential users, as shown in Table I.

- Terms: defines how each attribute will be searched, for example: equal, greater, close values, etc.

- Scales: represents how the difference between the cases and the search case will be searched mathematically, for example: linearly, logarithmically, etc.

- Search options: defines how the search results are sorted, the default option being to return the closest values.

The result of the search is a list of cases that, due to the proposed implemented configuration, will first display in the immersive application interface the cases that are most similar to the base tour, as recommendations, considering the preferences that were entered previously.

After the search, if the user enters one of the recommended tours, a new case is created in the case base, with the information stored in the user's profile, allowing to increase it, which will serve to make recommendations closer to the user's needs and preferences in future searches.

A. Proposed Architecture

For the development, the 4+1 architecture view model was selected, since it allows describing the system architecture using multiple concurrent views [45], as shown in Fig. 1. The views describe the system from the point of view of the main stakeholders, such as end users, developers, and researchers.

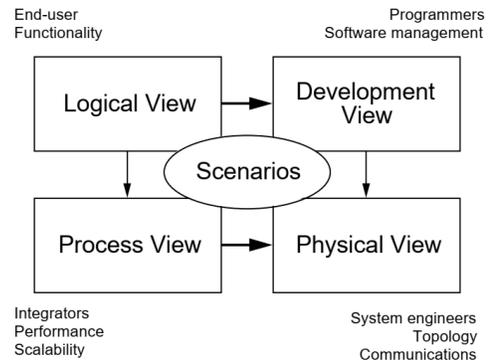
The proposed model consists of four components, where the intelligent component is responsible for adapting to the characteristics and needs of customers, which requires the identification and knowledge of the characteristics of the hotel,


Fig. 1. Proposed Architecture. Source: Own Elaboration.
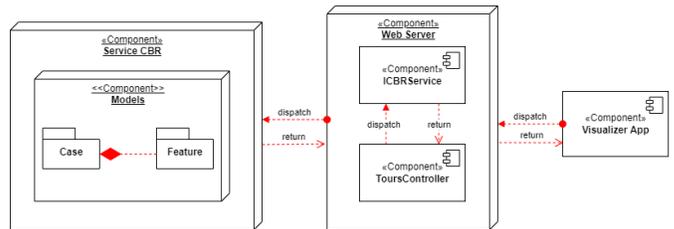

Fig. 2. Development View. Source: Own Elaboration.

its services and its environment, which will be represented in virtual objects, which must be provided to the customer, according to their characteristics and interests.

The application uses the client-server model, where the server is responsible for transmitting hotel and tour information to customers through the immersive application, and for collecting tour recommendations through the CBR.

B. Development View

The development view is shown in Fig. 2, and considers three main components: the server, the intelligent layer (CBR) and the visualization layer (immersive application). The connection between these components is based on HTTP requests that are originated by the application when the user searches for tour recommendations. The server receives the request and connects to the CBR, which returns the response of the recommendations, using the case and feature models, where a case can be composed of several features.

C. Process View

The process view in Fig. 3 presents the three most important actors: the application, the server, and the intelligent layer (CBR). The process checks if the user's preferences are saved. If they are not, or if they need to be updated, a form will be displayed and the data entered by the user will be saved. If the data is already stored and does not need to be updated, this step is skipped, and the list of recommended tours obtained from the CBR is sent.

D. Physical View

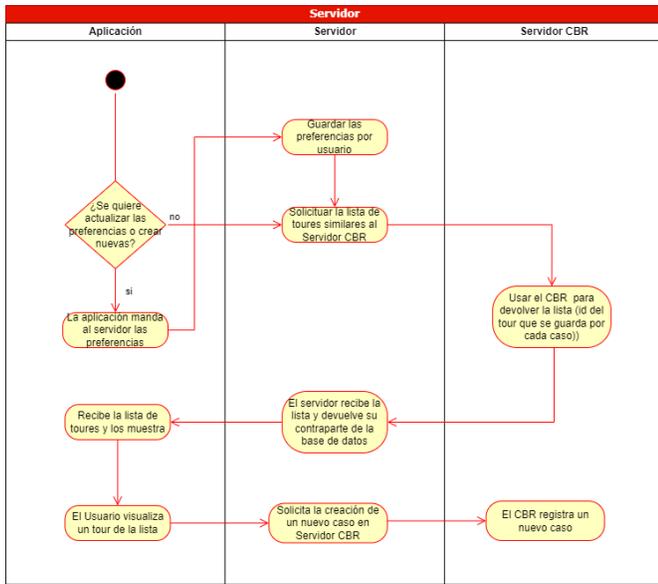
The view shows the interconnection between the web server and the immersive application, as shown in Fig. 4.


Fig. 3. Process View. Source: Own Elaboration.

Fig. 4. Physical View. Source: Own Elaboration.

The view presents five components, the web server that uses the CBR through an API and obtains the tour information through a database connection, using Entity Framework; the client that uses the connection with the web server to show the recommended hotels and tours to the user, and obtain the 360° images/videos. The intelligent layer connects to the server and only interacts with it. The application is not aware of the existence of this component.

E. Logical View

Fig. 5 shows the four main classes present in the intelligent layer: CBRController, Case, CBR, and Feature. The intelligent layer exposes a Rest API; its main controller is CBRController, whose methods expose two endpoints: getCases, to return the

Fig. 5. Logical View. Source: Own Elaboration.

list of tours related to the input tour, and addCase, to register new cases.

The CBRController class works with the Case class, which is a POJO that stores the attributes mentioned in section III. Along with this class, the CBR class is used, where the CBR cases will be converted to the Case class for its use since the CBR class works with an array of Feature instances, allowing a more comfortable handling of the CBR.

IV. METHODOLOGY

A. Model Development Methodology

For the development of the model, a methodology based on seven stages was followed:

1) Requirements and user story gathering with hotel managers.
2) Design of the customer journey map and analysis of the guest experience by management and marketing specialists.
3) Capture of 360° images and videos in test hotel establishments.
4) Design and prototyping of immersive application user interfaces.
5) Implementation of the visualization layer as an immersive application in Unity, targeting VR glasses.
6) Implementation of the intelligent layer, based on an RBC engine and a Rest API.
7) Functionality testing, based on test cases, and validation testing, based on the TLX-NASA method.

The operation of the CBR starts with the generation of a new search request for tour recommendations, based on the entry of a new case containing the following data: destination zone, reason for the trip, required services, company, and priority in the search.

The CBR configuration defines the terms, scales and weights for the search of recommendations. For this, each case is evaluated by independently comparing each of its attributes. Then, a total value (hit) will be displayed for each case, which represents the distance in the search space, and is used as an indicator of the similarity of the case. The lower the value, the greater the similarity to the search case, i.e., a hit of 0.0 translates as identical cases. At the end of the evaluation of all the cases, a list ordered by similarity will be returned, according to the hit value, eliminating the identical cases in order not to repeat results, and the information obtained from the CBR can be used.

The web server uses the list of tour IDs to retrieve the tour information to display and recommend to the user. If the user decides to view one of the recommended tours, it is considered to match the user's interests, so the search parameters and the selected tour are stored as a new case in the CBR, allowing it to be used in subsequent searches, and to obtain greater precision in future recommendations within the immersive application.

For the validation of the CBR, the case library subset test (CLST) technique, proposed by [46], is used, where the main idea is to select a subset of the case library and use this subset to evaluate the effectiveness of the recovery and adaptation functions of the system. For this purpose, the validation criterion is defined, which consists of two parameters:

- Result Acceptability Criteria (RAC): The maximum acceptable relative error of the solution compared to the standard. A RAC of 15% has been defined.

- System Validity Criteria (SVC): Threshold value to determine whether, after running and evaluating the subset of cases, the system can be considered valid. The percentage of accepted cases must be greater than this value. An SVC of 75% has been defined.

A total of 50 cases were used for the retrieval and adaptation tests under the CLST technique. The results obtained from the tests are shown in Table II.

After the tests were performed, 100% acceptance was obtained in the recovery tests, and 88% in the adaptation tests, so the proposed CBR model is considered valid, according to the SVC (75%).

B. Methodology for Validating the Effectiveness of the Model

The literature review on consumer behavior establishes that affective, cognitive and attitudinal responses are important elements in understanding consumer habits, the decision-making process and ultimately predicting user behavior. The specific research question to validate the results obtained with the architecture is:

How do traditional photo and video displays compare to 360o video displays in VR applications, in terms of (1) cognitive load, i.e., task and experience efforts associated with the technology? (2) affective responses, and (3) attitudinal/behavioral responses.

VR can trigger experiences in several dimensions, such as cognitive, affective, sensory, attitudinal and behavioral [7]:

1) Cognitive CLT Response [47]: and the limited perceptual capacity model of attention [48] give a theoretical framework for comprehension the processing of Virtual Reality visualizations. Virtual Reality hotel images will be associated with greater cognitive/perceptual load than traditional forms of imagery, and the next hypotheses are established:

Hypothesis 1a: 360° VR video visualizations of hotel en-

vironments and services will not elicit higher cognitive load compared to traditional photo and video visualizations of the similar scenes.

Hypothesis 1b: 360° VR video visualizations of hotel environments and services will elicit higher cognitive load compared to traditional photo and video visualizations of the similar scenes.

2) Affective Response: Many studies have found that VR experiences provoke emotional responses or conditions, like a galvanic skin response, skin conductance, increased heart rate, blood pressure and respiration [49], because VR engages the senses at an increase intense level, it generate an intense affective response compared with the traditional imagery. The immersive nature of VR, the intensified presence and sensory stimulation become a intense emotional experience. In addition, VR tends to be conducive to evoking a wide range of affective responses, such excitement, arousal, as general emotions of frustration, and pleasure [50]. For that reason, it is logical to assume that hotel VR 360° videos would evoke affective responses, which may be stronger relative to traditional photos and videos. As a result, the next hypotheses are established:

Hypothesis 2a: 360° VR video displays of hotel environments and services will not evoke stronger affective responses compared to photo and 2D video displays of the similar scenes.

Hypothesis 2b: VR 360° video displays of hotel environments and services will evoke stronger affective responses compared to photo and 2D video displays of the similar scenes.

3) Attitudinal and Behavioral Responses: Knowledge on how 360° videos in Virtual Reality affect customer behaviors and attitudes remains insufficient, particularly in tourism and hospitality [51]. Van Kerrebroeck et al. [52] report that consumers had more positive attitudes, satisfaction, and loyalty after being exposed to the VR experience in the mall context.

Studies by Choi and Taylor [53] and Stoyanova et al. [54], propose that sense of presence and representational richness (relevant to Virtual Reality) can produce more positive consumer attitudes towards a brand, as well as higher purchasing intentions.

Based on that assumption, the next hypotheses are established:

Hypothesis 3a: 360° VR video displays of hotel environments and services will not evoke more positive attitudinal responses compared to photo and 2D video displays of the same scenes.

Hypothesis 3b: 360° VR video displays of hotel environments and services will evoke more positive attitudinal responses compared to photo and 2D video displays of the same scenes.

Hypothesis 4a: VR 360° video displays of the hotel surroundings, environments, and services will not evoke stronger behavioral responses compared to photo and 2D video displays of the same scenes.

Hypothesis 4b: VR 360° video displays of the hotel surroundings, environments, and services will evoke stronger

TABLE III. RELIABILITY STATISTICS

Cronbach's alpha	Cronbach's alpha based on standardized elements	Number of elements
.830	.832	10

behavioral responses compared to photo and 2D video displays of the same scenes.

The procedure established is the next: All measurement items keep out demographic information were adopted from another studies.

For affective responses to the visualizations received, the Pleasure, Arousal, and Dominance (PAD) scale [55], widely validated in some studies measuring affective response to colors and physical environments [56], can be used. The scale begins with a statement, "After visualizing the images of the hotel, I feel ..." followed by 18 bipolar items:

1) Pairs of pleasure-related adjectives: unhappy-happy, annoyed-pleased, dissatisfied-satisfied, depressed-content, despairing-hopeful, bored-relaxed.
2) Pairs of arousal adjectives: relaxed-stimulated, calm-excited, slow-frenetic, bored-nervous, sleepy-awake, unexcited-excited.
3) Pairs of adjectives related to dominance: controlled-controlling; influenced-influential; insignificant-important; submissive-dominant; restrained-free.

A 7-point semantic differential scale, from 1 to 7, can be used to assess each bipolar pair [56].

Attitudes and behavioral intentions toward hotels were measured through a 7-item scale adopted from Slevitch and Oh [57]. The measure includes attitudinal questions such as:

1) How likely would it be, that you would decide to book at the hotel you saw?
2) To what extent would you be satisfied with your decision to stay at that hotel?
3) Does the hotel you viewed match its price?

The behavioral questions are as follows:

1) How likely would you be to book such a hotel?
2) How likely would you be to say positive things about the hotel to others?

To measure cognitive workload, one of the most established tests is the NASA TLX, which assesses subjective mental workload [58], and is based on the cognitive demand of a task [59]. The NASA TLX assesses workload in six areas: mental demand, physical demand, temporary demand, performance, effort, and frustration, which are assessed using a differential scale. Its reliability and validity have been confirmed in several studies.

The Cronbach's alpha approach was applied to validate the consistency of the survey questions of both groups, obtaining the satisfactory results shown in the Table III.

A quasi-experimental study was conducted to test the hypotheses. The lobby of a boutique hotel and a beach hotel and various environments were captured in both 2D photos and

videos, as well as 360° videos, which can be viewed through a PC and with an immersive helmet, respectively. Subjects were randomly assigned to two types of visualizations that serve as experimental conditions. The experiment took place in various locations and environments.

For the test case of videos in VR, the VR HMD device that allows immersive experiences based solely on smartphone was used to create an immersive virtual experience [60].

Participants are individually exposed to an experience and must be asked to imagine a situation in which they are choosing a hotel, considering one of the motivations established in the study, as well as a location. Cost was not considered. Subjects were then exposed to one of the experimental conditions for five minutes. Participants in the VR group received assistance in donning the devices and verbal permission was obtained from the participants to use their images in the study.

After receiving the experimental treatment, subjects were asked to fill out a questionnaire on Google forms. The duration of the trial was completed within one month.

V. Tests and Discussion of Results

The sample consisted of 312 potential customers, randomly selected from a population of 1620 users, composed of young people, including professionals, undergraduates and graduate and postgraduate university students. Tests 1 and 2 included an equal number of participants, 156 each. The analysis of the results is as follows:

A factor analysis restricted to the use of only three components was used to (1) establish the dimensionality of the PAD scale Pleasure, Excitement and Dominance - and (2) develop composite variables for based on the sum of values for each factor. Principal component analysis was used as extraction method and varimax with Kaiser normalization was applied as rotation method and the cut-off value of the correlation was 0.5. The factor analysis was adequate, based on Bartlett's sphericity test ($p < 0.0000$), and the KMO test (Kaiser-Meyer-Olkin), which yielded a statistic of 0.838.

A. Cognitive Load Answers

Test 1 and Test 2 produced responses with some differences for most items in the cognitive load component (see 2D Cognitive Dimension Table, available at [61]). Scores were significantly lower for Test 1 compared to Test 2 by 12.5% on the mental demand scale. There was a lower physical demand in 360° VRI visualization compared to 2D by 16.6%. There was also a lower temporal demand in 360° VRI visualization compared to 2D by 13.5%. Less effort was also found in 360° VRI visualization compared to 2D by 8.3%. The frustration level was slightly lower in 360° VRI compared to 2D by 4.2%.

B. Affective Answers

Test 1 and Test 2 produced responses with some differences for most items in the affective load component (see Affective Dimension 2D Table, available online [61]), as shown in the results, and statistically significant differences were identified, equivalent to 17%, with a larger difference observed for females. There was a statistically significant difference in responses between the visual conditions on how insecure,

discouraged, irritated, stressed and annoyed respondents felt about the task. Scores were significantly lower for Test 1 compared to Test 2 by 4.9% on the Pleased-annoyed scale. The 360° VRI images scored lower compared to the scores produced in the 2D condition by -2.1% for the Animated-Abashed scale. Participants who viewed the 2D images scored higher compared to those exposed to the 360° VRI by 9.4% on the tense-relaxed scale.

C. Attitudinal and Behavioral Responses

There was a significant difference between the attitude responses for Test 2 data and a behavioral response in Test 1. Participants in Test 2D felt more positive about staying at the hotel compared to those exposed to 360° VRI images, with a difference of 29%. Participants exposed to 2D photos were more likely to book into the hotel compared to their 360° VRI counterparts by 25.9%. It can be inferred that at this point bookings would have higher preferences for 2D because the hotel's website allows access to information on all the hotel's environments and services, while 360° VRI visualizations could be accessed in a free way through hotspots, or by providing user profile data and displaying only information of interest, showing partial information on the hotel, so further studies are required to corroborate the results obtained.

D. Limitations and Further Research

The data to model and validate the architecture were collected in the city of Arequipa, considering potential hotel clients, as well as Master's in Marketing and undergraduate students from the National University of San Agustín, who may not have accurately reproduced world conditions. real and limit the external validity of the results. Therefore, the application of the results to the hotel industry must be done with caution. In future research, an effort should be made to design conditions that are similar to real world experiences.

The samples met the minimum size requirements, derived in part from the sanitary restrictions derived from the Covid-19 pandemic, but they may still be small. The study also included a limited scope of affective responses as only three dimensions were examined and other potentially relevant emotions were not considered. In the future, psychophysiological measures could be included in the studies to correct deficiencies that could have been caused by the self-reported measures and those that may not have been the best way to capture affectivity.

E. Discussion and Implications

The findings suggest that 360° VR visualizations differ from traditional 2D images only in some dimensions of cognitive load.

At the same time, VR users felt less insecure, discouraged, irritated, stressed and annoyed by the task at hand. Such findings suggest that various visual aspects and the complexity of visual details produce a variety of impacts on cognitive load and task performance.

Visuals of hotel environments and services displayed in 360° VR produced stronger affective responses compared to 2D visuals, with a larger difference for women. The possible

explanation for the observed inconsistencies may lie in the fact that previous studies examined affective responses to VR in other contexts, such as gaming, food service, retail, etc. Gibson and O'Rawe [51] and Wan et al. [5] caution that the effects of RV may vary in different contexts; therefore, the ac-tual findings may point to peculiarities of the hotel context, which merit further investigation. Furthermore, the results might have been affected by weaknesses in self-reported measures when applied to affective responses. Self-reported measures are prone to cognitive biases and socially desirable responses and, more importantly, such measures are unable to capture respondents' unconscious affective reactions. It is also possible that, as explained, access to limited information through hotspot login or filtered by user profiles may have influenced attitudinal evaluation, and further studies with more complete information on 360° VRI are required.

The current study also produced evidence that VR images of hotel service layers may be more powerful in making users feel more positive about staying at the hotel and saying positive things about the hotel to other potential users compared to 2D images. The findings were not very consistent, indicating that further research is needed.

Regarding the challenges encountered, the use of 360° videos for immersive reality represents a great opportunity, given the low cost of display devices, which is why more empirical research is needed that can be used in other fields such as of hospitality, so that investments in this field get a good return on investment.

VI. Conclusion

An adaptive software architecture model based on hotel marketing concepts and strategies was proposed from 360° VRI videos and to validate the effectiveness of experiences with the model, 360° VRI visualizations were evaluated in comparison with 2D photographs. Since traditional 360° video immersion and 2D image viewing can trigger experiences in various dimensions, cognitive, affective, attitudinal, and behavioral loads were evaluated.

The results of the study suggest that 360° VR views differ from traditional 2D images only on a few dimensions of cognitive load. Also, 360° VR users felt less insecure, discouraged, irritated, stressed, and annoyed while performing viewing tasks, suggesting that visualizations and the complexity of visual details produce a variety of impacts on cognitive load and performance. task performance. Viewing hotel environments with 360° VR produced stronger affective responses compared to 2D visuals.

The study also found that 360°VR image displays of hotel environments and services may be more powerful in making users feel positive about booking the hotel and saying positive things to other potential users compared to 2D images. The findings were not very consistent, indicating that further research is needed to establish that investments in emerging technologies in hotel marketing are made based on a framework of adequate knowledge and experience.

Abstract—Edge-cloud computing is increasingly prevalent for Internet-of-Thing (IoT) service provisioning by combining both benefits of edge and cloud computing. In this paper, we aim to improve the user satisfaction and the resource efficiency by service caching and task offloading for edge-cloud computing. We propose a hybrid heuristic method to combine the global search ability of the genetic algorithm (GA) and heuristic local search ability, to improve the number of satisfied requests and the resource utilization. The proposed method encodes the service caching strategies into chromosomes, and evolves the population by GA. Given a caching strategy from a chromosome, our method exploits a dual-stage heuristic method for the task offloading. In the first stage, the dual-stage heuristic method pre-offloads tasks to the cloud, and offloads tasks whose requirements cannot be satisfied by the cloud to edge servers, aiming at satisfying as many tasks' requirements as possible. The second stage re-offloads tasks from the cloud to edge servers, to get the utmost out of limited edge resources. Experimental results demonstrate the competitive edges of the proposed method over multiple classical and state-of-the-art techniques. Compared with five existing scheduling algorithms, our method achieves 11.3% to 23.7% more accepted tasks and 1.86% to 18.9% higher resource utilization.

Keywords—*Cloud computing; edge computing; genetic algorithm; service caching; task offloading*

I. INTRODUCTION

Internet-of-Thing (IoT) devices have become ubiquitous in our lives. IoT services are becoming increasingly needed in both the number and variety, as revealed by the Cisco Annual Internet Report [1]. Eventhough some resources are equipped on various IoT devices, they are not enough for satisfying all requirements of users, due to the limited resource of a device.

To address the issue, mobile cloud computing (MCC) exploits the cloud computing with abundent computing resources to extend the service ability of IoT devices, by offloading some tasks to the cloud [2]. But the cloud has a poor network performance as it deliveries services over wide area networks (WANs), and thus, it usully cannot process delay-sensitive request tasks. Therefore, edge computing is proposed to address the problem, by placing some resources close to user devices [3] to provide services with low latency.

By combing both benefits of edge and cloud computing, edge-cloud computing (ECC) has begun to be used more and more in both industrial and academic [4]. While the cooperation between the edge and cloud computing needs to be further enhanced for improving the resource efficiency and user satisfaction [5]. The purpose can be achieved by a joint task offloading and service caching strategy for edge-cloud computing.

unfortunately, the joint task offloading and service caching problem (TOSCP) is NP-hard [6], and there is no available method providing the optimal solution within a reasonable time for a large-scale ECC system. There mainly two kinds of ways to solve the TOSCP for providing an accepted solution in polynomial time, heuristics and meta-heuristics. Heuristics uses local search strategies for local optimal solutions with a very few time consumption. On the contrary, meta-heuristics exploit global search strategies inspired by natural and social phenomena. Meta-heuristics usually have better performances, but require much more time costs, compared with heuristics. In this paper, we design a hybrid heuristic method by combining the genetic algorithm (GA), a representative meta-heuristic method, and a dual-stage heuristic search strategy which is designed for improving the cooperation between edge and cloud computing. The introducing of the heuristic method can improve both the quality of chromosomes and the convergence velocity for GA. Different from existing related works [5], [6], [7], [8], [9], [10], [11], [12], [13], [14], the main advantages of our work include the awareness of the heterogeneity between edge and cloud resources, providing the joint solution of the service caching and task offloading, and the integration of the dual-stage heuristic into GA.

The rest of this paper is organized as follows. Section II formulate the TOSCP concerned in this paper. Section III presents our proposed hybrid heuristic method. Section IV evaluates our proposed method by simulated experiments. And finally, Section V concludes the paper.

II. PROBLEM STATEMENT

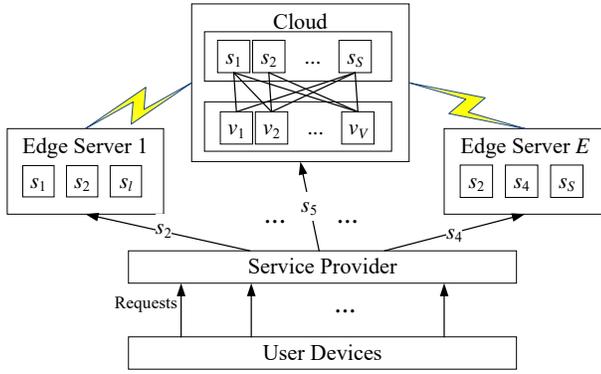
As shown in Fig. 1, in edge-cloud computing, the service provider uses multiple edge servers (ESs) and a cloud to provide various services for its users, where the cloud provide its resources in the form of virtual machine (VM). Due to a very limited resource, each ES can be deployed only a few services at a time. On the contrary, the cloud has seemingly infinite resources, and can be provide all services all the time. In general, an ES has local area network connections to users close to it. While the cloud provides its services over wide area network, e.g., Internet. Thus, the cloud has a much poorer network performance than ESs. Briefly, the cloud has abundant computing and storage resources but a high data transmission delay, but ESs have limited resources with low network delays.


Fig. 1. The Architecture of the Edge-Cloud Computing System.

To deliver services efficiently, the service provider should carefully design the service caching and task offloading strategy, where the service caching decides which services each ES provides with its limited resources, and the task offloading strategy provide the computing node (ES or VM) where each user's request is processed. In this paper, we aim at designing a hybrid heuristic method for solving the TOSCP formulated as followings.

Given an edge-cloud computing system, there are E ESs, and the cloud provide V VMs. Without loss of generality, we use $E + V$ computing nodes, $n_1, ..., n_E$ and $n_{E+1}, ..., n_{E+V}$, to represent these ESs and VMs, respectively. For a computing node, say n_j, it has g_j computing capacity and b_j downlink bandwidth. For each ES, say n_j ($1 \le j \le E$), it has m_j storage capacity for service deployments.

The service provider provide S services, $s_1, ..., s_S$, by the edge-cloud computing system. The storage requirement of service s_k is r_k. There are T request tasks, $t_1, ..., t_T$, to be processed in the system. Each task require one of S services. We use the binary constants, $a_{i,k}$ ($1 \le i \le T, 1 \le k \le S$), to represent the service that each task requires, where $a_{i,k}$ represents that task t_i require service s_k. For its processing, task t_i needs c_i computing resource, and has h_i amount of input data to be processed. The deadline of t_i is d_i, i.e., t_i must be completed before d_i.

For the formulation of TOSCP, we define binary variables by Eq. (1) to indicate the solution, where $x_{i,j} = 1$ means that t_i is scheduled to n_j for its processing. $x_{i,j} = 0$ represents t_i is not scheduled to n_j.

$$x_{i,j} = \begin{cases} 1, & \text{if } t_i \text{ is scheduled to } n_j \text{ for its processing} \\ 0, & \text{else} \end{cases},$$
$$1 \le i \le T, 1 \le j \le E + V. \quad (1)$$

As no more than one computing node that each task can be processed,

$$\sum_{j=1}^{E+V} x_{i,j} \le 1, 1 \le i \le T. \quad (2)$$

In addition, we use binary variables $y_{j,k}$ to represent the service cache strategy for ESs, where $y_{j,k} = 1$ indicates service s_k is cached (deployed) on ES n_j ($1 \le j \le E$). Noticing that if a task is scheduled on an ES to be processed, its required

service must be cached (deployed) on the ES. Then, following equations hold.

$$y_{j,k} = \min\{1, \sum_{i=1}^{T} (x_{i,j} \cdot a_{i,k})\}, 1 \le j \le E, 1 \le k \le S. \quad (3)$$

For each ES, the total storage space of all services cached on it cannot be larger than its storage capacity, i.e.,

$$\sum_{k=1}^{S} (y_{j,k} \cdot r_k) \le m_j, 1 \le j \le E. \quad (4)$$

For tasks scheduled on a computing node, their finish time can be calculated using the pipeline execution model with the deadline decrease order [10], as shown by Eq. (5). where $ft_{i,j}$ is the finish time of t_i when it is scheduled on n_j, and $ft_{i,j} = 0$ if t_i is not scheduled on n_j. As the output data is usually much less than the input data for a task, this paper ignores the latency of the output data transfer.

$$ft_{i,j} = x_{i,j} \cdot \max\{ \max_{d_{ii} < d_i} ft_{ii,j} + \frac{c_i}{g_j},$$
$$\max_{d_{ii} < d_i} (ft_{ii,j} - \frac{h_{ii}}{b_j}) + \frac{h_i}{b_j} + \frac{c_i}{g_j}\},$$
$$1 \le i \le T, 1 \le j \le E + V. \quad (5)$$

Then, the deadline constraints can be formulated as Eq. (6).

$$ft_{i,j} \le d_i, 1 \le i \le T, 1 \le j \le E + V. \quad (6)$$

For each computing node, its usage time is the latest finish time of tasks scheduled on it, which is

$$ut_j = \max_{1 \le i \le T}\{ft_{i,j}\}, 1 \le j \le E + V, \quad (7)$$

and thus, the occupied resource of each node is

$$or_j = ut_j \cdot g_j, 1 \le j \le E + V. \quad (8)$$

For a computing node, the amount of resources used for processing tasks is the accumulated resources required by these tasks, i.e.,

$$ur_j = \sum_{i=1}^{T} (x_{i,j} \cdot c_i), 1 \le j \le E + V. \quad (9)$$

The resource utilization of each computing node and the overall resource utilization of the edge-cloud computing can be calculated by Eq. (10) and (11), respectively.

$$U_j = \frac{ur_j}{or_j}, 1 \le j \le E + V. \quad (10)$$

$$U = \frac{\sum_{j=1}^{E+V} ur_j}{\sum_{j=1}^{E+V} or_j}. \quad (11)$$

Based on the above formulations, TOSCP can be modelled as following optimization objective with constraints (1)–(11).

Maximizing $N + U$ \quad (12)

Where $N = \sum_{i=0}^{T} \sum_{j=1}^{E+V} x_{i,j}$ is the number of tasks processed by the edge-cloud computing system. Noticing that U is no more than 1, and thus, the major objective is maximizing the number of processed tasks, and the utilization maximization is the minor one. Due to the discreteness of decision variables, this optimization problem is hard to be solved exactly for large-scale problems, as its complexity is exponentially increased with the number of decision variables. Thus, we present a hybrid heuristic method for solving this problem with a reasonable time.

III. GENETIC ALGORITHM WITH DUAL-STAGE HEURISTIC

Our proposed method, DGA, exploits the global search ability of GA, where each chromosome represents a service caching solution for the edge-cloud computing, as shown in Algorithm 1. Meantime, DGA uses a dual-stage heuristic method, as shown in Algorithm 2, to solve the task offloading problem.

As shown in Algorithm 1, first, DGA initializes a population, a set of chromosomes, randomly (line 1). Then DGA repeats the evolution of the population using crossover, mutation, and selection operators (lines 5–7). After the maximum repeat time is reached, DGA provides a service caching and task offloading strategy by decoding the best chromosome with the best fitness. Where the fitness function used by DGA is the optimization objective (12), i.e., the finished task number plus the overall resource utilization.

Each chromosome corresponds to a service caching solution. The length of the chromosome, i.e., the number of genes, is the number of ESs. Genes have a one-to-one relationship with ESs, and the value of a gene indicates which services are cached on the corresponding ES. There are S services, then a gene is a binary string with length S, where binary bits have a one-to-one relationship with services to indicate whether services are cached on the ES (i.e., $y_{j,k}$ for ES n_k in Eq. 3). For example, in an edge-cloud computing, there are 5 services and 2 ESs. The chromosome (00111b, 11100b) indicates that the first three services are cached on the second ES, and the last three services are cached on the first ES.

To increase the rate of convergence, DGA see each gene value as an integer for the population evolution. To ensure the population diversity for large-scale systems, DGA uses uniform crossover, uniform mutation, and tournament selection operators to evolve the population.

Given a chromosome, DGA uses a heuristic method with a dual-stage to map the chromosome into a service caching and task offloading strategy, and calculates its fitness, as shown in Algorithm 2. There are two stages for a task. In the first stage, for each task, DGA finds whether a VM that can finish the task within its deadline. If there is such a VM, the task is pre-scheduled to the VM (lines 3–9). Otherwise, DGA searches whether there is an ES that caches the task's requested service and satisfies the task's deadline constraint. If there is such an ES, the task is scheduled to the ES (lines 10–18). Otherwise, the task cannot be processed by the edge-cloud computing for satisfying its requirements, and thus is rejected. After the first stage is completed, the next stage aims at improving the overall resource cost by re-scheduling some tasks from VMs

---

Algorithm 1 DGA: The Improved GA with a Dual-Stage Heuristic Search

Input: The information of tasks, services, ESs, and cloud VMs;
Output: A service caching and task offloading strategy;
1: Randomly initializing chromosomes;
2: **while** the maximum iteration number is not reached **do**
3:     For each chromosome, calculating its fitness value using Algorithm 2;
4:     Updating the best fitness and the best chromosome;
5:     Executing uniform crossover operator for chromosomes;
6:     Conducting uniform mutation operator on each chromosome;
7:     Selecting chromosomes by the tournament selection operator;
8:     Increasing the iteration number by one;
9: **end while**
10: **return** the service caching and task offloading strategy decoded from the best chromosome by Algorithm 2;

---

to ESs (lines 20–26). For each task pre-scheduled to VMs, the second stage looks up an ES that can satisfy requirements of the task. If there is such an ES, the task is re-scheduled to the ES. Otherwise, the task will be processed by the VM where it is pre-scheduled.

Algorithm 2 The Decoding by a Dual-Stage Heuristic Search

Input: A chromosome;
Output: The service caching and task offloading strategy, the fitness;
1: Decoding the chromosome into the service caching strategy;
2: **for** Each task **do**
3:     **for** Each VM **do**
4:         **if** The VM satisfies requirements of the task **then**
5:             Pre-scheduling the task to the VM;
6:             Accumulating the processed task (N) and the used resource amount (ur_j) based on Eq. (9);
7:             **break**;
8:         **end if**
9:     **end for**
10:     **if** The task isn't Pre-scheduled to a VM **then**
11:         **for** Each ES **do**
12:             **if** The ES satisfies requirements of the task **then**
13:                 Scheduling the task to the ES;
14:                 Accumulating the processed task and the used resource amount;
15:                 **break**;
16:             **end if**
17:         **end for**
18:     **end if**
19: **end for**
20: **for** Each task pre-scheduled to VMs **do**
21:     **for** Each ES **do**
22:         **if** The ES satisfies requirements of the task **then**
23:             Scheduling the task to the ES;
24:         **end if**
25:     **end for**
26: **end for**
27: Calculating the resource utilization (U) by Eq. (11);
28: Calculating the fitness: $N + U$;
29: **return** the service caching and task offloading strategy, the fitness;

IV. PERFORMANCE EVALUATION

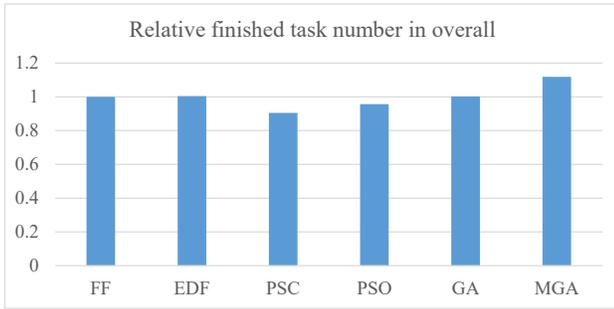
In this section, we evaluate the performance of DGA based on a simulated edge-cloud system, to verify the high efficiency


Fig. 2. The Normalized Numbers of Finished Tasks, Achieved by Various Methods.
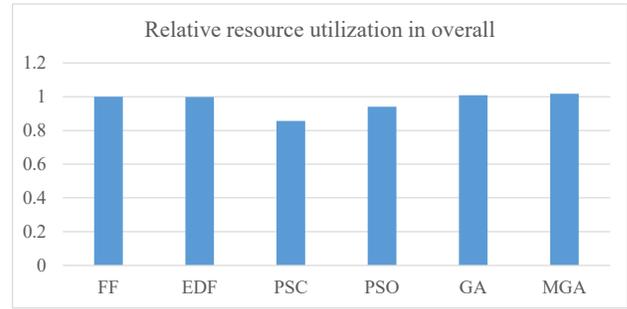

Fig. 3. The Normalized Resource Utilization Achieved by Various Methods.

of DGA in solving TOSCP.

A. Experiment Design

In the simulated edge-cloud system, we randomly generate 1000 tasks, 100 services, 10 ESs and one VM type. The computing resource required by a task is randomly set between 0.5GHz and 1.2GHz. The input data amount of each task is generated randomly in the range of [5MB, 6MB]. These two parameters are referring to [11]. The deadline is set to [1, 5] seconds for each task. Referring to [12], the storage space required by a service is in the range of [40, 80]GB, randomly. Each ES has 20GHz computing capacity. The network bandwidth between an ES and a user device is 60Mbps. The VM type is configured with 5GHz computing capacity and 15Mbps network bandwidth.

There are five benchmark methods in our experiments, First Fit (FF), Earliest Deadline First (EDF), Popularity-based Service Caching (PSC) [13], Particle Swarm Optimization (PSO) [5], and Genetic Algorithm (GA) [14]. The metrics used for the performance evaluation include the finished task number (the number of tasks whose requirements are satisfied) and the overall resource utilization, which used frequently to quantify the user satisfaction and the resource efficiency, respectively.

We repeat our experiment 100 times. In each repeat, we first generate an edge-cloud system with randomly set parameters. Then, we test the performance of our method and the five benchmark methods, respectively, in the generated system. To highlight the relative performance among these methods, we normalize each metric value of each method by dividing it by that of FF. In the following, we report the average normalized value for each metric and each method.

B. Experiment Results and Analysis

Fig. 2 shows the normalized numbers of tasks whose requirements are satisfied, when applying various methods. As shown in the figure, we can see that DGA can finish 11.3% to 23.7% more tasks than other methods. This verifies that our method has a better performance in optimizing the user satisfaction, compared with other method. This is benefited from the high population diversity of GA and the high efficiency of the dual-stage heuristic.

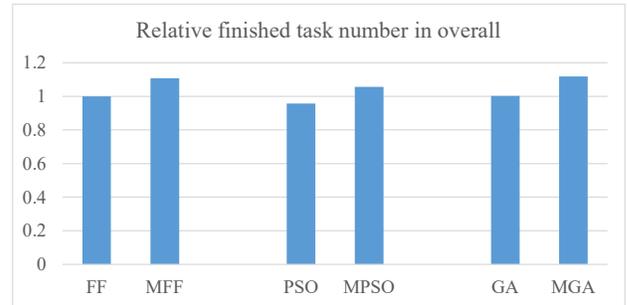
The normalized performances of various methods in resource utilization are shown in Fig. 3. From the figure, we


Fig. 4. The Improvement of the Dual-Stage Heuristic for Various Methods

can see that DGA achieves 1.86% to 18.9% high resource utilization than other methods. Thus, our method has a better resource efficiency.

One of the main advantages of our method is exploiting the dual-stage heuristic. The dual-stage heuristic can be applied for improving the performance of other methods, e.g., FF, PSO. Next, we conduct experiments for evaluating the improvement of the dual-stage heuristic for various methods, by comparing the performance differences between FF/PSO/GA and DFF/DPSO/DGA, where DFF/DPSO/DGA is the method of integrating FF/PSO/GA with the dual-stage heuristic. The results are shown in Fig. 4. DFF/DPSO/DGA can finish 10.8%/10.5%/11.6% more tasks than FF/PSO/GA. Thus the dual-stage heuristic can improve performance by about 10 percent for various methods.

V. CONCLUSIONS

We studied the service caching and task offloading problem for edge-cloud computing in this paper. We first formulated the problem as an binary non-linear programming with two optimization objectives, the finished task number and the resource utilization. Then, for solving the problem in polynomial time, we proposed a hybrid method which integrates GA and a dual-stage heuristic. Finally, we conducted extensive simulated experiments to evaluate the performance of our proposed method. Experiment results showed that our method can finish up to 23.7% more tasks and achieves up to 18.9% higher resource utilization, compared with five of classical and latest works.

In this paper, we focus on independent tasks without any data or logic dependency relationship. In the future, we will extent our work to support the workflow applications

consisting of interdependent tasks. In addition, we will exploit more global and local heuristic searching strategies to improve the performance of our method.

Abstract—Internet usage has increased social media over the past few years, significantly impacting public opinion on online social networks. Nowadays, these websites are considered the most appropriate place to express feelings and opinions. The popular social media site Twitter offers valuable insight into people's thoughts. Throughout the conflict between Russia and Ukraine, people from all over the world have expressed their opinions. In this study, "machine–learning" and "deep–learning" techniques are used to understand people's emotions and their views about this war are revealed. This study unveils a novel deep-learning approach that merges the best features of the sequence and transformer models while fixing their respective flaws. The model combines Roberta with ABSA (Aspect based sentiment analysis) and Long Short-Term Memory for sentiment analysis. A large dataset of geographically tagged tweets related to the Ukraine-Russia war was collected from Twitter. We analyzed this dataset using the Roberta-based sentiment model. In contrast, the Long Short-Term Memory model can effectively capture long-distance contextual semantics. The Robustly optimized BERT with ABSA approach maps words into a compact, meaningful word embedding space. The accuracy of the suggested hybrid model is 94.7%, which is higher than the accuracy of the state-of-the-art techniques.

Keywords—*Aspect based sentiment analysis, Twitter, LSTM, emotion analysis, Russia-Ukraine war, online social networks, Roberta model*

I. Introduction

People's voices are blaring out through social media in many communities. Modern society relies heavily on these platforms for sharing complete information and expressing opinions and feelings freely. Today, people spend a lot of time on social media websites [1] since the internet is so popular. Likewise, the popularity of social media platforms makes it very likely that people can positively or negatively impact society by sharing their opinions. Internet sources affect public opinion on politics, the economy, and social life. Most people are active on Twitter, sharing their views and feelings about a specific topic daily [2]. Millions of tweets are shared every day on Twitter. Sentiment analysis can mine vast amounts of text for information about people's views and responses [3,4]. People unable to express themselves in their daily lives for various reasons are more likely to express themselves on Twitter, a unique data source for sentiment analysis.

After annexing Crimea in 2014, Russia invaded Ukraine on February 24, 2022, turning the Ukraine-Russia crisis into war. Many deadly battles during the Russian invasion of

Ukraine sparked global reactions, especially on Twitter. Many journalists cover wartime events fairly and impartially [5]. Such conflicts cause long-term economic, political, and psychological issues in society. Social media is used worldwide to express political opinions. Online users are constrained to their social surroundings when examining contentious opinions. Obviously, one person cannot read all tweets about a topic. NLP analysis of tweets regarding the Ukraine-Russia war on Twitter will give us an objective view of global tendencies, providing a unique data source for press member stories and articles. Thus, a literature analysis on a Twitter debate topic may help machine and deep learning-based opinion categorization. Deep-learning-based methods automatically pick and learn features from the textual information, unlike machine learning-based methods [6]. Many degrees of deep learning view data differently. NLP approaches allow sentiment analysis and word cloud for visualization of massive Twitter data.

Deep-learning is used in various aspects such as object-detection, image-captioning [39], image segmentation [40], etc. This study uses machine and deep learning approaches to assess how twitter discussions regarding the Ukraine-Russia war affect public sentiment. Twitter API was used to evaluate the suggested approach on a large geographically tagged tweet dataset containing Ukraine-Russia war themes. Now sentiment analysis and word clouds help to discover general themes in the study. Sentiments about the Ukraine-Russia war and classify and display them into subgroups categories.

This study continues as follows: Section 2 offers a survey of relevant research. Section 3 describes the model's dataset, pre-processing, and ABSA-based Roberta-LSTM architecture for sentiment analysis. Section 4 compares the experimental results of the suggested model for the dataset with the sentiment visualisation data analysis. Finally, Section 5 concludes the study.

II. Related Work

Sentiment analysis uses data and text mining to identify textual sentiments [7]. Complex AI challenges let us determine whether a text has a favourable or bad subjective attitude. "Opinion mining" has three levels: "document", "sentence", and "aspect-based" [8–13]. Document-level sentiment analysis determines text polarity. It focuses on single-topic or entity papers. Sentence-level sentiment analysis examines positive, negative, and neutral sentences and their subjective or ob-

jective sentiment. Aspect-based sentiment analysis emphasizes "entity/object-identification", "feature-extraction", and "feature-polarity". Dictionary-based sentiment analysis models are common. A sentiment dictionary lists words having good or negative subjective orientations. In semantic orientation labelling, word types can be classed as positive or negative or given a numerical value depending on pre-established parameters. LIWC and HULIUO use common, context-free terms, while ANEW SenticNet and SentiWordNet [14] use sentiment strength and quantitative scores. Sentiment dictionaries are problematic because any human language has grammatical variances, idioms, slang, and spelling errors, which make automatic language analysis harder.

Machine learning, dictionary-based, and deep learning-based sentiment analysis are utilized nowadays [15,16]. A bag of words helps machine-learning-based approaches interpret texts into features. After that, "Naive-Bayes", "Decision-Trees", and "Support-vector-machine" classifiers are fed complex machine learning features [17]. Dictionary-based methods calculate text polarity by summing positive and negative emotion terms [18]. Machine learning-based systems may use sentiment dictionaries with positive and negative scores for words, unlike dictionary-based approaches. Thus, machine learning-based methods outperform dictionary-based ones. Hybrid machine and dictionary-based techniques coexist in the literature [19]. Deep learning-based approaches have replaced machine learning approaches, and experimental results are more promising [20, 21,37,38].

Researchers are impressed by deep-learning-based sentiment analysis. To enhance document-level sentiment analysis, the authors of this research [22] suggested a one-dimensional convolutional neural network model that incorporates temporal relations into user and product representations. The authors of [23] presented an artificial neural network-based system that suggests idioms for essay writing by analyzing similar contexts and potential phrases. In [24], the authors use feedback to improve the RNN architecture and create the LTSM model. Schuster and Paliwal utilized the "Bi-LSTM" model [25]. Deep learning methods automatically identify text emotion features. Deep learning predicts sentiment on a large Twitter dataset.

Internet use has made social media platforms popular in the past decade. Microblogs allow social media users to quickly share their daily experiences. Professionals share news and information on microblogs. Microblogs are the fastest way to report global news. As of 2021, Twitter has 330 million active users [26]. Thus, Twitter is vital for social media news dissemination. Sentiment analysis on Twitter can unlock a lot of unstructured data for researchers.

The authors of [27] sentiment analyzed tweets on coronavirus outbreaks using deep-learning classifiers. They suggested that harmful tweet content created fear, horror, and despair and that detecting such tweets would reduce the negative consequences of a pandemic on society. The authors of [28] used the BERT model to analyze attitudes by single and plural tags. The proposed method relied on emojis to convey emotions. The authors of [29] analyzed Twitter sentiment during and after the Syrian chemical attacks. The writers of [30] used the LDA algorithm to identify common debate themes from 4 million tweets regarding Covid-19 under 25 tags between "1 March 2020 and 21 April 2020". The writers of

[31] employed VADER natural language processing methods to assess coronavirus vaccine attitudes and behaviours using LSTM and Bi-LSTM-based and RNN-focused architectures. The authors of [32] employed topic modelling and sentiment analysis on tweets regarding global climate change to reveal public opinion. The authors of [36] used "IMDB", "Twitter-US-Airline-Sentiment", and "Sentiment140" datasets, and "Roberta-LSTM" outperforms state-of-the-art sentiment analysis algorithms.

The paper's contributions are threefold:

1) A hybrid ABSA-Roberta-LSTM model for sentiment analysis is proposed. Initially, aspect terms are generated, and then the Roberta model is used to tokenize words or subwords and build word embeddings. Meanwhile, the "LSTM" model encodes long-distance temporal dependencies in the word embeddings.

2) Due to the amount of Twitter data on the Ukraine-Russia war, a large spatially tagged dataset was collected from Twitter user's tweets about the war. This tweet collection was sentiment-analyzed using NLP.Twitter users often misspell and use contractions. Tweets may change tone due to spelling errors. Thus, our work performed powerful data cleansing, lemmatization, and noise removal.

3) Adjusting hyperparameters improves sentiment analysis outcomes. The empirical results reveal that ABSA-based Roberta-LSTM outperforms state-of-the-art approaches.

III. PROPOSED METHODOLOGY

This section describes the "ABSA-based-Roberta-LSTM" model for analysis. Pre-processing removes redundant tokens and symbols from the corpus. Our proposed model is then used to train and classify the dataset. The proposed methodology is shown in Fig. 1.

The "ABSA-based-Roberta -LSTM model" combines the Robustly optimised BERT method (Roberta) [33, 34] with "Long-Short-Term-Memory (LSTM)". The model efficiently maps tokens into meaningful embedding space using pre-trained Roberta weights.

A. Dataset Description

Sentiment analysis relies on data. Since the Twitter API allows real-time tweet extraction and sentiment analysis, research has expanded. For example, Twitter sentiment analysis helps to explain the Russia-Ukraine war by monitoring public opinion.

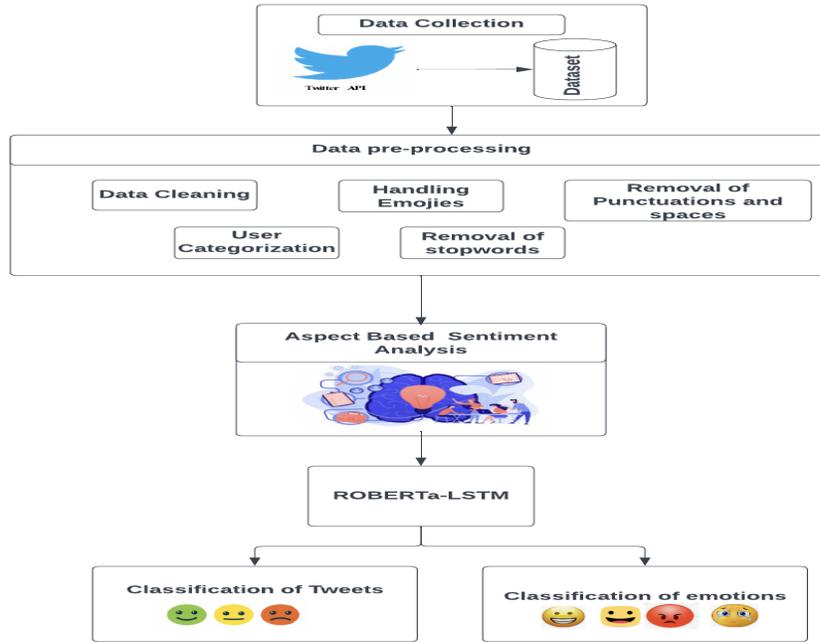
The study draws on a dataset obtained from Kaggle(https://www.kaggle.com/code/ssaisuryateja/eda-and-sentiment-analysis#EDA). The dataset is named "Ukraine Conflict Twitter Dataset". We collected the tweets from April and May of about 484221 tweets. Tweets were retrieved using hashtags. Hashtags can help with sentiment analysis, named entity recognition, and information extraction. Twitter hashtags included #ukraine, #russia,#Putin, #standwithUkraine, #Kyiv, #mariupol, #russian, #Ukrainewar, #nato, #standtogether and shown in Fig. 2.


Fig. 1. Overview of Proposed Model.
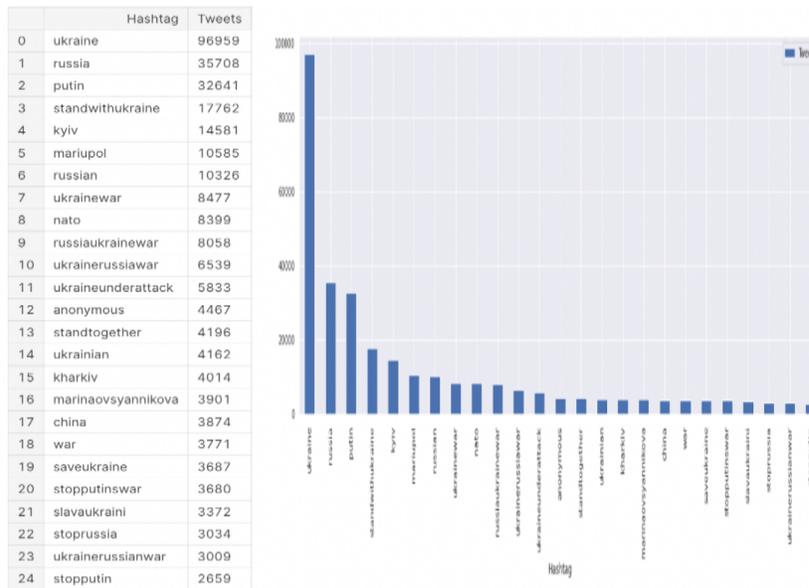

Fig. 2. Hashtag Analysis.

Overall, there were 17 distinct types of information included in the dataset, including Date, Hashtag, Followers, Friends, Location, Retweet, Username, Text, and Polarity.

B. Data Pre-processing

Data exploration helps uncover data patterns and trends. Check for missing or null values first. There are several steps involved in pre-processing data. Removal of Hashtags, removal of special symbols and punctuations, removal of stop words from data, removal of URL, stemming the words in the data, and deleting unwanted white space characters.

C. Aspect based Sentiment and Emotion Analysis

ABSA pinpoints the degree to which people's opinions differ about a specified topic.ABSA provides more detailed information than broad sentiment analysis. "Aspect Category Classification" determines an opinion text's subject and aspect pair. A dataset will receive a collection of present entities and one or more attributes based on the context of the text. Fig. 3 shows how ABSA Classification. In this example, general sentiment analysis yields "mixed" because there is one negative and one positive sentiment.

Fig. 3. ABSA based Sentiment and Emotion Analysis.

The ABSA aspect phrase "Zelensky" is positively received, whereas "Putin" is not. General sentiment analysis identifies only a tweet's predominant sentiment [34]. ABSA enables a more in-depth, sophisticated analysis by extracting sentiments from a single tweet. Since we wanted to examine how people felt about various topics across the time frame, we decided to use ABSA to glean further insight from each tweet. Using ABSA, a piece of more detailed information about the emotions in tweets is also analyzed. So in Fig. 3, the aspect term is "Woman", and the emotion of that woman illustrates "angry."

D. ROBERTa

Roberta extends Bidirectional Encoder Representation from Transformers (BERT). The Transformers [35] family developed BERT and Roberta for sequence-to-sequence modelling

to address long-range dependencies. The Transformer module implements the NLP model Twitter Roberta base-sentiment in Python. This "Roberta" based model has been pre-trained on 58M tweets and is optimised for sentiment analysis using the "TweetEval benchmark".

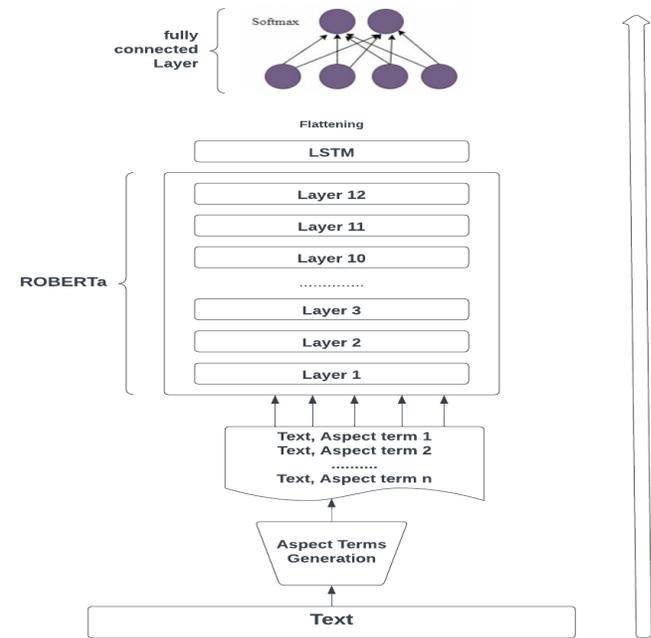
ABSA on pre-trained models functions extremely similarly to Roberta. The exception is that these models additionally get as input the aspect words of the sentences. Roberta tokenizes input sequences and sequence aspect terms. The suggested ABSA-based Roberta-LSTM model (Fig. 4) tokenizes the cleaned text into words or sub-words to simplify encoding word embeddings. For example, ¡s¿ is appended to the beginning and end of the text to indicate a sentence and vector length. To tokenize text at the byte level, the Roberta model uses the Byte-Pair Encoding tokenizer. The tokenizer doesn't split common words. Unusual terms are broken out.


Fig. 4. ABSA based Roberta LSTM Model.

The model learns better when words are converted into numbers. Roberta uses input ids and an attention mask to tokenize text. Token indices and their numeric representations are input ids. The attention mask is not required if the sequence is to be batch processed. Tokens requiring attention are highlighted by the attention mask. The attention mask and ids are sent to the "ABSA based Roberta -LSTM" model. The "Roberta base model" consists of "12 base layers" and "125 million" parameters. The Roberta base layers aim to generate a meaningful word embedding as the feature representation, from which the more advanced layers can easily extract the required information.

E. LSTM

The results of the dropout layer are then fed into a model called "Long Short-Term Memory". Long short-term memory (LSTM) models retain data for the purpose of identifying input

dependencies that are far away in the future. LSTM has shown effective in a variety of sequence modelling applications, including text classification, sentiment analysis, time series prediction, and others.

Flatten Layer This layer flattens the input from 3D to 2D to fit inside the dense layer.

Dense Layer Dense layers are fully connected. Information is supplied to the dense layer's activation units from below. Roberta-LSTM has two layers. First dense layer hidden neurons capture the input-class relationship. Then, classification layer neurons match dataset classes. SoftMax activation function produces sentiment analysis dataset's probabilistic class distributions dataset's probabilistic class distribution in the classification layer.

F. Training Parameters

Huggingface transformer provides both Pytorch and TensorFlow implementation of the Roberta models. The "Adaptive Moment Estimation" optimizer optimizes gradient descent in "ABSA based Roberta-LSTM" model training. The "Adam optimizer" avoids local minima by using the gradient moving average, enhancing gradient descent. The Adam optimizer can deal with sparse gradients even when applied to noisy problems. The optimization approach uses the loss function to estimate the model loss in each training period. Since sentiment analysis involves multi-class, the loss function is categorical cross-entropy.

IV. EVALUATION METRICS AND EXPERIMENTAL RESULTS

A. Evaluation Metrics

Accuracy, Precision, Recall, and F1-score were used to evaluate the classification and comparison of models. In addition, train and test validation accuracy confirmed model performance. "Accuracy" refers to how well the forecast was made, and its calculation looks like this:

$$Accuracy = \left(\frac{\text{``}Correct predictions\text{''}}{\text{``}Total predictions\text{''}} \right) \qquad (1)$$

The positive and negative accuracy of the binary classification can be determined using the following formulas:

$$Accuracy = \left(\frac{\text{''}TP\text{''} + \text{''}TN\text{''}}{\text{''}TP\text{''} + \text{''}FN\text{''} + \text{''}FP\text{''} + \text{''}TN\text{''}} \right) \qquad (2)$$

"True positive", "true negative", "false positive", and "false negative" are denoted by the letters TP, TN, FP, and FN.

Precision is the percentage of clusters labelled positive that are positive. It's computed as

$$Precision = \left(\frac{\text{''}TP\text{''}}{\text{''}TP\text{''} + \text{''}FP\text{''}} \right) \qquad (3)$$

Recall, a measure of integrity, is the percentage of genuine positive predictions properly classified and calculated as

$$Recall = \left(\frac{\text{''}TP\text{''}}{\text{''}TP\text{''} + \text{''}FN\text{''}} \right) \qquad (4)$$

The lack of a balanced dataset may make the accuracy evaluation measure unreliable. The F1-score is employed. The F1-score gives target class outcomes. It considers classifier precision and recall in statistical classification study and is calculated as

$$F1 - score = (2 * Precision + Recall) \qquad (5)$$

B. Experimental Results

This section explains the experimental settings and compares the "ABSA-based Roberta-LSTM" model with other state-of-the-art approaches. The training session is limited to 100 iterations and terminated early to prevent overfitting.

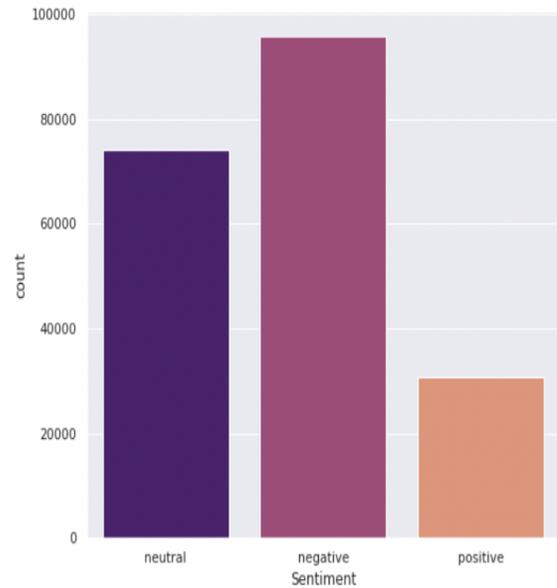
According to this study, people's emotions toward the Ukraine-Russia war were mostly unfavourable. After preprocessing tweets, the tweets are passed to the "ABSA-based-Roberta-LSTM model", classified into three sentiment polarities: negative, positive, and neutral. Fig. 5 exhibits tweet sentiment polarity. Word Cloud, a sentiment analysis visualisation tool, was used to discover and show words and concepts for three sentiment studies to understand the psychological underpinnings for these reactions. Fig. 6 shows twitter dataset terms for "positive", "negative", and "neutral" attitudes.


Fig. 5. The Percentages of Sentiment Polarities in the Ukraine-Russia Tweet Dataset.

Several "machine-learning" and "deep-learning" sentiment analysis approaches are tested for fairness (Table-I). The machine learning methods include "Bernoulli-distribution", "Logistic-Regression", "Decision-Tree", "K-nearest-neighbour", "Support-vector-classification" and "Random-Forest-Algorithm". The deep learning methods include "Long-Short-term-Memory" and "ABSA-based-Roberta-LSTM model". Machine learning algorithms and deep learning algorithms classify sentiments (positive,

negative, neutral) w.r.t. to precision, recall, F1score in Table I and a bar plot is plotted in Fig. 7.

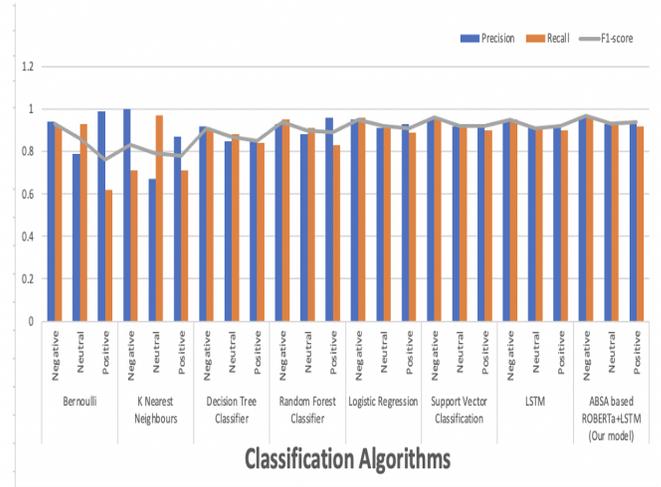
Fig. 6. Word Cloud Representation of Prevalent Words in each Sentiment Polarity.

Fig. 7. Experiment Result Analysis on Ukraine-Russia Tweet Dataset (Sentiments).

TABLE I. EXPERIMENT RESULTS ON UKRAINE-RUSSIA TWEET DATASET(SENTIMENTS)

Classification Algorithms	Sentiment	Precision	Recall	F1:score
Bernoulli	NEGATIVE	0.94	0.92	0.93
	NEUTRAL	0.79	0.93	0.86
	POSITIVE	0.99	0.62	0.76
K Nearest Neighbours	NEGATIVE	1.00	0.71	0.83
	NEUTRAL	0.67	0.97	0.79
	POSITIVE	0.87	0.71	0.78
Decision Tree Classifier	NEGATIVE	0.92	0.90	0.91
	NEUTRAL	0.85	0.88	0.87
	POSITIVE	0.86	0.84	0.85
Random Forest Classifier	NEGATIVE	0.93	0.95	0.94
	NEUTRAL	0.88	0.91	0.90
	POSITIVE	0.96	0.83	0.89
Logistic Regression	NEGATIVE	0.95	0.96	0.95
	NEUTRAL	0.91	0.92	0.92
	POSITIVE	0.93	0.89	0.91
Support Vector Classification	NEGATIVE	0.95	0.96	0.96
	NEUTRAL	0.92	0.92	0.92
	POSITIVE	0.93	0.90	0.92
LSTM	NEGATIVE	0.94	0.95	0.95
	NEUTRAL	0.91	0.91	0.91
	POSITIVE	0.92	0.90	0.92
ABSA based Roberta+LSTM	NEGATIVE	0.96	0.96	0.97
(Our model)	NEUTRAL	0.93	0.93	0.93
	POSITIVE	0.94	0.92	0.94

Highly followed Twitter users can affect the audience with their emotions. The number of followers can be used to estimate outreach, but a user's interactions (mentions, responses, retweets, attributions) are a superior indicator of influence. Fig. 8 shows tweet count versus emotion analysis. According to Fig. 8, anger (1,00,445) is the biggest feeling on Twitter associated with the Ukraine-Russia war, followed by optimism (39,284), joy (25,091), and sadness (25,795). Fig. 9 shows Ukraine-Russia Tweet Dataset in terms of joy, optimism, sadness, and anger emotions.

In order to provide a reliable basis for comparison, the experiments make use of a variety of "machine-learning" and "deep-learning" approaches for emotional analysis, i.e. shown in Table II and Fig. 10.


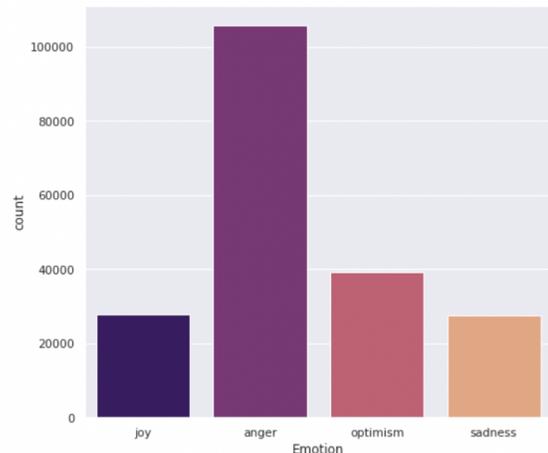


Fig. 8. The Percentages of Different Emotions in the Ukraine-Russia Tweet Dataset.

The Experiment results of the state-of-the-art approaches using the Ukraine-Russia Tweet Dataset in terms of accuracy (Sentiments) are illustrated in Table III, and a bar pot is plotted in Fig. 11.

V. CONCLUSION

Sentiment analysis plays a key role in various sectors, such as business and politics, to comprehend the public sentiments so that a strategic decision can be taken. Therefore, an effective algorithm is required to automatically determine the polarity (positive, negative or neutral) of the opinions. "Machine learning", "Deep learning", and "Recurrent neural networks" dominate sentiment analysis research. There are few works that employ transformers for sentiment analysis.

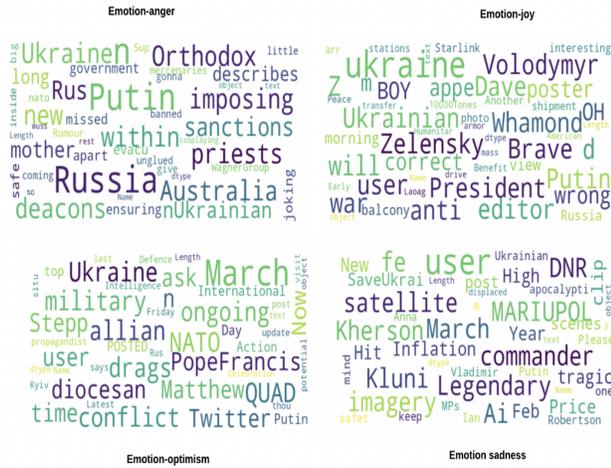
This paper provides an hybrid deep learning models for sentiment analysis i.e. "ABSA-based Roberta-LSTM" model.


Fig. 9. Word Cloud Representation of Prevalent Words in each Emotion.

Fig. 11. Comparison Analysis of Various Algorithms w.r.t to Evaluation Metrics.

Text pre-processing normalizes and removes unimportant words. Our Proposed model is trained and analysed on the cleaned corpus. Our Proposed model uses aspect terms, Roberta, and LSTM to efficiently encode words into word embedding and capture long-distance dependencies. The "ABSA based Roberta-LSTM" model outperforms state-of-the-art sentiment analysis approaches on Ukraine-Russia twitter dataset with an accuracy of 94.7 when compared to the existing approaches.

Abstract—**Covid-19 has been marked as a pandemic world-wide caused by the SARS-CoV-2 virus. Different studies are being conducted with a view to preventing and lessening the infections caused by covid-19. In future, many other wind-borne diseases may also appear and even emerge as "pandemic". To prevent this, various measures should be an integral part of our daily life such as wearing face masks. It is tough to manually ensure individuals safety. The goal of this paper is to automate the process of contactless surveillance so that substantial prevention can be ensured against all kinds of wind-borne diseases. For automating the process, real time analysis and object detection is a must for which deep learning is the most efficient approach. In this paper, a deep learning model is used to check if a person takes any preventive measures. In our experimental analysis, we considered real time face mask detection as a preventive measure. We proposed a new face mask detection dataset. The accuracy of detecting a face mask along with the identity of a person achieved accuracy of 99.5%. The proposed model decreases time consumption as no human intervention is needed to check an individual person. This model helps to decrease infection risk by using a contactless automation system.**

I. INTRODUCTION

Whenever the world faced any pandemic, history witnessed a pessimistic effect on economics, health, and national security both socially and globally [1]. Before the COVID-19, H1N1 or influenza was marked as a pandemic in the year 2009 [2] [3]. The COVID stands for "CoronaVirus Disease", it is referred to as "2019 novel coronavirus" or "2019-nCoV" as it was started in 2019 [4]. Form the beginning of this pandemic, around 228 countries have been affected by the COVID-19 to date [4]. The rapid growth of the COVID-19 infected cases has put the national healthcare capacity, modern ICU diagnostic methods, and public healthcare infrastructure to a test.

For instance, Bangladesh has less than 7,000 spaces in iso-lation units and therefore only 1622 health workers, including only 595 physicians to treat COVID-19 patients, whereas it has a population of about 165 million people [5]. On the other hand, the United States (US), which like Europe, spends about double as much per person on healthcare insurance as those other high-income counties, has drawn special criticism for its "maximum-possible-test-per-day" policy and use of its 96,596 ICU beds [5]. Overall, it became a chaotic situation which completely caught the whole world off guard. To prevent this disease, many effective vaccines have been invented [6] but these vaccines are not sufficient to give full protection to the people to prevent the COVID-19. So, people had to follow some non-therapeutic prohibitive measures like maintaining social distance, travel bans, remote office activities, country lockdown, wearing masks, etc. despite being vaccinated

Since 2019 almost all the nations of the world are strug-gling to get out of this misery. This kind of prohibition rules put a financial crisis as lockdown remains on all kinds of institutions [7]. In [8], according to the "Socio-Economic Aspects" about 60.5% of the respondents agreed that most of the low incoming people lost their jobs and around 54.8% of people also shifted to different places by leaving the city for livelihood. To ease the survival challenge of the people who lived from hand to mouth, the lockdown had to be lifted. Then there comes another challenge of ensuring that every individual wear masks in their working places. To ensure security in institutions or industries, many automation systems exist that can identify the registered person

One of them is a biometric system that works with measurements and by analyzing someone's unique features. Physical unique features like face, irises, veins, fingerprints, and behavioral characteristics such as voice, typing rhythm, or handwriting, is used for identification and authentication [9]. These systems are not contactless, and these require removing

the mask which can be one of the fatal reasons for any wind-borne disease [10]. For this, there is an increasing necessity to build a contactless surveillance system to detect facemask and person identification. So, there are a few systems that can perform both the operations. For designing such contact less automated systems, deep learning-based approaches are integrated.

The researchers tried to find out the best possible object detection model with the highest accuracy. Some of the models can even detect objects from video streams. In some cases, general convulation neural network (CNN) models are used; it cannot identify a specific object if a lot of background objects exist in a frame. Boundary box techniques and means Inter-section over Union (IoU) is mostly used for object detection.

The focus of our work is to develop an automated contactless preventive measurement system using a deep learning approach. More specifically, our system will identify if a person is wearing a mask or not, and at the same time detect the person's identity. For object detection task using face mask dataset, there are many models like CNN [12], NASNet [31], R-CNN [11], FAREC [27], CSPResNeXt-50 [23], etc., and the most recent model is YOLOv5 [19] which shows moderate inference speed and accuracy. The followings are the significant contributions of this paper:

- A new dataset is presented that consists of 177 pictures with 6 labels in total. There will be 97 photos of random people wearing masks and without masks, and 80 images of four persons, 20 images of each person wearing a mask. For each image, it contains a text file with information about the boundary boxes.

- A comparative analysis is performed using the new dataset using the YOLOv5 model. The YOLOv5 model is used for training the dataset. After 100 epochs with batch size of 8, the accuracy of 99.5% is obtained.

- This approach helps to identify any person along with detecting if he/she is wearing a mask or not in a real-life scenario. It works best for both images and video streams.

- A dedicated application is developed for contactless preventive measures using our proposed approach.

The rest of this paper is arranged in the following manner: related work that provides an overview of the relevant papers in condensed form, proposed work provides an initial overall view of the work process, materials and methods section provides an explanation of the preparation, preprocessing of the dataset, methodology, and training, result section provides the experimental analysis and conclusion provides the conclusive observations and future works.

II. RELATED WORK

There are usually two types of object detection methods based on the deep learning models: one-stage algorithms and two-stage algorithms. Two-stage methods such as R-CNN [11], Fast R-CNN [12], and Faster R-CNN [13] create bounding boxes of objects and then classify these objects. But these methods are comparatively slower and hard to implement

in real-time. So, for the efficient results, some one-stage algorithms have been developed such as You Only Look Once (YOLO) [14], RetinaNet [15], Single Shot Detector (SSD) [16] which are based on Anchor and ATSS (Adaptive Training Sample Selection) [17].

In the article [18], the authors used YOLOv5 to detect face masks, which is the most powerful object detection model at present. Their experiment has achieved a success rate of about 97.9% by using 7,959 images for training and testing. There are different forms of the YOLOv5 model. The YOLOv5x model is much heavier than the most used YOLOv5s [19].

Face Mask Recognition System has also been developed by using different versions of the YOLO algorithm [18] [20] [21]. In the article [20], the authors used improved YOLOv4 which is based on CSPDarkNet53. They used adaptive image scaling algorithms and PANet structure to get more information on the feature layer. The authors have shown a comparison between different models like YOLOv3, YOLOv4, SSD, and Faster R-CNN and have got the prominent outcome using their proposed model. Yet, there are some problems with feature extraction and false detection cases as well as low light performance has not been considered. In another the article [21], the authors have used YOLOv2 with ResNet-50 to detect medical face masks. They have used mean Intersection over Union (IoU) to estimate the best number of anchor boxes and have achieved 81% precision as a detector. For their model, they have used 1415 images as datasets. They proposed a detector model using YOLOv2 with Resnet-50 for extracting the feature and detecting different phases. Their model works better to detect medical face masks. They have also planned to use video-based deep learning models in the future. The article [22] presents the use of the YOLOv4 model which is the fourth generation of the YOLO model proposed by the authors of [23] in 2020. It is relatively faster and has better accuracy, and it is incredibly quick, easy to train, robust and also reliable. It produces promising results even for detecting small objects compared to the previous versions. It recognizes items from three types of input image/frame: unmasked faces, masked faces, and humans.

Face mask detection using YOLOv4 was introduced in [24]. As the YOLOv4 is built on the Darknet Framework and features an NVIDIA Graphics Processing Unit (GPU) with 16 gigabytes of RAM and a 2.30GHz Intel i5 CPU, its framework has created two models, one with three classes of the face veil, face concealed face, and face cover, and the other with only two classes of face cover and face cover. These models perform better for the video which creates a picture (or frame) with localized faces and a bounding box indicating whether the face is masked or not.

Multi-Stage CNN Architecture has been proposed in [25] for face mask detection. A pre-trained model that has been trained on a large dataset in order to achieve rapid generalization and reliable detection using RetinaFace [26], was selected as a single stage-1 model. Its' performance was evaluated to two other prominent face detection algorithms models, Dlib, and MTCNN [27] [28]. In stage 2, a CNN classifier was trained using three picture classification models: MobileNetV2 [29], DenseNet121 [30], and NASNet [31]. Recently, face identification along with face mask recognition using CNN approach was presented in [32]. To process a sequence of

TABLE I. COMPARISON OF RELATED WORK

Author/ref	Year	Approach/Model	Detection	Model Accuracy

pictures, the system uses the OpenCV computer vision library as well as a deep learning method for face mask identification. The receiver operating characteristic (ROC) and the calculated mean accuracy are used to estimate the system's performance (ACC).

For the face detection process, the training has been done by CNN model to recognize the owner's identity. The similarity identification approach utilizing the 68-landmark plotting and the face identification method were used for the process. To capture each frame of the video stream, a 50-neuron fully connected dense layer is flattened and fed from the output. It provides the probability for a person wearing a mask or not into 2-neuron layers in the convolutional neural network training. The CNN with Keras and Tensorflow is then implemented to train the face mask classifier and for face mask detection, the first 20 epochs, a model checkpoint trains and validates where using facial 68-landmarks is a technique that locates a human face in a picture and delivers values on the face Region of Interest (ROI) as dots. All the work was done with OpenCV, Keras and TensorFlow. Standard face recognition performance metrics were used for person identification at the time of using a face mask [33].

As it has been discussed earlier, some of the works as like [18], [20], [21] have used YOLO algorithms that function using IoU. The authors of [21] using YOLOv2 with ResNet-50 model achieved nearly 81% accuracy, in the paper [22] achieved nearly 95% accuracy. The authors of [18] achieved nearly 97.90% accuracy using YOLOv5 but all of these works only determined whether a person was wearing a mask or not. In [25], the authors have achieved more than 99% accuracy using Multi-Stage CNN. In the case of face detection, the authors of [27] and [28] have achieved up to 96% percent accuracy but they did not train their model for identifying people when they are using a face mask.

Table I presents a comparative analysis on all the related works that have been done. Although different types of object detection have been done so far, there is not a single work that matches with the objective of this paper.

III. EXPERIMENT

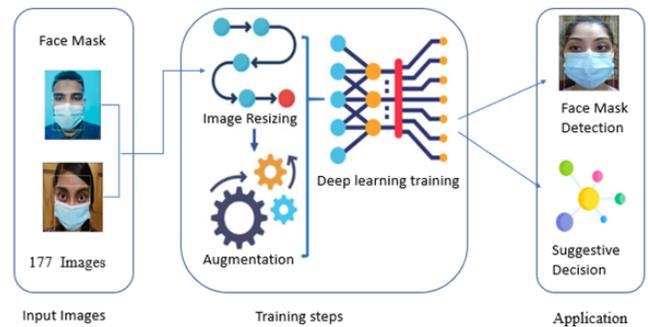
This section describes how the proposed methodology has been designed. At first, a dataset of images with specific formats has been generated and then classified into labels and classes. Furthermore, preprocessing on images has been done according to the need of the research model. Then the YOLO algorithm and how YOLOv5 incorporates this work is elaborated. In conclusion, all these steps lead to training that is the final step to get the desired outcome. Fig. 1 illustrates the proposed framework for using face mask dataset for predicting contactless surveillance having a machine learning backbone using deep learning.


Fig. 1. Example of the Proposed Framework for Face Mask Detection and Contactless Surveillance System.

The YOLOv5 model is used to detect faces with masks and identification of that person who is wearing a mask. To train the model, at first, the images are collected. After preprocessing the images, every picture is labeled with the necessary class name. Then a dataset.YAML file is created. Then after training the model, it has been implemented on hardware. Finally, the performance has been evaluated.

A. Dataset

The images are in jpg, jpeg, png format, and the labels are in txt format. The images are of people of different ages, gender, wearing face masks and without masks. Fig. 2 shows a sample dataset with masked faces.

Fig. 2. Sample Dataset Consists of Images for a few Type Labels.

Table II shows the labels depending on the types of images and presents the number of images. A total of 177 images are used for this work and among them 97 images are of random people wearing a mask and without a mask, and among 177 images, 80 of them are of 4 people, 20 images of each person wearing a mask along with their identification. So, there are a total of 6 labels in this dataset. They are mask, no_mask, bushra, ayshee, joy, samira.

