Editorial Preface

From the Desk of Managing Editor...

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Investigating the User Experience of Mind Map Software: A Comparative Study based on Eye Tracking

Junfeng Wang, Xi Wang, Jingjing Lu, Zhiyu Xu

College of Design and Innovation, Shenzhen Technology University, Shenzhen, China

Abstract—Software for creating mind maps is currently prevalent, and it should have strong usability and create a good user experience. Usability testing can help to uncover flaws in software's usability and support its optimization. This paper took the mind map software "Xmind" and "MindMaster" as study cases and conducted comparative research on three aspects: effectiveness, efficiency, and satisfaction. The research investigated 20 participants' interactions with the two software. Task completion rate, number of errors, and number of requests for help were collected to evaluate the effectiveness. Eye tracking data and task completion time are collected to evaluate efficiency. System usability, interface quality, and emotional dimensions were collected with subjective scales to assess the software's user satisfaction. The data together led to a conclusion: each software has a few usability issues. The use of jargon to explain functions was costly to learn and quickly undermined users' confidence in using the software; the interface's simplicity impacted satisfaction, although users tended to evaluate utility tools in terms of their ease of use and ease of learning. These findings could be used to optimize utility software.

Keywords—Usability; mind map software; comparative research; eye tracking; user experience

I. INTRODUCTION

The Mind Map was created in the twentieth century in England. Tony Buzan discovered a prototype of a form of representation concerning the radioactive mind and its images (i.e., mind map) while studying the neurophysiological science of the brain[1]. As a practical tool to visualize the thinking process, it has been widely used in teaching, business, personal, and team information management and is still penetrating other areas. Because of the continuous development of mobile network technology and application devices, software for drawing mind maps increased gradually and variously. Current research primarily focuses on applying mind map software in specific fields, with little concern about usability and user experience. As a utility tool, mind map software requires good usability and user experience to help users draw mind maps much simpler and increase efficiency and pleasure. In-depth usability research in this paper can help software designers understand better how the interaction logic, information quality, and interface layout influence the user experience together.

This study examines the usability of mind map software from three aspects: effectiveness, efficiency, and satisfaction. 20 subjects were invited to complete the given tasks with mind map software, and data were collected through eye tracking, user interview, and usability questionnaire. The usability problems in the interaction and visual aspects of the mind map software were explored.

The paper is organized as follows. The literature review is explained in Section II. Next, the methods adopted for this research is described in Section III, followed by the experimental tasks and procedure in Section IV, and evaluation metrics in Section V. The research results of usability and user experience are analyzed in Section VI. And the discussion in Section VII. Finally, the conclusion and future works are given in Section VIII.

II. LITERATURE REVIEW

For mind map software, good usability helps users to record and disperse their thoughts efficiently. User experience assessment can identify software problems regarding effectiveness, efficiency, and user satisfaction.

A. Implementation of Mind Map Software

Mind mapping is the process of constructing concepts graphically[2]. The core concept acts as the center, and related and subordinate concepts are grouped into various branches. A new concept is derived from an additional point of an existing concept, forming a tree structure in the diameter direction[3]. With eye-catching colors, simple graphics, and logical and precise lines, mind maps help increase learning and job productivity by making words and theories systematic and neatly structured[4].

In recent years, mind maps have become increasingly significant in education and teaching reform at all levels, from elementary school to university. Many studies use mind mapping to improve teaching and learning. For example, Fung D[5] investigated the effectiveness of mind maps in in Hong Kong Primary Science Classrooms; YANG A et al.[6] used mind maps in the teaching practice of elementary school composition; WEI C et al. [7] used mind maps in the teaching practice of human parasitology. These studies show how visual tools can improve teaching and learning and promote more profound knowledge. Olga Maksimenkova et al. [8] created an automatic grader for educational mind maps (AGEMM) based on the quantitative properties (node count, associations count, image count, and branching levels), which acts like a teacher's assistant.

In several other fields, including Finance [9], Medicine [10], Marketing [11], Economics [12], Engineering [13], Management [14], Computer [15], Fine Art and Design [16], Advertising [17] and Public Relations [18], etc., mind maps are also used to facilitate the collaboration in the workplace. Mind mapping contributes to collaborative work, especially during the COVID-19 pandemic today. Dilshod Kuryazov et al. [19] introduced the tool CMCM (Collaborative Mind-and Concept-Mapping) to demonstrate the viability of tool cooperation made possible by model differencing used for the collaborative modeling of Mind Maps.

However, little research has been done on drawing mind maps. According to Joeran Beel et al.[20], users generally construct "typical" mind maps that are relatively short, usually only a few hundred branches, seldom use annotations, linkages, and other features, and are typically modified repeatedly within a day or two. This indicates that people care more about mind maps' timeliness than the amount of information, which implies that more attention should be paid to the software's efficiency and efficacy while drawing.

However, being efficient and effective does not equate to a positive User Experience (UX). Many scholars have done a significant amount of usability research on digital libraries, online advertising, and systems engineering. Sudatta Chowdhury et al. [21] divided the concept of usability into two main lines (library intelligence and human-computer interaction). Hansen P [22] considered that usability in human-computer interaction systems refers to a particular interface's effectiveness, efficiency, and satisfaction. Usability is defined by the International Organization for Standardization (ISO) as the "extent to which a system, product or service can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use" [23]. The specific interpretations are as follows:

- Effectiveness: the user's precision and completeness in achieving the specified goal.

- Efficiency: the resources consumed by the user to precisely achieve the goal.

- Satisfaction: the user's comfort and acceptability of use.

However, ISO 9241 focuses too much on established tasks and goals, emphasizes efficiency and effectiveness, and ignores what is challenging to grasp in user experience. Furthermore, it does not apply to all scenarios, and satisfaction is also unsuitable as a usability indicator in many cases[24]. Even though ISO 9241 has been criticized for being inadequate as a criterion for evaluating usability, it is still extensively used.

Usability is a highly abstract term difficult to quantify and cannot be precisely tested. Many researchers have decided to build an assessment index system based on each index to assess the system's overall usability. According to Nielsen[25], usability can be divided into "efficiency of use," "ease of learning," "memory retention," "use reliability," and "user satisfaction." "response time," "learning time," "long retention time," "user error rate," and "subjective satisfaction" were chosen by Schneiderman[26] as indicators of user interface usability. Preece et al.[27] chose "throughput," "ease of learning," and "attitude" to measure the usability of HCI systems; Shackel[28] combined "effectiveness (speed)," "ease of learning (learning time)," "ease of learning (memory retention)," "effectiveness (error rate)," and "attitude" to define as usability evaluation index systems. In addition, content metrics and user-centered metrics can be categorized under the usability metrics system [29].

Current research has clarified the metrics for usability evaluation and established many theoretical foundations. However, there are specific variances between different genres, and the mind map software evaluation system should be updated to consider the peculiarities of mind mapping and user habits. This study employs a user-centered approach to usability evaluation, accounting for the efficacy, efficiency, learnability, and usability of mind-mapping software, user interface, and user sentiment metrics.

B. Usability Methods based on Eye Tracking

Typical usability assessment techniques include questionnaires, heuristic evaluation, focus groups, think-aloud, and card sorting[30]. However, the main limitations in implementation, particularly in user interface evaluation, are as follows[31]:

- The host will unavoidably affect the subjects and their behavior during the test through words, deeds, expressions, and expectations. This is especially true when there are several staff members.

- The test result's objectivity is not very good. The test mainly gathers qualitative information about individuals' preferences and inclinations.

- The experimental control is not strict enough during the test, and the reproducibility of the test results is low[32].

- The internal processing of the user is complicated for the test data to reflect directly, and the interpretation of the phenomenon is based chiefly on the tester's knowledge and experience, which is subjective.

- The test is costly, the sample size is limited, and there are issues with the statistical significance and representativeness of the test results.

Eye movement is crucial for visual processing information when using a computer interface. Eye tracking was initially recognized in reading studies in the late 19th century, and the first eye tracking apparatus was created in the early 20th century. As eye tracking technology advances, experts and academicians gradually discover the relationship between eye movements and human cognitive processes. Paul[33] and his colleagues were the earliest researchers who employed eye tracking in user experience research in 1947. This method was not frequently used until the late twentieth and early twenty-first centuries. According to Aga Bojko [34], objective data gained from eye tracking aids in better understanding how

different designs affect user experience and the demands, preferences, motivations, and processes of consumers or potential product users. According to Ivory and Hearst, visual recordings can be used for usability testing[35].

Eye tracking is a technology that records an individual's eye movements and can be used for usability assessment, especially for assessing visual user interfaces. This could be achieved by analyzing the data generated using this technology[35], including Fixation, Saccade, Behavior metrics, and data related to areas of interest (AOI) that dominate the data presented here. Data can also be visualized as gaze maps, scan paths, gaze videos, swarm maps, heat maps, focus maps, etc. According to Sandra Milena et al.[36], the aspects of usability evaluation that can be performed in digital information environments by eye tracking metrics primarily include search efficiency, interface quality, information visibility, and expectation flow.

Few studies have used eye tracking technology to evaluate dynamic processes and overall usability, while data from eye-tracking devices alone cannot shed additional light on user experience. This study attempts to assess mind map software's effectiveness, efficiency, and user satisfaction by combining subjective scale scoring and objective eye-movement data. The eye movement heat map was used to investigate the factors influencing the software's overall usability. We also combine interviews, and user behavior observations to more thoroughly argue the deeper reasons for user behavior. As a result, more reliable usability conclusions can be reached.

III. METHODOLOGY

The technique for the experiment's usability testing is described in the following section. The source of the sample software is discussed, along with how the task was created so that the participants could understand how to use the software and incorporate eye tracking into the experiment.

A. Study Design

An assessment test and a comparison test were both employed in this experiment. As much as possible, we gathered qualitative tendency data and quantitative operational data using simulated tasks, interviews, observations, and eye tracking [37]. We can evaluate which alternative is easier to use and learn by contrasting the various design possibilities of two software examples. Additionally, it aids in our comprehension of the advantages and disadvantages of multiple designs.

Due to variances in the mind-mapping process among the individuals, the functions and time spent generating distinct graphs varied. The task scenario was set to "You need to use the software which we offered to draw a mind map for work reporting as shown in the case diagrams" to control the variables. The individuals were instructed to execute the tasks using the sample software, and we gathered usability-related data.

B. Sample Software

A web-based questionnaire was used to conduct a study on the use of vector drawing software before the start of the experiment. Ninety-four valid questionnaires were collected,

with 64 people (68.09%) having previous vector image drawing experience. Mind maps were drawn by 82.81% of those with vector drawing experience in the sample. Xmind was chosen by 38 people, accounting for 71.7% of those who used related software. Visio (11 people, accounting for 20.8%), EDraw (8 people, accounting for 15.1%), MindMaster (6 people, accounting for 11.3%), and ProcessOn (6 people, accounting for 11.3%) were the others in that order. MindMaster is more focused on mind mapping because EDraw and MindMaster are owned by the same company and have similar product designs. According to market share, this study chooses Xmind and MindMaster as the study cases.