TABLE II. Details of the Images and their Labels

Types of Images	Labels	Number of Images
People wearing masks (including random people)	Mask	129
Random people wearing no mask (including random people)	No_mask	48
Person 1 wearing a mask with an identification	Bushra	20
Person 2 wearing a mask with an identification	Ayshee	20
Person 3 wearing a mask with an identification	Joy	20
Person 4 wearing a mask with an identification	Samira	20

When a dataset is created by collecting different pictures, all pictures cannot be of the same size. A model trains faster with smaller-sized images. If an image is three times as large, training the model will take six times as long, which will mount up over time. As all pictures vary in size, so if the picture is too small, it may appear unclear and if it is too big then the training time gets longer. That is why, all pictures have been resized. From the pictures, specific labeling is also needed to make classes which is the necessary step for training the model. Therefore, images are preprocessed before using the pictures as datasets.

At first, all images are resized to 1000×1000 pixels. Then all images are labeled by a software called "makesense.ai". In this software, all the labels are created first. Then on every image, the boundary box is drawn like Fig. 3 and then the labels are selected for the boundary boxes. A boundary box is drawn for each label and there are six labels used depending on the class. The class or label values are shown in Table III.

TABLE III. Class (Labels) and Values

Class (Labels)	Values
Bushra	0
Joy	1
Ayshee	2
Samira	3
Mask	4
no_mask	5

We organized boundary boxes in the following format: {Bx,By} = Coordinates of the boundary box's center

{Bh,Bw} = Width, height of the boundary box as a percent of the cell's width or height

Fig. 3. An Example of the Values from a Sample Image.

Fig. 3 shows the dot is the center of the boundary box. In Table IV, the boundary box values are shown for 1 and 4 number classes.

TABLE IV. Class (Labels) and Sample Bounding Box Values

Class	Bx	By	Bh	Bw
1	0.439	0.387	0.559	0.157
4	0.435	0.509	0.575	0.677

B. Deep Learning Framework for Training and Inference

To begin with, a dataset consisting of 177 images has been prepared where a total of 6 labels named mask, no_mask, bushra, ayshee, joy, samira are used. 97 images of random people wearing masks and without masks, and 80 images of 4 people, 20 images of each person wearing mask along with their identification are used to detect wearing mask and identify people.

After training the model, the images have split into training and validation labels, and validation prediction with confidence for the labels has been done. For training, Mosaic Data Loader [36] was used. Every training batch contains 8 mosaics, and each mosaic is a combination of four images.

The YOLOv5 [36] model works on a custom dataset that includes three cases i.e., 1st one to detect the identification of the person wearing a mask, 2nd one to detect face with a mask, and 3rd one to detect face without mask. The model is trained for predicting the label of classes for each input image.

YOLO stands for "You Only Look Once". Researcher Joseph Redmon and colleagues introduced YOLO in 2015 [35]. The General YOLO model works in three steps. In the

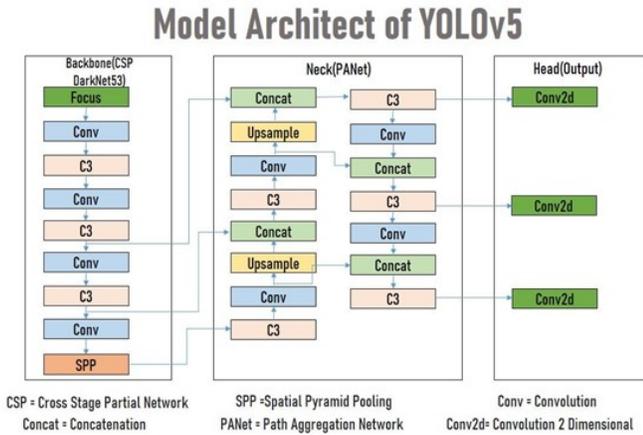
first step, it divides a picture into many cells with an m × m grid. Then in the second step, "s" bounding boxes are predicted in each cell. YOLO returns to the bounding boxes that exceed the minimum confidence threshold in the third step. The YOLO algorithm has various versions. In this paper, the YOLOv5 model is used. It is written in Python programming language's using Pytorch framework. This framework is user-friendly and a community driven github repository [36].


Fig. 4. YOLOv5 Model Architecture.

YOLOV5 consists of three parts: Backbone CSP darknet 53, Neck PANet, and Head Yolo V5 output layer depicted in Fig. 4. The backbone extracts feature from the inputs, Neck works to fusion features from backbone and Head generates the final results.

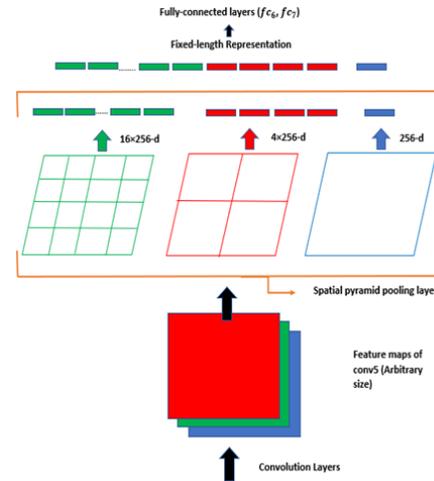
First part of the YOLOV5 is the Backbone CSP darknet or cross stage partial network. It focuses on the structure (Modified from Yolo V3) as well as on the CSP darknet 53 of Pytorch. CSP network has advantages like it solves repeated gradient problems, reduces model size, cuda memory layers, and increases forward, backward propagation. The CONV denotes convolution layers and C3 is composed of three convolution layers that are cascaded by various bottlenecks to find out the best fit in the network. And spatial pyramid pooling (Spp-Net) (Fig. 5) is a pooling layer that is used to extract features from the feature maps passed by previous layers. SPP works to generate fixed-size output for any type of input size. It is also used to extract necessary features by pooling that it's a multi-scale version of itself. Feature maps of inputs are duplicated to "n" numbers of versions. Using kernels of various sizes, each version is conducted by max pooling. This is how the SPP block extracts "n" number of various types of required and important features simultaneously [36].


Fig. 5. Representation of SPP-NET.

Second part of this model is the Neck path aggregation network (PA-Net) [37]. It uses a modified version of feature pyramid network (FPN) structure that utilizes the information passed by the backbone. It employs bottom up (up sampling) augmentation path along with top-down It is used in FPN to directly connect with the fine-grained or learned features from low-level layers to top-level layers from backbone. For boosting information flow, prevention of missing information, and duplicate prediction, this concatenation operation is applied. It improves accuracy of the location of the object.

Last part is of the YOLOv5 model is the Head Yolo V5 output layer that uses information passed from the neck layer. The head of Yolo V5 known as Yolo layer generates three different sizes which are 18 × 18, 36 × 36, 72 × 72 of feature maps using convolutional 2-dimensional networks to achieve multi scale prediction. It enables the model to handle small, medium, and big objects and the output is a boundary box of the predicted object along with accuracy and class of the object.

C. Performance Measure

In this approach, Generalized Intersection Over Union (GIoU) loss has been used to determine the loss of the bounding box. The formula and algorithm for GIoU loss [38] is shown in Algorithm 1.

Algorithm 1 Generalized Intersection Over Union(GIoU)

Input: *Two arbitrary convex shapes*; $C, D \subseteq S \in R^n$
Output: *GIoU*
  1: *For C and D, find the smallest enclosing convex object E, where $E \subseteq S \in R^n$*
  2: $IoU = \frac{C \cap D}{C \cup D}$
  3: $GIoU = IoU - \frac{|E \backslash (C \cup D)|}{|E|}$

Here in algorithm 1, to compare similarity IoU (Intersection over Union) between two arbitrary convex shapes $C, D \subseteq S \in R^n$ is determined by, IoU = $\frac{|C \cap D|}{|C \cup D|}$. IoU has a big defect that if $|C \cap D| = 0$ and then IoU (C, D) =

0. This proves that IoU does not determine that both shapes are in proximity or not from each other. That is why GIoU (Generalized Intersection over Union) is used.

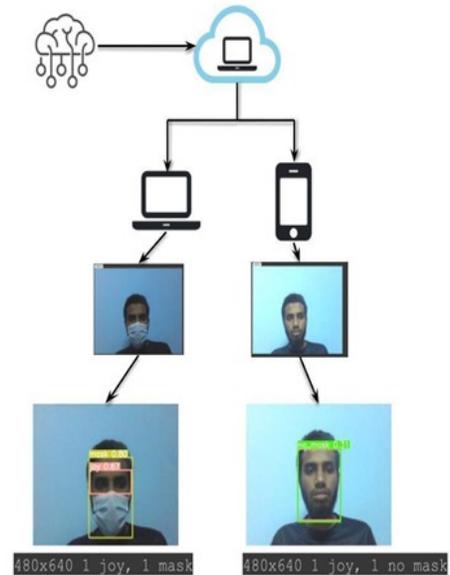
In GIoU, for both arbitrary shapes (volumes), $D \subseteq S \in R^n$, firstly the smallest arbitrary convex shapes are found $E \subseteq S \in R^n$ enclosing both C and D. E come from a similar type of geometric shape while comparing two geometric shapes. When both arbitrary ellipsoids are compared, E is smaller. They are encircled by ellipsoids. Then a ratio is computed between the area (volume) which is occupied by E subtracted from the area (volume) occupied by C and D and then divided by E's entire area (volume). This is a normalized metric that is focused on the vacant space area (volume) between C and D. Finally, GIoU has been determined. This ratio is subtracted from the value of IoU. Algorithm 1 summarizes the computations of GIoU.


Fig. 6. Implementation Diagram.

IV. RESULTS AND EVALUATION

A. Experimental Results

The model has been implemented practically in an enclosed environment to see how it works in a real-life situation. Hardware implementation is needed to analyze the efficiency of the model. Implementation of this system provides a contactless process which ensures safety. It mitigates the spread of respiratory transmittable diseases. Implementation of this system will compel people to use masks because the system will mark people without face masks as any organization may use this system at their main entrance.

The model's dataset consists of 177 images and corresponding labels. For labeling, a total of six classes are used which are mask, no_mask, bushra, ayshee, joy and samira. A custom yaml file is created that contains the path of the dataset, number of classes and class names that are used. To train the dataset and yaml file, the YOLOv5x model is used. After training, two weights best.pt and last.pt have been obtained. YOLOv5x is a large model for processing and the weights were also large, so it needs a powerful processor. Hence, Google Colab, a cloud computing system is used to run the model. It has 12GB free graphics support and between GPU or CPU any of these can be used. Real time analysis has been performed by using the 12GB GPU of "Google Colab". For experimental purposes, the mobile and laptop devices have been used to run the model in "Google Colab". The configuration for mobile is f/2.45 aperture, SONY IMX471 sensor, and for laptop CMOS sensor technology, RGB HD Camera configuration was used. This experiment yields to a successful result to detect a person's identity wearing a face mask. Fig. 6 shows the implementation diagram of the model.

The proposed model has used GPU runtime for training the YOLOv5x model using Pytorch libraries and Stochastic Gradient Descent (SGD) optimizer. Batch size of 8 is used for each epoch and there are a total of 50 epochs for training the model, thus the experimental configuration has been obtained. The optimizer that is implemented for training the model is SGD.

SGD is used because the training time is 4 seconds which is faster than any other optimizers. SGD can be implemented on the convex problem and simple linear problems and the learning rate is determined by, $\eta/(1 + \lambda_0 t)$. Where, $\lambda_0 =$ regularization constant and η_0 is achieved by conducting initial experiments on any subsample of a dataset [39]. When the epoch increases with time, every epoch's precision (P), Recall (R), and Mean Average Precision (mAP) increases, and the training and validation of the model is also improved.

TABLE V. TRAINING AND VALIDATION RESULT BASED ON SGD

Epoch	Precision (P)	Recall (R)	mAP@0.5	mAP@[0.5:0.95]
5	0.197	0.67	0.304	0.117
10	0.711	0.718	0.67	0.386
20	0.829	0.904	0.95	0.572
30	0.816	0.963	0.949	0.528
48	0.987	0.995	0.995	0.637

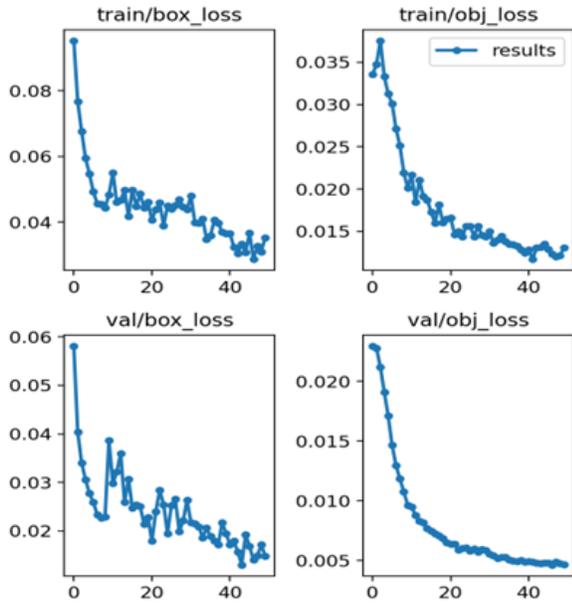
In Table V, it is visible that the epoch has a proportional relation with the precision and recall, that is when the epoch is increasing the precision and recall also gets improved. For detecting the identity of a person wearing a mask, "GIoU Loss" has been used. The test results of the model are shown in Fig. 7.


Fig. 7. The GIoU Loss Curve of Training where X Axis Represents Epoch.

After completion of the model training, the trained weights have been used for testing the model and then the performance is evaluated. The test results have classified into three types of categories.

True Positive (TP) indicates that in the test set the categories are equal to the results of the test. False Positive (FP) indicates that the sample number in the category of detected object is inconsistent. False Negative (FN) means that the resultant pattern has been detected as the inverse result or in the category of undetected. Precision refers to the ratio of TP to (TP+FP) where (TP+FP) is the number of all positive cases. Precision illustrates the sample proportions of the real positive cases from the samples detected by the model. The equation-1 shows the equation for precision.

$$Precision = \frac{TP}{TP+FP};\qquad(1)$$

Recall refers to the ratio of TP to (TP+FN) where (TP+FN) is the number of all positive test cases. The model's efficiency can be measured by recall which detects real positive cases of the test set out of the all-actual positive values. The equation that follows equation-2 shows the equation for recall.

$$Recall = \frac{TP}{TP+FN};\qquad(2)$$

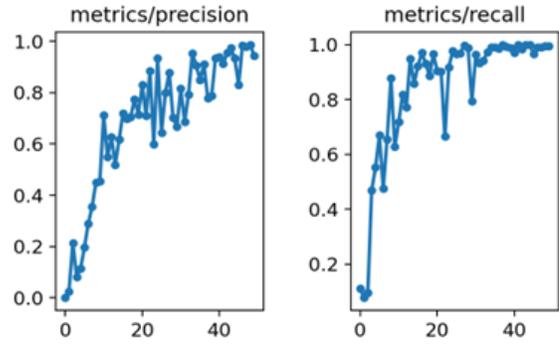
Fig. 8 shows the graphs based on the precision and recall of the applied model.


Fig. 8. Precision and Recall of the Model where X Axis Represents Epoch.

Then, to evaluate the accuracy of the model Mean Average Precision (mAP) is used. The following equation-3 shows hoe Map is determined:

$$mAP = \frac{\sum_{i=1}^{N} AP_i}{N};\qquad(3)$$

The performance evaluation from the training is shown in Table VI.

TABLE VI. PERFORMANCE EVALUATION

Class	Precision	Recall	mAP for IoU 0.5	mAP for IoU [0.5:0.95]
All	0.944	0.994	0.995	0.615
Bushra	0.719	1	0.995	0.331
Joy	0.979	1	0.995	0.639
Ayshee	1	1	0.995	0.48
Samira	0.975	1	0.995	0.733
mask	1	0.966	0.995	0.772
no_mask	0.99	1	0.995	0.736

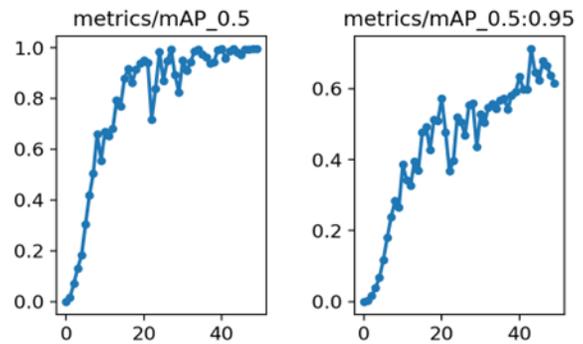
The graphs in Fig. 9 presents the performance evaluation of the model.


Fig. 9. mAP@0.5 and mAP@[0.5: 0.95] of the Model where X Axis Represents Epoch.

V. LIMITATIONS AND FUTURE WORK

This research includes the identification of individuals with face masks using the deep learning approach. The YOLOv5 model can detect whether any individual is maintaining the health protocols such as wearing a face mask or not. This

model is proven beneficial for preventing any airborne disease. Though it achieved the goal of the research, there are some limitations of the research. The dataset used for the model's implementation, contained only 177 images. Such small dataset does not ensure a significant accuracy if this research is applied for real-life events. Due to time constraints and inappropriate circumstances, it was not possible to conduct the research on a larger scale. A better accuracy could be expected from the model if a dataset containing more variety was used. Another limitation of the research is that the model is used only in detecting face masks, hence the user case of this model was confined into a specific object.

This research can be extended by overcoming the limitations and adding some insights to it. This model can be used while designing any other contactless surveillance systems. This model worked efficiently in face mask detection, but other object detection can also be included by implementing this model. Such systems significantly help to build any other contactless surveillance system that can highly be effective on controlling any contagious diseases as this ensures the social distancing. Another addition might be considered in this research that is, collecting enormous real-time data and implementing the model into that. Thus, ensuring the social distancing and detecting any kind of object with this model can be used to build further contactless system which can tend to prevent wind borne diseases. Enabling the unique biometric identification with the object detection system may prove as an enhanced version of this research.Such model can be utilized not only as contactless surveillance system, but also can keep the entrance record of any organization.

VI. CONCLUSION

This paper depicted the application of contact-less surveillance systems using a deep learning approach. For experimental analysis, we use YOLOv5 for object detection over a new dataset as mask detection. The ability of the YOLOv5 model to perform an efficient detection task was investigated in this research. The results demonstrate that YOLOv5 can achieve proficiency in detecting and spotting an item in a very short amount of time. In the case of surveillance of any organization at their entrance, the system not only identifies the person but also checks if he/she is wearing a mask or not. A masked face and a non-masked face dataset with no biased pictures have been developed and for the purpose of identification, the eye characteristics was examined. This system is unique in terms of operating in three different classes at the same time: a person with mask, without a mask, and the identification of a person. As the system identifies the person, it will be quite easier to detect if this specific person works in the organization or not. Using the system, if any individuals without masks are identified, they will be alerted and made conscious about wearing masks which is a preventive way to decrease COVID 19. The system also compels people to abide by the protocols of preventing this pandemic as well as helps to maintain hygiene for any wind-borne diseases. If the number of infected people decreases, the economic loss will also decrease. Manual identification of each people and checking if they are wearing masks or not is a difficult and time-consuming process. This process has been made easier and time-saving by this system. As it is a contact-less system, so social distancing can be highly maintained. This is a very useful technique for implementing in open spaces as well. An accuracy of 99.5% is achieved from this research. Some other models also have been implemented for this task but neither the accuracy was so high, nor the model could identify the features correctly in real-life scenarios whereas our chosen model successfully did the detections. Moreover, this trained model can perfectly identify features from the video streams along with the still images. This work will help to minimize the risk of air-borne viruses' spread during the time of the pandemic. Even if the COVID-19 pandemic fades away and life gets back to normal, this system can be quickly deployed to optimize the appropriate use of face masks in the workplaces so that a safe and secure work environment can be built.

Abstract—One of the main advantages of the new power grid over the traditional grid is the intelligent energy management by the customer and the Operator. Energy supply, demand response management, and consumption regulation are only possible with the smart metering system. Smart meters are the main component of that system. Hence, a compromised smart meter or a successful attack against this entity may cause data theft, data falsification, and server/device manipulation. Therefore, Smart grids' development and the guarantee of their services are related to the ability to avoid attacks and disasters by ensuring high security. This paper aims to provide a secure and lightweight security protocol that respects the IOT device constraints. The proposition deploys the distributed OTP calculations combined with the Blake2s hash function and the Ascon AEAD cipher to ensure authentication, confidentiality, and integrity. We propose a performance analysis, an informal and a formal security evaluation made by the AVISPA-SPAN tool. Also, we compare the proposed protocol to other similar works. The assessment proves that the proposed protocol is light, valid, secure, and robust against many attacks that threaten the NAN area of the smart metering system, namely, MITM and replay attacks.

Keywords—Internet of things; confidentiality; integrity; authentication; Ascon; Blake2; AVISPA

I. INTRODUCTION

The Internet of Things is growing rapidly and deploying more devices, systems, and other entities. These devices carry a lot of critical data, making these infrastructures a greedy target of attackers. The accessibility of these devices must be controlled so that only authorized users can access the destination server or gateway. Furthermore, any data leakage or corruption can cause serious problems for people, systems, and companies. Therefore, securing IOT must be an occupation for scientists to ensure the system's security and thus maintain its services' effectiveness.

One of the critical IoT applications is the smart grids, namely the smart metering system. Smart meters make information available to customers to manage their consumption behavior. They also provide the necessary information for operators to balance energy response and demand [1]. Smart meters are an energy revolution that will dramatically improve the efficiency and reliability of the power grid. Therefore, the metering system is a greedy target for attackers who could turn these benefits into an absolute disaster if security is not ensured.

Given such risks encountered by the grid, namely metering, a robust and secure system is a must. However, the nature of the smart metering system falls under the same limitations and constraints of the IoT but with major security risks. Indeed, smart metering systems face smart meters limitations such as computing and storage constraints [2] and those of wireless communication networks that further increase the risk of intrusions and attacks [3]. Under these conditions, deploying strong and efficient traditional security solutions is not feasible on smart meters as they involve cumbersome mathematical calculations. Therefore, the design of lightweight and strong security protocols is necessary to ensure the grid's safe operation, protecting data and users and thus maintaining customer confidence.

In light of these limitations, this article aims to propose a scheme to securely authenticate smart meters (namely in this work: SM/Device) to the neighborhood gateway (Namely in this work: SEVER/GATEWAY) while the association phase of the wireless communication. The proposed solution is based on the distributed OTP approach that lightens calculations and storage on the device side. We deploy lightweight and secure protocols for hashing and encryption. In addition, we use the blake2s as the hash function used in the OTP calculations and for the server's authentication. Ascon, the finalist of the Caesar Competition launched by NIST in 2014, is the AEAD cipher deployed in the proposed solution. Ascon cipher is a lightweight solution to ensure authenticity, integrity, and data confidentiality.

The contribution of this paper can be summarized as follows:

- We propose a secure and lightweight security protocol for the NAN area of the smart metering system to address the related security problems and the eventual limitations by using lightweight protocols and session varying parameters.

- We perform formal security analysis by the AVISPA-SPAN simulation to evaluate the proposed protocol's security, validity, and robustness against replay attacks and MITM attacks.

- We also perform informal security analysis to prove that the protocol is robust against many classical and well-known attacks.

- We perform a performance analysis of the protocol regarding computational costs, communication costs, and storage.

- According to the security and performance analysis, we compare the protocol against similar works, and we conclude that the proposed scheme achieves good security and performance results.

The rest of the paper is organized in the following way: Section 2, where we will introduce some related works that address the same issue. Section 3 will be dedicated to preliminaries about the Ascon cipher, the Blake2 hash function, and the distributed OTP approach. Then, we will present the proposition in Section 4 with the formal and informal security analysis. Performance analyses are made in Section 5. Before the conclusion, a comparison of the proposed work with other works is presented in Section 6.

II. RELATED WORKS

The authors of the work [4] provided a secure framework for IoT-based Healthcare systems that addresses four security issues in the fields. The healthcare system, an application of IoT, is also a target to malicious users that may cause dysfunctions. This paper addresses the system's access control by using AES128 with a common pre-shared key to stop the external sensors from accessing the healthcare system. The authors also ensure authenticity by using the public and private keys of the RSA-1024 to ensure that the sensors and medical persons that send messages are real and authorized to make the communication. This paper also addresses confidentiality thanks to the point-to-point encryption based on the AES128. To ensure Integrity, the authors deployed the message authentication code (MAC) based on AES-128 to ensure that the data was intact and not altered [4]. Another work that dealt with the same issue is [5]: The author proposed a protocol based on a mutual authentication based on OTP authentication for both the Device and the gateway. Once the authentication is ensured, a key is generated from an irreversible hashing function. The Key is used as an entry for the AES-GCM protocol. This work is based on AES-GCM to ensure the confidentiality and Integrity of message exchange and thus secure the channel. In the paper [6], The authors presented a security protocol in the smart home domain. The protocol is a combination of encryption algorithms (AES-GCM, RSAOAEP) implemented with SHA3-512 to ensure the confidentiality and integrity of the data communicated by the sensors. The system of [7] provides security based on X.509 certificate, RSA-based Public Key Infrastructure (PKI), hard tokens, challenge/response protocols, and operators' proxies. The system ensures confidentiality, integrity, non-repudiation, privacy, and anonymity.

The cited schemes all addressed the security issues in IoT. However, there are protocols that they deploy separated cryptographic protocols, which are slower and greedy on resource consumption. Other protocols deployed the AEAD AES-GCM, which is vulnerable to the nonce-misuse attack. This vulnerability makes the protocols vulnerable and compromises confidentiality and Integrity of the protocols.

III. PRELIMINARIES

A. Smart Metering System

The architecture of smart grids consists of three levels: the Home Area Network (HAN) with smart meters and home appliances, the middle level or Neighborhood Area Network (NAN) that connects the HAN with the WAN through gateways and concentrators, and the top level of the Wide Area Network (WAN) that is administered by a control center and MDMS servers.

At the HAN level, the smart meters collect data about the electricity consumption of the home equipment and communicate it to the Control Center through the neighborhood gateways. This data is used to make critical decisions about users and all participating parties in the grid.

The smart metering system has a potential role in the smart electrical grid. Indeed, Operator's control centers adjust the smart meters of their client remotely in order to respond adequately to the client's needs and specifications. These bidirectional operations monitor the client's equipment in the HAN area, such as consumption, device specifications, location, and pricing, thus deciding the amount of energy delivered to the client. Hence, confidentiality, privacy, and Integrity are major concerns of the grid to protect clients' consumption and their privacy to protect the grid from attacks and malware that could affect customers' privacy and cause a real disaster [8], [9].

In addition, The smart meters are accessed by multiple agents such as technicians, customers, and operators, which makes them vulnerable to physical attacks. Consequently, smart meters must be well protected in terms of authentication. Moreover, authenticity protects the Operator's system and the other customer from malicious technicians, neighbors, customers, or any other malicious intruder.

B. AEAD CIPHERS: Ascon

ENCRYPTION is a cryptographic method that encodes information to protect it and prevent unauthorized access. The encryption performs several operations(rounds, permutations.) on both Plaintext and a key. These operations produce an unreadable ciphertext that needs the previous Key to decrypt [10].

However, classical encryption does not ensure the authenticity of the message. To deal with this, authenticated Encryption with Associated Data brings up a new level of security thanks to the associated data. The associated data is data related to the sender's time and space that ensures the authenticity of the message and the sender [10].

1) Authenticated Encryption with Associated Data AEAD: Authenticated Encryption with Associated Data is a new cryptographic algorithm that ensures confidentiality, integrity, and authenticity. The technical difference between the AEAD and classical encryption is that the first one generates the ciphertext with a tag. Consequently, decryption and Integrity are performed simultaneously, and the Plaintext is readable only if the Tag is correct [6].

The AEAD encryption is defined as a set of algorithms: the key generation algorithm, the encryption algorithm, and the decryption algorithm.

The encryption algorithm has three inputs, the Nonce N, the associated data AD, and the Plaintext (message). It outputs the ciphertext and a tag : EK: N × AD × Plaintext → Ciphertext × Tag.

The decryption algorithm is the inverse algorithm with the nonce N, the associated data AD, the cipher C and the tag T as inputs. It outputs the Plaintext if C and T are valid : DK: $N \times AD \times C \times T \rightarrow M$ or Error [6].

The most popular and highly adopted lightweight AEAD algorithm is the AES-GCM, which is appropriate for the constrained devices of the IOT [6]. However, it has exposed several shortcomings. The nonce should be unique for each message and non-repeating to prevent nonce misuse attacks, which is not practical for message exchanges. Also, keys used in the hash have been found weak [11].

In order to overcome these shortcomings, NIST launched 2014 the Caesar competition to find out more efficient and lightweight encryption algorithms in terms of applicability, robustness, and security [12].

Among 54 candidates in the first round, only 29 passed to the second one, and 15 candidates were selected for the third round. The two finalist lightweight applications portfolio of the competition is Ascon and ACORN. Ascon is the selected algorithm for the proposed protocol [12].

The two variants of Ascon were selected as the first choice for lightweight applications. Several works evaluated the Ascon algorithm. All analysis supports its large security margin without practice risks, vulnerabilities, or weaknesses [13].

2) ASCON Principle: Ascon is based on the sponge and duplex construction. The algorithm of Ascon is illustrated in Fig. 1 and Fig. 2: Initialization step: An Initial Vector of 64bits (ACON-128 and ASCON-128a), the secret key K, and The nonce N are concatenated to form a 320-bit state. This state passes through the transformation "p" for "a" times/ Then, the secret Key is XORed with the transformed state [13] [14].

Associated Data: The associated data is divided into r-bit blocks and XORed with the first r-bit blocks of the state. After that, a transformation "p" is applied to the resulting state "b" times and XORed again with a 1bit constant.

After these steps, the algorithm moves either to encryption or decryption with two additional phases for each :

Encryption: The plaintext is divided into r-bit blocks, XORed with the first r bits of the state (identical to associated data). Then, it generates blocks of ciphertext that are updated with "p" transformation for "b" times.

Decryption: The ciphertext blocks are XORed with the first r bits of the state and replace the first r bits of the states. They are again updated with the p transformation b times.

The final step after encryption/decryption is the finalization which consists of XORing the secret Key with the state and applying the p transformation "a" time to the state. The secret Key K is once again XORed with the resulted state. The Tag is the least significant 128 bits of the output [13], [14].

3) Ascon Security: The best-known key recovery attack can find the Key with 2^{104} time complexity if the initialization round number is reduced to 7.

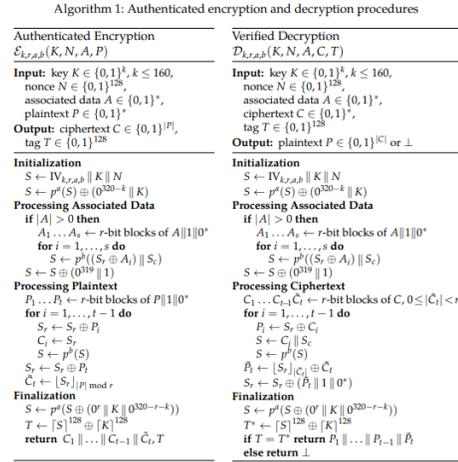
Even if the state is recovered, it is impossible to use it for key recovery or forgery attacks. Even the vulnerabilities are not useful for practical attacks.


Fig. 1. Ascon Algorithm [13].

Ascon provides security against collision attacks, pre-image attacks, length extension attacks and second-preimage attacks for long messages, misuse attacks, side channel, implementation attack [13], [14], [11].

C. The Distributed OTP Concept [15]

OTP (One-time-password) is a password that changes with each session because it is based on the various counter. This technique is based on an out-of-band exchange of information, such as the keys, counter, and hash functions used in the password calculation process. Thus, OTP has considered one of the most secure authentication techniques because replay attacks are impossible (Fig. 3). The algorithm of the OTP consists of hashes and several calculations , which makes it difficult to be guessed.

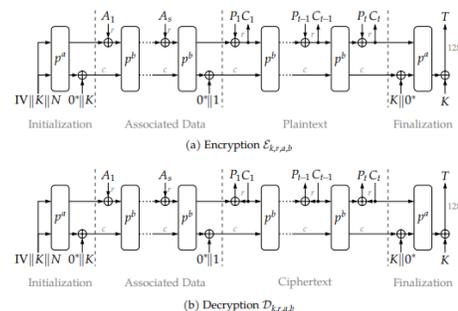
The proposal uses lightweight protocols such as Blake 2, a hash function that achieves efficient security results. Blake2 generates hash digests based on stream encryption [16], [17]. The Blake function algorithm uses a 16-word constant combined with the message, salt value, and an initial vector and generates a 4x4 matrix. Then the matrix rows go through eight sets of permutations, and combinations [18], [19].


Fig. 2. Ascon Encryption and Decryption Processes [13].
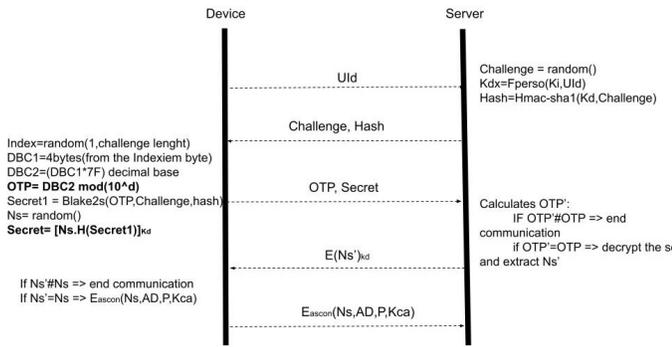

Fig. 3. Distributed OTP Authentication Protocol.

IV. PROPOSED PROTOCOL

Each wireless communication starts with an association step where the communicating objects identify each other through parameters such as identifiers or passwords. At this level, if these parameters are disclosed or intercepted by a malicious third party, the network will suffer an intrusion and lose its security. Hence, the importance of introducing and deploying secure authentication protocols for these communications, such as the proposed protocol which addresses wireless communication security at the NAN level of smart grids between the smart meters and the Gateways/concentrators of the grid.

A. Proposed Protocol Model

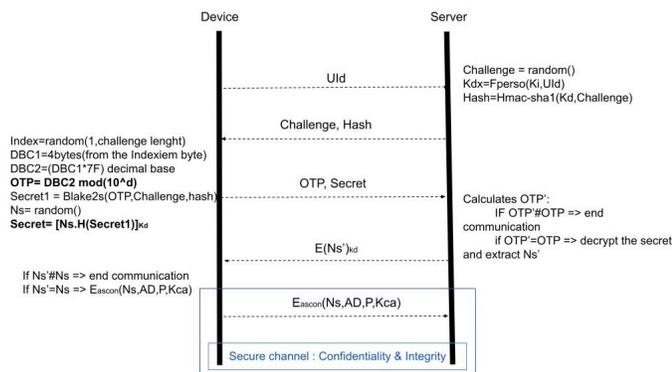
The proposed solution aims at designing a security protocol that ensures authentication, authenticity, integrity, and confidentiality. This proposal aims to complete the proposal of [15] while boosting its security by modifying some parameters. As shown in Fig. 4, the protocol is divided into three main parts. The communication starts with an authentication of the Device based on the OTP. Then the protocol moves on to the phase of mutual authentication by the server, based on a random value calculated by the Device. Finally, as soon as both entities are authenticated, they move on to secure the communication channel through Ascon encryption to ensure confidentiality, integrity, and authenticity.


Fig. 4. Proposed Scheme.

1) Pre-Phase: Keys Exchange: This phase is an off-line phase. The symmetric key Kia is affected to the Device and the server by a trusted authority. The secret key Kd is configured on the Device in an out-of-the-line mode based on its Id. In addition, the server gets its secret Key Ki. It keeps communication with an external base where Ids and their appropriate Keys will be stored. The base will avoid attackers trying to impersonate an already authenticated Device.

2) Device Authentication :

- Step 1: The Device will start the communication request by sending its Id to the server.

- Step 2: Once the Server receives the identifier, he will check first if it is already registered. If the Device is already registered and active, it will be dropped. Else, the server will generate a random value as a challenge and calculate the corresponding Key to the Device and a hash value with the HMAC-SHA1 of the calculated key Kd and the challenge. Then he will send the Hash value and the challenges to the Device.

- Step 3: The Device will start calculating the OTP. For this purpose, he will start calculating an Index value, a random value between 1 and the received challenge length. Then, it will truncate the 4 bytes starting from the index byte of the received hash. Next, it will calculate the DBC2 as a decimal value of the multiplication of the DBC1 and 7F. OTP is finally found by applying a modulo d to force the OTP length to "d ."In addition, the Device will calculate a secret value based on Blake2s of the OTP and the last received values of Challenge and Hash.

- Step4: The Server calculates the OTP on its own and compares it to the received value. If the OTP is correct, the server will move to its authentication. If not, it will stop the communication.

3) Server Authentication :

- Step 1: This step starts simultaneously with the third step of the device authentication. While sending its OTP, the Device also sends a secret containing an Ns Value. The secret is a random value Ns encrypted and its concatenation with the blake2s hash of the OTP, the challenge, and the received hash.

- Step 2: The Server will start by authenticating the Device based on its OTP. Once the Device is authorized, the OTP will try to extract the Ns value from the received expression. If the server is right, it can decrypt the secret value. Then, since it could authenticate the Device, it will have the true value of the OTP and the keys required to do the reverse calculation and extract the correct Ns. Thus, we will gain in the number of exchanges and in time.

- Step 3: The Device will start authenticating the server by the Ns value. If the value is correct, they will move to secure the challenge; if not, the communication is stopped.

4) Channel Security: Confidentiality and Integrity: In order to ensure the appropriate security of the channel, we will use authenticated encryption with associated data. The main feature of this step is that a lightweight AEAD cipher encrypts the data. The Device will start encryption based on the Plaintext, the associated data (related to the time of transmission to avoid revealing the location in the IoT context that involve the privacy of the clients), the secret value Ns, and the symmetric key Kia (pre-shared between the Device and the server). Thus, confidentiality, authenticity, and Integrity are ensured, and the data is protected.

V. SECURITY ANALYSIS

A. Informal Analysis

1) Security Considerations:

- Efficiency:
  All used protocols in the proposal are lightweight protocols that respect the limitations of constrained devices. Blake2s and Ascon are two protocols for hashing and encryption adapted to the specifications of connected objects, which has allowed them to be outclassed in NIST competitions. In addition, OTP's computational distribution method offers more advantages to objects in terms of reduced computation and storage in objects.

- Authentication:
  The protocol consists of mutual authentication. Both the Device and the server authenticate to each other. The device authentication is based on the OTP, which is known for a high level of security. In addition, server authentication requires that it compute the OTP value and compare it to the value computed by the Device. It can also decrypt the mathematical expression to extract the received nonce that varies with each session. So, mutual authentication is ensured, safe, lightweight, and robust.

- Data Confidentiality and Integrity:
  Thanks to Ascon CIPHER's potential, it was the first candidate for the final round of the CAESAR competition. Ascon is a lightweight authenticated encryption protocol that was evaluated by many designers who prove that it is secure against many attacks on confidentiality and integrity of data and identities [13], [14].

- One Point of Failure:
  Authentication is based on the distributed calculation of OTP, which means that calculation is not concentrated. Also, both the Device and the server have secret and random parameters that are not shared clearly. Each one needs to make the distributed calculation to authenticate to the other. In other words, the knowledge of the Device and the receiver are not the same, which means there is no point in failure in the protocol.

2) Resistance against Threats and Attacks :

- Impersonation Attack:

The attacker cannot impersonate the Device because the authentication is based on the OTP that changes every session. Also, the server registers the Id devices with their correspondent OTP to avoid malicious devices that would try to impersonate the Device. The attackers cannot either impersonate the server. At the same time, the Ns value is generated in every session. Its calculation is based on ulterior parameters, particularly the secret Key Ki, which is not exchanged in the channel.

- Eavesdropping:
  In the secure exchange step, each piece of data is protected by the Ascon AEAD. The Device uses the Ns nonce shared secret with the server and the associated data related to the precise transmission time. Combining these data allows us to verify the integrity and validity of the message securely. Thus, the attacker can neither listen nor modify the messages.

- MITM (Man in the Middle):
  The proposed security scheme emphasizes strong mutual authentication, also known as two-way authentication. The Device and the server identify each other with this authentication process before starting the data exchange. Without knowing the Device's private Key, the random and unique challenge, and nonce Ns and the corresponding computations, an attacker cannot compute the authentication or encryption data and therefore cannot validate the authentication and proceed to the data exchange. Thus, the Device and the server ensure that they communicate with legitimate correspondents. Therefore, the Man in the Middle attack is impossible in this scenario.

- Forward Secrecy:
  The leakage of a secret key does not affect the rest of the communication. All used keys are combined with the session variable. Even if an attacker intercepts a key, he will not be able to compromise privacy or confidentiality because the Key alone is insufficient to make an attack. In addition, the used keys are even pre-shared or require specific calculations. Hence, a non-legitimate participant has no way to compromise the forward secrecy.

- Forgery Attack:
  An intruder will not be able to authenticate and forge an appropriate request while he has to own the Id and the secret Key Kd. In addition, as we mentioned before, the scheme resists the replay attack and provides mutual authentication. Hence, a forgery attack is prevented.

- Replay Attack:
  In the authentication phase, the OTP and the random parameters Challenge, Ns varies every session. Then, in the transmission phase, the associated data is related to timestamps, which prevents an illegitimate entity that intercept communication from reproducing the same parameters and authenticates to one of the entities.

B. Formal Analysis: Avispa

We perform the formal analysis of the proposed protocol with the AVISPA simulation tool [20] to prove that it is safe and robust against MITM and replay attacks.

The AVISPA tool uses the HLPSL language to make security simulations. It allows the designers to verify their protocols' security and robustness.

1) CAS+: CAS+ is a simple syntax based on the Alice and Bob notation. While CAS+ has a simpler syntax than the HLPSL [20], we made the basic CAS+ algorithm, presented in the Fig. 5 that will be translated later to the HLPSL. The CAS+, even if it is simpler than the HLPSL, the CAS+ is not as performant as the HLPSL language. Also, in some cases, the translator cannot translate correctly [21], [20] Consequently, we started with the CAS+ algorithm. We made the required modifications and added the additional specifications of the protocol directly to the HLPSL file.

Fig. 5. Cas+ : proposed solution

2) HLPSL: SPAN is the tool that provides the translation CAS+/HLPSL and also makes the protocol simulation and verification [21], [20] Based on the CAS+ translation made with the SPAN, we added the proposed advanced functions and defined the goals and verifications. We started by defining the two roles, Server and Device. Then, we set up the sessions, environment, verifications, and security goals. Regarding the exchanged messages, we worked on the state's expressions to make actions look alike the proposed protocol. Advanced calculations like truncate and multiplications were performed as concatenations and Xor. We set goals as the verification of the mutual authentication based on OTP and Ns. In addition, we set verification of the secrecy of the plaintext P.

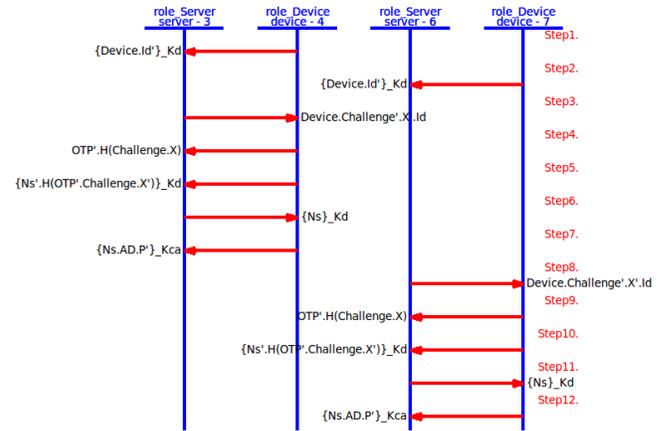
3) Protocol Simulation: Once the HLPSL is executable by SPAN, we get the diagram in Fig. 6. This diagram proves that the whole protocol is readable by the verifications and that the security verifications cover the whole protocol. we moved then to launch the security verifications by the OFMC, and ATSE [22]


Fig. 6. AVISPA-Span Simulation.

4) Execution Results: In order to evaluate protocols and verify whether the goals set out in HLPSL's algorithm are verified, the backends execute the protocol through multiple finite iterations until the protocol is considered safe for the number of sessions or an attack is found. The OFMC and CL-AtSe backends check if a legitimate entity can execute the protocol correctly while introducing a passive attacker in Fig. 7 and Fig. 8. The four backends of the AVISPA are:

- On-the-fly Model-Checker(OFMC): This uses several symbolic techniques to represent the state-space to perform protocol falsification and verification for the boundless number of sessions in a demand-driven fashion [23].

- Constraint-Logic-based Attack Searcher (CLAtSe): This is a constraint-based approach. It uses some simplification and redundancy elimination techniques to integrate a new specification for cryptographic

VI. Performance Analysis

we will evaluate each participant's computation and communication performance. We will separate the Device's computations and those made by the servers because of the different capacities of each.

Table I presents the different costs of the system's entities. While gateways are more powerful than devices in capacities and resources, we separate calculations to assess the protocols' weight on the constrained entity.

T refers to The time taken while (h: hashing, e: encryption, r: random, c: ascon cipher, and other: small calculations such as multiplications, truncating, and XORing). The storage is expressed by the estimated size of each parameter involved in the communication.

Table II depicts different costs generated from the three phases of the protocol in comparison with similar works that address the security of the communication between smart meters and the neighbor gateways.

As aforementioned in Table I , the proposition requires less storage than the other works. Communication cost is regular

but not the best, while the [28]'s work has better results. Regarding computation, the parameter that makes a difference is the Tc related to Ascon cipher performance. However, the difference in encryption requirement of all other works is more than the double value of the four encryptions used in this work. In addition, Ascon is a lightweight encryption cipher that is more optimized than the standard encryption algorithm.

VII. Discussion

Due to the multiple risks that threaten the smart metering system, accessible from different entities, We estimate that the risks are related to privacy and integrity authenticity. Therefore, we claim that the proposed solution is adapted to the smart metering context. The message size of smart meters is around 100bits and thus covered with the selected protocols, namely Ascon and blake2. In addition, the distributed calculation of OTP respects the constrained nature of smart meters. On the other hand, we claim the mutual authentication that requires higher costs by the side of the gateway does not affect the robustness of the protocol, while the gateway is not constrained in terms of resources. In terms of security, combining the selected protocols with the OTP distribution covers all well-known attacks against the Metering system of the smart grids.

The solution could be extended to other IoT applications. However, the obvious limitation is mainly related to energy aspects which have not been addressed in the scope of the proposed solution since smart meters are always powered by continuous power. However, it is worth considering this issue in a sustainable and ecological approach.

VIII. Conclusion and Perspectives

In this article, we have proposed a protocol that considers the three pillars of security: authentication, confidentiality, and Integrity. We started from the principle of distributing OTP for authentication, which alleviates the objects and respects their constraints in terms of performance. We have carefully chosen secure and lightweight cryptographic algorithms Ascon Cipher and Blake2, two finalists of the competitions launched by NIST, to effectively choose lightweight protocols. The informal and formal security evaluation through AVISPA revealed that the protocol is secure. The comparison has shown that the protocol is better optimized than other similar proposals. However, the costs may seem to be a drawback to the protocol's performance which needs more optimization, especially in the context of smart meters requiring real-time communications.

In addition, the generic architecture of smart metering systems can be a key for deploying innovative technologies within the overall architecture to boost performance and security more efficiently. Hence, it is worth investigating new and

Abstract—Cloud computing provides on-demand access to a diverse set of remote IT services. It offers a number of advantages over traditional computing methods. These advantages include pay-as-you-go pricing, increased agility and on-demand scalability. It also reduces costs due to increased efficiency and better business continuity. The most significant barrier preventing many businesses from moving to the cloud is the security of crucial data maintained by the cloud provider. The cloud server must have complete access to the data to respond to a client request. That implies the decryption key must be sent to the cloud by the client, which may compromise the confidentiality of data stored in the cloud. One way to allow the cloud to use encrypted data without knowing or decrypting it is homomorphic encryption. In this paper, we focus on improving the Paillier cryptosystem, first by using two protocols that allow the cloud to perform the multiplication of encrypted data and then comparing the two protocols in terms of key size and time.

Keywords—Cloud computing; cloud security; homomorphic encryption; paillier cryptosystem; sockets

I. INTRODUCTION

Cloud computing opens up previously untapped possibilities for storage and computation outsourcing. Many people are interested in using this technology since it gives flexibility, accessibility, and cost savings [1], [2], [3]. Over the last two decades, a surge in data has been generated and stored due to the creation of the internet of things, artificial intelligence and cloud computing [4]. However many authors have proposed solutions to optimize the offloading decision and the computing resource allocation to minimize the overall tasks processing time and energy [5], [6], many users are hesitant to commit sensitive data to the cloud due to concerns about privacy and security, making cloud security a critical matter. Indeed, cloud security literature has proposed and evaluated different encryption schemes [7], [8]. Particularly intriguing is homomorphic encryption, which allows any data to remain encrypted while being processed and manipulated. The organization of this paper is described as follows: Section 2 will mention some related works to secure the cloud. Section 3 begins with a summary of Paillier's cryptosystem. Section 4 goes on to describe the two protocols that we use to perform multiplication on encrypted values, followed by our conclusion in Section 5.

II. RELATED WORKS

Research efforts are directed toward several types of homomorphic encryption to secure the cloud, including partially homomorphic encryption. These schemes allow for the execution of a single operation on encrypted data, mainly addition, as in Goldwasser-Micali [9] and DGK [10], or multiplication, as in El Gamal [11] and unpadded RSA [12]. This paper will focus on the well-known additively homomorphic Paillier scheme [13]. It enables the computation of sums on encrypted data, which is useful in a variety of applications, such as encrypted SQL databases [14], machine learning on encrypted data [15], and electronic voting [16]. The authors in [17] address issues, possibilities, and potential improvements related to homomorphic encryption. They describe how we can use homomorphic encryption to process computations in big data. The authors of [18] provide a comprehensive assessment of homomorphic encryption, highlighting current application needs and future potential in areas such as security and privacy. This paper will present two protocols to improve Paillier's encryption scheme and allow the cloud provider to perform multiplication on encrypted data.

III. PAILLIER'S CRYPTOSYSTEM

A. Background

Paillier [13] proposes a new probabilistic encryption method relying on group computations based on calculations over the group $\mathbf{Z_{n^2}}$, where n is an RSA modulus. This scheme is captivating because it is homomorphic, enables the encryption of many bits in a single operation with a constant expansion factor, and enables effective decryption. As a result, it has the potential to be suitable for a variety of cryptographic protocols, such as electronic voting and mix-nets. This approach is similar to Okamoto and Uchiyama's voting and mix-nets cryptosystem [19], in which the group $\mathbf{Z^*_{p^2 \cdot q}}$ is used, where p and q are large primes. The principal difference is that the homomorphic property of this scheme necessitates that the sum of the messages being added be less than p, which is unknown. Because the homomorphic computations in Paillier's method are simply modulo n, this problem is avoided.

B. Paillier Original Algorithm

In [13], Paillier describes two partially homomorphic cryptosystems, schemes 1 and 2. Scheme 1 is the basic Paillier scheme, while scheme 2 is a quicker decryption variant. The Paillier scheme's security relies on the n-th residues in $\mathbf{Z_{n^2}}$ and the toughness of integer factorization. Therefore, we only concisely review the fundamentals and comment on key generation and parameter selection here. Finally, we refer to the original article [13] for more information on the scheme's security. The multiplicative group $\mathbf{Z_{n^2}}$, for $n = pq$ and two prime numbers p and q serve as the setting for the Paillier's scheme. Notice that $\mathbf{Z_{n^2}}$ has $|\mathbf{Z_{n^2}}| = \phi(n^2) = n \cdot \phi(n) = (p-1)(q-1)n$ elements. The Carmichael's function on n, $\lambda(n)$, is short-handed to λ .

1) Scheme 1: In Table. I, Paillier's method is provided in it's most basic form:

TABLE I. PAILLIER'S SCHEME 1

Parameters	prime numbers $n = p.q$ $\lambda = lcm(p-1, q-1)$ $g, g \in \mathbf{Z_{n^2}}$ the order of g is a multiple of n
Public key	n, g
Private key	p, q, λ
Encryption	plaintext $m < n$ select a random $r < n$ such that $r \in \mathbf{Z^*_{n^2}}$, ciphertext $c = g^m r^n mod\, n^2$
Decryption	ciphertext $c < n^2$ plaintext $m = \frac{L(c^\lambda \, mod\, n^2)}{L(g^\lambda \, mod\, n^2)} mod\, n$

Following the notation of [14], $L(u) = \frac{u-1}{n}$, for $u = 1\, mod\, n$. This function is only used on input values u that actually satisfy $u = 1\, mod\, n$.

2) Scheme 2: This is a faster version of the original Paillier algorithm. We work in the subgroup $<g>$ generated by an element g of order αn rather than the entire group $\mathbf{Z^*_{n^2}}$. This enables exponentiation decryption using the exponent $alpha$ instead of $lambda$, which speeds up decryption depending on the size of $alpha$. Scheme 2 is described in Table II:

TABLE II. PAILLIER'S SCHEME 2

Parameters	prime numbers $n = p.q$ α divisor of $\lambda = lcm(p-1, q-1)$ $g, g \in \mathbf{Z_{n^2}}$, the order of g is a multiple of αn
Public key	n, g
Private key	p, q, α
Encryption	plaintext $m < n$ select a random $r < \alpha$ ciphertext $c = g^m (g^n)^r mod\, n^2$
Decryption	ciphertext $c < n^2$ plaintext $m = \frac{L(c^\alpha \, mod\, n^2)}{L(g^\alpha \, mod\, n^2)} mod\, n$

C. Paillier's Cryptosystem Propreties

Paillier's homomorphic encryption has the following Propreties as it is shown in Fig. 1:

- As it's a public key system, anyone with the public key can encrypt, but decryption requires the private key, which is only known to a trustworthy individual.

- It is based on probabilities. It means, an attacker cannot tell whether two ciphertexts are encryptions of the same plaintext or not.

- For addition, it includes the homomorphic properties listed below:

$$E[(m1+m2)]\, mod\, n = E[m_1] \cdot E[m_2]\, mod\, n^2 \quad (1)$$

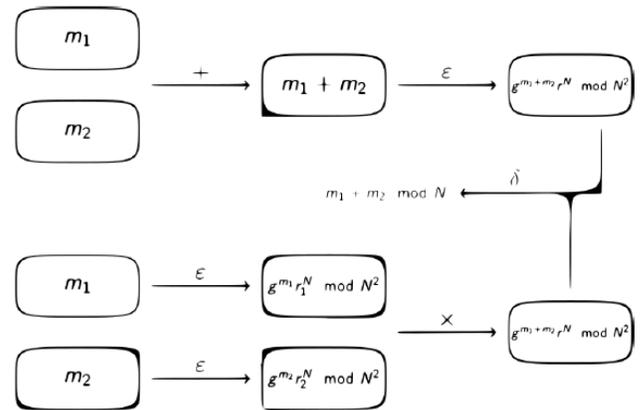
$$E[(a \cdot m)]\, mod\, n = E[m]^a\, mod\, n^2 \quad (2)$$


Fig. 1. Paillier Homomorphic Multiplicative Properties.

In which m is the encryption modulus and one of the public key elements. The key generation scheme is as follows:

- Choose p and q as two huge prime numbers such that:

$$gcd(p \cdot q, (p-1) \cdot (q-1)) = 1 \quad (3)$$

This condition is guaranteed if p and q have the same bit lengths.

- Calculate $n = p \cdot q$ and $\lambda = lcm(p-1, q-1)$

- Choose a random integer g from $\mathbf{Z^*_{n^2}}$

- Ensure n divides the order of g by determining whether the following modular multiplicative inverse exists: $\mu = (L(g\, mod\, n^2))^{-1}\, mod\, n$ where $L(u)$ is the quotient of the Euclidean division of $\frac{u-1}{n}$

- The public encryption key is g and n

- The private encryption key is μ and λ

The following operations can then be used to encrypt the message: $m_1 + m_2\, mod\, n$

- Let m represent a message that has to be encrypted from $\mathbf{Z_n}$.

- Choose a random r from $\mathbf{Z^*_n}$

- Calculate ciphertext as:

$$E[m] = c = g^m r^n mod\, n^2 \quad (4)$$

The decryption is basically one exponentiation modulo n^2 :

$$m = L(c^\lambda \, mod \, n^2) \cdot \mu \, mod \, n \qquad (5)$$

The decryption takes advantage of the fact that discrete logarithms are simple to compute,for example if g is chosen as $g = n + 1$ then $L(g^x) \, mod \, n^2 = x \, mod \, n$. Proof can be provided using the binomial. theorem.

IV. APPLYING RUSSIAN MULTIPLICATION AND LOGARITHM PROTOCOLS

In this section, we will describe two protocols that make the Paillier encryption scheme act like fully homomorphic encryption by allowing multiplication of two encrypted values: the Russian multiplication and the continuous logarithm protocols.

A. Paillier Encryption and the Russian Multiplication Protocol

The Russian Peasant Multiplication Method is a common practice in Russian communities. This approach substitutes the frequently used multiplication procedure and only needs the usage of the table of twos. This theorem is currently included in many number theory textbooks [20]. To proceed, multiply the partial products on the left by two and divide the partial products on the right by two. It is similar to expressing the multiplier in base two and then doing multiplications and additions by two. It's a variation of the ancient Egyptian multiplication method. This method's algorithm is as follows:

Algorithm 1 Russian Multiplication

Input: m1,m2,table tab
Output: $m1 \times m2$
1: **while** $m1 > 0$ **do**
2:   **if** ($m1\%2 = 1$) **then**
3:     $e2 = encrypt(m2, pubKey)$
4:     Add $e2$ to tab
5:   **end if**
6:   $m1 = m1//2$
7:   $m2 = m2 * 2$
8: **end while**
9: **return** tab

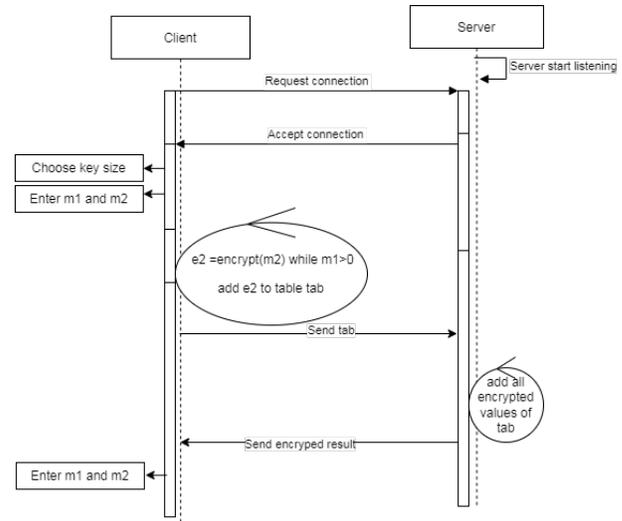
We used sockets that allow remote machines to communicate with each other using their IP addresses. When a client machine needs a service, it contacts a server machine. This is known as the client-server logic. One asks, the other answers, as illustrated in the sequence diagram Fig. 2:


Fig. 2. Russian Multiplication Protocol Sequence Diagram.

Once the Server accepts the connexion, the client request multiplication of $m1$ times $m2$. Let's take the example where $m1 = 73$ and $m2 = 96$. The client interface will transform 73×91 by 91, 728 and 5824 using the Russian multiplication algorithm, encrypt those values and send them to the cloud provider. The cloud can easily add those encrypted values using the Paillier algorithm and then return the result to the client, who could use his private key to see the plaintext. As is shown in the following algorithm:

Algorithm 2 Russian Multiplication Protocol

Input: m1,m2,table tab
Output: $m1 \times m2$
1: {Client Side}
2: **while** $m1 > 0$ **do**
3:   **if** ($m1\%2 = 1$) **then**
4:     $e2 = encrypt(m2, pubKey)$
5:     Add $e2$ to tab
6:   **end if**
7:   $m1 = m1//2$
8:   $m2 = m2 * 2$
9: **end while**
10: send tab
11: R = socket.recieve {result send by the cloud}
12: {Cloud Side}
13: R_tab = socket.recieve(tab)
14: sum = 0
15: **for** x in R_tab **do**
16:   sum = sum + x
17: **end for**
18: socket.send(sum)

B. Paillier Encryption and Continuous Logarithm

Without logarithms, many of our modern technological advances would be nearly impossible. We take advantage of the intriguing rule that transforms multiplication into an addition.

$$log(a \times b) = log(a) + log(b) \qquad (6)$$

Algorithm 3 Continuous Logarithm Multiplication

Input: m1,m2
Output: $m1 \times m2$
  1: $l1 = log(m1)$
  2: $l2 = log(m2)$
  3: $e1 = encrypt(m1)$
  4: $e2 = encrypt(m2)$
  5: $e = e1 + e2$
  6: decrypt(e)
  7: prod=exp(m)

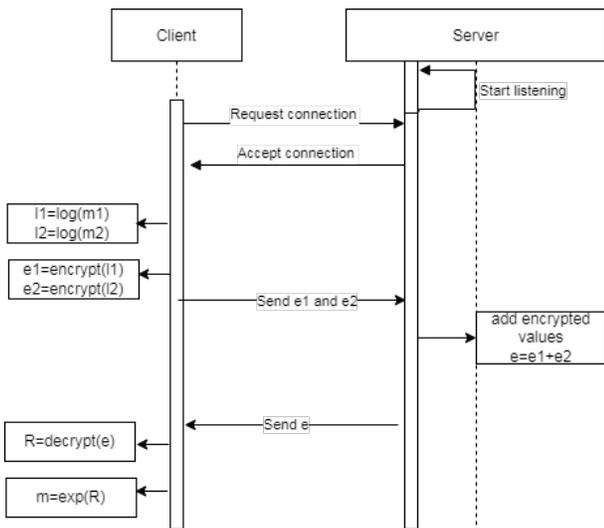
Lets $e1$ and $e2$ be the respective encryption of $m1$ and $m2$ in Fig. 3, by applying the continuous logarithm protocol, the client will be able to compute $m1$ times $m2$ just by sending $e1$ and $e2$ to the cloud.


Fig. 3. Continuous Logarithm Protocol Sequence Diagram.

Once the Server accepts the connexion, the client request multiplication of $m1$ times $m2$, and the client interface will apply logarithms on both values. Then, encrypt them and send them to the cloud provider. The cloud will add those encrypted values using the Paillier algorithm and then return the result to the client interface, which could decrypt and apply exponential to display the answer for the client. For a better understanding, we provide the algorithm of the logarithm protocol that allows the cloud to compute production on encrypted values:

Algorithm 4 Continuous Logarithm Multiplication

Input: m1,m2
Output: $m1 \times m2$
  1: {Client Side}
  2: $l1 = log(m1)$
  3: $l2 = log(m2)$
  4: $le1 = encrypt(l1)$
  5: $le2 = encrypt(l2)$
  6: send(le1,le2)
  7: sum=socket.receive
  8: m=decrypt(sum)
  9: message=exp(m)
10: {Cloud Side}
11: sum=0
12: c1=socket.receive(le1)
13: c2=socket.receive(le2)
14: $sum = c1 + c2$
15: socket.send(sum)

C. Implementation and Results

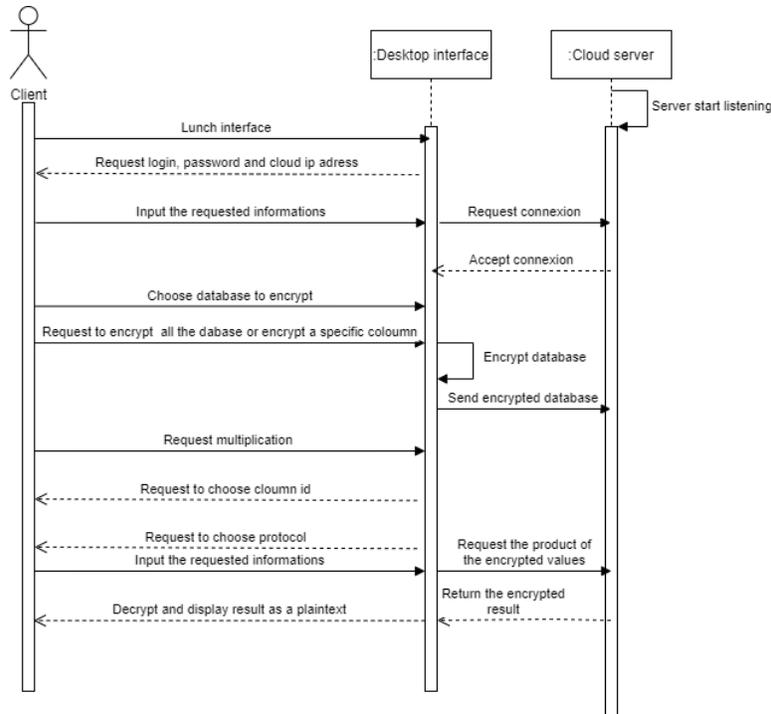
In this section, we propose a description of an implementation of a desktop interface that will allow clients to encrypt a database and request the cloud provider to make calculations on the encrypted data as it is shown in Fig. 4:


Fig. 4. The Client Desktop Interface Sequence Diagram.

The client desktop interface encrypts the database and sends it to the cloud server. Since the database is stored all encrypted in the cloud, the client sends a request to perform an operation or processing to benefit from the storage and calculation capacity of the cloud servers. Then, the client application decrypts it and returns the same result as if the operation is performed on the data in clear. We validate the applicability of our approach in different cloud solutions by implementing and managing encrypted database operations on a real cloud Hetzner. The current version of our prototype supports TinyDB databases. We chose TinyDB [21] because of the following advantages:

- Written in pure Python

- No dependencies

- Python2 and Python3 compatible

- Easy to use, very clean API Lightweight (2000 lines of code)

To improve security, we encrypted the database name, table names, and field names. This technique will allow us to do a variety of tasks without revealing any information about what we want to accomplish or the contents of our database. Which can be beneficial in many fields, such as medicine to protect the privacy of patients' information [22] or finance and Banking

[23]. To provide additional flexibility to the client so that he does not need to encrypt the whole database, especially if the vital data is on a single column. The client might use the following algorithm to encrypt just that single column:

Algorithm 5 Encrypt Column

Input: column_names table
Output: encrypted column
1: Function encryptcolumn(*id*)
2: **if** column type is String **then**
3:    encrypt column using RSA
4: **else**
5:    encrypt column using Paillier
6: **end if**

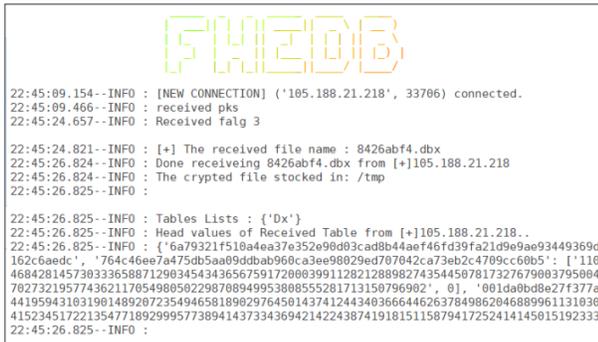
Fig. 5 illustrate the result that the cloud gets after a client decided to encrypt all the database using the Algorithm 6.


Fig. 5. Encrypted Database Received by the Cloud.

To encrypt the entire database we used the following algorithm:

Algorithm 6 Encrypt All Database

Input: Xtable table ,checked_ele String
Output: encrypted database
1: **if** Xtable exists **then**
2:   **for** non encrypted column **do**
3:     checked_ele = id_of_nonencryptedcolumn
4:     encryptcolumn(checked_ele)
5:   **end for**
6: **else**
7:   create table Xtable
8:   **for** each column in Xtable **do**
9:     **if** column type is String **then**
10:       encrypt column using RSA
11:     **else**
12:       encrypt column using Paillier
13:     **end if**
14:   **end for**
15: **end if**

Table III describes the comparison of the two protocols, using sockets, in terms of time and key size:

TABLE III. RESULT AND COMPARISON OF THE TWO PROTOCOLS USING SOCKETS

Key Length	Russian Multiplication Protocol(ms)	Logarithm Protocol(ms)
N=64	3.3	2.3
N=128	3.6	2.5
N=256	5.3	5.0
N=512	19.7	23.6
N=1024	66.4	60.4
N=2048	425.6.6	409.0
N=4096	2936.0	2830.0

With a tiny key size, we notice that both algorithms provide the same result in about the same amount of time. However, when the key size is increased, the Product encryption protocol employing Russian multiplication takes longer but performs better than the continuous logarithm method. As a result, if the operations performed on the cloud require precision, we should use the Russian multiplication protocol. Still, we can use the continuous logarithm protocol if we want speed with approximate values.

V. CONCLUSION

In this paper, we focused on improving Paillier's method by implementing two protocols that allow the cloud to conduct multiplication on encrypted data by including two protocols that transform multiplication into addition. To show the effectiveness of our approach, we created a desktop interface that enables users to benefit from the cloud while protecting the security of sensitive data held on remote servers and controlled by cloud providers. The client interface adds an extra layer of security to a database by encrypting the names of columns and tables in the database. The proposed solution would have a significant economic effect due to the assurance of data security, confidentiality, and data protection through its use. Additionally, this would encourage more businesses and financial institutions to keep their data in the cloud.

Abstract—**A good face detection system should have the ability to identify objects with varying degrees of illumination and orientation. It should also be able to respond to all the possible variations in the image. The image of the face depends on the relative camera face pose such as the nose and one eye. The appearance of a face is directly influenced by the facial expression of a person and partially occluded by objects around it. One of the most important and necessary conditions for face recognition is to exclude the background of reliable face classification techniques. However, the face can appear in complex backgrounds and different positions. The face recognition system can mistake some areas of the background for faces. This paper solves some face recognition problems including segmenting, extracting and identifying facial features that are thought to face from the background.**

Keywords—Image processing; multi-core platforms; machine learning; face recognition; parallelizing

I. Introduction

People have an excellent ability to analyse images and we can recognize the face very reliably. Indeed, humans can easily find the surrounding face despite difficult situations such as obscure parts of the face or heavy lightning. Facial recognition is considered a prerequisite for many computer vision applications such as security, surveillance, and content-based image search. So much research has been done to automatically replicate this process on machines [1]. For face detection methods, several authors have defined a vast range of methods for face detection [2]. The feature-invariant approach is primarily aimed at finding structural features that are present even when "the pose, the angle of view, or lighting conditions change". People are expected to easily recognize faces, so they need constant properties or capabilities for these fluctuations. The problem with this approach is that lighting, noise, and occlusion can severely damage image features. The template matching process defines some standard patterns for the face.

These patterns are stored in templates to describe the entire face or individual facial features. The correlation between the entered pattern and the saved pattern is calculated for recognition. In the appearance-based method in contrast to template matching, the model is trained from a series of training images aimed at capturing typical variations in facial appearance. One of the problems with this approach is that training the model can take hours or even days. Face recognition method considerations represent the boundaries between knowledge-based methods and template comparison methods. The latter is usually because it implicitly requires human knowledge to define a face template.

The aim of this work is to implement parallelize Image Processing Algorithms for Face Recognition on Multi-core Platforms. In order to reach our goal we started by analyzing the challenges associated with face detection which involves factors such as pose, presence or absence of structural components, facial expression and imaging conditions. When the face detection methods were analyzed, it was determined that the ones based on learning algorithms (appearance-based) provides better results. Because these methods eliminate the possibility of modeling error, which can occur when face knowledge is either insufficient or inaccurate.

II. Related Works

Face recognition techniques based on learning algorithms (appearance-based) have recently received a lot of attention to eliminating potential modelling errors due to incomplete or inaccurate face knowledge. A neural network-based face recognition framework developed by Rowley et al. [3] proposed, reasonably connected NN (neural network) examines small windows in the image to determine if each window contains a face. Fig. 1 shows Neural network face detection.

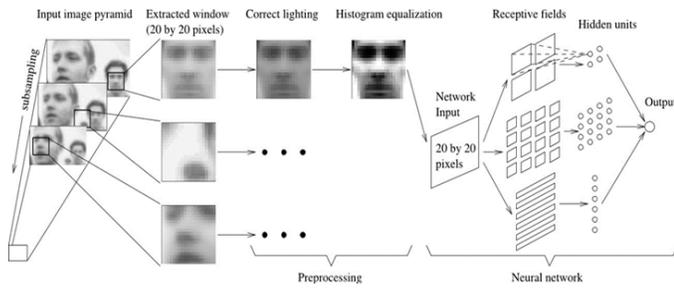
Authors of [1] ilustrated the understandings of computer vision and image processing. Authors of [2] mentioned many


Fig. 1. Neural Network Face Detection.

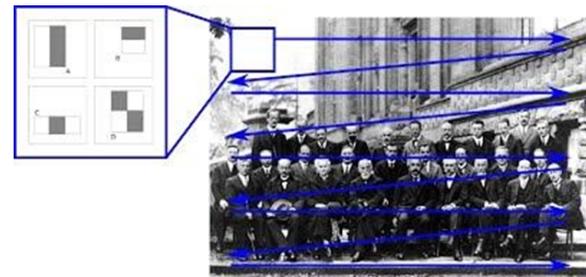
Fig. 2. Pyramid of Scales.

Fig. 3. Detection Window (Sub-Window).

approach of detecting face in an image. Authors of [4] used deep learning for image recognition. Authors of [3] used neural network for face detection. Authors of [5] showed an improved algorithm in this aspect. Authors of [6] showed GPU performance in computer vision aspect. Authors of [7] worked on Parallelizing face detection. High perfomance computing for image processing is analysed by authors of [8]. Haar-like features were implemented by authors of [9] and [10]. For face detection CNN can be used [11][12] for robust face detection. Multiple faces can be detected with adaboost and Camshaft algorithms [13]. Moreover, artificial intelligence and internet of things based solution can make changes in medical sectors [14], hotel sectors [15], covid-19 patient management sectors [16], and many other sectors [17]. Remote sensing [18] makes a great change in virus-affected people monitoring [19]. IoT-based systems are also secure [20]. These systems can also help in agriculture [21], poultry farm [22], disable people management [23], electronic voting [24], gaming [25], farming [26], nursing [27], remote data sensing [28], virus affected area monitoring [29][30] from remote places [31]. IoT based irrigation systems are helping farmers [32] and farming [33]. Robotics and IoT are doing great in medical fields also [34][35]. So, in multicore platform parallelizing image processing algorithm should work better for face recognition and help mankind.


III. Face Detection Optimization

We would like to optimize the face detection task to reduce its computation time [4][3]. To do so it's important to understand how it works inside. The face recognition task first creates an image pyramid, which is a multi-scale representation of the image. This makes the face recognition scale invariant and it recognizes faces in the same recognition window. Fig. 2 shows Pyramid of scales.

On each scale it is important to notice that the size of the detection window is the same in all the scale. This process is such that smaller faces are detected on early scales while bigger faces are detected later. Fig. 3 shows Detection window (sub-window).

A. The Scale Factor

It allows the creation of the image pyramid, by re-scaling the input image we can resize a larger face to a smaller one. Each scale will reduce the size by 10% concerning the previous one. The algorithm works leisurely since a lot of scales are created. It is possible to grow 1.40 for faster detection with

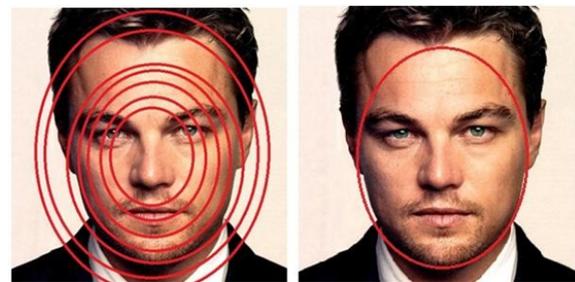
the missing some faces altogether. To precisely detect the face, all the scales that return a face result are merged into one final result. In Fig. 4, 46 scales were generated. Scales (1 - 35) and (43 - 46) did not find any face, scales (36 - 42) did find a face (left image), and all the scales that found a face are merged into one final result in the right image.


Fig. 4. 46 Scales were Generated. Scales (1 - 35) and (43 - 46) did not find any Face, Scales (36 - 42) did find a Face (Left Image), and All the Scales that found a Face are Merged into One Final Result in the Right Image.

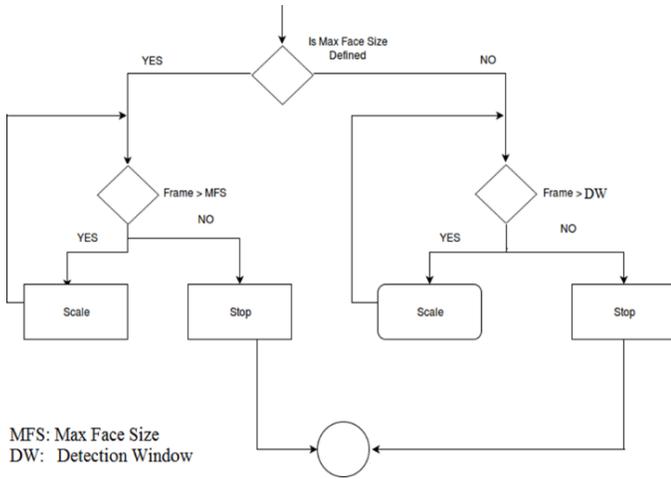
B. Minimum and Maximum Object Size

The standard for this parameter is usually [30, 30] pixels, and for bigger objects than the size, we want this to be ignored. Now that the parameters are known, we would like to work with the low scale factor (1.1) so that all the possible faces are detected but also with a few numbers of scales. The stopping condition for the creation of scales is based on the two parameters defined above (min and max object size). Fig. 5 shows Stopping condition for the creation of scales. The size

Fig. 5. Stopping Condition for the Creation of Scales.

Fig. 8. Computation Decreased as the Min Face size Gets Closer to the Real Face Size.


of the detection window is defined as double the min object size. So only objects that a greater than the min object size and smaller than the detection window are considered. Fig. 6 shows the detection window. By experiment was possible

Fig. 6. Detection Window.

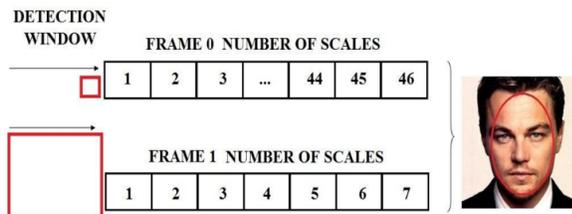
to notice that the most important factor to optimize the face-detection is the min object size, as it directly affects the size of the detection window and the number of scales [5]. A final optimization solution for a stream of images can be seen as: first, we start by considering the worst-case scenario in which the parameter for min face size is (30, 30) and a scale factor of 10% which will generate a lot of scales once a face is found, adjust the detection window to the size of the face for the next frames (min_face_size = real_face_size ∗0.8). This process allows reducing drastically the number of scales as they are determined based on the previously detected face dimensions as it's possible to see from Fig. 7. As it is possible to notice


Fig. 7. Optimized Solution.

from Fig. 8, the computation time decrease drastically as the min face size gets closer to the real face size and the number of scales is reduced.

This face detection optimization should be applied only for cases where the goal is to find exactly one face or at most multiple faces that are somehow equidistant from the camera. When the algorithm is applied for the first time (left image), we do not have any a priori knowledge of the size of the faces, and almost all of them are found [36]. Because of the image pyramid of scales, the smallest faces (the ones much farther away from the camera) are the first to be found. Then the intermediate faces (the ones in the center) and finally the largest faces (the ones in the front line). In this way, the largest faces are the last ones to be found, so they will set the threshold of what size of face to look for. When the algorithm is applied for the second time (right image) only the front-line faces are found. Table (I) shows the Styles Summary.

IV. PARALLEL IMPLEMENTATION

We will start by studying the parallel patterns and tools that will be applied later on to parallelize the application. The potential sources of parallelism of the Viola-Jones algorithm [37] will be also analysed followed by a detailed study of the OpenCV parallel implementation [6]. An improvement to the OpenCV parallelism will also be addressed along with the GPU implementation of the Viola-Jones algorithm. We will discuss techniques for the design of parallel computations and the tools that allow implementing such techniques [38].

A. Pipeline Paradigm

This paradigm is defined for the stream of computations only. It is applied when we have a computation that can be expressed as a composition of functions. The service time of the pipeline depends on the slowest stage. This paradigm is generally characterized by a latency (time between the input of a data and the output of its result after processing) worst than the sequential version due to the communication between the stages. The Pipeline may be used to improve the service time, however, to remove application bottlenecks with this paradigm we must ensure that the number of functions is equal to or greater than the optimal parallelism degree and the stages are somehow balanced. Fig. 9 shows the Pipeline process.

Fig. 9. Pipeline Process.