In the beginning, the similarities between Xmind and MindMaster as mind map software are primarily centered on the functional level, as both are designed to suit the needs of a daily mind map. Both provide a range of templates when producing a new drawing; the basic features of the drawing are essentially the same. Both provide labels, pictures, and other elements, and both may export standard image formats after the drawing is completed.

In addition to the preceding similarities, the two software differ significantly in information hierarchy, page layout, and visual style. MindMaster externalizes more information than Xmind in terms of information hierarchy, stacking as many functions as possible on the top toolbar. In contrast, Xmind hides more functions in the secondary directory, which must often be retrieved via the top menu bar or right-click. Table I displays the exact differences.

TABLE I.   DIFFERENCES IN DESIGN BETWEEN THE TWO SOFTWARE

Differences	*Xmind*	*MindMaster*
Top Toolbar	Other functions in the first level of the menu bar drop-down menu are only for frequently used parts in the form of text with icons in the second level.	Using tabbed management, huge categories beneath the text and icons to indicate specific available options, and the default state to display the most often used tools.
Free Themes	Different levels from "Topics" and "Subtopics" are placed at the top of the page under "Insert."	In the top toolbar category, "Topics" and "Subtopics" are on the same level.
Side Format Panel	Default Hidden	Default Expand
Presentation of Auxiliary Functions	Preference for textual descriptions.	Pure icons are preferred, with text descriptions loading after the mouse hovers over.
Visual Style	The Minimalist style is dominated by grey and white tones.	Simple yet not excessively energetic green as the theme color
Online Features	None	Cloud files, online sharing, etc.

C. Participants

Five people can discover around 77%-85% of the detection system's usability difficulties, according to Nielsen's fitted regression curve $n=N\ 1-(1-L)^n$ [38] where n is the number of users, N is the total number of usability problems in the design and L is the proportion of usability problems discovered while testing a single user. However, because substantial variations between participant groups from a smaller number of participants are difficult to uncover, Spyridakis [39] stated that

10-12 people would better properly investigate the product's usability concerns.

Based on their familiarity with the software, time spent using it, and frequency of use, inexperienced and experienced participants were purposefully picked for the experiment. Twenty participants were chosen from a Chinese university with various specialties. They were split into two groups, A and B; each group had five novice participants and five veterans.

D. Materials

1) Experimental equipment: The eye movement data were recorded by the Tobii-Glasses2 RU-type oculomotor, and the data were analyzed using the Tobii Pro Lab software. With a weight of only 45 grams, this eye-tracking head module model provides an ultra-lightweight and sturdy non-intrusive head-tracking module that ensures the interviewee's comfort and freedom of movement. Lenses for vision correction are also appropriate for a wider variety of people (independent of age, gender, or myopia)[40].

Under Windows 10, Xmind version 11.2.2 and MindMaster version 9.0.9 were used, as they were the newest versions available in China at the time of the experiment. For post-test interviewing, EV recording software was utilized to record during the task. All software is available in Chinese.

2) Test sample images: According to Beel J's[20] research and pre-test interviews with the participants, users strive to complete the mind map in a timely and efficient manner by adding topics, changing styles, and finally completing the drawing and exporting the required file format. In contrast, mind map software features such as annotations and hyperlinks are used less frequently. A standard tiny mind map is defined as the target, which involves using high-frequency functionalities such as topics, subtopics, floating topics, relationship lines, branches, and styles. When users completed the drawing work under the usage scenario, the collected data was used to examine the usability issues. Fig. 1 shows an example of each software provided to participants as reference.

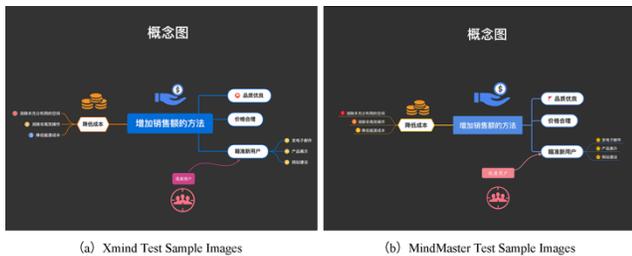
(a) Xmind Test Sample Images   (b) MindMaster Test Sample Images


Fig. 1.   Test Sample Images (Chinese Version).

IV. EXPERIMENTAL TASKS AND PROCEDURE

By having the participants create an identical mind map using each software, the experiment aims to compare the many interaction forms of the two kinds of software in-depth and assess the usability of the entire system. The drawing process is divided into ten key operations (see Table II) to collect the critical nodes in the software more effectively and identify the essential components affecting the user experience. The entire task is finished once all ten tasks have been completed.

TABLE II.   EXPERIMENTAL TASKS

Task Number	Task content	Key Operation
Task 1	Launch the software to start a new [mind map].	Find the New entry.
Task 2	Enter [Central Topic] and add [Main Topic].	Find the add Topic entry and its interaction.
Task 3	Add [Subtopic].	Find the add Subtopic entry and its interaction.
Task 4	Add [Floating Topic] and [Relationship].	Free Topic entry and insertion of a Relationship form.
Task 5	Modify the style of [Central Topic], [Main Topic], [Subtopic] and [Branch].	Efficiency and degree of comprehension of the style adjustment area.
Task 6	Add [Mark].	Find the Mark entry.
Task 7	Add [Clipart] from the materials folder.	Clipart add form.
Task 8	Modify [Background Color].	Find the Background Color entry.
Task 9	Modify [Text] size, style, color.	Text adjustment area positioning and understanding efficiency.
Task 10	[Save] file to desktop/personal cloud and [Export] PNG.	Save and Export entry.

Within-subjects design was used in this experiment. The mind maps were created by each participant in the experiment using Xmind and MindMaster, respectively. To prevent the learning effect brought on by order of use. Group A was assigned to use Xmind first, then MindMaster, and group B vice versa.

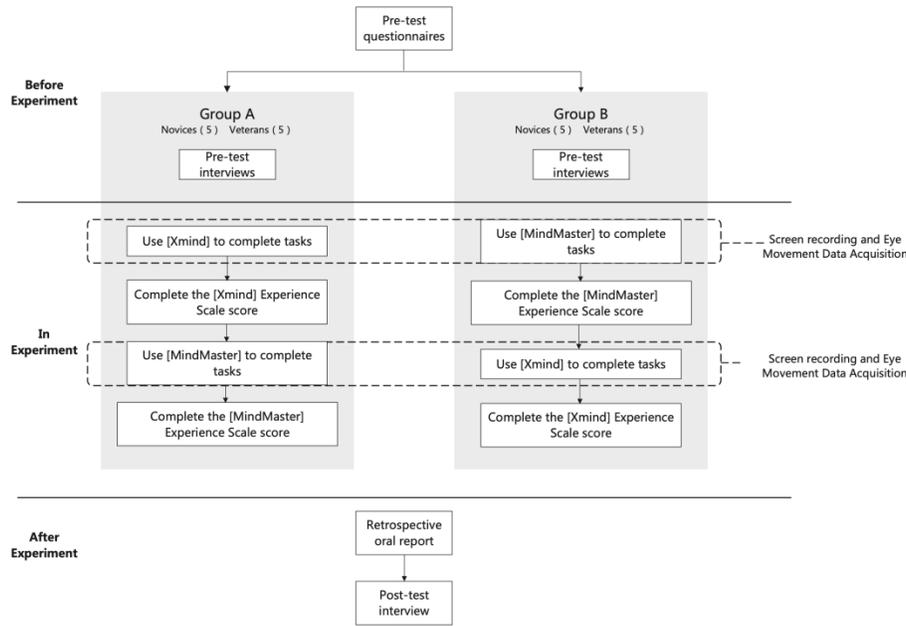
Fig. 2 depicts the experimental procedure. The participants were briefed on the purpose and details of the experiment before it began. They were also asked to sign an experimental consent form. Pre-test interviews were done to assuage any potential uneasiness in the participants and to learn how they think about the mind map software and how it was used in their ordinary work. Then, the participants were assisted in donning the apparatus, and the machine was calibrated to guarantee the validity of the results. Following the commencement of the experiment, the participants utilized the first software and finished tasks 1 through 10 concerning the example. The participants were not required to speak aloud during the procedure to guarantee the correctness of the task completion time. The subject completed the subjective questionnaires and scales when the task was finished. Then repeat the process above using the second software after a five-minute break and recording every action on screen. After completing all tasks with the two software, participants watched the recorded video while giving a retrospective oral report to help them remember particular usability difficulties. Post-test interviews were conducted afterward to delve deeper into the underlying causes of the users' behavior.


Fig. 2.   Experimental.

V.   EVALUATION METRICS

This study divides the usability index of mind mapping software into three categories based on the ISO definition: effectiveness, efficiency, and satisfaction. Data were gathered by eye tracking and subjective scales corresponding to the subdivided indicators for each category after it had been divided into smaller sub-dimensions. Table III can provide more information. Throughout the test, user behavior and interviews are recorded.

A.   Effectiveness

By counting the task completion rate of 20 participants, the software's effectiveness in attaining the stated objectives can be evaluated. However, the quantity of errors reflects how accurate it is. Additionally, we allowed the participants to seek assistance during the experiment and record the results to make the test procedure more thorough. "Task completion rate," "Number of errors," and "Number of requests for help" together provide for a more comprehensive assessment of the software's effectiveness.

B.   Efficiency

Time is an essential resource for achieving goals while using mind map software. The efficiency of both software can be measured by comparing the "Task Length." Eye movement analysis can be used to measure efficiency in addition to task completion time. The heat distribution before entering the AOI and the time spent before entering the AOI can infer the area where participants are used to finding the target and can reflect the target visibility. Scan routes can be used to compare user interfaces. The search behavior is less effective the more extended the scan path[31]. The duration of the first glance at the AOI and the number of visits can be used to assess the participant's comprehension of the specific area of interest and the ease of operation.

TABLE III.   METRICS FOR EVALUATING USABILITY AND DATA-GATHERING TECHNIQUES

	Evaluation Metrics	Date gathering techniques	
Effectiveness	Task completion rate	Percentage of completers	Experimental records
	Number of errors	Overall errors	
	Number of requests for help	Overall requests for help	
Efficiency	Task Length	Timing	Eye-movement data
	Target Visibility	Heat Map	
		Time to first fixation in AOI	
	Target identifiability	Scan Path Map	
		Duration of first look at AOI	
		Number of AOI visits	
Satisfaction	System Usability	Ease of use	SUS Scale
		Easy to learn	
	Interface Quality	Interface comfort	Subjective Likert scale
		Preference for the interface	
		Richness of interface functions	
		Simplicity of interface	
		Attractiveness of the interface	
	Perceptual Emotional Experience	Level of comfort	
		Level of enjoyment	
		Level of excitement	
		Level of clumsiness (inverse)	
		Level of frustration (inverse)	

C. Satisfaction

In this study, satisfaction was primarily measured using the SUS system usability scale[41], and Bangor[42] determined its reliability coefficient as 0.91 based on a significant sample of trials. The interface quality and user-perceived emotional experience were two additional variables that this experiment added to the user experience[43]. A total of 20 items on a 7-point Likert scale made up the questionnaire, which vehemently opposed is "1," whereas firmly in favor is "7."