B. Embarrassingly Parallel Paradigm or Farm

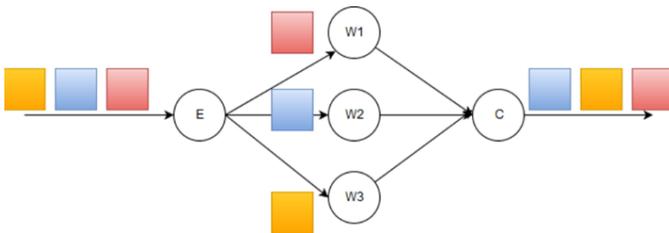
This is a streaming paradigm that replicates the same function that distinct stream elements can be processed by DIM in parallel. This paradigm is composed of three modules: "Emitter, Workers, and Collector". The emitter provides to send every received input stream to one of the workers according to a certain policy. Each input element is transmitted to exactly one worker. Each worker applies the function F to the received data and sends the result to the collector which transmits each of them to the output stream. To apply the farm paradigm the function F must be a pure function, that's it without an internal state. The farm paradigm is good for applications where the order of the output is not so important as the relative speed of the workers can be different. In Fig. 10, we can see the farm as a three-stage Pipeline, in which the emitter is the first stage, the workers in the second, and the collector in the last stage.


Fig. 10. Embarrassingly Parallel or Farm.

C. Map or Parallel for Paradigm

This is a data-parallel paradigm that can be applied on streams as well as on single data values. This paradigm is characterized by data partitioning and by function replication. For stream-based computations, besides service time, it also optimizes latency and memory capacity [39] which is not the case with the paradigms introduced above. During the execution of function F, each of the functions on its local data exclusively in the Map paradigm, without any collaboration

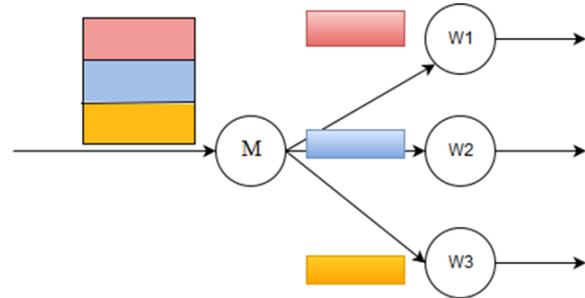
with the other workers. Parallel for is a paradigm characterized by parallelizing sequential iterative for loops with independent iterations [7]. Fig. 11 shows the Map paradigm.


Fig. 11. Map Paradigm.

D. Fast Flow (FF)

Fast Flow is a C++ parallel programming framework that focuses on high-level, pattern-based parallel programming. It supports streaming and data parallelism. It allows expressing the combination of different patterns which increases the parallelism exploitation possibilities [8].

V. Parallel Implementation of OpenCV

OpenMP is a programming framework that greatly simplifies writing multi-threaded programs in Fortran, C, and C++. This programming framework provides loop parallelization with parallel for. Besides being able to implement parallel loops when iterations are independent, it also has the notion of task parallelism which allows assigning different dependent or independent tasks to different threads. To write efficient programs with OpenMP, we need to understand all the additional parameters of the OpenMP pragmas and also the concurrent accesses performed on shared data structures. To implement parallelization, OpenCV uses a hierarchy of tools [9]. The first tool found in the user machine is the one that is going to be applied. For our specific case, all the parallelization implemented by OpenCV was performed with OpenMP. For the object detection task, OpenCV automatically parallelizes the data in each scale with a row-wise Parallel which divides the computation space into a collection of detection windows. Each detection window is calculated independently without any need for synchronization. If the user doesn't specify the number of threads to be used, OpenCV will automatically use all of the available threads. Fig. 12 shows the OpenCV parallelization inside each scale.

A. Convert an RGB Image to a Grayscale

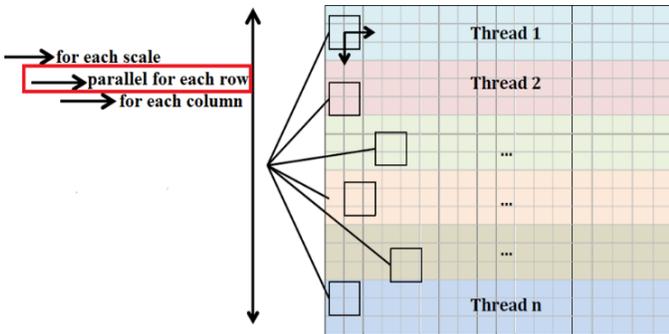
There is no data dependency between the three channels composing an RGB image when performing the grayscale conversion [40]. In this way, we can exploit the Map paradigm to parallelize this task. Synchronization is needed to have the equivalent grayscale of each channel. The final step is to merge the three-channel grayscale images into a single one. Fig. 13 shows the process of Converting an RGB image to a grayscale.


Fig. 12. OpenCV Parallelization Inside each Scale.
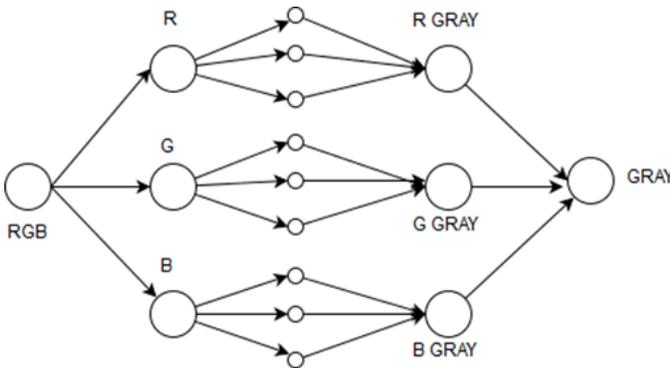

Fig. 13. Converting an RGB Image to a Grayscale.

B. Histogram Equalization

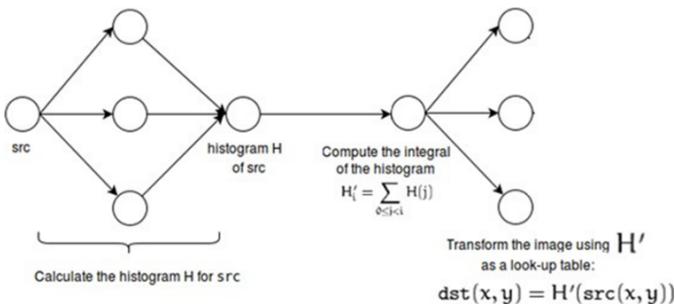
When performing histogram equalization, it's possible to exploit the Map paradigm in which the image is split to compute the histogram H of the source [11]. A synchronization point is needed to have the final histogram H. The computation of the histogram integral image is performed using a pair of recurrences. Transforming H´ as a look-up table can also be performed independently by applying the Map paradigm. Fig. 14 shows the process of Histogram equalization.


Fig. 14. Histogram Equalization.

C. Detection Window

The face detection computation space is partitioned into a set of detection windows, which can be computed independently without the need for synchronization. The schema for this case is the same as Fig. 11 showed for the Map paradigm

in which the input image is partitioned and detection windows would be applied in parallel in each of the partitions.

D. Haar-Feature Calculation and selection

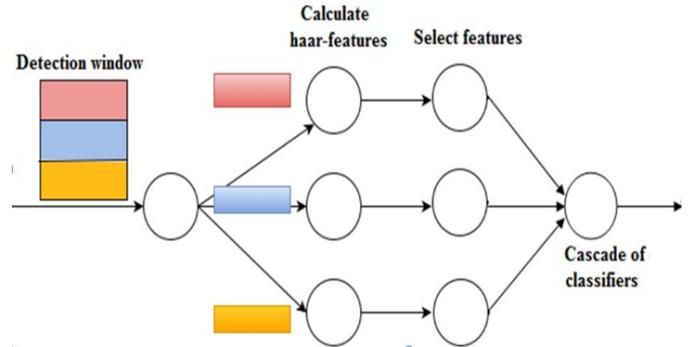
Inside each detection window no data dependence on the feature value calculation and selection in such a way that each feature can be calculated and selected in a completely independent way [12][10]. All the selected features are sent to the cascade of classifiers shown in Fig. 15.


Fig. 15. Haar-Feature Calculation and Selection.

E. Feature Evaluation

All the chosen functions are evaluated through the levels of the cascade classifiers which may be parallelized to the usage of the pipeline paradigm. Map paradigm in which each feature instead of being partitioned is sent entirely to all the filters. This process is known as multicast. A synchronization point is needed to compute the outcome of the stage. The detection window is automatically discarded if the outcome of one of the stages is negative. The face detection cascade of classifiers has 22 stages. The number of filters for each stage can be seen in Fig. 16 below.

Stage	0	1	2	3	4	5	6	7	8	9	10	11	12
Filters	3	15	21	39	33	44	50	51	56	71	80	103	111

Stage	13	14	15	16	17	18	19	20	21
Filters	102	135	137	140	159	177	181	210	213

Fig. 16. Stages of Face Detection Classifier.

Fig. 17 shows Cascade of classifiers.

F. Feature Evaluation

We must scale down the input picture according to the supplied scale factor until it is the same size as the detection window to locate all potential faces of various sizes. Without the requirement for synchronization, each scale of the incoming picture may be handled in parallel. The schema for this case is the same as the figure shown on the Farm paradigm in such a way that each scale would be sent to a worker. The overall parallelization scheme can be seen in Fig. 18 below which the red circles represent.

Fig. 19. Stages.

use FastFlow. The pipeline completion time depends on the slowest stage which in this specific case is stage 2. This stage completion time can be approximated by the face detection task time, so the cost model of the pipeline can be derived as Tc = N x face_detection() where N is the size of the stream. Therefore, to fully exploit the pipeline paradigm and take into account the completion time of each task, it becomes very important to be able to parallelize the face detection procedure internally.

A. Face Detection Task Parallelization

The face detection task processes a pyramid of scales of the same frame. The image pyramid allows face detection to be scale-invariant. There is no dependency between the processing relative to the different scales, they can be executed in parallel without any need for synchronization. The computation time is different between the scales due to their different size while applying the same detection window. Fig. 20 shows Image pyramid.

Fig. 17. Cascade of Classifiers.

Fig. 18. Overall Parallelization Scheme.

Fig. 20. Image Pyramid.

VI. Additional Parallelism to the OpenCV Viola-Jones Implementation

We will focus on providing additional parallelism to the OpenCV implementation of the Viola-Jones algorithm. We will also discuss ways of improving the existing OpenCV parallel implementation. The most straightforward approach to parallelizing a stream computation made up of phases that must be executed serially is to implement a pipeline paradigm. One important aspect to take into account when using the pipeline paradigm is that the stages must be somehow balanced to exploit all the benefits of this parallelization. The proposed pipeline stages are in Fig. 19. For the results that support this pipeline configuration to implement this paradigm, we will

B. Considerations about OpenCV Parallel Implementation

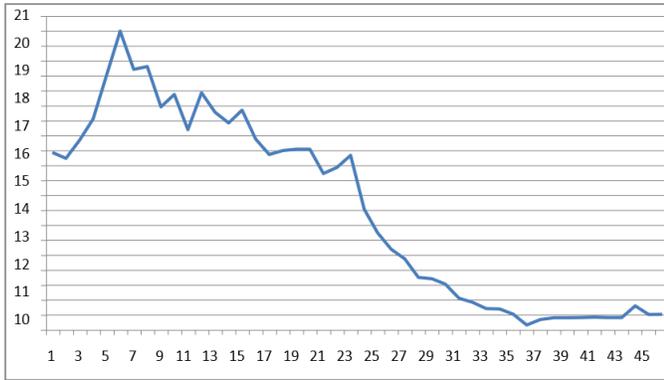
OpenCV internally parallelizes the computation relative to each scale using the parallel paradigm. Externally, the scales are executed sequentially, one after the other. Even though the image scales are of different sizes, the same number of threads is assigned to compute all of them. For this specific case, the face detection task generated an image pyramid of 46 scales. We measured the time of each scale using a thread number between 1 and the maximum number of threads available (24 in this case). As evidenced in Fig. 21, the scalability achieved with 24 threads is very significant for scales of bigger size while on the other hand is negligible for scales of smaller size. If we consider the efficiency, it decreases as the number


Fig. 21. Scalability Achieved with 24 Threads.

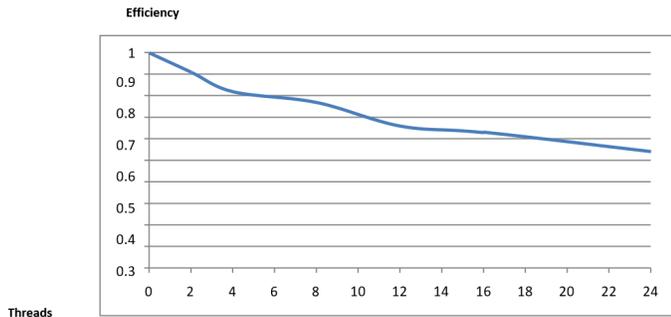
of threads increases Fig. 22. When considering the efficiency of each scale with 24 threads Fig. 23, it decreases drastically from the second half (from scale 24 to 46 of Fig. 23).


Fig. 22. Efficiency Achieved (1).
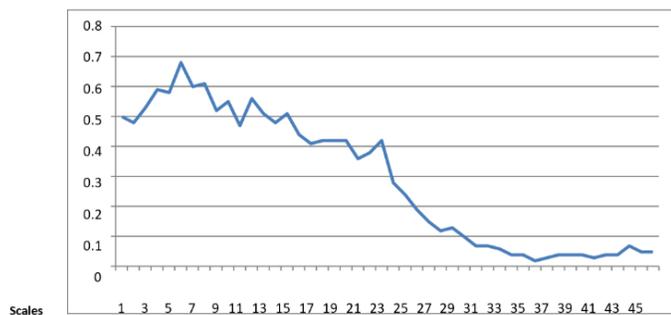

Fig. 23. Efficiency Achieved (2).

C. Improvement to the OpenCV Parallel Implementation

Analyzing deeply the results obtained from the Fig. 23 above, it's possible to realize that we can optimize the parallelization with 24 threads in the following alternative ways shown in Fig. 24.

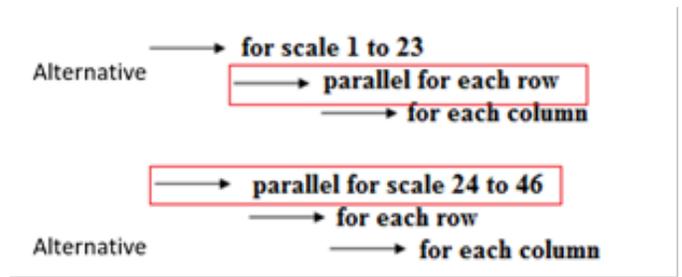
Since in both alternatives we are parallelizing for loops, OpenMP is the most suitable parallelization tool. We can see that executing in parallel from scale 24 to 46 but inside executing serially each scale, without taking into account any


Fig. 24. Parallel Implementation.

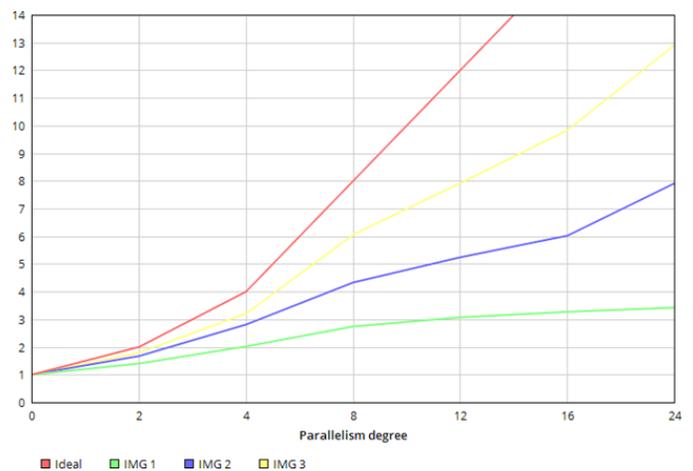
overhead, the computation time can be roughly approximated to the time spent to execute the slowest scale (which is scale 24) with 20.62 milliseconds. But if we take the OpenCV approach which executes the scales serially while performing a row-wise parallel computation inside each scale, the execution time from scale 24 to 46 with 24 threads is roughly the sum of the times of each scale on this range which is 44.437 milliseconds. So, with the optimized approach, we can get about 2.15x speed up for the OpenCV approach. Assigning computation of different scales to different threads would fall under the category of embarrassingly parallel or farm paradigm. A dynamic load balance technique can be applied in this case such that when each scale finishes its execution, it frees the resource. In all circumstances when the exact quantity of labor of activities cannot be exactly stated before the activities take place, this strategy may provide better load balancing. Based also on other performed tests which demonstrated similar (scalability) results like the ones shown before, we divide the total number of scales by half. The heavy-sized scales in the first half would be parallelized using a row-wise parallel, while the light-sized scales in the second half would be parallelized by computing each scale in parallel. From Fig. 25 is possible to notice that the face detection parallelization is rather coarse-grained as the best scalability was achieved while the smaller one achieved the worst result.


Fig. 25. Face Detection Parallelization.

D. Specific Approach: Single Face Detection

For this specific case, before finding a face the paralleliza-tion technique is the same as the one described above in the proposed heuristic solution. Once the face is found, taking advantage of the optimization, where the number of scales and the computation time is reduced drastically, as it is possible to see from the Table (II) below, the parallelization paradigm that could be applied is the farm where each scale would be assigned to a specific number of the worker. One could argue that after finding a face no further parallelization is needed taking into account that the number of scales and the computation time of each scale is reduced drastically. For our specific case, we can see from Table (II) that the sequential implementation would take as much as 4.01 milliseconds to complete while in the best-case scenario, without overheads, the parallel implementation would take 0.95 milliseconds. It is worth remembering that the results of the Tab. 2 were obtained with the largest image of our experiments (Size 2448 x 2448) which represents the worst case of the face sizes. When introducing further parallelization to this part, we need to take into account the trade-off between the gains of the parallelization and the additional overheads that it comes with as even in the best-case scenario the gains can be very negligible (around 3 ms for our case).

TABLE II. OPTIMIZED RESULTS FOR SINGLE FACE DETECTION

Scale	Size	1-thread[ms]
1	2348x2348	0.87
2	2134x2134	0.95
3	1940x1940	0.80
4	1764x1764	0.76
5	1604x1604	0.44
6	1458x1458	0.18
7	1325x1325	0.01

E. Feature Detection Parallelization

In this case, we are not interested in parallelizing each feature detection phase internally, as the optimization proposed already allows for achieving higher speed up. The important point is to run all the features (eyes, mouth, and nose) in parallel using the MISD pattern which is a variation of the Map paradigm where each worker computes in different codes. Fig. 26 shows Feature detection parallelization.

A possible approach for detecting features in parallel for multiple faces could be applying the Farm paradigm in which each face would be assigned to a certain work and inside each worker [41], the MISD paradigm would compute the features in parallel in Fig. 27.

VII. RESULTS AND DISCUSSION

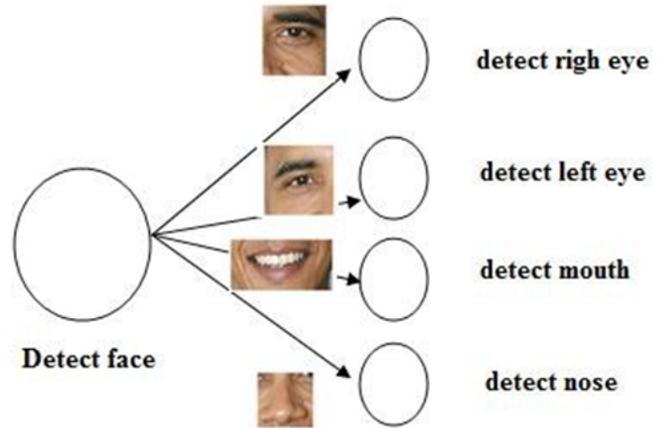
Our authors saw the testing on this application, and it was determined that splitting the face did not improve performance, therefore we opted to use the four-stage pipeline. When using the Multiple Face Detection Approach to test the application, the smallest image was able to achieve real-time processing with the GPU (around 38 FPS) and quasi-real-time processing with the CPU parallelized version (around 10 FPS), while the intermediate size image was able to achieve quasi-real-time processing with GPU (Around 17 FPS) [42]. The least and intermediate photos were able to achieve real-time processing


Fig. 26. Feature Detection Parallelization.
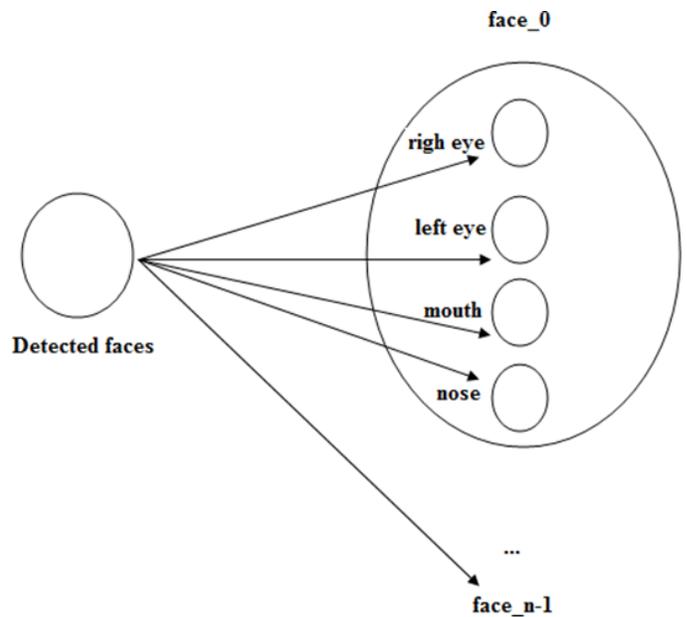

Fig. 27. Detecting Features in Parallel for Multiple Faces.

with all implementations save the originally sequential one when we ran the same trials with the Single Face Detection Approach. With the parallel CPU and GPU implementations, the largest image was able to accomplish real-time processing [43] [44]. When the application was tested on video frames, it was discovered that the size of the face had a direct impact on the sequential and parallel CPU implementations optimized for single face detection. We demonstrated that for the largest image size, the optimization introduced, allowed to decrease in the number of scales from 46 to 7 and the number of processed sub-windows from 8 443 722 to 704 which implies a reduction of 99.99% of processed sub-windows. The reliability tests showed that our application is very reliable in different scenarios such as distance, light conditions, occlusion, and rotation [45]. We demonstrated that it is possible to coexist the two parallel programming frameworks utilized in our application (Fast Flow and OpenMP) to exploit all the available resources on CPU Multi-Core Platforms.

VIII. Conclusion

This paper aimed to Parallelize Image Processing Algorithms for Face Recognition on Multicore Platforms. The heavy-sized scales in the first half would be parallelized using a row-wise parallel, while the light-sized scales in the second half would be parallelized by computing each scale in parallel. When the face detection methodologies were analyzed, was concluded that the ones based on learning algorithms (appearance-based) allow for achieving better results because eliminate the potential modeling error as a result of incomplete or inaccurate face knowledge. The state-of-the-art algorithms can process images extremely rapidly based on three innovative contributions: "The integral image, the AdaBoost learning algorithm, and a cascade of classifiers". The Viola-Jones algorithm is still not optimal as the detector becomes unreliable for faces with a certain rotation, the detector may fail when the faces are very dark while the background is relatively light and the detector fails on significantly occluded faces. To render the face detection process faster two optimizations were proposed. The first optimizes the face detection task based on the size of the face found on the previous frame. This optimization allows decreasing drastically the computation time. The drawback of this optimization is that it should be applied only for one face, or at most multiple faces that are somehow equidistant from the camera. The second optimization also allows decreasing the computation time as the size of the facial features to look for is based on a ratio to the size of the face found. To parallelize the entire face detection process, it was shown that the pipeline paradigm is the most suitable solution as the whole process is performed in a sequence of phases. To take advantage of the face detection parallelization on GPUs specifies that we need to minimize access to devise memory, transfers to and from the GPU must be timed to coincide with computation, and memory accesses to the GPU's global and shared memory must prevent bank conflicts, and branching inside kernels should be kept to a minimum. Our tests have demonstrated that our application can achieve real-time processing rates in different scenarios and it is reliable in various situations. A theoretical study on the reasons why the Viola-Jones algorithm may not allow multi-core platforms to be exploited to their full capacity. Future work includes studying in more detail the aspects and implementing them to verify their efficiency. Also, a more detailed analysis of some of the principles mentioned to take full advantage of the GPU hardware requires further investigation.

Abstract—Medical patient data need to be published and made available to researchers so that they can use, analyse, and evaluate the data effectively. However, publishing medical patient data raises privacy concerns regarding protecting sensitive data while preserving the utility of the released data. The privacy-preserving data publishing (PPDP) process attempts to keep public data useful without risking the medical patients' privacy. Through protection methods like perturbing, suppressing, or generalizing values, which lead to uncertainty in identity inference or sensitive value estimation, the PPDP aims to reduce the risks of patient data being disclosed and to preserve the potential use of published data. Although this method is helpful, information loss is inevitable when attempting to achieve a high level of privacy using protection methods. In addition, the privacy-preserving techniques may affect the use of data, resulting in imprecise or even impractical knowledge extraction. Thus, balancing privacy and utility in medical patient data is essential. This study proposed an innovative technique that used a hybrid protection method for utility enhancement while preserving medical patients' data privacy. The utilized technique could partition information horizontally and vertically, resulting in data being grouped into columns and equivalence classes. Then, the attributes assumed to be easily known by any attacker are determined by upper and lower protection levels (UPL and LPL). This work also depends on making the false matches and value swapping to make sure that the attribute disclosure is less likely to happen. The innovative technique makes data more useful. According to the results, the innovative technique delivers about 93.4% data utility when the percentage of exchange level is 5% using LPL and 95% using UPL with a 4.5K medical patient dataset. In conclusion, the innovative technique has minimized risk disclosure compared to other existing works.

Keywords—*Medical patients data publishing; anonymization; protection method for preserving the privacy*

I. INTRODUCTION

Data publication is the simplest data-sharing method, allowing research institutions to conduct data mining operations on published medical-patient databases for knowledge extraction. This knowledge represents, interprets, or discovers new patterns [1] [2]. However, the potential of published data has yet to be explored because scholars face several challenges when extracting information from published medical-patient data. One of these challenges is the patient data privacy, which results in the exposure of individuals' identities, unauthorized access to information and private data, and use of personal information for unintended purposes [1] [3] [17]. Even if the identity attributes (IAs) (such as names and social security numbers) that identify users from the patient table are removed based on data protection, the remaining patient data can be used to re-identify the person in most cases. Furthermore, sensitive attributes (SA) may continue to flow due to linking attacks, in which sensitive data are revealed by linking the remaining attributes, such as those in published patient data, with other available data sources. This is referred to as a composition or intersection attack [3] [17]. Several anonymization techniques in PPDP have addressed data privacy concerns while preserving data utility. The goal of data anonymization is to reduce the threat of revealing personal information while preserving the possibility of using published data and causing uncertainty in identity inference or sensitive value estimation [50] [3]. However, information loss is inevitable when attempting to achieve a high level of privacy. In addition, the anonymization techniques may affect the use of patient data, resulting in imprecise or even impractical knowledge extraction via data mining. In data applications, balancing privacy and utility is crucial. In addition, nearly every technique leaves a question unanswered about whether anonymized data can be used effectively for data mining [1] [3].

The main contribution of this paper study is to propose an innovative technique that utilized a hybrid protection method to increase the utility of medical patients' data publishing while preserving privacy. This study aims to solve the problem of identity disclosure individuals or disclosing the sensitive value in medical patient's tables whilst preserving data utility. This research's accomplishments are summarised in the following points:

- The design of an innovative technique based on the UL technique in order to prevent attackers from

identifying individuals or disclosing sensitive values in medical patient tables. In addition, the proposed technique stroked a better balance between utility, information loss, and privacy. The utilized technique could partition information into horizontal and vertical partitions. In the vertical partition, firstly, the attributes were separated into more than one. Then, the similar attributes were further grouped in a subset in a fashion that designated every attribute to a subset. Therefore, the subset of each attribute was called a cell (a pair of attributes), and the combination of these yielded the column. In the horizontal partition, the table was divided into different subsets so that each tuple could only be assigned to a single subset. Every subset of these tuples was referred to as a bucket or an equivalence class.

- A hybrid protection method can address the deficit in other existing works in determining the amount of protection required to prevent personal information disclosure. Instead of the random procedure employed in other works to break the correlations between the attribute values, the lower and upper protection levels (LPL and UPL) are then utilized in each equivalence class to determine the values of the unique and identical attributes for data privacy protection while keeping data utility. The LPL and UPL determine the level of protection surrounding the attribute values, ensuring that an attacker cannot get the sensitive information required to identify the record owner during such periods. This work also relied on value swapping within UPL and increasing the number of fake tuples within LPL as a safeguard against attribute exposure to any attack. The innovative technique protects published data from disclosure while increasing data value.

This paper falls into six sections: Section I provides the introduction and highlights the crux of the issue. Background and highlights the axes of privacy-preserving data publication are reviewed in Section II. Section III reviews relevant studies, Section IV describes the flow of research procedures in this paper, and Section V presents the evaluation of performance analysis. Finally, Section VI provide the conclusion and discussion of the study.

II. BACKGROUND

One of the advantages of pervasive computing (ubiquitous computing) is the generation of large information volumes known as "big data". The explosion of information has made retrieving private and public information on individuals a major part of everyday life [1] [30]. Typically, companies, such as health care, maps, and education acquire data to meet legitimate needs. Most data can be unstructured or intricate; a considerable portion of this data has been generated by a number of sources, like records of business sales, sensors in the use of Internet of Things, medical records of patients in hospitals, social media, and images and video archives. Big data processing using traditional data processing applications is becoming difficult [2]. Nevertheless, considering the Internet co-dependency and the IS, i.e., information systems, this data can be susceptible to corruption, theft or individual privacy

violations [3].The ability to own data and extract new knowledge, which is known as data mining, is now considered a key competitive advantage [4].

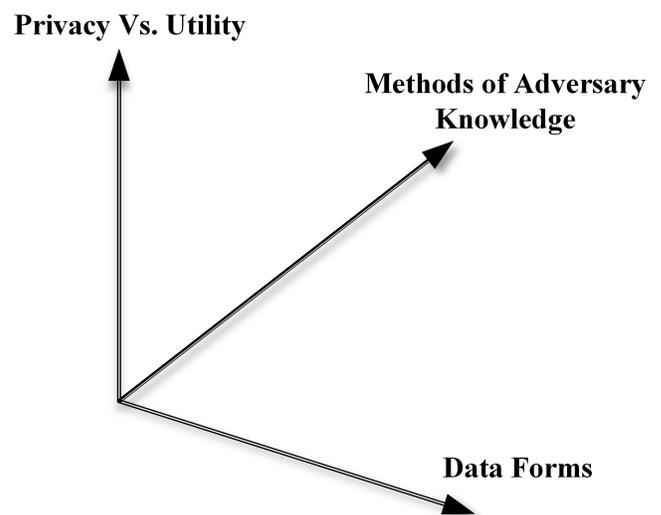
Apart from the importance of extracting new knowledge (data mining), which is significant in many applications, an increasing concern has been focused on the privacy threats that emerge during data publishing for data mining operations, where numerous establishments need to publish data in different formats to extract new knowledge [4]. As a result, there has been a lot of focus on potential data privacy infractions as well as data exploitation; hence, effective data protection must be assured because failure may result in scenarios that can harm individuals and organizations [5] [6]. As a result, many organizations must choose between providing information and safeguarding their privacy in order to obtain this essential information [1]. This situation has motivated and prompted researchers to create a new research area known as privacy-preserving data publishing (PPDP) [7] [8]. This new research area is a sub-field of data mining that has gaining traction, which began as an encouraging model for providing first-hand solutions to address the current dilemma. Besides that, various methods have been developed for protecting information privacy, or wide-ranging policies have been imposed to safeguard sensitive data in PPDP [1] [3]. The primary goal of PPDP is to make a portion of these data available to all, from which it is utilized effectively for various tasks of data publication like application in future research and, at the same time, achieving the privacy of individuals' information [3]. Although it is helpful, information loss through protection methods is inevitable when attempting to achieve a high level of privacy. In addition, these protection methods in PPDP may affect the use of data, resulting in imprecise or even impractical knowledge extraction. Furthermore, the privacy-preserving data publication (PPDP) is dependent on three axes: 1) data forms 2) Privacy Vs. Utility, and 3) methods of adversary knowledge (Fig. 1). These three axes will be described in the subsequent subsections in detail.


Fig. 1. Overview of Research Axes in PPDP.

A. Data Forms

Nowadays, the fast-growing number of Internet users and linked devices to ubiquitous computing have led to the generation of massive data volumes. It is essential to transform this gigantic, generated data into various forms for extracting valuable information embedded in massive data and providing many opportunities for advantages in different fields [2] [9]. Data forms, from which the types of data to be handled are selected, are seen to be a crucial component of the PPDP. The medical-patient database is one field where the deployment of big data can result in substantial changes. It can significantly raise the standard of patient care and provide insightful data that will help enhance patient outcomes, lower healthcare delivery costs, lower preventable diseases, and increase the overall quality of life.

Medical-patient databases are comprised of a wide range of records. Every record (i.e., row) signifies one client and includes a number of attributes specific to the selected client as shown in Table I [10] [11]. Such attributes are categorized into three categories [12] [13]: Identifying Attributes (IA), which distinguish explicitly the owner's records like his/her name, mobile number or the number of the driving license; Quasi-Identifier (QI) attributes, which denote the non-explicit attributes' sequence of individuals, including his/her age, gender, race, ZIP code, and date of birth as these attributes identify the record of the owner when these attributes are combined; and Sensitive Attributes (SA), which contain confidential data of individuals, such as diseases [14].

TABLE I. MEDICAL PATIENT DATABASE

Identifier (IAs)	Quasi-Identifier (QI)			Sensitive (SA)
Name	Age	Gender	Zipcode	Disease
Carl's	29	Female	462350	Disease
Abraham	22	Male	462351	Cancer
William	27	Male	150352	Flu
Linda	43	Female	462350	Heart Disease
Camila	52	Female	462350	Cancer

Much of the work done in PPDP is related to the static data publication form, with the idea of one record per person, and these records are presumed to be independent of various data publishers [10] [15] [16] [17]. However, the data form may be dynamic, i.e., it may be published consecutively while being changed by the same data publisher [18] [19] [20] [21]. The problem with static data publication forms is that it is possible for multiple organizations to publish a person's information at once [22]. In this situation, an attacker can use the published dataset and then, use a composition attack [23] [17] to change the dataset's privacy. An intruder commits a composition attack when he or she tries to find out who someone is by linking the different available attributes (QIs) in published available data to an external database to get sensitive information [23]. Therefore, the only way to protect people's privacy is to change these attributes in the available published data to hide the connection between a person and a specific value. This will stop these kinds of attacks and keep the public data usable [17].

B. Privacy vs. Utility

This aspect might be the most significant and fascinating aspect of the PPDP paradigm because any sanitized release of published data needs to address the trade-off between privacy and utility [1]. The common practice of sanitized data primarily depends upon certain guidelines and policies for restricting the publishable data types to achieve privacy. This common practice of sanitizing data is limited because it excessively falsifies data or demands a high level of trust in different scenarios of data-sharing impractically [24]. However, data privacy involves protecting private data from people who must not access this information and the individuals' capability to determine or interfere with the identity of individuals who can have access to their personal information. Developing protection tools and mechanisms for data publication is of is a major challenge so that the published data are practically usable and valid while the individuals' privacy is protected. A privacy policy is, therefore, a must to ensure that the sanitized release is safe from any attempts of intrusion while still being beneficial to the end-users. This means that there should be a balance conceived between these two notions, including utility and privacy [1].

One of the most prevalent and commonly utilised procedures in PPDP for providing privacy for individuals while retaining data utility is the anonymization technique of data before publication, which has previously been defined according to [25] as a group of certain protection methods, which aim to mitigate the risks of information disclosure for individuals, organizations or other businesses. The anonymization techniques use different protection methods and may be combined within the same technique, with the goal of causing uncertainty in identity inference or sensitive value estimation [25]. Some of these existing and most used protection methods are suppressing or generalizing [21] and perturbation [26] [27] [28] [29].

C. Methods of Adversary Knowledge

The assumption regarding the methods of adversary knowledge has led to the creation of alternative techniques and innovative protection methods. Although these techniques with protection methods provide a certain level of privacy preservation, it is crucial to examine the existing resources on adversaries regarding externally accessible data and different potential inferences for privacy-preserving of data. Privacy-preserving is classified into three categories based on the methods of adversary knowledge [24]:

The first category is that a certain privacy threat can occur when the attacker links the QI attributes within the published information with other available data sources. The attacker relies on the intersection of the datasets to exploit sensitive information since datasets are rarely isolated. This situation is known as a composition attack (i.e., the linking attacks), or an intersection attack [3] [17].

The second category is known as background knowledge attack. The attacker knows that the victim's record is in the released table or that the attacker has knowledge of some QIs for victims because the attacker is a close relative of the patient. The aim of the attacker is to link this knowledge for disclosure of sensitive attribute [1] [3]. The publishing table

is regarded as privacy-preserving when it effectively prevents the attacker from performing linkages successfully.

An uninformative principle is the aim of the third category. This published table must give the attacker very little extra information outside the specified background knowledge. When the attacker possesses a larger distinction between prior and posterior beliefs, this attack is called a probabilistic attack. The inability to categorize many QIs attributes into a published table and to keep it without change (or modification) leads to a probabilistic attack and the possibility of accurately extracting the attributes of a person [1] [17] [24] [29].

III. RELATED WORK

Data collectors collect a large amount of information from data owners and publish it so that data mining can provide a wide range of unprecedented potentials deemed necessary for providing meaningful information about data and improving the quality of medical patient data [2]. The data collected possibly hold the sensitive personal data of individuals. Thus, the goal of privacy-preserving data publishing (PPDP) is to release the data without publishing the private information about the owner of the data whilst preserving data utility in order to use them in any kind of medical or social analysis, etc. [48] [51] [52]. Differences in their concepts lead to differences in their protection methods. Binjubeir et al. [1] asserted that no general solutions could handle all privacy issues related to keeping sensitive information from unwanted disclosure. Hence, many techniques are used to provide privacy [53].

Despite the overlap between privacy and confidentiality in some contexts, when it comes to protecting people's privacy, there are certain ways they differ, especially related to their concepts and methods of protection. Confidentiality is seen as data-related, meaning that it is more about the data themselves, and it aims at protecting data from unauthorized access, alteration, or loss when transferred over a network [1] [54]. On the contrary, privacy has an additional "data owner-oriented" concept as it deals mainly with the data owners and aims to protect the private information of the data owners [55]. Hence, the current study uses PPDP as a way to keep sensitive data from being used illegally and to keep it safe from any threats. Consequently, there has been a lot of research on PPDP techniques over the past few decades.

The PPDP began with k-anonymity by Samarati and Sweeney [31]. Their work has been extended to cover various anonymization techniques like t-closeness [10], the l-diversity [32], (α, k)-anonymity [33], and Mondrian [34]. However, the aforementioned techniques have been susceptible to the composition attack [2] [23] because if two separately published tables satisfy a certain privacy principle, there will be no assurance that each pair's intersection for the equivalence classes of these two tables will be satisfying this same principle. Besides that, a higher dimensionality renders these techniques useless because the main record holders' identities are disclosed by combining the data with a public data (i.e., composition attack) [17] [35]. Readers can refer to [1] [36] [37] [38] for comprehensive studies on these techniques. Table II presents a summary of the PPDP protection techniques by offering the advantages and limitations of each technique.

Moreover, there are some techniques based on the dynamic data publication form [18] [20] [21] in addition to the static data publication form [10] [15] [16] [17]. The introduced techniques tackle composition attacks explicitly by utilizing an intersection of two or further sets of published data for uncovering individuals' sensitive information. In this anonymization process, which manages the dynamic data publication form, the data owner recognizes the entire versions of these published data and uses this information in these published versions for anonymizing the existing data set. For this study, the data owner has no knowledge of other datasets, which might be manipulated for the composition attack. Consequently, the data publications of various data custodians will be independent. However, the problem can be more challenging.

The most recent famous techniques for static and dynamic data publication form are the hybrid technique [35], e-differential privacy technique ($e-DP$) [39], slicing technique [29], merging [17], and UL method [3]. All techniques have endeavoured to create privacy-preserving by using different protection methods.

As a protection method against sensitive value disclosure, the hybrid technique in [35] uses a combination of sampling, generalization, and perturbation. While the generalized data have been used as a method of protection in the $e-DP$ technique. The $e-DP$ technique in [39] probabilistically constructs a generalised contingency table and then adds noise to the counts. By using differential privacy-based data anonymization, the $e-DP$ can give robust privacy assurance for statistical query response and protect against the composition attack [23]. According to [17] [35] [40] [41], utilising the $e-DP$ for composition attack protection can result in significant data utility loss during anonymization.

The disclosed slicing technique [29], which is regarded as an innovative data anonymization technique in PPDP, has garnered a lot of attention. The authors [17] [29] [3] presented a non-generalizable risk disclosure preventative protection method. As a result, because the attribute values are not generalised, slicing protects data privacy while also preserving data utilities. These techniques [17] [29] [3] partition the data horizontally and vertically. In the vertical partitions (i.e., attribute grouping), the extremely associated attributes can be grouped into specific columns with every resulting column containing the attributes' subset. In horizontal partitions (i.e., the tuple partition), these tuples can be grouped in specified buckets or equivalent classes (Table III). The adoption of various protective methods causes the relationship between separate columns to be broken. This solution protects the privacy of public records from the hazards of attribute and membership exposure. Furthermore, slicing is preferred for high-dimensional data anonymisation since it preserves more data utility than attribute value generalisation. It is thus preferable to formalise slicing for a fuller comprehension. Consequently, the slicing formulation has been followed as suggested by Li et al. [29].

A. Attribute Grouping

The microdata table T consists of a set of t, $t \in T$ and n the number of a attributes, where t is a tuple of T and t is represented as $t = (t[a]_1, t[a]_2...t[a]_n)$, where

TABLE II. A SUMMARY OF PROTECTION METHODS FOR PPDP TECHNIQUES

Techniques	Protection Methods	Strength	Weakness
K-Anonymization	When the values of the QI attributes are modified, it is harder for an attacker to figure out who a person is. At the same time, the released data remains as helpful as possible, and the K value is used as a measure of privacy	This technique protects an individual's identity while releasing sensitive information	Indirect attacks on k-anonymity, like homogeneity attacks, background knowledge attacks, and composition attacks, make it possible to figure out exactly what a person looks like. Also, the high dimensionality renders this technique ineffective
L-diversity	This technique works to treat the values of a specific attribute similarly, regardless of its distribution in the data, thereby resulting in the sufficient representation of SAs within each equivalence class	This technique attempts to preserve privacy by a sufficient representation of SAs within each equivalence class	This technique is subjected to skewness attacks, similarity attacks, and composition attacks. Also, the high dimensionality renders this technique ineffective
T-closeness	The SA distribution in any equivalence class should be similar to the distribution of the attribute in an overall table	This technique works to distribute SAs in any equivalence class similar to the distribution of the attribute in an overall table, which leads to preserving privacy	This technique can't protect the critical values of the records from a composition attack reliably and constantly. In addition, The high dimensionality renders this technique ineffective
Mondrian	Partitioning the domain space recursively into several regions, each of which contains at least k records. A set of QI values are generalized in each equivalence class	Getting an anonymous dataset	This technique can't reliably and always protect the important values of the records from a composition attack. Also, most classification tools don't work well with overlapping intervals because they make it hard to classify things
(α, k)-anonymity	This technique integrated two novel concepts: (α, k)- anonymization by sampling and generalization for independent datasets to protect against composition attack	This technique effectively protects privacy and preserves data utility	There is still more data loss

TABLE III. A PUBLISHED DATA BY SLICING

(Age, Gender)	(Zipcode, Disease)
(30, F)	(130350, ovarian cancer)
(23, M)	(130350, heart disease)
(28, F)	(130352, Flu)
(53, F)	(130350, heart disease)
(39, F)	(130352, Flu)
(60, M)	(130351, heart disease)

$t[a]_i \leq i \leq n$. In attribute partitioning, first, the attributes are separated into more than one; then, relevant attributes can be arranged in a specified subset, whereby each set can belong to a single subset only. Hence, the subset of each attribute is called a cell, and the combination of these yields the column. In the microdata table T, there are col columns, including $col_1, col_2...., colc$ satisfying $\bigcup_{i=1}^{c} col_i = a$ and for any $1 \leq i_1 \neq i_2 \leq col$, $col_{i,1} \cap col_{i,2} = \emptyset$. In these sensitive attributes, the sensitive attribute can be placed into the last-place position for an easy representation.

Definition 1 (cell): A cell represents one pair of attributes like (Gender, Age), where any cell $C_{col,E}$ is identified by the number of columns col_i and number of an equivalence class E_e. For example, in Table III, any cell in column (Age,

Gender) is identified by col_i and E_j, where $1 \leq i \leq col$ and $1 \leq i \leq E$ and the first equivalence class is consisting of tuples $t = t_1, t_2, t_3, t_4$.

B. Tuple Partition

The goal of tuple partition is to generate different subsets of T in a manner that each tuple can only be assigned to only one subset. Each subset of tuples is known as a bucket or an equivalence class. Assume there are E equivalence classes, $E_1, E_2, ...E_e$ then, $\bigcup_{i=1}^{e} E_i = T$ for any $1 \leq i_1 \neq i_2 \leq e$, $E_{i,1} \cap E_{i,2} = \emptyset$.

C. Problems of Slicing

Slicing depends on the application of attribute grouping and tuple partition T. In Table III, by measuring the associations (similarity) among the attributes, the attribute group is applied, where very associated attribute values can be sorted into specified columns and uncorrelated attributes can be aggregated into other columns. The attribute partition can be characterized by Gender, Age, Disease, Zip Code, whereas the tuple partition is applied by grouping tuples into an equivalence class $\{t_1, t_2, t_3\}$, $\{t_4, t_5, t_6\}$. The central part of this tuple partition involves grouping all tuples that contain identical values in a similar equivalence class or it can be close to one

another, thereby making it easier to breakdown uncorrelated attributes, and check whether an equivalence class satisfies I-diversity [1] [3] [34].

For slicing, the values of attributes are randomly permutated between the uncorrelated attributes for breaking the association among distinctive columns, whereas the attributes in columns that are highly correlated remain unchanged. However, the aspect of it remains an open question, i.e., "Does randomness always protect the identities of individuals from disclosure?" Slicing can have an impact on data utility and privacy, such as randomly permuting attribute values in each bucket, which increases the likelihood of creating bogus tuples, which reduces the utility of the released microdata. Furthermore, bogus tuples can easily cause various problems and wrong results in data mining process challenges. An attacker can learn about the implemented anonymization technique by analysing the spurious tuples in the published table, potentially breaching the privacy of public data [42] [3].

Hasan et al.[17] developed the merging technique to secure personal identification from disclosure. This been regarded as an extension of slicing. Merging's primary purpose is to preserve privacy in many separate data releases by employing cell generalisation and random attribute value permutation to seperate connection between various columns. Regarding privacy risks and data utility, the merging technique conserved data usefulness while posing minor privacy hazards because of increased false matches in the released datasets. Nonetheless, the merging technique's significant weaknesses are the randomised permutation way for the attribute values to breach the relationship between the columns and the increase in false matches for unique attributes. However, there will be a large number of matching buckets (more than the initial tuples), resulting in utility data loss, and could generate inaccurate and infeasible knowledge acquisition from data mining operations cite43 [44]. As a result, the main reasons for revealing people's identities are unique attributes or the ability of some cells in the tuple to match with cells in other tuples in the same equivalence class, allowing precise extraction of a person's attributes [1] [17] [29].

BinJubeir et al. [3] developed the UL technique as an efficient means of identifying the level of data protection required and selecting the best way to accomplish that level while keeping data utility. A lower level of protection, i.e., (LPL) and an upper level of protection, i.e., (UPL) can be employed to overcome these unique attributes with an identical data presence for data privacy protection. The unique attribute values are overcome by LPL, whilst the high identical attribute values are overcome by UPL. The LPL and UPL variables determine the level of protection surrounding the attribute values, ensuring that an attacker cannot access the sensitive information required to identify the record owner within such a time frame. The UL technique also makes use of value swapping to reduce the danger of attribute disclosure and increasing l-diverse slicing. Table IV illustrates the previous works which has been discussed of PPDP techniques for multiple independent data publishing. Some note that PPDP techniques are typically used to determine the level of privacy protection and information loss [56]. The two essential principles discussed here are privacy protection from any attack and data loss. The privacy preservation level refers to the degree of

difficulty of estimating original data from perturbed data [57]. On the other hand, the information loss is a situation in which a significant portion of information of the original data set is lost after data anonymization.

The main contribution of this paper is to suggest an innovative technique that uses a hybrid protection method to enhance utility while protecting the privacy of medical patients' data. The new technique proposed in this work is expected to keep data private while making patient data publishing more useful.

IV. Flow of Research Procedures

The flow of the research procedure is described in this section. It talks about the stages and methods that were used in this study to reach the research goals. As mentioned in the related work, many techniques have been proposed to address all privacy issues concerning protecting sensitive information from uninvited disclosure while preserving the utility of the data. However, there are still ways to enhance the utility of data while preserving user privacy. In essence, this study focuses on designing an innovative technique-based on UL technique that uses a hybrid protection method to enhance utility while protecting the privacy of medical patients' data. Besides, this work used the UPL and LPL methods for anonymisation, which is more effective in determining the amount of protection required. UPL and LPL are choosing cell values that help identify disclosure and break the link between them by using a hybrid protection method (see Stage 3: protection methods) to keep data private while making patient data publishing more useful. This study aims to get a certain level of privacy while ensuring that as little information as possible is lost during data mining. So, this study aims to ensure that composition attacks and background knowledge attacks are less likely to happen when different independent hospitals release anonymous patient data while keeping the data intact. The flow of the research procedure consists of three main components, as depicted in Fig. 2. These three components are described in depth in the subsections that follow.

A. Research Gap

In related work, an analysis of how published data can be kept private is given. The main problem that has been found is when hospitals share patient information that could help them improve their efficiency and achieve their goals for the future. Sensitive Attribute (SAs) may still flow due to linking attacks wherein sensitive data may be revealed by linking the QI attribute in the published data with other available data sources. This situation is known as a "composition attack" or "intersection attack". Also, many anonymization techniques fail to show a better balance of usefulness and privacy before any data product is made public. The criterion for evaluating the efficiency of the anonymization technique is the capability of data privacy preservation by decreasing the vulnerability of revealing people's data and protecting the likelihood of the published data being used [3] [50] [17]. Previous techniques [29] [17] [34] [35] [39] recurrently resort to using protection methods, such as suppression and generalization, randomization, and/or combined. This work proposes designing an innovative technique based on the UL technique that uses a hybrid protection method to enhance utility while protecting

TABLE IV. A SUMMARY OF PPDP TECHNIQUES

Techniques	Protection Methods	Strength	Weakness
hybrid	This technique combines sampling, generalization, and perturbation by adding the Laplacian noise to the count of every SA value in each equivalence class	The proposed work reduces the risk of composition attacks and preserves data utility	There is still more data loss
$(e-DP)$	First probabilistically generates a generalized contingency table and then adds noise to the counts	$e-DP$ provides a strong privacy guarantee for statistical query answering and protection against a composition attack by differential privacy-based data anonymization	This technique is subjected to skewness attacks, similarity attacks, and composition attacks. Also, the high dimensionality renders this technique ineffective
Slicing	This technique uses vertical partitioning (attribute grouping), horizontal partitioning (tuple partition), and its sliced table should be randomly permutated	Slicing provides data privacy by randomly permutated of data and preserves data utilities that is devoid of generalization	Random permutate for attribute values are led to creating invalid tuples which will negatively affect the utility of the published microdata
Merging	The primary aim of merging approach is to preserve privacy by increasing the false matches in the published datasets and it uses vertical partitioning, horizontal partitioning, and its sliced table should be randomly permutated	Getting an anonymous dataset and preserves data utilities	The major drawback of merging is the random permutation procedure and increasing the false matches in the published datasets
UL method	The (LPL) and (UPL) can be used to determine the level of data protection needed and employed to overcome unique attributes and an identical data presence for data privacy protection whilst preserving data utility	This technique effectively protects privacy and preserves data utility	There are alternative protection strategies that may preserve data utility and privacy.

the privacy of medical patients' data. The goal of the hybrid protection method is to discover the peculiar features to swap between them rather than a random way of separating the relationship amongst the attribute values used in other existing works to enhance the privacy of published patients' data and keep more data utility.

B. Research Methodology (Design The Innovative Technique)

The overall methodology for designing the innovative technique, as shown in Fig. 2, comprises three stages for protecting the published patient data from unsolicited disclosure. Meanwhile, published patient data remains as useful as possible. Fig. 2 illustrates the proposed innovative technique for patient data protection, at the same time preserving the utility of the data. The following is the discussion of these three stages.

Stage 1 is preparing the dataset. The datasets stage aims to initialize the dataset and measure the correlation between attributes. To evaluate the experiments with other existing works, a medical patient database was used for the experiments [45]. This dataset is the standard machine learning dataset known as the "Adult" [46] has been changed and added one new column called disease. The main reason for adding this column is to mimic the medical patient dataset. Ronny Kohavi, together with Barry Becker extracted and congregated this dataset from the 1994 United States Census Bureau. Accordingly, this dataset is made up of fifteen QI attribute with 48,842 tuples.

In the dataset initialization process, independent patient datasets were required for the simulation of the existent medical patient data publishing case, particularly in a case in which such datasets are separately published by various medical organizations that have similar records. However, the pitfall of this proposition lies in the fact that the data of an individual is often published by many medical organizations [22]. Under such conditions, any intruder can initiate a composition attack or background knowledge attack [23] [17] on such published patient datasets just to alter the privacy of the dataset. In the process of dataset initialization, this independent dataset is taken from a database of medical patients.

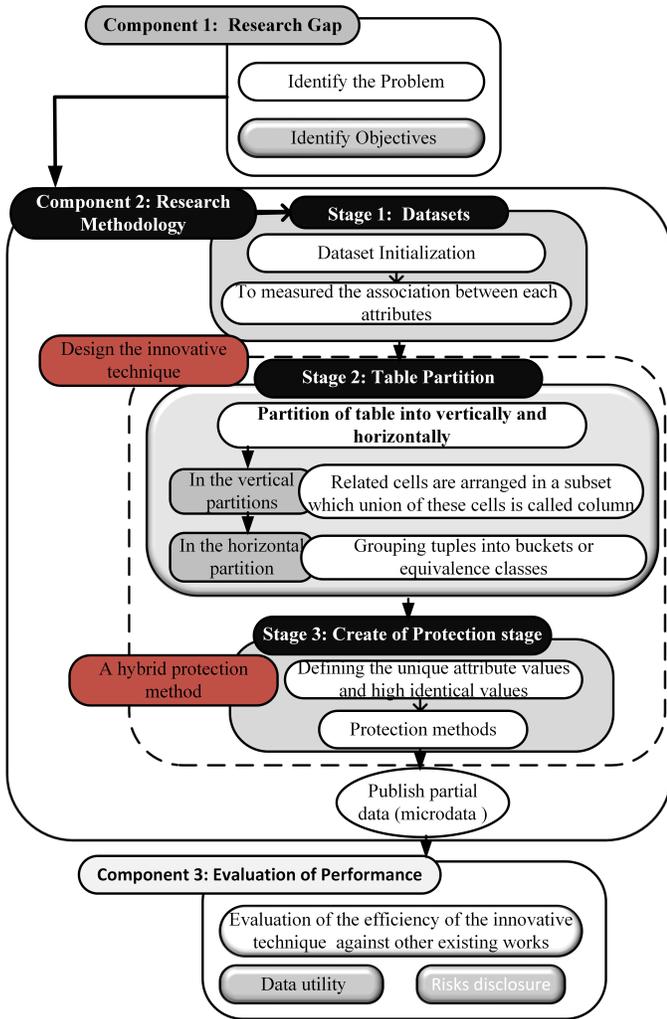
After the initialization process, the correlation between attributes is measured, where the initialization of dataset generates various medical patient datasets to simulate the actual independent medical patient data publishing scenario. Each medical patient dataset should be treated as microdata table T. In a case in which the microdata table T applied possess a_i attributes, where $i = 1, 2, ...$. The strength of the correlations between pairs of attributes can be computed using several methods [17] [3]. Because most attributes are categorical, the most suitable method for the estimation of the correlations between pairs of attributes is the mean square contingency coefficient (MSCC). The MSCC is a chi-square useful measure of the correlation between two categorical attributes. The value of this coefficient r ranges from $[0, 1]$. If there is a perfect relationship between the two attributes, it would be preferable to have the measure of the association have a value of 1.


Fig. 2. Flow of Research Procedures.

Otherwise, these measures differ in their maximum value. In case of no relationship between the two attributes, the measure of association has a value of 0. The MSCC between a_1 with value domain $\{v_{11}, v_{12}, ...v_{1d1}\}$ and a_2 with value domain $\{v_{21}, v_{22}, ...v_{2d2}\}$, and their domain sizes are d_1 and d_2, respectively. The MSCC between a_1 and a_2 is defined as follows [17] [3]:

$$r^2(a_1, a_2) = \frac{1}{min\{d_1, d_2\}} \sum_{i=1}^{d_1} \sum_{j=1}^{d_2} \frac{f_{ij} - f_i * f_j}{f_i * f_j} \quad (1)$$

, where $r^2(a_1, a_2)$ is the MSCC between a_1 and a_2 attributes; $f_{i.}$ and $f_{.j}$ refer to the occurrence fractions of the v_{1i} and v_{2j} in the data, respectively; and f_{ij} is the fraction of cooccurrence of v_{1i} and v_{2j} in these data. Therefore $f_{i.}$ and $f_{.j}$ are the marginal totals of $f_{ij} : f_{i.} = \sum_{j=1}^{d_2} f_{ij}$ and $f_{.j} = \sum_{i=1}^{d_1} f_{ij}$. $0 \leq r^2(a_1, a_2) \geq 1$.

Stage 2 deals with vertical and horizontal fractionalization of table. The dataset in the table is vertically and horizontally

fractionalized, depending on the computation of correlation r for respective attributes pairs. This phase is aimed at categorizing similar attributes according to the degree of their inter-attribute connections that are suitable for utility and privacy. Concerning the utility of data, closely connected attributes are categorized in order to make warrant that their inter-attribute connections are maintained. Notwithstanding, as regards privacy, detection of vulnerabilities is greater as a result of the categorization of unrelated attributes in comparison with the categorization of more connected attribute values, which makes them highly identifiable. In order to guarantee a higher level of protection, it is important to dissolve the connection that exists among the unrelated attributes [29]. The microdata table T consists of a set of t, $t \in T$ and n the number of a attributes, where t is a tuple of T and t is represented as $t = (t[a]_1, t[a]_2...t[a]_n)$, where $t[a]_i \leq i \leq n$. In the vertical partition, firstly, the attributes are separated into more than one, then, the similar attributes are further presented in a subset in a fashion that designates every attribute to a subset. Therefore, the subset of each attribute is called a cell (a pair of attributes), and the combination of these yields the column. In the microdata table T, there are col columns, including $col_1, col_2...., col^c$ satisfying $\bigcup_{i=1}^{c} col_i = a$ and for any $1 \leq i_1 \neq i_2 \leq col$, $col_{i,1} \cap col_{i,2} = \emptyset$. Furthermore, QIs, SAs, and all other attributes presented in columns $col_i, 1 \leq i \leq n$ They are clustered in n columns denoted by col_n, upon which the size of sensitive column col^c is not dependent. In some cases, the number of attributes a_s in the sensitive column col^c may be predetermined to be c. The col^c is determined in size by the use of parameter c, mathematically presented as $|col^c| = c$, in a case where $c = 1$, $col^c = 1$ also. That is, $col^c = \{S\}$. In a scenario where $c = 2$, the procedure is said to be equal to bucketization. In the case where $c > 1$, $|col^c| > 1$. QI attributes are contained in the sensitive column col^c. So as to ease the discussion in this study, the sensitive attribute a_s is focused on as one. Assuming the column in which a_s is contained is last column col^c. The column is as well referred to as sensitive column, as presented in Table V. In a case where several sensitive attributes are contained in the data, their individual or collective distribution may be employed [14]. Attributes (cells) that are highly related are put together in a column in vertical partitions, while unrelated are as well put in separate columns in a way that individual attributes a_i becomes designated to one subset. As shown in Table V, col_i columns $\{col_1, col_2...., coln\}$ contain all attributes a_i. In Table V, the three partitions for the Col_i columns are presented:

(1) T^* contains all columns with highly correlated attributes col^*, where $col^* = \{col_1^*, col_2^*, ...col_i^*\}$, and $col^* \in T^*$.

(2) T^{**} contains all columns with uncorrelated attributes col^{**}, where $col^{**} = \{col_1^{**}, col_2^{**}, ...col_i^{**}\}$, where $col^{**} \in T^{**}$.

(3) T^c contains columns with SA col^c when a single SA exists, and its SA is placed in the last position for easy representation, where $col^c \in T^c$ and $(col^* \cap col^{**}) \cap T^c = T$.

K-medoid clustering algorithm that is otherwise called partitioning around medoids algorithm (PAM) [47], is employed in the presentation of similar attributes in columns in a manner that designates each attribute to a column is used to organize the similar attributes into columns for each attribute to be part of a column. This algorithm guarantees the resolution of

TABLE V. EXAMPLE OF PARTITION THE TABLE T INTO THREE COLUMNS

T^* contains all columns with highly correlated attributes.		T^{**} contains all columns with uncorrelated attributes.		T^c contains a column with sensitive attributes.
col_1^*	col_2^*	col_1^{**}	col_2^{**}	col^c
(a_1, a_2)	(a_3, a_4)	(a_5, a_6)	(a_7, a_8)	(a_s)

every attribute in the form of a point in the cluster space, while the inter-attribute disparity in the clustered space is represented thus: $d(a_1, a_2) = 1 - r^2(a_1, a_2)$, that falls within the range of 0-1. However, the disparity amongst affiliated data points becomes less within the clustered space if two attributes are firmly correlated. After determining the disparity amongst affiliated between the related data points, the k-medoid method arranges related attributes in a subset called a cell, and the combination of these yields the column $(T^*, T^{**}$ and $T^c)$.

In horizontal Partition, the table is divided into different subsets so that each tuple can only be assigned to a single subset. Every subset of these tuples is referred to as a bucket or an equivalence class. Assume there are E equivalence classes, $E_1, E_2, ... E_e$ then, $\bigcup_{i=1}^{e} E_i = T$ for any $1 \leq i_1 \neq i_2 \leq e$, $E_{i,1} \cap E_{i,2} = \emptyset$. In addition, all tuples containing similar values are categorized into categories referred to as bucket or equivalence classes. Here, every individual is joined to 1 specific sensitive value in a way that makes it impossible for an attacker to penetrate the SA values of an individual where the probability is greater than 1/l. The tuples were categorized by the Mondrian [34] algorithm. They are separated in the equivalence classes, in the absence of generalization attributes, according to the top-down technique.

Stage 3 is the protection. The table partition stage generated the partition of microdata table T into partitions vertically and horizontally partitioned. The aim of the table partition stage is for all attributes to be clustered into columns (including both QIs and SAs) to prevent the unauthorized disclosure of an individual's identity by altering attributes (QI values) so that the connection that exist among the individual and specific values are hidden while ensuring that the data published is used through the application of protection methods. In this stage, the hybrid data protection method will provide robust patient data privacy while increasing medical data publishing utility for microdata table T partitioned using the innovative technique based on the UL technique via two steps, namely defining the unique attribute values, high identical values, and protection method.

1) Defining the Unique Attribute Values and High Identical Values: When it comes to a hybrid protection method, the magnitude of the connection among attributes is chiefly measured by the correlation coefficient r. Formula 2 illustrates the manner in which UPL and LPL attempt to define the unique attribute values and high identical values through the extraction of two kinds of cell values: (1) the values of the exclusive (unique) cells and (2) high identical cell values in T^{**}. Each cell that possesses unique values and such values are within the range of $0.0 < LPL \leq \Theta$ are determined by the LPL. For such attributes, the r value is usually hovering around 0 but not equivalent to 0. In a similar vein, the UPL determines those cells that possess numerous similar attributes with values that are in the range of $\Theta \leq UPL < 1.0$. r

value for such attributes usually hover around 1 but is not equivalent to 1. Assuming those cells possess high r value in T^{**}, that will imply that the possibility of cells are in the same equivalence class. A hostile party has a higher degree of certainty around the SA when such cells are linked to other cells in T^*, thereby resulting in violation of privacy. In the remaining cells, the attributes and membership remain secured since they appear in multiple equivalence classes. In addition, the remaining cell categories need to be greater than a given limit, i.e., it should have a diversity value that is greater than or equal to 2 in respective equivalence classes, for the proposed privacy goal to be achieved.

$$(UPL \text{ and } LPL) = \begin{cases} \overline{C_{col,E}} = \Theta \leq UPL < 1.0 \\ \underline{C_{col,E}} = 0.0 < LPL \leq \Theta \end{cases} \quad (2)$$

It is the goal of UPL and LPL to discover the collection of unique cells and high identical values for cells from T^{**}, that are assumed to be known to intruders into these periods: $0.0 < LPL \leq \Theta$ and $\Theta \leq UPL < 1.0$. The attributes that are for discovering within this period are referred to as the protection attributes. Protection rate, represented by $theta$, refers to values that have been initially tagged to be discovered. Typically $theta$ is in the range of $1\%-10\%$, implying that the fraction of protection qualities will be smaller than one.

Definition 2 (Matching Buckets): Assuming col^{**} represents the columns, and $col^{**} = \{col_1^{**}, col_2^{**}, ... col_n^{**}\}$, and $col^{**} \in T^{**}$. Let t^{**} represent a tuple, and $t^{**}|col_i^{**}|$ represent the col_i^{**} value of t^{**}, then let E^{**} represent an equivalence class in microdata table T^{**}, and $E^{**}|col_i^{**}|$ stand for the multiset of col^{**} values in equivalence class E^{**}. E^{**} denotes a matching bucket of t^{**} if for all $1 \leq i \leq col^{**}$, $t^{**}|col_i^{**}| \in E^{**}|col_i^{**}|$.

2) Protection Method: This study's hybrid protection method guarantees the privacy criteria in every equivalence class. In order to enhance utility as well as individual privacy in the suggested innovative technique, the connection amongst unique attributes as well as cells that possess similar identical values are eliminated through two steps.

- Creation of Fake Tuples
  During the protection method step, a random permutation in a bucket may not be shielded from attribute or membership disclosure because permutation increases the risk of attribute disclosure rather than ensuring privacy [42]. In addition, increasing the false matches as a protection method in both unique attributes and high identical values, this method may generate a slight fraction of these fake tuples; however, this can result in countless matching buckets (i.e., more than the number of original tuples), leading to a huge data utility loss, producing erroneous or unfeasible extraction of the knowledge via operations of data mining [43] [44] [3]. Therefore, the fake tuples are used in a bucket as a protection method for all unique attributes (LPL) only. A few fake tuples do not change how useful the published patient dataset is, but they make it more likely that false matches will be found during a composition attack on the published

table [17] [29]. As a protection method, n fake tuples with similar QI values are made and given sensitive values based on how sensitive values are spread out in the original dataset. The main goal of creation of fake tuples is to obtain the anonymized table T.

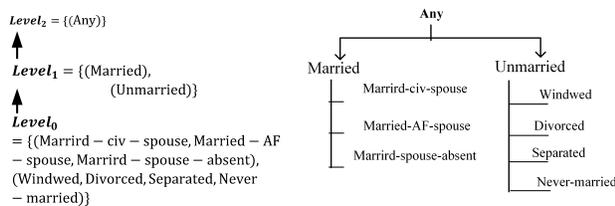
- Swapping or Generalization of Attributes
  The protection method for UPL attributes is attribute swapping or generalisation. This study's innovative technique ensures the privacy criterion in each equivalence class. To boost diversity and personal privacy, rank swapping is utilised to break the relationship between attributes with high identical values. Attribute swapping modifies tuple data with high identical values (UPL) by switching the values of these characteristics across record pairs in a defined proportion of the original data. When it is not possible to swap attributes, the attributes must be generalised. The primary purpose of swapping or generalising attribute values is to create the anonymized table T, which has no nonsensical combinations in the record (invalid tuples) while satisfying the l-diverse slicing.
  Definition 3 (Attribute Generalisation): Let T^{**} be part of microdata table T, and a_i^{**} be a QI attribute set in T^{**}. Generalisation replaces the QI attribute values with their generalised version. Let d_i^{**} and d_j^{**} be two domains with dimensional regions $\{d_{i1}^{**}, d_{i2}^{**}, ...d_{in}^{**}\}$ and $\{d_{j1}^{**}, d_{j2}^{**}, ...d_{jn}^{**}\}$, respectively, where $\bigcup_{d_{in}^{**}} = d_i^{**}$ and $d_i^{**} \cap d_j^{**} = \emptyset$. If the values of d_j^{**} are the generalisation of the values in domain d_i^{**}, we denote $d_i^{**} < d_j^{**}$ (a many-to-one value generalisation procedure). Generalisation works according to a domain generalisation hierarchy, which refers to a collection of domains that is ordered according to relationship $d_i^{**} < d_j^{**}$ (see Fig. 3).


Fig. 3. Example of the Domain (Left) and Value (Right) Generalization Hierarchies for the Marital-Status(MS) Attributes.

In Fig. 3 (right), the likely domain generalisation hierarchy for marital-status (MS) attributes is described. At lower levels in the generalisation hierarchy for (MS) attributes, generalisation is not used. Nonetheless, at the top of the hierarchy levels, the MS tends to be more general. A singleton is a maximal domain level element that denotes the likelihood of values to be generalised in every domain to a single value.

C. Evaluation of Performance

This study describes maintaining privacy as minimizing disclosure of information on individuals. The usefulness of the data means to what extent we can use the sterile medical patient dataset for intensive analyses. For instance, by suppressing each QI, a medical patient dataset can be generalized. Maximum privacy is provided in this manner, but the information obtained is useless. Finding a good balance between privacy and utility is necessary because the published datasets (sanitized) must permit tasks related to data mining operations for search and analysis. As a result, the usefulness of data in the published medical patient dataset is assessed by how well statistical and aggregate data are used. The ability to protect data privacy by lowering the risk of disclosing personal information and maintaining the potential use of published data is the criterion for judging the effectiveness of the anonymization technique [3] [17] [1].

V. COMPARISON OF EVALUATION

Python was used to implement this experiment. The independent medical patient datasets were the experimental prerequisite to complete the experimentation of the actual independent data publishing setup. The independent datasets, known as the medical-patient-dataset, were pulled from the medical patient dataset [45], which contained eight QI attribute values: marital status (categorical, 7), relationship (categorical, 6), gender (categorical, 2), age (continuous, 74), work class (categorical, 8), salary (categorical, 2), disease (categorical, 16), as well as occupation (categorical, 14).

Each dataset contains 4K tuples chosen at random, with the remaining 8K tuples being used to generate an overlapping tuple pool and to check for potential composition attacks. By injecting 100, 200, 300, 400, and 500 tuples into the medical-patient-dataset, five copies of the remaining tuple pool were created, yielding datasets of the following sizes: (4.1K), (4.2K), (4.3K), (4.4K), and (4.5K) for the medical-patient-dataset.

In the experimental analysis, the static data publication form might be employed. There are two basic approaches for making the published medical patient dataset available. The first way is an interactive setting in which the data collector computes a function on the medical patient dataset in order to answer the data analyser's inquiries. The second way is a non-interactive setup in which the medical patient dataset is sanitized and then released [3]. The experiment was designed to evaluate non-interactive privacy settings; however, the majority of the work was done on differential privacy [39], which was consistent with interactive settings because medical patient datasets were commonly known to be made public. As a result, for the experiment on differential privacy, which was noted in [39], the noninteractive mode was chosen. Furthermore, the merging, $e-DP$, hybrid, UL, and Mondrian techniques yielded the quasi-identifier equivalence class as k-anonymity [16].k = 6 was chosen to build an equivalence class, where L-diversity was also provided as 6. The primary goal of L-diversity is to protect privacy by increasing the diversity of sensitive values. The Laplacian noise in a differential privacy equivalence class was added to the sensitive values' count [49] with e= 0.3 for the e-differential privacy budget.

The experiments on the medical patient database were performed in two parts. The first part was designed to evaluate the effectiveness of the innovative technique in data utility preservation by comparing it to other existing works. The second part was designed to assess the innovative technique

to see how well it can fight and prevent composition attack occurrence. The innovative technique's effectiveness was tested by relating it to the effectiveness of similar techniques, like hybrid [35], merging [17], $e - DP$ [39], UL method [3] and Mondrian [34] techniques, in the non-interactive privacy settings. The experimental results showed that the innovative technique provided privacy protections against the considered attacks while preserving data utility.

A. Data Utility Comparison

This experiment measured the data utility obtained from the distortion ratio (DR). The DR in published medical patient dataset can be evaluated by different methodologies [21] to quantify the anonymisation outcome on the overall distortion data. The generalised distortion ratio (GDR) is a suitable measure for estimating the DR [44] used to quantify the anonymisation outcome on the overall distortion data.

The swap and generalise method was used to break the association of the attributes because the majority of these attributes were categorical. For any two categorical attributes $(a_1^{**}, a_2^{**} \in T)$, where t is its taxonomy tree and a node p in t is used to swap or generalise the attributes, the DR with p is defined as follows:

$$DR(a_1^{**}, a_2^{**}) = \begin{cases} 0, a_1^{**} = a_2^{**} \\ \frac{|common(a_1^{**}, a_2^{**})|}{|N|}, a_1^{**} \neq a_2^{**} \end{cases} \quad (3)$$

, where $|N|$ denotes the set of all the leaf nodes in t and $|common(a_1^{**}, a_2^{**})|$ is the set of leaf nodes in the lowest common tree of a_1^{**} and a_2^{**} in t.

Fig 3 denotes the taxonomy of the marital-status (MS) attribute; if the values of a_1^{**} and a_2^{**} are in the same rank group and have no nonsensical combinations, then their swap values are equal, and the DR is 0. Moreover, if the values of a_1^{**} and a_2^{**} are not in the same rank group or have any nonsensical combinations, then, their generalized values are equal to $\frac{|common(a_1^{**}, a_2^{**})|}{|N|}$, and the DR is equal to $\sum_{j=1,k=1}^{n,m} d_{j,k}$, where $d_{j,k}$ represents the attribute's distortion of a_j^{**} of the tuple t_k.

The distortion ratio (DR), also known as data utility, is a proportional measure that compares the amount of distortion in a generalised medical patient dataset to the amount of distortion in a fully generalised medical patient dataset. It is possible to determine the value of the data by subtracting the DR from Equation 4 shown below [21]:

$$Datautility = (100 - DR)\% \quad (4)$$

Fig. 4 displays the data utility experimental results based on data loss on the medical-patient database. The innovative technique in Fig. 4 had a protection rate (θ) of 5% using LPL and 95% using UPL. The assessment of the innovative technique, done through its comparison with hybrid [35], merging [17], $e - DP$ [39], UL method [3], and Mondrian

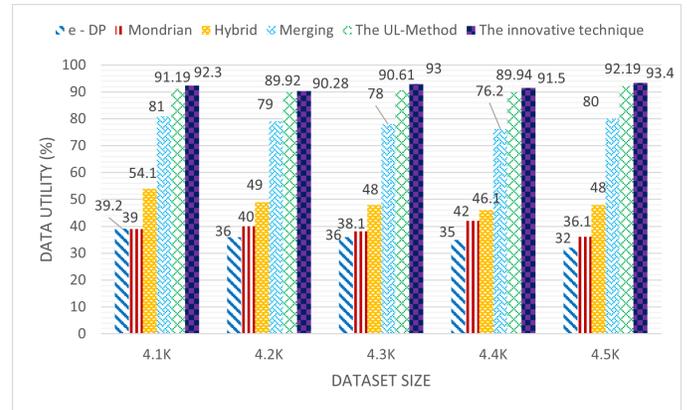
[34] techniques revealed that the data utility obtained by the innovative technique was higher than that of all the known works. The merging technique had N fake tuples with the same QI values as in the original table. The sensitive values were assigned to them based on the sensitivity value distribution in the initial dataset. Hybrid, $e - DP$ and Mondrian techniques used the generalization procedure as a protection method. Therefore, these techniques resulted in more data loss than the innovative technique.The innovative technique employs selective generalization within the cell when satisfying the privacy requirements is essential; hence, more data utility is preserved.


Fig. 4. Data Utility on the Medical-Patient Dataset (Protect Rate (θ) of 5% using LPL and 95% using UPL).

B. Measuring Risks

The measurement of disclosure risk in microdata during a composition attack is covered in this section. A composition attack occurs when an intrusive party, especially one knowledgeable about some of the QI values, attempts to identify a specific person in the microdata by linking several readily accessible records to an external database to disclose restricted information [8] [3]. As a result, gauging disclosure risk is essentially measuring the rareness of a cell in microdata publishing.

Medical patient dataset publishers should strive to measure the risk disclosure of PPDP outputs to ensure privacy preservation. This step is key in defining the level of protection needed. Therefore, differentiating the risk disclosure measures is important because the quantity to be measured must not depend on how the data representation method is selected. According to the works done previously, the risk disclosure can be quantified by determining the proportion of the true matches to the total matches, as expressed in Equation 5.

$$Disclosure\ risk\ ratio\ (DRR) = \frac{Matched\ records}{Total\ records} X100\%$$
$$(5)$$

Fig. 5 shows the experimental result for the disclosure risk ratio (DRR). DRR defines the adversary confidence level followed to elucidate the sensitive values in the medical-patient database. The $e - DP$ technique [39] revealed the least privacy risks compared to the innovative technique and other available

approaches. The $e - DP$ technique achieved approximately 0.63% disclosure risk ratio privacy risk for medical-patient database when k = 6, l = 6 for size of 4.5K. Based on the proposed solution [39], it probabilistically generated a generalised possibility table and added noise to the total. The $e - DP$ offered high privacy assurance and protection opposed to composition attack by differential privacy grounded data anonymization [23] [3], as shown in the results. It was observed by [35] [40] [41] [17] [3] that using $e-DP$ to protect against composition attacks generates a significant amount of data utility losses during anonymization, confirming the result discussed in Fig. 4.

The hybrid technique [35] generated a lower probability of sourcing the end-user's private data than Mondrian technique [34] and merging technique [17]. The hybrid technique achieved approximately 1.55% disclosure risk ratio (privacy risk) for medical-patient database when the K= 6, l = 6 for size of 4.5K.

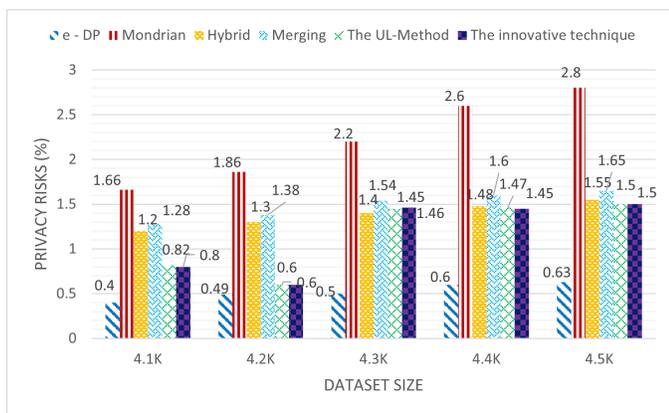
Compared to the innovative technique, the UL method and the innovative technique decreased the likelihood of composition attacks on the released medical patient datasets than the hybrid [35], merging [17], and Mondrian [34] techniques by disabling the unique attributes and high identical attribute values by UPL and LPL, and providing multiple matching cells in each equivalence class, leading to protection against identity disclosure. The UL method and the innovative techniques achieve approximately 1.5% disclosure risk ratio when the K= 6, l = 6 for size of 4.5K. Meanwhile, the innovative technique enhanced the data utility (Fig. 4) through the use of hybrid protection method. Increasing the false matches for a unique attribute in LPL and value swapping for high identical values in UPL helped to enhance the data utility and guarantee a lower risk of attribute disclosure.


Fig. 5. Privacy Risk Medical-Patient-Database (k = 6, l = 6).

VI. CONCLUSION AND DISCUSSION

This paper presented an innovative technique using a hybrid protection method for utility enhancement while preserving data privacy for medical patient dataset; and for limiting the prospect of popular composition attack when the independent medical organizations cannot coordinate prior to medical patient dataset publication. The experiment showed that the innovative technique could satisfy the requirements of privacy after intersecting the separately published medical patient datasets. By contrast, many existing techniques reduced the published medical patient data utility due to the protection method used such as generalization and perturbation. This work, however, introduced a robust hybrid protection method by finding the unique attribute values (LPL) and high identical attribute values (UPL), then creating a fake tuple for the unique attribute and swapping values for the high identical attribute to decrease the attribute disclosure risk and ensure attainment of l-diverse in the published microdata table against the composition attacks. The model's effectiveness lies in the selection of specific attributes to enhance the privacy of published data and maintain data utility. The experimental findings revealed that the introduced method in this study could provide greater data utility compared with the state-of-the-art techniques. The achieved performance using our innovative technique helps researchers, decision-makers, and experts benefit from the published medical patient dataset to extract knowledge that may be used for disease prevention, medical decision-making, and many other areas of medical organizations. Similar to other scholarly research, this study leaves ample room for additional works to address its limitations and to expand upon its foundation to focus on adding or replacing another new protection methods to the innovative technique or extending some stages of the innovative technique to increase data utility and decrease risk disclosure. Moreover, the effectiveness of the innovative technique has been tested against composition attacks and background knowledge attacks, and by using the medical patient dataset; thus, it is important to test its performance against different attacks and by using different types of datasets.