D. Credibility Analysis

Measures of scale assessment include validity and reliability. The term "reliability" refers to the consistency and dependability of the results; if these characteristics are weak, the results are unstable and subject to the effects of place and time. The capacity to measure accurately is implied by validity or accuracy. The dependability quality level of the 20 question items in this experiment was measured using Cronbach's α[44]. The result of Cronbach's α was 0.919, which suggests good internal consistency and high-scale reliability. The sample size was appropriate, the KMO values for the three satisfaction-related features were 0.855, 0.739, and 0.635, all of which were higher than 0.6, and Bartlett's sphericity test, $p=0 < 0.05$, was compatible with the sphericity test.

VI. RESEARCH RESULTS

A. Effectiveness

As shown in Fig. 3 and Fig. 4, the fact that MindMaster outperforms Xmind in task completion and has much fewer errors and help requests per task indicates that it is more efficient. It can be noticed that each software has some challenges for inexperienced users by contrasting the two categories of users. Task V had the most mistakes made by the participants, with 72 made using Xmind and 26 using MindMaster. The task also included the majority of requests for assistance. This suggests that there are issues with both software when it comes to changing the drawing style, which is a crucial factor in the software's effectiveness.

B. Efficiency

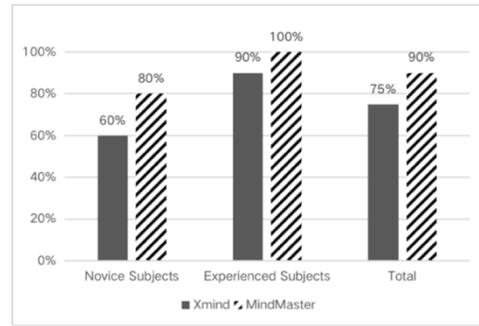
The difference in efficiency between the two software can be ascertained by contrasting the two software's total and individual task lengths. Table IV shows that the overall task time of MindMaster is lower than Xmind and that this difference is significant, demonstrating that MindMaster is much more efficient than Xmind. The tasks that revealed notable variations were tasks 2, 5, and 10. For tasks 2 and 5, MindMaster performs better than Xmind. Xmind spends less time on task 10. Eye movement data for the three tasks mentioned above was examined to investigate the apparent disparities.


Fig. 3. Task Completion Rate of the Two Software.
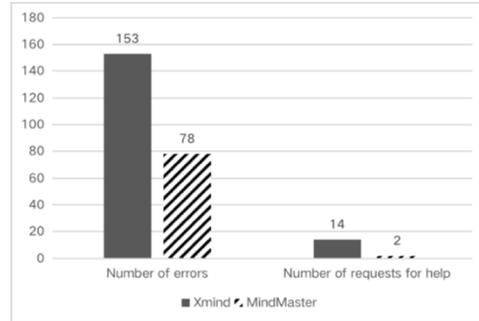

Fig. 4. The Number of Errors and Helps of the Two Software.

TABLE IV. TASK LENGTH AND THE RESULT OF PAIRED t-TEST

Items	Paired(M±SD)		Mean difference	t	Sig.
	Xmind(s)	MindMaster(s)			
Task 1	12.20±5.79	14.10±8.10	-1.89	-0.778	0.450
Task 2	112.19±37.41	88.66±45.11	23.53	2.425	0.029*
Task 3	119.87±34.12	110.15±51.27	9.71	1.000	0.334
Task 4	56.34±23.47	69.26±58.34	-12.92	-0.844	0.413
Task 5	591.76±247.08	246.51±110.79	345.25	5.902	0.000**
Task 6	68.80±36.81	55.75±21.29	13.05	1.333	0.204
Task 7	111.06±60.01	92.11±60.83	18.95	0.761	0.459
Task 8	74.24±35.22	90.45±54.71	-16.20	-1.026	0.322
Task 9	65.79±34.83	94.58±32.95	-28.79	-1.975	0.068
Task 10	59.35±20.11	94.38±31.38	-35.03	-3.700	0.002**
Total Task Length	1271.60±325.95	955.94±301.47	315.66	3.866	0.002**

*Sig.<0.05 **Sig.<0.01

1) Task 2 – add [main topic]: According to the Heat Map in Fig. 5, the participants could concentrate on the "Add Main Topic /Subtopic" choice quite well. And the majority of users also add subjects by selecting "Subtopic." As for the time to the first fixation in " Main Topic, "using Xmind takes more time than using MindMaster (according to Table V). However, it takes 14.316 s to view the "Subtopic" for the first time using MindMaster, compared to 2.283 s while using Xmind. Consequently, in this work, the target visibility of the two programs is quite close.

TABLE V. TIME TO THE FIRST FIXATION IN AOI OF TASK2

	Software	Mean	Std. Dev.	Sig.
Time to first fixation in " Main Topic "	Xmind	18.534	9.781	0.013*
	MindMaster	10.050	9.239	0.018*
Time to first fixation in " Subtopic "	Xmind	2.283	1.890	0.172
	MindMaster	14.316	6.394	0.000**

*Sig.<0.05 **Sig.<0.01

The Scan Path Maps show a few users' saccades when looking at the menu bar at the top of MindMaster and the "Adjust Style" toolbar on the right side. Although this happened just a few times, it made it harder for the subject to find the target and decreased the effectiveness of use.

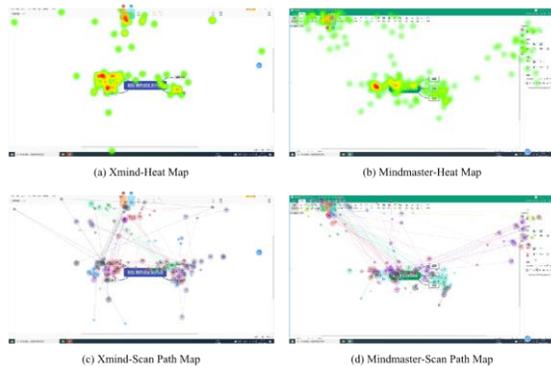
(a) Xmind-Heat Map (b) Mindmaster-Heat Map
(c) Xmind-Scan Path Map (d) Mindmaster-Scan Path Map


Fig. 5. Heat Map and Scan Path Map of Task2.

The "Subtopic" of Xmind was organized in the top-center toolbar, where there were fewer function options, and participants could locate the desired option more quickly. During this exercise, it was seen that the more skilled participants used shortcut keys more frequently, and these shortcut keys were consistent across both software. As a result, there wasn't much difference between how the experienced participants used the two kinds of software in this assignment. And when it comes to installing the "Subtopic," novice users typically find Xmind to be more user-friendly.

2) Task 5 – modify the style: Task 5 measures how well the two software performs regarding branching, adjusting graphics, and other features. According to Table VI, MindMaster performs better in target visibility since it takes less time for its first fixation in the AOI than Xmind. However, when using MindMaster to complete Task 5, the first stare at AOI is too long. Presumably, participants had

trouble identifying "shapes" and "branches." Division and literal description of function play a significant role. MindMaster uses only icons—no text—that are both small and strikingly identical in appearance, making it more challenging for participants to locate and recognize the target icon.

TABLE VI. TIME TO THE FIRST FIXATION IN AOI OF TASK5

	Software	Mean	Std. Dev.	Sig.
Time to first fixation in "shape"	Xmind	47.298	76.678	0.191
	MindMaster	14.476	31.291	0.121
Time to first fixation in "branch"	Xmind	21.597	29.904	0.023*
	MindMaster	18.003	13.279	0.021*
Duration of the first gaze at "shape."	Xmind	7.540	5.203	0.016*
	MindMaster	13.959	13.146	0.002**
Duration of the first gaze at "branch"	Xmind	7.910	7.633	0.034*
	MindMaster	18.366	13.107	0.000**
Number of visits to "Shape"	Xmind	10.333	6.501	0.011*
	MindMaster	14.462	15.967	0.007**
Number of "branch" visits	Xmind	20.286	16.226	0.000**
	MindMaster	9.857	8.153	0.019*

*Sig.<0.05 **Sig.<0.01

The fact that the side formatting panel was default hidden and had to be opened by selecting the "Panel" button in the top right corner was one of the primary causes of the increased time spent on Xmind. Some participants (mostly the less skilled ones) complained that they could not comprehend what the "panel" meant and that the placement of the alternatives did not correspond to their cognitive tendencies, making them challenging to identify the target.

The Heat Map (Fig. 6) also demonstrates that the participants' perspectives were primarily dispersed in the panel editing area and the right toolbar region when completing task 5 using MindMaster. However, when using Xmind, its viewpoints increasingly straddle other sections. The main challenge is finding the operation target. The mind map's branches are not free by default; you have to check the "Branch Free Layout" box in "Layout," and the user has to move the top tabs in the style panel to discover the "Layout." Users can more easily locate what to do with MindMaster because its control options are more consistent.

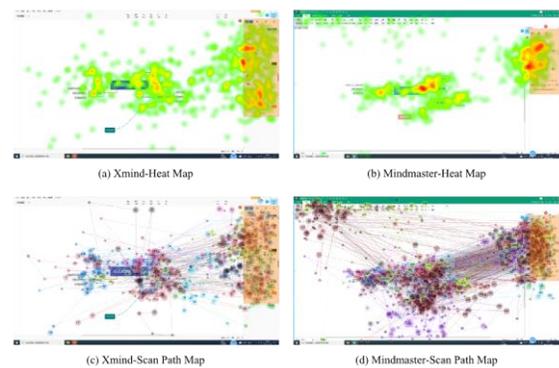
(a) Xmind-Heat Map (b) Mindmaster-Heat Map
(c) Xmind-Scan Path Map (d) Mindmaster-Scan Path Map


Fig. 6. Heat Map & Scan Path Map of Task5.

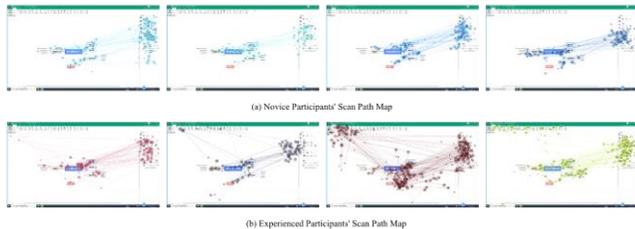
While MindMaster's Scan Path Map makes it clear that users will also focus on the menu bar region in the upper left corner of the interface during work, in addition to the right toolbar and the primary drawing interface, Xmind's Scan Path Map is disorganized and erratic. We attempted to analyze a specific topic to investigate the causes of this. According to the findings, novice and skilled users differ significantly, as illustrated in Fig. 7 As you can see, new users of MindMaster are accustomed to looking for functions in the menu bar area in the top left corner of the screen.


Fig. 7.   Novice & Experienced Participants Scan Path Map.

3) Task 10 – [save] and [export]: Although Xmind's interface has a wide distribution of hotspots, as seen in Fig. 8, but users use Xmind to do Task 10 significantly more quickly than MindMaster. Combined with the post-test interview, it can be found the save & export feature in Xmind uses a conventional drop-down menu is consistent with participants' habits. But it lacks innovation and does not offer features like sharing and cloud storage. In contrast, MindMaster is far more feature-rich and provides greater ease by permitting the export of files in various formats and cloud storage. However, the full-page switching format in MindMaster is pretty abrupt.

Fig. 8.   Task10 Heat Map Comparison.

According to the post-test interview, some participants expressed shock at seeing this switching format, and they initially believed they had done it by accident. Efficiency decreases since more storage alternatives lengthen the user's time to find the target.

C. Satisfaction

The ease of learning and usability scores were multiplied by 12.5 and 3.125, respectively, to match them with the SUS composite score (0～100)[41]. The amount was then multiplied by 20/7 to convert the metrics measuring user affective experience and interface satisfaction results to percentages. The computer analyses of the data from the usability scale produced the statistical findings in Table VII. As can be observed, the two software is significantly different in terms of user satisfaction. In this essay, "S" stands for the overall score, and "M" for the mean value.

TABLE VII.   COMPARISON OF USER SATISFACTION DIFFERENCES

	Variables	Xmind (n=20)	MindMaster (n=20)	t	Sig.
Usability	A1 Intention to use	3.40	3.85	-1.303	0.202
	A2 Complexity	3.55	4.40	-2.628	0.012*
	A3 Ease of operation	3.35	4.30	-2.832	0.007**
	A5 Degree of integration	3.25	4.15	-2.764	0.009**
	A6 Consistency	3.35	3.90	-1.297	0.203
	A7 Universality	3.00	3.95	-2.084	0.044*
	A8 Friendliness	3.25	4.10	-1.732	0.091
	A9 Confidence	3.35	4.60	-2.549	0.015*
	Total Usability	57.81	78.91	-2.457	0.019*
Learnability	A4 Information Support	3.50	4.40	-2.538	0.015*
	A10 Learning Cost	3.60	4.55	-1.736	0.091*
	Total ease of learning	63.75	86.88	-2.324	0.026*
Interface Quality	B1 Interface comfort	4.65	6.05	-2.278	0.028*
	B2 Preference of interface	4.35	6.00	-2.675	0.011*
	B3 Functional richness of the interface	4.45	5.85	-2.004	0.052
	B4 Simplicity of interface	5.65	5.90	-0.373	0.711
	B5 Interface Attractiveness	4.25	5.25	-1.287	0.206
	Total interface quality	66.71	83.00	-1.827	0.076
Emotional Dimensions	C1 Comfort level	4.35	6.25	-2.462	0.018*
	C2 Enjoyment level	4.05	5.95	-2.289	0.028*
	C3 Excitement level	3.80	5.20	-1.544	0.131
	C4 Clumsiness (inverse)	4.40	3.75	0.6	0.552
	C5 Frustration level (inverse)	3.00	3.25	-0.22	0.827
	Total perceived emotional experience	53.71	69.71	-3.762	0.001**
Total user satisfaction		59.81	77.74	-2.761	0.009**

*Sig.<0.05 **Sig.<0.01

The overall satisfaction rating data for the two software revealed a 0.01 level of significance (t=-2.761, Sig.=0.009), and the participants' overall satisfaction with MindMaster was considerably higher than Xmind (S_M=77.74>S_X=59.81). Less experienced participants gave MindMaster higher ratings. Some participants claimed that MindMaster's operating logic and page structure are more similar to Office, which is more recognizable and user-friendly. Moreover, MindMaster has more features that users value most, such as more drawing flexibility and support for online storage. Thus, MindMaster scores higher in these categories.

MindMaster outperformed Xmind in every category of usability, scoring significantly higher than Xmind in A2 complexity, A3 Ease of operation, A5 Degree of integration, A7 Universality, A9 Confidence, and overall usability. All participants stated that both products satisfied their usage requirements and that their willingness to use increased after becoming familiar with the product. However, MindMaster received a higher total score for usability.

The participants evaluate MindMaster's information support and learning costs over Xmind for novice users because the function's descriptions are simpler to understand. The design is similar to traditional office software, making learning easier and less expensive. Participant 18 stated, "MindMaster is simple to use, and the toolbar is identical to the standard Office software," for example.

The evaluation of the two software's interface quality also showed substantial variances. Many participants in post-test interviews praised Xmind's straightforward and consistent visual style. However, it also means that more function entries have been hidden deeper, which makes user difficult to find them. Another group of users was dissatisfied with Xmind's pages because they were too "basic." Even though the green theme color of MindMaster is visually arresting and vibrant, the 13th participant claimed that "the green appearance of the interface has an effect on the user's choice of color when drawing and makes people unconsciously want to choose a color close to the theme color of the software interface." The layout of the functional area's icons and buttons also gives MindMaster a more complicated appearance. The same results were also supported by user ratings, with MindMaster significantly outperforming Xmind in every category except for interface simplicity (M_{XB4}=5.90>M_{MB4}=5.65).

Users gave MindMaster's overall emotional experience a modest edge over Xmind in terms of perceived emotional intensity ($S_{X-sense}$=53.71<$S_{M-sense}$=69.71). The participants experienced greater comfort and enthusiasm after using MindMaster. On the other hand, Xmind made people feel even more awkward and frustrated. For instance, the 3rd participant commented, "Using Xmind was challenging, and I got frustrated." The 12th participant said, "Xmind is not very free, and the experience is not very nice."

VII. DISCUSSION

The study discovered that MindMaster performed better than Xmind in efficacy, efficiency, and satisfaction. The result is based on satisfaction questionnaires, eye-tracking data, and usability testing. This section will detail the causes and provide guidelines for software designers to adhere to.

Effectiveness-wise, a function's cognitive difficulty and location in the user interface determine whether a task can be completed successfully. The inability to modify the branch-free layout under the default "Balanced Layout" is the leading cause of task failure using Xmind. However, the "free-form" and "unconstrained structure" of mind mapping itself are its benefits[45]. This advantage is undermined by how Xmind is designed, which reduces its validity. In MindMaster, the participants can freely drag the branches to change their places, and at the same time, the branches can be intelligently adhered to the next nearest trunk. Intelligent features like this will become a trend. Simultaneously, the panel's entrance is generally difficult to discover. Thus, participants asked for help for a few times. There are two main causes for this. Firstly, the button was difficult for novices to notice in the full-screen mode because it was in the top-right corner of the screen. Second, it was challenging to understand the button's meaning due to ambiguous symbol semantic expressions and overly professional text descriptions. It suggests that designers should carefully take into account both the clear depiction of icons and the visibility of function buttons in the interface layout.

In terms of efficiency, MindMaster performs better. The interface of Xmind is simpler and conceals more functional entrances. Users' search processes become more time-consuming and ineffective due to the low visibility of functional entries. On the contrary, MindMaster directly displays some commonly used functions by default. It reduces the interaction steps for users and improves efficiency. Therefore, designers should consider the usage scenario when software is designed. And optimize the interaction design of the software's fundamental functions to match the user's behavior. The interviews and eye-tracking data show that participants are more drawn to graphical design objects than textual objects. Consumers generally are unwilling to read lengthy passages of text; therefore, using the appropriate graphic elements in the user interface can help users get the content rapidly while keeping their interest. However, it also should be carefully exercised to prevent confusing users with similar icon shapes and layouts. For instance, the MindMaster right toolbar's icons are small and neat. The branch and theme adjustments have similar layouts, identical icons, and repeating issues. As a result, the operation takes longer than it should because users have to take the time to examine the hover text descriptions. However, icons on MindMaster's top-right toolbar have auxiliary textual information and are arranged according to function. They help users to understand and use easier. So, designers can combine the relevance of functions and the level of information for interface design. And suitable auxiliary information is also important.

In terms of user satisfaction. A product's usability and learnability depend on how well it fits into the user's routines and how helpful and amiable it is to them. Xmind's entry position, iconography, and text are inconsistent with users' cognitive habits. And this is why users have low usability ratings for Xmind. On the other hand, MindMaster's top and right sides, which have a multi-entry format and take into

account the preferences of many users, are more inclusive. It makes Mindmaster's usability and learnability scores higher. Adding a multi-entry to functions does improve usability to some extent. At the same time, designers should be careful to use this method to avoid interface quality degradation. For mind map software, users choose designs that are specific and present functions in interface quality. Emotional dimensions are mainly related to the fluency of the operation process. Therefore, the designers must be mindful of the interaction logic's jumps to prevent user operations interruptions.

VIII. CONCLUSION AND FUTURE WORKS

The objective of this paper is to explore the usability and user experience of the existing mind map software. Comparative usability research is conducted to determine the key influential elements. A total of 20 participants participated in the study. According to the experiment results, the interactive logic, level of information, and interface design of mind map software all affect their effectiveness, efficiency, and user satisfaction. The study also suggests that designers must base their decisions on user needs, scenarios, and habits to create a better user experience for users of the mind map software. When evaluating the usability of their design solutions, both software design teams can benefit from the assessment techniques described in this paper.

The limitations of this paper are that the drawing examples used in the tests were slightly more complex and required using multiple functions to complete. It is somewhat different from the actual drawing scenarios of the users. This could be amended by testing as many functions of the software as possible. The future work will expand the number of experiment samples, focus on providing answers and optimize the design by merging the enumerated usability issues, followed by experiments to confirm the optimization's effects.