Abstract—**Covariance Model (CM) has been quite effective in finding potential members of existing families of non-coding Ribonucleic Acid (ncRNA) identification and has provided excellent accuracy in genome sequence database. However, it has significant drawbacks with family-specific search. An existing Hierarchical Agglomerative Clustering (HAC) technique merged overlapping sequences which is known as combined CM (CCM). However, the structural information will be discarded, and the sequence features of each family will be significantly diluted as the number of original structures increases. Additionally, it can only find members of the existing families and is not useful in finding potential members of novel ncRNA families. Furthermore, it is also important to construct generic sequence models which can be used to recognize new potential members of novel ncRNA families and define unknown ncRNA sequence as the potential members for known families. To achieve these objectives, this study proposes to implement Particle Swarm Optimization (PSO) and Genetic Algorithm (GA) to ensure the CCMs have the best quality for every level of dendrogram hierarchy. This study will also apply distance matrix as the criteria to measure the compatibility between two CMs. The proposed techniques will be using five gene families with fifty sequences from each family from Rfam database which will be divided into training and testing dataset to test CMs combination method. The proposed techniques will be compared to the existing HAC in terms of identification accuracy, sum of bit-scores, and processing time, where each of these performance measurements will be statistically validated.**

Keywords—Covariance model; ncRNA identification; swarm intelligence; hierarchical clustering

I. INTRODUCTION

Distinguishing many different classes of noncoding (nc) ribonucleic acids (RNA) according to the performance of its variety roles has been an prevalent area in bio-computational technology [1], [2], [3], [4], [5]. For example, after the relationship between RNA structure and its function is discovered, it is desirable to know the common structure of homologous RNAs to find out the functional signatures. It is also desirable to scan a genome looking for ncRNAs. Strategies employed in protein coding gene identification are not commonly applicable for ncRNAs. Therefore, the identification of ncRNA remains an open problem in bioinformatics. However, two-bases are not necessarily covary, since some point mutations, such as G–C to G–U, are still considered as base pairing [6].

Thus, methods searching for covariation may miss valuable information. The main drawback of covariance model (CM) is the use of information of a specific gene family to gain in accuracy [7]. In areas of ncRNA identification, CM has been quite effective in finding potential members of existing families and has provided excellent accuracy in genome sequence database [8], [9], [10]. Representation of multiple secondary structure alignment using a hairpin loop based on an ordered tree are constructed automatically from existing sequence alignments or even from unaligned example sequence [11].

However, it also has considerable disadvantage, such as computationally expensive and thus hindering its application in practice [6], [12]. Apart from having problems with family-specific search that includes large processing requirements, ambiguity in defining which sequences form a family and insufficient numbers of known sequences to properly estimate model parameters are known to be a big challenge in identification of ncRNA. To improve CM performance, hierarchical clustering, as the most frequently used mathematical technique, tries to group genes into small clusters and to group clusters into higher-level systems [13]. Hierarchical clustering provides a series of nested partitions of the dataset. It splits the data into a nested tree structure, where the levels of the tree show similarity or dissimilarity among the clusters at different levels [5], [7].

In regards to this issue, hierarchical clustering has been known as a efficient and useful technique for analyzing genome data and can be applied to group known ncRNA gene families [13], [14], [15], [16]. Past researchers have applied hierarchical clustering to support the identification process in combining and clustering group of families [15]. Lessening the computational cost imposed by covariance model (CM) based noncoding RNA (ncRNA) gene finding is desirable to search the sequence data using a large number of ncRNA families [14], [17], [18]. The main consideration of CM is searching a gigabyte database of sequences for all known ncRNA gene families, which will take quite a long time, and thus is not practical [19], [22].

Hierarchical clustering has successfully reduced the search time to find members from all original ncRNA families using dot-bracket notations [13]. However, its performance continuously declining when additional families of CMs are

introduced into the CCM. This is because more structural information will be excluded, and the sequence features of each family will be significantly less apparent as the number of original CMs increase [5]. Furthermore, it is not sufficiently covering all the problem spaces. A swarm intelligence-based hierarchical algorithm is proposed in this study to select base pairs from two or more CMs of ncRNA families, such as Particle Swarm Optimization (PSO) and Genetic Algorithm (GA). The general idea is to select base pairs from one sequence feature that has fewest conflicts with the base pairs in another structure and construct new CCM structures, which will increase the discernibility performance of the CCMs. Thus, the paper is organized as follows: the next section further describes the problem which motivated this study, while Sections III and IV elaborate the proposed method and present the results, respectively, followed by the discussion of the results in Section V, and the last section concludes this work.

II. HIERARCHICAL CLUSTERING FOR COVARIANCE MODEL

In the previous study conducted by [14], a technique was introduced to reduce the search complexity when a target genome is searched for more than one known ncRNA gene family. The basic construct of the technique is to combine different CMs into one single CM which captures part of both sequence and structure features of each CM by selecting randomly three sequences, known as cluster, from each family by using hierarchical clustering. Hierarchical clustering is a powerful and useful technique for analyzing genome data because hierarchical clustering can generate a dendrogram which helps organize the CCMs. Each non-leaf node of the dendrogram is a CCM of its child nodes, and each leaf node represents a single CM of a ncRNA gene family [5]. Fig. 1 shows an example of possible structure of a dendrogram.

The existing technique applied the agglomerative approach to cluster ncRNA genes [5]. After the clustering of ncRNA gene families, the existing technique built the CCM for any two CMs in the dendrogram that share a common parent which combined the two selected CMs such that the new CCM captured features of both original CMs. CMs are built from multiple sequence alignment with annotated secondary structure. Thus, the general idea of combining two CMs of the existing technique was to select part of the multiple sequence alignment columns of each CM and connect them together to create a new multiple sequence alignment, which the new CM is built from [5].

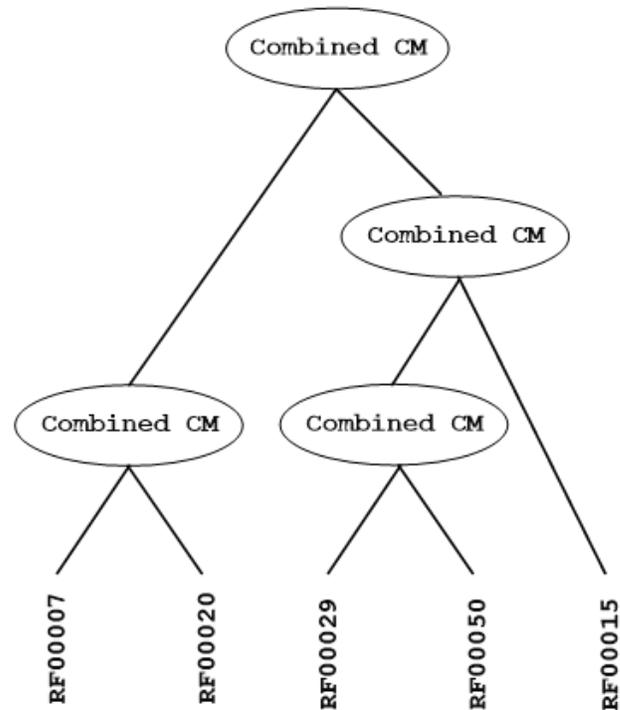
Since the multiple sequence alignment is annotated with secondary structure, and each column of multiple alignment corresponds to a secondary structure symbol, either a dot or a bracket, indicating whether it is a paired base or not, combining the multiple sequence alignment is equivalent to combining the annotated secondary structure [18]. To combine secondary structures, the key point is to determine how to select base pairs from the two original secondary structures and put them into the new structure. It is obvious that the algorithm cannot just select all the base pairs from both original structures and simply connect them together, since it will significantly increase the complexity of the CM and make no difference to searching with the two original CMs separately [4].


Fig. 1. A Sample of Hierarchical Clustering Result of Five ncRNA Families from Rfam Database.

In most methods of hierarchical agglomerative clustering (HAC), a measure of dissimilarity between clusters is required to decide which clusters should be combined [20], [21]. In the existing technique [23], the members of the cluster are ncRNA gene families, each of which is represented by its secondary structure in dot-bracket notation. Dot-bracket notation is widely used in describing RNA secondary structure. It uses matching brackets to indicate paired bases and dots to denote unpaired bases. This study defines a different distance function that is particularly suitable to deal with the secondary structure data in dot-bracket notation. However, there are two definitions that need to be introduced [5].

Definition 1. *Base pair conflict: Given two RNA secondary structures, a base pair (m, n) from one secondary structure is called base pair conflict if there exists a base pair (i, j) in the other secondary structure such that $m < i < n < j$, or $i < m < j < n$.*

Definition 2. *Structure distance: Given two RNA secondary structures, the structure distance between them is the average of the number of base pair conflicts in each secondary structure.*

The definition of base pair conflict is similar to the definition of pseudoknots, but the difference is that base pair conflict is for base pairs in two different structures while pseudoknots is for those in one structure [14], [24], [25]. Since CM cannot deal with pseudoknots which should be avoided in the combined structure, only one of the two conflict base pairs can be retained in the combined structure [5], [23].

Unlike the distance functions used in most clustering algorithms that measure dissimilarity between observations,

structure distance, the distance function applied in the existing technique, is a measurement of compatibility of two RNA secondary structures [5]. The smaller this value is, the more compatible the two secondary structures are. The compatibility between two secondary structures shows how much structural information can be retained when they are combined. Since the objective is to build a CCM that can capture as much information as possible about both original CMs, two CMs with more compatible secondary structure components would be perfect to be combined. The basic process of HAC [5] is as shown in Algorithm 1.

Algorithm 1 HAC Process

1: Start
2: Assign each ncRNA gene family to its own cluster, then build the distance matrix by computing the structure distance between each family.
3: Find the closest pair of clusters (the minimal element in distance matrix) and combine their secondary structures to create a new family, which corresponds to a non-leaf node in the dendrogram, and then remove the cluster pair from dendrogram.
4: Compute structure distance between the new cluster and each of the old clusters.
5: Repeat steps 2 and 3 until there is only one cluster, which corresponds to the root of the dendrogram.
6: End

Ref. [5] proposed three criteria that should be followed for selecting base pairs from two secondary structures. First, the set of selected base pairs should contain as many base pairs as possible. Since the greater number of base pairs are selected, the more secondary structure components are retained, which also means the more likely a target sequence will be found when searching the genome database. Second, the base pairs selected from one CM should not conflict with those from the other CM. This means there are no pseudoknots in the combined secondary structure due to the reason that CM cannot deal with pseudoknots. Third, each CM should have roughly the same number of base pairs selected, which means this study wants to make a balance between the two original secondary structures.

A greedy algorithm to select base pairs from two secondary structures to form a new secondary structure that satisfies the above three criteria is outlined in Algorithm 2, which is termed as Hierarchical Agglomerative Clustered Covariance Model (HACCM) by [5]. The general idea is to select a base pair from one structure that has fewest conflicts (pseudoknots) with the base pairs in the other structure, which means selecting this base pair will cause fewest deletions of base pairs in the other structure, and such selection takes turns between the two structures.

This existing technique of [5] performs rather well, in most cases, when not too many CMs are combined, where the CCM can successfully represent members from all original families and hardly provide any false alarms. However, its performance gradually deteriorate as more families of CMs are added into the CCM, since more structural information will be discarded, and the sequence features of each family will be significantly diluted as the number of original CMs increase

---

Algorithm 2 Pseudocode to Construct CCM using HACCM [5]

1: Start
2: Generate a list of N_f gene families (each family consists of five randomly selected clusters, one cluster from each original family)
3: Calibrate the gene families using *cmcalibrate* tool from Infernal package
4: **while** $N_f > 0$ **do**
5:     Generate distance matrix between gene families
6:     Select two nearest gene families
7:     Construct CCM from two nearest families by using base pair conflicts
8:     Exclude the two families from future distance matrix calculation
9:     Calculate the TP, TN, FP, and FN from the bit-score of the CCM using members of gene families
10: **end while**
11: End

---

[5]. Furthermore, the original technique is not sufficiently covering all the problem spaces, which means the solution provided may not be the best solution. The frequently used strategy to explore wider problem spaces is by employing evolutionary and swarm intelligence, where each member of the swarm represents one possible solution. By adjusting the number of unique members based on the resource availability, the problem spaces can be further explored.

To achieve this objective, this study proposes to implement swarm intelligence to ensure the CCMs have the best quality for every level of dendrogram hierarchy. On the initialization phase of the swarm intelligence technique, several possible combinations of the CMs will be generated and considered as a single member of swarm intelligence. The selected number of sequences will be unique and the number of sequences for these particles will vary to ensure the maximum coverage. This study will also apply distance matrix as the criteria to measure the compatibility between two CMs.

However, the difference between this study and the previous one is that the selected CCMs will be directly evaluated by CM scoring model, which will be assigned as one of the components of fitness value of the member of swarm intelligence instead of producing the complete dendrogram before evaluating the CM scoring model. The CM from the best member in the current iteration will be then combined with other CMs to generate the new CMs in the subsequent iterations. Furthermore, this study aims to generate reliable cluster pool by having proper selection approach to reduce sequence features dilution in CCMs and to optimize the CCMs selection models which is based on Hierarchical Agglomerative Clustering using Swarm Optimization in finding potential members of novel ncRNA. By the end of the optimization process, this study will construct generic sequence models which represent multiple families to identify unknown family members of ncRNA.

III. Proposed Swarm Intelligence-Based HACCM

This section discusses the tasks undertaken to develop the proposed techniques by hybridizing them with swarm intelli-

gence (SI) techniques, such as Particle Swarm Optimization (PSO) and Genetic Algorithm (GA). In Algorithm 3, the hybridization with SI techniques is primarily to prevent the existing HACCM technique [5] selects the local optima and forces it to reevaluate the candidates with the same merit in every iteration to find the global optima.

Algorithm 3 Optimization Process using SI for HACCM

1: Start
2: Step 1
3:    Generate balanced cluster pool based on minimum number
4: Step 2
5:    Generate similarity matrix between clusters
6:    Find the closest pair of clusters using greedy algorithm and combine it
7:    Construct tree-based CCM structures
8: Step 3
9:    Measure the fitness value of each combined clusters using CM search score and confusion matrix
10: Step 4
11:    Compare and get best hierarchical CM structure with highest fitness value
12:    Update clusters combination with PSO's velocity composite values
13: Step 5
14:    Set threshold Fit = 1 or stagnant fitness for 5 iterations
15:    Proceed to Step 2 if threshold not fulfilled
16: End

The fitness function for the PSO and GA should be identified beforehand. Although there are several possible performance measurements available, such as sensitivity or recall, precision, F_1-score, specificity, and accuracy, this study prefer to use accuracy as the parameter of fitness function because they do not solely rely on the true and false positives. However, in case of the similar fitness value between two or more PSO particles or GA individuals, other criteria should be taken into consideration, which is the sum of bit-scores, which is obtained by evaluating the CM using the *cmsearch* program from Infernal package [3]. In this study, the sum of literal value of bit-scores or similarity score of the families will be used in the fitness function as the tiebreaker parameter. Thus, the proposed fitness function of this study is given in Eq. 1.

$$F_i = \alpha \times \frac{Acc_i(t) - Acc_i(0)}{Acc_i(0)} + \beta \times \frac{SS_i(t) - SS_i(0)}{SS_i(0)}, \quad (1)$$

where Acc_i is the accuracy of ith member (particle in case of PSO and individual in case of GA) in the tth iteration ($t = 0, 1, ...$), and SS_i is the sum of bit-scores from the families of ith member, with $Acc_i(0)$ and $SS_i(0)$ are the accuracy and sum of bit-scores of the original HACCM, which is inspired from the fitness function of HelixPSO for finding RNA secondary structure [28], given in Eq. 2.

$$F = \alpha \times \frac{|S| \cap |C|}{|C|} + \beta \times \min\left(0, \frac{E(S)}{mfE}\right), \quad (2)$$

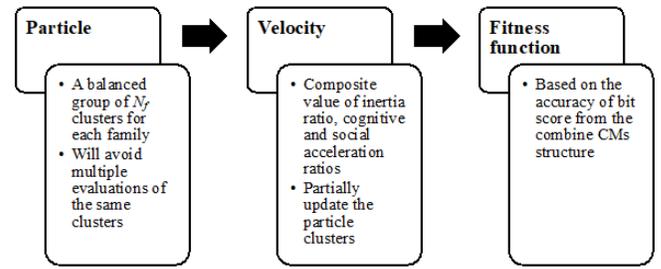
where α and β in Eqs. 1 and 2 are the parameters used to determine the importance of classification accuracy and the


Fig. 2. Optimization Process using PSO.

subset size, where $\alpha \in [0, 1]$ and $\beta = 1 - \alpha$. In this study, the α is set to 0.9, while β is set to 0.1. By setting the accuracy and sum of bit-scores of the current PSO particle or GA individual relative to the original HACCM, the values of fitness value can be guaranteed to not deviate too much to the original HACCM performance.

A. PSO and HACCM Hybridization

In this study, Particle Swarm Optimization (PSO) [26], [27] is selected as one of swarm intelligence techniques to optimize HACCM. One of the main considerations taken for selecting PSO is due to its simple yet effective implementation. The main idea of Particle Swarm Optimized HACCM (PSO-HACCM) is that fitness function of PSO is modified by implementing confusion matrix-based performance measurement techniques calculated from the results of bit-score obtained from *cmsearch* of Infernal package. This is to allow the most optimal interaction between PSO and HACCM, and thus allow for wider search space exploration. Furthermore, there are multiple instances of HACCM executed concurrently; each of them is executed in PSO particle.

This study uses the sum of bit-scores value to be assigned as the particle position. Meanwhile, the fitness value must be identified beforehand since there are several possible confusion matrix-based performance measurement techniques, however this study found the accuracy. Each particle will examine diverse set of CM family clusters, and thus produce unique results, this is because the examined CM family clusters set and its results are recorded, to prevent different particles from examining the same set multiple times.

Apart from the modification to the fitness function, the particle velocity update strategy is also modified which is shown in Fig. 2. Like original PSO, the velocity of the PSO v_i in the $(t+1)$th iteration is affected by inertia ratio I_i, cognitive acceleration ratio C_i, and social acceleration ratio S_i, although is it slightly modified such that

$$v_i(t + 1) = I_r + C_r + S_r, \quad (3)$$

$$I_i = I \times v_i(t), \quad (4)$$

$$C_i = C \times rand() \times (p_i - x_i(t)), \quad (5)$$

$$S_i = S \times rand() \times (p_{best} - x_i(t)), \quad (6)$$

where I, C, and S are the inertia weightage, cognitive acceleration coefficient, and social acceleration coefficient, respectively. In this study, the constants I is set to 0.729844

while C and S is set to 1.49618 [29]. Since the particle is made up N_f clusters, the implementation of these ratios is that there will be maximum $\lfloor \frac{I_r \times N_f}{v_i(t)} \rfloor$ numbers of clusters are reselected from clusters pool, maximum $\lfloor \frac{C_r \times N_f}{v_i(t)} \rfloor$ numbers of clusters are reselected from the particle's personal best, and maximum $\lfloor \frac{S_r \times N_f}{v_i(t)} \rfloor$ numbers of clusters are reselected from the global best particle. The algorithm of PSO-HACCM is illustrated in Algorithm 4.

Fig. 3. Optimization Process using GA.

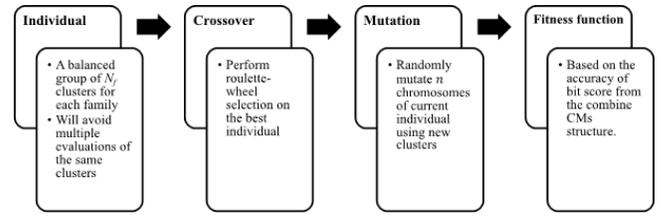
2: Set number of particles $N_p = 3$
3: Set number of iterations $N_t = 100$
4: **for** $i = 1...N_p$ **do**
5:     Generate particle P_i, which is the CCM
6:     Calculate initial sum of bit-scores of CCM as position X_i
7:     Calculate fitness value F_i
8:     Calculate inertia ratio I_i, cognitive acceleration ratio C_i, and social acceleration ratio S_i
9:     Initialize velocity $V_i = I_i + C_i + S_i$
10:     Select global best G_{best} based on maximum fitness value
11: **end for**
12: **for** $t = 1...N_t$ **do**
13:     **for** $i = 1...N_p$ where $P_i! = G_{best}$ **do**
14:         $NumInert = I_i * N_f/V_i$
15:         $NumCog = C_i \times N_f/V_i$
16:         $NumSoc = S_i \times N_f/V_i$
17:         Randomly select $n1 \leq NumInert$ clusters from cluster pool
18:         Randomly select $n2 \leq NumCog$ clusters from P_{best}
19:         Randomly select $n3 \leq NumSoc$ clusters from G_{best}
20:         Generate hierarchical CCM from new clusters
21:         Update X_i, F_i, I_i, C_i, S_i, and V_i
22:     **end for**
23:     Select new Gbest
24:     **if** $F_{G_{best}} == 1$ OR is stagnant after 5 iterations **then**
25:         Stop iteration
26:     **end if**
27: **end for**
28: End

B. GA and HACCM Hybridization

In this study, Genetic Algorithm (GA) [31] is selected as another swarm intelligence techniques to optimize HACCM. The main idea of GA-based HACCM (GA-HACCM) is similar to PSO-HACCM, where the fitness function of GA is modified by implementing well-known performance measurement techniques based on the results of bit-score calculation. This is also to allow the most optimal interaction between GA and HACCM, and thus allow for wider search space exploration based on the modified parameters of the optimization process in Fig. 3.

Similarly, there are multiple instances of HACCM executed concurrently; each of it is executed in GA individual. Each individual I_i will examine different set of CM family clusters, and thus produce unique results, this is because the examined CM family clusters set and its results are recorded, to prevent different individuals examine the same set multiple times. However, unlike PSO-HACCM, there are not much changes modification required to hybridize GA and HACCM. The algorithm of GA-HACCM is illustrated in Algorithm 5.


Algorithm 5 The Pseudocode to Construct Hybrid GA and HACCM

1: Start
2: Set number of individuals $N_i = 3$
3: Set number of iterations $N_t = 100$
4: **for** $i = 1...N_p$ **do**
5:     Generate individual I_i, which is the CCM
6:     Calculate initial sum of bit-scores of CCM as X_i
7:     Calculate fitness value F_i
8:     Select global best individual G_{best} based on fitness value
9: **end for**
10: **for** $t = 1...N_t$ **do**
11:     **for** $i = 1...N_i$ where $I_i! = G_{best}$ **do**
12:         **if** Randomly selected for crossover **then**
13:             Crossover with G_{best} using roulette-wheel selection
14:             Randomly mutate n chromosomes of I_i using new clusters from pool
15:             Generate hierarchical CCM from new clusters
16:             Update X_i and F_i
17:         **end if**
18:     **end for**
19:     Select new Gbest
20:     **if** $F_{G_{best}} == 1$ OR is stagnant after 5 iterations **then**
21:         Stop iteration
22:     **end if**
23: **end for**
24: End

IV. EXPERIMENTAL SETUP

With the goal stated in the section above, an extensive and rigorous empirical comparative study is designed and conducted. In this section, a detailed description of the experimental method is provided.

A. Dataset Collection and Preparation

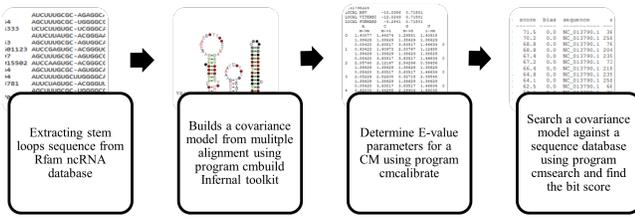
This study obtained the dataset from Rfam database, the most commonly used database that store ncRNA gene


Fig. 4. Steps of Data Collection and Preparation.

TABLE I. SUMMARY OF TRAINING AND TESTING DATASET PREPARATION

Family	Number of Sequences	Number of Selected Sequences	Number of Unselected Sequences
RF00007	51	51	0
RF00015	137	51	86
RF00020	131	51	80
RF00029	86	51	35
RF00050	144	51	93

families from various species [30]. This database is a collection of ncRNA families represented by manually curated sequence alignments, consensus secondary structures and annotation gathered from corresponding taxonomy and ontology resources. The summary of the process of collecting and preparing the dataset is as shown in Fig. 4.

In this study, five sets of ncRNA gene families were selected to test CMs combination method. The selected gene families have roughly similar average length so that their CM combination would not have bias towards either of them. Thus, the number of selected sequences will be set to the minimum number of sequences available, which is fifty-one sequences. This study proposes to randomly divide the selected sequences within one family into groups of three sequences for each gene families by following steps of dataset collection and preparation in Fig. 4 then generate a balanced cluster pool from selected sequences for each family, while the rest of the unselected sequences will be used to form the testing dataset and validate the proposed technique. The process to construct from the generic CCM using existing and proposed techniques is as shown in Algorithm 6, while the summary of the training and testing dataset is shown in Table I.

Algorithm 6 The Pseudocode for the Dataset Preparation

1: Start
2: Set number of families $N_f = 5$
3: Identify minimum number sequences N_s for each family
4: Set number of sequences per cluster $N_{sc} = 3$
5: Set number of clusters per family $N_c = FLOOR(N_s/N_{sc})$
6: Generate cluster pool containing N_c clusters by randomly selecting sequences for each family
7: Set unselected sequences as testing dataset
8: End

Each family obtained from Rfam database is stored in one plain-text file. Each file consists of multiple lines, where each line represents the known ncRNA sequence from that family. There are two data contained in each line separated with tab

space: the first data is the name of the sequence, while the second data is the ncRNA sequence. The unique pattern of each family is stored in the last line of the plain-text file. Apart from the plain-text file, it is also possible to visualize the ncRNA sequence in the Rfam database.

After the ncRNA family dataset has been successfully obtained from Rfam database, the dataset must be prepared and processed so that it can be used by the tools in the Infernal package. Prior to processing by Infernal package tools, the dataset must be stored in .CM file format, which is constructed from .STO file format. The data format in .STO file format is almost similar to the format obtained from Rfam database, with only minor differences, such as the first line of the file in .STO file format must be annotated with *# STOCKHOLM 1.0* syntax and the gene family pattern of .STO file format is only limited to the dot-bracket notation, which consists of left-angle bracket ($<$), right-angle bracket ($>$), and dot symbol (.).

As mentioned earlier, the dataset must be stored in .CM file format. To generate .CM file format, *cmbuild* program from Infernal package must be used. After the .CM file is generated, it is also necessary to calibrate the data using *cmcalibrate* program so that the dataset can be used by other programs in Infernal package. However, calibrating the dataset to .CM format takes a rather long time; thus, this study needs to adjust the parameters of *cmcalibrate* program to reduce the calibration time. The *cmcalibrate* is executed without the forecasting capability, which estimates the execution time by running a small sample of data, reduced its tail loss probability to 10-2 instead of the default 10-15, and the sample size to 0.5 MB instead of the default 1.6 MB.

B. Experimental Design

The quality of the proposed technique must be validated using various performance measurement criteria, because evaluating the performance of learning algorithms is a fundamental aspect of machine learning. In this study, the performance measurements for evaluating the performance of the existing and proposed techniques are the sum of bit-scores, the processing time, and the value of confusion matrix-based performance measurement technique. Despite there are several confusion matrix-based performance measurement techniques available, such as sensitivity, specificity, precision, F_1-score, accuracy, prevalence, phi coefficient, Fowlkes–Mallows index, informedness, markedness, and a few others, this study will only focus on the accuracy as the primary performance measurement by comparing the most commonly used techniques. The sum of bit-scores and processing time are considered as supplementary performance measurements to support the results of the primary measurement.

The bit-score indicates the performance measurement for selected ncRNA sequence. The bit-score is obtained from the *cmsearch* program from Infernal package, and it is used to measure the probability of similar sequence to be found on a given set on covariance model gene family. The processing time can be measured directly while executing the existing and proposed techniques in the clean room environment.

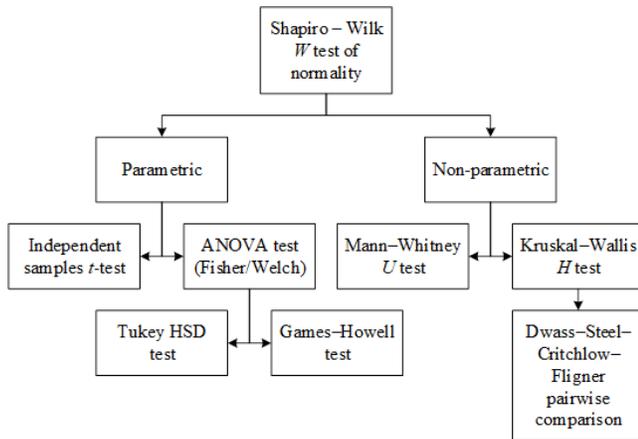
The proposed ncRNA search model techniques are developed to construct generic sequence models which can be used to recognize new potential members of novel ncRNA


Fig. 5. Summary of Statistical Validation

families. Therefore, it is important to construct a performance measurement to assess this capability. However, since it is practically difficult to obtain the novel and unknown sequences of ncRNA to assess the existing and proposed techniques, this study instead proposed a scenario to simulate this situation.

The scenario of identifying the unknown ncRNA sequences is similar to identifying a set of testing instances by using supervised learning method. By using the datasets mentioned earlier, a portion of the data from the datasets must be set aside to form the testing dataset and the remaining data will be used to form the training dataset, which will be used to construct the CCM. After the CCM has been completely constructed, the testing dataset will be used to validate the CCM, where the result is either the sequence can be found or not found in the combined covariance model. The result will be used to validate the generic sequence models.

The performance measurements are conducted fifty times to ensure the statistical consistency of the results using the datasets mentioned earlier. These performance measurements are validated using various statistical validation techniques available in jamovi statistical package software. The summary of the statistical validation is depicted in Fig. 5.

V. RESULTS AND DISCUSSION

This section provides the results of the comparative study used to identify the most suitable technique to improve the quality of original HACCM proposed by [5]. Table II presents the descriptive test results for the accuracies and the sum of bit-scores of the best member from 50 executions using 3 members for each technique, as well as the total processing time to complete these 50 executions.

Based on the results shown in Table II, the PSO-HACCM produces the best accuracy, sum of bit-scores, and processing time compared to the original HACCM and GA-HACCM. The percentage of the differences between the PSO-HACCM compared to the GA-HACCM and original HACCM is shown in Table III.

The PSO-HACCM results shown in Table III are higher than other techniques are due to its cognitive and social accelerations capabilities, which are not present in the original

HACCM and GA-HACCM. However, to validate whether the difference between PSO-HACCM, GA-HACCM, and original HACCM is statistically significant, in-depth comparison of these techniques must be conducted. The results summarized in Table II are then validated to determine the significance of PSO-HACCM and GA-HACCM compared to original HACCM using either ANOVA or Kruskal–Wallis H test, because it is suitable for comparing the means from more than two distinct groups of data. However, before either ANOVA or Kruskal–Wallis H test is conducted, all techniques must be tested for normality to determine whether its data is normally distributed. Table IV presents the result of Shapiro–Wilk W tests of normality.

Table IV presents the results from Shapiro–Wilk W test of normality. It is concluded that the accuracies of PSO-HACCM,

PSO-HACCM vs GA-HACCM	6.80	< 0.001

GA-HACCM, and original HACCM techniques are not normally distributed since $p < 0.05$, therefore non-parametric test such as Kruskal–Wallis H test should be conducted instead. On the other hand, the sum of bit-scores and processing time criteria for these techniques are normally distributed, and thus the ANOVA can be conducted for testing the score of these techniques.

The Kruskal–Wallis H test results for the accuracy of PSO-HACCM, GA-HACCM, and original HACCM are shown in Table V, with the post-hoc results using Dwass–Steel–Critchlow–Fligner pairwise comparison is shown in Table VI. Meanwhile, the assumption checks and test of homogeneity of variances for the sum of bit-scores and processing time of PSO-HACCM, GA-HACCM, and original HACCM are shown in Tables VII and VIII, respectively.

Based on the results shown in Table V, there are a statistically significant effect of three techniques $[H(2) = 50.9, p < 0.001]$. Post-hoc comparisons using Dwass–Steel–Critchlow–Fligner pairwise comparison on each pair of groups which is shown in Table VI indicated that there is a statistically significant difference between the accuracy of HACCM and PSO-HACCM ($W = 9.42, p < 0.001$), HACCM and GA-HACCM ($W = 5.29, p < 0.001$), and PSO-HACCM and GA-HACCM ($W = -6.07, p < 0.001$).

On the other hand, based on the results shown in Tables VII and VIII, the sum of bit-scores is normally distributed and there is homogeneity of variances for the sum of bit-scores between groups of techniques, therefore the assumption of ANOVA has been validated, and thus, the Fisher's test must be conducted and Tukey HSD post-hoc tests must be used consequently. On the contrary, the processing time is not normally distributed and there are no there are homogeneity of variances for the processing time between groups of techniques, therefore the assumption of ANOVA has been violated, and the Kruskal–Wallis H test must be conducted instead.

Thus, the ANOVA for the sum of bit-scores of PSO-HACCM, GA-HACCM, and original HACCM are shown in Table IX with the post-hoc results using Tukey HSD and Games–Howell are shown in Table X for the sum of bit-scores, while the Kruskal–Wallis H test results for the processing time of PSO-HACCM, GA-HACCM, and original HACCM are shown in Table XI, with the post-hoc results using Dwass–Steel–Critchlow–Fligner pairwise comparison is shown in Table XII.

Based on the results shown in Table IX, there is a statistically significant effect of the sum of bit-scores between PSO-HACCM, GA-HACCM, and original HACCM techniques $[F(2, 147) = 15.0, p < 0.001]$ at the $p < 0.05$ level. Post-hoc comparisons using the Tukey HSD test shown in Table X indicated that the mean score for the sum of bit-scores of PSO-HACCM is statistically significantly better than HACCM $[t(147) = -5.35, p < 0.001]$ and GA-HACCM $[t(147) = 3.68, p < 0.001]$, while there is no statistically significant difference between HACCM and GA-HACCM $[t(147) = -0.167, p = 0.222]$.

Meanwhile, based on the results shown in Table XI, there are a statistically significant effect of three techniques $[H(2) = 35.3, p < 0.001]$. Post-hoc comparisons using Dwass–Steel–Critchlow–Fligner pairwise comparison on each pair of groups which is shown in Table XII indicated that the mean score for the processing time of PSO-HACCM is statistically significantly better than HACCM ($W = -7.72, p < 0.001$), and GA-HACCM ($W = 6.80, p < 0.001$). These statistical test results of accuracy, sum of bit-scores, and processing time confirm that PSO-HACCM technique is indeed improving the performance of the original HACCM.

To further validate the performance of the proposed techniques, these techniques should be validated by simulating the identification of unknown ncRNA sequences using the combined covariance model constructed by these techniques.

The identification will be using the testing dataset discussed in Section IV which has been set aside prior to the construction of the generic sequence models that simulates the identification of unknown ncRNA sequences. The result of this identification simulation is summarized in Table XIII.

Based on the summarized results in Table XIII, it can be seen that the mean accuracy of PSO-HACCM is higher compared to the GA-HACCM and original HACCM. This is due to PSO-HACCM successfully constructed the generic sequence models which can be used to recognize potential members of novel ncRNA families. To determine the significance of the PSO-HACCM results presented in Table XIII compared to GA-HACCM and original HACCM, another statistical validation using ANOVA or Kruskal–Wallis H test must be conducted. As mentioned earlier, all techniques must be tested for normality to determine whether its data is normally distributed. Table XIV presents the result of Shapiro–Wilk W tests of normality for these techniques.

Based on the results presented in Table XIV, it is concluded that the identification accuracies of PSO-HACCM, GA-HACCM, and original HACCM techniques are normally

PSO-HACCM vs GA-HACCM	9.851	4.685	147	< 0.001

distributed since $p \geq 0.05$, and thus the ANOVA can be conducted for validating the identification accuracy of these techniques. The assumption checks and test of homogeneity of variances for the identification accuracy of PSO-HACCM, GA-HACCM, and original HACCM are shown in Tables XV and XVI, respectively.

Based on the results shown in Tables XV and XVI, the identification accuracy is normally distributed and there is homogeneity of variances for the identification accuracy between groups of techniques, therefore the assumption of ANOVA has been validated and the Fisher's test results must be considered and Tukey HSD post-hoc tests must be used consequently. The ANOVA for the identification accuracy of PSO-HACCM, GA-HACCM, and original HACCM is shown in Table XVII with the post-hoc results using Tukey HSD is shown in Table XVIII.

Based on the results shown in Table XVII, there is a statistically significant effect of the identification accuracy between PSO-HACCM, GA-HACCM, and original HACCM techniques $[F(2, 147) = 13.6, p < 0.001]$ at the $p < 0.05$ level. Post-hoc comparisons using the Tukey HSD test shown in Table XVIII indicated that the mean score for the identification accuracy of PSO-HACCM is statistically significantly better than HACCM $[t(147) = -4.31, p < 0.001]$ and GA-HACCM $[t(147) = 4.685, p < 0.001]$, while there is no statistically significant difference between HACCM and GA-HACCM $[t(147) = 0.373, p = 0.926]$.

From the comparative performance measurements and statistical validations conducted throughout this section, it can be concluded that PSO-HACCM is indeed performing better compared to the original HACCM as well as GA-HACCM, thanks to its generic sequence model construction.

VI. CONCLUSION

The comparison of accuracy, sum of bit-scores, and processing time have been conducted between original HACCM,

PSO-HACCM, and GA-HACCM to demonstrate the capability of the proposed techniques in constructing generic sequence models, which can be used to recognize potential members of novel ncRNA families. Performance measurement results show that proposed PSO-HACCM performs better than the original HACCM and the proposed GA-HACCM technique, in terms of optimization performance, identification accuracy, sum of bit-scores, and processing time. This finding opens up the possibilities of future works, such as leveraging Graphical Processing Unit (GPU) to speed the computation process, explorations of other swarm intelligence techniques, and inclusion of more gene families for the dataset.

Abstract—A novel coronavirus disease (COVID-19) has been a severe world threat to humans since December 2020. The virus mainly affects the human respiratory system, making breathing difficult. Early detection and Diagnosis are essential to controlling the disease. Radiological imaging, like Computed Tomography (CT) scans, produces clear, high-quality chest images and helps quickly diagnoses lung abnormalities. The recent advancements in Artificial intelligence enable accurate and fast detection of COVID-19 symptoms on chest CT images. This paper presents COVIDnet, an improved and efficient deep learning Model for COVID-19 diagnosis on chest CT images. We developed a chest CT dataset from 220 CT studies from Tamil Nadu, India, to evaluate the proposed model. The final dataset contains 5191 CT images (3820 COVID-infected and 1371 normal CT images). The proposed COVIDnet model aims to produce accurate diagnostics for classifying these two classes. Our experimental result shows that COVIDnet achieved a superior accuracy of 98.98% when compared with three contemporary deep learning models.

Keywords—Coronavirus disease; reverse transcription polymerase chain reaction; computed tomography; deep learning

I. INTRODUCTION

The COVID-19 pandemic was the outcome of the Corona virus's rapid global spread. By 2022, there were 575 million COVID-19 patients, 6 million fatalities, and 12 billion vaccination doses [1]. The symptoms of COVID-19 include fever, chills, cough, headache, exhaustion, loss of smell, sore throat, runny nose, vomiting, and diarrhea. Affected individuals may also be asymptomatic. Affected individuals may also be asymptomatic. At least one-third of infected individuals don't have any symptoms at all. Identifying and reducing the spread of COVID-19 is a challenge task for medical experts. Therefore, there is an essential need to identify a faster and more accurate diagnostic methods for COVID-19.

Reverse Transcriptase and Polymerase Chain Reaction (RT-PCR) is a highly specific test that uses a sample taken from a human nose or throat. There have been reports of low COVID-19 sensitivity and it takes 3 to 4 days [2]. Patients with COVID-19 who undergo chest radiography (X-ray) [3] are defined as having bilateral air space consolidation due to inaccuracies in laboratory methods.

Chest radiography is crucial in the early detection and treatment of individuals with suspected or confirmed chest infections during the COVID-19 pandemic. It is entirely accessible in urgent care centers and emergency rooms. The combination of multi-focal peripheral lung abnormalities, such as GGO and/or consolidation, is described by X-ray [4]. These are frequently bilateral, and the COVID-19 diagnosis is challenging since other reasons of respiratory problems prevent consistent detection in X-rays.

Chest CT, a high-sensitivity alternative method for accurate COVID-19 diagnosis, is utilized in conjunction with X-ray imaging[5]. When COVID-19 is detected, the chest CT's main function is to diagnose the disease early [6]. Several advantageous COVID-19-related chest CT scenarios: There is no distinct test for COVID-19 and there is no additional expense to discover COVID; the chest CT examination is performed for other purposes such as cancer screening [7], operations [8], and neurological examinations [9]. People with poorer respiratory conditions underwent simply a chest CT and no other testing right away to figure out their COVID-19. Close contact with the infected patients results in probable COVID-19 [10], but the viral testing come out negative in this instance. To confirm COVID-19 confirms the abnormalities displayed inside the lungs, chest CT imaging is the sole treatment option.

Physicians and radiologists can assist COVID patients with a quick diagnosis by using an automatic diagnostic tool for COVID-19. For the detection of COVID-19 using chest CT, numerous investigations have been carried out. To create an automated technique for detecting COVID-19 [11], computer scientists have thoroughly researched the deep learning models. Despite these efforts, there is a growing need to make these models more reliable and realistically useful by improving their diagnostic performance. This work presents *COVIDnet*, an enhanced and effective deep learning model architecture. To increase COVID detection accuracy on chest CT images, the proposed COVIDnet is built on CNN architecture and has 22 layers. We created a dataset of 5191 CT images (3820 COVID-infected and 1371 normal CT images) from 220 CT scans from hospitals in Tamilnadu, India, in order to evaluate our model. When compared against three current deep learning models, including CNN, VGG16, and MobileNet, our COVIDnet model had the greatest accuracy of 98.98%.

The paper is organized as follows: Section II summarizes the related studies; Section III presents the proposed methodology. Section IV describes the experimental setup and results, and Section V concludes the paper.

II. RELATED WORK

The COVID-19 pandemic has turned into a significant worldwide problem as researchers try to find a way to stop the virus' spread and infection rate. Several research projects have started based on the AI systems recommended for COVID-19 detection CT images. Studies have shown the efficiency of CT scan image processing for diagnosing COVID-19 while also demonstrating the degree of infection, which can be significant for improved treatment options. Several researchers have presented AI-based COVID-19 identification methods. For the most part, deep learning-based approaches have generated very encouraging detection accuracy for COVID-19. We have reviewed a few studies and compared them to our proposed model.

Several studies are cited when discussing chest CT imaging. 746 chest CT scan pictures are analyzed using the LeNet-5 CNN model [12], which forecasts COVID and normal. Here, the dataset has been upgraded and increased utilizing augmentation techniques, making it more useful and accurate to 86.06%. The 746 chest CT scans were trained using 147 million parameters and three distinct learning techniques using the EfficientNet model [13], which achieved an accuracy of 89.7%. For COVID-19 feature extraction and binary classification, an optimized DL network Whale Optimization Algorithm (WOANet) [14] was used. They employed CCT pictures to diagnose COVID-19 using the ResNet-50 CNN network. They optimized the hyperparameters to achieve the best performance using the backpropagation and WOA algorithms. Preprocessing and Region of Interest (ROI) extraction are not required for the suggested technique. They applied COVID-CT dataset.

A deep learning-based system for the automated diagnosis of COVID-19 patients was built via GAN architecture [15]. The suggested framework offered a strong performance at many phases and an efficient feature extraction. To produce additional Chest Computed Tomography (CCT) images for DL network training, the initial step is augmenting the data using a generative adversarial network (GAN) architecture. In the second stage, the Generative Adversarial Network (GAN) hyperparameters are optimized using the WOA optimization. The major goal was to prevent overfitting and instability problems. Finally, COVID-19 patients were automatically classified during the classification step using a pretrained InceptionV3 DL model. They made use of the 2,482 CCT scan images from the SARS-CoV-2 CT-Scan dataset. The experimental investigation demonstrated that the suggested model performed better than other cutting-edge models.

A deep learning-based automated screening strategy was developed by the local attention classification model [16] to separate CT samples found to have COVID-19 or influenza-A viral pneumonia from the sample of patients with healthy lungs. The experimental result showed an overall classification accuracy of 86.7% for the 618 lung CT images dataset. In order to extract the best attributes for identifying COVID-19 and differentiating it from healthy cases and pneumonia infections, a completely automated system was presented using CNN [17]. The 400 CT scans in the used dataset resulted in an overall COVID-19 case detection accuracy of 96%.

A better version of DRENet [18] is an autonomous deep-learning identification method to help medical professionals

TABLE I. TN-COVID DATASET

S.No.	Category	No. of chest CT studies	No. of images
1	COVID	166	3820
2	Normal	54	1371
	Total	220	5191

find and identify COVID-19-infected individuals. The obtained dataset included CT scans from 100 bacterial pneumonia samples, 88 COVID-19 samples, and 86 healthy samples. With an accuracy of 95%, this DRENet deep learning network could identify and categorize samples that were contaminated with COVID-19 and bacterial pneumonia. A system to provide a clinical identification of the pathogenic examination utilizing a CNN-based [19] automated technique in detecting distinctive COVID-19 characteristics. With 217 cases in the dataset, the accuracy was 82.9%.

Using a dataset with 1495 patients with COVID-19 and 1027 patients with CAP, an adaptive feature selection guided deep forest (AFSDF) algorithm [20] was used to classify COVID-19 from chest CT images. This model was developed using a high-level feature representation. A feature selection method was applied to lessen the redundancy of the features based on the trained deep forest model. The COVID-19 classification model was adaptively updated to include this feature selection technique. There were 91.79%, 93.05%, 89.95%, and 96.35% values for accuracy, sensitivity, specificity, and area under the ROC curve, respectively.

Developing an automated approach for classifying lung CT scans is still challenging due to the complexity of diagnosing inflammatory and infectious lung illness via visual assessment. An appropriate norm as a visual examination is subject to errors due to the vast number of patients requiring diagnosis. A method that uses a CNN-based [21] automated technique to identify specific COVID-19 traits to provide a clinical identification of the pathogenic evaluation. With 217 examples in the sample, the accuracy was 82.9%.

The aforementioned deep learning models for COVID-19 detection use chest CT images to address the working models. We performed tests on the independently gathered raw TN-COVID dataset and contrasted its performance with that of the publicly integrated dataset using accepted assessment metrics. The effectiveness of the current deep learning models to be further enhanced in order to create new models for future development and to offer visualizations for better model explanation.

III. MATERIALS AND METHODOLOGY

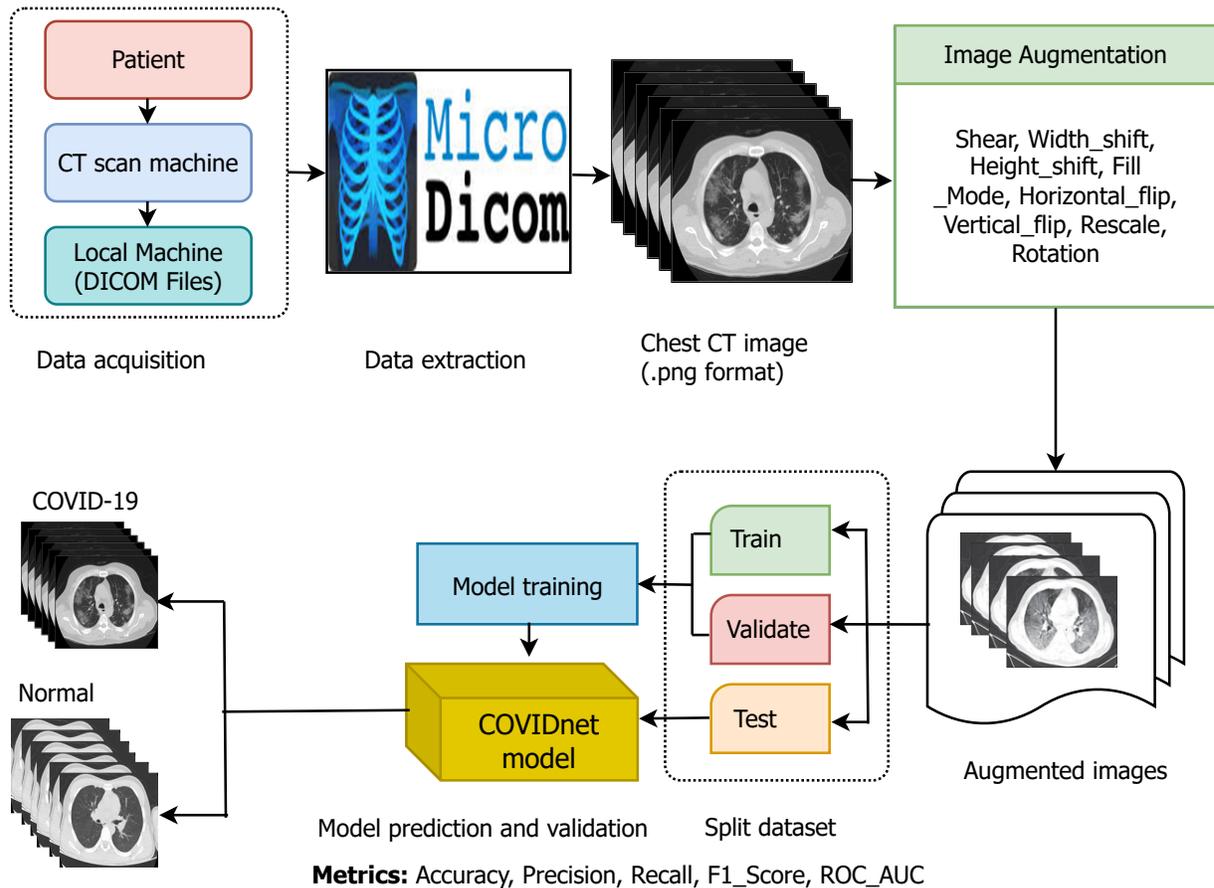
Fig. 1 shows the proposed methodology for COVID-19 detection using deep learning and chest CT images. Chest computed tomography (CT) images from different hospitals in Tamilnadu were gathered to create the dataset. The chest CT images are cleaned, annotated, and expanded using image augmentation techniques. Then, the final chest CT dataset is split into training, testing, and validation sets to evaluate the efficacy of the proposed COVIDnet model using five performance metrics. The final model is implemented into a


Fig. 1. The Proposed COVID-19 Detection Methodology using COVIDnet Model.

web-based application to identify whether the given chest CT image is from COVID-19 or a normal patient.

A. Data Collection

The chest CT dataset used in this study is directly collected from a hospital in Tamilnadu, India. The CT scanner (Aquilion Lightning Model Tsx 035a), which scans the chest and records the information on a local device, is used to acquire the data. The *MicroDicom viewer* application is used to extract the chest CT images from the DICOM (Digital Imaging and Communications in Medicine) format files that the CT scan machine stores internally. The extracted 16-bit grayscale images in .PNG format have a resolution of 512 by 512 pixels. With the assistance of radiologists and medical professionals, the extracted chest CT images are cleaned. After cleaning, there were 1371 and 3820 images belonging to 54 healthy and 166 COVID-infected patients, respectively. The final dataset, named the *TN-COVID dataset*, consists of 5191 images from 220 CT studies. Additional metadata and anonymized patient information, including patient history and RT-PCR report, are collected. Table I displays an overview of the dataset.

B. Image Augmentation

Data Augmentation techniques are usually employed to increase the size of a training set in order to improve the performance while reducing the overfitting of deep learning models. A number of of common image transformation operations are used to generate more training samples. They are, random rotation and zoom, height and width shift, horizontal and vertical flip, and shear. These operations generate multiple images from each image and help increases the generalization of the trained models.

C. COVIDnet Architecture

For accurate COVID diagnosis in chest CT scans, the proposed COVIDnet model is built with 22-layers. Convolutional layer, pooling layer, flattening layer, dense layer, and activation function are the five key components of the proposed model. Fig. 2 shows the COVIDnet model architecture employing these layers. Below is a description of each of these layers.

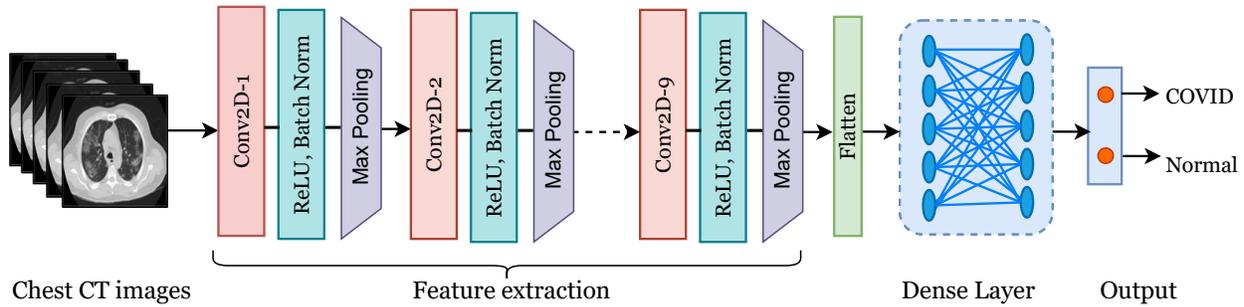
Convolutional Layer The convolution operation is applied to the input in the convolution neural network and the output is passed to the following layer. Convolution reduces the size


Fig. 2. The Proposed COVIDnet Architecture with 22-Layers for COVID-19 Detection on Chest CT Images.

of the image by combining all of its pixels into a single value. The parameters F, m, B, and W_j can be used to conduct convolution operations. F gives the kernel filter size, m sets feature mappings, B stands for bias, and W_j assigns the kernel weight. By employing a dot product to create one or more matrices, it extracts the feature from the input photos. To remove the features from left to right, convolutional filters are employed. Equation (1) denotes the output of the convolutional layer operation.

Pooling Layer A pooling layer is included when the image size is too huge, to shrink the feature map's size. It helps in speeding up computation, lowering the number of training parameters, and avoid overfitting. The pooling layer is usually added after convolutional layer. There are two categories of pooling: average pooling and maximum pooling. The average value for each component on the feature map is computed using average pooling, while the highest value for each component is generated using maximum pooling. The two hyper-parameters for the pooling layer are Filter and Stride. Equations (2) and (3) denotes the pooling operations. The step that kernels take to shift on the input image is marked by S, while the kernel size is denoted by F.

Flatten Layer It reduces the feature map matrix in its entirety to a single column. The fully linked layer received this input from the single column matrix to categorize the chest CT image.

Dense Layer The dense layer's function is to categorize the output from the convolutional layer for classification. Which features match mostly in a given class are determined by the preceding layer output. It outlines the high-level feature's weights. The input is the weighted average, which is then processed by a nonlinear function acting as an activation function. To calculate the weights and the previous layer, the fully linked layer supplies the accurate probabilities from various classes. The output is classified using the activation function.

Activation Function The activation function defines the sum of the weighted inputs transformed into outputs in the network. Three common activation functions are ReLU, Sigmoid, and Leaky ReLU. The performance of MaxPooling2D is proved by these three activation functions, as shown in equations (4) and (5).

It shows that x is a real number. A sigmoid function has a 0 to 1 range and resembles an S-shaped curve. To change an

TABLE II. LIST OF SYMBOLS

Parameter	Description
F	Specifies the kernel (filter) size
B	Bias
W_j	Weight of the kernel
S	Stride size
$f(z)$	Softmax function
Y_i^1	Output of a convolutional layer, where i indicates the ith feautre map
W_1, H_1	Width and Height of input
$l-1$	Fully connected layers
$m_1(l-1)$	Feautre maps

actual value into one that is easier to understand and can be translated into a probability score. Because sigmoid function networks take longer to train than other types of networks, the vanishing gradient problem quickly converges to 0. ReLU is a linear function that resolves the vanishing gradient issue by setting zero on all negative inputs. Based on the ReLU activation function, a "leaky ReLU" model leaks some positive values to 0 while defining the small slopes with negative values. The slope of the small negative function is represented by the value of x, which is less than zero.

Fig. 2 shows the proposed 22-layer CNN model. Moreover, Table III shows the list of steps used in the development and validation of the proposed COVIDnet model. Nine convolutional, max-pooling, and leaky ReLU layers make up the proposed COVIDnet model. Batch normalization speeds up and improves the stability of the model processing by normalizing, re-centering, and scaling the input. The neural network can be trained more quickly and effectively using the Adam optimizer by adjusting the parameters, first and second gradient moments to modify the learning rate and lower the loss. To discover the optimum accuracy for our suggested model, the deep learning model construction process combines all the layers, activation functions, and optimizer values. We changed the activation function and optimizer settings for every parameter in the extra layers of the proposed model. Our basic layer model is enhanced with 2D Convolutional and MaxPooling layers to produce improved results for two class

classifications.

IV. EXPERIMENTAL RESULTS AND DISCUSSION

A. Experimental Setup

Python 3 was used to implement the proposed COVIDnet model utilizing the Keras and TensorFlow frameworks. To increase the training pace, we ran all of our tests on the GPU-powered Kaggle platform. Adam optimizer is used to train the proposed 22-layer COVIDnet model. The batch size is 32, and the learning rate is 0.0001. Different models were trained using various epochs (25, 50, 75, 100, 125, 150, 175, and 200), and we compared the model performance to prevent over-fitting and increase the model's generalizability. The model evaluation is generalized using a 5-fold cross-validation method. Additionally, accuracy, precision, recall,

F1-Score, and ROC-AUC, five common performance metrics, were utilized to compare the performance of the proposed COVIDnet with three conventional deep learning models: simple CNN, VGG16, and MobileNet. Based on ImageNet, the weights of the VGG16 and MobileNet models were initialized.

B. Results

Table IV to Table VIII and Fig. 3 to Fig. 7 compare the experimental findings. As shown in Table IV and Fig. 3, the COVIDnet model obtained the highest classification accuracy of 98.98% with epoch 200. The VGG16 model comes in second with a 96.91% accuracy rate. The accuracy rate for the MobileNet is the lowest (94.10%) as shown in Table IV and Fig. 3. As shown in Table V and Fig. 4, the COVIDnet model also obtained the highest precision of 97.87% with epoch 200. The VGG16 model comes in second with a precision score of

TABLE III. COVIDNET MODEL DEVELOPMENT AND VALIDATION

Input:	TN-COVID chest CT image dataset (5191 images)
Output:	**COVIDnet** model and prediction results (accuracy, precision, recall, F1-Score, and ROC-AUC)
Step 1:	Import sklearn, tensorflow, keras, and other libraries
Step 2:	Load the TN-COVID dataset
Step 3:	Perform image augmentation using ImageDataGenerator() by Rotation, shear, width_shift, height_shift, channel_shift, fill_mode, horizontal_flip, vertical_flip, and rescale.
Step 4:	Split the augmented images into train(60%), validation (20%) and test (20%) sets and load them into different variables.
Step 5:	Initialize *COVIDnet* model and add nine Conv2d layers and nine Maxpool2d layers. The convolution operation is performed by the below equation:

$$Y_i^1 = B_i^1 + \sum_{j=1}^{m_1(I-1)} F_i, j * W_j^{(l-1)} \tag{1}$$

Pooling operations are performed by adjusting the width and height of feature maps which is performed by the below equations:

$$W_2 = \frac{W_1 + F}{S} + 1 \tag{2}$$

$$H_2 = \frac{H_1 + F}{S} + 1 \tag{3}$$

Step 6:	Add batch normalization and activation (ReLU) function to the model. The ReLU function is shown below.

$$f(z) = \max(0, x) \tag{4}$$

$$f'(z) = \begin{cases} 1 & \text{if } z > 0 \\ 0 & \text{if } z \leq 0 \end{cases} \tag{5}$$

Step 7:	Add a dense layer using dense() with an activation function of Softmax

$$f(z)_i = \frac{e^{z_j}}{\sum_{k=1}^{k} e^{z_k}} for j - 1, ..., k \tag{6}$$

Step 8:	Train the *COVIDnet* on the training dataset using fit_generator(). The validation set is used to evaluate the model performance during training.
Step 9:	Test the accuracy of the trained *COVIDnet* model on the test set and report the final results using five performance measures.

96.56%. The model from MobileNet has the lowest precision at 93.05%. Aditionally, the COVIDnet model obtained the highest recall rate of 96.57% with epoch 200, as shown in Table VI and Fig. 5. The VGG16 model, which has a recall rate of 93.33%, comes next. The CNN model's 91.32% recall rate is the lowest.

Additionally, as shown in Table VII and Fig. 6, the COVID-net model had the highest F1-score of 97.99% with epoch 200. With an F1-score of 93.89%, the MobileNet model comes in second. With an F1 score of 91.46%, CNN and VGG16

models are tied for last. As shown in Table VIII and Fig. 7, the COVIDnet model also obtained the highest ROC-AUC score of 98.11% with epoch 200. With a ROC-AUC score of 94.66%, the MobileNet model comes in second. The CNN model's ROC-AUC score of 90.00% is the lowest. Table IX and in Fig. 8 compare each of the five performance measures for four models with 200. It should be highlighted that the proposed COVIDnet model outperformed all other models on the TN-COVID dataset in every statistic. These enhanced outcomes show that the COVIDnet model may aid automated diagnosis of COVID in hospitals.

V. CONCLUSION

The human society is severely impacted by COVID-19. Several automated methods for precise and speedy COVID-

to identify COVID-19 using chest CT images, this research introduces a new deep learning-based model called COVIDnet. For precise COVID-19 detection on chest CT scans, a 22-layer binary classifier (normal or COVID) is proposed. On the TN-COVID dataset, the proposed COVIDnet outperformed three current deep learning models (basic CNN, VGG16, and MobileNet) with an accuracy of 98.98%, precision of 97.97%, recall score of 96.57%, F1-score of 97.99%, and ROC-AUC of 98.11%. These excellent outcomes demonstrate the path in which the COVIDnet model is being implemented into COVID-19 diagnostic tools in hospitals.

Abstract—**Implementation of Rao-blackwellized Particle Filter (RBPF) in grid-based Simultaneous Localization And Mapping (SLAM) algorithm with range sensors commonly developed by using sensor with dense measurements such as laser rangefinder. In this paper, a more cost convenient solution was explored where implementation of array of infrared sensors equipped on a mobile robot platform was used. The observation from array of infrared sensors are noisy and sparse. This adds more uncertainty in the implementation of SLAM algorithm. To compensate for the high uncertainties from robot's observations, neural network was integrated with the grid-based SLAM algorithm. The result shows that the grid-based SLAM algorithm with neural network has better accuracy compared to the grid-based SLAM algorithm without neural network for the aforementioned mobile robot implementation. The algorithm improves the map accuracy by 21% and reduce robot's state estimate error significantly. The better performance is due to the improvement in accuracy of grid cells' occupancy value. This affects the importance weight computation in RBPF algorithm hence resulting a better map accuracy and robots state estimate. This finding shows that a promising grid-based SLAM algorithm can be obtained by using merely array of infrared sensors as robot's observation.**

Keywords—*Simultaneous Localization And Mapping (SLAM); occupancy grid map; Neural Network; Rao-Blackwellized Particle Filter; infrared sensor*

I. INTRODUCTION

Sensor is an important element in mobile robot. Sensor such as vision sensor, range sensor and depth sensor are commonly serves as robot's observation of the world. Depending on the environment and task of the robot, different sensor have different advantages. For example, for underwater applications, acoustic based sensor such as sonar sensor is widely applied [1] while for drone navigation, vision sensor is more suitable [2]. Similar to other fields, a cost-effective solution is also a fundamental requirement in mobile robot implementation. Although, current sensors are very reliable for autonomous navigation, but to implement these fast and high accuracy sensor comes with significant cost. Hence, there is research that focuses on developing low-cost navigational method [3]. To achieve this objective, sparse and noisy sensors such as ultrasonic sensor or infrared sensor modules is an alternative to reduce the overall cost [4], [5]. Infrared sensor is commonly used in array configuration on robot's platform

to avoid obstacles using obstacles avoidance algorithm such as Braitenberg algorithm [6]. This configuration gives sparse measurements as the measurements only available at certain angles. In contrast to range sensor such as laser ranger finder or ratating infrared sensor that gives more dense measurements at much higher cost.

There are previous works in robot's simultaneous localization and mapping or SLAM that uses sparse and noisy sensors with neural network as a method to evaluate cells' occupancy in grid map [7], [8], [9]. Using neural network to interpret sensor measurements into occupancy grid cell gives multiple advantages on noisy and sparse sensors implementation. The first one is that from the training data, neural network can generally distinguish erroneous sensor measurements or also called "maximum range" readings. These readings can be caused by poor reflecting surfaces such as glass materials [10] and in situations where no obstacle is within the measurement range of the sensor. Neural network is a simpler approach compared to identify the properties of surface's reflection and compute angle of incidence of sensor's beam to differentiate erroneous measurements [11]. Another advantage is that, the noise caused by injective and non-linear sensor model of infrared sensor can be reduced based on training data [9]. Other than that, neural network can interpret multiple sensors reading concurrently rather than interpreting range measurements independently. This way, the correlation between adjacent sensors can be exploited. This can gain more information for sensors in ring or array formation [7], [12].

To implement grid-based SLAM with array of infrared sensors, the proposed method is to counterbalance the limitation of sparse measurement produce from array of infrared sensor by expanding or extrapolating the sensor measurements. Thus, in this research, the integration of neural network with grid-based SLAM algorithm were developed and experimented with array of infrared sensors.

Overall in this paper, Section 2 describes the method used to carry out the experiments, which consists of the framework for Rao-blackwellized Particle Filter algorithm and neural network configuration. Next, Section 3 reports the results of neural network training, robot's state estimate and map estimate of the SLAM algorithm described. The analysis of the algorithm performance is included as well. Lastly, Section

4 concludes the results of this paper.

II. METHOD

In this section, the Rao-blackwellized Particle Filter (RBPF) algorithm with neural network are explained and elaborated. This consists of the method applied in each component of the RBPF framework.

A. Rao-Blackwellized Particle Filter Algorithm

The Rao-Blackwellized Particle Filter uses particles to estimate robot's state, like the particle filter algorithm. Here, each particle maintains a hypothesis of robot pose that assume its position is correct. Each particle build a map based on its trajectory which is also their own version of the map [13]. The algorithm of learning grid maps using RBPF or grid-based SLAM algorithm is described as follows:

1) **Sampling**: Sample i^{th} particle, $x_t^{[i]}$ to generate current set of particles, X_t by sampling from a proposal distribution.
2) **Importance weighting**: Calculate the importance weight of ith particle, $w_t^{[i]}$, which accounts for how the robot's observation, z_t match with the current map estimate, $m^{[i]}$.
3) **Map update**: Update the particles' map estimate, $m^{[i]}$, conditioned on robot's state, $x_t^{[i]}$ and robot's observation, z_t.
4) **Density extraction**: Calculate the density of X_t by using weighted mean method. The density of X_t, is the single state that represent the robot's position state estimate, x_{est}. The map update for x_{est} is computed as well.
5) **Resampling**: Resample the particles proportionally to the particles' weight. Particles with higher weight will be most likely to be resampled for the next generation of particles.

B. Sampling from Motion Model

In the sampling step, the current set of particles, X_t is sampled from a proposal distribution. In this paper, the particles, X_t is sampled from motion model proposal distribution to predict robot's state. Looking at the ideal case, if particles can be sampled from a true target distribution, the weight of all particles will be equal and the same set of particles, X_t can be maintained without the resampling step [14]. However, a closed form of this posterior is not available in general. As a result, typical method is to sample from motion model, $p(x_t|a_t, x_{t-1})$ as the proposal distribution and use the observation model, $p(z_t|m, x_t)$ as the importance weight.

The motion model makes used of robot's transition model which can be modelled either using velocity information or odometry measurements [15]. For this research, odometry-based model is used by utilizing the wheel encoders' measurements in the robot system. A transition model for two wheels robot from [16] is adapted.

Equation (1) describes the transition from previous state, $x_{t-1} = (x, y, \theta)^T$ to current state, $\bar{x}_t = (\bar{x}, \bar{y}, \bar{\theta})^T$. The notation $\bar{x}_t$ is used (instead of x_t) to denote that this is the

predicted value of current robot's state. The robot movement is illustrated in Fig. 1. Here, l and r are the traveled distance by left wheel and right wheel respectively. While b is the distance between two wheels. $\Delta\theta$ is the change of robot orientation where the calculation is $\Delta\theta = (r - l)/b$ [16].

$$\begin{pmatrix} \bar{x} \\ \bar{y} \\ \bar{\theta} \end{pmatrix} = \begin{pmatrix} x \\ y \\ \theta \end{pmatrix} + \begin{pmatrix} \frac{r+l}{2}\cos(\theta + \frac{r-l}{2b}) \\ \frac{r+l}{2}\sin(\theta + \frac{r-l}{2b}) \\ \frac{r-l}{b} \end{pmatrix} \qquad (1)$$

The essence of probabilistic SLAM is to model measurements by taking into account the uncertainty that comes with the measurements. The odometry measurements were described using probabilistic motion model $p(x_t|x_{t-1}, a_t)$. The motion model defines uncertainties or noise from transition model described earlier. $p(x_t \mid x_{t-1}, a_t)$ gives the likelihood of a robot current position, x_t given that previously it was at x_{t-1}. Subsequently, it moves and odometry data, a_t is measured. The odometry motion model makes used of robot's odometry data. Odometry motion model sampling is an approach where the relative odometry at time $t-1$ to t is divided into three consecutive actions; initial turn, δ_{rot1}, a translation, δ_{trans}, and a second turn, δ_{rot2} as illustrated in Fig. 2 [15].

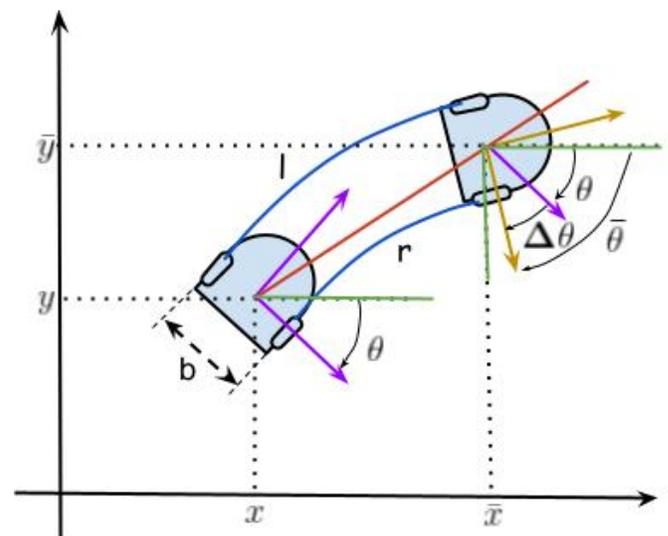
Algorithm 1 shows the complete algorithm to sample from motion model distribution. The relative odometry is calculated using trigonometry (see line 4 to 6). At line 7 to 9, noise terms; ϵ_{rot1}, ϵ_{trans}, and ϵ_{rot2} are sampled from Gaussian probability distribution with mean zero and the standard deviation of robot-specific parameters, α_1 to α_4. These parameters specify the noise in robot motion where α_1 and α_4 are the rotational errors or angular error, and α_2 and α_3 are the translational errors. These errors come with the motion of relative odometry, δ_{rot1}, δ_{trans}, and δ_{rot2}. In the next subsection the computation of importance weight of each particle is explained.


Fig. 1. Robot Moves from $(x, y, \theta)^T$ to $(\bar{x}, \bar{y}, \bar{\theta})^T$.
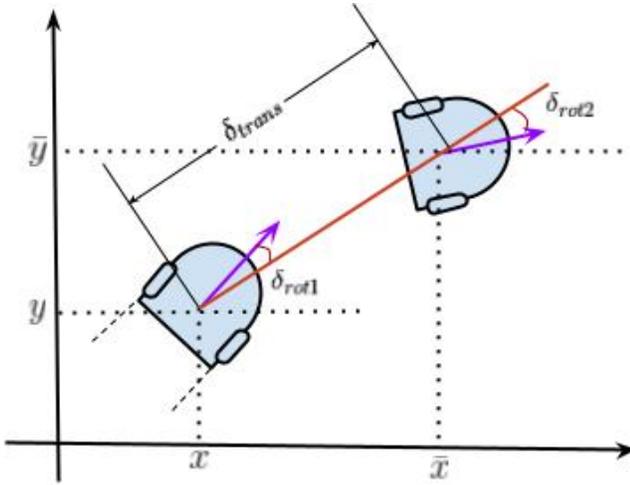

Fig. 2. Relative Odometry shows Initial Turn, δ_{rot1}, a Translation, δ_{trans}, and a Second Turn, δ_{rot2}.

Algorithm 1 Sampling with Odometry Motion Model

Require: x_{t-1}, a_t

1: $\bar{x}_t = g(x_{t-1}, a_t)$
2: $\langle x, y, \theta \rangle = x_{t-1}$
3: $\langle \bar{x}, \bar{y}, \bar{\theta} \rangle = \bar{x}_t$
4: $\delta_{rot1} = atan2(\bar{y} - y, \bar{x} - x) - \bar{\theta}$
5: $\delta_{trans} = \sqrt{(\bar{x} - x)^2 + (\bar{y} - y)^2}$
6: $\delta_{rot2} = \bar{\theta} - \theta - \delta_{rot1}$
7: $\epsilon_{rot1} \sim \mathcal{N}(0, \alpha_1|\delta_{rot1}| + \alpha_2\delta_{trans})$
8: $\epsilon_{trans} \sim \mathcal{N}(0, \alpha_3\delta_{trans} + \alpha_4|\delta_{rot1}| + \alpha_4|\delta_{rot2}|)$
9: $\epsilon_{rot2} \sim \mathcal{N}(0, \alpha_1|\delta_{rot2}| + \alpha_2\delta_{trans})$
10: $\hat{\delta}_{rot1} = \delta_{rot1} + \epsilon_{rot1}$
11: $\hat{\delta}_{trans} = \delta_{trans} + \epsilon_{trans}$
12: $\hat{\delta}_{rot2} = \delta_{rot2} + \epsilon_{rot2}$
13: $x' = x + \hat{\delta}_{trans} \cos(\theta + \hat{\delta}_{rot1})$
14: $y' = y + \hat{\delta}_{trans} \sin(\theta + \hat{\delta}_{rot1})$
15: $\theta' = \theta + \hat{\delta}_{rot1} + \hat{\delta}_{rot2}$
16: **return** $x_t = (x', y', \theta')^T$

C. Importance Weight with Map Matching

Map-matching algorithm is used to obtain the importance weight of ith particle, $w_t^{[i]}$ at current time step, t. The map matching method uses similarities of local and global map of a particle. In this research, the map matching approach uses a match function introduced in [17]. The function compares the local map and the global map of each ith particle and recorded the number of match values. The match number, $match$ is then applied to the function in equation 2. In this equation, f is a parameter that will influence the distribution of particles' weight.

$$w_t^{[i]} = w_{t-1}^{[i]} e^{\frac{match^{[i]}}{f}} \qquad (2)$$

The if and else cases in (3) shows how $match$ is calculated. A local map denotes by m_l and a global map denotes as m_g. $p(m_{g,j})$ and $p(m_{l,j})$ are the probability of occupancy for global map and local map at jth cell respectively. While occ and $free$ are the threshold values that a cell is considered

occupied or free respectively. The $match$ value is added by one if the jth cell of both local and global map exceed the occ threshold value. While for a contradict value of jth cell, the $match$ value is deducted by one.

$$match = \begin{cases} +1, p(m_{g,j}) \geq occ \land p(m_{l,j}) \geq occ \\ -1, p(m_{g,j}) \geq occ \land p(m_{l,j}) \leq free \\ -1, p(m_{g,j}) \leq free \land p(m_{l,j}) \geq occ \end{cases} \qquad (3)$$

D. Selective Resampling

After the computation of weight for each particle, particles are resampled proportionally to their weight. The resampling step is executed based on a heuristic measure of how well the proposal distribution approximates the target distribution called number of effective sample size, N_{eff}. N_{eff} measures the variance of particles' weights. The N_{eff} value is calculated using equation (4), which is the reciprocal of the sum of squares of all particles' weight. Here, N is the number of particles or sample size. Practically, the normalized value of particles weight is used in the N_{eff} calculation.

$$N_{eff} = \frac{1}{\sum_{i=1}^{N}(w^i)^2} \qquad (4)$$

A lower N_{eff} value reflects that there is high variance in particle's weight distribution. This signals that some of the particles have significantly higher weight compared to the others. Algorithm (2) shows integration of selective resampling in particle filter algorithm whereas particles only resampled when N_{eff} value falls below a certain threshold. In this research, the threshold is set to $N/2$ [18]. Thus, particles are only resampled if N_{eff} value falls below half of the number of particles. This shows that the variance of particles' weight is significantly large and particles need to be resampled in order not to waste the particles on particles with low weights. If N_{eff} value is still within the threshold, all the particles are kept, with their normalized weights (see line 1 to 3). Normalization step gives more significant weight values to all particles.

Algorithm 2 Selective Resampling Algorithm

Require: $w_t^{[i]}, i \in \{1, \ldots, N\}$

E. Particle Density

As particle filter maintains a set of hypotheses of robot's state, the estimates of robot's state need to be represented. In other words, from the set of particles, X_t, the density of the particles, x_{est} is computed to evaluate the performance of the SLAM algorithm. There are multiple methods that can be implemented to estimate particles' density. One of the method is to calculate the weighted mean of all particles as the overall robot's state estimate, x_{est}. For the x and y state of x_{est}, equation (5) is used, where w^i is the weight of each particle. As for robot's heading, θ_{est}, a separate equation (6) is used to prevent discretization error in the mean heading.

$$x_{est} = \sum_{i=1}^{N} w^i x^i \qquad (5)$$

$$\theta_{est} = \arctan \frac{\sum_{i=1}^{N} \cos(\theta^i) w^i}{\sum_{i=1}^{N} \sin(\theta^i) w^i} \qquad (6)$$

F. Neural Network Configuration

In this research, neural network served as the inverse sensor model, $p(m_t|x_t, z_t)$ to evaluate the cell's occupancy value. $p(m_t|x_t, z_t)$ is termed as inverse sensor model because the model reasons from effects to causes, where the model provides world information (m_t) from sensor measurements (z_t) instead of the other way around, $p(z_t|m_t, x_t)$. The cell's occupancy value is then converted into log odd notation in the occupancy grid map algorithm which is part of the map update step. The overall map update step implemented is described in our previous work [19]. To interpret cell's occupancy, selected sensor measurements with encoded cell's position were used as the neural network inputs. The following describes the input configuration of the neural network, $\mathcal{N}$:

- Four sensors measurements, $\acute{z}_t^k$, $k \in \{1, 2, 3, 4\}$ that are closest to the cell, m_j.

- Encoded m_j's position using the distance, d_{m_j} and angle, θ_{m_j}.

Fig. 3 illustrates the measurements of d_{m_j} and θ_{m_j}. In the figure, array of infrared sensor on a mobile robot named Khepera III was used. This array configuration has nine infrared sensors, labelled as one until nine. The distance, d_{m_j} and angle, θ_{m_j} are determined by the sensor that is closest to cell m_j. In this illustration, sensor three has the closest distance. Thus, the position of cell m_j is encoded using the distance between m_j and sensor three and the angle of m_j to the same sensor. The four closest sensor measurements in this case will be sensor one, two, three and four, which are selected to be the input of neural network, $\mathcal{N}$.

At each time step, the sensor measurements and the predicted robot's state from motion model are preprocessed to determine the four closest sensor measurements, d_{m_j}, and θ_{m_j}. Hence, follows the configuration of the neural network, $\mathcal{N}$ input. The output of $\mathcal{N}$ is interpreted as probability of cell's occupancy $p(m_j|x_t, z_t)$. This process is repeated for all cells surrounding the Khepera III mobile robot, in order to build a local occupancy grid map, $\mathcal{G}$, with $n \times n$ cells as depicted in Fig. 3.

Fig. 4 shows part of the configuration of the neural network, $\mathcal{N}$. The input layer consists of input nodes that received the sensor measurements, encoded cell's position, and one bias node. There is no computation done on the input nodes but rather just to pass the inputs to the hidden layer. In the hidden layer, there are three neurons and one bias neuron. Bias neuron is used to provide every node in the adjacent layer with a constant value apart from the normal inputs that the node receives. Following normal practice, the bias for neural network, $\mathcal{N}$ is set to value 1. As for the output layer, since there is only one output which is the cell's occupancy value, thus there is only one neuron is in the output layer.