Abstract—**The number plate recognition system must be able to quickly and accurately identify the plate in both low and noisy lighting conditions, as well as within the specified time limit. This study proposes automated authentication, which would minimize security and individual workload while eliminating the requirement for human credential verification. The four processes that follow the acquisition of an image are pre-processing, number plate localization, character segmentation, and character identification. A human error during the affirmation and the enrolling process is a distinct possibility since this is a manual approach. Personnel at the selected location may find it difficult and time-consuming to register and compose information manually. Due to the printed edition design, it is impossible to communicate the information. Character segmentation breaks down the number plate region into individual characters, and character recognition detects the optical characters. Our approach was tested using genuine license plate images under various environmental circumstances and achieved overall recognition accuracy of 91.54% with a single license plate in an average duration of 2.63 seconds.**

Keywords—Character segmentation; convolutional neural networks; bilateral filter; character recognition; SVM classifier

I. INTRODUCTION

An automatic number plate recognition (ANPR) system identifies the vehicle's license plate without a person's involvement. Image acquisition and character retrieval are the two primary operations of ANPR systems. During this step, images of the vehicles are acquired. These approaches are used to process images of number plates and extract their characters. Surveillance cameras are often used in ANPR systems. Due to the fact that they are used for broad purposes, these cameras tend to capture larger-than-average images. The first step is to find the number plate area in the image and extract it. Afterward, the number plate's alphanumeric characters need to be deciphered from the backdrop. Then deep learning-based methods are used to identify the characters. The ANPR system comprises different phases as seen in Fig. 1: (1) image acquisition (2) number plate identification and extraction (3) character segmentation and (4) character recognition [1]. The first two phases identify and capture an image of the vehicle. Next, a number plate's

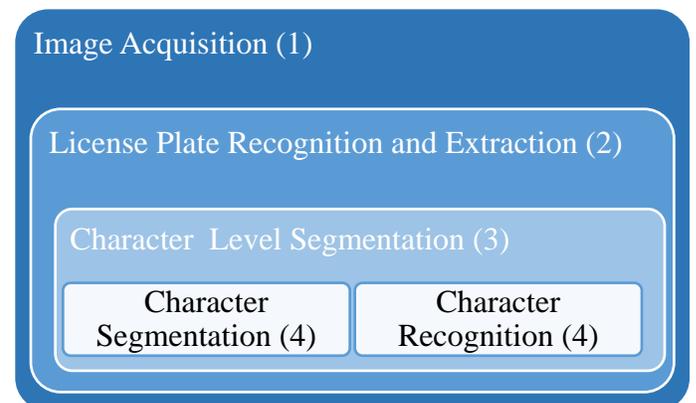
possible locations in an image are identified. The identified area is used to isolate the characters in the third phase. Finally, the characters are identified in the last stage. This paper focuses on the character isolation phase. Therefore, this study does not include vehicle detection techniques. The contribution of this paper is to improve character recognition accuracy.


Fig. 1. Different Phases Involved in the ANPR System.

The paper is structured in the following manner. Section II gives an overview of the ANPR systems and techniques. Section III outlines the nature of the issue and the difficulties. The proposed methodology is narrated in Section IV. Section V details the results of the experiments and evaluations of the performance. Section VI concludes the paper.

II. RELATED WORKS

The convolutional neural network (CNN) has a state-of-the-art accuracy in HCR [2]. The performance of the recurrent neural network (RNN) is improved in [3]. In [4], presented a novel technique by combining the conventional RNN and deep CNN. HCR technology has been researched for a while and is used by the industry, but its poor accuracy hinders its usability and overall performance. The current character recognition systems aren't very reliable and require additional research to be used widely.

The YOLOv3 algorithm and background subtraction are suggested in [5] for the identification of vehicles and the localization of license plates. In [6], developed a system for optical character recognition to identify stolen vehicle license plates. CNN is used in [7] to develop an embedded system that can identify and recognize Brazilian license plates. Finally, the system uses a Tiny YOLOv3 architecture and a NN is trained on synthetic images and fine-tuned on actual license plate images to identify the license plate characters.

A. Character Segmentation

Using k-means clustering to discover linked pixel areas and combining appropriate pixels into components to efficiently extract each character, a method known as connected components labelling analysis (CCLA) was described in [8] for segmenting license plate (LP) characters. In [9], created a unique sharpness-based methodology for segmenting the characters in LP images. In the segmentation procedure, the model faced a gradient vector and a lack of accuracy. In [10] used a successful model for LP detection on a variety of lighting systems. Binarization and the superpixel paradigm were used in conjunction with this model to segment the characters in LP. LP recognition is expected to be implemented using edge detection and CNN [11] [12].

Prediction and identification of LP vehicles based on character features were utilized by [13] [14]. Segmenting characters from LP areas was initially the model's first step toward refinement. There were both vertical and horizontal projection elements in the approach for character segmentation. For images with challenging backgrounds, the features given may not work. In [15] developed a technique for character segmentation using a binarized input image without character shapes or presence among the characters improves the performance quite a little. It is thus exceedingly difficult to use a binarization model that distinguishes foreground and background data in images consisting of complicated backgrounds. Finally, it was discovered that a greater variety of ways had been explored in an effort to address the problems caused by the reduced light impacts on the environment. However, it does not include issues such as blur, touch, and challenging backdrops.

B. Character Recognition

Riesz fractional-centric detection and identification of LPs was proposed in [16]. This method is used to explain why LPs are difficult to find and identify. An enhancement in LP images may lead to an increase in recognition outcomes, which is not ideal for real-time environments, according to the experimental results. For low-quality images, [17] used an ensemble of Adaboost cascades for LP recognition. Classification models for LP analysis from images impacted by different variables are used in this model to identify that the texture assigned relies on the LBP job completed by the user. Consequently, this technique's primary job is to learn from and count examples of simulated situations. Text prediction has also been constrained in terms of value, although the established technique still allows for recognition. Due to the fact that the detection procedure does not acquire whole character forms, text detection is simpler than text recognition. In recent years, there is more development of numerous DL techniques for the identification of low-level features, such as LPs. In [18], suggesting a CNN-based approach to LP identification. LP analysis has been performed by using R-CNN. In [19], developed a deep localization and error detection technique for LP detection. In [20], used kernel-based Extreme Learning Machines (ELM) with significant attributes to develop Chinese vehicle LP identification. Once this was established for LP identification, the researchers looked at how CNN and ELM might be combined to improve performance. Deep learning (DL) modules that function effectively in the presence of a large number of predefined samples were found to have these characteristics. However, images impacted by a number of negative circumstances make it difficult to identify a predetermined instance that demonstrates plausible distinctions from LP recognition. Additionally, the DL approach is hampered by inadequacies like as parameter optimization for various databases and the ability to retain the dependability of DNN in the face of these issues [21]. The established criteria show that there is a discrepancy between the previous models and the more current demands. This discovery prompted the development of a new method for LP identification that did not rely on classification models and counted more labelled samples than the prior techniques. Based on the genetic algorithm and an improved neutrosophic set (NS), a new LP recognition model has been developed in [22].

III. CHALLENGES IN ANPR

A. A Lack of Standardized Number Plates

Various nations and areas within the same country have different number plates [23]. Number plates are not standardized. Several factors, such as plate sizes, plate backdrops, character sizes, and plate textures, all contribute to the variety of number plate forms [24]. Intelligent algorithms [25] are necessary for improved number plate recognition. It has been suggested that a number of strategies may be used to enhance the system. As a result, this study is a difficult one that is limited to a small area.

B. Erroneous Character Interpretations

The characters such as "O - 0, I - 1, B - 8, C - G, A - 4, D - 0, D - O, G - 6, and 2 –Z" are close enough that character recognizers may get them mixed up. All of these flaws should be addressed by character recognition algorithms [1, 10, 20]. In spite of the increased emphasis given to character recognition in ANPR systems, the ambiguous character problem remains a major issue. Furthermore, the issue of ambiguous characters has not been examined in depth.

In addition, segmenting the characters, which is the third stage in the ANPR process, is one of the most difficult. There are a variety of techniques used to categorize the characters of various license plates in the literature. Optical character recognition systems for letters and numbers may be employed separately to address the issue posed by ambiguous characters. This will improve the accuracy rate of the character identification phase since it will eliminate the ambiguous character issue.

In this paper, an image processing-based approach is described to address the issues outlined above. In the character recognition stage, we may employ various models specifically built for letters and numbers provided we accurately segregate the areas. The first step is to determine whether a character is a letter or number before we can do anything further. According to our knowledge, no research has looked at identifying the character's kind (letter, number).

IV. METHODOLOGY

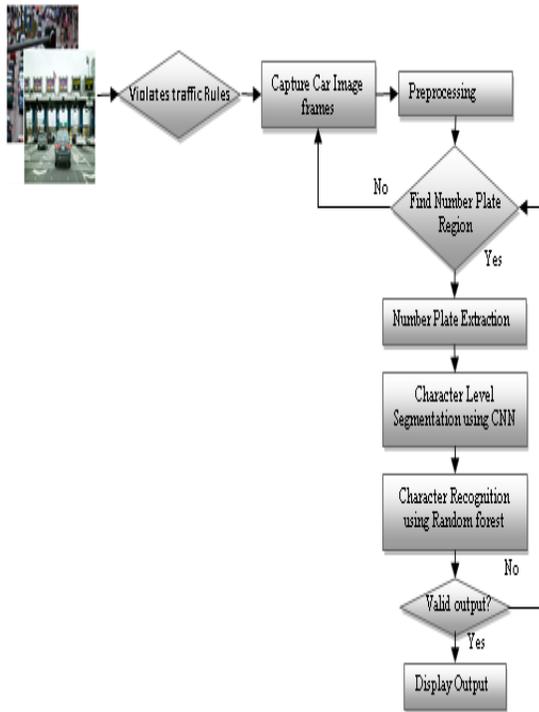
Fig. 2 gives the workflow of the proposed license plate recognition, which will be explored in more detail below. This method includes different phases. The four processes that follow the acquisition of an image are pre-processing, number plate extraction, character segmentation, and character identification. Character level segmentation is performed using CNN and character recognition is done by using a Random forest classifier. The proposed method would expedite registration and provide additional advantages such as vehicle security and traffic control.


Fig. 2. Flow Diagram of the Proposed License Plate Recognition.

A. Pre-Processing

Input images face a myriad of issues, including interference, deformation, underexposure, and other. These effects may be minimized by doing image preprocessing on the input, which simplifies and speeds up the processing of images. In the pre-processing step, first, the input images are converted into grayscale images. The reason behind this is, standard number plates come in white and black, which are the only two colors available. As a result, it's not necessary to include all of the colors in the image.

1) Bilateral filtering: Noise reduction is made possible with the employment of a bilateral filter. To remove noise while maintaining the sharpness of characters, a kernel size of 3x3 is highly recommended. Filtering is the process of replacing each pixel value in an image with the average weighted sum of nearby pixels. The number of pixels in the weighted average is determined by the kernel size. Because larger kernels take longer to process and smaller kernels are useless at removing noise, a kernel size of three is the most efficient in this paper for decreasing noise.

2) Contrast enhancement: When the lighting is dim, boosting the contrast is a necessary step in number plate recognition. In order to better distinguish between the black text and the white background on the number plate, the contrast between the two colors must be increased. CLASH is used to increase contrast. Using this method, the image is broken up into smaller units known as tiles. Then histogram equalization is performed on each 8x8 tile separately. After contrast enhancement, the image can be converted into binary. When converting an image in to a binary image, the pixel values are reduced to two values [0 and 255].