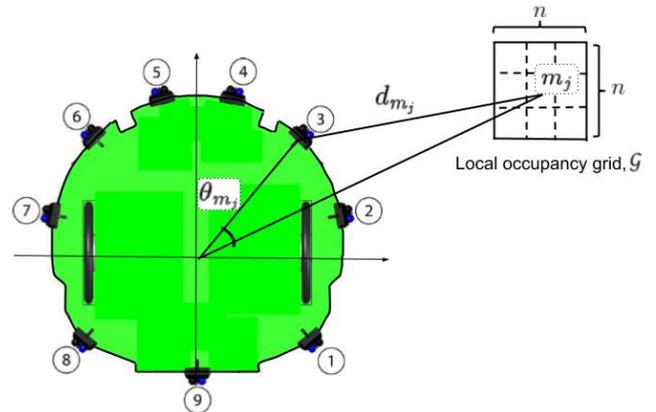
In neural network, each neuron in connected to all neurons in the adjacent layer as showed in Fig. 4. For each connection that connect from a neuron in one layer to the adjacent layer, there is a weight associated with the edge. Thus, in neural network, $\mathcal{N}$, there are $3 \times 7 = 21$ weights for the edges that connect the input layer to the hidden layer and $1 \times 4 = 4$ weights that connect the hidden layer to the output layer. Within these weights, four of them are associated with the bias neuron. Initially all the edges weights are random values.


Fig. 3. The Position of Cell m_j is Encoded using d_{m_j} and θ_{m_j} Relative to the Robot.
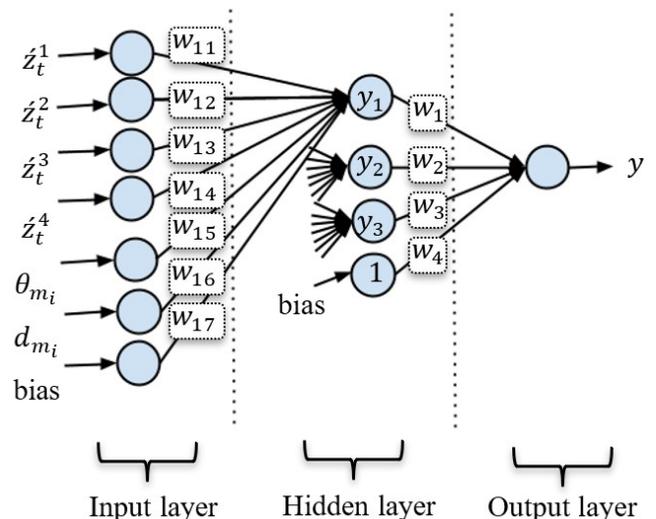

Fig. 4. Part of the Neural Network $\mathcal{N}$ Configuration.

Then, during the training process, for every set of input in the training dataset, each neuron in the hidden layer and the output layer in the neural network, $\mathcal{N}$ (excluding the bias neuron) is activated via an activation function. For example, for the first neuron in the hidden layer, the output of the neuron is obtained via equation (7).

$$
\begin{aligned}
y_1 = F(w_{11}\dot{z}_t^1 + w_{12}\dot{z}_t^2 + w_{13}\dot{z}_t^3 + w_{14}\dot{z}_t^4 \\
+ w_{15}\theta_{m_j} + w_{16}d_{m_j} + w_{17})
\end{aligned}
\tag{7}
$$

Here, w_{xx} is referred to the weight associated with the input neuron as illustrated in Fig. 4. While F is an activation function that compute the output of that neuron, y_1. The same equation with respective weights is applied on all neurons in the hidden layer which will produce the rest of the outputs, y_2 and y_3. Then y_1, y_2, and y_3, becomes the input to the activation function for the neuron in the output layer using equation (8). Here, w_x, referred the weights on edges that connects the hidden layer to the output layer as seen in Fig. 4 as well.

$$
y = F(w_1 y_1 + w_2 y_2 + w_3 y_3 + w_4)
\tag{8}
$$

The output, y, is then compared with the output in the training data for that inputs. Then, the error is propagated back to the previous layer. From the error, the weights for the edges are adjusted. This process is known as backpropagation technique. To analyze the performance of the RBPF SLAM algorithm integrated with neural network $\mathcal{N}$, implementation of inverse sensor model with $\mathcal{N}$ will be tested and compared with the RBPF SLAM algorithm without neural network in simulation experiments.

G. Overall Grid-based SLAM Algorithm with Neural Network

Fig. 5 shows the overall algorithm for the RBPF SLAM algorithm with neural network, $\mathcal{N}$ implemented. In summary, the importance weight of the particles is the observation likelihood $p(z_t|x_t)$. The process and entities in red color describes the integration of neural network, $\mathcal{N}$. Initially, measurements from infrared sensors and sampled particles are preprocessed to build the inputs for $\mathcal{N}$. In the preprocess step, encoded position of cell, m_j, and the measurement of four closest sensors, $\dot{z}_t^k$, $k \in \{1, 2, 3, 4\}$, are calculated. Then, these values are fed into $\mathcal{N}$ to build the local grid map, $\mathcal{G}$. Note that global occupancy grid map is maintained by each particle. Local map and global map are then used to calculate the importance weight of the particles by using the map matching algorithm.

The green boxes indicate selective resampling method described in section II-C. The dotted arrow lines represent the map update step which is executed after the particle's importance weight has been calculated. The final output is the density of robot's state estimate, x_{est} and its map, M, showed at the bottom part of the flowchart. The particles' density, x_{est} then updates the overall robot's trajectory, $x_{1:t}$.

III. RESULT AND ANALYSIS

The experiment was divided into two main parts. In the first part of the experiment, neural network, $\mathcal{N}$ was trained

with the input configuration described in section II-F. Then, in the second part of the experiment, the resulting map and robot's state estimate are analyzed by comparing the results to the ground truth occupancy grid map and the ground truth robot's trajectory.

A. Training Neural Network, $\mathcal{N}$

A neural network tool in MATLAB named patternet was used to train the neural network, $\mathcal{N}$. At the end of the training, the MSE value obtained was 0.0965. Table I shows the weights of edges that connecting the input layer to the hidden layer where y_1, y_2, and y_3 are the neuron in the hidden layer. Table II shows the weights for the edges connecting the hidden layer to the output layer.

Next, the resulting map and robot's state estimate from the RBPF algorithm integrated with the neural network, $\mathcal{N}$ is analyzed by comparing the result to the ground truth data. The ground truth was obtained from the robot simulator platform used in the simulation experiment named Webots robot simulator [20].

B. Map Score and RMSE

Table III shows the performance of the RBPF with neural network, $\mathcal{N}$ SLAM algorithm in terms of map's accuracy and

TABLE III.   MAP ACCURACY AND ROBOT'S STATE ESTIMATE ERROR OF RBPF SLAM ALGORITHM.

RBPF-SLAM	f_{occ}	f_{map}	RMSE(cm)
Without NN	0.2311	0.7012	34.84
With NN	0.7365	0.8491	9.42

robot's state accuracy. For the map state estimate, two methods of analysis were adapted; a fitness score for occupied cells, f_{occ}, and fitness score for all cells, f_{map}. While for robot's state accuracy, the root mean squared (RMSE) value was used as performance measure. This analysis methods is described in our previous work [19].

From Table III, it can be observed that the performance of robot's state estimate and map estimate are in agreement. Both analysis show that the accuracy of RBPF algorithm with neural network, $\mathcal{N}$ is better compared to RBPF algorithm without neural network in terms of robot's state estimate and map estimate accuracy. By adding neural network integration, the score of overall map estimate increases from 70.1% to 84.9%. While the RMSE of the robot's state estimate decreases from 34.84 cm to 9.42 cm.

C. Closing the Loop

Fig. 6 shows the test environment that was used in the simulation experiment with the Khepera III mobile robot in the middle. The rays of infrared sensors and ultrasonic sensors are also shown in the simulator. Fig. 7 shows the resulting map obtained from the simulation experiment. In the resulting map, three trajectories are shown. The robot's ground truth trajectory is the green line. The trajectory of robot state estimate from RBPF with neural network, $\mathcal{N}$ is shown in blue line, while the red line is the trajectory obtained from robot's odometry.

The visual observations of the resulting maps shows that when the robot revisited a known place (i.e. closing the loop) at approximately time step 1550, robot state estimate was able to have better estimate compared to odometry's trajectory. Fig. 7 shows robot's state estimate of RBPF with $\mathcal{N}$ algorithm in red rectangle managed to close the loop despite of robot's odometry begin to diverge from the actual path. This is a significant improvement because by using high variance sensor such as infrared sensor with sparse measurements, a grid-based SLAM algorithm with ability to correct robot's pose in indoor environment with static condition is obtained.

D. Effect of Resampling

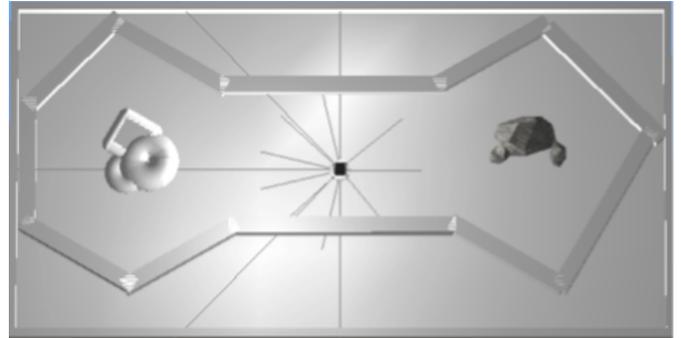
As mention in section II-D of the methodology section, the resampling step was executed when the efficiency of particles, N_{eff} has become lower than half of number of particles, N (i.e. $N_{eff} < N/2$). In this experiment $N = 20$ was used. Thus, whenever N_{eff} has become lower than 10, the particles will be resampled and particles' weight will be equal again with value 1. When resampling occurred, the particles that has lower weights are eliminated probabilistically, and the higher weight particles are duplicated. Hence, in some cases, good particles (i.e. particles with better robot's state estimate) are deleted as well. This will cause the spikes in pose error of robots' state estimate.


Fig. 6.   Test Environment Created in Webots Simulator.
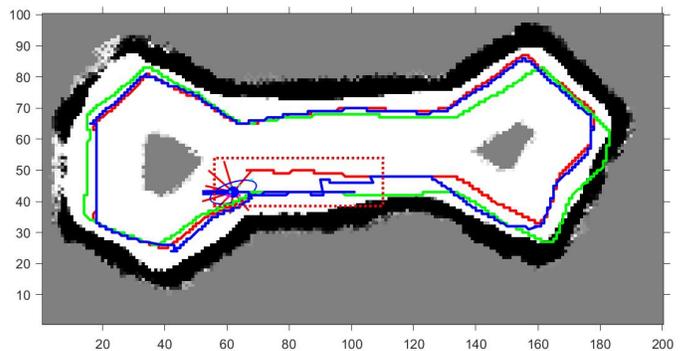

Fig. 7.   Map and Trajectory of Robot's State of RBPF with $\mathcal{N}$ in Blue Line.

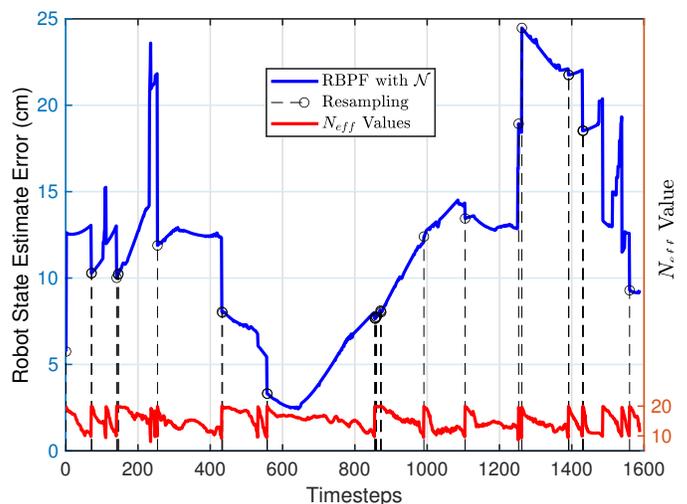
Fig. 8 shows the error of robot's state estimate of the RBPF algorithm with $\mathcal{N}$ along with the N_{eff} value at each time step throughout the robot's exploration. In this figure, some of the resampling steps are marked with black dashed line. From the figure, it can be observed that, whenever N_{eff} value drop below 10 and increased abruptly to 20, this is when the resampling steps occurred. If good particles were deleted, the pose error will increase. However, if bad particles were deleted, the robot's state estimate is better, hence the pose error decreases.


Fig. 8.   The Pose Error of RBPF with $\mathcal{N}$ Align to the Values of N_{eff} at Each Time Step.

E. Number of Particles, N

The experiment is repeated multiple times and it is observed that by using 20 particles the consistency of a converge solution is not achieved. To achieve a more stable and consistent result, a higher number of particles were used. In the subsequent experiment, 100 particles were used with a longer travelled path, where the robot was set to navigate the same route twice in the test environment. Two methods of density extraction is compared which is weighted mean, as described in Section II-E and particle with the highest weight to represent the particles' density.

Fig. 9 shows the robot state estimate error for x_{est} using weighted mean, denotes as x_{mean} and the highest weighted particle, denoted as x_{max}. The robot finished navigate the environment in the first round at approximately time step = 200 and continue on the same path afterwards. The value of the time steps is lower in this experiment, as we increased the time interval between each sensor and odometry measurements taken. It can be observed that after time step 200, the state estimate of both x_{mean} and x_{max} gradually decrease. At this point, robot is basically computing localization using particle filter algorithm with known map. It is also noted that, after time step 200, x_{mean} and x_{max} has maintained below the error of robot state from odometry, x_{odom}. This is because, robot's state from odometry x_{odom} is increasing and as it diverges from the ground truth path.

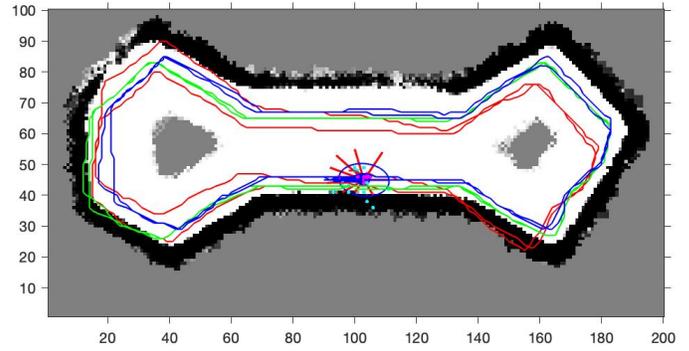
Fig. 10 shows the resulting map obtained from particle with the highest weighted, x_{max}. The robot's trajectory uses the same color notation, which are green, blue and red lines referring to the ground truth trajectory, RBPF with $\mathcal{N}$ state estimate, and robot's odometry respectively. As the robot travelled further, the error in robot's state estimate accumulates. From the figure, it is observed that in the second loop of the robot's trajectory, the robot state estimate from RBPF with $\mathcal{N}$ (i.e. blue line) is able to localize itself within the map as it travelled through the revisited area. This has contained the error from accumulating further compared to odometry's trajectory (i.e. red line) that begin to diverge from the actual path. As mentioned before, this outcome is also reflected in


Fig. 10. Map of x_{max} of RBPF with $\mathcal{N}$ Algorithm with Robot's State Estimate and Actual Trajectory.

the pose error graph in Fig. 9, where after half way of the trajectory (i.e. approximately time step = 200) the robot state estimate error of both x_{mean} and x_{est} are below the error of odometry, x_{odom}.

The average RMSE of x_{mean}, x_{max}, and x_{odom} after completed the exploration is shown in the bar graph in Fig. 11. The bar graph shows the average RMSE for the distance error, denoted as x, y state, the x state, y state, and θ state. The x, y state uses the calculation of pose error of robot's From the bar graph, it can be observed that both density; x_{mean} and x_{max} have significantly lower average RMSE error from x_{odom} in red bar for all element of robot's state computed.

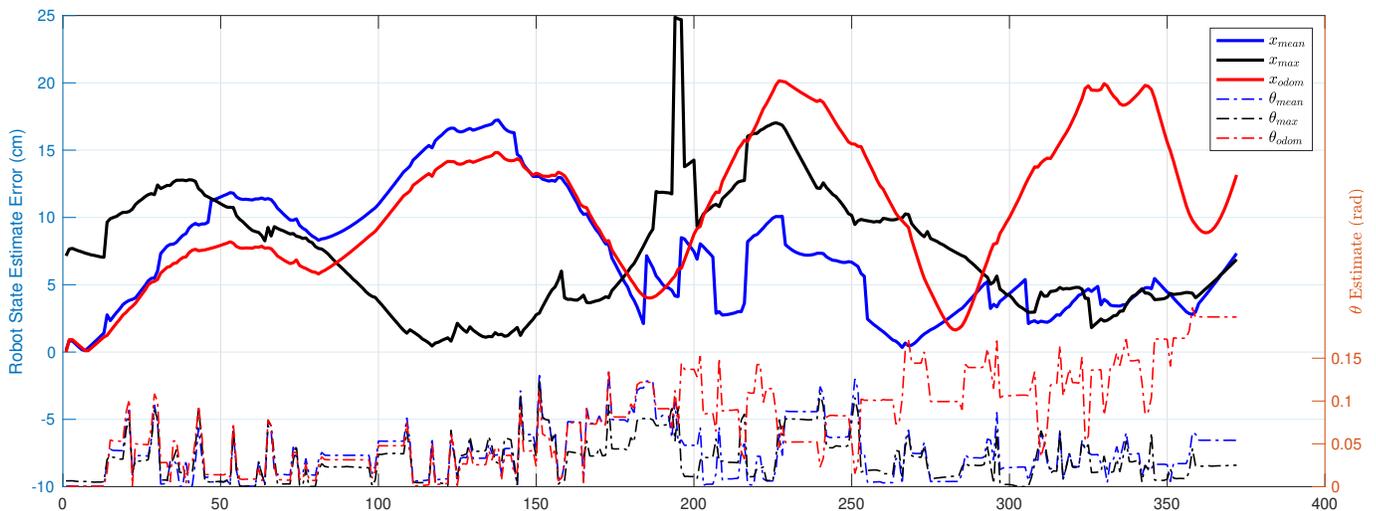
To test the consistency of the result, the experiment was repeated 25 times by using the same data set. The average RMSE of state estimate of all 25 trials is computed and shown in Fig. 12. From the bar graph it can be seen that the error of state estimate, x_{mean} and x_{max} are greater than odometry, x_{odom} for all states, except the θ state. This shows a rather different result compared to the one obtained in Fig. 11. It is concluded that, although RBPF with neural network $\mathcal{N}$ can achieve a lower error compared to odometry, x_{odom}, but it is not an entirely consistent result even with 100 particles. By using noisy sensor such as array of infrared sensors, a good


Fig. 9. The Pose Error of x_{mean}, x_{max}, and x_{odom} Align to the θ_{est} of Each Density.
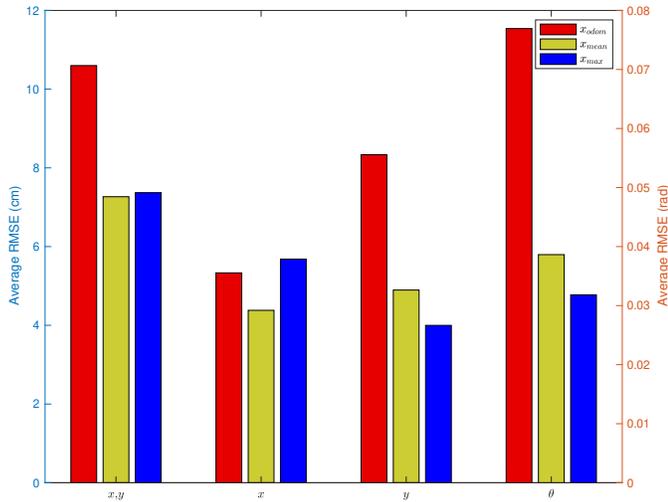

Fig. 11. Comparison of Average RMSE of x_{odom}, and Particles' Density x_{mean} and x_{max}.
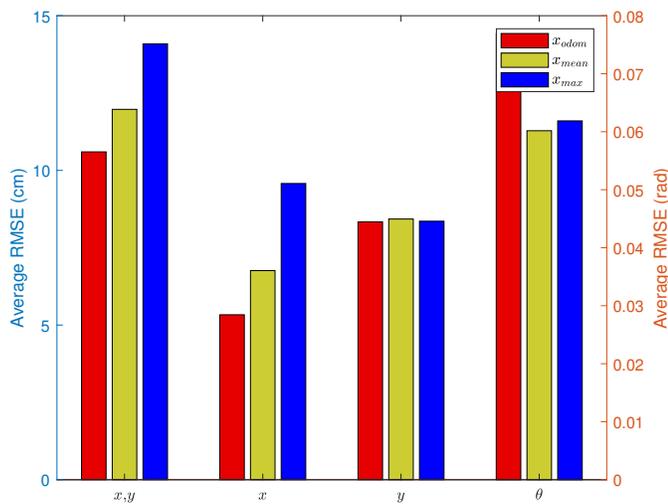

Fig. 12. Average RMSE of Robot's State Estimate after the Robot has Completed Navigation for 25 Trials of Experiment Conducted.

result can be obtained provided multiple trials were conducted.

IV. CONCLUSION

The first objective of this research was to develop grid-based SLAM algorithm with Rao-Blackwellized Particle Filter (RBPF) integrated with neural network for indoor environment. The algorithm was developed with motion model proposal distribution, a map matching function for particles' weight assignment and selective resampling method. The results show that integration of neural network has managed to increase the accuracy of map estimate and decrease the error of robot state estimate.

By using selected sensor measurements and encoded cell's position as neural network input, the neural network configuration is more robust in multiple ways. The neural network can be applied on robot platform with different sensors configuration. This is because the configuration does not require for sensors to be distributed equally apart or any specified

angle for each sensor. Furthermore, by using cells encoded value (or polar coordinate) rather than Cartesian coordinate, local occupancy grid can be resized according to the sensor's maximum range without having to retrain neural network. This is because cell's position is encoded independent of the size of local map.

The consistency of the RBPF algorithm with neural network $\mathcal{N}$ is tested with multiple trials of the experiments. It is shown that the average RMSE of robot's state estimate exceed the RMSE of state computed from odometry even after the number of particles N is increased from 20 particles to 100 particles. This concludes to obtain an adequate map and state estimate from noisy sensors such as array of infrared sensors using the RBPF with neural network algorithm multiple trials should be conducted.

Abstract—In computer vision, there are various machine learning algorithms that have proven to be very effective. Convolutional Neural Networks (CNNs) are a kind of deep learning algorithms that became mostly used in image processing with a remarkable success rate compared to conventional machine learning algorithms. CNNs are widely used in different computer vision fields, especially in the medical domain. In this study, we perform a semantic brain tumor segmentation using a novel deep learning architecture we called multi-scale ConvLSTM Attention Neural Network, that resides in Convolutional Long-Short-Term-Memory (ConvLSTM) and Attention units with the use of multiple feature extraction blocks such as Inception, Squeeze-Excitation and Residual Network block. The use of such blocks separately is known to boost the performance of the model, in our case we show that their combination has also a beneficial effect on the accuracy. Experimental results show that our model performs brain tumor segmentation effectively compared to standard U-Net, Attention U-net and Fully Connected Network (FCN), with 79.78 Dice score using our method compared to 78.61, 73.65 and 72.89 using Attention U-net, standard U-net and FCN respectively.

Keywords—*Convolutional neural networks; image processing; semantic brain tumor segmentation; convolutional long short term memory; inception; squeeze-excitation; residual-network; attention units*

I. INTRODUCTION

In recent years, there have been a large number of contributions to the field of deep learning. Year after year, deep learning proves its superiority by surpassing state-of-the-art solutions in various domains such as computer vision [1], natural language processing [2], speech recognition [3] and many other application domains. In particular, in the field of computer vision, which is the main focus of this paper, deep learning has been enormously successful for tasks such as image classification [4], face recognition [5], object detection [1] and image segmentation [6]. The significant improvement in the field of deep learning is due to multiple factors. High-performance computational resources (GPU, TPU) have become more easily available. At the same time, the investments made in research as well as the amounts of collected data have also increased.

Deep learning algorithms, like other machine learning algorithms are categorized into two main categories: supervised and unsupervised algorithms. Unsupervised algorithms, an example of which is Deep Belief Network (DBN), work with unlabeled data. They use a greedy layer-wise learning strategy to fine-tune the network's parameters. This learning strategy, which is based on a contrastive version of the wake-sleep algorithm [7], performs quickly and can find a good set of parameters, even with relatively very deep architectures. Supervised algorithms, an example of which is Convolutional Neural Network (CNN), work with labeled data. CNNs have been particularly successful for solving computer vision tasks. The fine-tuning phase of a CNN is composed of consecutive convolution and pooling operations for extracting fine-tuned features, which are then used in the discriminative phase of the training process. This automated process of extracting features is what made deep learning algorithms powerful, as opposed to conventional machine learning algorithms that use hand-crafted features.

Nowadays, the use of CNNs is widespread across industries and businesses. In healthcare, CNNs achieve very promising results due to their robust feature extraction capabilities. For example, in medical image segmentation, they have achieved state-of-the-art performance [8] with a significant margin compared to conventional machine learning models, which makes them the most popular choice in different medical imaging fields. They also dominate the health informatics literature on brain [9], lung nodule [10], spleen [11], and cardiac [12] medical imaging issues, to mention a few.

In this work, we perform brain tumor semantic segmentation using a novel deep learning architecture. Brain tumors are considered one of the deadliest cancers in the world. There are various brain tumor types, but gliomas are the most common ones among adults. Furthermore, gliomas can be present with different degrees of aggressiveness with an average survival time for patients diagnosed with glioma lesser

than 14 months [13]. Therefore, time is a critical factor for doctors to act regarding gliomas. To diagnose a brain tumor, there are different types of medical image acquisition involved, such as MRI, CT scans and X-Ray, each having its pros and cons. For example, CT scans have the advantage of speed of tissue acquisition at the cost of lower quality of tissue contrast and higher radiation risk. On the other hand, MRIs are slow compared to CT scans but they are best suitable for capturing abnormal tissues with more details due to their accuracy in acquiring different types of contrasts. After the acquisition of the brain region, radiologists perform a manual segmentation of brain tumors from MRI images, which is time-consuming. Therefore, designing an automatic brain tumor segmentation is mostly desirable.

In this paper, we propose a novel deep neural network, called Multi-Scale ConvLSTM Attention Neural Network (MSConvLSTM-Att), to automatize brain tumor semantic segmentation. Our architecture is multi-scale-attention based with each level using Convolutional Long Short Term Memory (ConvLSTM) [14], Squeeze and Excitation-inception (SE-inception) [15] and Squeeze and Excitation-Residual-Network (SE-ResNet) [15]. The motivation behind using such architecture is to gather state-of-the-art feature extraction methods, the LSTM and the attention mechanism in one multi-scale architecture and perform brain tumor semantic segmentation efficiently compared to conventional deep learning based architectures.

The use of such multi-scale architecture, which is composed of multiple stages, is to generate multiple versions of the same image with different resolutions, each containing diverse semantics. The first low-level stage serves to model the spatially sequential relationship between different parts of each MRI modality (FLAIR, T1w,T1gd,T2w)[1], while the next stage manages the extraction of local features in addition to decreasing the size of the images for computational optimization. Finally, the third high-level stage captures the global representations. Thereafter, at each level, we introduce a stack of attention modules to gradually emphasize the regions that contain a large number of semantic features.

The integration of attention mechanism in the image segmentation of natural scenes has been widely adopted [16], [17], [18], [19]. However, in medical imaging, the inclusion of attention mechanism is rare [20], [21], [22], [23]. For this reason, we investigate the impact of a simple attention module in boosting the performance of standard deep networks for brain tumor semantic segmentation. Experimental results show that our proposed method improves the segmentation performance by modeling a combination of rich contextual features with local features.

The remainder of this paper is organized as follows. Next section presents related works. In Section III we introduce our proposed method in detail. Thereafter, we present and discuss the obtained results in section IV. Finally, we conclude our paper in section V.

II. Related Work

Most of the state-of-the-art deep learning architectures used for automatic medical image segmentation are inspired from

Fully Convolutional Networks (FCN) [24] or U-Net [25]. Many variants of these architectures have been proposed to perform semantic segmentation in different application domains [26], [27], [28], [29].

FCN is an architecture in which fully connected layers are replaced by deconvolution layers to generate segmentation masks [24]. Jesson *et al.* [30] proposed a variant of the standard FCN with a multi-scale loss function. With this approach it is possible to model the context in both the input and output domains. A limitation of this approach is that FCN is not able not explicitly model the context in the label domain. Compared to U-Net, FCN does not use skip connections between the contracting (i.e feature extraction path) and the expanding paths (i.e data reconstruction path).

The U-Net architecture was introduced by Ronneberger *et al.* in 2015 [25]. It overcomes the limitations of FCN by including features from the contracting path. In order to obtain the missing feature-contexts, multi-scale features are concatenated in a mirroring way. Many works have adopted this architecture to perform medical image segmentation over different parts of the human body. In a previous work of ours [26], we also adopted the U-Net architecture to perform lung CT image segmentation.

A limitation of both FCN and U-Net is that they both do not perform very well in multi-class segmentation tasks [31]. To overcome this issue, cascaded architectures can be used. They have the beneficial effect of decomposing a multi-class segmentation problem into multiple binary segmentation problems. This approach is also used in various medical image segmentation works. For example, Chen *et al.* [32] adopted a cascaded classifier to perform a multi-class segmentation. Furthermore, in [33] authors proposed a cascaded architecture to merge different feature extraction methods. Nonetheless, these models still face a problem of focusing on pixel level classification while ignoring adjacent pixels' connections. To overcome this issue, Generative models were adopted. A widely used variant of generative models is Generative Adversarial Network (GAN) [34]. GANs are employed for semantic segmentation in the following way: a convolutional semantic segmentation network is trained along with an adversarial network to discriminate segmentation maps [35]. That is, two models are trained; the first captures data distribution, while the second is used for a discriminative purpose.

To capture sequence patterns in medical imaging, Recurrent Neural Networks (RNNs) are typically used as they they are well suited for handling sequential data. Specifically in medical image segmentation, RNNs are used to keep track of features in previous image slices in order to better generate the corresponding segmentation maps. There are various RNN architectures mentioned in the literature, and amongst them Gated Recurrent Units (GRU) [36] and Long-Short Term Memory (LSTM) [37] are likely the most robust and widely used. GRU is memory efficient, nonetheless not very suitable for keeping track of long-term features. LSTM is better adapted to such tasks due to the forget gate that preserves features from previous sequences to use in upcoming sequences. [38], [39], [40] are some examples of employing RNNs for performing image segmentation for sclerosis lesions and brain tumors respectively.

---

[1]https://case.edu/med/neurology/NR/MRI Basics.htm

In the last few years, a new concept called *attention mechanism* was introduced into computer vision tasks. Attention mechanism was introduced first in neural machine translation [41] to help remember long range context from long source sentences. The added value brought by attention modules is the creation of shortcuts between the input sentence and the context vector. Attention in deep learning can be interpreted as a vector of weights that represent the importance of an element within a context. The attention vector is used to estimate how strongly is an element related to other elements (elements in this context are image pixels), it takes the sum of these elements' values weighted by the attention vector as the approximation of the target context.

The success of the attention mechanism for neural machine translation has encouraged its application to computer vision immediately [42]. In medical image segmentation, the attention mechanism was adopted in many works and various variants of attention modules have been introduced. In [43], authors propose a combination of FCN with a Squeeze and Excitation (SE) attention-based module to perform whole-brain and whole-body segmentation. They integrate the SE block in three ways: channel SE (cSE), spatial SE (sSE) and concurrent spatial-channel SE (csSE). In [20], Wang et al. perform prostate segmentation in ultrasound images using deep attentional features. They use an attention module to extract refined features at each layer, eliminate non-prostate noise and focus on more prostate details at deep layers. Furthermore, Li et al. propose an auto-encoder CNN-based architecture, called hierarchical aggregation network (HAANet) [21], which combines the attention mechanism and hierarchical aggregation to perform 3D left atrial segmentation. In another work, Oktay *et al.* propose an attention U-net [44] which extends the U-Net architecture by incorporating an attention gate in the expanding path in order to accurately segment the pancreas area.

III. METHOD

In this section, we describe our proposed architecture for brain tumor segmentation. Our method combines different techniques in order to extract relevant features and keep track of them during the entire process of segmentation.

We combine Inception, ResNet and Squeeze-Excitation blocks in one part of our architecture for relevant feature extraction, and attention modules in another part to perform brain tumor segmentation. The combination of Inception, ResNet and Squeeze-Excitation is known as the most successful architecture in the ImageNet challenge. With this combination, the team Trimps-Soushen achieved 2.99% error rate in object classification in the ImageNet challenge[2].

We first feed our network different modalities of brain MRI images (FLAIR, T1w, T1gd, T2w) to include various intensities and to better perform the semantic segmentation. Each modality is split into four patches, then for each modality, three scales of feature extraction are performed. The motivation behind this multi-scale mixture is to best separate each tumor label (enhancing tumor, tumor core, whole tumor and background).

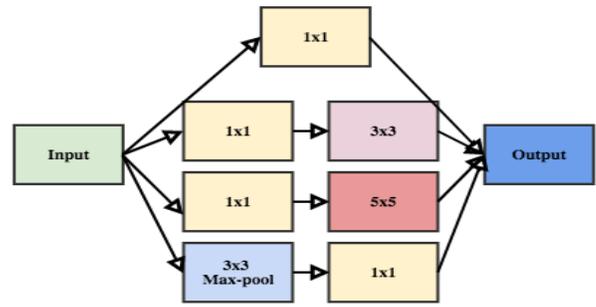
At the first scale, ConvLSTM is used over each of the four patches to preserve the correlation among features. ConvL-STM are best suitable for catching spatiotemporal information without any much redundancy [14]. At the second scale, an SE-inception [45] module is used over the output of the first scale to extract low level features and decrease the computation cost. Fig. 1 shows the inception module [46] and Fig. 2 shows the SE-inception block.


Fig. 1. Inception Block.
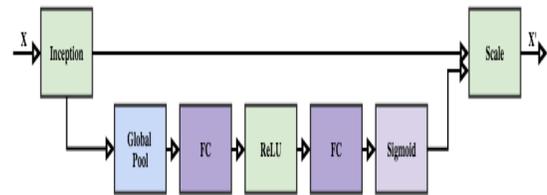

Fig. 2. SE-Inception Block.

At the third scale, we extract high level features by integrating an SE-ResNet module [45]. The use of such block increases computational complexity with a thin margin but in exchange of increasing the accuracy [45]. The ResNet block [47] and SE-ResNet are described in Fig. 3 and Fig. 4 respectively.

At each scale (different scales are highlighted by green color in Fig. 6), we combine the four outputs to form what we call *single-scale features* as stated in Fig. 6. These three *single-scale features* are then concatenated and convolved to form *multi-scale features* as mentioned in the same figure. We then take the *multi-scale features* and we combine them with each single-scale feature.

At this stage, our model holds general context feature-maps that contain different levels of features, from low to high level features. Thereafter, we add a convolution layer to refine these features.

Furthermore, in order to explore more global contextual characteristics by building connections among features, we

---

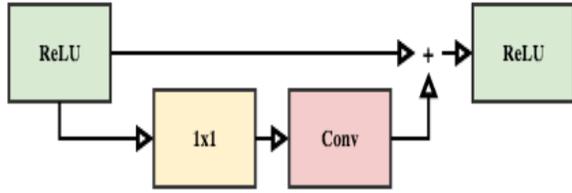
[2]https://image-net.org/challenges/beyond_ilsvrc


Fig. 3. ResNet Block.
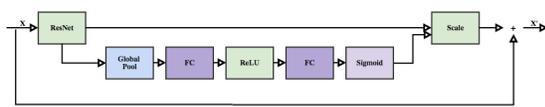

Fig. 4. SE-ResNet Block.

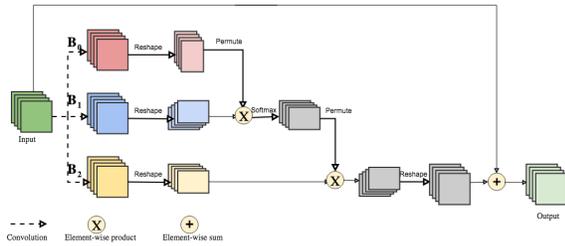
include attention mechanism in the form of a location-based attention module, we call it Spatial Attention Module (SAM). The attention mechanism is presented in the Fig. 5.


Fig. 5. Spatial Attention Module.

In Fig. 5, we assume the input to the SAM module is V, which is a 3D shaped input (W, H, C), here W, H and C represent the width, height and depth respectively. In the red branch, we perform a convolution operation, resulting in a feature map B_0 with same width and height but with depth equals to $C/8$. B_0 is then reshaped to (W, H, C). The same operation is applied to the blue branch B_1. Thereafter, we perform a matrix multiplication $B_0 * B_1^T$ and apply a softmax operation to calculate the spatial attention map following the formula in (1), where $S_{i,j}$ represents the impact of the pixel in the ith position on the pixel in the jth position.

$$S_{i,j} = \frac{exp(B_0 * B_1)}{\sum\limits_{i=1}^{W*H} exp(B_0 * B_1)} \qquad (1)$$

The yellow branch performs a convolution and results in B_2 with the same shape as V. B_2 is then reshaped to (C, W, H)

then it is multiplied by the transpose of the spatial attention map S. Furthermore, the output R is reshaped to $C \times (W \times H)$ and multiplied by a parameter λ and then an element-wise sum with input V is performed to obtain the output O as expressed in (2).

$$O = \lambda \sum\limits_{i=1}^{W*H} exp(S_{i,j} * B_2) + V \qquad (2)$$

In (2), λ is initialized by 0 and gradually updated to give more weight to the spatial attention map, as adopted in [17].

At the last level, we perform a convolution operation to generate the final prediction map for each scale and then average all these maps to output the segmentation map. Fig. 6 presents an overview of our proposed architecture.

IV. EXPERIMENTS AND RESULTS

To evaluate our architecture, we are using BRATS'18 data set for brain tumor segmentation, provided in the Medical Segmentation Decathlon Challenge[3]. This data set contains multimodal MRI data (FLAIR, T1w,T1gd,T2w)[4]. Furthermore, it contains 210 High Grade Glioma (HGG) scans and 75 Low Grade Glioma (LGG) scans. In this data set, the focus is mainly on the segmentation of different sub-regions of the glioma. First, the enhancing tumor (ET), the tumor core (TC) and finally the whole tumor (WT) as can be seen in Fig. 7. Each one of these sub-regions have some specific characteristics regarding their intensities, hence different modalities are responsible for capturing different characteristics. For example, the ET is described by areas that are hyper-intense in T1gd. The appearance of the non-enhancing tumor (NET) (solid parts) and the necrotic (NCR) (fluid-filled) is represented by areas that show hypo-intensity in T1gd when compared to T1. The WT describes the whole disease and it contains the TC and the peritumoral edema (ED), which is characterized by hyper-intensity in the FLAIR modality. The provided labels in this data set are as follows: 1 for NCR and NET, 2 for ED, 3 for ET and finally 0 for other parts of the brain. The annotations were created by domain experts and approved by other domain experts as described in [48].

Given the presence of different features related to gliomas in different modalities, we feed the four modalities as input to our architecture, then we get the semantic segmentation that belongs to these inputs. The loss function we use is the dice loss optimized using the Adam optimizer [49]. The learning rate is initially set to 0.001 and then multiplied by 0.5 after each 30 epochs. We used 500 epochs to train our network. Due to limitations in computational resources, we reduced the input size to 190×190 by cropping some of the background area and we only took from the 30th slice to the 120th given that most of the brain information is present in that interval. Furthermore, we normalize the inputs to have zero mean and unit standard deviation.

In addition, given that each session of the notebook used for training has 12 hours lifetime, we use the following strategy to train our network. We save our model and its weights after each 50 epochs and we reload it and continue training with

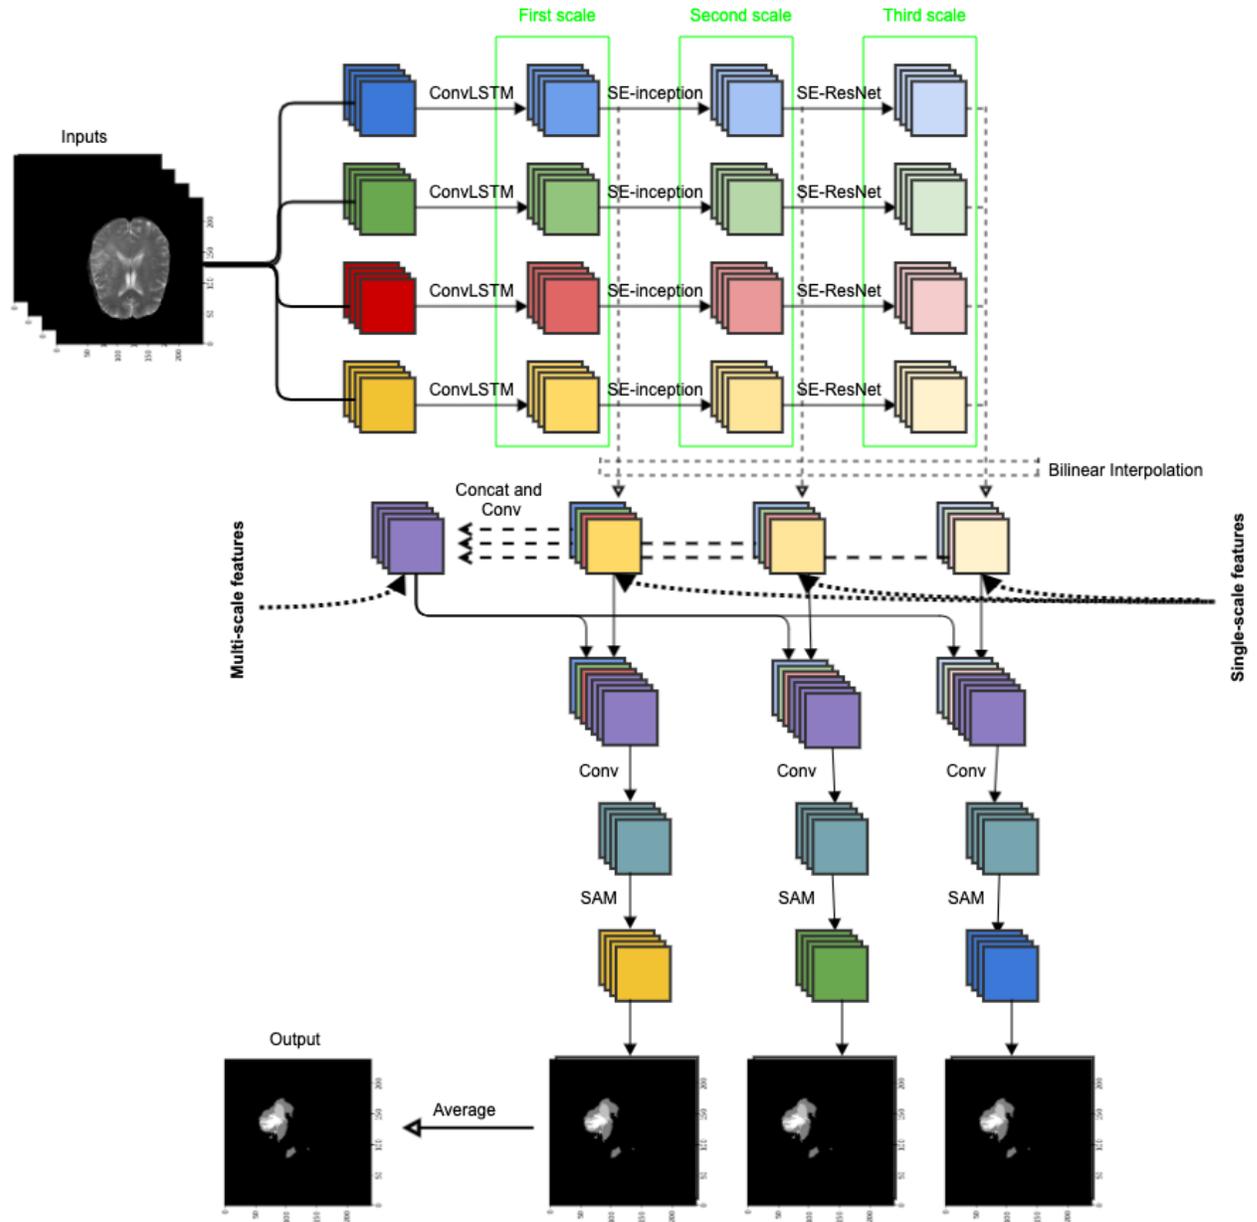

Fig. 6. Overview of our Proposed Architecture.

new data. For development, we shuffled and randomly split the images into training (225 patients), validation (30 patients), and test (30 patients). Experiments were performed in a server equipped with a single 12GB NVIDIA Tesla K80 GPU.

We compare our method with the standard UNet [25], standard FCN [24] and the Attention U-Net [44] architectures. And we evaluate their performance using the dice coefficient (DSC) as a comparison metric. Table I contains experimental results obtained using the different segmentation methods described above, and compared regarding their DSC score. Our proposed architecture achieved the best score with 64.95, 88.16 and 86.50 in ET, WT, and TC respectively and a mean score

of 79.87.

It can be observed that both our method and AttUnet, which also includes attention modules, perform better than the other ones without attention modules. This proves that adding attention modules surely enhances the segmentation procedure by putting more attention into the tumor location. Oktay *et al.* have reported the same observation in their work with MSConvLSTM-Att [44].

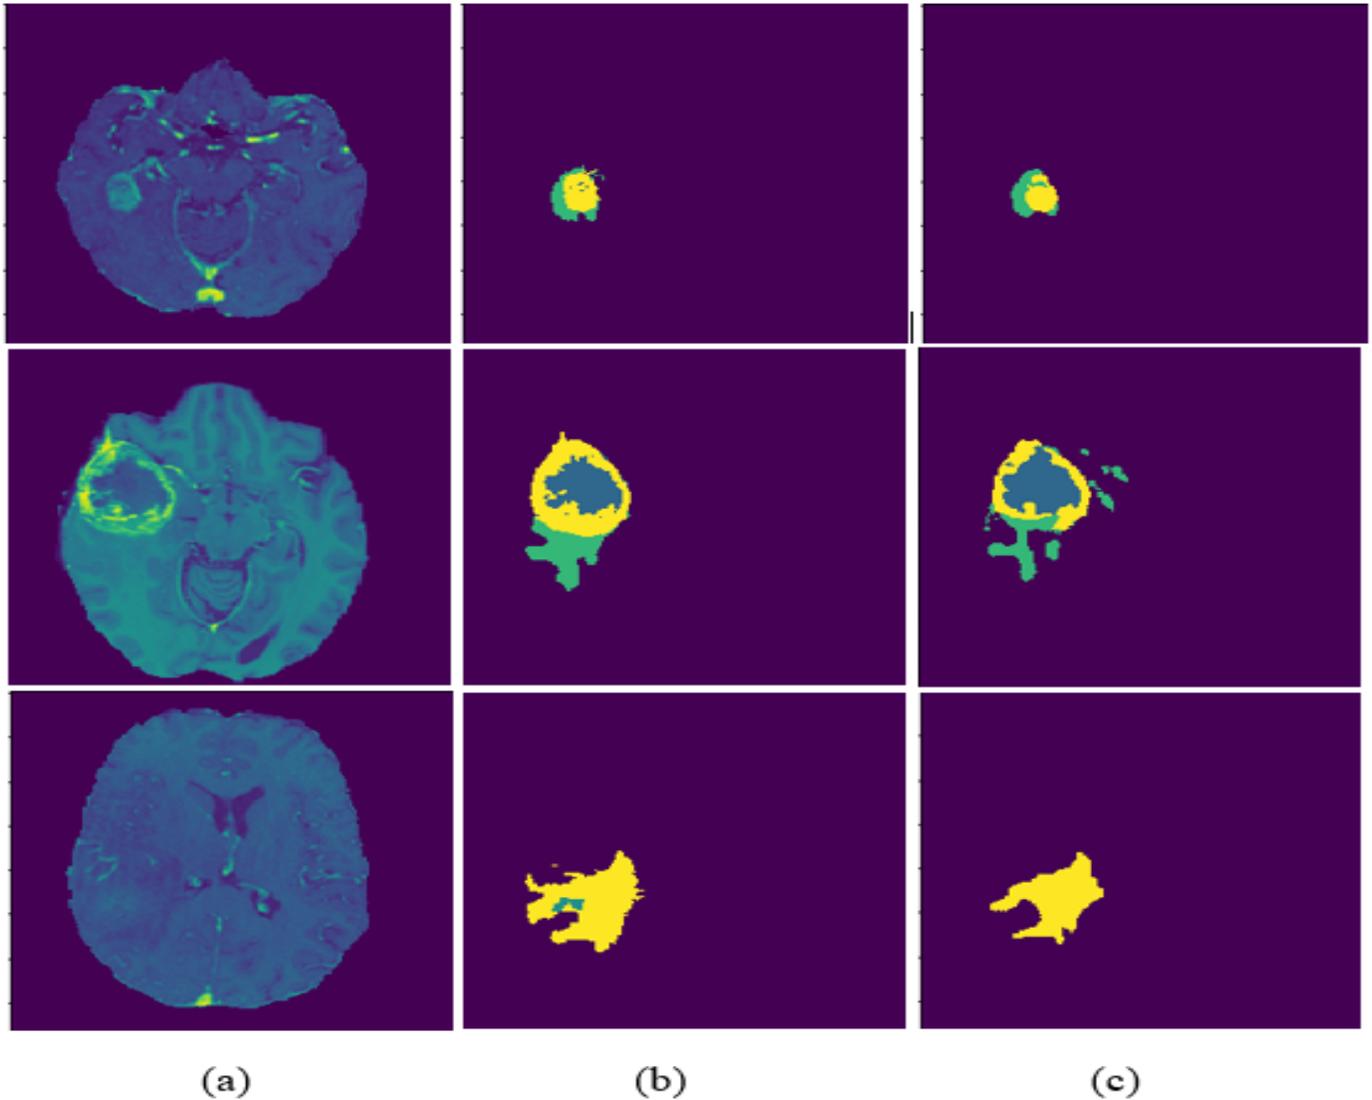
Our architecture outperforms AttUNet with a significant margin, this is mainly due to the focus on location attention modules, besides the use of powerful feature extraction modules (ConvLSTM, SE-Inception and SE-ResNet) in the


Fig. 7. Segmentation Results Sample: (a) is the Input MRI Images, (b) is the Ground Truth and (c) is the Segmentation Results using our Proposed Architecture.

TABLE I. PROPOSED METHOD'S DSC SCORE COMPARED TO THOSE OF U-NET, ATT-UNET AND FCN

Labels	ET	WT	CT	Mean
U-Net	0.563	0.848	0.797	**0.736**
Att-UNet	0.637	0.875	0.845	**0.786**
FCN	0.551	0.853	0.781	**0.728**
ours	0.649	0.881	0.865	**0.798**

first part of the architecture, which is beneficial in eliminating irrelevant features. Our proposed architecture can be implicitly considered as a cascaded architecture even though we do not explicitly use multiple cascaded architectures.

Fig. 7 displays a sample of the input MRI images, ground truth and the segmentation results using our proposed architecture. As seen in Table I, the ET segmentation has the smallest DSC value. It can be seen also in Fig. 7, where the ET region is not well detected especially in the first and third row.

It has to be mentioned that our method is slightly slower compared to the other methods, which is normal given the fact that complex building blocks has been used in order to ensure a better segmentation result.

V. CONCLUSION

In this paper, we propose a novel deep learning architecture for brain tumor segmentation we call multi-scale ConvLSTM Attention Neural Network, and we compare its performance to various deep learning architectures that are tailored to such kind of tasks. Our proposed method is built as a multi-scale

architecture composed of different state-of-the-art feature extraction blocks such as Inception, Squeeze-Excitation, Residual Network, ConvLSTM and finally Attention units. We compare the performance of our architecture to standard U-net, AttU-net and FCN that have shown effective results in semantic segmentation. Experimental results show that our proposed model outperforms standard U-net, AttU-net and FCN in terms of dice score. Our model reached 79.78 as a mean dice score for the three parts of the brain tumor, while Attention U-net, standard U-net and FCN reached 78.61, 73.65 and 72.89 respectively. We observe that both our method and the AttU-net perform better than the other ones, which can be explained that the integration of attention modules enhances the segmentation procedure. Besides, our method outperforms the AttU-net, and this is due to the use ConvLSTM, SE-Inception and SE-ResNet.

Abstract—Measuring the semantic similarity between words requires a method that can simulate human thought. The use of computers to quantify and compare semantic similarities has become an important research area in various fields, including artificial intelligence, knowledge management, information retrieval, and natural language processing. Computational semantics require efficient measures for computing concept similarity, which still need to be developed. Several computational measures quantify semantic similarity based on knowledge resources such as the WordNet taxonomy. Several measures based on taxonomical parameters have been applied to optimize the expression for content semantics. This paper presents a new similarity measure for quantifying the semantic similarity between concepts, words, sentences, short text, and long text based on NGram features and Synonyms of NGram related to the same domain. The proposed algorithm was tested on 700 tweets, and the semantic similarity values were compared with cosine similarity on the same dataset. The results were analyzed manually by a domain expert who concluded that the values provided by the proposed algorithm were better than the cosine similarity values within the selected domain regarding the semantic similarity between the datasets' short texts.

Keywords—*Arabic text; Ngram; semantic sentences similarity; short text; ALMaany; natural language; semantic similarity of words; corpus-based measures*

I. INTRODUCTION

In this paper, semantic similarity is estimated by considering the similarity between bigrams synonyms related to the same domain. Paraphrase identification can detect different linguistic expressions with the same meaning or similar meanings [1]. Analyzing the similarity of meanings is part of the semantic text similarity task.

Recent advances have made social media a major source of news, with users flooded with news about similar events. Paraphrasing news articles and recognizing semantic similarities between them is a useful practice both in many general natural language processing applications and in new event detection (first story detection) on specific events [1].

For a long time, word semantic similarity has been essential to the processing of natural language and information retrieval (IR) [2]. For instance, in academic and industrial communities alike, semantic similarity has become a vital aspect of various applications in various fields. Word sense disambiguation, information retrieval, semantic searches, and explorations of biological macromolecules are prominent examples of semantic similarity applications [3]. Furthermore, it is possible to understand and categorize documents and obtain informative knowledge using semantic annotation [2].

Semantic text similarity measures the semantic similarity between two texts (documents, paragraphs, sentences, or a combination thereof). Most of the work to date on such measures has been done at the document level (that is, comparing two long texts, or one long text and one short text). Sentence-level analysis has received a lot of attention recently. As a result, training and test data were provided in multiple languages, and different approaches were developed for detecting sentence similarity. These approaches are generally classified into three types: vector space approaches, registration approaches, and other approaches such as: B. Use topic modeling for feature extraction [1].

Typically, the process of detecting two text segments' level of similarity involves, first, employing a straightforward lexical matching method and then detecting how many lexical units are contained in both input segments to calculate the similarity score [4]. This method can be improved by employing various techniques (e.g., stemming, part-of-speech tagging) or by considering different weighting and normalization factors. While these lexical similarity methods have been somewhat successful, they sometimes fail to adequately identify the semantic similarity between two texts. For instance, even though the phrases "I own a dog" and "I have an animal" are clearly similar, most contemporary similarity detection techniques do not recognize this. Often, knowledge-based or corpus-based approaches are used to detect semantic similarity at the word level [4]. These approaches have shown some success, particularly when applied to language processing tasks. Two of the most popular text-based semantic similarity approaches are to use approximations generated by query expansion and to employ the latent semantic analysis method. The former is often used for information retrieval tasks, while the latter is used to detect the similarity between texts by automatically acquiring second-order word relations from extensive collections of texts [4]. Other noteworthy methods for detecting semantic similarity are listed below [5]:

1) Structure-based measures, which use a function that computes the semantic similarity measures on ontology hierarchy structures.

2) Information content measures, which are based on the frequency of terms in a given document.

3) Feature-based measures, by which each term is described by a set of features and the similarity measure between two terms is defined as a function of their

properties.

4) Hybrid measures, which combine the structural characteristics of the previous methods to compute semantic similarity.

The following are basics and backgrounds knowledge:

WordNet created as part of a research project at Princeton University [6]. This is an extensive English vocabulary database. In WordNet, nouns, verbs, adverbs, and adjectives are organized by semantic relationships into synsets, each representing a concept.

Semantic similarity (or topological similarity) detects the similarity between terms, sentences, and documents. Similarity between sentences and documents is calculated by considering terms that describe internal concepts. Similarity at the sentence level is detected using syntactical and lexical measures [7].

The syntactic approach primarily uses syntactic dependencies to recognize semantic similarities and build a more comprehensive picture of the meaning of the compared texts. In this way, these approaches identify whether a noun is the subject or object of a verb. Lexical-based similarity approaches, on the other hand, measure similarity between texts based on character matching.

Three problems with the existing semantic measurements are the primary motivations for this work. The first issue relates to how text is represented and similarity calculations are performed. Text representation mainly concerns converting text to vectors by using lexical representation or word embedding representation. The drawback of the first one is that it depends on the occurrences of words in the text, either it occurred in the same order of occurrence or not. And it is a critical point in the semantic similarity measure and the limitation of word embedding. Most word embedding models are trained on corpora in different domains and the semantic similarity degree of the keywords depending on the domain concepts. The second issue relates to the external dictionary and ontologies. Most of them were static and not concerned about the same topic. For example, in Arabic, there is a need for more presence of these dictionaries. The third issue is the need to represent the two texts. In some applications, like in plagiarism, there is a need to find similarities between a fragment of sentences.

These problems motivate us to current work. This work depends on an updated dictionary ALMaany [8], and all needed synonyms extracted depending on the same domain. In addition, the proposed algorithm can be applied to various varieties of text length, and consider the order of keywords by taking NGram words from all texts. The present work describes a new method for measuring semantic similarity between words and concepts that uses Ngram synonyms connected to the same domain.

The first step of the proposed algorithm is crawling articles from sites to collect the most frequent words for the same domain. The extracted keywords used in the following steps:

1) Searching for tweets depending on extracted words.
2) Extracting synonyms from ALMaany [8] and concentrate on the selected domain or topic.

The proposed algorithm depends on the synonyms, and NGrams was evaluated based on 700 tweets and compared the proposed algorithm's output with the cosine similarity values. An expert assessed the results and determined that the proposed algorithm detected the semantic similarity between the dataset's short sentences more accurately than the cosine similarity values.

The remainder of the paper is organized as follows. Section II discusses previous works related to semantic similarity measures. The proposed method is described in Section III. The experimental results are then discussed in Section IV. Finally, the paper is concluded and directions for future studies are recommended in Section V.

II. RELATED WORKS

Semantic text similarity is a measure of the degree of semantic similarity between two texts, such as documents, paragraphs, sentences, words, or a combination of them [1]. Various semantic similarity approaches have been described and summarized in many surveys. For example, [9] presented the fundamental aspects of the theoretical and practical backgrounds of semantic similarity assessments of texts. They also discussed the general technology used for sophisticated text analyses (i.e., text mining), alongside discussions of relevant methodologies, architectures, and challenges. In other work, [10] explored the development of semantic similarity methods. They classified different methods as knowledge-based, corpus-based, deep neural network-based, and hybrid methods, according to their underlying principles. It starts with traditional NLP techniques (e.g., kernel-based methods) and progresses to the most recent research on transformer-based models while examining each approach's merits and disadvantages.

[11] reviewed existing approaches to measuring semantic similarity at either the document, sentence, or word level, focusing on Arabic text. The approach utilized by [1], [12] employs a set of extracted features based on lexical, syntactic, and semantic computations to detect the similarity between tweet pairs. One approach uses knowledge and corpora to express the meanings of terms to solve the issue of polysemy and includes a constituency parse tree to capture the syntactic structures of short texts. The approach also uses word alignment features to detect the similarity between tweet pairs.

Semantics is an essential aspect of studies on natural language processing. Previously, in [13], they surveyed various deep learning approaches that have been used to detect the semantics of words, sentences, and documents. However, most previous studies have considered the semantics only of documents (i.e., either two long texts or one long text and one short text have been compared). Recently, though, comparisons between individual sentences have become more common [1]. Previous researchers have also used measured semantic similarity to compare words or concepts. However, such measures are rarely used to compare multi-word phrases [4]. Three broad categories of semantic similarity detection methods are used to determine the level of similarity between words: Dictionary/ontology-based methods consider knowledge bases to gather the semantic information that is compared when determining semantic similarity [14]. Meanwhile, corpus-based methods primarily use word frequencies to determine semantic similarity. This is done based on statistics taken from extensive corpora. Finally, hybrid methods consider more than one information source to determine semantic similarity [14].

The statistical methods employed by corpus-based approaches have recently evolved. Thus, such approaches can follow one of two principal orientations [14]:

- The first is the unsupervised orientation, which involves the use of training sets and unannotated corpora. Approaches that follow this orientation can be further divided depending on the method of discrimination used (type-based or token-based). When type-based discrimination is employed, the similarity is measured by an algorithm after the contexts have been represented, which is done via high-dimensional spaces, which are defined by word co-occurrences. Meanwhile, when token-based discrimination is used, all contexts containing the target word are clustered together. Each resultant cluster comprises contexts that contain similar usages of the target word.

- The second orientation includes supervised and semi-supervised approaches, by which an annotated training corpus with the appropriate classification models is applied. Supervised methods include probabilistic methods, and they typically employ the naive Bayes algorithm and follow the maximum entropy approach [14]. Which methods are followed when using such an approach depends on how similar the evaluated examples are. These methods compare sets of learned vector prototypes using a similarity metric. This is done for each word sense. Meanwhile, other methods consider discriminating rules to make comparisons. Such methods rely on specific rules that apply to each word sense. In turn, methods based on these specific rules merge heterogeneous learning modules [14].

The Arabic language is an official language used by the United Nations, and more than 450 million people in the world speak Arabic as their first language [1]. The vocabulary of this language is rich, and its morphology is complex. It is also a synthetic language, meaning that a given morpheme can comprise a stem and affixes, which can indicate different aspects (e.g., tense, gender, and what word class a word belongs to). Moreover, different parts of speech can be affixed to each other. Arabic is a derivational, flexional, and agglutinative language. These characteristics make it difficult to conduct research on language processing and text mining, as special tools and resources are needed. An additional problem arises from the fact that the lexical and morphological features of Arabic have a profound effect on sentence analyses. If the research question addressed in this study is to be adequately answered, such challenges must be overcome. Much research has focused on various problems related to analyses of semantic similarity and developed methods for overcoming these problems. However, most of these methods are either domain-dependent or language-dependent. Moreover, little research on this matter has examined Arabic [1]. Another shortcoming of previous studies focusing on the Arabic language is that the semantic similarity analyses employed have not utilized enough resources (e.g., tools and benchmark data) due to a lack of availability. One such research work was conducted by [15], who determined semantic similarity at the sentence level using supervised learning. Specifically, their method analyzed semantic, lexical, and syntactic-semantic features, which were extracted using an Arabic dictionary, a lexical

markup framework, and a learning corpus. After the method was used, its outcomes were assessed by Weka; the assessment showed that the proposed model produced highly accurate results [1]. However, the results were not as favorable when the method was used to detect semantic similarity between phrases and sentences. This is because, compared to word-level estimations, sentence-level estimations are substantially more challenging to perform since sentence-level semantics are noncompositional and involve many more possible interpretations.

When considering the Arabic language, similarity approaches face several significant challenges [16]:

- Arabic is a complicated (and often ambiguous) language.

- Arabic WordNet is a multilingual concept dictionary that maps Arabic word senses with their equivalents in English WordNet [17]. However, the Arabic database was built manually and does not contain sufficient essential information. It also contains many fewer concepts than English WordNet, and it is lacking several important semantic relations between synsets.

- Few Arabic corpora consider all possible domains and words. This is because each Arabic corpus focuses on only one domain; thus, these corpora do not contain all essential information.

Based on the above points, the cosine similarity measurement has been employed in many Arabic systems. Results show that this measure outperforms other lexical measurements.

Lexical similarity methods are unreliable when assessing the Arabic language because of the language's unique features, such as its morphology. Furthermore, the semantic similarity approach is undesirable when considering Arabic because of the aforementioned shortcomings of Arabic WordNet and Arabic corpora. Recently, the hybrid similarity approach has been considered potentially useful for examining semantic similarity in Arabic since it utilizes multiple measurement methods, thus providing more robust analyses than other techniques [16].

Twitter is a fast-growing social media tool with which people can connect and share microblog posts called tweets [18]. This tool also produces vast amounts of information. We have considered tweets in our research because tweets are limited to 280 characters. Thus, compared to the text posted on other social media platforms like Facebook (which has no post length limitations), tweets are brief yet tell complete stories that can be compared relatively easily.

Different methods for semantic similarity approaches have been recently proposed based on the aforementioned algorithms. Most of recent works based on word embedding techniques. Authors in [19] applied Word2Vec model on an English corpus to represent words in vector form. Then a Cosine Similarity method was used to calculate the similarity value. Authors in [20] presented an approach that combining LDA topic model approach with BERT word embedding for pairwise semantic similarity detection. A hybrid approach based on Word Embedding and External Knowledge Sources was used to find the semantic similarity value between two

short text. Another hybrid approach based on a WordNet proposed in [21] to measure concept semantic similarity.

This is clearly evident from previous works that most of suggested approaches applied on English datasets. Therefore, more research effort is needed for computing semantic similarity for Arabic Language. In summary, a good amount of work has been invested to calculate semantic similarity either depending on external static external knowledge or by using word-embedding models that created on large corpus that is not related with the tested datasets. The reduction in problem dimension at the expense of the real values' interpretability is one of the key drawbacks of word embedding that form the vector representations [22]. And, due to Arabic WordNet limitation in keyword synonyms [23], [24], we chose ALMaany [8] to extract synonyms related to Arabic keywords within specific domain. We depended on ALMaany because it is one of the most recent dictionary and continuously updated. In addition, ALMaany is fast, free, electronic and easy to use [25], [26].

Most previous related works have considered a single corpus or a dataset when detecting the semantic similarity between sentences or documents. Differently, this work proposes a new method that considers n-gram synonyms within a single domain to detect the semantic similarity between concepts and words. Furthermore, the contributions of this work are relevant to any sentence, paragraph, or document.

III. PROPOSED WORK

Due to its nature, the Arabic language may allow more than one meaning (and sometimes opposite meanings) to be assigned to the same word. Therefore, semantic similarity detection methods should find similarities between words related to the same domain. Because Arabic WordNet is limited to extract synonyms for Arabic terms within a particular domain [16], we choose ALMaany's [8]. ALMaany is essential to us because it is one of the most modern dictionaries and is regularly updated it is quick to access, free, computerized, and simple to use.

In this work, we considered a common news topic, namely the current relationship between Qatar and the UAE during the last quarter of 2017.

The following steps were conducted to find synonyms of the most frequently used keywords. First, sources were searched for relevant articles through Google. This was done because Twitter has a short-text format, and this step ensured that we would consider all keywords that could be found in tweets mentioning the news topic of interest. The data sources considered in this work were the websites of news agencies such as Reuters, news channels such as Aljazeera, and online versions of printed newspapers such as the Middle East. The sources used to obtain articles are presented in Table II. We searched for the main keywords, such as those found in Table I. Initially, we found almost 10,000 articles from online sources. After the main keywords were used to filter the articles, around 3000 remained. Table III shows a sample of the search results.

Second, we found the keywords most frequently used in the articles after removing stop words. Table V shows some of these words.

Third, we manually extracted synonyms related to the topic under investigation from ALMaany [8]. Table VI presents some of these synonyms.

The dataset of articles was used to find the most frequent words that needed to be used to extract tweets from Twitter. In an initial step, we need to prove our algorithm on short Arabic text; and then, in future works, it will be applied in paragraphs, and after that, on long articles

REST APIs and Streaming APIs make up most of the Twitter APIs[1]. Use the RESTful state transfer (REST) search API to search tweets from Twitter's search index. The REST API offers historical results going back as long as the search index allows (usually last seven days). The streaming API, however, returns information from the query's starting point. Real-time monitoring of a particular query is possible using streaming API. According to their website, Twitter's search API contains several restrictions.[2]. We developed a number of searches that include all combinations of the most frequent keywords extracted from websites' articles. Table IV shows a sample of the tweets. The results were filtered, and only tweets containing "إمارات" and "قطر" and "امارات" or "يمن" were kept.

TABLE I. LIST OF MAIN KEYWORDS THAT ARE USED IN SEARCHING FOR ARTICLES

2) Extract all synonyms of the most frequent unigrams.
3) Estimate the number of similarities between the bigram and trigram of two texts.

In this work, only unigrams and bigrams are used. The n-gram comparison can be increased if the degree of similarity between two sentences in terms of their meaning and structure is known. Algorithm 1 describes the steps taken to estimate semantic similarity.

TABLE VII. ABBREVIATIONS

Value	Abbreviation
Semantic Similarity for S1 UniGram	SS_S1U
Semantic Similarity for S2 UniGram	SS_S2U
Number if similar unigrams between S1 and S1	UniS1S2
Number of words in S1	S1L
Number of words in S2	S2L
Semantic Similarity for S1 BiGram	SS_S1B
Semantic Similarity for S2 BiGram	SS_S2B
Number if similar bigrams between S1 and S1	BiS1S2

$$SSV = (0.75 * B) + (0.25 * A) \qquad (1)$$

UniSemilarity (A)

$$SS\_S1U = UniS1S2/S1L \qquad (2)$$

$$SS\_S2U = UniS1S2/S2L \qquad (3)$$

Algorithm 1 Semantic Related Words Extraction

Require: S1, S2 two Arabic short complete text (as Tweets), with lengths n and m, respectively
Ensure: Semantic similarity value (SSV)
1: Take only nouns and verbs as features from S1, S2
2: Apply the following preprocessing on S1 and S2
3:     Remove non-Arabic characters
4:     Remove stop words
5:     Remove low-frequency tokens
6:     Determine the stem of the remaining text
7:     Take bigrams and trigrams of the two texts S1 and S2
8: Estimate the number of similarities between the bigrams and trigrams of the two texts (if the bigrams have the same token, give a higher value than if the two words are synonyms)
9: Estimate the SSV using Equations (1)–(5)(Depend on Table VII.

BiSimilarity (B)

$$SS\_S1B = BiS1S2/(S1L/2) \qquad (4)$$

$$SS\_S2B = BiS1S2/(S2L/2) \qquad (5)$$

Comparing two texts using bigrams provides an improved indication of their similarity because considering the meanings of two words gives a more accurate similarity value than considering the meaning of a single word.

Example

Assume the two texts given below are text1 and text2:

text1= وزير الخارجية البحريني: إقامة علاقات طيبة مع إيران مرهون بعدم تدخلها في الشؤون الداخلية للدول ووقف دعمها للإرهاب

text2= وزير خارجية البحرين: النظام الإيراني يدعم عددا من التنظيمات الإرهابية منها حزب الله اللبناني والميليشيات الانقلابية في اليمن

Starting from step 1 in Algorithm 1. Extracting only nouns and verbs causes text1 to become nVtext1 and text2 to become nVtext2, as follows:

nVtext1= وزير الخارجية إقامة علاقات طيبة مع إيران مرهون بعدم تدخلها في الشؤون الداخلية للدول ووقف دعمها للإرهاب

nVtext2 = وزير خارجية البحرين النظام يدعم عددا من التنظيمات منها حزب الله في اليمن

After completing all pre-processing steps(2-4) in Algorithm 1, nVtext1 becomes Text1Processed, and nVtext2 becomes Text2Processed, as follows: .

Text1Processed= وزر خرج قوم علق طوب رين رهن عدم دخل شون دخل دول وقف دعم رهب

Text2Processed= وزر خرج بحر نظم دعم عدد نظم منها حزب له يمن

Table VIII presents the results obtained from extracting unigrams, bigrams, and trigrams from Text1Processed and Text2Processed. By referring to ALMaany synonyms. The result will be as the following:

1) Number Of similarities using stemmed_Unigrams by computing how many similar words between the two

lists UniGramListText1Stemmed and UniGramList-Text1Stemmed and their synonyms equals 6.

2) Number Of similarities using stemmed_Bigrams by computing how many similar phrases between the two lists biGramListText1Stemmed and biGramList-Text2Stemmed and their synonyms equals 3.

Depending on Equation 1, SSV for text1 and text2 was 0.42 SSV=0.75 * (3/(14/2)) + 0.25*(6/14)= 0.42

Applying the cosine similarity measure to the same texts (text1 and text2) and considering term frequency as the features of words generated a similarity value between the two texts of 0.3.

In other research, they used Arabic WordNet to find the extent to which two concepts are related [3]. However, the similarity values they calculated did not depend on a specific domain, so the obtained values may have been substantially different from the actual values. For example, when extracting synonyms of an Arabic word (قوات), the related words and synonyms from Arabic WordNet, such as قوات المارينز الأمريكية, أسطول, and وحدة (see Table IX) were presented. Such comparisons between ambiguous words yield misleading values.

TABLE VIII. NGram of Text1Processed and Text2Processed

Text1Processed UniGram	Text2Processed UniGram	Text1Processed BiGram	Text2Processed BiGram	Text1Processed TriGram	Text2Processed TriGram

IV. Experimental Result

Java was utilized in implementing the proposed algorithm, and the implementation was run to collect full articles from websites (see Table II) using Google Search API [27]. We used the same keywords in Table I to search Twitter accounts. We utilized Twitter4J, an unauthorized Java tool for the Twitter API, to extract tweets. The proposed algorithm's ability to detect the semantic similarity between 700 tweets was tested.

The semantic similarity measure used most often in previous work is cosine similarity. We applied cosine similarity to the same data set. Table X illustrates sample of the comparison between the SSV values and cosine similarity values. The results were analyzed manually by a domain expert who concluded that the values provided by the proposed algorithm were better than the cosine similarity values within the selected domain regarding the semantic similarity between the datasets' short texts. Trigrams and more n-grams can be considered to search for more equivalent documents. NGram can be increases as long as the length of the text increases. For examples For very short text, unigrams can be used. And for short text, bigrams can be used. So, as long as text length increases, n can be increased fot example triGram and FourGram.

Now, let us take a closer look at the values of the comparison results from examples in Table X. The semantic similarity values were enhanced based on the following:

1) We took into consideration synonyms of NGram words from the updated dictionary and concentrated on the synonyms from the same domain.
2) BiGrams similarity value increases the indication of similarity between the sentences. In our approach, BiGrams similarity value was given more weight over UniGram similarity.

As an initial step, the proposed algorithm was tested on short text. This algorithm can be applied to long text like documents and articles. Also, it can be applied to paragraphs, sentences,...etc. This algorithm has some limitations. One of these limitations it is based on an external dictionary. This problem can be solved by automatically extracting semantically related words depending on the same corpus.

V. Conclusion and Future Work

Freely available semantic similarity measurements are essential for advancing many NLP research areas, especially for under-resourced languages such as Arabic. The lack of a commonly used, trustworthy, comprehensive dictionary and ontology of semantic similar words and phrases is recognized as one of the most challenging and exciting problems facing Arabic NLP applications. However, manually computing the similarity degree of two texts is costly and nearly impossible. In this study, we have sought to tackle the phenomenon of computing the degree of semantic similarity of Arabic short texts.

This work introduced a novel similarity measure based on n-gram synonyms connected to the same domain designed to quantify the semantic similarity between concepts and words. The proposed algorithm was evaluated on a dataset of 700 tweets, and the semantic similarity values and cosine

similarity were compared. A domain expert carefully examined the results and concluded that, considering the semantic similarity between the short sentences of the datasets, the values produced by the proposed algorithm were more accurate than the cosine similarity values within the chosen domain. This work can be a basis for other works investigating the same semantic similarity problems. Semantic similarity between texts written in the Arabic language can help determine, for example, who originally published a piece of news, who rephrased a previously published news article and claimed to be the original source, and how to extend it to solve problems related to plagiarism. Further research is a domain ontology that includes all relations between words in the domain. This domain will help determine how some words are related and how they are different. This knowledge can then be used for other purposes, such as to perform sentiment analyses of the Arabic language in this domain.

Abstract—**Diabetic Retinopathy (DR) is the major cause of the loss of vision among adults worldwide. DR patients generally do not have any symptoms till they reach the final stage. The categorization of retinal images is a remarkable application in detecting DR. Due to the level of sugar available in the blood, the categorization of DR severity becomes complicated to determine the grading level of the damages caused in the retina. To rectify these challenges, a new DR severity classification model is proposed for detecting and treating the DR. The main objective of the proposed model is to classify the severity grades that occurred in the retinal region of the human eye. Initially, gathered retinal images are enhanced and the blood vessel segmentations are done by utilizing the optic disc removal and active contouring model. The abnormalities such as "microaneurysms, hemorrhages, and exudates" are segmented by utilizing Fuzzy C-Means Clustering (FCM) and adaptive thresholding. Then, the segmented images are given to "VGG16 and ResNet", in which the two different feature sets are acquired. Then, these features are added to obtain the second set of features as F2. Again, the enhanced images act as an input to the "VGG16 and ResNet", which are attained as the first feature set as F1. In the feature concatenation phase, the resultant of two features is used for feature fusion with the aid of weights parameter that is optimized by Modified Mating Probability-based Water Strider Algorithm (MMP-WSA), where the feature fusion is carried out using the mathematical expression. Finally, the multi-class severity classifications are done by using the Optimized Deep Neuro-Fuzzy Classifier (ODNFC), where the optimization of hyper-parameters is done by the proposed MMP-WSA. Thus, the experimental results of the proposed model have been acquired by the precise segment of the abnormalities and better classification results regarding the grade level.**

Keywords—Multi-class severity classification; diabetic retinopathy; modified mating probability-based water strider algorithm; optimized deep neuro-fuzzy classifier; fuzzy clustering model; adaptive thresholding; optic disc removal; image enhancement

I. INTRODUCTION

The retinal image evaluation is a diligent investigation platform in Diabetic Retinopathy (DR). It is the major cause of serious eye difficulties or even loss of sight in developed countries [9]. The retina mainly comprises of the optic disc, fovea, and blood vessels. A few basic symptoms of DR are "sudden changes in vision, eye pain, double vision, Eye Floaters, blurred vision/fluctuating vision and Shadow in Field of View (FOV) and Spots" [11]. The DR is considered one of the deep-rooted visual problems that tend to vision loss if it is

not identified on time [15]. Early detection by utilizing regular periodic evaluations is a determinative factor in declining the hazard of serious visual deterioration [16]. The major lesions present in the DR are referred to as exudates, cotton wools, hemorrhages, and Microaneurysms. Hence, the identification of "Microaneurysms and hemorrhages" plays a significant role in the automatic detection of retinopathy [19]. Furthermore, the determination of this disease needs a huge amount of experience and adequate knowledge from doctors. Also, because of the presence of inadequate ophthalmologists and the lack of resources, the screening of patients with Diabetes Mellitus (DM) is considered to be complicated [20], which leads to loss of vision [12]. The DR is broadly categorized into a couple of sections known as proliferative and non-proliferative. The non-proliferative refers to the weakening of blood vessels inside the retina, which causes "leakage of fluids and blood on the retinal surface" due to DR [13]. This leakage minimizes the retinal sensitivity, while it is wet and swollen. The proliferative refers to the developed levels of DR, which creates neovascularization, a creation of bloody vessels newly and naturally in the variety of microvascular network forms that originate on the retina internally [14].

In automated DR diagnosis and segmentation, soft computing models play a remarkable role. Models for DR diagnosis and classifications are genetic algorithms, neural networks, and evolutionary algorithms [21]. Early detection of diabetic retinopathy can prevent the loss of vision in future [10]. Other than automated DR categorization, the fuzzy classifiers are modeled to be translucent with steps of categorization and logic descriptions that are detectable and understandable [22]. However, it needs a huge amount of labeled data for monitoring the training networks. The categorization of retinopathy images is considered a difficult task and so many experienced clinicians are required for the manual interpretation of a high number of retinopathy images. Because of this, Fuzzy C-Means Clustering (FCM) is considered [23]. The fuzzy methodology supports providing enhanced image representations and also in enhancing the analysis performance and providing a more dependable system for screening [24]. The screening of the DR disease at the early stage itself is complicated and so the "Neuro-Fuzzy Hybridization" provides a synergistic intellectual system that joins the human-like reasoning model of a fuzzy system with a neural network's learning structure. The Neuro-Fuzzy hybrids are broadly termed "Neuro-Fuzzy Systems (NFS) or Fuzzy Neural Networks (FNNs)" [25]. Thus, the latest investigators

aim on establishing a new DR diagnosis model through deep learning approaches.