3) Dilation of image: Dilating a number plate's characters makes them more prominent, which in turn makes their edges more prominent. When an object's area rises, so does the image's overall perimeter (edges). The number plate may be more precisely located if the character's borders are thicker, as edge-detection is used to do so. A number plate frame with no extra edges avoids the false edges from being picked up by the camera.

B. Localization of Number Plate

By recognizing the image's boundaries, edge detection can be utilized to determine the location of a number plate. The number plate region, which is actually the number plate characters themselves, has a lot of edges. This is because most of the number plates have black writing on a white background. As a result, the edges of the characters stand out against the background. Number plates tend to be densely packed with letters and numbers since it is where localized edges are found to be the most numerous. The number plate has the highest concentration of edges in the picture, despite the fact that the edges are visible across the image. Through the use of pre-processing, the contours of these objects become clearer. Because of this, the number plate is shown by a bounding rectangle. The picture is visited to count the number of edges it covers. The number plate is located in the portion of the image that has the most localized number of edges in the enclosing rectangle. Number plate locator software used an ingenious edge-detecting mechanism. Because it is more accurate, Canny edge-detection can pick up on both horizontal and vertical edges. When a car is in motion, the horizontally structured rear windshield usually sits immediately below the license plate just above it. Similarly, the bumper just under the license plate has a structure that is almost horizontal as well.

C. Character Segmentation using CNN_CL4 Network

The characters of the number plate are retrieved using a localized number plate as input. CNN has garnered a lot of attention as one of the most successful deep-learning models

for picture segmentation. It's employed in a slew of new applications, including medical picture categorization, vehicle monitoring, self-driving vehicles, and face recognition, among others. Because of the self-optimization feature of artificial neurons, CNNs are able to learn just like brain neurons. Other algorithms cannot extract characteristics and segment images as accurately as it does because of this self-optimizing nature. The input data has to be processed minimally, yet it produces very accurate and exact outputs. HyperOn the basis of these qualities, CNN attempts to comprehend and distinguish between the images. Low-level information such as edges, gradient direction, or color may be captured by the first few layers of convolutional neural networks (CNNs). However, as the number of convolutional layers increases, it begins to extract characteristics at a higher level. Higher dimensions and convolution lead to exponentially increasing network parameters. As a result, CNN computations are slowed. This is because the number plate images have a lower pixel density than the images that are given to the input layers.

The CNN model for character-level segmentation is given in Fig. 3. Layers of the convolutional network are fed images from the input layer. Because it only contains four convolutional layers, the model is small and quick to run on a computer. Convolutional layer with 3 x 3 kernels and ReLU activation function in the first layer. 2D convolutional layer in the second layer. There are several deep learning algorithms that make heavy use of the ReLU activation function. In contrast to other activation functions, such as tanh, neurons are only partially stimulated when using ReLU. Except for zero, the continuous and differentiable function ReLU is a piecewise linear one. Additionally, it has a lower probability of a vanishing gradient than other methods because of its simplicity and empirical ease. Negative values can be simply returned as zero, which is shown in Fig. 4 by ReLU's basic concept of returning positive input values to output. A max-pooling layer and ReLU-activation function follow the first three 2D convolutional layers. To reduce the size of our input images, a sample-based discretization max-pooling is used. It helps to minimize the network's dimensionality by pooling the maximum value from each feature map patch. Over fitting may be avoided by removing non-essential factors and thereby reducing the overall number of parameters. To avoid overfitting the initial convolutional layer, a 2 x 2 max-pooling layer is added to all except the first layer. A 1D string is formed as a result of the fourth convolutional layer, which is then passed on to the final fully connected layer. The activation units in the next layer are linked to all neurons in the completely connected layer. The first layer's neurons are all linked to the activation unit of the second layer's neurons in a two-layer model. All inputs are then passed to the Soft max activation algorithm, which segments the characters on the number plate. Finally, the segmented characters are given to the SVM classifier to classify the numbers and the alphabet.

D. Character Recognition

The maximal margin classifier and random forest (RF) classifier have been utilized to categorize these segmented characters into respective digits and alphabets, and their performance has been evaluated.

1) Support Vector Machine: SVM is a maximal margin classifier. By constructing hyperplane, it categorizes the data. It works better for categorizing binary classes. It is also used for solving multiclass issues. Figure shows the maximum margin hyper plane of the support vector machine. There are two types of SVM classifications are there name one-vs-one (OvO) and one-vs-rest (OvR).

In this paper, a polynomial kernel of degree three is used. The magnitude of the allowable misclassification is determined by parameter 'C.' Larger values of 'C' will choose a hyperplane with a narrower margin. Smaller values of 'C', on the other hand, compel the classifier to search for a bigger margin, even if the hyperplane misclassifies the points. In general, a high 'C' value is desired, although it may lead to over fitting [2]. The shape of the class dividing hyperplanes affected by the parameter γ. When γ is high, only points near the hyperplane are considered, while a lesser value of γ considers points far away from the hyperoverplane. In general, a low value of γ is preferable, since a higher number might result in overfitting. The low value of kernel width parameter is selected with greater value of optimal cost parameter. Table I lists all of the critical parameters [5].

TABLE I.   PARAMETERS OF SUPPORT VECTOR MACHINE

Classifier	SVM
Approach	One-versus-all
Cost parameter (C)	1
Kernel width parameter (γ)	Auto-deprecated
Degree of polynomial kernel	3

2) Random Forest (RF) Classifier: It is based on an ensemble of decision trees. Nodes make up a tree, and each node makes a decision based on a parameter. It has been trained using a bagging technique. Random forest employs a slightly different method to bagging, in which a subset of characteristics is chosen for node split, while bagging utilizes all features. As a consequence, an RF is a collection of trees that lowers the influence of noise in a single tree. As a consequence, bagging improves the overall outcome. Two key parameters must be set: Two variables are the number of features in each split (F_s) and the number of decision trees in the forest (N_t). Although the big value of parameter N_t is maybe superfluous, it has no negative impact on the model. It will almost certainly improve the accuracy of the forecasts, but it may slow down the model. The number of features to take into account while dividing a node is specified by the parameter F_s. It is always a subset of the whole amount of characteristics. The value for N_t was set to 100, and the value for F_s is set to the square root of the model's number of features.

V.   RESULTS AND DISCUSSIONS

The characters from the number plate are extracted using character segmentation, which is subsequently used to train different classification models. All segmented characters for training have been reduced to 20 x 20 pixels. SVM and Random Forest classifiers are used in this study. The performance is also compared with other existing methodologies such as KNN, and Neural networks. The simulation results are given in Fig. 5. Initially, the number plate region is extracted from the car, and the extracted region is given in Fig. 5(a). Then the images are given to preprocessing stage where the input images are preprocessed, enhanced and finally converted to a binary image and it is shown in Fig. 5(b). The bounding box for character segmentation is given in Fig. 5(c). Finally, the recognized number plate is given in Fig. 5(d).The comparative analysis on the recognition accuracy of different methods are tabulated in Table II. The performance of four different classifiers such as Random Forest Classifier, SVM Classifier, KNN and Neural network has been analyzed. From the analysis, we can clearly say that, the random forest classifier gives better recognition accuracy of 91.54% whereas, the lowest recognition accuracy is given by the neural network classifier.

A. Comparative Analysis

The graphical representation on the comparative analysis of different classification methods are given in Fig. 6. The graphical analysis shows that the random forest classifier performs well when compared to other techniques.

TABLE II.   COMPARATIVE ANALYSIS

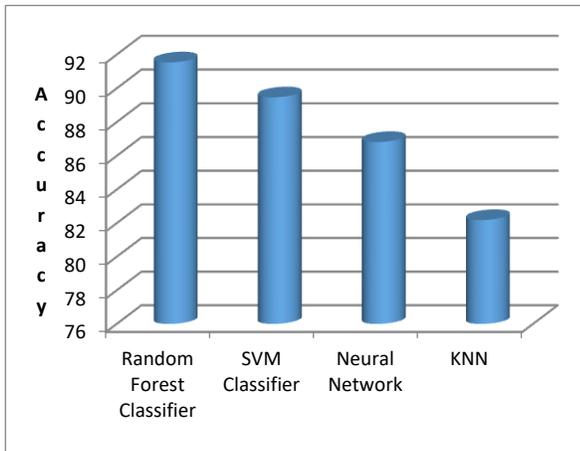
Classifier	Recognition Accuracy
Random Forest Classifier	91.54
SVM Classifier	89.47
Neural Network	86.82
KNN	82.19


Fig. 6.   The Graphical Representation of Comparative Analysis of Different Methods.

For a variety of reasons, RF outperforms SVM in this scenario. SVM is a binary classifier, but random forests are inherently multiclass classifiers. It is necessary to convert the multiclass issue to a multiple binary class problem for SVM to operate. Despite this, random forest beats SVM since it is a multiclass classifier. The second problem is that pictures, no matter how much preprocessing is done, will always be noisy. In this instance, the noise-resistant classifier is expected to perform better. There is evidence to support this notion since RF outperforms SVM. Consensus results from several trees are used to form RF's overall classification. As a consequence, even if some trees are trained using noisy input, the end outcome should still be as predicted. While SVM is notoriously slow to train, using RF you can train several models at the same time, which is something you can only accomplish with SVM. Neuronal networks can handle noise, thus they are accurate. There is no substitute for a random forest, which is an ensemble of decision trees based on a kind of bagging strategy, in terms of accuracy.

VI.   CONCLUSION

The four stages: Preprocessing, number plate localization, character level segmentation, and character recognition are the processes discussed in this study. Converting the RGB image to grayscale, using the bilateral filter to reduce noise, improving the image's contrast, translating the image to a binary image, and finally distorting the image are all part of the preprocessing stage. Character segmentation begins by segmenting the characters from the number plate that have been accomplished using CNN after removing an unnecessary area of the number plate, The first step in character segmentation is to separate the characters from the number plate, which is done using CNN. Individual characters are recognized using character recognition utilizing random forest classifier and support vector classifier. The proposed method achieved an overall recognition accuracy of 91.54% with a

single license plate in an average duration of 2.63 seconds. This method is also compared to state-of-the-art methods, demonstrating that the suggested method outperforms other existing methods.

Abstract—A collection of metabolic conditions known as diabetes mellitus (DM) is defined by hyperglycemia brought on by deficiencies in insulin secretion, action, or both. In terms of mortality rate, type-2 diabetes is 20 times higher when compared with type-1. Based on the earlier research, there is still scope to identify different risk levels of type-2 diabetes complications. To achieve this, we have proposed a T2DC machine learning-based prediction system using a decision tree as a base estimator with random forest to identify the severity of T2-DM complications at an early stage. Our proposed model achieved accuracies of 95.43%, 94.62%, 96.25%, 97.55%, and 97.83% for Nephropathy, Neuropathy, Retinopathy, Cardio Vascular and Peripheral Vascular complications in T2-DM patients. The proposed model has the potential to improve clinical outcomes by promoting the delivery of early and personalized care to T2-DM patients.