The major offerings of this paper are as follows:

- To develop a novel DR severity classification approach based on deep learning approaches for categorizing severities caused by DR, to enhance the early disease diagnosis rate, and to reduce the fatality of patients regarding vision loss.

- The image enhancement process utilizing RGB channels and processing segmentation in two stages known as "blood vessel segmentation and abnormality segmentation" by utilizing the "optic disc removal, adaptive thresholding, FCM and active contouring" model to improve the quality of segmented images.

- To establish the weighted optimal feature selection process in two models by choosing the remarkable features utilized with weight function by developing a Modified Mating Probability-based Water Strider Algorithm (MMP-WSA) for limiting the features and enhancing the performance of categorization.

- To develop an ensemble known as an Optimized Deep Neuro-Fuzzy Classifier (ODNFC), for classifying the DR severity with parameter optimization such as "hidden neurons of DNN, the learning rate of DNN, EXP-bound in fuzzy and weights" are optimized with the developed MMP-WSA for obtaining improved validity in DR categorization.

- To establish a new meta-heuristic algorithm known as MMP-WSA for mounting the weighted optimal feature selection by optimizing the weight function and enhancing the classification accuracy by optimizing the hyper-parameters of developed ODNFC.

The contribution of this research work is as follows. In Section II, the relevant works and their related difficulties are briefed. In Section III, the proposed DR diagnosis model by utilizing ODNFC and image enhancement processing is elaborated. In Section IV, the blood vessel and abnormality segmentation are discussed. In Section V, feature extraction and optimal weighted feature selection for DR diagnosis are explained. In Section VI, the developed MMP-WSA and the developed ODNFC are briefed. In Section VII, the experimental results are discussed. In Section VIII, the proposed DR diagnosis is concluded.

II. LITERATURE SURVEY

A. Related Works

In 2020, Vaishnavi *et al.* [1] established a new classification approach based on segmentation to categorize the 'DR images", effectively. The proposed approach comprised three major processing known segmentation, feature selection, preprocessing, and categorization. The proposed model has undergone pre-processing utilizing "Contrast-Limited Adaptive Histogram Equalization (CLAHE)". The "AlexNet" model was utilized for feature extraction to collect the most important features. Finally, the categorization of DR images was done by utilizing the SoftMax layer. The experimentation results

represented that the established approaches have achieved the maximum categorization rate.

In 2021, Bhardwaj *et al.* [2] proposed a system known as Hierarchical Severity Level Grading (HSG) for the identification and categorization of disorders in DR. The images of the retinal fundus available in the developed HCG system were classified into grades 0, 1, 2, 3 based on the count of anomalies, hemorrhages, and microaneurysms in the images of the fundus. The complications of the "landmark segmentation of retinal images, DR severity grading and DR retinal discrimination" have been notified in this paper contributing to the proposed model. For the categorization of DR and non-DR images, the developed systems have attained greater accuracy with SVM [17] and KNN [18] classifiers. The hierarchical inequities into more grades of harmfulness in disease have resulted in a certain accuracy range for the KNN classifier. The HCG system attained a remarkably minimum time for computation when compared with other state-of-art models.

In 2022, Vasireddi *et al.* [3] established an automated DR identification screening model that was needed to enhance the detection speed and accuracy of the diagnosis. Proper treatments have been given to patients to prevent blindness when the complication levels of DR were detected in earlier stages accurately. The utilization of the optimization algorithm along with the required parameters for tuning enhanced the model's performance. The experimentation results have indicated that the proposed model attains superior accuracy.

In 2020, Gharaibeh *et al.* [4] proposed soft computing models for the diagnosis of Hemorrhages and microaneurysms in fundus images. This process comprised of several steps "such as i) pre-processing, ii) blood vessel segmentation, iii) blood vessel removal, iv) fovea localization, v) fovea elimination, vi) feature extraction, vii) feature selection and finally viii) detection of Diabetic Retinopathy disease" known as Hemorrhages and microaneurysms. It enhanced the performance of precision, accuracy, specificity, and sensitivity and the diagnosis of the DR easier and faster and the results were efficient and provided effective outcomes in categorization models.

In 2022, Kuna Sri Laxmi et al [5] employed various CNN architectures used to classify the severity levels of Diabetic Retinopathy. In 2022, Das and Saha [6] proposed a technique on the basis of a genetic algorithm to detect the CNN parameter automatically and further classification of DR. This approach has comprised a series of "pooling and convolution layers" for the feature extraction. The hyper-parameters in the pooling layer, convolution layer, kernel count, and size of the kernel were analyzed by utilizing the genetic algorithm. The proposed model was validated on a normally available dataset known as "The Messidor dataset". Finally, the SVM utilized for DR categorization has attained greater accuracy than other available models on the basis of a genetic algorithm.

In 2020, Luo *et al.* [7] aimed on embedding a self-monitored model into an un-monitored deep learning approach. Remarkably, it has developed a "Self-supervised Fuzzy Clustering Network (SFCN)" along with a module for feature learning, fuzzy self-monitoring, and reconstruction. The

reconstruction approach and feature learning have assured the capacity of the network and the fuzzy self-monitoring module was in charge of giving more training paths for the entire network. To analyze the efficiency of the proposed model, it has established the network on three datasets, in which the results described the good performance of the un-monitored image categorization task.

In 2020, Wang *et al.* [8] proposed a hierarchical architecture to consolidate the common inter-relationship in-between the features and severity levels of DR. The proposed model was analyzed on two individual testing elements by utilizing the "receiver operating characteristic analysis, quadratic weighted Cohen's kappa coefficient and precision-recall analysis". The experimentation outcomes have demonstrated that the proposed model has enhanced the performance of DR severity in comparison with other deep-learning approaches and attained a performance close to the experienced ophthalmologists during the detection of DR severity level.

B. Problem Statement

Diabetic Retinopathy is one of the major diseases in humans, which affects the retinal region of the eye. In the medical industry, there is no early predicted symptom for retinopathy. This disease is caused in two ways: the initial stage is NPDR and the most affected phase is PDR. The remarkable symptoms are leaking blood vessels, swelling of the retina, exudates, damage to nerves, and so on. Hence, the detection and diagnosis of retinopathy become the most challenging task. The screening is targeted at an affected individual that is highly unpredictable. CLAHE and AlexNet [1] enhance the performance in terms of accuracy, sensitivity, and specificity. But, the last layer of AlexNet produces a multiclass classification problem. Gray Level Co-Occurrence Matrix and Support Vector Machine [2] yield the accurate classification of the severity grade level and increase the accuracy. However, it does not consider blood vessel bleeding and neovascularisation problem. Also, due to retinal detachment, acute blindness occurs. Deep Fuzzy Neural Network (DFNN) and Lion Optimization Algorithm (LOA) [3] provide a better severity classification. But it has more time computation complexity. PSO and fuzzy membership [4] obtains higher accuracy and extracts the blood vessels precisely. However, it mitigates the performance since it has fewer quality data. Fuzzy Neural Network [5] improves the classification rate. Moreover, the limitation is to need more numbers of rules to perform in a better way. The Genetic Algorithm and SVM [6] provide higher accuracy for different datasets. But it possesses structural and computational burdens. Fuzzy Clustering [7] yields a higher accuracy value and does not contain most qualitative criteria. However, it has an imprecision dependency on the model. Multi-task DNN [8] obtains less error and more accuracy. Moreover, due to various confidence levels, it may get inaccurate results. To overcome the mentioned challenges, it is provoked to establish a new approach for diagnosing diabetic retinopathy disease.

III. ARCHITECTURAL VIEW OF MULTI-CLASS SEVERITY CLASSIFICATION OF DIABETIC RETINOPATHY

A. Proposed DR Classification Model and Description

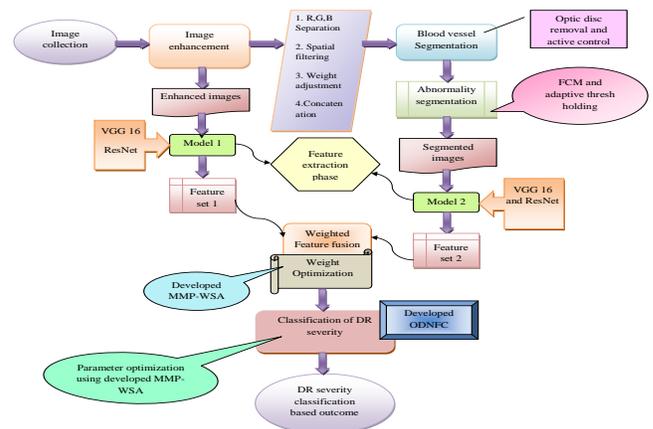
A new DR severity classification model is developed with a weighted feature fusion model and deep learning approach depicted in Fig. 1. In this model, the DR images data set is considered from the standard data set DIARETDB1 as input. These images are preprocessed by four steps enhancement process such as R, G, and B channel separation, entropy-based spatial filtering, fuzzy-based weight adjustment, and concatenation of R, G, and B channels. Then, the blood vessel segmentation is carried out by utilizing optic disc removal and active control using enhanced images. The abnormality segmentation is done with segmented images by FCM and adaptive thresholding. Then, the feature extraction phase is done by using a couple of models. In model 1, the obtained enhanced images are provided as the input to VGG 16 and ResNet, and the required set of features is extracted as feature set 1. In model 2, the abnormality-segmented images data set is provided as the input to "VGG 16 and ResNet" and the required set of features is extracted as feature set 2. For both feature set1 and 2, the feature fusion is carried out for obtaining "fused features with optimized weight function using the developed MMP-WSA" to obtain optimal weighted fused features. Finally, the DR severity classification is done by using developed ODNFC using the weighted fused features, in which the parameters such as "hidden neurons of DNN, the learning rate of DNN, EXP-bound in fuzzy and weights" are optimized by utilizing the developed MMP-WSA. At last, the DR severity-based outcome is obtained as four categories of DR known as normal, earlier, moderate and severe for the proposed DR severity classification model.


Fig. 1. Developed Multi-Class DR Severity Classification Model with Adaptive Weighted Feature Fusion and Deep Learning Approach.

B. Novel Image Enhancement Process

The images for input are taken from "https://www.it.lut.fi/project/imageret/diaretdb1/". It is a public database for the process of benchmarking the DR severity classification from digital images. the collected database images are denoted as IMG_m^{COL}, where $m = 1,2,\cdots,M$ and the total image count is represented as M. The IMG_m^{COL} is provided as input for the process of image enhancement in the

proposed DR severity classification. The image enhancement process is carried out as follows:

- Separation of RGB channels: The input images IMG_m^{COL} are pre-processed for enhancing the quality of the image by removing unwanted elements. The separation of the R, G, and B channels is utilized for the evaluation of elements of primary colors of each region of an image. Hence, the enhanced image obtained after the separation of R, G, and B channels is denoted as ENH_c^{sep}.

- Applying entropy-based spatial filtering: In this step, the RGB-separated images ENH_c^{sep} are given as input. The spatial filtering on the basis of entropy is created for global contrast enhancement of the images. Hence, a single entropy function is applied to the entire image. The algorithm gives contrast enhancement without remarkable deformation on the output image. Thus, the enhanced image obtained from the spatial filtering is represented as ENH_c^{spa}.

- Concatenation of RGB channels: Finally, the separated images are concatenated after removing all kinds of unwanted elements from the image channels. Thus, the quality of the images is enhanced for further processing. Hence, the enhanced image obtained is represented as ENH_c^{img}.

IV. ENHANCED DIABETIC RETINOPATHY SEGMENTATION MODEL THROUGH NEW ABNORMALITY SEGMENTATION

A. Optic Disc Removal

The optical disc is removed from enhanced images ENH_c^{img} of the data set for further processing. In the process of optic disc removal for the developed DR severity classification, the enhanced images ENH_c^{img} are provided as the input, and further processing is made. For removing it, the edge-enhanced image on the basis of the curvelet is opened by using a disk-shaped element, which is eliminated from the inverted equalization image. The matching filtering will intensify the visibility of blood vessels present in the enhanced image. The morphological operation is carried out for the processing of optic disc removal. Thus, the segmented image obtained after the process of optic disc removal is represented by SEG_c^{opt}

B. Active Contour-based Blood Vessels Segmentation

In the process of blood vessel segmentation, the optic disc removed image SEG_c^{opt} is provided as input to segment the blood vessel using active contour. The active contour is a technique of segmentation that utilizes energy forces and difficulties to split the pixels' interest from images for later evaluation and processing. Active contouring is the methodology of collecting the degradable structures of an image with problems and energy forces for the process of segmentation of blood vessels. The contour model determines

the borders of the image elements to create a contour. The curvature of the structure is identified by utilizing various methodologies that comprise internal and external forces. The energy functions are always interrelated to the curve of images. The contour blood vessel segmentation constraints for available images are identified on the basis of requirements. The needed structure is obtained by determining the energy function. A gathering of points that position a contour is utilized to define deformations in contour. Thus, the blood vessel segmented image obtained from active contouring is represented as SEG_c^{act}.

C. Abnormality Segmentation by Fuzzy Logic-based Adaptive Thresholding

The abnormality segmentation of the developed DR severity classification is carried out on the basis of two models known as FCM and Adaptive Thresholding on the basis of fuzzy logic and it is briefed below.

FCM [31]: Here, the blood vessel segmented images are provided as input and that is segmented into five classes, which are remarked as the blood vessel, the outer area of the eyeball, the healthy area in the background of the retina, cotton wools and hard exudates. In the processing of clustering, the input images are subdivided into 3×3 non-overlapping regions. Then, for each region, the average intensity is computed. There exists p total number of 3×3 regions present in the image.

Suppose we have a collection of N data (xi; i = 1, 2, 3, ... , N) to be segmented into five fuzzy sets. There will be a membership matrix *em* of size 5XN

Then, the value of entries of the matrix *em* is initiated randomly between 0 and 1 while keeping the sum of each column of *em* to 1 and computed on the basis of the following Eq. (6)

$$\sum_{a=1}^{h} em_{ab} = 1 \ \forall b = 1,2,\ldots,p \tag{6}$$

The FCM divides the data into five categories as h and then determines the center of cluster for every group iteratively during the minimization of cost function on the dissimilarity. Thus, the function of dissimilarity is determined on the basis of the following Eq. (7).

$$B = \sum_{a=1}^{h} \sum_{b=1}^{k} (em_{ab})^{we} ed_{ab}^2 \tag{7}$$

Here, the term em_{ab} denotes the entries of *em*, ed_{ab} indicates the Euclidean distance between a^{th} cluster h_a, b^{th} is the data point, and we **represents the weighting exponent.** Then, the cluster center and the entries are upgraded by utilizing the following Eq. (8) and Eq. (9)

$$Ci = \frac{\sum_{b=1}^{em} em_{ab} Y_{ab}}{\sum_{b=1}^{p} (em_{ab})^{we}}, \forall \ b = 1,2,\ldots,C \tag{8}$$

$$em_{ab} = \frac{1}{\sum_{c=1}^{C} \left(\frac{ed_{ab}}{ed_{cb}}\right)^{\frac{2}{we-1}}} \tag{9}$$

The output from the FCM is obtained in the form of non-overlapping regions indicating five clusters. The abnormality segmented image obtained from FCM is denoted as SEG_c^{fcm}.

Adaptive Thresholding [32]: The segmented image SEG_F^{fcm} obtained from FCM is provided as input and further processing is made. This method generates local thresholds for various areas of images. This is also called the dynamic threshold. By utilizing thresholding, the value of pixels of the images can be categorized from the background. The "adaptive thresholding algorithm" is processed by determining the weighted averages available locally in the image by utilizing the recursive filters. Thus, by using adaptive thresholding, the objects can be separated from the background and also the boundaries are separated. This is attained by generating the surface of the threshold so that the threshold value will be available for each pixel. Hence, the adaptive thresholding is computed based on Eq. (10).

$$Th_{gaussian} = \frac{1}{\sqrt{2\pi \sigma_{a,b}}} e^{\frac{pix(a,b)\mu_{a,b}}{2\sigma_{a,b}^2}} \qquad (10)$$

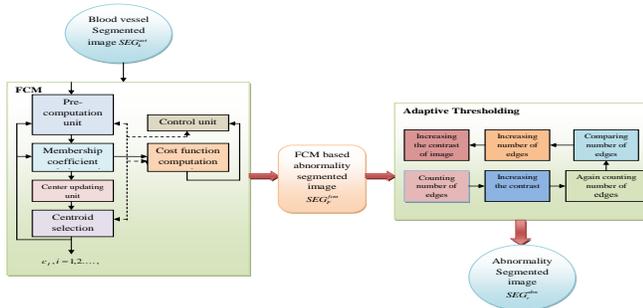
Here, the term a denotes the column pixel index, and b indicates the row pixel index σ denotes the standard deviation and μ represents the averages. The abnormality segmented image obtained from adaptive thresholding is indicated as SEG_c^{abn}. The process of abnormality segmentation based on FCM and adaptive thresholding is indicated in Fig. 2


Fig. 2. Abnormality Segmentation based on FCM and Adaptive Thresholding.

V. DEEP FEATURE EXTRACTION AND OPTIMAL FEATURE SELECTION PROCESS IN TWO STAGE

A. Deep Feature Extraction

The deep feature extraction process for severity classification is determined in "model 1 and model 2". In model 1, the enhanced image obtained from pre-processing is provided as input to VGG16 and ResNet models for extracting the first set of features. In model 2, the abnormality-segmented images are fed as the input for VGG 16 and ResNet models, and the second set of features is extracted as feature set 2. Then both sets of features are optimized by utilizing the proposed MMP-WSA to obtain the optimal deep features, which are elaborated below.

VGG 16 [29]: In this, the enhanced images ENH_c^{img} and segmented images SEG_z^{abn} are provided as input. It is composed of three divisions named "convolutional layer, totally connected layer, and pooling layer". It also consists of a total of 10 layers that are different from the pooling layers. It has a developed network design. For this, the input size of an image is fixed as "224×224 pixels" and the size of the filter in the obtained image is fixed at "3×3 pixels". The output division in the VGG 16 is named "SoftMax". The gathered deep feature element from the VGG-16 is represented as $FESEG_d^{deepVGG16}$ and $FEEN_f^{deepVGG16}$ from ENH_c^{img} and SEG_z^{abn}, respectively.

ResNet-150 [29]: For this, the selected features of enhanced images ENH_c^{img} and segmented images SEG_z^{abn} are provided as input for the ResNet model. It is a developed form of the CNN model. The ResNet gives the shortest route between the divisions to resolve the problems. It also eliminates the level of dispersion, which occurs at the time of complex generation of the network. Moreover, the "bottleneck blocks" are used to fasten the learning process in the ResNet mode. The extracted features from the ResNet model are denoted as $FESEG_e^{deepRN}$ and $FEEN_g^{deepRN}$ from ENH_c^{img} and SEG_z^{abn}, respectively.

B. Optimal Feature Selection: Model 1

In model 1, the enhanced images ENH_c^{img} are provided as input for the feature extraction with VGG 16 and ResNet. Then, by utilizing developed MMP-WSA, the extracted features such as $FEEN_g^{deepRN}$ and $FEEN_f^{deepVGG16}$ are optimized for obtaining optimal deep features denoted as F_1. Total counts of 10 features are extracted from model 1.

C. Optimal Feature Selection: Model 2

In model 2, the abnormality-segmented form of images is fed as input and the feature element extraction is done by utilizing two models known as VGG 16 and ResNet. Then, by utilizing the developed MMP-WSA, the selected segmented features such as $FESEG_e^{deepRN}$ and $FESEG_d^{deepVGG16}$ are optimized for obtaining optimal deep features denoted as F_2. Total counts of 10 features are extracted in model 2.

D. Proposed Feature Fusion

The obtained optimal features F_1 and F_2 from model 1 and model 2 are then fused for obtaining optimal fused features. The weight function is considered during the process of feature fusion, which is optimized using the developed MMP-WSA, and the fusion process takes place as shown in the following Eq. (11).

$$F_{fu} = \left[F_1 * W + (1 - W) * F_2 \right] \qquad (11)$$

Here, the terms F_1 and F_2 indicate the optimal features sets from model 1 and model 2, represent the optimized weight function and denote the feature fusion.

VI. DIABETIC RETINOPATHY SEVERITY CLASSIFICATION BY OPTIMIZED DEEP NEURO FUSSY CLASSIFIER

A. Proposed MMP-WSA

The developed MMP-WSA algorithm is utilized and implemented in the DR severity classification approach for optimization of parameters such as "hidden neurons of DNN, the learning rate of DNN, EXP-bound in fuzzy and weights" in the feature fusion phase for enhancing the DR classification performance. WSA [26] is selected in this model since it attains efficient performance in optimization issues. In the stage of mating, the probability of attraction is transferred to adaptive or dynamic instead of static, which gives effective convergence performance, but there exist certain limitations in WSA such as the evaluation count is not an acceptance function of the internal elements and so there exists potential complexity in programming languages, which cannot help the global variable to control the total function and evaluation count. Due to the presence of such difficulties in conventional WSA, it is essential to propose an enhanced WSA named MMP-WSA for improving the DR severity classification. In this MMP-WSA, the probability of mating is updated with an adaptive concept, whereas in the traditional algorithm, it is updated with a random parameter.

WSA is an algorithm designed on the basis of feeding mechanism, mating style, territorial behavior, and succession of water strider bugs. The step involved in the algorithm is briefed below.

Initial Birth: The creation of candidate solutions randomly in the searching platform as indicated in Eq. (12) below.

$$Ws_j^0 = l_b + rand.(u_b - l_b): \quad j = 1, 2, \ldots, NWs \tag{12}$$

Here, the initial positions *Ws* are analyzed by utilizing an objective function to compute the fitness. The term u_b and l_b indicates the lower and upper bound of variables, Ws_j^0 denotes the initial positions of the jth *Ws* in the searching space, *NWs* indicates the population size and *rand* represents the random number that lies between $[0,1]$.

Territory Establishment: For introducing *ni* count of territories, the ith member of every group is allocated to the ith territory $(i = 1, 2, \ldots, ni)$. Hence, the number of Ws_r nesting in every territory is equal to $\frac{NWs}{ni}$ and $\frac{NWs}{ni}$ count of groups is generated orderly and Ws_r are sorted on the basis of fitness. The territory locations with good and bad fitness are obtained as female and male, respectively.

Mating: The male *Ws* gives a "ripple to the female" *Ws* for the process of mating. Since the female side response is not clear, the mating probability Pr is considered for attracting the female. In the conventional algorithm, Pr is fixed in the constant range of 0.5, which degrades the performance of an algorithm. Hence, in the developed MMP-WSA, the mating probability P_r is updated on the basis of upper-bound and lower bound based concepts as shown in Eq. (13) below.

$$Pr = [(me(R) - me(l_b))/(me(u_b) - me(l_b))] * (1 - 0) + 0 \tag{13}$$

Here, the term $me(l_b)$ denotes the mean of the lower bound and $me(u_b)$ indicates the mean of the upper bound. Then, the value of *R* is computed by the following Eq. (14).

$$R = Ws_j^s - Ws_j^{s+1} \tag{14}$$

Then, the male location is upgraded in Eq. (15).

$$Ws_j^{s+1} = \begin{cases} Ws_j^s + T.rand & \begin{array}{l} if\ mating\ happens \\ (with\ probablity\ of\ \mathrm{Pr}) \end{array} \\ Ws_j^s + T.(1 + rand) & otherwise \end{cases} \tag{15}$$

The length *T* is computed by Eq. (16).

$$T = Ws_f^{s-1} - Ws_j^{s-1} \tag{16}$$

Here, the term Ws_j^{s-1} and Ws_f^{s-1} indicates the male and female *Ws* in (s-1)th cycle.

Feeding: The process of mating requires a huge amount of energy for male water sliders *Ws* searches the food later than the process of mating. The access of objective function for the presence of food is carried out. If the value of fitness is better than the prior condition, the male *Ws* has identified food in a new location, or else it was not. In the further circumstance, the male *Ws* transport to the superlative *Ws* of the pond $\lfloor Ws_{bp} \rfloor$ for founding the food, which is computed in Eq. (17).

$$Ws_j^{s+1} = Ws_j^s + 2rand * (Ws_{bp}^s - Ws_j^s) \tag{17}$$

Fatality and Progression: If the chap *Ws* could not identify food in a new location, then it will die and another male *Ws* will replace the position of the old one. This process is expressed in Eq. (18)

$$Ws_j^{s+1} = l_{b_i}^s + rand * (u_{b_i}^s - l_{b_i}^s) \tag{18}$$

Here, the term $u_{b_i}^s$ and $l_{b_i}^s$ indicates *Ws* location for the maximum and minimum values inside the ith territory.

WSA Execution: If the circumstance of the termination is not satisfied, the baseline approach will send back to the step of mating again for creating a new disk. Here, the "Maximum Number of Function Evaluation (MaxNfes)" is represented as the execution condition. The pseudo-code of the developed MMP-WSA is indicated in Algorithm 1.

Algorithm 1: Pseudo Code of Developed MMP-WSA

Initialize random population
Compute the value of fitness *Ws*
While (execution circumstance is not satisfied) do
    Introduce *ni* region count and allow the *Ws*
    For (every region) do
    Update the mating probability Pr
      The male gives "mating ripples" and the chosen female predicts the reply to attract the female by Eq. (13)
      Update the location on the basis of the female response with Eq.

---

(15)
Analysis of the new location to search for foodstuff for compensate the obsessive power during the process of mate
    If (the male could not identify the foodstuff) then
        Searching for foodstuff sources and reaching the territory of the food-rich region by Eq. (16)
           If (male could not identify the foodstuff again)
                The starving male will be died due to malnourishment
                Another male is replaced in the place of died one by Eq. (18)
           End
        End
    End
Return Ws_{opt}

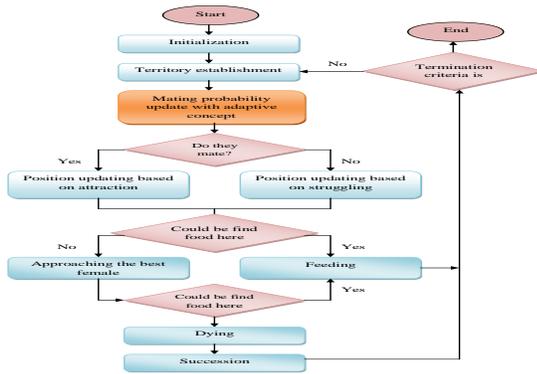
The flowchart of the projected MMP-WSA is represented in Fig. 3


Fig. 3. Flowchart of Proposed MMP-WSA.

B. Optimized Deep Neuro-Fuzzy Classifier

The obtained optimal fused features are given as input for the process of "DR severity classification" by utilizing the developed ODNFC. For the process of image analysis, a rule-based system is modeled by fuzzy network operation. Fuzzy logic is a type of many-valued logic whose variables' truth values can be any real number between 0 and 1. To enhance this operation, the computation of "Single-Input-Multi-Output (SIMO)" is carried out based on Eq. (19).

$$if \ y \ is \ A_n \ then \begin{pmatrix} f_{1n}(y) \\ f_{2n}(y) \\ f_{3n}(y) \end{pmatrix}, n = 1,2,\dots,N \qquad (19)$$

Here, the term y represents the input variable from the discourse universe *(Y), N* is denoted as count of rules, n indicates the output count, A_n denotes the fuzzy set for n^{th} rule determined over *(Y)* and f_{in} implies the output of nth rule, the outputs are considered as non-linear functions of the inputs. For the process of analysis of images, the universe of discourse is considered as the sub-region set of the considered image. Also, the set of fuzzy is considered as the remarkable pattern. Lastly, the membership grade is considered as the similarity in-between the provided pattern and the sub-regions. Every fuzzy rule present in the rule set is entrapped in various patterns present in the image. Hence, the rewrite equation is obtained as shown in Eq. (20).

$$\begin{pmatrix} f_{1n}(y) \\ f_{2n}(y) \\ f_{3n}(y) \end{pmatrix}, n = 1,2,\dots,N \qquad (20)$$

Thus, the proposed model considers SIMO-based system, where the provided image is given as the individual input, the nth rule attracts the pattern in the images of sub-regions, every output represents a non-linear function against the sub-regions for n^{th} pattern, and the output of de-fuzzification is affected by joining of the specific patterns by fuzzy set in every image rules. The operation of fuzzy interference involves the following steps:

1) Computing of the membership: For every rule, the membership grade (M_n) of the matrix is computed, where every element present in the matrix indicates identity in between the sub-regions present in the image and fuzzy set (A_n). The membership values are allotted at the range of $[0,1]$.

$$M_n = [m_{in}] = [a_i, A_n] \qquad (21)$$

Here, the term a_i is the ith image sub-region and m_{in} is the item in M_n.

2) Computing firing strength: The firing strength of every rule is determined by membership grade normalization matrix grade as represented in Eq. (22).

$$\overline{M}_n = \frac{M_n}{\sum_{x=1}^{N} M_x} \qquad (22)$$

3) Computing final output: The final outputs of the system rules are provided as shown in Eq. (23) below.

$$w_i = \sum_{n=1}^{N} w_{in} = \sum_{n=1}^{N} \overline{M}_n f_{in}(y) \qquad (23)$$

Here, the term w_i denotes the output while w_{in} indicating the output of nth rule. From the categorization by developed ODNFC, the output is obtained in the form of severe, moderate, normal, and abnormal DR.

The proposed approach focuses on the main objective function for parameter optimization in developed DR severity classification. The parameters considered for the optimization are "hidden neurons of DNN, learning rate of DNN, EXP-bound in fuzzy and weights of fused features". The objective function is computed in Eq. (24).

$$OBFN = \underset{\{HN_{DVV}, LR_{DNN}, EX_{FUZZ}, WE\}}{\arg\max} (ACCU) \qquad (24)$$

Here, the term HN_{DVV} indicates the hidden neurons of DNN, LR_{DNN} denotes the learning rate of DNN, EX_{FUZZ} indicates the Exp-bound in fuzzy, and *WE* represents the weight. The hidden neurons count for DNN is fixed in the "range of $[5,255]$ and the learning rate count for DNN is fixed in the range of $[0.01,0.99]$ and the weight range is fixed in-

between $[0.01, 0.99]$", respectively. The term *ACCU* represents the accuracy "closeness of measuring the distance to a specific value", which is computed in the following Eq. (25).

$$ACCU = \frac{(tru_p + tru_n)}{(tru_p + tru_n + fal_p + fal_n)} \tag{25}$$

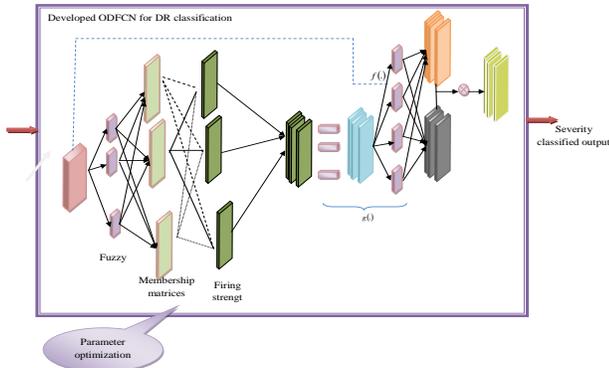
Here, the term tru_p and tru_n denotes" the true positive and true negative values" and the terms tru_p and fal_n indicates the "false negative and false positive values". The developed ODNFC-based DR severity classification is diagrammatically depicted in Fig. 4.


Fig. 4. Flowchart of Proposed MMP-WSA.

VII. RESULTS AND DISCUSSIONS

A. Experimental Setup

The developed DR severity categorization sculpt was established in python and the experimentation analysis is carried out. The concert evaluation of the projected approach was done by the relative examination with traditional models using several quantitative procedures. These quantitative procedures were further divided into two divisions named "positive measures and negative measures". "Positive measures or Type I includes Negative Predictive Value (NPV), Specificity, Accuracy, MCC, Precision, Sensitivity, and F1Score. Negative measures were taken as Type II measures such as False Discovery Rate (FDR), False Negative Rate (FNR), and False Positive Rate (FPR)". The experimentation was carried out on "10 counts of population and the total count of iterations was considered as 25". The proposed MMP-WSA was compared with various algorithms like "Particle Swarm Optimization Algorithm (PSO) [4], Grey Wolf Optimization (GWO) Algorithm [28], Butterfly Optimization Algorithm (BOA) [27], Water Strider Algorithm (WSA) [26] and machine learning algorithms like Deep Neural Network (DNN) [8], Resnet-VGG16 [29], Fuzzy [7], and ODNFC [30]".

B. Performance Metrics

The concert of the established DR severity classification model was tested for quality evaluation of the enhanced approach with several quantitative measures that are briefed as follows.

a) MCC *Mcc* is "a measure of the quality of binary classifications of testing" as Eq. (26)

$$Mcc = \frac{tru_p \times tru_n - fal_p \times fal_n}{\sqrt{(tru_p + fal_p)(tru_p + fal_n)(tru_n + fal_p)(tru_n + fal_n)}} \tag{26}$$

b) Specificity *Spe* is "the proportion of negatives that are correctly identified" as Eq. (27)

$$Spe = \frac{tru_n}{tru_n + fal_p} \tag{27}$$

c) NPV *Npv* is "the sum of all persons without disease in testing" as denoted in Eq. (28)

$$Npv = \frac{tru_n}{tru_n + fal_n} \tag{28}$$

d) F1-score *Fsco* is "the measurement of the accuracy in the conducted test" as Eq. (29)

$$Fsco = 2 \times \frac{2tru_p}{2tru_p + fal_p + fal_n} \tag{29}$$

e) FNR *Fnr* is "the proportion of positives which yield negative test outcomes with the test" as Eq. (30)

$$Fnr = \frac{fal_n}{fal_n + tru_p} \tag{30}$$

f) Sensitivity *Sen* is "the proportion of positives that are correctly identified" as Eq. (31)

$$Sen = \frac{tru_p}{tru_p + fal_n} \tag{31}$$

g) FPR *Fpr* is "the ratio between the numbers of negative events wrongly categorized as positive (false positives) and the total number of actual negative events" as Eq. (32).

$$Fpr = \frac{fal_p}{fal_p + tru_n} \tag{32}$$

h) FDR is "a method of conceptualizing the rate of errors in testing when conducting multiple comparisons" as denoted in Eq. (33)

$$Fdr = \frac{fal_p}{fal_p + tru_p} \tag{33}$$

C. Performance Evaluation on Several Baseline Approaches

The concert evaluation of the developed DR severity classification is carried out by comparison with several algorithms as shown in Fig. 5 at different learning percentages. By taking into consideration, the precision of the proposed MMP-WSA, the performance is 0.3%, 0.42%, 0.38%, and 0.49% enhanced than the PSO-ODNFC, GWO-ODNFC, BOA-ODNFC, and WSA-ODNFC, respectively at the learning percentage of 75. Likewise, for every performance measure, the proposed MM-WSA outperformed in terms of the developed DR severity classification model than the traditional approaches.

D. Evaluation of the Proposed DR Diagnosis Model for Different Optimized Algorithms

The performance of the proposed DR severity classification model is carried out on the basis of developed ODNFC on comparison with different conventional classifiers as shown in Fig. 5 at varying "learning percentages". The DR severity classification model is compared with several meta-heuristic baseline approaches as indicated in Table I for analysing the performance. The comparative analysis of the proposed algorithm with other models denotes the improved performance of the proposed MMP-WSA by minimizing the errors. The performance of the proposed MMP-WSA is

0.0.9%, 0.1%, 0.08% and 0.045% enhanced than the PSO-ODNFC, GWO-ODNFC, BOA-ODNFC, and WSA-ODNFC, respectively. Hence, the proposed DR severity classification model improves its performance among several available models.

E. Evaluation of the Proposed DR Diagnosis Model for Various Classifiers

The complete evaluation is made on the proposed DR severity classification model for performance estimation among several classifiers as portrayed in Table II. By considering the precision of the developed ODNFC, the performance improves O.047%, 0.035%, 0.037% and 0.045% than the DNN, RESNET-VGG16, FUZZY, and DNFC, respectively. Therefore, the proposed DR severity classification model improves its performance than other available models.

VIII. CONCLUSION

This paper has developed a novel DR severity classification model with enhanced meta-heuristic-based feature fusion and fuzzy categorization approaches. It includes a number of procedures, together with image enhancement, optic disc

removal, image segmentation, and two sets of "model 1 and model 2" characteristics. The acquired fused features were then obtained after performing feature fusion between two feature sets. Where the weighted utility was optimized by utilizing the developed MMP-WSA in fused features and the optimal weighted fused features were obtained, then the classification of DR severity was carried out by utilizing developed ODNFC, in which its hyperparameters such as hidden neurons and learning percentage of DNN, EXP-bound in fuzzy were optimized by utilizing the developed MMP-WSA. The developed MMP-WSA-ODNFC model has provided higher accuracy as 0.047% than DNN, 0.035% than ResNet-VGG 16, 0.037% than fuzzy, and 0.045% than ODNFC. Hence, the developed DR severity classification model with ODNFC-based categorization using MMP-WSA has provided improved performance than other available DR severity classification models. It also acts as a potential path for clinicians for evaluating huge data and for fastening up DR severity classification.

Abstract—**Blockchain technology is based on the idea of a distributed, consensus ledger, which it employs to create a secure, immutable data storage and management system. It is a publicly accessible and collectively managed ledger enabling unprecedented levels of trust and transparency between business and individual collaborations. It has both robust cryptographic security and a transparent design. The immutability feature of blockchain data has the potential to transform numerous industries. People have begun to view blockchain as a revolutionary technology capable of identifying "The Best Possible Solution" in various real-world scenarios. This paper provides a comprehensive insight into blockchains, fostering an objectual understanding of this cutting-edge technology by focusing on the theoretical fundamentals, operating principles, evolution, architecture, taxonomy, and diverse application-based manifestations. It investigates the need for decentralisation, smart contracts, permissioned and permissionless consensus mechanisms, and numerous blockchain development frameworks, tools, and platforms. Furthermore, the paper presents a novel compendium of existing and emerging blockchain technologies by examining the most recent advancements and challenges in blockchain-enabled solutions for a variety of application domains. This survey bridges multiple domains and blockchain technology, discussing how embracing blockchain technology is reshaping society's most important sectors. Finally, the paper delves into potential future blockchain ecosystems providing a clear picture of open research challenges and opportunities for academics, researchers, and companies with a strong fundamental and technical grounding.**

Keywords—Blockchain; blockchain applications; consensus algorithms; distributed ledger; smart contract

I. Introduction

According to the National Institute of Standards and Technology (NIST), blockchains are "tamper-evident and tamper-resistant digital ledgers executed in a distributed form, i.e., without a single repository, and usually without a central authority," i.e., a government, bank, or company. In their most basic form, blockchain technologies provide a platform for the secure movement of data involved in any transaction, including contracts and financial transactions [1]. Cryptography is at the core of blockchain technology, ensuring that the data being exchanged has not been tampered with and gives integrity and authenticity. The transactions involved in blockchain are just a transfer of assets, and the assets are essentially data, which may represent financial information, healthcare information, or even company information [2]. Blockchain is a buzzword that will likely be heard more in the future. Bitcoin and blockchain are gaining technical insight and becoming the chosen technology for implementing a wide range of commercial solutions in the current technological age. Most businesses worldwide are considering using blockchain technology, and even the government is laying the groundwork for the future. In general, individuals may become perplexed by the terms bitcoin and blockchain. Bitcoin is a digital cryptocurrency that may be used to make online payments without relying on a third party. In contrast, blockchain is the platform and structure that ensures every transaction is visible and unchangeable [3].

Blockchain is a public distributed ledger accessible to everyone, and anyone can become a member of this network. Bitcoin is considered the first step in developing blockchain technology [4]. Satoshi Nakamoto, the creator of bitcoin, originally announced the cryptocurrency in 2008 [2]. Satoshi Nakamoto was an unknown individual or group of individuals who began working on the bitcoin concept in 2007 under the name Satoshi Nakamoto. On the 18th of August, they registered the domain name bitcoin.org. Soon after, on the 31st of October, they issued a whitepaper detailing bitcoin, the transaction procedures, Proof-of-Work (PoW), and other aspects of the cryptocurrency. On the 9th of November, 2008, the sourceforge.net website registered the first bitcoin project. At 18:15:05 GMT on the 3rd of January, 2009, the Genesis Block (also known as block 0) was established. Blockchain is not only about tokens and coins. Blockchain is more than bitcoin [5]. The information on a blockchain is stored in blocks, which are bits of data that have been cryptographically encrypted [6]. To build a chain, each consecutive block must contain information about the previous block. As a result, the word blockchain was coined. Cryptographic hash functions and public key cryptography are used to ensure the anonymity of the blockchain [7]. It also aids in the achievement of transparency. New transactions are added to the current information based on the miners' agreement in the network. As a result of existing economic processes such as PoW, Proof-of-Stake (PoS), and others [8], the rules for validating

transactions are codified in the form of algorithms applied by miners who are also paid with a native coin.

Moreover, because the ledger operates on a distributed network, all nodes participating in the network receive a duplicate of the original information [9]. Depending on the scenario, every node in the network serves as a client and a server. Blockchain technology is available in many forms as it has undoubtedly advanced over the last decade. There are several types of blockchain technologies, each with its purpose and set of difficulties. The two most frequent types are public and private, widely utilized by bitcoin networks and private businesses. Also gaining popularity are hybrid blockchains. Besides ensuring the secure movement of currency, the technology creates a permanent historical record of all transactions and a single version of events. This condition is entirely transparent and shown in real-time for the convenience of all participants. However, blockchain technology, irrespective of the type of blockchain protocol implemented, will significantly impact the transformation of

centuries-old business practices, the establishment of greater levels of legitimacy in government, and the creation of new avenues of economic opportunity for common citizens. Fig. 1 gives a brief overview of blockchain technology.

The primary objective of this manuscript is to provide an overview of the many blockchain-related technologies and developments currently in progress. For this purpose, the proposed scheme is based on the desk research methodology considering all the major implementations from the most reputable publishers (such as IEEE, ScienceDirect, MDPI, etc.). Overall, 223 manuscripts were read and evaluated, but only 144 were chosen to be included in this paper. This review only considers papers that primarily discuss implementation strategy and results. As shown in Fig. 2, leading academic publishers like Wiley, Taylor & Francis, ScienceDirect, MDPI, Springer, and IEEE have all published increasing numbers of articles about blockchain technology in the last five years. The outcome shows a spontaneous increase in publication in the last three years.

| A digital ledger that keeps a record of all transactions taking place on a peer-to-peer network | All information transferred via blockchain is encrypted & every occurrence recorded, meaning it cannot be altered | It is decentralised, so there's no need for any central, certifying authority | It can be used for much more than the transfer of currency; contracts, records other kinds of data can be shared | Encrypted information can be shared across multiple providers without risk of a privacy breach |

A. Organization of the Study

This study is organized as follows: Section I briefs about the significance of using blockchain in current times with a brief on its usage and formation in the industry. Section II discusses the history of blockchain with respect to multiple generations and the essential characteristic of its evolution. It also presents a clear idea about the crucial blockchain features required for confirming the proper functioning of blockchain technologies irrespective of any application. Further, this section discusses three essential types of blockchain: public, private, and hybrid forms, with compact information about its features and associated issues. This section also illustrates all the reported research attempts and highlights their advantages and limitations. Section III reviews existing architectures and components of blockchain along with its working. This section also highlights scientific developments in consensus algorithms. Further, it also presents the rationale behind migrating to SHA-3 encryption and a compact-and-illustrative discussion of approaches of consensus approach in the blockchain. The blockchain framework and platform are illustrated with respect to its advantages and shortcomings in Section IV. Section V examines emerging blockchain applications concerning their utilization and prominent issues. Section VI highlights some of the study's essential findings that offer a contributory inference from the viewpoint of analyzing the strengths and weaknesses of existing approaches in the blockchain. It also presents a briefing about the novelty of the proposed review with some existing notable reviews. A thorough examination of the challenges and unsolved research problems linked to blockchain security is included in Section VII. Further, the characteristic of a unified blockchain and its associated concerns are highlighted. Section VIII discusses the open research questions from the literature review that should be pursued in the future, and Section IX provides conclusions. References are listed at the end.

II. HISTORY, FEATURES AND TYPES OF BLOCKCHAIN

A. History of Blockchain: A Brief Overview of Three Generations

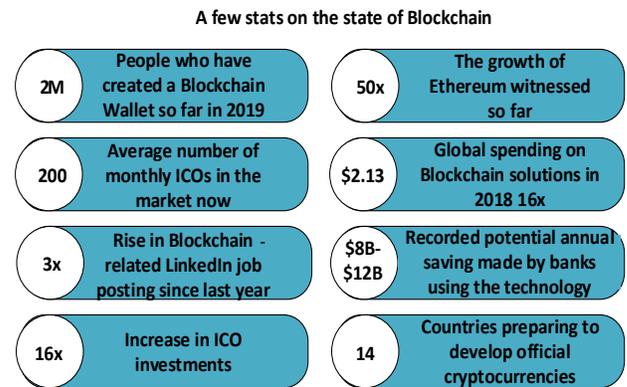
Blockchain technology began as an infrastructure for the bitcoin cryptocurrency and has since evolved into a true game-changer. Unfortunately, in addition to regularly providing new possibilities and applications, this technology has also attracted its fair share of hype and fraud. As a result, many entrepreneurs and engineers remain confused about the actual economic implications of blockchain technology. They are still unsure about its impact on businesses and whether or not they should invest in its development in the first place. Albeit, going over a few data shown in Fig. 3 shows the actual state of the technology and how the world responds to the most essential yet cliche topic of all: how to the technology. This will help better understand blockchain technology's impact on the global economy.


Fig. 3. A Few Statistics Illustrating the Current Development of Blockchain Technology [8].

1) Blockchain 1.0: Blockchain's first generation was intended to improve the traditional monetary system. During this time, bitcoin and other cryptocurrencies were introduced, most of which were written in C++ and followed the PoW consensus paradigm. Although blockchain-based cryptocurrencies improved transactional experience, developers discovered that the technology has far-reaching applications beyond cryptocurrencies. This became the impetus for the creation of the second generation.

2) Blockchain 2.0: As bitcoins remained a hot topic in the market, Ethereum and intelligent contracts became famous in the second blockchain generation. As a result, Ethereum's developers began addressing the coin as a cryptocurrency and platform for delivering a scalable experience and developing decentralized applications, DAPPs. They have also started to investigate the concept of smart contracts, which may be used to make agreements more secure, automated, and practical [7].

3) Blockchain 3.0: In theory, the third generation of blockchain 3.0 is the generation that showcases the most effective blockchain-based solutions currently available. As a result of this generation's focus on the economic and market implications of blockchain technology, several issues related to the creation of blockchain solutions, such as the inability to conduct cross-chain transactions, have been successfully addressed [8]. Furthermore, when it comes to developing blockchain applications, professional blockchain software developers have taken cognizance of the opportunity to use a variety of consensus algorithms other than PoW. Additional concepts such as DLT (Decentralized Ledger Technology), Information for Operational and Tactical Analysis (IOTA), and Currency of the Internet (COTI) have been developed in this generation. They have emerged as the best explanation for how blockchain will transform the world.

4) Blockchain 4.0: Business leaders are lining up to adopt blockchain technology and make it the focal point of their technological solutions. Blockchain 4.0 delivers ideas and solutions for industries that make it functional for the demands of modern business. Automation, integration of execution frameworks, and enterprise resource planning are the focal points of industry 4.0. Blockchain contributes to this modern industrial revolution by giving an increased level of privacy and security insurance to participants in it. Data collecting, asset management, supply chain management, healthcare, and financial transactions are just a few sectors where blockchain has proven beneficial. This means that blockchain 4.0 is improving the suitability of blockchain 3.0 for use in real-world business applications.

Blockchain technology is continually evolving and improving in terms of efficiency and reliability [10][11]. Blockchain technology is, thus, continually evolving and improving in terms of efficiency and reliability. There are various recent advancements towards the utilization of the blockchain-based technology. One such field is to ensure the participation of vehicles in a smart grid environment [12]. One of the critical problems in a smart grid environment is an intruder's theft of user information. Another point of vulnerability in the smart grid is the usage of central nodes for storing and sharing data. There are more malicious activities and vulnerabilities towards such a centralized storage system.

Over time, cryptography's relevance has started to increase in blockchain deployments. The primary role of cryptography in the blockchain is to protect data consistency and user privacy through symmetric or asymmetric encryption [13]. Aside from that, the adoption of digital signatures in the blockchain is more noticeable, which facilitates signing up the data block with transactional records. To date, multiple cryptographic-based approaches have been applied to secure blockchain technology [14]. The main reasons why cryptographic techniques are used in the blockchain are their ability to encrypt data, their inability to change, their ability to be scaled up, and their failure to be disputed [14].

The work carried out by Li et al. [15] used a signature-based blockchain protocol to resist key leakage attacks. The authors have used a puncturable signature scheme where an adaptive signing is carried out based on the bloom filter and Diffie-Hellman structure. Another signature-based scheme was introduced by Shahid et al. [16], where hashing is used for performing one-time signatures. The outcome offers a significantly reduced size of signatures and keys. Cai et al. [17] have constructed a protocol for quantum blind signatures and a blockchain smart contract system. Zhang and Lee [18] have presented a blockchain-based security system using group signatures to authenticate the blocks. The model is claimed to resist multiple attacks related to consensus algorithm vulnerabilities. Xiao et al. [19] have used a multi-signature approach to secure the blockchain platform. The model is claimed to maximize the efficiency of transactions. Existing schemes have also introduced secret-sharing methods to strengthen blockchain operations' security features. Private key distribution protocols that rely on secret sharing have been developed to secure financial applications, as demonstrated by the work of Xiong et al. [20]. Zheng et al. [21] have used generative adversarial networks to develop a unique secret-sharing scheme to mitigate the lost key issue and reduce the communication efficiency using blockchain. Kim et al. [22] have developed a distributed blockchain operation using a local secret-sharing scheme to enhance the cost of communication and storage. Yin et al. [23] have used a unique cryptographic deployment where a decentralized attribute key is used for encryption. A script interpreter is used for implementing ciphering processes to ensure the secret sharing of private data. Lyu et al. [24] have used a combined regulation scheme using threshold secret sharing over blockchain miners and regulatory authority. Further steganography-based blockchain schemes are also noted to be implemented in the existing system. According to this process, the embedding capacity of the host data is initially computed, followed by hiding the secret information and then formulating a blockchain network. The work by Mohsin et al. [25] used Particle Swarm Optimization for carrying out the image steganography process over a blockchain. Sarkar et al. [26] have developed a decentralized network of steganography blockchains. The secret shared key is used for further encrypting the stego-image. The outcome of the study is known to offer a higher payload. The work carried out by Giron et al. [27] has investigated steganographic structures over blockchains using Least Significant Bits over bitcoin. However, the adoption of cryptographic techniques is also associated with various limitations, as follows:

- Expensive Nature: Various studies, for example [27]-[29], have used sophisticated forms of public key encryption, which not only necessitate higher maintenance costs for key infrastructure management but also result in delays.

- Attack-Specific Solution: Most cryptographic-based approaches are highly effective at identifying and stopping predefined attacks [29]-[31], but they have received little attention regarding new evolving threats or dynamic attacks.

- Challenges in Accessibility: In the event of a network attack, data or services may be difficult to access due to the use of digital signatures or potential encryption in a critical time frame.

B. Blockchain Features

Blockchain technology has the following critical characteristics:

1) Security: Due to the usage of asymmetric cryptography, blockchain systems are intrinsically safe. Asymmetric cryptography consists of a series of public keys visible to everyone and private keys only visible to the system's owner. Using these keys, you can confirm that you own the transaction and cannot be tampered with [32]-[34]. The decentralized structure of blockchain systems, which utilize peer-to-peer (P2P) consensus processes, removes single points of failure for data compared to centrally kept data and

hence is substantially more susceptible to being compromised [34].

2) Disintermediation / Decentralization: Decentralization gives users data control and reduces the need for strong central authorities, making the system more equitable and secure. The blockchain system is more reliable and robust because each distributed node is mainly autonomous and has equal obligations and rights. If one distributed node fails, the entire network is not affected [33]. The blockchain's distributed information eliminates data loss or destruction due to reliance on a centralized place and eliminates misuse of information. Decentralized transaction execution and validation reduce intermediary costs and improve performance at central servers [33].

3) Transparency: The blockchain ledger allows anybody to see the history and specifics of each transaction. This amount of transparency is unheard of in massive financial systems. This kind of openness is achieved using a blockchain network with numerous validating peer nodes and no central authority [35]. Aside from the economic suitability of large corporations, the transparency feature has found application in healthcare and clinical trial data disclosure. Individual patients can utilize blockchain technology to readily examine their claims, medical history, transactions, and past-due payments. Researchers, doctors, and patients have long kept clinical trial data secret, causing a lack of trust in findings [36]. The transparency of blockchain has been found to assist supply chain management malpractices and product history obscurity [36]. Transparency may also help ensure fair elections and increase voter confidence [29].

4) Autonomy: Trust is established between the parties in most transactions, ensuring mutual commitment. Trust is no longer an issue with blockchain technology. The blockchain can work as a P2P system without a responsible third party. Participating nodes on the blockchain system using advanced distributed consensus algorithms [33] to handle the owner confirmation problem in transaction processes while maintaining system integrity. These blockchain transactions are executed without the intervention of a third party due to failsafe consensus mechanisms [36].

5) Immutability: It is also referred to as unforgeability, untameability, immutability, and persistency. Immutability indicates that it cannot be changed or interfered with once data is added [34]. To prevent tampering, data blocks in a blockchain structure are timestamped and encrypted with a hash algorithm [33][36]. However, immutability poses its own difficulties and obstacles for blockchain technology, and some are now questioning its benefits [37].

6) Traceability: Transparency is the capacity to track data's origin, destination, and update sequence between nodes. While data traceability is required to ensure data integrity and trust, it also improves data governance, compliance with legislation, and understanding of the impact of change [37]. Data traceability is supported by blockchain technology due to the time stamping of data updates and additions.

7) Anonymity: Blockchain's anonymity protects privacy against unlawful entry or surveillance. To maintain anonymity, transactions must be authorized without revealing personally identifiable information about the parties involved. The data is shared between nodes utilizing a trust-based method. Thus, node information is not disclosed or validated, and the data transfer is anonymous [38]. Users can communicate with produced blockchain addresses to hide their real identities. However, due to the public and distributed nature of the blockchain, total privacy cannot be guaranteed.

8) Democratized: P2P voting allows all nodes in a blockchain system to make choices democratically. Decentralized nodes employ consensus processes to enable particular nodes to introduce additional blocks to an existing blockchain, ensuring the bitcoin is correctly recorded to the shared data ledger, and its duplicates are perfectly synchronized. Nodes can accept blocks by extending them and reject incorrect blocks by not extending them [39].

9) Integrity: Blockchains are designed to resist data modification. Data integrity ensures data accuracy and consistency throughout its life cycle [35]. To do this, the blockchain network uses decentralized, immutable shared ledgers. Once a data block is approved to be included in a blockchain, it cannot be modified or amended. As a result, data reliability and integrity are essentially guaranteed [33].

10) Programmability: A standard application programming interface, API, allows users to design apps using blockchain technology. Smart contracts and decentralized apps can be created using the flexible scriptwriting framework. A programming interface for network administration is provided by the node software-defined networking (SDN) controllers [32]. Users, data query layers, infrastructure layers, and existing database layers are all data structuring provenance proposed by authors [40]. All blockchain systems provide a scripting language [41]. Authors in [32] recommend a user-friendly API. Ethereum, Tron, and Cardano are examples of programmable blockchains.

11) Fault tolerance: Blockchain is designed to be redundant and inefficient to enable excellent fault tolerance and immutability [42]. The P2P architecture of the network allows each node to act as both a client and a server, giving the network an extremely high error margin for node failures and network transit issues [42]. Blockchain is supposed to be Byzantine Fault-Tolerant, meaning that even if some nodes are down or functioning incorrectly, the network will still reach a consensus.

12) Automatic: Using specialized consensus protocols, all nodes in the system may validate and transact data automatically. Blockchain is managed and confirmed without manual involvement by a protocol [41].

C. Types of Blockchain

Blockchain can be divided into public and private categories: A public blockchain is a permissionless distributed ledger. Anyone with an internet connection must sign up on a blockchain platform to join the network. As it is primarily

used for cryptocurrency mining and trading, a public blockchain user or node can access past and present data, validate transactions, and mine cryptocurrencies. The most common public blockchain is bitcoin and Litecoin. A private blockchain is typically utilized within an organization or industry where only a small number of individuals are allowed to participate in a blockchain network instead of a public blockchain. Both public and private blockchains are further divided into permissioned and permissionless blockchains. Table I compare and contrast the permissions of various blockchain types:

Another form of blockchain is called a hybrid blockchain which integrates private and public blockchains. Users can

control who has access to the blockchain data. Encrypted data can be made public while the remainder of the blockchain remains secret. Due to the flexibility of the hybrid system, users can quickly join a private and public blockchain. An example is the Dragonchain. The similarities and differences between different types of blockchains are illustrated in Table II.

Currently, various scientific research contributions are made toward the above-mentioned different forms of blockchain. Table III highlights the frequently encountered problems being addressed by notable researchers using multiple blockchains.

TABLE I. PERMISSIONS OF VARIOUS BLOCKCHAINS

Public and Permissioned	Public and Permissionless	Private and Permissioned	Private and Permissionless
Restricted and open	Transparent and open	Restricted (hybrid methodology)	Read transparent but restricted
Read restricted and write all	Read all and write all	Read restricted and write restricted	Read all and write restricted
All can connect and transact, but read and audit is limited to permissioned users only	All can connect, transact, audit, and read	No one is allowed to connect, transact, audit, and read	All can connect, none is allowed to transact, and all can audit and read
Full write equity	Strictly democratic owing to total equity	Restricted	Full read equity
Example: Ethereum	Examples: Litecoin, Ethereum, and bitcoin	Example: Corda, Hyperledger Fabric, and R3	Example: Hyperledger Fabric

TABLE II. PERMISSIONS PERSPECTIVE OF SIMILARITIES AND DIFFERENCES OF BLOCKCHAINS

	Public	Private	Hybrid	Consortium
Membership	Unidentified Permissionless Can be malicious	Identified Permissioned Trustworthy	A mixture of Permissionless and Permissioned Identified Trustworthy	Permissioned Identified Trustworthy
Consensus Methodologies	PoW, PoS, Proof-of-Authority, Proof-of-Elapsed time, etc.	Voting or multi-party consensus Algorithm	Private Sidechains Consensus Mechanisms	Multi-party consensus algorithm or voting
Speed of Transaction	Time-consuming	Faster and lighter	Faster and lighter	Lighter and faster
Consumption of Energy	Huge energy consumption	Small energy consumption	Small energy consumption	Small energy consumption
Data in Blockchain	No finality 51% attack	Enable finality	Enable finality	Enable finality
Network	Decentralization	Partial decentralization	Partial decentralization	Partial decentralization (Hybrid between Private and blockchain)
Description	Anyone can write and read on the network, irrespective of its location. Data is validated by each network member ("node").	Permission to write and read data onto the blockchain is controlled by a "highly trusted" organization - the blockchain owner.	Controlled Permission on Read and Write.	Permissions to validate, write and read on the blockchain are regulated by some predetermined nodes, which might not be the same for every blockchain entity.
Benefits	- Secure - Transparent	- Efficient - Private	- Access control - Better performance - Scalability	- Efficient - Private
Challenges	- Inefficient -Performance -Scalability -Security	- Controlling (power is confined to one organization only) - Challenging to align several organizations to use a single blockchain - Trust - Auditability	- Difficult to align many organizations (Especially Competitors) & Set Consensus rules to join the blockchain as board members & share their data.	
Use Case	Cryptocurrency Document validation	Supply chain Asset Ownership	Medical Records Real Estate	Banking Research Supply chain

TABLE III.   EXISTING RESEARCH CONTRIBUTION FROM VARIOUS TYPES OF BLOCKCHAIN

	Authors	Problems	Methodology	Advantage	Limitation
Public Blockchain	Lee et al., 2019 [43]	Immutability	Hashing, sidechains	Higher scalability in design	Model not benchmarked
	Guo et al., 2019 [44]	Storage optimization	Redundant Residual Number System	Highly fault-tolerant	No comparative analysis
	Baza et al., 2021 [45]	Security in ride-sharing applications, fair payment	Analytical modeling based on trust, reputation	Ensures privacy preservation	Lacks comparative analysis, no extensive analysis towards security
	Asheralieva and Niyato, 2021 [46]	Resource management	Stochastic Stackelberg game, deep learning	Effective convergence performance	Success depends on a singular environment
	Mohammadzadeh et al., 2021 [47]	Invoice factoring	Smart contract management, Diffie-Hellman Key exchange	Highly simplified implementation scheme	Involves extensive time for signature verification
	Cai et al., 2021 [48]	Data privacy in crowdsensing	Open service system, private blockchain, SHA-256	Offers better verifiability, trust, and robustness	Assumption depends on the discretion of the client and could narrow down to the centralized crowd
	Bai et al., 2022 [49]	Participation of public	Consensus algorithm	Address scalability issues	Couldn't resist other forms of attacks apart from Denial of Service (DoS)
Private blockchain	Wu and Tsai, 2019 [50]	Securing agriculture network	Dark web technology	Effective privacy preservation	Resistive against only Distributed Denial of Service (DDoS) attack
	Hou et al., 2021 [51]	Data tampering in Internet of Things (IoT)	Secure consensus network	Better latency performance	Demands predefined information of the incoming malicious transaction
	Toyoda et al., 2020 [52]	Bottleneck analysis of private blockchain	Analytical framework on Ethereum	Better throughput performance	Doesn't exhibit extensive analysis with comparison
	Xu et al., 2021 [53]	Privacy on data sharing	Publishing protocol using histogram	Ensure data anonymity	Highly complete encryption scheme for large network
	Huang et al., 2020 [54]	Consensus problem	Analytical approach using the probability of network splitting, time out period of election, and rate of packet loss	Optimizes consensus algorithm	No comparison with the existing consensus-based approach
	Chattaraj et al., 2022 [55]	Access control in Software-Defined Network	Access control using a certificate, attribute-based encryption	Applicable for next-generation network	Not resistive against dynamic attackers
	Baucas et al., 2021 [56]	Monitoring of smart homes	Trilateration using the received signal strength indicator	Highly reduced execution time	Not benchmarked
	Shah et al., 2021 [57]	Resource optimization in a power grid	Heuristic approach	Reduced computational time	Demands extensive resources to process
Hybrid blockchain	Kim et al., 2022 [58]	Interoperability in heterogeneous hybrid blockchain	Analyzing multiple blockchain architecture	Identified tradeoffs in existing blockchains	Study applicable to a specific form of blockchain
	Liu et al., 2020 [59]	Energy management	Stackelberg game, blockchain	Optimal energy scheduling	Utility allocation is based on limited constraints
	Akkaoui et al., 2020 [60]	Data exchange in healthcare	Blockchain and edge computing	Significant reduction in execution time	No comparative analysis to prove its effectiveness
	Polge et al., 2021 [61]	Extensibility of blockchain operation	Emphasizing upper layers with real network infrastructure	Enhanced rate of propagation	Complex deployment cost, specific to the bitcoin application
	Zhu et al., 2020 [62]	Leveraging Crowdsensing operation	Blockchain and crowdsensing, dual consensus protocol	Extensive privacy protection	Cannot resist dynamic attacks
	Subramanian et al., 2021 [63]	Supply chain in pharmacy	Cryptocurrency, mobile application	Offers reliable suggestions for critical illness	Not assessed for a large number of operations
	Fan et al., 2021 [64]	Privacy in IoT	Federated learning, reverse auction	Offers better computational efficiency	Not assessed for a large number of operations
	Zhang et al., 2021 [65]	Controllable decentralization	Unique account scheme, an unspent transaction output	Enhance transaction processing	Higher maintenance cost
	Subramanian and Thamppy, 2021 [66]	Tracking automobiles	Ethereum blockchain, Truffle platform, Astute contract	Transaction transparency	Not assessed for a large number of operations
	Cui et al., 2020 [67]	Authentication in sensor network	Local and public chain, mutual authentication	Better security performance	Doesn't address resource demands

From the above table, it is noted that various significant research work is being evolved to improvise the performance and address multiple problems on different taxonomies of blockchain. Irrespective of various methodologies being adopted, it is observed that almost all the existing approaches toward different types of blockchains are witnessed with limiting factors. The most prominent limiting factor is narrowed implementation scope, where the system model's performance is not practically or mathematically proven for its efficiency over a large-scale deployment environment. Apart from this, the lack of benchmarking is another questionable factor towards reliable implementation over ground reality.

III. BLOCKCHAIN ARCHITECTURE

Blockchain is a decentralized database organized in a linked list of blocks, as shown in Fig. 4. Block: A block is a set of valid transactions [68]. In a blockchain system, each node can initiate an exchange of information and broadcast it to all other nodes in the network. The network nodes use past transactions to validate the transaction, and after the transaction is validated, it is added to the current blockchain. The number of transactions is aggregated and inserted into the blockchain block depending on the time window. "A block may include more than 500 transactions on average," according to bitcoin, "and the average block size is roughly 1 MB, an upper bound proposed by Satoshi Nakamoto in 2010" [69]. The type of blockchain used determines the type of data recorded within a block. In the case of bitcoin, a block comprises sender information, receiver information, and the number of bitcoins to be transmitted. The Genesis Block, often known as block 0, is the foundation for all subsequent blocks in a blockchain. In the chain of blocks, each new block is linked to the previous block by a connecting link, as shown in Fig. 4.

As illustrated in Fig. 5, each block has a header and a body. The block header (Fig. 5) contains metadata about the block, such as the previous block's hash, the nonce, the Merkle tree root, and the date.

- Previous block hash: Every block in the blockchain derives from the block before it in the inheritance chain, as shown in Fig. 6. The blockchain system is tamper-proof by using past blocks' hash to generate the new ones' hash.

- Mining statistics used in the block construction: The technique must be complex enough to prevent tampering with the blockchain.

- Bitcoin Mining: Using the previous block hash value, the transaction root hash value T, and the nonce value $nonce$ obtained by solving the consensus method, the current block hash value is calculated using (1).

$$H_k = Hash(H_k - 1|T| \,|nonce|) \tag{1}$$

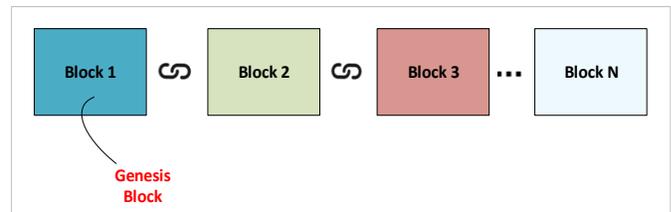
- Merkle Tree Root: A Merkle tree structure organizes the transactions. The Merkle tree's root is a verification of all transactions. The Merkle root illustrated in Fig. 7 is utilized to build the block hash.


Fig. 4. Blockchain: a Chain of Linked Data Blocks.
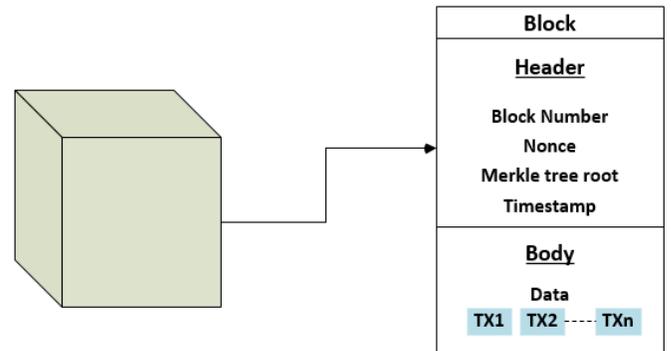

Fig. 5. Structure of a Block.
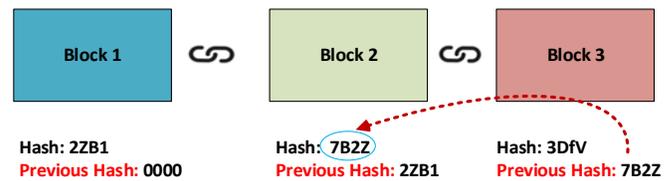

Fig. 6. Blocks Linked by Reference to the Previous Block Header Hash.

Blocks are linked together in a "chain," as depicted in Fig. 8, by incorporating the previous block header hash. This preserves the chain's integrity because modifying one last block will necessitate updating every subsequent block.

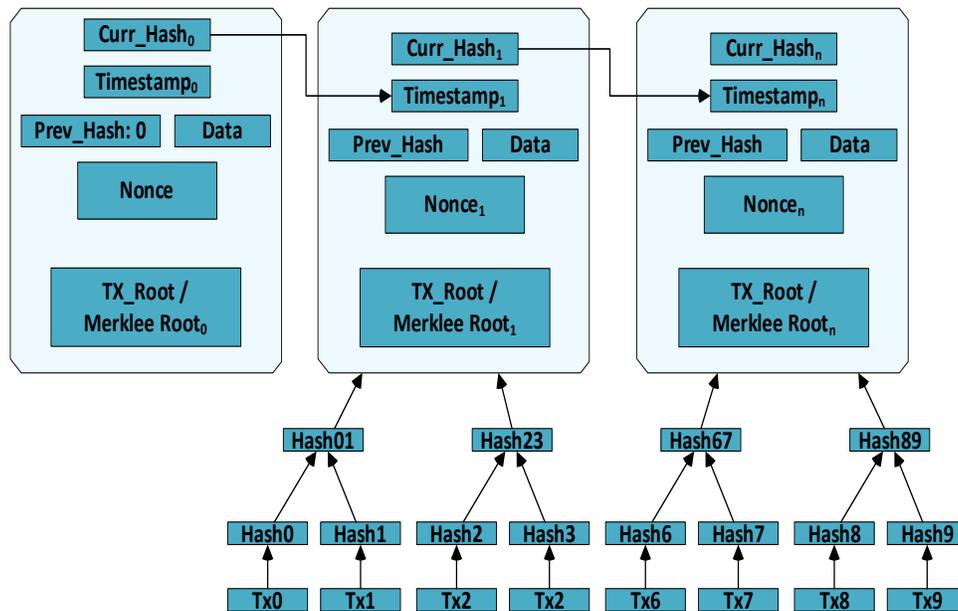
Blockchain technology is based on three fundamental principles: transparency, authenticity, and auditing. Its transparent and encrypted chain design allows everyone to witness the information flow between numerous blocks with all the details. It is like a well-connected distributed network. At the start of every new transaction, every computer database competes with all other databases to produce a new block with the necessary features. The database that successfully solves the mathematical coding and creates the block wins. This block is audited and authenticated by the other blocks. After all the blocks confirm the transaction, the data is encrypted but transparently stored in the database. Auditing and authentication processes are automatically initiated and run in the background for every block. Blocks are connected in an appropriate linear, chronological sequence, with every block holding a hash of the previous block. The transition history is still available in other blocks even if the initial original traction block is removed or hacked. As illustrated in Fig. 8 and Fig. 9, the blockchain architecture comprises six significant components integrated into the many layers of the blockchain.


Fig. 7.   A Merkle Tree Example (Binary Hash Tree).
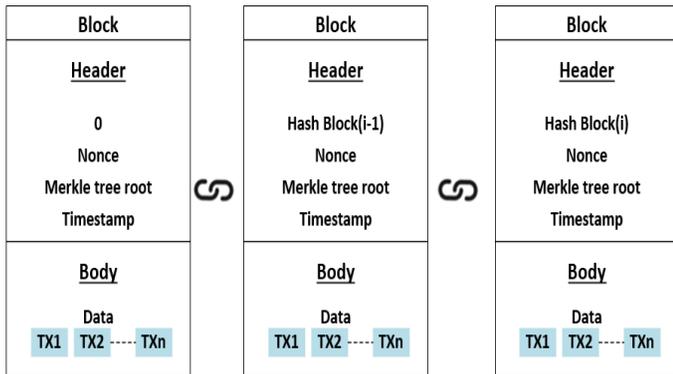

Fig. 8.   The Architecture of a Data Chain in a Blockchain Network.

Fig. 9.   Blockchain Layered Architecture.

1) Data layer: This layer comprises the chained data blocks and the techniques that go with them, like hash algorithms (e.g., SHA256 [75]), timestamp technologies, asymmetric encryption (e.g., Elliptic Curve Digital Signature Algorithm (ECDSA) [76]), and Merkle trees [77]. Each node employs various strategies to encapsulate transactions and received code in new blocks, including the hash function and Merkle tree. Each block is given a timestamp showing when it was created. After that, this new block will join the chain by connecting to the original block [70].

2) Network layer: The network or the P2P layer handles inter-node communication. It handles block propagation discovery and transactions. Also known as propagation, nodes cannot discover each other and synchronize without this P2P layer.

3) Consensus layer: This layer contains several consensus techniques (such as Proof-of-Stake (PoS) and PoW [76]) for maintaining data consistency and fault tolerance in distributed networks.

4) Incentive layer: With this layer, the blockchain's security verification can be strengthened by offering specific incentives to nodes cooperating in security verification. This layer incorporates economic rewards into the blockchain, the

currency distribution system, and the currency issue mechanism to ensure that individuals who help generate the next block receive a possible benefit [70]. Miners (the creators of new blocks) are rewarded with incentives (some coins) to encourage the network to continue working on data verification and ensuring the chain's security [71].

5) Contract layer: In this layer, there are a variety of scripts and algorithms, as well as smart contracts, which are self-executing code that is saved and secured by the blockchain.

6) Application layer: This layer consists of potential applications, scenarios, and use cases [70], among other things.

A. Components of Blockchain

A blockchain comprises many different components, each serving a specific purpose in its creation. These components are [72]:

1) Ledger: A blockchain ledger is a distributed, immutable record of its history used for decentralized data storage.

2) Peer network: A P2P network is a distributed network architecture that allows participants to share resources. The participants make their resources (such as storage capacity, processing power, link capacity, printers, etc.) accessible to other participants at their leisure. Each peer (participant node) in such a network performs the functions of both (server and client).

3) Membership services: Some blockchain types require prior authorization to participate. Indeed, membership services on the blockchain are responsible for authorizing, authenticating, and managing users' identities.

4) Smart contract: It is a self-executing contract in which the agreement's terms are encoded in lines of code that both parties can read and comprehend. Put another way. It is the digital equivalent of a traditional paper contract. Nick Szabo, an American computer scientist and digital currency researcher, suggested smart contracts in 1994. The smart agreement is executed over a blockchain network, duplicating its code throughout the network's machines. This makes it possible to be secure and transparent and facilitate contractual obligations.

*5) Wallet:* Stores key pairs and users' credentials to initiate and sign digital transactions.

6) Events: Refers to notifications of blockchain updates and activities; examples of events include adding a new block to the blockchain, alerts from smart contracts on the blockchain that enable such contracts, and the creation and propagation of a transaction made across the peer network.

7) Systems management: Blockchain is a constantly growing system that must evolve to suit its participants' needs. Indeed, systems administration provides the capability to update, monitor, and build blockchain components to suit users' needs.

B. Consensus Algorithms

A consensus technique is used in the blockchain network to reach a consensus on the status of the distributed ledger [73]. With no central authority, all network participants should collaborate to make the best choice for the network. In a context where strangers do not have faith in one another, achieving consensus among participating nodes was perhaps the most significant development that opened the way for blockchain and resulted in a set of methods to reach an agreement among participating nodes. Consensus mechanisms are communication protocols that allow robots or humans to operate together decentralized. Fig. 10 depicts our classification of the blockchain consensus model, developed after surveying the literature. As shown in Fig. 10, consensus models may be divided into nine broad groups with some different varieties based on subtle changes in how they operate.

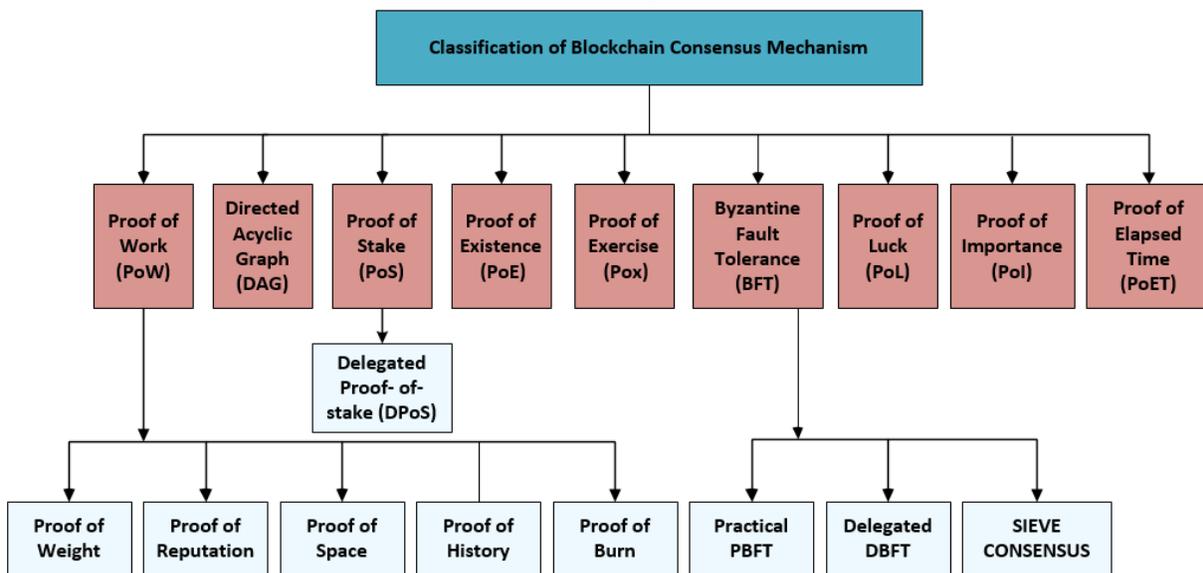

Fig. 10. Blockchain Consensus Algorithms.

TABLE IV.   COMPARATIVE ANALYSIS OF CONSENSUS ALGORITHMS

Consensus Algorithm	Chief Characteristic	Fault Tolerance	Scalability	Power Consumption
Proof-of-Work (PoW)	Power of computation	Poor	High	Enormous
Directed Acyclic Graph (DAG)	Consensus for IoT blockchain	NA	Very high	High
Proof-of-Stake (PoS)	Stake in terms of the number of coins	Less than 51 per cent stake	High	Poor
Proof-of-Existence (PoE)	Use the timestamp of the transaction to validate document existence	NA	Unknown	Unknown
Proof-of-eXercise (PoX)	Miner shall solve a matrix-based problem	NA	Unknown	Fractional energy saving
Delegated Proof-of-Stake (DPoS)	Voting to choose the witness node	Less than 51 per cent of validators	High	Poor
Proof-of-Elapsed Time (PoET)	Lottery based election	Yes		Massive
Byzantine Fault Tolerance (BFT)	Reach consensus despite the failure of some nodes to respond	33 per cent of nodes are Faulty	Poor	Poor
Delegated Byzantine Fault Tolerance (DBFT)	Reach a consensus with Untrustworthy participants	Less than 33 per cent of replicas	Low	Medium
Proof-of-Importance	Estimate importance counts coins that have been in an account for a fixed period	Unidentified	Moderate	Low energy saving
Proof-of-Luck	Cumulative luck value	NA	It does not scale well	Reduced power of computation

Table IV compares consensus algorithms based on essential criteria such as consensus model prominence, scalability, and fault tolerance.

1) Proof-of-Work: PoW is widely considered the blockchain's fundamental consensus model. PoW is built on the idea of competing for computational power to create new blocks in the blockchain. This approach requires a miner to compute and output a value. The winning value is lower than the value set by the network. PoW through the nodes is used to deal with forking (i.e., two nodes provide the winning value). The research community has developed various PoW techniques [73], such as:

a) Proof-of-Weight: Based on algorithm consensus, Proof-of-Weight consensus adds "weight" to the essential principle of PoW. These weights are proportionate to the values generated by the nodes in the network. The goal is to avoid "double-spending," where a consumer can use the same digital token twice by adding relative weight.

b) Proof-of-Reputation: A node's reputation is built by participating in transactions and holding assets. Blockchain validates a new block created by the highest reputation node. This technique prevents nodes from a reputation for prior misbehavior and adds to the blockchain's security.

c) Proof-of-Space: It is a PoW where a node requesting service must allocate more disc space than usual. This data is given to the verifier node to prove that enough space is allocated for a service request.

d) Proof-of-History: This consensus approach demands nodes to offer evidence of history. It establishes a historical record to prove an event that happened at a particular time. This is an alternative to trusting the transaction's timestamp.

e) Proof-of-Burn: This consensus method relies on burning coins to mine the next blockchain block and sending bitcoin to an unrecoverable address. Nodes burn more coins to increase lottery odds. Compared to PoW, Direct Acyclic Graph (DAG) is advocated as a viable blockchain consensus method for the IoT blockchain framework (IOTA). Scalability is an advantage of DAG since data is uploaded to the blockchain in parallel. It adds a block to the ledger as the previous transaction is processed. DAG also combats "double-spending" using powerful algorithms.