Keywords—*Diabetes mellitus; micro vascular; macro vascular; machine learning; type-2 complications*

I. INTRODUCTION

One of the most widespread health problems affecting all age groups is diabetes mellitus (DM). According to WHO (World Health Organization) statistics, nearly 180 million people worldwide have type 2 diabetes mellitus (T2-DM), with 95 percent having DM in this structure [1]. The number of people having this T2-DM is estimated to rise drastically by 2030. As per the highest cases recorded in the world, India ranked in 2nd place with 60 million DM records and is estimated to rise by 109 million people with DM by 2035 [2]. It is a condition that is identified when the pancreas fails to produce insulin in the required amount needed for the body, or due to damage to tissues and cells in the human body. T2-DM is a condition that is strongly connected to both micro vascular (MIV) and macro vascular (MAV) problems, which include nephropathy, retinopathy, neuropathy (MIV), and peripheral vascular disease (MAV), contributing to the effect on internal organs and blood vessel-related complications [3]. DM can be identified in three different forms, namely: type 1 diabetes mellitus (T1-DM) affects the pancreas by producing insulin in a lower amount than needed by the entire human body [4]. To keep the body's insulin level at the right level, it needs supplements from outside the body. T2-DM is a condition characterized by a significant increase in blood sugar levels. In this structure of DM, the insulin levels are disturbed, and the body fails to utilize and produce [5]. It is a type of

hormone developed in the pancreas that aids in maintaining sugar levels in the blood. In particular, this hormone maintains the amount of glucose that flows through the cells. In general, after the consumption of food, blood sugar levels in the blood are identified in the high range [6]. The extra glucose in the blood is transferred into the cells when the pancreas secretes insulin, which diminishes the quantity of glucose in the bloodstream [7]. When this abnormality is not identified at an early stage using proper diagnosis, this T2-DM can lead to severe chronic health disorders. Chronic hyperglycemia, a side effect of diabetes, can damage, weaken, or kill many organs over time, especially the kidneys, eyes, heart, nerves, and blood vessels [8].

A. MIV and MAV Complications

Based on the research on DM, it is evident that the following are the damaging factors for human health:

- latent loss of eyesight with Retinopathy (RET).

- fluid accumulation causes Nephropathy (NEP), which in turn leads to hyperglycemia.

- Neuropathy (NEU) is a condition that affects the supply of blood by causing late healing in the functioning of nerves, shortening the sensation in the feet, and ulcers.

- the obstruction and shortened flow of oxygenated blood to the bladder and kidneys are caused due to cardio vascular disease (CVD).

- the internal layers of large and small arteries are the complications caused due to peripheral vascular diseases (PVD).

B. Role of Machine Learning in Diabetes Detection

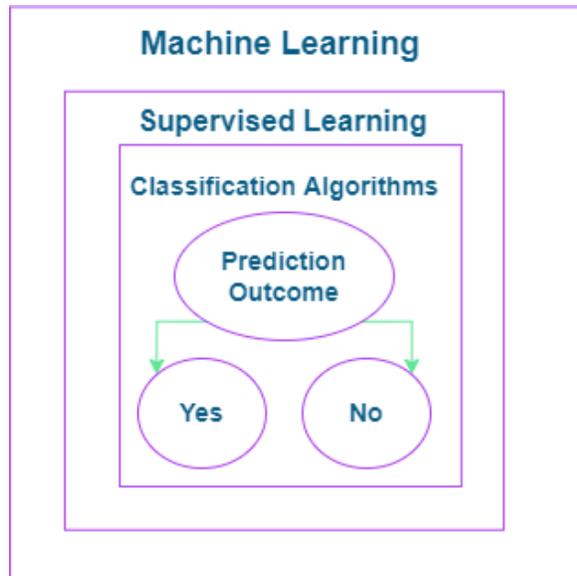
Machine Learning (ML) models [9] have been developed in most medical implementations as an encouraging tool to help in taking spontaneous conclusions related to various infections, along with DM, which produces favorable results. With ML algorithms, vast amounts of data are processed by minimizing the effort [10]. This data is used to train models, which then generate the most appropriate results associated


Fig. 1. Machine Learning Classification.

with the input data [11]. It is possible to train the models using any characteristics that are feasible and medically necessary. These parameters differ in accordance with the wide range of symptoms. Some of the learning models used for classification purposes are decision trees, support vector machines, and regression analysis [12]. The approaches are often embedded in statistical analysis to extract useful information from the core data. A combination of these approaches can be used to build a predictive model that identifies the risk complications of T2-DM based on the deciding risk prediction calculator. A scenario of disease prediction with machine learning models is depicted in Fig. 1.

This research study focuses on identifying the risk levels of MIV and MAV complications in T2-DM using different ML algorithms. Accurate prediction of MIV and MAV complications could aid in more targeted measures that would prevent or slow their progression.

The rest of this paper has the following structure. Section II discusses related research and its limitations. Section III presents the proposed methodology. Section IV discusses the experimental results, and Section V concludes the study with potential future work.

II. RELATED WORK

Allen A. et al. [13] trained two ML algorithms to predict DKD severity stages. To assess performance, they compared them to the Centers for Disease Control and Prevention (CDC) risk score. The algorithms were validated using both a hold-out test set and an external dataset obtained from different facilities. In both the hold-out and external datasets, their proposed algorithms outperformed the CDC risk score, achieving an area under the receiver operating characteristic curve (AUROC) of 0.75 on the hold-out set for the prediction of any-stage DKD and an AUROC of over 0.82 for more severe endpoints, compared to the CDC risk score, which had an AUROC of less than 0.70 on all test sets and endpoints. Lu H. et al.

[14] suggested that the perception of acute infection changes and predicting people inculcating the threat of treatment-resistant infection are mainly considered. For chronic disease identification, an ensemble of original patient-channel and ML techniques is proposed. This proposed method is used in networks with health scenarios. T2-DM is identified in a subset of patients for this purpose. This method identified the factors in identifying the acute infection threat using eight ML techniques. The significant observations show that the advanced structure with ML classifiers achieved an AUC ranging from 0.79 to 0.91. Rashid, M. et al. [15] identified a root cause of death among T2-DM patients due to micro vascular problems. Their study aims to examine the use of the entire ML procedure in identifying issues using people's medical, clinical, and statistical examinations. The records of 96 people from Bangladesh were examined with T2-DM. They are examined through a chi-squared examination to demo-graphically represent the major key points in identifying the micro vascular problems like CAN, DPN, and RET. Various ML models like LR, RF, and SVM were used for the exam-ination of micro vascular problems. The exact outcomes are determined through the random forest through hypertension, gender, micro albuminuria, and smoking habit. The authors showed ML represents accurate results in identifying micro vascular problems in T2-DM patients. Based on their records, which aid in controlling these people by later micro vascular problems that lead to early death. Deberneh, H. et al. [16] considered factors like FPG, triglycerides, HbA1c, gamma-GTP, BMI, family history, physical activity, smoking, drinking, gender, age, and uric acid in their study. Then the engaged LR, RF, SVM, XGBoost and ensemble ML procedures relied on these attributes to identify the result as normal, diabetic, or pre-diabetic. Depending on the hypothetical outcomes, the execution of the identified method strives to preferably better in predicting the circumstance of type 2 diabetes. This method also helps doctors and patients with required forecasting data on the probability of occurring type 2 diabetes. Fazakis et al. [17] proposed a worker-centric, IoT-enabled, unobtrusive health, well-being, and functional ability monitoring frame-work with AI tools for the early detection of T2-DM. Their diabetes risk prediction system used several ML models to ap-ply, evaluate, and incorporate KDD components. The ensemble WeightedVotingLRRFs ML model's AUC of 0.884 improves diabetes prediction. Jian, Y. et al. [18] proposed multiple ML algorithms to predict and classify eight diabetes complications. Metabolic syndrome, dyslipidemia, neuropathy, nephropathy, diabetic foot, hypertension, obesity, and retinopathy are among the complications. The authors used a dataset with 884 cases and 79 features. The models' performance was evaluated using accuracy and F1-score metrics, which reached a maximum of 97.8% and 97.7%, respectively. Neha Prerna et al. [19] proposed a research study that uses different ML algorithms to predict the risk of type 2 diabetes among individuals based on their lifestyle and family history. The experiment was carried out with 952 instances collected via an online and offline ques-tionnaire, which included 18 questions about health, lifestyle, and family background. The proposed ML algorithms were also tested on the "Pima Indian Diabetes database." Their experimental results revealed that the random forest classifier performed the best in terms of accuracy. Jung, L. C et al. [20] described a method for identifying subtle effects of genetic variants using whole genome sequencing data and improving

the prediction accuracy of T2-DM at the population level. The method entailed first performing sparse principal component analysis to genotype data to obtain orthogonal features, then creating a new classifier with single nucleotide polymorphism (SNP)-specific regularization parameters to reduce the false positive rate of feature selection, and finally verifying feature relevance with penalized logistic regression. The researchers used a dataset containing 625597 SNPs and 23 environmental variables from 3326 people. The method identified 271 genetic variants with minor effects on T2DM prediction. It is also more than 15 times faster than random forest and extreme gradient boosting (XGBoost) classifiers. Hasan, M.K. et al. [21] proposed a method for DM identification for the metadata, involving 768 women, 268 of who had high blood sugar levels and 500 of whom were normal. In their study, initialization is critical for maintaining cutting-edge results. This includes edge elimination, replacement with the average for lost numbers, data stabilization, factor alternative, and five-fold validation. K-Nearest Neighbor, Decision Trees, Random Forest, AdaBoost, and other Different ML models were used. The authors also proposed a weighted ensembling of different ML models. AUC was chosen as the performance metric. The experiments demonstrated that the ensembling classifier outperforms all others, with sensitivity, specificity, false omission rate, diagnostic odds ratio, and AUC values of 0.789, 0.934, 0.092, 66.234, and 0.950, respectively. Islam, M.S. et al. [22] proposed a study to predict the Hemoglobin Alc (HbAlc) levels in advance using ML methods in order to enable early diagnosis and prevent diabetes complications. The fractional derivative, glucose variability, time in range, and wavelet decomposition methods were used to extract features from continuous glucose monitoring (CGM) data. The CGM data from the Diabetes Research in Children Network (DirecNet) was utilized. According to the results, the ensembling of the random forest and extreme gradient boosting algorithms, combined with the feature fusion, produced the best performance with a low mean absolute error (MAE) of 3.39 mmol/mol and a high coefficient of determination (R-squared) score of 0.81. Kopitar, L. et al. [23] compared ML models for the prediction of T2-DM by using various regression techniques on undiagnosed patient data. Fasting plasma samples are measured over a six-month period using 100 computational iterations. These iterations were examined using various data subsets. According to the study analysis, the linear regression model had the lowest average RMSE of 0.838, followed by random forest with 0.842 and Xgboost with 0.881. Dagliati et al. [24] proposed a data mining pipeline to derive a set of predictive models of T2DM complications from nearly 1000 patients' electronic health record data. Clinical center profiling, predictive model targeting, predictive model construction, and model validation are all part of the pipeline. The logistic regression-based method with stepwise feature selection was used to predict the onset of retinopathy, neuropathy, or nephropathy at three different time intervals: three, five, and seven years after the initial visit to the Hospital Center for Diabetes. Gender, age, time since diagnosis, BMI, hypertension, HbA1c, and smoking habit were all factors considered in the study. The final models, customized for the complications, had an accuracy of up to 0.838. For each complication and time scenario, different attributes were chosen. This led to specialized models that are easy to use in clinical practice. Wei, S. et al. [25] used a variety of machine learning techniques, i.e., Neural Net-