2) Proof-of-Stack: This method avoids the need for expensive mining equipment. A PoS node can execute mining or block validating based on its stake [74]. PoS recommend buying cryptocurrencies to increase block formation chances.

a) Delegated Proof-of-Stack (DPoS): It is a PoS variant where participants are encouraged to vote for the witness node, which will generate a block in the blockchain and serve as a witness [94]. The witness node is paid for producing blocks but is barred from future voting if it cannot create blocks.

3) Proof-of-Existence (POE): It is a system for authenticating the presence of documents at a specific time. Without releasing the data itself, data ownership information might be revealed. This POE paradigm helps show the existence of intellectual property documents such as patents.

4) Proof-of-Exercise (PoX): It offers a Proof-of-Exercise alternative to the PoW [95]. An exercise in PoX is a matrix based on a real-world scientific issue. It works on matrices created by system employees. Ribonucleic acid (RNA) and Deoxyribonucleic acid (DNA) sequencing and data comparison are excellent examples of matrix problem-solving.

5) Byzantine Fault Tolerance (BFT): System failure due to Byzantine fault in blockchain requires consensus [73]. Even if some nodes fail to reply, the network should reach an agreement and maintain data consistency. The distribution system makes it difficult.

a) Practical Byzantine Fault Tolerance (PBFT): Authors in [87] suggest PBFT in their work. Authors in [75] offer the first state-machine replication mechanism for asynchronous networks - a distributed file system with BFT.

b) Delegate Byzantine Fault Tolerance (DBFT): The DBFT described in the NEO whitepaper is a variation of the traditional BFT [76]. NEO blockchain's core library is currently utilizing this technology. According to them, a novel mathematical model may be used to test consensus behavior when combined with a discrete model. When compared to other algorithms, this method is more capable of coping with participants who are not trustworthy.

c) Sieve consensus: Sieve is a form of PBFT consensus for non-deterministic chain code execution [77]. Replicates can create non-deterministic chain code output. The sieve can assess the output if a small number of replicas show minimal divergence.

6) Proof-of-Luck (PoL): A new consensus approach reduces the necessary processing power and increases transaction throughput [78]. This algorithm is based on Trusted Execution Environment (TEE). PollRound and PollMine are the primary functions where each block is given a luck value between 0 and 1. The total of all luck values included within each blockchain block is combined to provide a cumulative luck value. A miner will choose to join the luckiest chain.

7) Proof-of-Importance (PoI): New Economy Movement (NEM/ XEM) uses this algorithm. This system assigns a rating to accounts based on the number of vested and unvested coins. PoI measures "importance" by how long a node's coins have been in their account. Every day, 10% of the current unvested sum becomes vested. It also depends on the account's position within the network and the number of coins vested.

8) Proof-of-Elapsed Time (PoET): For each block, a new leader is chosen by a lottery system under this consensus option. TEE is used to ensure the integrity of the electoral process. The basic steps in choosing a leader are as follows:

- It runs on miner and validator nodes.

- The validator node with the least wait time wins the election as a leader node.

The fundamental disadvantage of this consensus technique is that it requires specialized hardware [74]. A good consensus algorithm is efficient, safe, and easy to implement. Recently, efforts have been made to improve the consensus algorithms used in blockchain technology. New consensus mechanisms are being developed to solve some challenges associated with the technology. The central concept of PeerCensus [79] is to isolate block generation from transaction confirmation to boost the consensus speed dramatically. An improved consensus algorithm for ensuring blocks is produced orderly and predictable has been suggested by authors in [80]. Bitcoin's security is known to be compromised by fast block production. The Greedy Heaviest Observed Subtree (GHOST) chain selection rule [81] was devised to address this. It weighs the branches so that miners can choose the best one. Authors

in [82] proposed a consensus protocol that rewards non-interactive retrievability evidence for P2P blockchain networks. Miners save storage space by storing old block headers instead of complete blocks.

IV. BLOCKCHAIN FRAMEWORK AND PLATFORM

A blockchain framework is a software system that facilitates the deployment and creation of blockchain applications. The blockchain frameworks provide infrastructure and libraries for application development. Nodes and the software they run make up the network infrastructure. The node can be physical, virtual, or containerized. Blockchain identity management is controlled by software that provides capabilities and features such as transaction data, user identification, and the consensus mechanism for blockchain. A smart contract application is composed of code that operates within its architecture. The client application communicates with the infrastructure. The latter serves as an external interface to the application. Developing applications outside the blockchain network should be possible with a good blockchain platform. As long as the program works on a small network, it should work on a more extensive infrastructure [83]. Before developing the software, there is no need to set up the network infrastructure. Choosing an enterprise blockchain framework is difficult because no single framework has all the functionalities. As demonstrated in Fig. 11, the primary blockchain framework challenges are storage, processing power, and scalability.

Fig. 11. Blockchain Computational Complexity.

Stakeholders must be highly cautious before, during, and after using blockchain in the enterprise. Many factors must be addressed while selecting a blockchain framework. Table V shows some of the selection criteria for blockchain frameworks.

TABLE V. STANDARDS OF SELECTION FOR BLOCKCHAIN FRAMEWORKS

Criterion	Explanation
License	Features and kind of license (paid or free)
Activity	Framework upgradability support
Support model	Framework support, popularity, longevity
Roadmap	Framework roadmap and vision
Reliable backing	Corporate or open-source community
Ease of use	Intuitive and widely adopted

This section describes the most popular blockchain frameworks and platforms and is as under:

1) Bitcoin - (programming language: C++): It is the world's first and most popular cryptocurrency. Someone or a group using the pseudonym Satoshi Nakamoto established it in 2009. Cryptocurrencies like Ethereum, Litecoin, Dash, and

bitcoin cash are the blockchain's descendants. Bitcoin is a P2P electronic payment system that does not require a central clearing agency. Cryptocurrency users execute transactions by sending electronic instructions that specify who should be credited and debited and where the change should be deposited (if any). The pros and cons of bitcoin are depicted in Table VI.

TABLE VI. ADVANTAGES AND DRAWBACKS OF BITCOIN

Advantages	Drawbacks
Payment flexibility	Volatility and risk
Security and control	The size of the blockchain is about 242.2 GB
High capitalization	Time-consuming (7 transactions per second)
Minimal commission fee	Complete lack of fully-fledged smart contracts
Large-scale trading	Lack of understanding and awareness

2) Ethereum – (programming language: Go, Solidity): Ethereum is a framework with an open code for developing and launching almost any decentralized online services for a blockchain (DApps), whose work is based on smart contracts. Ethereum is a cryptocurrency that is built on the Ethereum blockchain. Vitalik Buterin made an offer in 2013 that was accepted. There are four chief components in Ethereum:

- Instead of designing different frameworks for each application or language, EVM allows all of them to be used on one blockchain. This helps create DApps in lotteries, for example.

- Smart Contracts are computer algorithms for trading gold, cryptocurrency, and other assets without a third party. If the smart contract's code's criteria are met, it executes automatically.

- DApps use smart contracts for market predictions, digital signatures, and asset transfer assurances. Most existing DApps utilize Ethereum.

- Network performance is improved via a collection of programming solutions. Ethereum now leverages Merkle trees to improve transaction hashing and scalability [108].

The pros and cons of Ethereum are depicted in Table VII.

TABLE VII. ADVANTAGES AND DRAWBACKS OF ETHEREUM

Advantages	Drawbacks
Capitalizes on blockchain	Slow transaction processing
With a $9.7 billion market worth, it's backed by huge names such as JPMorgan Chase, Amazon, Microsoft, IBM, etc.	Centralization - The Data Access Object (DAO) attack emphasized the importance of developers' word over community votes
Daily traffic	PoS update
A powerful team	The downside of being the first mover
Reliable	Scams in the marketplace

3) Tezos - (programming language: OCaml): It is an innovative contract platform created in 2014. In Leased Proof-of-Stake (LPoS), a participant makes a new block, which thirty-two other participants accept. Tezos has certain unique features that set it apart from other platforms:

- Formal verification of smart contract code.

- It is possible to upgrade the network without branching (fork).

The pros and cons of Tezos are depicted in Table VIII.

TABLE VIII. ADVANTAGES AND DRAWBACKS OF TEZOS

Advantages	Drawbacks
Community Governance (The protocol rewards its community for conducting needed or desired improvements)	In-Fighting (After its successful ICO, Tezos experienced a lot of conflict between the Tezos Foundation and the Breitmans' company in the US)
Supportive Community	Token Issuance Delays
Formal Verification	Lawsuits

4) Hyperledger (Sawtooth, Fabric, Burrow, Indy, Iroha, Cello): It is not a coin, a blockchain, or a firm, but a complex project of the Linux Foundation (Fabric, Sawtooth, and Burrow). It is a kind of open-source platform for developing enterprise blockchain applications which began in 2015. The pros and cons of Hyperledger are depicted in Table IX.

TABLE IX. ADVANTAGES AND DRAWBACKS OF HYPERLEDGER

Advantages	Drawbacks
Modularity in architecture	Intricate fabric architecture
Performance optimization	A shortage of verified use cases
Hybrid model	Fault tolerance in the network
Membership with permission	A lack of expertise among programmers
Query capability resembling SQL	

5) Hedera Hashgraph: The platform is still in the early stages of development. Histogram consensus is used by the Hedera PoS open network to ensure maximum security (ABFT) while consuming little bandwidth. The pros and cons of the Hedera Hashgraph are depicted in Table X.

TABLE X. ADVANTAGES AND DRAWBACKS OF HEDERA HASHGRAPH

Advantages	Drawbacks
Highly secure	Not open-sourced but patented
Faster: Transactions being processed in parallel	There are only 19 governors, which brings decentralization into question
The platform supports the same object-orient programmed language, Solidity, which is used for smart contracts	Lack of proven use cases

6) Ripple - (programming language: C++): Its unique feature is the absence of blockchain. Instead, it "runs a network of independent checking nodes." People, banks, organizations, and states can check nodes. A distributional

registry is created every second, and XRP is the cryptocurrency token. The pros and cons of Ripple are depicted in Table XI.

TABLE XI.   ADVANTAGES AND DRAWBACKS OF RIPPLE

Advantages	Drawbacks
Transactions with XRP are quick and inexpensive	The consensus protocol appears to be potentially less secure
The use of Ripple's payment network has already begun in financial institutions	Numerous Ripple's financial partners exclusively use RippleNet, not the company's XRP cryptocurrency
Small company owners and consumers can utilize XRP to conduct safe money transactions	Ripple has sparked controversy due to its private ownership and the Securities and Exchange Commission (SEC) lawsuit
Currency transfers on a global scale are possible	Purchasing XRP is challenging in the United States

7) Quorum - (programming language: Java): It is an Ethereum fork that maximizes transaction and contract anonymity in banking and related fields. JP Morgan created it to solve critical financial issues with smart contracts and distributional registries. It facilitates institutional volume deals and can restrict access to transaction history while maintaining system openness. When it comes to transaction verification and controlling communication between nodes, they rely on the BFT and Raft transaction algorithms to keep operations private. This solution's flaw is centralization. The pros and cons of Quorum are depicted in Table XII.

TABLE XII.   ADVANTAGES AND DRAWBACKS OF QUORUM

Advantages	Drawbacks
Exceptional performance	Framework features are only partially utilized
Consensus mechanisms based on voting	Message overheads
Privacy of transactions and contracts has been improved	Multiple "chosen" nodes confirm transactions.
Blockchain with permission	Anonymit.
	Block size restrictions

8) Corda - (programming language: Kotlin): This is a private distribution platform using Java Virtual Machine (JVM) based smart contract. Corda was created by R3 (R3CEV LLC) to record, monitor, and synchronize financial agreements. For this, a new consensus mechanism was developed, which checks and signs contracts using notarial nodes. Nodes confirming valid interest in the transaction's assets can access the data. The pros and cons of Corda are depicted in Table XIII.

TABLE XIII.   ADVANTAGES AND DRAWBACKS OF CORDA

Advantages	Drawbacks
The ability to reach a consensus on individual agreements and contracts	Using oracles (humans) to verify information and papers decreases their credibility
Restricted access	Financial sector-specific
Based on the R3 industry standard	Only financial sector users

9) Electro-Optical System (EOS) - (programming language: C++): EOS is a platform for decentralized applications; Platform rights are shared according to interest. Buying 20% of EOS blockchain firm tokens gives you 20% of the project's revenues, property, copyright, and reputation. The pros and cons of EOS are depicted in Table XIV.

TABLE XIV.   ADVANTAGES AND DRAWBACKS OF EOS

Advantages	Drawbacks
Throughput is 1200 transactions per second	There isn't even a Graphical User Interface (GUI) wallet for this project, which is still in development
New crowdfunding model	Crowdfunding conditions might frighten DApp developers
The delegate PoS consensus algorithm has a high scalability potential	The EOS team is slow to report to investors
DApps toolbox for developers	Cryptocurrency is the most criticized

10) Stellar Smart Contracts (SSC) - (programming language: JavaScript, Python, Golang, PHP): The smart contracts used are not Ethereum smart contracts. It is a transactional turing, not a thorough one. SSC can be written in any Stellar language. The pros and cons of SSC are depicted in Table XV.

TABLE XV.   ADVANTAGES AND DRAWBACKS OF SSC

Advantages	Drawbacks
Fast Transaction Speed	Less Literature
Multi-currency Support	Smart Contracts issues
Extremely Low Transaction Fees	

11) iOlite - (programming language: iOlite): To create smart contracts using natural language, iOlite provides an easy-to-use engine that understands natural language and compiles smart contract code. Regarding people who do not want to spend time learning, iOlite is a great option - it creates smart contracts. The pros and cons of iOlite are depicted in Table XVI.

TABLE XVI.   ADVANTAGES AND DRAWBACKS OF IOLITE

Advantages	Drawbacks
No battery life restrictions or need to recharge	iOlite Vaporizer is more significant than other portable models
iOlite makes it very convenient for use on the go	The vaporizer can become too hot during long vaping sessions
A vaporizer is very compact	Vapor is less dense than other portables
Stylish design that comes in many colors	It does not diminish the effectiveness of the vaporizer
The vapor produced by the model has a fresh taste	

12) Neblio: Incorporating blockchain into existing businesses is the goal of Neblio, which has an easy-to-use API in eight popular programming languages. Neblio's primary

goal is to help established enterprises use blockchain. The Neblio blockchain technology should be accessible to developers. The pros and cons of Neblio are depicted in Table XVII.

TABLE XVII. ADVANTAGES AND DRAWBACKS OF NEBLIO

Advantages	Drawbacks
Easy-to-use	Use of private keys, which are questionable at times
Single token protocol for unique tokens	Immutable Data storage means there is no going back
Secured from third-party intervention	
Users can code in eight different programming languages	

13)Lisk - (programming language: JavaScript): This flexible blockchain technology creates a simple user interface and platform for everyone to use. Lisk begins each app on its independent side chain, the development of which can be complex. The pros and cons of Lisk are depicted in Table XVIII.

TABLE XVIII.ADVANTAGES AND DRAWBACKS OF LISK

Advantages	Drawbacks
Lisk is a decentralized DApp development platform that makes the creation of apps easy and readily accessible	Lisk is in direct competition with the leading smart contract and DApp platform in the world, Ethereum
Lisk makes use of advanced Software development kit (SDK) technology, allowing developers to produce DApps and separate blockchain	
Lisk and the process involved with creating DApps make the entire platform truly decentralized and independent	

14)Dragonchain - (programming language: Java, Python, Node, C#, Go): Disney created Dragonchain in 2014. After a year of development, the firm released the first open-source code in 2016. DragonChain provides clients with "ecosystems" without central servers. The platform's multilayer security architecture aims to carve a unique position in the cryptocurrency market. The pros and cons of Dragonchain are depicted in Table XIX.

TABLE XIX. ADVANTAGES AND DRAWBACKS OF DRAGONCHAIN

Advantages	Drawbacks
Regulated platform	Poor market performance
Great functionality	
Ease of Use	

15)NEO - (programming language: Python, JavaScript, Java, C#, Go): It is an open-source platform that uses the consensus technique DBFT (DBFT) and smart contracts and cross-platform capabilities. Smart Contracts can access external resources through Oracle's built-in component. The pros and cons of NEO are depicted in Table XX.

TABLE XX. ADVANTAGES AND DRAWBACKS OF NEO

Advantages	Drawbacks
Energy-Efficient Consensus Mechanism	Unpopularity among Westerners
Ease of Developers	To compete with Ethereum, NEO has to outperform it in every way
NEO can handle around 1000 transactions per second	

16)IOTA: IOTA is a platform designed specifically for the IoT. It is a global network of connected devices. In terms of construction, IOTA is dissimilar to Ethereum, bitcoin, and other famous blockchains because it lacks the traditional linear structure of blockchain. Such a structure limits network scalability, so IOTA uses Tangle instead. A user must confirm two other users' transactions to gain confirmation for a transaction. The pros and cons of IOTA are depicted in Table XXI.

TABLE XXI. ADVANTAGES AND DRAWBACKS OF IOTA

Advantages	Drawbacks
Micro-payments	Ternary logic
Lightweight	IoT-specific framework functions
Scalable	The code has cryptic regions
Quantum-secure	No smart contract support

17)Cosmos SDK/Tendermint - (programming language: Golang): A modular execution stack at the system's heart lets apps mix and match components as needed. All modules are also sandboxed for increased application security. Consensus algorithms include PoS and BFT. The pros and cons of Cosmos SDK/Tendermint are depicted in Table XXII.

TABLE XXII. ADVANTAGES AND DRAWBACKS OF COSMOS SDK/TENDERMINT

Advantages	Drawbacks
Fully open-source project	Delegated staking freezes ATOM while validators work
Cosmos protocol allows separate blockchains to connect effortlessly	Staked ATOM are locked in a minimum of 3-weeks
ATOM can be staked to receive interest	
The interoperability does not compromise the security that Cosmos offers	
Cosmos is a community governance system that uses keys to identify users	

18)Waves: It is a Russian platform for ICO, crowdfunding, exchanges, and payment gateways. It is a software platform that includes many useful utilities and tools for developers. Users pay for the apps with the Waves tokens. The pros and cons of Waves are depicted in Table XXIII.

TABLE XXIII. ADVANTAGES AND DRAWBACKS OF WAVES

Advantages	Drawbacks
Perfect for crowdsourcing	Unclear legal status
Fair transfers	Support issue
Scalable, fast, and low-cost	Performance issue
Extremely easily accessible	Exchange is not yet mature

19)NEM (XEM): This cryptocurrency may be used to build trade, philanthropic, and banking applications. The Proof-of-Importance (PoI) consensus generation approach distinguishes this framework from others. PoI grants block development privileges to participants with the best reputation to ensure system integrity. The pros and cons of NEM are depicted in Table XXIV.

TABLE XXIV. ADVANTAGES AND DRAWBACKS OF NEM

Advantages	Drawbacks
Less energy usage	Low NEM consumer
Good capacity	Weak debut
Low commission	PoI centralized
Anti-counterfeiting	Fewer pieces of literature

20)OpenChain - (programming language: C#): It is a general ownership register that anyone may use. It may be modeled to work with virtually any use case. This application leverages partitioned consensus. There is no miner, and transactions are free and quick. Smart Contracts are autonomous actors that receive and send transactions based on business logic. The amount of privacy is adjustable from transparent to private. It suits enterprises that want to manage and issue digital assets reliably, securely, and scalable.

21)Multichain - (programming language: C++): It is a private P2P network that uses enhanced blockchain technology for financial operations. The pros and cons of Multichain are depicted in Table XXV.

TABLE XXV. ADVANTAGES AND DRAWBACKS OF MULTICHAIN

Advantages	Drawbacks
Flexible asset metadata	No smart contracts support
Permitted follow-up issue	Since they are 100% centralized, Private blockchains are beneficial as sandboxes, but not for production as they are meant only for a specific task
Multi-asset atomic payments	
Multi-way atomic asset swaps	
Multi-signature security and escrow	
Easy to setup and configure	

22)Monax - (programming language: Go): It is an open-source framework enabling business ecosystem developers to create, send, and release blockchain-based applications. The pros and cons of Monax are depicted in Table XXVI.

TABLE XXVI. ADVANTAGES AND DRAWBACKS OF MONAX

Advantages	Drawbacks
Only Monax's contract management platform can notarize electronic signatures on the blockchain	Legal Issues
Simple integration	User acceptance
Simple, smart, and Secure	
A database of digital contracts to track your commitments in real-time	

23)NodesPlus – (programming language: C++): This Russian project uses a programmed consensus to guard against server-side assaults and assure block authenticity. It also features built-in web applications for data, safes, and software protection. The framework includes a built-in smart contract system based on JavaScript and multi-currency wallets and payments. The pros and cons of Nodesplus are depicted in Table XXVII.

TABLE XXVII. ADVANTAGES AND DRAWBACKS OF NODESPLUS

Advantages	Drawbacks
When authorized nodes have access to certain transactions, the nodes Plus software platform allows you to deploy data clustering technologies	Updates and patches
Provides the strictly irreversible transaction required by government organizations, thus equating electronic data with paper documents	User acceptance

24)Blockchain Service Network (BSN) - (programming language: DAML): The China State Data Center created the BSN, unveiled in October 2019 as a blockchain platform for individuals and small businesses. It provides its developers with tools to construct blockchain applications in major business networks to assist the digital economy and smart city efforts. The pros and cons of BSN are depicted in Table XXVIII.

TABLE XXVIII. ADVANTAGES AND DRAWBACKS OF BSN

Advantages	Drawbacks
Reduced development, deployment, and operation costs	However, faith in Chinese technology has been eroding over the last year, with many countries opposing China's dominance of the 5G rollout
Access to blockchain apps made simpler	User privacy issues; Currently, the BSN Dev Alliance has no control over user activity
Access modes are flexible	
Expanding rapidly	

25)Exonum - (programming language: Rust): It is a blockchain platform developed by the Bitfury Group specifically for enterprise projects. The source code for Exonum and its application programming interfaces (APIs) are available for anybody to view. Besides providing access to the whole codebase, Exonum also provides blockchain administration tools. The pros and cons of Exonum are depicted in Table XXIX.

TABLE XXIX.   ADVANTAGES AND DRAWBACKS OF EXONUM

Advantages	Drawbacks
Developed in Rust which is among the most secure programming languages, with extensive predictable resource utilization and execution safety	Networking improvements needed
Restrict data visibility in blockchain, protecting user privacy without sacrificing security	This is a difficult time to use the network. So, even if they aren't supposed to, third parties can obtain access to blockchain data
Provides auditability	

26)Masterchain: It is a nationwide Russian blockchain network launched in 2016. It uses the Ethereum blockchain network as its foundation, but it is created with respect to Russian encryption requirements, user identification procedures, and secure scalability, among other things. The pros and cons of Masterchain are depicted in Table XXX.

TABLE XXX. ADVANTAGES AND DRAWBACKS OF MASTERCHAIN

Advantages	Drawbacks
Enables "prompt confirmation of data actuality" to a transacting customer	Closed network, Controlled by the security monitor
Instant communication	Less decentralized than blockchain

V.   EMERGING APPLICATIONS OF BLOCKCHAIN

Blockchain has been suggested to be used in many applications and cases following the successful application of technology in bitcoin because of its distinguishing characteristics. The following section provides a high-level summary of each domain, shown in Fig. 12.

A. Financial Applications

Blockchain technology is now being applied in several financial sectors, including prediction markets, asset settlement, economic transactions, and business services [113]. Blockchain is expected to be essential to the global economy's long-term growth, providing benefits to the current financial system, consumers, and society [42]. The adoption of blockchain technology in financial services can provide various benefits that can help alter the financial industry. As Klynveld Peat Marwick Goerdele (KPMG) reported, blockchain technology may minimize errors by up to 95%, enhance efficiency by 40%, and cut capital expenditure by up to 75% [84]. Blockchain technology in finance is a revolutionary idea that might transform the financial services industry. Here are a few examples of blockchain financial services applications that are gaining popularity in the industry:

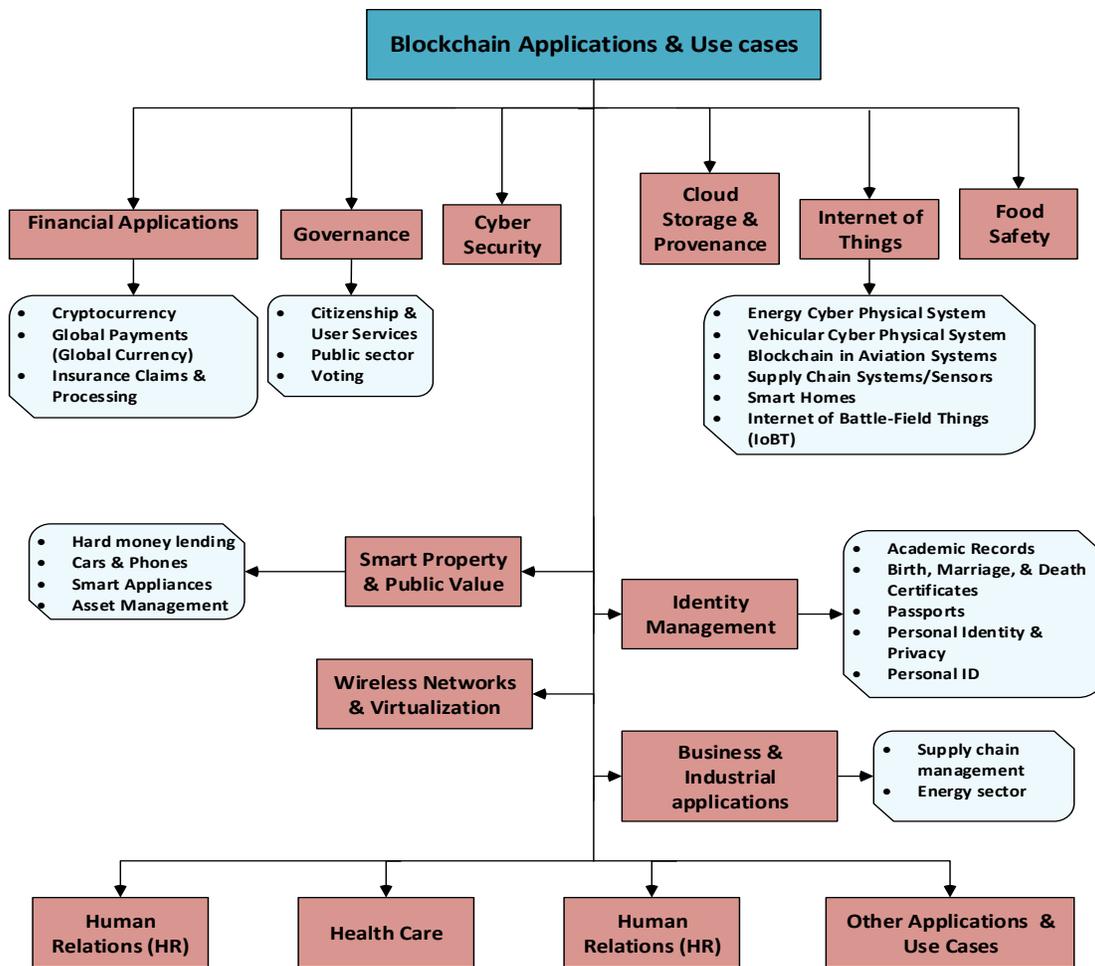

Fig. 12. Blockchain Applications.

1) Cryptocurrency: The earliest application of blockchain technology was to record digital currency transactions, and it remains the most popular usage to date. Bitcoin was the first widely adopted cryptocurrency [85]. Since then, the numerous versions of blockchain technologies have resulted in a wide range of cryptocurrencies and blockchain applications in markets and economics. Hundreds of cryptocurrencies are presently trading, according to 2017 worldwide cryptocurrency benchmarking research [86]. While many of these cryptocurrencies are labeled as "altcoins" and are essentially copies of bitcoin or other coins with different parameter settings, a small proportion of the various offerings have made significant progress.

*2) Global payments (global currenc*y): Numerous intermediaries are engaged in verifying transactions, making international payments more complicated and time-consuming to complete. The entire process has the potential to be error-prone and expensive. In large part, these problems arise because financial transactions have been centralized; entities like banks and other financial institutions prescribe methods while also being accountable for verifying the transactions. Blockchain technology, which introduces a decentralized public ledger and a robust verification technique to validate transactions, minimizes the complications associated with these transactions. Global payments are made more verifiable, immutable, secure, and faster when made through this peer-to-peer network. It is currently being used by various remittance firms [87], like Abra and Bitspark, to provide remittance services using blockchain technology.

3) Insurance claims and processing: Numerous false claims have plagued the insurance industry. Thus, to efficiently handle an insurance claim, it is vital to have up-to-date data and policies associated with each claim, which is challenging with conventional methods. Blockchain technology allows for a speedy and secure approach. Similarly, because several participants or miners must consent to each transaction's legality, any false transactions or claims may be easily identified and destroyed. This ensures that the insurers receive the compensation as fast and efficiently as possible.

The open-end issues in this regard are as follows: Irrespective of some of the notable designs in recent times [88], there are still open-ended problems in applying blockchain to financial applications. Adopting blockchain in financial applications renders mainly bitcoin usage using different forms of cryptocurrencies without any dependencies on the centralized authorization. The advantage of such a scheme is highly reduced transaction fees and risks; however, deploying a secure blockchain architecture over a heterogeneous and integrated form of financial transactions is not free from the potential risk of attacks.

B. Governance

In the government sector, the usage of blockchain technology has been demonstrated in work [89]. The authors highlight better service quality, accessibility, and transparency. Blockchain technology is immune to internet attacks; transactions are public and cannot be changed or deleted once posted, making all data transactions open, safe, and secure. According to the authors [90][91], blockchain technology is suitable for the government since it is secure, P2P, decentralized, and accessible to anyone. Some of the use cases are Citizenship and User Services [92], Public Sector [93] [94] and voting.

The open-end issues in this regard are as follows: A closer look into the applications of governance using bitcoin, as mentioned above, reveals a higher dependency on consensus from the validating nodes and the users over the network. This is challenging to confirm as a regular network is usually populated by various unknown attackers and variable traffic. While using blockchain on such an application, it is challenging to conform to the robust model to promote voter participation based on common interests. Apart from this, the usage of bitcoin still doesn't witness any universally accepted governance model.

C. Internet of Things

The number of devices with internet access continues to rise annually. Connecting numerous devices together results in the Internet of Things. The IoT will revolutionise people's lives by making smart homes a reality. While having more and more of your devices online sounds like it would make life easier, the truth is that you run a significant risk of experiencing privacy and security breaches. When there are millions of interconnected devices, it is crucial to protect data and ensure accountability. The IoT could be secured by blockchain. Some of the use cases are Energy Cyber-Physical Systems [95], Vehicular Cyber-Physical Systems [96], unmanned aerial vehicle (UAV) [97], blockchain in Aviation Systems [98], Supply Chain Systems/Sensors: [99], Smart Homes [100], Internet of Battlefield Things (IoBT) [101].

The open-end issues in this regard are as follows: With its autonomous and decentralized capabilities, blockchain technology has the potential to resolve the privacy concerns surrounding the IoT by addressing the gaps and requirements of existing solutions. However, when used in an IoT setting, they still have some problems [102]. The primary issue is that if blockchain is used to improve IoT's scalability, it could eventually lead to centralization. When dealing with IoT networks, which typically have limited computational resources, the second issue is the need for ample processing time and power to carry out ciphering. The third issue is related to the storage concern brought on by the ledger's ever-increasing size, which necessitates storing all crucial data within the node. Finally, it is challenging to demonstrate the applicability of the current research work due to potential impending factors such as compliance and legal issues in various settings.

D. Cybersecurity

Blockchain technology also has potential applications in the realm of cybersecurity. When harmful data is shared among participants/organizations using blockchain, cyberattacks can be avoided in the future [103]. Because competitors could use it unilaterally if it contains identifying information, companies and governments are hesitant to discuss cyberattacks and threat intelligence. But with

blockchain and a private and public key pair, data can be sent anonymously (such as bitcoin [104]). This alleviates concerns about disseminating sensitive company or government data to potential competitors. Here are some unanswered questions: Blockchain has been touted for its purported security benefits, but if implemented incorrectly, it could expose significant vulnerabilities in the cyber security infrastructure. As a result, the blockchain is open to attacks that could slow down the formation of new chains, steal users' private keys, reverse transactions, and more. In addition, security researchers have been focusing on DoS attacks rather than developing a foolproof solution to prevent Sybil attacks, blockchain endpoint threats, routing attacks, or phishing.

E. Cloud Storage and Provenance

Blockchain can store and share metadata that documents the history of actions and creation, particularly data or file access. Data management is crucial for forensics and accountability [105]. For example, when users view and edit collaborative documents like Google Docs, the modifications are kept in the blockchain. The blockchain saves all revisions and changes made. Again, using blockchain and provenance, cloud storage, and processing can ensure accountability and integrity. Similarly, several people can easily track, modify, and alter data in the cloud for accountability and integrity. The open-end issues are as follows: Storage and provenance in the cloud by blockchain is not a simplified task. It involves a more significant deal of complexity. There is a dependency on adopting a highly sophisticated mathematical model in blockchain that can perform secure processing and transferring of data to the cloud storage system. Consequently, this viewpoint has a more significant imbalance between computational efficiency and security effectiveness.

F. Healthcare and Food Safety

Healthcare will likely be one of the most aggressive industries to adopt or drive blockchain technology. Blockchain, the future supply chain business paradigm, can be applied to the healthcare value chain. Everything from medical records to payments to processing and analytics will be automated, benefiting all stakeholders, from patients and consumers to administrators, providers, and healthcare organizations. Using blockchain in healthcare will help achieve [3]:

- Interoperability: A single format will be used to store and share data.

- Decentralized data storage: A single technology to handle all patient data.

- Power to patients: Patients who wish to be data owners will be able to choose with whom their health records are shared.

Over 0.6 billion (equal to one in every ten people) people worldwide become unwell every year due to eating contaminated food [106], making it one of the most pressing challenges to address. Every day, approximately 1167 individuals perish [106]. Due to the transparency provided by blockchain technology, users may receive information about food, such as its composition, origins, expiry dates, and so on,

in seconds to help avoid food fraud. For food safety, food customers will have greater control over their information, which will be accurate and transparent.

G. Smart Property and Public Value

Blockchain technology may be utilized to maintain track of all actions and property records for any entity or property, including but not limited to: land, house, stocks, autos, and other investments. The information included in the blockchain is distributed to all parties interested or involved, and it can be used to make contracts and verify them. The lost data can be quickly recovered by copying it from the network [107]. Some use cases are hard money lending, cars and phones, smart appliances, and asset management. The efficiency and cost of conducting business are increased by removing the requirement for an intermediary to validate the transactions.

H. Wireless Networks and Virtualization

Wireless networks and virtualization are two topics that have been discussed recently. The increasing expansion of IoT and cyber-physical system (CPS) applications is putting a strain on wireless networks, and several approaches have been investigated to increase network capacity and coverage [108]. By preventing double-spending, in which multiple parties sublease the same wireless resource [109], blockchain can help network service providers like Mobile Virtual Network Operators (MVNOs) reliably maintain control over their users' quality of experience [110]. The open issues in deploying blockchain in wireless networks are mainly associated with data security.

I. Identity Management

This subsection discusses many identity management applications and their supposed effects on blockchain technology. Some of the essential use cases are Academic Records [111], Birth, Marriage, And Death Certificates [112], Passports [113], and Personal Identity and Privacy [114].

The open-end issues in this regard are as follows: Irrespective of essential studies towards identity management by blockchain, there are still open-ended issues to confirm the claimed identity's uniqueness and legitimacy. Apart from this, it is also challenging to verify the legitimacy of the owner at the same time. A specific form of threat is called synthetic identity proofing, where the social identification information of one individual is combined with different identity information (e.g., address, date of birth, etc.) from another person to generate a new form of a counterfeited identity. Unfortunately, blockchain cannot mitigate such problems as its prime task is to maintain a record being a ledger and not to perform identity verification.

J. Business and Industrial Applications

Blockchain can significantly improve, optimize, and automate commercial operations [115]. It is becoming increasingly common to see IoT and blockchain-powered e-business concepts in process today. In [170], the authors propose a business model in which transactions between devices are handled using smart contracts operating within a decentralized system based on a blockchain network. Many businesses could benefit from blockchain-based solutions that

act as distributed Business Process Management systems. The blockchain could store each business process instance, and smart contracts could handle the workflow routing, automating and streamlining intra-organizational activities while lowering costs and increasing efficiency [116]. Supply chain management [3] and Energy Sector [117] are essential use cases. Blockchain is considered a decarbonization facilitator, allowing the energy sector to shift toward more decentralized energy sources [118].

The open-end issues in this regard are as follows: Despite some promising efforts, widespread implementation of blockchain technology in the energy and supply industries has yet to overcome significant obstacles. The primary concern in applying blockchain in supply chain management is determining the degree of usage of blockchain and offering higher data quality. Further, providing a secure access protocol for a legitimate user is another significant problem in using blockchain for supply chains. From the energy sector's perspective, blockchain adoption still couldn't solve problems related to power consumption and scalability.

K. Financial Human Relations (HR)

Human resources departments identify and hire the best candidates for the best jobs, train and educate them to help the company achieve its goals, and maintain a safe and pleasant workplace where employees can be creative and productive. While blockchain's immediate disruption in the capital markets is well-known, its role in transforming HR processes and the workforce is even more fascinating and significant. Companies worldwide have recognized the great promise of blockchain technology to improve human resources and recruitment operations [3][5]. Recruitment, background checks, employee data protection, and smart contracts are just a few critical use cases for blockchain in HR.

L. Other Applications and Use Cases

Blockchain technology can be used without a trusted third party or P2P transaction system for transparency, decentralization, immutability, integrity, privacy, and security. On the other hand, the technology has some restrictions, such as the significant delay produced by the consensus mechanism when many blocks are involved [3].

VI. Essential Findings of the Study

Some of the essential findings of the study are as follows:

- A more excellent way to build a highly transparent trust can be done via public blockchain, however, it lacks an efficient control system. Furthermore, its increased price volatility makes it unsuitable for financial products. Most existing schemes are in the nascent stage of development with narrowed implementation scope over the practical ground and less benchmarked models for a public blockchain.

- A better form of control can be established by adopting existing private blockchain-based schemes making them highly reliable and secure. However, its growth is limited owing to inferior incentives. In addition, the costs associated with its management and administration are pretty complex. Existing schemes of private blockchain offers better data security, but still, they suffer from higher coverage of security options.

- Although hybrid blockchain offers beneficial features for public and private blockchains, it's not affordable compared to a public blockchain. Conventional research work on hybrid blockchain is witnessed to provide a balance between security and data transmission; however, they were not testified over larger scale of network in existing scheme.

- Majority of the existing study towards blockchain technology was found to emphasize the consensus layer for improving its functionalities. However, it should be noted that the consensus layer plays a core role in authenticating transactions and incorporating decentralization and encryption. However, there is no report of a robust model where all the above three entities have been securely protected from intrusion over the consensus layer. Further, less emphasis towards the network layer and incentive layer in existing approaches is also witnessed, which could lead to the continuation of further intrusive activities.

- Although more significant research is being carried out towards improving consensus algorithms in blockchain, but these approaches suffer from low performance and weak scalability (PoW). They also have minimal fault tolerance (PBFT) and lower decentralization (DPoS) with a complex implementation process (PoS).

- Various existing review works are being carried out to exhibit the progressive work in blockchain technology. The work carried out by authors in [119] gave some essential information about the challenges and solutions of blockchain over IoT systems. However, the work is specific towards agriculture-based applications, whereas the presented review work encompasses all the internal approaches to make any application more resilient and secure. Similar environment-specific-based review work using blockchain was also carried out in [32] which draws potential conclusive remarks about the challenges of blockchain in IoT. In contrast, the presented review work focusses on discussing the strengths and weaknesses of different types of utilization and methods of blockchain over its different taxonomies. The notable review work carried out towards smart grid systems by authors in [120] and [121] furnishes some of the transforming techniques towards decentralization scheme; however, it lacks essential discussion of limitations and research gap, which is encompassed in the presented review work. The best notable review work was witnessed in manuscript framed by authors in [122] that contains almost all the potential strengths and weaknesses of a higher number of research-based schemes in blockchains. The proposed work further contributes towards upgrading this information by focusing more on the overall compact picture of blockchain, referring to all the significant works of literature published to date.

VII. OPEN CHALLENGES

Despite the rapid growth and research interest in blockchain technology, obstacles and concerns must be addressed before they can be widely adopted. Here, Fig. 13 illustrates a few blockchain concerns and challenges:

1) Privacy: It is necessary to safeguard the user's identity, location, and data from unauthorized users. The authentication of users entails using a private key to sign documents and the identification or verification of those documents utilizing the hash values compared to the public key. Based on all transactions shared between peers, anonymity cannot be guaranteed. The sharing of transactions makes it straightforward for other parties to investigate such activities and establish the genuine identities of the users involved in the transactions. While the decentralized consensus is built based on past transaction data that has been made publicly available, random users and their associated transaction data may also be made publicly available. In a similar vein, the location may be jeopardized. So, the question of confidentiality and privacy protection becomes a specific challenge.

2) Scalability: The distributed blockchain ledger includes several fields, such as events, users, and so forth. Users generate transactions, which are then appended to the blockchain as a block by a miner, forming a blockchain. This is a moderately challenging operation to do. As the application generates a significant number of transactions and related data, and as the communication infrastructure between nodes develops in size, the network's total performance will suffer. Though there are currently numerous blockchain protocols, research and development are still ongoing to create newer protocols that will address the difficulties in the technology. As a result, one of the most challenging tasks is ensuring that different protocols work together. More recent frameworks cannot scale after reaching a particular block and system size limit. As a result, the larger the blockchain, the longer it takes for the procedure to complete. Given this rapid growth in size and volume of data, scalability has emerged as a problem that must be addressed immediately.

3) Interoperability/Integration: Interoperability and integration - are important since blockchain technology is not a stand-alone application; instead, these applications are typically coordinated with diverse applications within and outside businesses. Blockchain will continue introducing new functionality to strengthen its capabilities and expand action plans. The integration of blockchain technology with current applications might be a difficult task. Specifically, interoperability and security issues are posing a significant barrier. Another concern is the numerous operating environments and platforms that may be required to interoperate to work on blockchain-based apps. Various developers may have produced old and new apps and hybrid applications utilizing multiple development processes,

programming languages, and environments. As a result, the integration technique turns out to be a significant amount of work that becomes increasingly difficult over time. Some work is underway to develop viable integration models that integrate blockchain technology into various industrial applications. Despite this, there is still work to find and establish increasingly practical and flawless solutions.

4) Standards: Because cryptocurrencies are involved, valid conclusions can impact blockchain applications immediately. As a result, it is a critical issue that cannot be ignored. Numerous nations have developed rules for regulating the use of cryptocurrencies. Still, these regulations are currently inaccessible to transactions involving these currencies in the real world due to black marketing. As a result, constructing a fully legal blockchain remains a pipe dream. Regulators like the General Data Protection Regulation (GDPR) safeguard users' data. However, the technology is not capable of complying with all applicable legislation. As a result, the information the user provides may raise concerns about security, accuracy, and privacy.

5) Software testing: Compared to standard software testing methodologies, applications produced using blockchain technology must be examined for special features. Verification and validation of smart contracts must be implemented, as well. Testing the individual components and the overall software engineering process is necessary. One of the unique issues is the testing of blockchain applications. Smart contracts provide the capability of trustworthy oracles that can be readily integrated into applications while verifying the validity of these external entities [3]. Smart contracts are becoming increasingly popular.

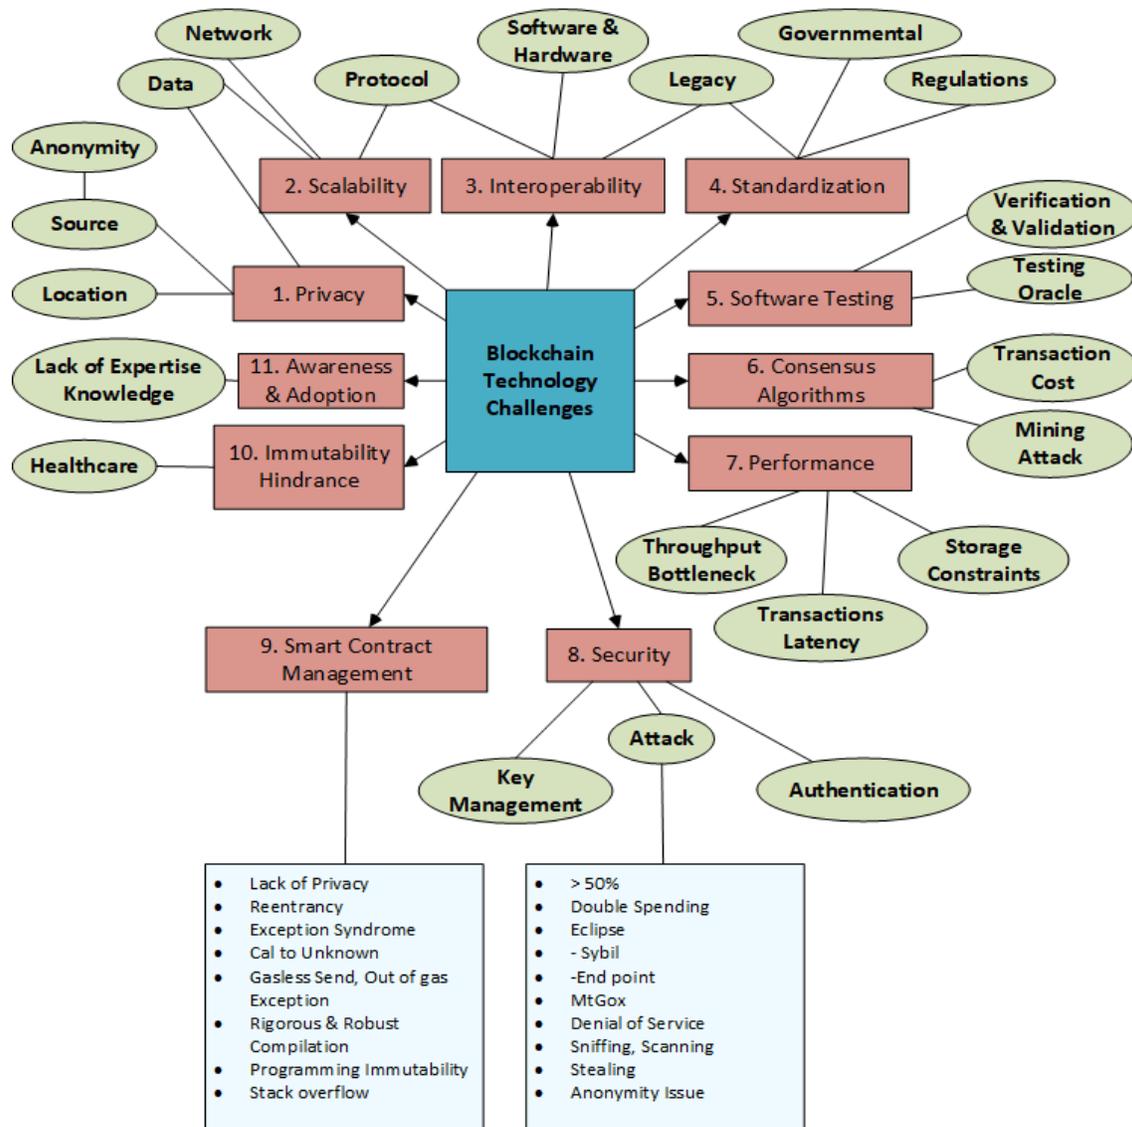
6) Consensus algorithms: A wide range of consensus algorithms is available, each with advantages and disadvantages [123]. Attacks such as the 51 per cent attack are feasible due to this. A new consensus approach must be adopted to meet the application's needs. Different algorithms have different types of loopholes based on the features that have been changed to distinguish them from one another. Working towards a consensus algorithm requires consideration of scalability, tolerance, performance, complexity, and energy usage. New organizations that provide innovative blockchain solutions for various enterprises and business domains are emerging. A few of these solutions have already been implemented in apps, whereas others are still in the development stage, with further research being conducted to improve them [3]. It is critical to improving the application's adaptability, usability, scalability, security, dependability, and effectiveness. This can be accomplished through a variety of methods. As already noted, it is crucial to consider the numerous challenges in developing solutions to make blockchain more helpful and easier to integrate into organizational applications.


Fig. 13. Blockchain Challenges and Issues.

7) Performance issues: Blockchain systems have performance issues, like throughput bottleneck, storage constraints, and transaction latency authors in [124]. Bitcoin transactions are generally validated in an hour, which is acceptable but insufficient [9]. Blockchain-based solutions are efficient and effective when evaluated using empirical evaluation methods like experimental analysis and benchmarking [125].

8) Security: As blockchain apps become increasingly interconnected with the internet, they are subject to cyberattacks like scanning, sniffing, Sybil attacks, endpoint attacks, and DoS attacks. Blockchain miners and users control their entire system, unlike traditional methods where an external organization contains the end user. So, phishing can take the user's private keys. One example is the MtGox attack. In 2014, a bitcoin deal in Tokyo, Japan, lost $600 million. Another example is a $55 million loss versus Ether digital currencies. It is also known as a >50% attack [126]. Without adequate security measures against such attacks, all apps suffer. The idea of blockchain and its usage models is compelling. However, issues like many platforms, open access, impending developments, using open systems, and others may compromise the system's security. Existing security mechanisms help, but additional research is needed to develop more effective security models for blockchain. Attacks on key management and authentication of users and data are common.

a) Key management: A client's private key is an unrecoverable private key. However, since no central entity handles the blockchain and can track down and restore the changed data, stealing the attacker's private key is risky. Establishing reliable critical management systems in the blockchain is thus another considerable difficulty.

b) Authentication: Blockchain ensures the authenticity of a ledger and other sensitive data stored in blocks in a decentralized manner [210] by encrypting the data. To create, survey, or modify data in the blockchain, a user must first utilize a private key connected with a public key. These credentials are tied to an address in a wallet. Users can digitally sign transactions using such software keys and check their authenticity. The Elliptical Curve Digital Signature Algorithm (ECDSA) is the most often used Digital Signature Algorithm. There is still a need for a lot of studies to authenticate the information and the user. There is also the risk of a compromised wallet to be considered. Its ability to confirm identity and identity paperwork has made it a studied issue.

9) Smart contract management: Developing, deploying, and interacting with a blockchain among various members and stakeholders is a highly tough task [127]. Indeed, no matter what form of blockchain is used (public, private, or consortium), severe challenges such as management, administrative services, and smart contract debugging arise. A few of the smart contract-related concerns are as follows:

a) Privacy preservation: When building a smart contract, it is challenging to consider privacy concerns. Given the inclusion of bytecode analysis tools, the agreement faces the risk of being insecure [7][8].

b) Re-entrancy: The DAO assault extensively used re-entrance to achieve success. It impacts the execution of functions, says A and B; in most cases, A is the first to execute, followed by B. However, in this circumstance, B executes first, followed by A. Consequently, the situation deteriorates, resulting in a loss. A function is, for example, the "withdraw" function, which retrieves cryptocurrency from a record by giving cryptocurrency to a user and then "updating" the account balance. If the value of the currencies is less, the "update" should occur before the "withdraw".

c) Call to the unknown: Some Solidity functions can call the callee's fallback function when the callee's signature does not match any available users in a Solidity contract. When an attacker executes the malicious fallback function identified in their contract, they can use the call, transmit, or delegate call function to send the Ether to an address that does not exist [128]. Unlike other attacks on Ethereum, this one posed a high risk.

d) Exception syndrome: Incorrect handling of exceptions causes a syndrome that must be dealt with and a loss of currency. These occur due to an unintentional halt in the execution, and the gas quantity is deducted [128]. If an interruption happens, how to deal with it becomes a serious concern.

e) Gas exception: When a transaction is given, the "gas" is a measure of Ether used to cover the transaction's cost. If an exchange runs out of gas while being executed, it will be rescheduled; nevertheless, the sender will be obligated to pay the miner the total amount of available gas [128].

f) Programming smart contracts: Because smart contracts are immutable, security is one of the most challenging hurdles to overcome while programming them. If Ether is taken from users, it will be impossible to recover it. The other issue is data integrity and uniqueness, which are required for blockchain-based systems to be reliable and trustworthy. The economy is also a key source of concern. This is the cost of creating, executing, and deploying smart contracts, also known as the gas cost in Ethereum [128]. A single programming error will harm the economy as a whole.

10)Immutability hindrance: The immutability attribute of blockchain may make it challenging to employ the technology in some applications. For example, when used in healthcare area, the immutability feature may make it more challenging to comply with privacy rules, establishing an individual's right to have their health data erased and rendered inaccessible to third parties [129]. This is a delicate subject, and the use of technology in healthcare cannot proceed without first addressing this legal requirement [129].

11)Awareness and adoption: One of blockchain's most critical challenges is the lack of understanding and adoption. For example, many individuals are unfamiliar with how it operates. The technology's future development depends on how many parties use it, which is still an open subject.

a) Lack of expertise knowledge: A blockchain project's implementation and management are challenging tasks. The firm must have extensive expertise in the subject matter to complete the process. They must engage a large number of professionals in the blockchain sector, which creates difficulty, and as a result, it is considered one of the blockchain's downsides, according to some. Additionally, businesses must train their employees on using the technology by ensuring that the management team knows the intricacies and outcomes of running a blockchain-powered organization. They will be able to grasp client requirements and assist them in transforming their business operations to use blockchain. Not to mention that if you locate its developers and specialists, they will be more challenging to come by and more expensive than regular developers due to the demand and supply ratios. Table XXXI summarises key traits, literature references, and concerns.

TABLE XXXI.   CHARACTERISTICS OF A UNIFIED BLOCKCHAIN AND RELATED CONCERNS

	Mapped Literary Jargons	Related Concerns
Decentralization	Decentralization [33], [35], [128]	Complex security management Significant resource requirements Resource inefficiency Out-of-date and long chains are pruned out Poor performance and latency issues Scalability Inefficient use of energy
Transparency	Transparency [33], [35], [128] Openness [131] Auditability [32]	Privacy concerns Opposite of anonymity
Autonomy	Anonymity [130] Trust-Free [133] Trustlessness [131]	Few large firms rely on computing power to make decisions
Security	Security [32], [131], [18]	Various attacks
Immutability	Immutability [32], [35], [130][133] Unforgeable [128] Persistency [130] Untamperability [131]	Irreversible smart contract bugs Difficulty applying smart contracts patches Obstacles in some applications, like patient privacy in healthcare
Anonymity	Anonymity [22][131], [128] Pseudonymity [133] Transactional Privacy [32]	Lack of transparency about real transaction participants
Democratized	Democratized [33] Synchronized through Consensus [35] Collective Maintainability [131]	Low performance owing to an excessive number of decision nodes Few large firms use computational power to make decisions
Integrity	Integrity [21] Data Reliability & Integrity [32][133] Reliable Database [131]	Various types of attacks
Programmability	Programmability [23]-[132], [133] Open Source [130] Blockchain -Based Control [35] Openness [128]	Poor user interface
Fault Tolerance	Fault Tolerance [32]	Data duplication at several nodes necessitates substantial storage Synchronization Overhead
Automatic	Automatic [133] Independence [128]	Irreversible smart contract bugs Difficulty updating smart contracts Computer software is susceptible to hacking and attacks

VIII. FUTURE RESEARCH OPPORTUNITIES

Blockchain technology can completely transform the way businesses and payments are conducted worldwide without the need for trusted intermediaries or consideration of geographical limits. As a result, many parts of the blockchain will continue to be popular study areas, including consensus methods and managed services in terms of efficiency. The following section discusses some of the most important discoveries and future directions.

- Blockchain technology must address many existing challenges to become a cornerstone technology for various domains in the future. As a starting point, it should be scalable and overcome the restrictions of high latency, low throughput, and increasing storage requirements. The research community should work around the challenge of efficiently updating smart contracts with minimal overhead. Finally, the blockchain community must handle the enormous energy consumption of many nodes taking part in the consensus process, which could become a primary climate concern.

- To assist enterprise blockchain, Intel and Microsoft have already joined forces [134]. According to the alliance, the success of its enterprise will be determined by how well it addresses concerns such as performance, confidentiality, and governance [135]. Anomaly detection frameworks (ADFs) should fundamentally incorporate support for these issues if they are to be widely accepted across a wide range of business areas. The combined capabilities of blockchain and artificial intelligence offer enormous potential for developing applications in various fields. For example, the trust in blockchain technology and the decision-making capabilities of artificial intelligence in healthcare and driverless vehicles will be an excellent fit for special applications [136]. Therefore, it will be necessary for future ADFs to include intrinsic support for these types of functionalities.

- There will be two significant hurdles in the future for promoting blockchain security. The first is to strike a balance between an individual's privacy, security, and accountability, which is made feasible primarily

through Distributed Ledger Technology. On the other hand, it is necessary to cope with the privacy and security problems arising from the IoT. These issues include legal challenges, interoperability, developmental concerns, rights concerns, regulatory concerns, a lack of standards, and issues related to the emerging IoT economy, among other things.

- It is noted that blockchain is intended to operate as a decentralized system. Meanwhile, there is a growing trend toward miners being centralized within the mining pool. To date, 51 percent of the total hash power on the bitcoin blockchain is controlled by the top five mining pools combine [135][136]. Aside from that, the selfish mining method [137] shows that pools with more than 25 percent of the overall processing capacity might generate more money than their fair share of the revenue. The selfish pool's total power might fast approach 51 percent of the full power available. A solution should be given since the blockchain is not built for a few companies.

- Blockchain's economic benefits have been thoroughly researched [3][8]. Individual businesses must comprehend how the technology affects their organizational structure, method of operation, and management approach. The market must assess whether blockchain can address market failures caused by information asymmetry and improve market efficiency and societal welfare. However, more incredible research is required to understand how it affects business and market efficiency.

- Research on throughput, latency, size and bandwidth, hard forks, versioning, and many forks is also required. This is a significant research gap that will require further research. Understandably, given the tiny size of current blockchain applications, they are not the most exciting research areas for now. Currently, bitcoin, the most popular solution, has a much lower transaction volume than VISA. It is necessary to perform additional studies on scalability in the future when blockchain solutions are utilized by tens of millions of users and transaction volumes skyrocket.

- The other research gap is usability. This study found publications that explored usability from the user's perspective, but not the developer's, as the work [138] suggests. For example, the bitcoin API is still challenging to use. This has to be researched and improved as it could lead to more bitcoin applications and solutions. Future research will likely focus on bitcoin, other cryptocurrencies, and viable blockchain uses. This study identified some research on smart contracts, licensing, IoT, and smart properties in a blockchain setting. These studies will have a considerable impact in the future and may even be more exciting than cryptocurrencies. For example, using a decentralized environment to share a virtual property might alter how corporations sell their items. Considering this, it can be confidently posited that

further adoption of this technology by industry and academics will result in the significant new research.

- Improving blockchain's Interoperability and Compatibility with Existing Health Information Technology (HIT) infrastructure: Companies must know how to connect their HIT blockchain to other blockchains or non-blockchain platforms. Interoperability and data standards should be explored besides ascertaining effective integration governance mechanisms. Researchers should look at cross-authentication (for interoperable blockchains), oracles (which send external data to the blockchain for on-chain use), and application programming interfaces (APIs) (for incompatible blockchains). Many open standards exist for connecting proprietary systems to blockchain HIT, but the feasibility of using them to connect proprietary systems to blockchain HIT is still unknown [139]. Diverse stakeholders in blockchain silos cause complexity and interoperability issues that should be investigated. Security and privacy concerns require knowledge of blockchain interoperability's legal and regulatory consequences.

- HIT researchers are growing in awareness of the technological constraints of blockchain data storage and are exploring alternate techniques to comply with GDPR. Keeping addresses, hash values, and timestamps on the blockchain while storing Protected Health Information (PHI) off-chain in the cloud or on hospital servers is advised [140]. Data storage splitting can reduce system performance. On-chain and off-chain data storage should be optimized in future studies.

- The sharing economy is frequently defined as the P2P exchange of goods and services. In the future, the new sharing economy may include enterprise sharing. As a result, interconnecting blockchains may become a trend. These interfaces will let commercial operations connect identity authentication, Soft Computing and Measurements (SCM), and payment processes. They will also enable real-time data sharing and collaboration between businesses and industries.

- The vast amount of data stored in blockchain makes it possible to do Blockchain-based big data analytics. Other forms of ample data storage (for example, tensor computing) could also be improved to efficiently store and process blockchain data to save space, make it more accessible, and provide other benefits.

- Many blockchain consensus algorithms seek to replace PoW due to its massive energy waste. These new native protocols may introduce additional security risks or be impossible to deploy in reality [141]. The blockchain consensus mechanisms present a research opportunity. Future investigations are needed to seek more robust and more secure protocols than PoW while consuming less energy besides ensuring that the proper protocol is utilized in suitable applications [142].

- The threat of quantum computers to blockchain security necessitates efficient and well-proven post-quantum digital signature systems and other relevant investigations. The affordability of quantum computers is desirable, but systems like blockchain must be protected from quantum computers. Apart from ECDSA, RSA, and Digital Signature Algorithm (DSA), alternative cryptographic methods (post-quantum cryptos) are not impacted by quantum computers. Asymmetric key cryptography (Merkle signature system) and hash-based cryptography (McEliece public key system) both have such systems (e.g., AES). These include lattice-based (e.g., NTRU public key cryptosystem) and multivariate quadratic public key methods. Research is still needed to improve post-quantum cryptosystems' usability (key size), efficiency, and confidence against quantum computer threats [143]. More research is needed on quantum channels and effective post-quantum consensus techniques [144].

- Blockchain-based Decentralization Finance, sometimes known as 'DeFi,' is a new field based on blockchain technology. It is a unique, experimental type of finance, not relying on central authority or intermediaries such as exchanges or banks. DeFi is an umbrella term for many decentralized financial services and applications based on the technology. It has numerous potential study possibilities because it is new compared to the other blockchain research subjects stated above. A surge in interest in DeFi research in the coming years is anticipated.

- The interoperability of blockchain should also be investigated. Many blockchain platforms may interoperate to improve security, usability, and efficiency. Blockchain may also be used to supplement existing systems. Many businesses want to implement it but do not want to abandon their present systems. The optimal strategy to integrate the blockchain with an organization's existing systems must be researched. It is also essential to consider how different blockchain systems might work together for mutual gain.

IX. CONCLUSION

Blockchain technology is becoming increasingly popular for conducting decentralized transactions and data management without the involvement of an intermediary. Open and decentralized, the blockchain keeps track of all transactions between all parties involved in a form that can be independently verified. Since 2008, there has been a rise in interest in bitcoin and blockchain. However, it was just the beginning then, with no frequency of research papers. The data presented in the proposed paper (with respect to the percentage of increase in research publications in blockchain technology) now shows increasing attention towards evolving with more secure blockchain technology, witnessed only in the last three years. One of the prime reasons could be the adoption of blockchain as a new alternative for securing digital copyright data, supply chain management, the financial sector, etc. As a result of its inherent decentralization, persistence, anonymity, and auditability, the technology has drawn considerable interest from both the business and academic communities. A growing number of corporations and governments worldwide using blockchain technology to enhance their services' efficiency, scalability, and security. A complete description of blockchain technology was provided in this manuscript. At the outset, it introduced blockchain technology and its key features, including its architecture. After that, some of the most common consensus algorithms in the blockchain were discussed. Different aspects of these protocols were compared and evaluated. The study covers the basics of blockchain and some more interesting new applications and uses cases. For example, blockchain technology can have a revolutionary effect on the financial sector, e-Government, and Business Process Management (BPM) besides entertainment, healthcare, insurance, law firms, the Internet of Things, trading platforms, etc. However, there are just a few examples of the technology used with these systems. As a result, this technology is unlikely to replace existing systems or applications anytime soon wholly. Nonetheless, blockchain technology may undoubtedly be used in conjunction with existing systems and may even result in the construction of new techniques in the years ahead. For this reason, additional research into the technology is needed, as it is still in the experimental stage and numerous technical and legal challenges need to be overcome. This work serves as a helpful beginning point for future research issues related to the development of blockchain applications. It will be of use to practitioners and researchers alike in their efforts. Even though there are numerous ongoing active research projects in this field, this technology is still in its infancy; as a result, future study avenues have been identified, with an emphasis on in-depth research.

Abstract—e-Commerce is booming everywhere, and Saudi Arabia is no exception. However, the adoption and prevalence of online mobile auctions (aka m-auction) remain unsatisfying in Saudi Arabia and the MENA region. This paper uncovers the enabling factors and hindering barriers against the use of mobile auctions by online consumers. To this end, a multiphase mixed methods design is applied to acquire an in-depth understanding of online mobile bidding or auctioning attitudes and practices of the Saudi auctioneers and bidders. Initially, an interactive mobile auction app was developed by applying the principles of user-centered agile software development (UCASD) methodology, which incorporated several design iterations based on feedback from 454 real users. The mobile auction requirements were collected using a mix of research methods, including a survey, focus groups, prototyping, and user testing. The UCASD methodology positively influenced the early evidence-based adoption and use of mobile auctions in the Saudi market. Subsequently, three consecutive focus groups were conducted with another 22 participants to induce further insights regarding the antecedents impacting the intention to embrace online auctions using mobile phones. A taxonomy of requirements coupled with thematic analysis of the discussions gave rise to 13 influential factors of mobile auctions, namely risk, quality of products, trust, ubiquity, usefulness, access to valuable products, ease of use, age, social influence, monetary costs, enjoyment, past experience, and facilitating conditions. Our inductive approach resulted in an early technology acceptance model of mobile auctions. We conclude by reflecting on the challenges observed to suggest some practical guidelines to pave the way for other researchers in this promising area to carry out experimental studies to ameliorate the proposed model.

Keywords—Online auction; mobile auction; technology acceptance model; eBay; human-centered design; agile software development; factors

I. INTRODUCTION

e-Commerce revenues in Saudi Arabia have approximated 10.44 billion USD in 2022, with projections that its value will surpass 23.46 billion USD by the end of 2027 [1]. Moreover, the number of Saudi consumers who indulged in e-commerce activities reached approximately 25.6 million users in 2020, and this number is prognosticated to surpass 34.5 million users with 92.5% user penetration by 2025 [2]. Although e-commerce websites in Saudi Arabia are gaining unprecedented popularity, their actual adoption and use by consumers are still below par compared to the world. e-Commerce takes various forms and includes many activities. In this paper, we shed light on one specific type of e-commerce, that is, online auctions performed using mobile devices (i.e., m-auction) for several motifs. Firstly, online shopping using mobile phones (i.e., mobile e-commerce) is constantly increasing. A Saudi Communications and Information Technology Commission report revealed that 93% of online shoppers use their smartphones to make online purchases in Saudi Arabia [3]. Secondly, the online auction market growth rate is anticipated to increase by 7.2% in 2022 [4], with global sales of art and antiques already exceeding 26 billion USD in 2021 [2]. However, the USA, China, and the UK hold 86% of the global auction market share leaving only 14% to the rest of the world.

Hence, our main intriguing research question is straightforward. Why does Saudi Arabia, despite its recent major digital transformations, still lag in the use of online mobile auctions? We believe that our findings about online mobile bidding attitudes and practices may be generalized to similar developing countries in the Middle East and North Africa (MENA) region. Software solutions often face critical challenges that lead to their failure. In fact, a weak understanding of user views and requirements and failure to engage users throughout the design process is deemed to be among the common reasons that lead to software failure [5][6]. However, developing easy to use software applications does not always guarantee successful adoption and use by the final users. Technology acceptance models have been proposed for decades as theoretical stipulations to understand the motivations and critical factors that must be present before users would start using a new technology [7]. This is the case for Saudi Arabia and the gulf region, where online auctions in general and mobile bidding in particular are still not being used

despite the high technological penetration levels experienced in these countries.

Studies investigating the adoption of mobile commerce have recently gained momentum worldwide [8][9][10][11] and in Saudi Arabia [12][13]. For example, Alkhunaizan and Love proposed a mobile commerce acceptance model where performance expectancy, cost, and effort expectancy were perceived as significant factors for user adoption [14]. However, to the best of our knowledge, there are no studies related to mobile auction adoption in Saudi Arabia. Moreover, the literature does not offer comprehensive studies exploring the critical success factors and challenges impacting the adoption of mobile bidding by Saudi consumers. In line with the above motivations, our research offers several crucial contributions.

1) The design of an interactive mobile auction app (which we call iBid) by applying an integrated user-centered design and agile development process [15][16]. We contribute a participative methodology that shows how to capture and apply user feedback in an ongoing process to improve software artifacts until an acceptable version is reached quickly. At the end of the design process, a real mobile application is produced and introduced to Saudi consumers to gauge their acceptance and capture genuine feedback.

2) The conceptualization of the factors that impact user attitudes, behavior, and adoption of live auctions using mobile devices. Such in-depth understanding was captured through a series of qualitative studies in the form of focus groups with real users. This phase induced a solid theoretical foundation elaborating the factors and potential influence on the intention to use online mobile auctions.

We organized the rest of the paper into five sections. Section II elaborates on the concept of mobile auctions and technology acceptance models that predict shoppers' intention to bid on products. Section III presents the UCASD research methodology that was applied to create our mobile auction app. Section IV presents the key results of the iterative development process along with the m-auction requirements. Section V reports on the theoretical observations concerning the factors influencing Saudi consumers' mobile bidding perceptions and behavior. Section VI discusses the practical implications and suggests a research roadmap for online mobile auctions in MENA countries.

II. RELATED WORKS

A. e-Commerce and Mobile Auction

This research revolves around online mobile auctions (aka m-auction), which can be conceived as a form of electronic commerce (e-commerce). e-Commerce is a type of business that incorporates the activities and operations of selling and/or buying services or goods/products online [17]. Payments may also take place using dedicated payment gateways, like PayPal. Various technologies and frameworks, such as transaction processing and inventory systems, were developed to achieve seamless e-commerce. e-Commerce prevails in various shapes. Nowadays, C2C and B2C e-commerce are offered through online auction channels. For instance, eBay reported a net revenue of 10.27 billion US dollars in the year 2020 [18]. Moreover, online C2C e-commerce usage in 2021 by the European Union reached 20% of its population [19].

Mobile commerce (m-commerce) was coined in the late 90s to refer to purchasing and selling goods or services using mobile devices [20]. The pervasiveness of mobile devices enabled quick access to various services, including, but not limited to, mobile banking, mobile marketing, mobile money transfer, and mobile auctions [21]. A Delphi study involving experts has revealed that the factors leading to m-commerce success included ease of use, convenience, trust, and ubiquity (real-time) [22].

Online auctions refer to online marketplaces where sellers display their services or products for sale through bidding [23]. The selling price is usually not determined at the start of the auction, and buyers compete for a particular item, which is won by the highest bidder [24]. This e-commerce model offers various advantages, such as access to services and products irrespective of the geographic location, accessibility to a large pool of customers, and lower prices compared to other traditional marketplaces. Online mobile bidding refers to the auction activities that take place within e-marketplaces using mobile devices. In mobile auctions, customers are empowered to watch live auctions directly from their phones and bid on the displayed services and goods [25].

B. Online Auction and Mobile Bidding Acceptance

Technology acceptance literature proposes and examines information systems theories and models to predict how people adopt and eventually use new technologies [26]. A variety of technology acceptance models were proposed for different electronic services, like e-commerce [27], e-government [28], e-payment [29], m-banking [30], and mobile learning [31]. These studies augmented the original technology acceptance model (TAM) with several key success factors, including perceived trust, perceived risk, cost, security, lifestyle, and compatibility. However, research efforts in online auctions / mobile bidding are limited despite their growing penetration among e-commerce customers [32]. Among the notable studies of online auction acceptance is that of Turel et al., [33]. Results of two surveys with eBay users showed that addiction toward online auctions impacts perceived enjoyment, usefulness, and usability, which consequently influence intentions to use online auction systems. Chang identified that the use of autonomous agents for online auctions is positively correlated with well-known technology acceptance factors such as usefulness, ease of use, and enjoyment [34]. This is an example of the unconventional factors that must be considered in modern technologies.

In Saudi Arabia, the acceptance, adoption, and use of e-commerce [35], online banking [36] and mobile commerce have been explored to a limited degree. Eid showed that e-commerce intention to use is influenced by the satisfaction of customers but not trust. The satisfaction, in turn, was influenced by the quality of the user interface and the quality of information [35]. Moreover, the use of e-shopping in Saudi Arabia was influenced by enjoyment, usefulness, and personal norms [37]. However, the level of education, resistance to change, and perceived trust were found to impact customers'

readiness to adopt online banking [36]. Alkhunaizan and Love suggested that successful customer adoption of mobile commerce in Saudi Arabia is strongly linked to perceived performance expectancy and incurred costs [14]. However, social influence and perceived trust were not found to impact mobile commerce usage intention.

In light of the above, we identify several challenges and unanswered questions that motivate our research agenda in this paper. Firstly, mobile bidding is a relatively new technology still yet to be explored in the Saudi context. Secondly, previous studies are confirmatory in nature (i.e., statistical), assuming links between constructs concerning online auctions and e-commerce theories. The aim here is to build a user-centered mobile app and explore the mobile features, characteristics, and context that truly influence consumers' intention to use mobile bidding and formulate those in a preliminary theoretical model of mobile bidding adoption, which can be confirmed in a subsequent confirmatory study.

C. Significance of Mobile Auction

Consumer behavior research has generated considerable attention, especially with the abundance of modern technologies in our daily life. Online auction is spreading rapidly amongst technology enthusiasts; for example, the number of eBay active users increased dramatically from 89 million users to 138 million active users in 2022 [38], with the annual bidding sales exceeding 10.42 billion US dollars in net revenue in 2021 [2]. These figures emphasize the importance of investigating mobile auctions for Saudi Arabia's economy and e-shopping customers within the Kingdom. There are other qualifying motivations for selecting this research topic, including the arguments below.

- e-Commerce is accelerating in Saudi Arabia, with more than 25 million users [1]; hence, it is worth investigating trendy e-commerce topics, such as mobile auctions, which is a promising C2C e-commerce model.

- There are conflicting findings in the literature regarding the specific factors that encourage or inhibit the use of e-commerce technologies among customers.

- Existing adoption models were introduced for non-Arab cultures (i.e., the developed countries), thus restricting these technology acceptance models to those environments and raising serious questions about their applicability in Saudi Arabia, a culture with unique characteristics and user needs. The literature has already demonstrated that different cultures perceive technologies differently (e.g., US vs. Korean) [39]. Such findings necessitate the development of m-auction models that fit the Saudi society.

- Existing technology acceptance models cannot continue to predict the correct use and adoption of modern technologies such as mobile bidding. For example, Röcker argues that as new technologies are introduced to support use in personal and specific contexts, old factors like perceived ease of use may not accurately predict technology use [40].

To the best of our knowledge, no explicit and systematic study explored the acceptance of online mobile auctions by Saudi e-shoppers. This is the first study in this direction, and its contributions will give real practical implications for e-commerce in the gulf region.

III. THE UCASD RESEARCH METHODOLOGY

Generally, a research methodology refers to the set of procedures to be followed to investigate a particular research problem scientifically, leading to reliable and valid results [41]. Creating theoretical models that accurately predict the acceptance and use of new technology has attracted significant attention [42] and usually follows a purely quantitative approach, which applies statistical tests to establish new constructs and relationships. However, such a deductive approach is practical only when a set of critical success factors have been identified a priori.

We argue that the topic of mobile auctions in Saudi Arabia and MENA is under-explored and Saudi e-shoppers are yet to adopt and use mobile bidding. In our view, the first step necessitates developing an in-depth understanding of the factors impacting mobile auction attitudes and use. Therefore, we opted for a qualitative approach to pave the way, through inductive reasoning, to suggest a tentative model that is ready for quantitative confirmation in future studies.

Fig. 1 depicts the integrated UCASD methodology that we applied to develop a mobile auction app and collect mobile auction requirements. Our methodology combined UCD and agile development processes, with focused system refinements emerging from the iterative testing of the 'm-auction' concept with real users [43]. Salah et al., argue that this complementary integration empowers the developers to 1) create a deep understanding of user needs, 2) consider user interface (UI) design and user experience (UX) during the development process and produce software quickly while reducing costs [44]. Although combining UCD activities with agile software development during software creation is no easy task [43], UCD, if implemented correctly, can strengthen the agile values [45], as presented in the next section. Table I summarizes the research methods used and the number of participants in each study. The details of each study are provided in the following sections.

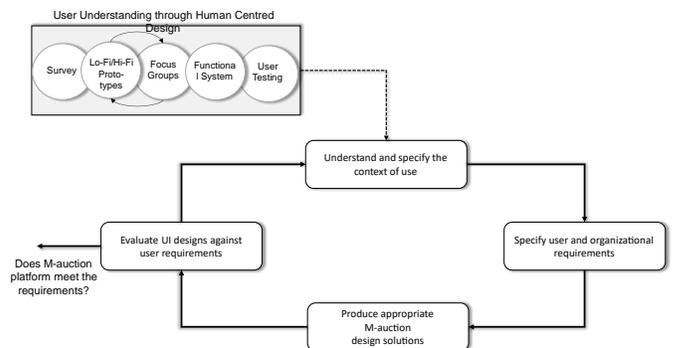

Fig. 1. Our Integrated User-Centered agile Software Development Methodology (UCASD).

TABLE I.   RESEARCH METHODS USED AND NUMBER OF USERS SOLICITED

Research Method	Type	No. of Users
Online Survey	Mixed	417
Focus Groups	Qualitative	9
Lo-Fi and Hi-Fi Prototyping	Qualitative	NA
User Testing	Mixed	28
Focus Groups	Qualitative	22

IV. THE USER-CENTERED DESIGN (UCD) OF THE IBID MOBILE APPLICATION

We argue that adopting a user-centered design philosophy is crucial to ensure various benefits ranging from rapid development, reduction in requirement changes, and high user satisfaction and acceptance. According to Wever et al., the User Centered Design (i.e., UCD) puts the final user at the center of the whole design process, where the user actively contributes his perceptions, requirements, and feedback so that a highly usable solution is created [41]. The added value of UCD in agile software development is further emphasized by Zorzetti et al., [46]. During our UCD, we captured the real requirements of bidders and introduced the mobile app for actual use. Subsequently, we held two focus groups and a user testing to discuss users' thoughts, perceptions, and reactions toward the designs of mobile auctions.

As a first contribution, this paper aims to showcase how it is possible to create a modern mobile app while applying the User-Centered Agile Software Development (UCASD) methodology. We closely followed and applied the principles suggested by Brhel et al., to realize the UCASD benefits [45]. The specific recommendations that were integrated during our development include:

- Principle One: the separation of 'product discovery' and 'product creation'.

- Principle Two: the design and development of systems through 'short, iterative, and incremental' software activities.

- Principle Three: parallel design and development tasks

- Principle Four: continuous stakeholder involvement from start to end.

- Principle Five: use tangible artifacts to facilitate communication of concepts to stakeholders.

A. Mobile Auction Discovery Through a Survey Study

Our research quest started by gathering and defining the requirements for mobile auctions. To this end, a survey was administered and distributed to university students via the university mailing lists. Surveys are cost-effective, enable access to a large pool of users quickly, and assist in capturing unique requirements [47][48][49]. In this first study, a total of 417 users responded to our online survey, which incorporated 59 quantitative and qualitative questions spanning across three different sections, namely (1) past e-shopping practices, (2) desired auction functions and features, and (3) respondents' demographic information, as shown in Fig. 2.

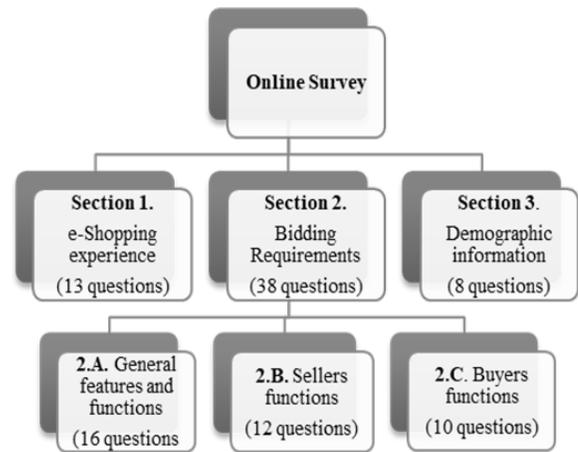

Fig. 2.   Distribution of Online Survey Questions.

The past e-shopping experiences section explored users' practices regarding e-commerce, e-shopping and online bidding that resulted in selling or buying products or services using the Internet or mobile applications. The bidding requirements section identified users' needs with respect to the general features of mobile bidding and functions supporting the seller and buyer. The requirements' questions were rated on a seven-point Likert scale (where 1=not necessary at all and 7= very important). The demographic section collected users' age, study level, mobile subscription package, smartphone brands, etc.

369 (88%) of our respondents were students, while the remaining respondents (i.e., 51 users) were professionals. 254 (60.9%) were males, and 163 (39.1%) were females. More than 75% of the respondents indicated they had an excellent experience using smartphones. Furthermore, 363 (87%) respondents in the past indulged in some sort of e-commerce activities using online websites or mobile apps. 51% of the respondents owned Apple smartphones, while the rest owned Android smartphones (e.g., Samsung and Huawei). Regarding mobile auctions, we succinctly summarize the key features and requirements desired by our respondents as follows.

- RQ1. Localization of platform: support of the local language.

- RQ2. Search functionality: availability of search functionality to look for products and services.

- RQ3. Information quality: adding photos and videos to the products or services.

- RQ4. Auction details: setting price limits for products and services on bidding.

- RQ5. Trustworthiness: displaying reviews about sellers, products, and bidding experience.

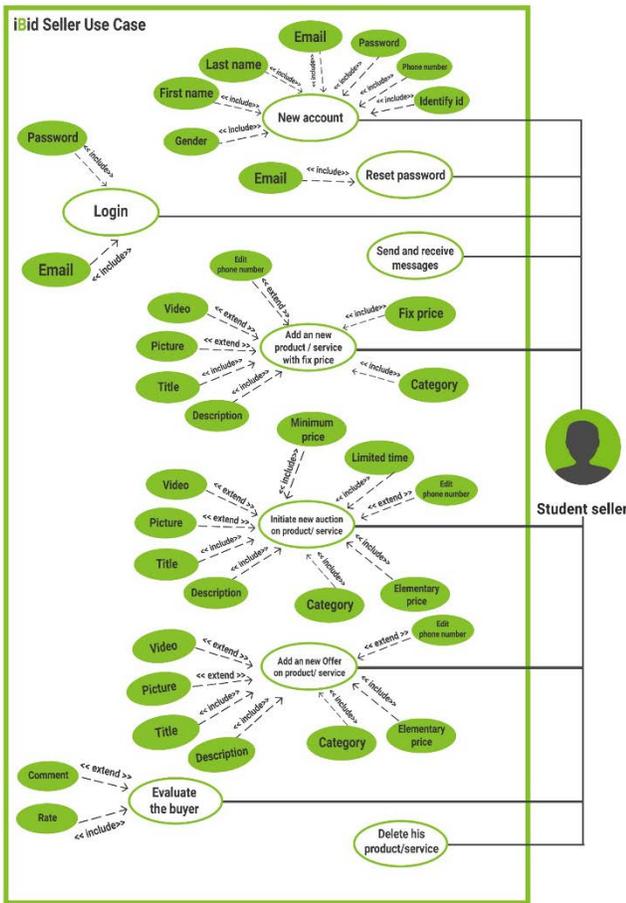
- RQ6. Live customer support via instant messaging.


Fig. 3.   A Use Case Diagram for a Seller using the Mobile Auction System.

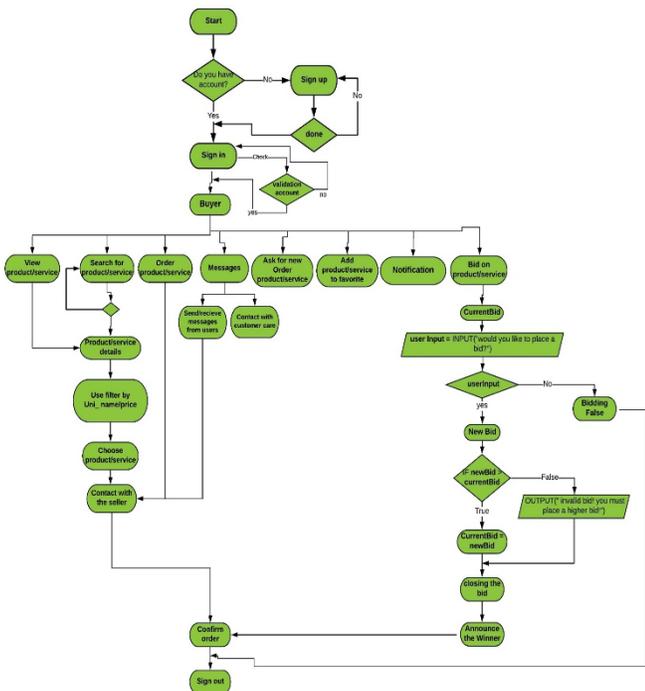

Fig. 4.   A Flow Chart of a Mobile Bidding Buyer.

We separated the concept discovery and product development tasks, as recommended by Brhel et al., [45], by carrying out an up-front analysis. The online survey helped us conceptualize the design models, such as, the use case and flow chart diagrams, of the main stakeholders of our mobile auction system. For the sake of brevity, we include only two exemplary UML diagrams derived from the user suggestions (as depicted in Fig. 3 and Fig. 4). Fig. 3 shows the use case diagram of the seller. Fig. 4 shows the flow chart of the bidder.

B. Low-Fidelity Prototypes of the Mobile Auction App

Next, we applied the second principle of effective UCASD, stipulating to design and develop the mobile app using iterative and incremental software activities. To this end, we created early prototypes of the intended mobile auction application. Low-fidelity prototyping is the process of converting product concepts and visions into simple visual representations using pen and paper [50]. The tangible benefits are well-known, ranging from cost-effectiveness, ability to inflict quick changes, and validation of requirements [51]. In this phase, we created eight low-fidelity screens to showcase the most prominent functionalities and requirements of mobile bidding, as depicted in Fig. 5. These functionalities and features were extracted from the results of an online survey study.

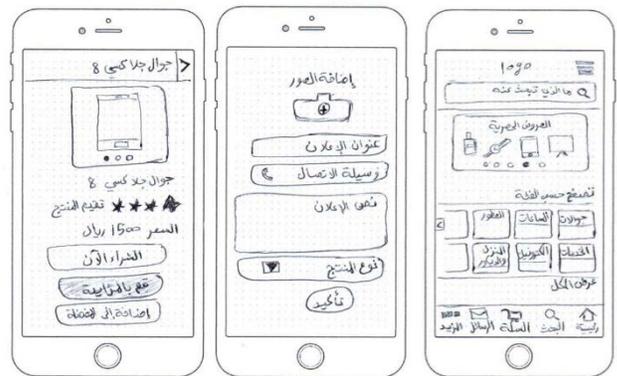

Fig. 5.   Early Prototypes of the Mobile Auction Concepts and App.

C. Mobile Auction Creation through Focus Group

Subsequently, we conducted three separate focus groups, including a total of 10 participants, to reflect on the mobile bidding requirements and early prototypes (depicted in Fig. 5). In each focus group, we mixed participants from different backgrounds and specialties to diversify the views and enrich the discussion. Focus groups are well-known methods for generating in-depth views and insights about the users' feelings and opinions about a particular technology [52].

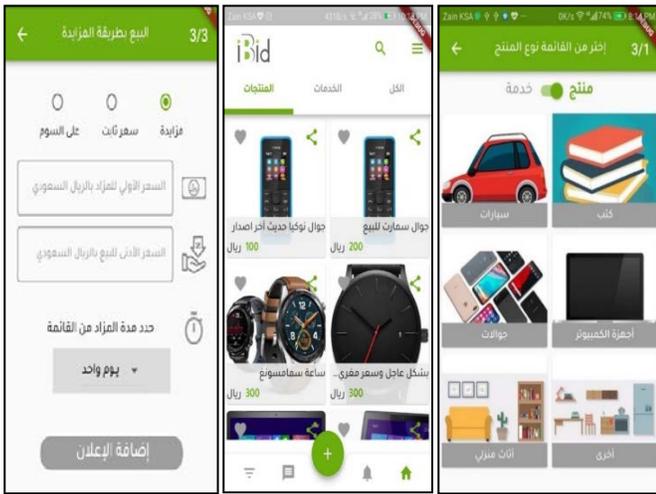
However, to achieve the highest level of engagement and communication with our participants, we created high-fidelity interactive artifacts, as shown in Fig. 6. This empowered us to realize principles three, four, and five of Brhel et al. [45]. As we kept continuously collecting feedback from the participants, we augmented our mobile bidding platform with new requirements. High-fidelity prototypes are interactive visuals that exhibit various real functionalities, such as navigation and information architecture, of the software at hand [53].


Fig. 6.   High-Fidelity Prototypes of the Mobile Bidding Concepts and App.

We applied consistent procedures in each focus group, where we first presented the idea of mobile auctions to the participants, followed by a discussion about their general impressions. Next, we presented the high-fidelity prototypes and tested various interactive functionalities to capture feedback from the participants. The results helped us hone the requirements and user interface designs of the iBid app. Overall, the focus groups gave rise to 33 new requirements, spanning the following concepts:

- RQ7. Social media sharing of products and services.

- RQ8. Consideration for culture-specific information, such as the gender.

- RQ9. Diverse payment methods, including E-payment systems.

- RQ10. Clarify of terms and conditions of auctions.

- RQ11. Measures to add trust factors, such as sellers' history and ratings.

- RQ 12. Preview products before committing to the auction.

- RQ13. Availability of a dispute process in case of auction frauds or complaints.

- RQ14. Logistic services to support the buying process (e.g., packaging and shipping).

D. Mobile Auction Implementation Decisions

Since we aimed to explore and promote online auctions using mobile devices, we first decided to create a mobile-friendly and cross-platform app. We selected robust and well-supported mobile development frameworks to expedite the implementation process. Moreover, our mobile bidding architecture implemented the three-tier client-server architecture [54], namely the presentation layer, business layer, and data management layer. E-bidders issue requests and events on the mobile interface, representing the presentation layer. The business logic layer is responsible for managing and executing the business processes and functionalities of the

bidding system. The data management layer handles product inventory, auctions, user profiles, and so on.

We used the Flutter framework [55] to develop the user interfaces of the aforementioned mobile bidding app (i.e., the presentation layer). Flutter is an open-source UI framework for creating high-performant native interfaces for Android and iOS applications. It offers plenty of ready-made and customizable widgets enabling fast development and production. Moreover, we used Google Firebase [56] to implement the business logic and database layers to achieve the architecture depicted in Fig. 7. There are several qualifying reasons for choosing Firebase. Firebase is a back-end-as-a-service web and mobile development framework, offering a wide range of functionalities, such as user authentication, real-time database, cloud storage, cloud functions and messaging, and ready-to-use API/HTTP requests, API/Authentication, among others.

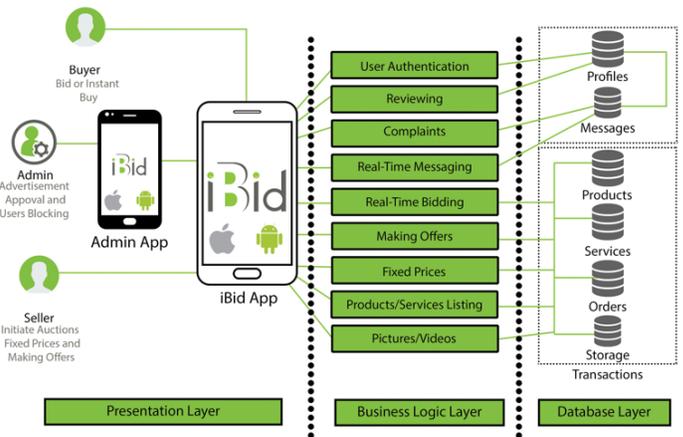

Fig. 7.   A Three Tier Architecture of our Mobile Auction App.

For the Database layer, NoSQL database [57] was preferred to store information about user profiles, messages, products and services, and orders and make them accessible through native mobile SDKs. The entities of these data were implemented in the Cloud Firestore Database, which empowers the creation of document databases that are stored as nested JSON objects. This choice was motivated by the fact that data are updated and synchronized in real-time to the devices of millions of connected clients, thus achieving the goal of real-time bidding. Moreover, Cloud Firestore Realtime Database enables scalability easily, which is critical to growing the concept of mobile bidding. Data are organized in the form of collections, where each collection contains a set of documents that can store simple or complex hierarchical data structures. Moreover, Cloud Firestore can protect and secure access to the data using Cloud Firestore security rules and firebase authentication.

E. Live Deployment of the Mobile Auction System

The primary API services and infrastructure for our live mobile auction system were implemented on Firebase, as shown in Fig. 8.

- Cloud Firestore: enables the real-time storage and access of auction collections (e.g., products, orders, etc.).

- Firebase Authentication: enables users (auctioneers and bidders) verification through a valid email and password.

- Cloud Storage: enables the storage of complex media such as videos and pictures.

- Real-time Database: enables the storage of real-time messages between the system's auctioneers and bidders.

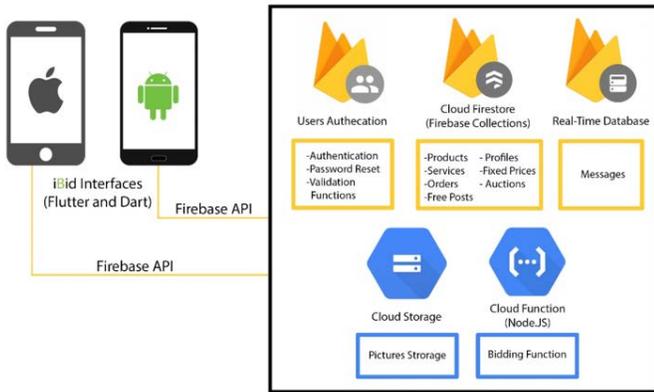

Fig. 8.   The Infrastructure of our iBid Mobile Auction App.

We deployed our bidding app on Google PlayStore to gauge users' real reactions and collect market-specific requirements. Within seven days, 103 real users downloaded our auction app (see Fig. 9). Next, we communicated directly to those registered users asking for feedback and suggestions upon their actual use of the iBid app, resulting in the below requirements:

- RQ15. Emphasis on allowing cash payment

- RQ16. Filter options to find specific products/services

- RQ17. Enforce user identities using phone numbers (e.g., OTP registration)

Fig. 9.   iBid App Installs during the Testing Period.

F. User Testing of the Mobile Auction App

In the subsequent phase of the UCASD methodology, we conducted an acceptance testing to confirm users' attitudes and perceptions toward the use of e-auctions using mobile phones. Therefore, we distributed an evaluation survey to the users who had installed and used our m-auction app. In total, 38 users responded to our survey. However, only 28 respondents

(approximately 73%) had actually used our app to bid for products and services. Therefore, we discarded the answers of the other ten users. The respondents rated the questions measuring their satisfaction with various aspects of mobile auctions. In doing so, they rated their agreement with the evaluation statements on a 5-point Likert scale, ranging from 1= strongly disagree to 5= strongly agree. In general, the rating questions assessed two main aspects; the first aspect is related to the usability of the mobile bidding app, and the second aspect is related to user acceptance and intention to continue using the app.

24 (85.71%) real users rated our mobile bidding app as 'easy to use' (4 or 5/5), while only two users disagreed (Fig. 10). 20 (71.42%) users agreed that 'learning to use iBid app is quick' (Fig. 11). On the other hand, 22 users (78.57%) disagreed that iBid app is cumbersome to use (Fig. 12).

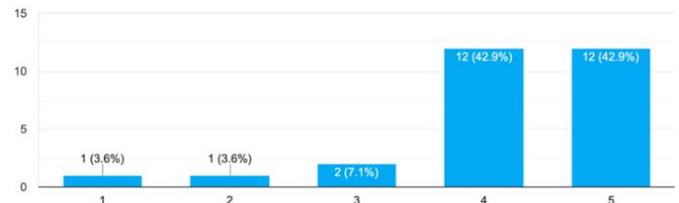

Fig. 10. Rating Distribution of: "iBid App is Easy to Use.".
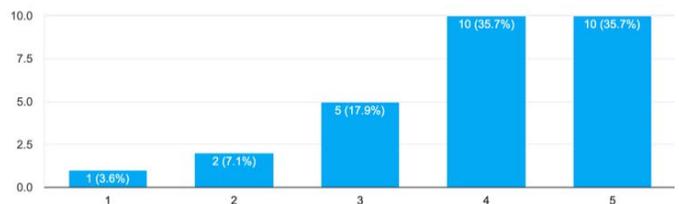

Fig. 11. Rating Distribution of: "Most Users will Learn to use iBid App Quickly.".
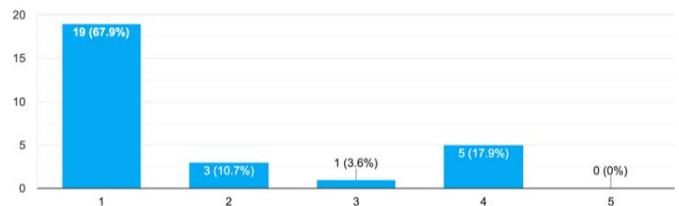

Fig. 12. Rating Distribution of: "iBid App is Cumbersome to Use.".

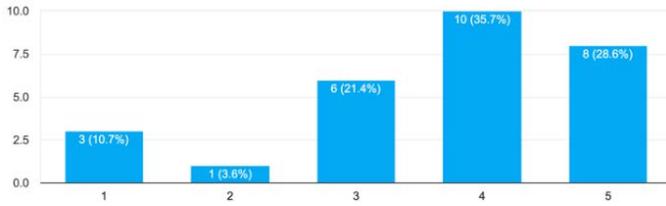
However, when it came to user intention to use mobile auctions, the ratings were quite encouraging. 19 (67.85%) users indicated their intention to use mobile bidding regularly, while only three users did not like the m-auction concept (Fig. 13). 18 (64.28%) users planned to reuse mobile auctions in the near future; however, five users did not show interest in auctioning again (Fig. 14). Approximately 20% of the respondents were neutral about the future use of m-auctions.


Fig. 13. Rating Distribution of: "I Intend to Use Mobile Auctions Regularly.".
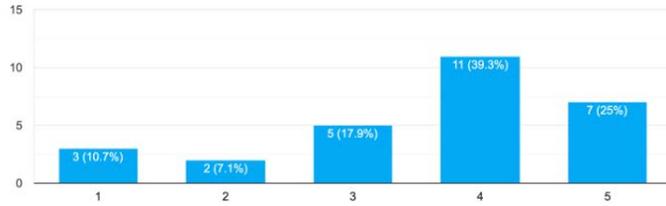

Fig. 14. Rating Distribution of: "I Plan to Reuse Mobile Auctions in the near Future.".

With respect to the qualitative feedback, we received a total of 46 positive comments and 20 negative comments from our users about the mobile bidding experience. We applied inductive thematic analysis [58] to identify potential m-auctions enabling drivers and deterrents. The emerging themes emphasized the following aspects:

- RQ24. Simplicity and aesthetics of bidding app
- RQ18. Time-constrained auctions
- RQ19. Transparency in showing sellers' details
- RQ20. Variety of products and services
- RQ21. Competitive pricing of offerings
- RQ22. Support of multi-languages (Internationalization of platform)
- RQ23. Platform quality and reliability (Free of glitches and errors)
- RQ24. Quality of products descriptions
- RQ25. Authenticity and seriousness of sellers
- RQ26. Consistency between product description and product received.

G. Card Sorting of m-Auction Requirements

In this phase, we applied card sorting to categorize the collected requirements into meaningful groups. Cart sorting is a well-tested technique used in user experience research to create a structured taxonomy of concepts [59]. We applied open card sorting (i.e., with no pre-determined groups) to establish a hierarchy of factors emerging from the UCASD activities. Fig. 15 depicts the final taxonomy of m-auctions requirements.

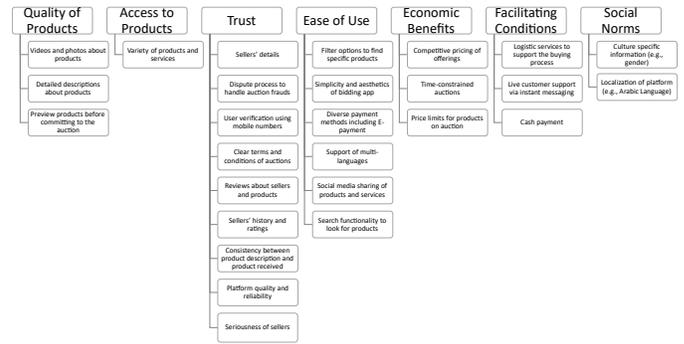

Fig. 15. Final Taxonomy of Mobile Auctions Requirements and Factors.

V. ENABLING AND INHIBITING FACTORS OF MOBILE AUCTIONS

Following the UCASD activities, we held three consecutive focus groups to establish an in-depth understanding of the factors that may influence consumers' acceptance of online mobile bidding in Saudi Arabia.

A. Focus Groups as a Means of Theory Formation

Qualitative research is adopted to develop theoretical explanations [60] that underpin users' attitudes toward mobile auctions. Focus groups are chosen as the method of exploration since they enable focused discussions with the selected participants on a particular topic [61], [62]. We organized three focus groups consecutively, where the outputs of one focus group were used to motivate the discussions of the next focus group. Overall, 22 undergraduate students participated in our focus groups (7, 8, and 7, respectively), with each focus group lasting approximately one hour and a half.

The focus groups' discussions were fully transcribed, and the data was anonymized and analyzed using thematic analysis. 156 high-level codes emerged, distributed across 28 major themes, as depicted in Table II. The comments are divided into enabling and inhibiting m-auction factors.

TABLE II. STATISTICS OF THE HIGH-LEVEL CODES AND THEMES EMERGING FROM THE FOCUS GROUPS

	Enabling	Inhibiting
High Level Codes	81	75
Themes	14	14

The below sub-sections summarize the classification of the key positive and negative factors that may impact the acceptance of mobile bidding by e-shoppers in Saudi Arabia.

B. Enablers of Mobile Auctions

The focus groups participants gave a total of 81 positive perceptions and 75 negative perceptions. These perceptions were classified into 13 critical factors: risk, quality of products, trust, ubiquity, usefulness, access to valuable products, ease of use, age, social influence, monetary costs, enjoyment, past experience, and facilitating conditions. Table III summarizes the key factors, themes, and occurrence percentage of each theme.

TABLE III.   THE PROMINENT FACTORS PERCEIVED TO INFLUENCE THE USE OF MOBILE AUCTIONS; PERCENTAGE OF POSITIVE (+) AND NEGATIVE (–) COMMENTS

Factor (%)	Themes	Positive (%)	Negative (%)
Risk (15.38%)	(-) Non-seriousness of bidders	-------	18.67%
	(-) Bid rigging and underpricing products and services	-------	5.33%
	(-) Non-eagerness of sellers	--------	6.67%
	(-) Monopolistic markets	-------	1.33%
Quality of Products (13.46%)	(+) Guarantees about products quality	6.17%	12%
	(-) Uncertainty about products quality		
	(+) Clear Information about products	8.64%	--------
Trust (12.82%)	(+)/(-) Trust of the platform and sellers	17.39%	5.33%
	(+) Sense of being secure using online transactional platforms	2.47%	--------
Ubiquity (12.18%)	(+) No geographic restrictions	12.36%	-------
	(+) Availability of auctions any time	3.70%	8%
	(-) Auctions are restricted to specified time windows		
Usefulness (9.62%)	(+) Functional benefits	11.07%	-------
	(+) Economic benefits	7.41%	-------
Access to Products (8.33%)	(+) Access to valuable products	12.28%	4%
	(-) Unavailability of products		
Ease of Use (7.69%)	(-) Technical issues	-------	8%
	(+) Easiness of communication	3.70%	-------
	(+) Easiness of bidding	3.70%	-------
Moderating factors (6.41%)	(-) Age	--------	10.67
	(+) Past experience using e-commerce platforms	2.47%	-------
Social Influence (5.13%)	(-) Community readiness and awareness	--------	8%
	(+) Marketing and advertisement	2.47%	--------
Monetary costs (5.13%)	(-) High prices	-------	8%
	(-) Platform commissions and charges	-------	2.67%
Enjoyment (3.21%)	(+) Experience of mobile auction	4.94%	-------
	(+) Excitement	1.23%	-------
Facilitating Conditions (0.64%)	(-) Slow delivery of products	-------	1.33%

Risk (15.38%): potential risk was perceived as the major concern during the use of mobile auctions by our participants. The fears were centered on the non-seriousness of auctioneers and bidders when committing to selling and buying decisions, bid rigging when merchandises are over-valued or under-valued by the platform users, and the monopolization of markets regarding specific products (see Table IV).

Quality of products (13.46%): participants indicated that the quality of products available in the auctions would highly influence their attitudes towards mobile bidding. The factors that determine their judgment include the availability of clear information about products (8.64%) and the guaranteed quality of the products (6.17%). However, concerns about the products' quality could be a major deterrent to indulging in bidding (12%), as shown in Table V.

Trust (12.82%): trust came out as the third important m-auction factor that our participants discussed. The high-level themes included trust of the auction platform and sellers

(22.61%) and the feeling of being secure using online systems because of the Corona pandemic (2.47%); see examples in Table VI.

TABLE IV.   EXAMPLES OF PARTICIPANTS' EXCERPTS ABOUT THE RISK FACTOR

Risk Themes (Frequency in Percent)	Evidence
(-) Non-seriousness of bidders (18.67%)	(-) Participant 2, Focus Group 3 " It is difficult to prevent interferences from bid/product owners." (-) Participant 3, Focus Group 2 " Many people don't participate on some mobile bidding websites because is impossible to enter a bid which goes with higher and higher prices so you might suspect that bidders are same people as sellers."
(-) Non-eagerness of sellers (6.67%)	(-) Participant 4, Focus Group 3 " The owner of the item cancels the sale." (-) Participant 2, Focus Group 2 " The seller's lack of seriousness by displaying pictures of the fake item, and when the sale is done, he does not send the item to you"
(-) Auction rigging and underpricing products and services (5.33%)	(-) Participant 3, Focus Group 3 " I guess bidder might don't give the product its fair price." (-) Participant 1, Focus Group 1 " Undervalued of goods that means you bid and give a lower price gives the commodity its value"
(-) Monopolistic markets (1.33%)	(-) Participant 6, Focus Group 1 " Actually, some applications provide a monopolized auctions on certain products." (-) Participant 2, Focus Group 3 " Some buyers buy all the quantity so once the bidding is over, they sell it at double its price"

TABLE V.   EXAMPLES OF PARTICIPANTS' EXCERPTS ABOUT THE PRODUCTS QUALITY FACTOR

Quality of Products Themes (Frequency in Percent)	Evidence
(+) Clear information about the products (8.64%)	(+) Participant 2, Focus Group 1 " A bidder can search on the Internet for the items that he is bidding on to learn more details about them on the web, where the person has a wide field to search for what is bidding on." (+) Participant 2, Focus Group 3 " Mobile bidding should provide a live show feature so that the seller can display his products clearly"
(-) Uncertainty about products quality (12%)	(-) Participant 5, Focus Group 3 " If I bid on a product, and once I got the product it appeared that it wasn't the same product, I mean it came out of with different specifications. How do I get my rights back? A solution to this point must be (product return guarantee)" (-) Participant 1, Focus Group 1 " If you are bidding on artifacts and goods, you don't know its exact specifications. It's best to inspect it personally so I feel there is less guarantee than the traditional bidding."
(+) Guarantees about products quality (6.17%)	(+) Participant 1, Focus Group 1 " Mobile bidding can provide a solution to this point (i.e., product return and guarantee); this will be the supporting factors to use the auction app." (+) Participant 4, Focus Group 3 " Sellers can also provide a warranty if the product, for example, has a defect. The whole process will be safe."

TABLE VI. EXAMPLES OF PARTICIPANTS' EXCERPTS ABOUT THE TRUST FACTOR

Trust Themes (Frequency)	Evidence
(+) Trust of the bidding platform and auctioneers (22.61%)	(+) Participant 6, Focus Group 3 " Through mobile auctions, you can register the seller's name so if you are confident in them, you can visit their shops and buy from them." (+) Participant 1, Focus Group 1 " I expect that a trusted party that can see the product and inspect what its defects are, and present it to us." (-) Participant 6, Focus Group 3 " Because what is happening now is that there are many biddings mobile applications that you feel it's kind of a fraud and manipulation." (-) Participant 1, Focus Group 1 "Online auction sites sometimes contain scam sellers"
(+) Feeling of being secure (2.47%)	(+) Participant 2, Focus Group 1 " If you want to spread the culture of electronic bidding, this is the best time. This is the right time, especially after the Corona pandemic people will feel secure right now." (+) Participant 6, Focus Group 1 " It will succeed especially after the current crisis in Corona, people feel more secure delaying with online transactions, there is no longer this freedom of movement"

Ubiquity (12.18%): participants' views were appreciative concerning the time and location freedom auctioneers, and bidders enjoy while using mobile auctions. The critical themes under ubiquity were no geographic barriers (12.36%) and availability of bidding all the time (3.7%). However, participants were worried about the timed auctions (8%), which could only make commodities available for certain time frames (see Table VII). In other words, mobile auctions must be available 'anytime from anywhere'.

TABLE VII. EXAMPLES OF PARTICIPANTS' EXCERPTS ABOUT THE UBIQUITY FACTOR

Ubiquity Themes (Frequency in Percent)	Evidence
(+) No geographic restrictions (12.36%)	(+) Participant 4, Focus Group 3: " It is great there is no compulsion about the geographic location; a person in one country can bid in an auction in another country, as it is considered as facilitating the bidding process. "
(-) Limited to specific times (8%)	(-) Participant 5, Focus Group 3 " I think mobile bidding is almost limited at a certain time, so it is not flexible like the traditional bidding." (-) Participant 1, Focus Group 1 " The time difference might be a problem imagine if the commodity is offered in faraway country, and you are bidding on it in your country."
(+) Availability of auctions any time (3.7%)	(+) Participant 2, Focus Group 1: "Facilitates meeting of buyers and sellers, it is possible to save time and effort, for seller and buyer there are no time obstacles." (+) Participant 1, Focus Group 1: " The auctions should be long and continuous. It does not stop, that means it should be available 24 hours."

Usefulness (9.62%): our participants emphasized that indulging in mobile auctions is motivated by two benefits: functional and economical. Examples of functional gains include convenience and saving time and effort. However, economic gains often refer to cost savings through bidding

activities. References were made mainly to the competitive pricing strategies that auctioneers set to win new bidders for their goods and services. See participants' comments in Table VIII.

TABLE VIII. EXAMPLES OF PARTICIPANTS' EXCERPTS ABOUT THE USEFULNESS FACTOR

Usefulness Themes (Frequency in Percent)	Evidence
(+) Functional benefits (11.07%)	(+) Participant 2, Focus Group 1 " You can do the bidding while you are relaxed at your home." (+) Participant 1, Focus Group 1 " Mobile bidding is a fascinating idea to bid on products and save your time and effort"
(+) Economic benefits (7.41%)	(+) Participant 7, Focus Group 3 " With mobile bidding you can buy the goods you want. For example, a specific device, you can get it used for a cheaper price." (+) Participant 6, Focus Group 3 " You also can find special prices I mean like special offers."

Access to products (9.88%): participants highlighted that m-auctions would enjoy a wider acceptance if they were to provide access to unique and rare merchandise, as demonstrated in Table IX. However, they should also act as a marketplace for other regular products (4%).

TABLE IX. EXAMPLES OF PARTICIPANTS' EXCERPTS ABOUT ACCESS TO PRODUCTS FACTOR

Access to Products Themes (Frequency in Percent)	Evidence
(+) Access to valuable products (9.88%)	(+) Participant 4, Focus Group 2 " If you want to buy from online mobile auctions, you must find a rare product or something special you need that is not available in the market." (+) Participant 5, Focus Group 1 " There is a possibility of finding a competition, but it will be for certain rare products."
(-) Unavailability of Products (4%)	(-) Participant 3, Focus Group 3 " There is no bidding mobile application that provides you with all the products that you may need it.

Ease of use (7.69%): 'ease of use' fared into the middle of the table with respect to frequency of occurrence, but it was still perceived to impact intentions to use m-auctions. The themes of ease of use included ease of communication (3.7%) and simplicity of the bidding process (3.7%). Moreover, the platform should have no technical failures and glitches (8%). In other words, the auction platform should be technically sound and reliable, as shown in Table X.

Control factors (6.41%): first, participants were quite doubtful that mobile auctions are suitable for the aging population (10.67%); second, there were indications that prior experience using e-commerce and transactional platforms would encourage users to place bids (2.47%), as listed in Table XI.

Social influence (5.13%): social influence, in the form of marketing, was expected to have a mass effect on the adoption of mobile bidding positively. As demonstrated in Table XII, there is an absolute necessity to improve awareness to ensure that society is ready to accept the concept (8%).

TABLE X.   EXAMPLES OF PARTICIPANTS' EXCERPTS ABOUT THE EASE OF USE FACTOR

Ease of Use Themes (Frequency in Percent)	Evidence
(-) Technical issues (8%)	(-) Participant 6, Focus Group 3 " Technical reasons, because the site might be out of service and the product bidding available only for a short time." (-) Participant 4, Focus Group 2 " There might be some problems with the mobile application which prevent some users from bidding in a timely manner"
(+) Easiness of communication (3.7%)	(+) Participant 1, Focus Group 3 " Of course, there will be a certain number of sellers and buyers. The buyer can browse hundreds of items at the same time and communicate with their sellers through the app." (+) Participant 3, Focus Group 1 " the platform will provide easy communication between the seller and buyer"
(+) Easiness of bidding (3.7%)	(+) Participant 6, Focus Group 2 " I tried an online biding auction, I found it ease without any difficulties." (+) Participant 2, Focus Group 13" The mobile biding application must have a button to go back and unbid if I have done a mistaken biding"

TABLE XI.   EXAMPLES OF PARTICIPANTS' EXCERPTS ABOUT THE AGE AND PAST EXPERIENCE FACTORS

Themes (Frequency in Percent)	Evidence
Age (10.67%)	(-) Participant 2, Focus Group 3 "Older people do not prefer to use mobile bidding. Older people prefer to go by themselves to the site and see the product for themselves." (-) Participant 5, Focus Group 2 " The elderly are very important part of our communities. How you can communicate with the elderly when they do not have a broad background in technology:"
(+) Past Experience (2.47%)	(+) Participant 2, Focus Group 1 "I can say that this is the right time, 85 percent of population have a background in electronic auctions." (+) Participant 3, Focus Group 1 "These days most people are using electronic ways of selling and buying"

TABLE XII.   EXAMPLES OF PARTICIPANTS' EXCERPTS ABOUT THE SOCIAL INFLUENCE FACTOR

Social Influence Themes (Frequency in Percent)	Evidence
(-) Community readiness and awareness (8%)	(-) Participant 6, Focus Group 3 "I guess people here in Saudi Arabia are not comfortable with mobile bidding, so we need to raise awareness about the concept of electronic bidding in general." (-) Participant 4, Focus Group 1 "Some communities don't have experience in electronic bidding. Individuals must be educated so they understand the electronic bidding process"
(+) Marketing and advertisement (2.47%)	(+) Participant 7, Focus Group 3 " It is necessary to intensify the advertisement about m-auctions in the targeted areas." (+) Participant 2, Focus Group 2 " The platform for mobile bidding must be free and offer gifts; Also, advertisement must be extensive about the concept."

Monetary costs (5.13%): concerns were raised about setting high prices in certain auctions and any platform charges, as exemplified in Table XIII.

TABLE XIII.   EXAMPLES OF PARTICIPANTS' EXCERPTS ABOUT THE MONETARY COSTS FACTOR

Monetary Costs Themes (Frequency in Percent)	Evidence
(-) High Prices (8%)	(-) Participant 6, Focus Group 2 " Sometimes in an auction the seller says this product, for example, starts from 100 riyals. Many buyers say we won't participate and withdraw from the auction." (-) Participant 2, Focus Group 1 " Celebrities can use these mobile bidding and the prices go high because of them and their fans."
(-) Platform commission (2.67%)	(-) Participant 4, Focus Group 3 " The commission must be at a symbolic price." (-) Participant 5, Focus Group 1 " The owner of the product might delay or even hesitate to display their goods because the platform raises the commission price"

Enjoyment (3.21%): one interesting motif, albeit infrequent, for e-shoppers to carry out m-auction was perceived enjoyment. The themes under enjoyment included the sense of excitement and auction experiences, as shown in Table XIV.

TABLE XIV.   EXAMPLES OF PARTICIPANTS' EXCERPTS ABOUT THE ENJOYMENT FACTOR

Enjoyment Themes (Frequency in Percent)	Evidence
(+) Experience of mobile auction (4.94%)	(+) Participant 2, Focus Group 1 " I want to try it after the current crisis of covid-19; there is no longer freedom of movement." (+) Participant 3, Focus Group 2 " We can go to the physical environment of such auctions; we can go to auctions and ask the bidders to see how they carry out the bidding"
(+) Excitement (1.23%)	(+) Participant 6, Focus Group 3 " I had seen this live bidding before which was on precious stones, and the situation was in which there was a competition and enthusiasm among bidders."

Facilitating conditions (0.64%): lastly the participants mentioned some comments about the logistic services supporting the after-sale activities (e.g., delivery) which could impact mobile auctions, as stated in Table XV.

TABLE XV.   EXAMPLES OF PARTICIPANTS' EXCERPTS ABOUT THE FACILITATING CONDITIONS FACTOR

Facilitating Conditions Themes (Frequency in Percent)	Evidence
(-) Slow delivery of products (1.33%)	(-) Participant 6, Focus Group 3 " I believe that a slow delivery of goods will be the main challenge in using the mobile bidding application."

VI.   DISCUSSION, PRACTICAL IMPLICATIONS, AND LIMITATIONS

To the best of our knowledge, our research is the first work to quest for the enablers and deterrents of using mobile auctions in Saudi Arabia. Two reasons inspired the selection of

this topic. First, despite the recent e-commerce boom and high user penetration, the adoption of online auctions is almost non-existent in the Saudi e-commerce market. Second, the online global auction industry is expanding year-on-year, with an estimated 7.2% yearly growth [4]. As such, the findings of our studies offer a foundational comprehension of the current attitudes and practices of Saudi auctioneers and bidders.

When coupled with user-centered design, agile development of software helps achieve numerous benefits [45] [63] In our case, the adoption of the User-Centered Agile Software Development (UCASD) empowered us to build a user-driven mobile application through a series of quick improvement cycles. The emerging design features were gathered from potential users (i.e., user-centered philosophy) and added to the m-auction platform in an incremental fashion (i.e., agile practices), thus reducing user frustration and improving customer traction. We demonstrate the procedures we followed and the lessons from applying UCASD. We were able to develop a user-validated m-auction platform since our design decisions were mainly based on user research. To this end, our focus was not to develop a feature-rich application but rather to create an excellent user experience by keeping our users at the center of the design and development activities. On another positive aspect, the short design iterations enabled us to tackle the tangible issues early, identify new relevant requirements, and quickly produce a functional mobile application to gauge users' attitudes toward mobile auctions. Another strong aspect of our research is the delivery and deployment of mobile bidding in the real world, where real bidders used the mobile platform and provided valuable feedback.

The use of UCASD, albeit beneficial in multiple ways [64], has caused us several challenges. We enumerate and suggest ways to remedy these challenges. The first challenge we faced was to fit usability studies, which typically take a long time, within quick development cycles. The second challenge was to accommodate some of the conflicting principles of UCD and agile development (e.g., up-front user research in UCD vs. reduction of up-front planning to produce working software in agile quickly). We found that building flexible team compositions, containing the necessary design, development, and testing skills, helped to minimize this challenge. We devised a cross-functional team to work on different tasks and processes, with the possibility of re-location if required. Using an online survey enabled us to reach a vast number of users within a short time, thus reducing up-front planning activities. We also found that considering user experience from the start of the project helps incorporate user views. Moreover, we had to adapt the complexity of our user-centered design activities to accommodate the agile sprints. In this sense, we shortened the usability studies and conducted them with fewer participants. We also employed low-fidelity prototyping to engage our users in a cost-effective manner. Finally, we found that planning our reasonably timed sprints (4/5 weeks) to embed design, implementation, and usability testing activities quite fruitful.

Now let us attempt to answer the main question of our research; why does Saudi Arabia, despite its recent major digital transformations, still lags regarding the use of online mobile auctions? The acceptance of new technologies is well-known to be triggered by the existence and amalgamation of several factors [65][66]. Our research is no exception. The qualitative inspection of a new phenomenon (e.g., the use of emerging technologies) is advocated by several studies [67][68]. Applying an inductive approach in our research, 13 distinct factors emerged as the key determinants of mobile bidding activities in Saudi Arabia (see Fig. 16).

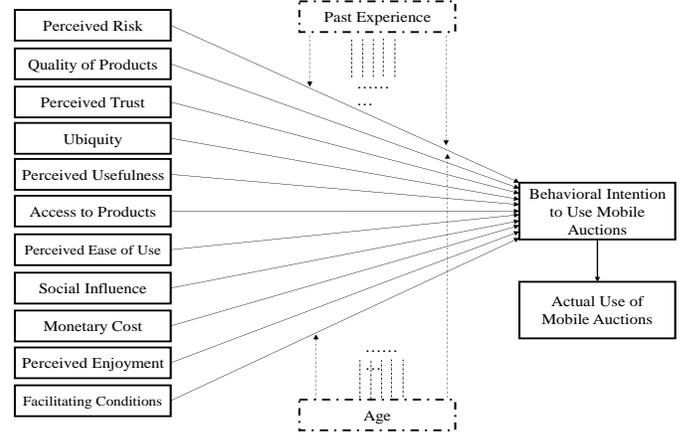

Fig. 16. Preliminary Online Mobile Auctions Technology Acceptance Model. Dashed Rectangles Represent the Moderating Factors, Which Influence all other Factors (Listed on Left Hand Side).

Perceived risk and trust were the dominant m-auction themes from our qualitative inspection, accounting for nearly a third (28.2%) of the concerns. Bidders were particularly worried about the genuineness of sellers, potential frauds, and auction rigging during the live mobile auctions, among other fears. Our findings are in line with the previous claims. For instance, Xu et al., demonstrated that perceived risk impacts the buyer's intentions to participate and engage in online consumer-to-consumer buy-it-now auctions [69]. Perceived risk, in return, was influenced by the buyer's risk attitude, the seller online reputation, and the product's price and type. Gull et al. showed that online shoppers are still concerned about their security in Saudi Arabia [70]. A recent laboratory study demonstrated that shill bidding remains a serious threat in mobile auction platforms [71].

The quality of products was the second most important factor to our participants in the bidding decision-making process. According to our bidders, products' quality is determined by clear information and specifications that reduce any uncertainties about the business deal. In a recent study, the authors investigated the behavior of bidders in mystery auctions where products' information was purposefully concealed [72]. The results showed that if information about the products' quality has not been provided, the seller's reputation will be greatly influenced. Moreover, when products' quality is unclear, reputation becomes more influential on the trustworthiness of the auctioneers.

Ubiquity refers to the property of being available anytime and anywhere. This is probably a natural factor to emerge as smartphones are characterized by their availability and mobility. Participants valued the possibility of making bids without geographic or time restrictions. Previous works back our findings [73], where ubiquity was found to be a significant

predictor of attitudes toward mobile payment services in Korea.

Perceived usefulness, represented by functional and economic gains, stood out as an influential factor in making online mobile bids. This is no surprise since usefulness has been a foundational construct in almost all types of technology acceptance models [74][75].

Similarly, when Vadovič explored Internet bidding behavior using dynamic auction settings, results showed that bidders with presumably higher search costs tend to offer a higher bid to secure the product [76]. In other words, bidders who are allowed to search for prices during the bidding process from other e-commerce websites are more likely to submit higher bids since they can assure of economic gains.

Interestingly, age and prior experience were discussed in our research to impact consumers' intention to conduct mobile bidding. Other e-commerce studies also found demographic characteristics (i.e., age) to have a moderating effect on technology acceptance [77][78]. However, Hernández et al., found that socioeconomic variables, such as age, gender, and income, do not alter e-commerce shopping intentions in developed countries [79]. Such observations are worth investigating in follow-up studies. Other constructs that arose in our studies include ease of using the mobile bidding platform, social influence, monetary costs, and enjoyment of m-auction activities. Once again, these factors are supported by several studies [80][81][82].

The implications of our results are both theoretical and practical. Theoretically, we developed a solid understanding of the factors that could encourage or inhibit the adoption of mobile auctions in Saudi Arabia. Our evidence-based factors, which were identified through several studies, represent the cornerstone for creating a technology acceptance model for live mobile auctions. The demonstration of applying the user-centered agile development will serve as a roadmap for practitioners and startup companies. Practically, we accumulated a set of m-auction requirements for e-commerce companies that might be interested in embedding bidding processes into their mobile platforms.

Our findings are indeed interesting and, we hope, will pave the way for further research about mobile auctions in developing countries. However, we would like to highlight a few limitations in this research that could restrict the validity of our observations, as follows.

The use of qualitative research empowered us to investigate consumers' behavior and probe their opinions and decision-making in detail; however, our interpretation of the themes and factors impacting mobile auctions might have been influenced by our subjective views. To reduce this bias, we checked the data analysis and themes' classification multiple times by four researchers to ensure the inter-rater reliability and accuracy of our analysis. However, there is also a likelihood that we might have missed some factors or misclassified some comments. Moreover, this type of research does not empower us to draw any causal relationships between the potential factors of m-auctions. More studies need to be conducted to verify any hypothesized relationships.

We used convenience sampling [83] to recruit participants in our user-centered design activities. This type of non-probabilistic sampling technique is subjective and, therefore, may not be representative of the intended population. It is, however, an effective approach when the research is restricted with respect to time and resources. Most of our participants were students, aged between 18 and 30 years, with a good technical background. Our sample lacked representative of elderly users. Moreover, our target group might have different characteristics, views, and behavior. We studied the e-shoppers' reactions to m-auctions in Saudi Arabia. Thus, our findings should be cautiously generalized to other user groups and MENA countries.

VII. CONCLUDING REMARKS AND FUTURE WORKS

We demonstrated the effectiveness of developing an interactive mobile auction platform through the application of a multi-phased User-Centered Agile Software Development (UCADS) methodology. 454 potential users participated in our mixed research studies, including an online survey, focus groups, prototyping, and user testing. Consequently, a taxonomy of the key mobile bidding requirements is presented. Integrating user-centered design and agile development principles showed that Saudi e-shoppers are ready to embrace mobile bidding activities. However, our follow-up qualitative studies identified 13 prominent factors that might impact consumers' intention to accept mobile auctions in Saudi Arabia. These enabling factors include trust, risk, usefulness, ubiquity, monetary costs, ease of use, merchandise information quality, access to valuable merchandise, enjoyment, social influence, facilitating conditions, age, and past experience. We recommend that these factors merit a profound investigation in upcoming confirmatory studies.

In the future, we plan to propose and test a mobile auction technology acceptance model for the MENA region. Our factors, coupled with evidence from current e-auction research works, will assist in establishing sound mobile auction hypotheses. Moreover, we intend to conduct a cross-sectional study to ensure the validity of the model in other developing countries that currently exhibit similar characteristics (e.g., Emirates, Malaysia, etc.).

Hieu Le Van, Nghia Huynh Huu, Tran Nguyen Huyen, Loc Van Cao Phu, Duy Nguyen Truong Quoc,
Bang Le Khanh, Kiet Le Tuan
FPT University, Can Tho City, Viet Nam

Abstract— The role of the testing process cannot be denied in the diagnosis and treatment of patients' diseases in medical facilities today. The results from this process help doctors and nurses in medical centers make a preliminary and detailed assessment of symptoms and provide a specific course of treatment for their patients. In addition, these results are stored as a patient's medical record that serves as a reference for subsequent therapies. However, the storage of this information (i.e., paper-based, electronic-based) faces some difficulties for both approaches. Especially for developing countries (i.e., Vietnam), this process encounters some major obstacles at health centers in rural areas. Many centralized/decentralized storage methods have been proposed to solve the above problem. Besides, the current popular method is patient-centered (all information shared is decided by the patient) can solve the above problems and be applied by many research directions. However, these methods require the user (i.e., patient) to have a background in security and privacy as well as the cutting-edge technologies installed on their phones. This is extremely difficult to apply in rural areas in developing countries where people are not yet conscious of protecting their personal information. This paper proposes a mechanism for storing and managing test results of patients at medical centers based on blockchain technology - applicable to developing countries. We build a proof-of-concept based on the Hyperledger Fabric platform and exploit the Hyperledger Caliper to evaluate a variety of scenarios related to system performance (i.e., create, query, and update).

Keywords—*Blockchain-based system; hyperledger fabric; medical test results; medical institution at developing countries*

I. INTRODUCTION

All current treatments are based on the results of the clinical examination/test of the patient's symptoms and medical history. Indeed, doctors and nurses give their diagnosis about the patient's condition (i.e., consultation) and treatment. In other words, the testing process plays an extremely important role in the entire treatment of the patient [1]. In addition, these test results are recorded to build the patient's medical history. Nurses and doctors have a more general view of symptoms from early (i.e., first detected) to the current stage.

However, the storage of medical test results varies widely depending on the region (i.e., city or rural) and the country (i.e., developed or developing). Most hospitals in large cities and or in developed countries, adopt electronic records to store medical test results and patient medical records (aka electronic-based). While rural hospitals or some hospitals in developing countries still use paper records (aka paper-based). Paper records are extremely risky for the healthcare system because i) it is easy for patients to lose the medical test records

due to natural issues (e.g., flood, fire) or their failure (e.g., lost); ii) it is very difficult to back up those results because of technology and equipment limitations [2]. Due to these risks, some patients often take pictures of the medical test results to give to doctors for their next visit. For the recent model, almost all hospitals or medical centers in Vietnam applied manual input for the medical test record (see III-A for more details). Besides, determining timelines based on this approach is extremely difficult. For example, in addition to taking pictures, the patient must annotate all information related to those photos. Nevertheless, this method also carries risks, as loss of the device or memory card/memory limitations are the main barriers to this approach [3].

A study that collected patient responses to interviews about the role of using paper and electronic records was conducted by [4]. Their findings clearly indicate that electronic records are considered more reliable than paper records. Specifically, about 51% of interviewees indicated that they are less burdened in preserving paper records, and in case of loss of their records, they have to tell all their medical records to all. hospitals they visit if using paper records. An interesting finding of the author is that patients are willing to spend extra money each month to keep their health records in electronic form. In addition to the above reasons, the study by Muchangi and Nzuki [5] conducted a survey in medical centers in developing countries (i.e., India) that showed that patients did not trust the treatment. Using electronic records will reduce the risk of privacy invasion. They argue that the methods of building a user-centric health data sharing system are facing a lot of difficulties due to the limitations of the method of building a centralized data system (i.e., data) stored and processed centrally in cloud servers).

The risks that such systems may face come from unintended events such as natural disasters, fires or possible attacks by hackers to exploit sensitive patient information. For the first risk, studies[1] have shown that lost health information must be recreated, requiring in-depth time and resources. Because critical data such as patient health must require an electronic record using secure information systems to store and access patient health information and to ensure that the information contained updated and available when needed [2]. In addition, being attacked by hackers is inevitable. These hackers take advantage of existing security holes from the system to get personal information of patients and use them for purposes of violating privacy (e.g., selling personal information) [6]. It is impossible to recover stolen information. We can only find ways to overcome the current risks (i.e., centralized storage).

---

[1]https://www.hl7.org/FHIR/

The transition from centralized to decentralized medical data processing storage brings a lot of risks as well as benefits [7]. Nghia et al. [8] has argued that the challenges may outweigh the benefits, such as scalability, availability, data transparency (i.e., for the field). building systems on Blockchain), as well as giving more rights to users. Specifically, the authors argue that users can see who is working on their data and what benefits they have.

For the second approach (i.e., applying electronic record method to store patient information), in large cities in developing countries (e.g., Vietnam) archival methods are only centrally stored on a server of a center or a hospital in big cities (e.g., Ho Chi Minh City, Can Tho). Therefore, patients face a great challenge when they want to share medical data (i.e., test results, medical history) from previous facilities to the new facility [9]. Centralized data processing and storage systems exhibit at least one of the following disadvantages: instability due to a faulty central point, lack of security due to greater vulnerability, and greater potential for malicious attacks (i.e., unethical activities) due to the presence of central authority [10]. In contrast, the decentralized system has no central authority; instead, permissions are shared between each computer (node), each with equal permissions [11]. Instead of all processing and storage requirements being centralized in a central machine (i.e., cloud server), the distributed system divides computations into smaller computations to be performed by multiple nodes as well as storing the collected data in many different memory areas [12]. Thereby, increasing the processing and storage capacity for the whole system. This also increases interaction with users (i.e., patients, nurses, doctors) and reduces the risk of attacks from hackers because of the lack of a central point to attack [13]. This feature also makes them stable and fault tolerant since each node has the same role (i.e., regardless of Client-Server); thereby, privacy-invading operations are unlikely to be performed [14]. The peer-to-peer system uses these features and benefits to allow the network to remain fully operational even if one node fails.

In addition, because of the requirements for supporting equipment and supplies, the current testing procedures are all done in hospitals or medical centers (i.e., it is difficult to meet a large number of requests. patient testing at the same time). Patients have to wait a long time for testing and consultation results before their disease can be identified. Therefore, there is a need for a mechanism to support patients in storing and sharing medical records (e.g., test results, medical history) as well as limiting waiting time for results at centers. medical center. Besides, security and privacy issues depend greatly on the context in which the system is deployed. For example, in developing countries (i.e., Vietnam), exploitation and risk assessment and privacy have not been given due attention [15]. The developing countries' citizen do not have the concept of protecting personal privacy (especially countryside people). This argument is completely correct and can be applied to developed countries, where the education level is high and there are many supporting facilities and infrastructure.

To solve the problems mentioned above, this paper proposes a medical test result management model based on blockchain technology. Methods to prove the effectiveness of applying Blockchain technology to medical facilities to solve problems related to supply chain (e.g., blood and its produces [16], [17]) curative problem (e.g., emergency data assessment) that current health care systems have not fully addressed. Another example demonstrating the effectiveness of applying the strengths of Blockchain technology and patient care is introduced by Roehrs et al. [18]. Specifically, they emphasized non-functional requirements such as network usage, disk space, response time, CPU usage, and memory footprint, and their importance in implementing a pool management system. Health records based on blockchain technology. They evaluated the performance of both systems (i.e., traditional archiving system and blockchain-based storage system) by deploying two models on two hospital databases (i.e., 40,000 patients) adult person). Analyzing the results obtained, they concluded that the results achieved were much more effective than traditional practices in maintaining integrity, security, ownership, and decentralization. Various technologies can be used to create patient-centered healthcare systems where blockchain-based approaches provide a single solution [19]. Specifically, Blockchain uses features (security, stability, fault tolerance) to allow a network to remain fully functional even if a node fails [20]. However, these approaches (listed in the II section) suffer from many user-related (i.e., patient) limitations, which are highlighted in the Prior Work section.

Therefore, the research problem of this article is to introduce the blockchain-based approach for medical test result management used for developing countries (i.e., Vietnam) For the objective of this article, our contribution is threefold: i) proposing a model for managing test results for patients in developing countries (i.e., Vietnam); ii) building a proof-of-concept based on the proposed model via Hyperledger Fabric satisfying the specific properties of the regions/applicable areas; and iii) evaluate the system's capabilities based on how well it supports initialization, retrieval, and update requests (i.e., overall rating based on system performance - number of successful and failed requests; system-wide latency) based on exploiting Hyperledger Caliper.

The next section presents the state-of-the-art. Sections III and IV present our approach, processing model, and system implementation. Section V builds an environment for evaluating proposed models and makes comments on their strengths and weaknesses as well as future directions in Section VI. Finally, we summarize the study in Section VII.

II. RELATED WORK

There are many approaches that have proposed methods for remote diagnosis and treatment of diseases, which are data mining and other practical applications based on medical data by exploiting the strengths of the blockchain technology. For example, Chen et al. [21] proposes a model for storing and controlling personal data in a healthcare environment based on Blockchain technology. This system can collect information from IoT devices (i.e., medical devices in real time). To improve the security of the system, the authors build an anonymous data sharing environment and encrypt the patient's personal data before storing them on cloud servers. Similarly, Du et al. [22] and Son et al. [23] used medical centers (i.e., hospitals) to store data and manage access and those hospitals. Specifically, they categorize two types of medical data protection policies: global for all data shared outside

of the medical center, and local, which is accessed only by individuals at the medical center. medical (i.e., doctor, nurse).

However, one of the major limitations is that through this solution, patients do not have full control over their data as the data and policies are stored in the hospital. Patra et al. [24] proposes a cloud-based model to build an information system at the national level, providing a more convenient solution for patients in rural areas at the lowest cost. Specifically, instead of having to go to health care centers in large companies, they propose a solution to diagnose and treat diseases remotely. Specifically, citizens are encouraged to provide their personal healthcare information, which will be stored in the health cloud and accessed by health professionals and policymakers to provide more medical services. Similarly, Rolim et al. [25] proposes a framework that covers the process from data collection to cloud-based data delivery. Using sensors mounted on medical equipment, data can be collected and stored directly in the cloud, which can be accessed by authorized medical professionals.

Some other approaches build a user-centric (i.e., patient) model, who has full discretion to share their personal data with providers/health care facilities. economic (i.e., in a medical setting). For example, Makubalo et al. [26] has summarized the above approaches in their publication. They argue that the methods of building a user-centric health data sharing system are facing a lot of difficulties due to the limitations of the method of building centralized data system (i.e., data) stored and processed centrally in cloud servers). Yin et al. [27] introduced a patient-centric system built in the cloud with a data collection layer, data management layer, and medical service delivery layer based on medical records of the patient. To protect data privacy, many approaches have adopted attribute-based encryption (ABE), one of the most common encryption schemes used in cloud computing, to define patient data object. Depending on the context, the policy tells to lose (or not) grant the corresponding access rights. For example, Barua et al. [28] proposes an ABE-based access control model based on patience and privacy protection; Chen et al. [29] described a new framework with a cloud-based, privacy-aware Role-Based Access Control model that can be used for control, data traceability, and access allowed access to healthcare data resources. Methods for applying the Access Control model are also introduced for dynamic policies [30], [31] or protection policies for both security and privacy [32].

In addition, Madine et al. [33] has introduced a Smart Contract-based system that provides patients with reliable, traceable and secure control over their medical data (i.e., which is stored non-invasively). concentrate). To increase the security and privacy of medical data, they used the decentralized storage feature of the interplanetary file system (IPFS) to store and share patient medical data safely. For practical applications, HealthBank has proposed a healthcare system and surrounding ecosystems that allow users (i.e., patients) to manage and control their data.[2] This solution is recommended to be able to comply with strict security and privacy regulations (e.g., GDPR) and to assist users in using their services. In addition, the system also proposes solutions for storing personal data with complex data encryption algorithms, immutability and

accountability. Similarly, HealthNautica and Factom Announce Partnership have used blockchain technology to ensure the integrity of patient medical data while providing transparency based on blockchain technology and encryption of sensitive data (e.g., personal information, health status).[3]

With the same approach based on Blockchain technology and IPFS, Misbhauddin et al. [34] introduced the MedAccess platform, A Scalable Architecture for Blockchain-based Health Record Management. The platform supports on-chain storage and processing allowing doctors, lab technicians and patients to securely manage medical records. However, these systems face some problems in the processing and storage of personal data. Specifically, Le et al. [35] has argued that not all data collected must be processed on-chain. Instead, Son et al. [2] argues that personal data that is either not directly related to treatment or diagnosis may be stored off-chain (i.e., offchain). Similar to the above approach, to increase the processing capacity for the whole system, Zyskind et al. [36] presented an approach based on in-chain and out-of-chain processing. Onchain processes require all entities of a typical personnel management system, where patient and medical staff information is stored; in contrast, encrypted medical data is stored on a separate centralized storage server to enable faster access and low cost. However, the above methods have major limitations, including that any information that is validated must be executed on-chain instead of local processing. This only benefits storage but does not change data handling (i.e., since all information still executes on-chain) [17].

To solve the on-chain storage problem, Zhang et al. [37] have proposed FHIRChain (Fast Healthcare Interoperability Resources), a blockchain-based system that allows patients to securely share their clinical data in a medical setting. For this approach, users are allowed to share their personal data directly with hospitals and medical centers instead of having all their personal information stored directly on the banana. Another approach suggested by Patel et al. [38] has empowered hospitals to be the creators of medical records and patients to be owners of their records. In this approach, all medical data processing and updating are done off-chain (e.g., medical record sharing, and all query requests to patient data). In addition, the issue of threading while exporting medical data is also very important because data stored on the same system can be accessed by a malicious user on the same system [39], [14]. Therefore, Iryo is introduced as a healthcare ecosystem that uses blockchain technology to decentralize access to medical records.[4] Specifically, it uses the NuCypher KMS key management system (i.e., [40]) to address the limitations of adopting the peer2peer model for storing and executing on encrypted data. Also adopting an advanced cryptographic-based approach and blockchain technology, Chen et al. [41] proposed a system that only stores the searchable index of records on the blockchain. The patient information is organized as Key-Value. Where "key" contains records presented as hash (i.e., reduced index) while actual patient data (i.e., "value") is encrypted and stored on a public cloud server.

Tith et al. [42] proposed a system based on blockchain technology to ensure privacy, scalability, and availability of

[4]$https://iryo.network/iryo_whitepaper.pdf$

patient data in the medical environment combined with data encryption methods. patient data using the public key. It uses a proxy re-encryption mechanism on a centralized server to transfer encrypted data from the patient to the doctor. In this solution, the patient-centered aspect is still lacking because the medical records are under the control of the hospitals. Another limitation is that the re-encryption is done on a single server. During the Covid-19 pandemic, there are several approaches to exploiting blockchain technology as a workaround in providing telemedicine support services (e.g., [43]). Specifically, they proposed a blockchain-based model to solve 5 problems at that time, including i) Managing patient consent for unwanted accesses from service providers health care service/center; ii) Traceability of remote diagnoses and treatments; iii) Traceability of home medical supplies and equipment; iv) Secure access to individual health records (i.e., combined with an IPFS-based approach); and v) Automated billing for all telehealth services (e.g., drug bills).

Instead of focusing only on the two main target groups in the medical environment, patients and staff at the healthcare facility (i.e., nurses, doctors), Kassab et al. [44] has expanded its blockchain-based medical data processing and storage system to include (insurance companies and regulatory agencies). In addition, the processed data is also extended to the supply chain of equipment and drugs from the suppliers/hosting agencies to the respective hospitals and pharmacies. However, the role of the patient is not mentioned as a major contribution of the paper. Similar to Xiao et al. [45] has proposed Healthcare Data Gateway (HGD) that allows patients to easily and securely own, control, and share their own data without violating privacy. This article presents a direction to combine Blockchain and Machine learning systems to achieve the system's ability to quickly handle "emergency" situations and ensure the privacy of medical data. [46] proposes a review, demonstrating how the inherent properties of the blockchain (e.g., synchronous processing, decentralized storage) can enhance or hinder current healthcare systems in improving healthcare services in healthcare facilities.

However, the above approaches (i.e., state-of-the-art) have brought many solutions to today's traditional healthcare systems. But those approaches only consider the general problem rather than consider a specific area (i.e., country). Thereby, in developing countries (e.g., Vietnam) where medical equipment and supplies are one of the barriers that directly affect people's healthcare process. In addition, the above approaches require a certain knowledge of information technology as well as the risks related to security and privacy. It is for the above reasons that a few case studies (i.e., applied to a specific geographical area - country, region) address the upper limits of [47]. In this article, we provide Blockchain-based support for the management of test results in medical centers.

III. The Blockchain-based Medical Test Results Management System

A. Traditional Model

To build the traditional model, we conducted a survey of 10 hospitals and medical centers in Can Tho city. We act as the medical check-up patient and the interviewer taking information directly from the test patients. We also surveyed

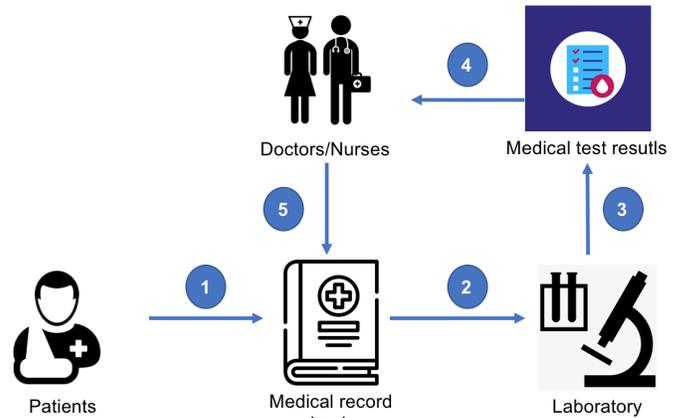

Fig. 1. The Traditional Process for Medical Test Results Management System.

medical opinions on the diagnosis process of a doctor who used to work at Children's Hospital - Can Tho. The traditional model surveys were conducted from June to August 2022. All the collected procedures are evaluated and graded step-by-step by the team before building the medical test results management model as shown in Fig. 1.

Fig. 1 shows the basic steps of the traditional medical test results management process. This model describes the five main steps, excluding the risks of losing medical test results. In other words, this process will be repeated for each patient whenever they have a routine checkup or a health-related reason. Specifically, in the first step, the patient registers for a medical test result, which includes basic information about the patient, such as full name, address, phone number, or medical condition. The medical test result number is also the patient number at that hospital. In the second step, the patient brings the medical test result to a specialist at the hospital, called a laboratory (e.g., eye, blood, urine) for sampling. This procedure requires a very long wait time from the patient. The patient then receives information about this form in the third step before forwarding this information to the doctors and nurses for consultation in the fourth step. Finally, the consultation results are updated in the medical test result of the patient in the fifth one.

For the process of storing patient information, the storage of their information is completely manual. Only a few major medical centers in major cities support the storage of medical results on their centralized database. This demonstrates that it is not feasible to share a patient's medical result between different healthcare facilities. It is easy to see that there are many inconveniences for both patients and hospital staff when using the current testing/receiving process, respectively. The first limit comes from the patient, all information stored on the medical test result must be ensured carefully, and the medical test result must not be lost otherwise, all procedures will have to be repeated from the beginning with a new medical test result. Changing the place of treatment/examination is extremely difficult because the patient has to bring the medical test results issued at the previous medical facility to a new one. In addition, the loss of medical test results is extremely risky, besides the reason for having to repeat the entire sampling

process, since they relate to the diagnosis process. Regarding the responsibility of physicians (i.e., doctors/nurses), they must reread a patient's entire medical history each time their patient has a follow-up visit. This is similar to the process of examining a new patient.

B. Proposed Model

To solve the above problems, we introduce a model based on Blockchain technology, where all information related to the testing process and the storage of patient's medical test results are updated and shared freely in the healthcare environment. Fig. 2 shows our proposal system based on Blockchain technology and distributed ledger (i.e., Distributed Ledger). As a first step, the patient initializes a global ID for not only a certain healthcare facility but also for others ones (e.g., the hospital in the same city). Unlike the traditional process, in another word, this ID will identify the user globally, which means that the patient can be examined at another medical facility without affecting the diagnosis process. Specifically, doctors/nurses can retrieve information about a patient's medical history based on their global ID (this will be covered in more detail in the next steps). From the initial global ID, users can generate more than 1 medical test result (i.e., per medical facility or healthcare service). These records store all test results and related patient information (i.e., similar to a medical test result in the paper). The data stored on the medical test result is always updated to Distributed Ledger (step 3). Users will then go to the respective Laboratories to take samples (step 4) before seeing a doctor in person to receive advice on their health status (step 6). This is the biggest difference between our model compared to the traditional model. Patients do not need to wait a long time at the facility; instead, an appointment is delivered to their device (e.g., smartphone) whenever their result is available. Meanwhile, the remaining steps will be executed independently at the system under the confirmation of the relevant parties. Specifically, after testing, the results are updated to the Distributed Ledger, and this information includes the user's corresponding medical test results and metadata about the time and location of the test as well as the doctors participating in the consultation. In case the patient goes to another medical facility, the patient's permission (or the patient's family member's/relatives in some special cases) must be obtained before accessing the patient's medical data (i.e., over-privileged permission). After receiving the request from the system, the doctors will enter the diagnostic results into the system (i.e., Distributed Ledger). The whole process will be confirmed by the stakeholders during the execution. The data will be encrypted when there is no request for access or update from the relevant parties (e.g., patient, nurse, doctor). The next section presents our approach based on Hyperledger Fabric.

IV. IMPLEMENTATION

A. Permission Diagram

Fig. 3 presents the working mechanism of the request authentication process in this paper. Specifically, we built two organizations with corresponding encrypted material certificates, each organization includes two users and two peers. Each peer is responsible for maintaining the version of the

ledger so that the network and data can be maintained even if other peers are shut down.

When the user initiates a request and sends it to the service. The back-end service processes the data and sends it to the smart contract API. When receiving the request and the data, the smart contract sends this to the peers in the network for authentication and data interaction purposes. During the creation, querying or updating data processes, peers check the identity of the request to decide whether to allow access to the data at the distributed ledger. If the identified user of the request is not defined in the data collection, the system denies access and sends a message to the back-end API to notify the user; the system allows access and proceeds with further processing steps.[5]

B. Hyperledger Component

The model in this paper is implemented on the Hyperledger Fabric platform. Fabric is a permissionless blockchain platform that integrates smart contracts, the storage of data to the distributed ledger is controlled through the smart contract APIs, from which the data is simplified and easily traced. Each request that goes through the smart contract is verified with public and private key pairs. In other words, if the user does not exist in the system, the system is better protected from malicious requests outside the system.

The Fabric system in this paper includes two organizations. Each organization consists of 2 peers to store smart contracts, where each peer registers two users and is authenticated with public and private key pairs. The components of the model are shown in Fig. 4

When user devices access the system to initiate/query or update data for a particular transaction, requests are sent from the client to the services of the existing system. Then, these services send access information to the peers belonging to the organization located in the blockchain network. At this step, the peers conduct verification of that user's key pairs, and if the successful peer authentication process proceeds to send information to the smart contract with the transaction type declared in a smart contract requested by the user, the smart contract will go through the designed features function to access the distributed ledger to initiate/query or update specific data.

C. Our Proposed Model's Diagram

One of the most important parts of the model lies in the validation and interaction with the patient's global ID and their medical data described in Fig. 5 and 6. In particular, the main functions include initializing and querying the patient's global ID and their medical data.

Fig. 5 depicts the process of storing new record data (e.g., patients' global ID and their medical data). In step 1, when the user initializes information about a certain ID, the data is sent to the back-end service of the health center's information management system. In the next step, the back-end APIs (i.e., backend) check, authenticate, and initialize the

Fig. 4. Hyperledger Fabric Component.

null field data.

Fig. 6 presents the process of retrieving data of a particular (e.g., patients' global ID and their medical data). When the user sends a query request to the system, the service query data checks and confirms whether the parameter ID of their medical data exists or not. Then, the smart contract's APIs are called and passed into the corresponding parameter. Next, the smart contract's APIs check for the existence of data in the request before querying. In the case that the ID does not exist, the smart contract sends an error notification to the user's device; otherwise, it returns the relevant data/record of the patient corresponding to the requested ID.

V. EVALUATION SCENARIOS

A. Environment Setting

Our paradigm is deployed on the Hyperledger Fabric network maintained inside docker containers. In this section, we measure the performance of chaincode in the two scenarios: initializing (i.e., creating data) and accessing data. The experiments are deployed on Ubuntu 20.01 configuration, core i5 2.7Ghz, and 8GB RAM.

default values, then pass the parameters to the API inside the smart contract. At this point, a smart contract transfers data and stores transactions to the distributed ledger of the blockchain network. The default values for parameters sent from the request are intended to minimize errors caused by

Fig. 7. Data Creation/Initialization for the Medical Test Results of the Patient in Terms of Latency.

To prove the effectiveness of our model, we also define several experiments by exploiting the Hyperledger Caliper[6] that is used to design the test scenarios and collect all the information regarding the performance.

B. Evaluation Results

As introduced in the whole article, we consider the three main execution tasks for the blockchain-based system, namely data creation, data access, and data update. The three following sub-section will target our evaluation of the ten scenarios in terms of the supported performance of the system.

1) Data Creation: In this scenario, the study measures the performance of the data initialization function/data created (e.g., medical record book) performed through smart contracts. The number of requests sent simultaneously from two users[7]. Table I shows the execution results of the data initialization/creation function in terms of the success and fail requests. The data initialization/creation script is conducted with two users concurrently making 1000 - 10000 requests to the system. Based on the execution results in Table I, it can be seen that the number of successful and failed requests is stable (except in the case of 10000 requests/second). Specifically, the number of failed requests is limited to less than 15,000 requests (i.e., on average 11.4K requests - 23.32%). Meanwhile, the

lowest case was with only 17.34% (8,128 requests at 3K requests/second). The maximum of failed request rate is in the fourth row 4,000/s request with 14,705 requests - 29.46%. In contrast, the system is more stable in terms of data creation with only an average of approximately 37.5K success requests for each scenario (from 1K requests to 10K).

We also measure the parameters of the system latency for each request (i.e., max, min, avg) in Fig. 7. In particular, for system-wide latency, we recorded the number of requests with response delays per 1,000 requests/second to 10,000 requests per second. The data in Fig. 7 demonstrate that the highest latency ranges from 1,461.58 to 1,642.91 seconds. The minimum is less than 10 seconds. The average delay when creating new data is less than 940 seconds. This is acceptable because creating thousands of new records at the same time is very unlikely in medical centers. The results observed in this scenario also demonstrate that the system supports very well with the continuous generation of new profiles.

2) Data Access (Retrieving/Querying): In the second experiment, we consider the data access (e.g., medical record book). We also set up 6 scenarios from 1000 to 10000 requests which access the medical record book from two users. Table II shows the execution results of the data access function (e.g., medical record book). Compared with the creation tasks, the results of 10 scenarios to evaluate the data accessibility of our proposed blockchain-based system are more balanced. Given the number of successful and failed requests, we also collect the number of requests at every 1000 to 6000 requests per second. The number of successful and failed requests is fairly balanced, with only 21 fail request for 10 scenarios (especially without the fail request at the seventh and ninth scenarios) around 99.99% of the requests are successful in all 6 scenarios.

[7]We set up one organization with two users and two peers

TABLE II. Data Access (Retrieving/Querying) for the Medical Test Results of the Patient in Terms of the Success and Fail Requests

#Request/second	Success	Fail	Percentage of the fail requests
1000	104435	2	0.0019%
2000	105102	3	0.0029%
3000	105103	1	0.0010%
4000	105294	4	0.0038%
5000	105348	4	0.0038%
6000	105373	1	0.0009%
7000	105119	0	0.0000%
8000	105222	1	0.0010%
9000	105104	5	0.0048%
10000	105122	0	0.0000%

TABLE III. Data Edit/Update for the Medical Test Results of the Patient in Terms of the Success and Fail Requests

#Request/second	Success	Fail	Percentage of the fail requests
1000	23018	23509	50.5277%
2000	21503	25012	53.7719%
3000	22642	25497	52.9654%
4000	22042	24782	52.9258%
5000	24547	23376	48.7782%
6000	22499	24091	51.7085%
7000	21775	23820	52.2426%
8000	22690	22972	50.3088%
9000	22496	23656	51.2567%
10000	25557	20470	44.4739%

Retrieval of stored data is extremely important. Indeed, considering health data retrieval time directly affects the patient's health care. To solve this problem, we consider the latency of the system (i.e., the maximum/average/minimum time it takes to process the request of data accessed from the system) which presented in Fig. 8. Specifically, the maximum time to wait for a data retrieval request is 0.6 seconds at the third scenario with on average 0.513 seconds. [8] The minimum wait time is almost instant response (i.e., with only 0.01 seconds for the whole scenarios - from 1K to 10K requests/second). The average time for each data retrieval request is less than 0.1 seconds - between 0.08 and 0.1 seconds.

3) Data Edit/Update: Finally, we look at the user's ability to update the medical test result's data. This parameter reflects whether a doctor or nurse updates information about a patient's medical record (e.g., new symptoms, diagnoses). In this scenario, we also conduct a review of 10 different scenarios, each of which will require processing from 1000 to 10000 requests per second. We also measure two parameters, similar to the two scenarios above, the number of successful and failed requests in Table III and the overall latency, which is shown Fig. 9.

For the first aspect (i.e., #request for success and fail), The number of failed requests was also higher than the success requests in all 10 scenarios (with an average of about 51%). On average, there are 22,876.9 request is success and this amount for fail requests is 23,718.5. Generally, the number of fail requests in data update task is higher than that in the two above tasks (see section VI for the details of reason).

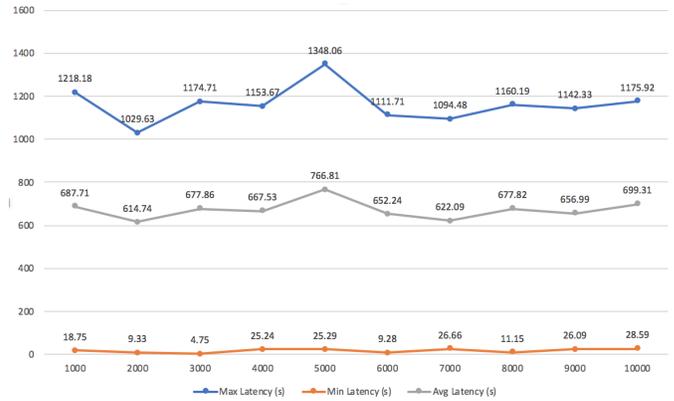
For the latency aspect of the data update requirement, we


Fig. 9. Data Edit/Update for the Medical Test Results of the Patient in Terms of Latency.

present the collected performance in Fig. 9. In terms of time for execution, updating data is more complex than the previous two previous tasks (i.e., creation and access data). Specifically, we must determine if user information exists in Distributed ledger, then we determine which information needs updating (e.g., symptoms, disease diagnoses). Because of the above requirement, the execution time for the update task is longer. Specifically, the latency of all scenarios ranges from 1029.63 to 1348.06 seconds in the maximum case. The minimum latency ranges from 4.75 seconds to 28.59 seconds, while the average latency required by an application to process ranges from 614.74 seconds to 766.81 seconds.

VI. Discussion

Comparing all three evaluation scenarios, we find that real-time is acceptable. We also describe why there is a difference between the time lag in the execution of requests from the system depending on the complexity of the query. Specifically, the most prolonged time lag was recorded in data initialization due to updating to Hyperledger. This is different from the traditional way of storing data, where the information is only stored in tables and is done by the system administrator. On the contrary, initiating a medical test result requires confirmation from all relevant parties. In addition, defining constraints in an update request is more complex than in a retrieval request. The update time clearly defines the information the requester wishes to add/update to the existing medical test results. Finally, the fastest execution time is the data retrieval request which offers more promise for a Blockchain-based system than traditional storage systems.

However, Section V provides a marked change in all three data creation, retrieval, and update scenarios regarding the number of success and failed requests. Specifically, in the update scenario, the failure rate of requests is much higher than in the data initialization scenario (with more than 50% compared to less than 20%). A similar method occurs when comparing initialization/data creation and access/data retrieval with more than 20% and nearly 0% of failed requests, respectively. This happens because we build a system that simulates the interactions between the parties (e.g., patient, nurse, doctor). In particular, the update and retrieval request must require the data to be initialized before. Otherwise, the request is

considered a failure. For the update scenario, the system also requires that the updated information be initialized before being replaced with new data (e.g., patient information and medical history). Initializing a dummy data system according to the above requirements is extremely difficult because we do it on two separate user groups.

For the system specification, we have not included encryption and decryption times for the data stored on Hyperledger. We assume that a trusted third party will take care of this. In terms of execution time, including the user critical generation time, as well as encryption and decryption, will increase the execution time for the whole system. This is hard to meet on our simulation system. In addition, this proposed model is also the first attempt to build a blockchain-based system that aims to offer a test management model in medical centers in developing countries.

For future work, we intend many potential research directions to follow after this work. One of the mandatory requirements for health systems is confidentiality (i.e., authentication and authorization). We apply the proposed models based on the dynamic data support the environment of IoT devices [11], [48]. For authorization, a model based on ABAC [31], [30] and supporting dynamic policy [49], [50] is an appropriate choice in the context of the current health system. For encryption requirements, we use a trusted authority that provides a solution to store and protect patient data on Hyperledger [51]. Moreover, we plan to combine the NFT and IPFS to define the medical test result for the patients.

VII. Conclusion

We have built a blockchain-based system for healthcare facilities in developing countries (i.e., Vietnam) to manage and store patient medical test results. Our proposed model is based on a balance between many unique criteria including limitations of medical facilities in developing countries (i.e., in terms of equipment), patient effort (i.e., waiting time, requirement background about security and privacy as well as technique), sharing information about test results and patient medical records between different healthcare centers; and system transparency. In addition, we build a proof-of-concept based on the Hyperledger Fabric platform. To demonstrate the feasibility of the proposed model, we evaluate the actual w.r.t performance of the system (i.e., create, access and update) based on 10 scenarios that change the number of requests per second (i.e., 1000 requests increaing for each scenario) by exploiting Hyperledger Caliper. The review highlighted our findings based on a review of the system as well as of the proof-of-concept; thereby suggesting possible future development directions.