works, Support Vector Machines, and Decision Trees to detect diabetes. The best accuracy acquired was 77.86% through the 10-fold cross-validation approach. Fan Yuting et al. [26] proposed an effective ML model for identifying the problem of blood sugar levels in non-adherent T2-DM. The authors looked at people who had not had glycosylated hemoglobin in the previous month to identify the risk in blood sugar levels. Seven different ML procedures are utilized to implement eighteen identification methods. Identification achievement is majorly analyzed through the AUC of the examining group. Based on 800 patients' data, 20.6% could meet the insertion range, of which 78.2% had poor glycemic guide. The greater AUC of the analysis set for nephropathy, peripheral neuropathy, angiopathy, retinopathy, and glycosylated hemoglobin is determined as 0.902 ± 0.040, 0.859 ± 0.050, 0.889 ± 0.059, 0.832 ± 0.086, and 0.825 ± 0.092 accordingly. Both the ML models and univariate testing attained an equal outcome. Fiarni et al. [27] proposed Naive Bayes and C4.5 classification approaches, as well as k-means clustering, for identifying the risk complications of T2-DM patients. The authors analyzed each technique's reliability and identified the associated elements and sub-features as clinical contributing factors. As a result, the most major risk factor for retinopathy is a female patient who is now experiencing a hypertensive problem. In terms of nephrotic syndrome, the most major risk factor is a history of diabetes lasting over four years. Furthermore, it was more prevalent in female patients with a BMI over 25. There is no clear association between the duration of diabetes and certain complications. The overall accuracy of the suggested model is 68%, which means that it could be used as an alternative way to find diabetes complications early. Sudharsan, B. et al. [28] proposed a reducing phenomenon of blood sugars in people having T2-DM. The authors analyzed the risk of complications through different data sets. The quantity of self-regulation of blood sugar levels required by the method is nearly ten per week. The vulnerability of the method for identifying blood sugar levels in the coming 24 hours is 92%, and the selectivity is 70%. In their work, the identification group was four hours of blood sugar, and the selectivity advanced to 90%. The advanced ML methods can identify blood sugar levels with an accurate level of vulnerability and selectivity.

After taking earlier research work into consideration, we observed that the majority of the work concentrated on identifying the T2-DM with limited complications. To overcome this limitation and to identify the severity levels, in this proposed work, we concentrated on predicting the risk levels at an early stage, falling under low, medium, and high categories. These levels are discriminated against among the T2-DM patients with MIV and MAV complications such as Nephropathy, Neuropathy, Retinopathy, cardio vascular and Peripheral vascular.

III. METHODOLOGY

This section goes into more detail about the statistical analysis of the dataset used for this study, the T2-DM patient network, data preprocessing approaches, ML methods, and the proposed model.

A. Statistical Analysis of the Dataset

For this study, 3068 records are considered, particularly with subjects between 30 and 80 years of age, of which 1565

are males, and 1503 are females. The mean, standard deviation, error rate, and P-value of primary attributes that are available in the dataset are displayed in Table I. These attributes are mainly considered in identifying the risk levels of MIV and MAV complications in T2-DM patients collected from various multi-specialty hospitals in India [29].

The distribution of samples depends on the parameters in a dataset and can be represented using frequency tables. These are useful in making decisions that appear more or less within the dataset. Every parameter and its selection range can be easily identified. From this, basic charts like histograms and bar charts can be generated for data visualization. The representation of some primary attributes in the dataset is depicted using a histogram, shown in Fig. 2.

B. T2-DM Complications Network

In this work, the graph theory concepts are used to construct the T2-DM complications network. This network represents the common complications among different patients. For this, four different patients with MIV and MAV complications are considered from the dataset. The relation among patients and various complications are determined by Eq. (1).

$$G = (V, E) \tag{1}$$

where 'V' represents the nodes that indicate the patient's complications. The common complications for these patients are connected through 'edges' (E). Hence, these sets of nodes and edges are combined together to form a complication network (G).

Fig. 3. represents the complication network among T2-DM patients to identify the relationship between patients and their common health complications. The left-hand side of this figure shows three male and one female patients' data along with their disease complications, respectively. The middle part represents the edge relation between patients connected through nodes. For instance, patients p1, p2, and p4 all have T2-DM in common. Due to this, "neuropathy" is a common complication. Also, patients p2 and p4 show a common complication of "nephropathy". Hence, by considering this scenario, the patient's p1, p2, and p4 are connected through nodes, and their common health comorbidities are interlinked with edges, thereby forming a subgraph to construct a complications network. By constructing this network, the classification between T2-DM and non-T2-DM becomes easier through ML models.

C. Data Preprocessing

When developing ML models, data preprocessing is the first step in the process. Real-world data is tainted and contaminated by inconsistencies, noise, incomplete information, missing values, inaccurate (containing errors or outliers), and lack of specific attribute values [31]. This is where data preprocessing comes into play; it helps to clean, format, and organize raw data, preparing it to build ML models. Simply put, data preprocessing helps improve data quality and promotes the extraction of meaningful insights from data to train more accurate prediction models. The data preprocessing procedure in ML includes the following steps [32].

- **Missing Values:** This step involves identifying and appropriately handling missing values; failing to do so could lead to inaccurate and erroneous conclusions and inferences drawn from the data. There are two methods for dealing with missing data: (a) deleting a specific row, in which we remove a particular row that contains a null value for a feature or a particular column where more than 70% of the values are missing; and (b) calculating the mean, median, or mode of a specific feature, column, or row that contains a missing value and replacing the outcome with the missing value. This method is helpful for features with numeric data, such as salary, year, and so on, and it can add variance to the dataset while efficiently negating any data loss. As a result, it produces better results than the first method.

- **Removing Duplicates:** This step includes deleting duplicate entries. During model training, an entry that appears more than once is given disproportionate weight. Where identical entries are not all in the same set, duplicate entries can ruin the split between training, validation, and test sets. This can lead to biased estimates of how well the model will perform, which can cause the model to underperform in production.

- **Removing irrelevant data:** This step involves removing irrelevant entries from the dataset. Data often comes from a variety of sources, and a given set of data is likely to have entries that don't belong.

- **Detecting Outliers:** This step entails detecting outliers by exploring the ranges and possibilities for categorical and numerical data entries. For instance, a negative price for a vehicle is an outlier. Outlier detection or anomaly detection algorithms, such as Isolation Fores or KNN, can also be used to detect and remove outliers automatically.

- **Categorical Data Encoding:** This step includes transforming categorical data (i.e., a patient's gender) into numerical values. ML models are built on mathematical equations that can only work with numbers. As a result, the categorical values of the features must be converted into numerical values, which can then be fed into ML models to learn from and improve performance.

- **Feature Selection:** This step always plays an important role in machine learning, where we will have several features in the dataset and have to select the best ones when building a model. The inclusion of irrelevant features reduces the model's generalization capability and may reduce a classifier's overall accuracy. In addition, the model's overall complexity grows as more features are added. Feature selection methods in machine learning can be broadly classified as Wrapper, Embedded, and Filter. Wrapper methods use a greedy search approach, evaluating all possible feature combinations against the evaluation criterion. Embedded methods are iterative in the sense that they handle each iteration of the model training process and extract those features which contribute the most to the training for that iteration. Filter methods pick

TABLE I. SUMMARY OF PRIMARY ATTRIBUTES OF THE DATASET [29]

Parameter	Description	Range	Population Size (n)	Mean	Standard Deviation	Standard Error Mean	P-value
Age	Life span of patient	30 to 49	1222	54.92	14.494	0.262	0.011
		50 to 59	600				
		60 to 69	598				
		70 to 80	648				
Sex	Identity of patient	Male	1565	0.51	0.500	0.009	0.048
		Female	1503				
BMI	Determines the level of fat	18.5	155	28.823	6.3138	0.1140	0.025
		18.5 to 24.9	779				
		25.0 to 29.9	736				
		30.0	1398				
SBP	Pressure in arteries when heart beats	120	462	139.32	20.008	0.361	0.015
		120 to 139	891				
		140	1715				
DBP	Pressure in arteries when heart rest among the beats	80	822	84.67	11.348	0.205	0.037
		80 to 89	755				
		90	1491				
HbA1C	Blood pressure attached to hemoglobin	5.7%	127	11.1308	2.671	0.4823	0.016
		=5.7% to 6.4%	617				
		=6.5%	2324				
FBS	Blood sugar level after fasting	=100 mg/dL	40	230.19	76.879	1.388	0.006
		100 to =125 mg/dL	288				
		=126 mg/dL	2740				
PPBS	Determine type of sugar	180 mg/dL	447	334.67	123.539	2.230	0.001
		=180 to 250 mg/dL	492				
		=250 mg/dL	2129				
DIA_LIFE	Span of diabetes in months	40	1350	43.14	12.367	0.223	0.038
		=40 to 60	1388				
		=60	330

TABLE II. PERFORMANCE OF MICRO VASCULAR AND MACRO VASCULAR MODULES

Module	Model	Accuracy	Precision	Sensitivity	Specificity	F1-Score
Nephropathy (NEP)	RF with base DT	95.43%	96.57%	94.0%	96.81%	95.27%
	RF with base LR	94.78%	97.80%	91.13%	98.12%	94.35%
	RF with base AB	92.91%	93.85%	90.73%	94.81%	92.26%
Neuropathy (NEU)	RF with base DT	94.62%	96.84%	92.0%	97.13%	94.35%
	RF with base LR	93.05%%	94.57%	91.26%	94.81%	92.88%
	RF with base AB	91.12%	93.52%	88.54%	93.75%	90.96%
Retinopathy (RET)	RF with base DT	96.25%	96.78%	95.85%	96.66%	96.32%
	RF with base LR	93.37%	94.83%	92.25%	94.58%	93.53%
	RF with base AB	90.78%	92.65%	88.94%	92.71%	90.76%
Cardio Vascular (CVD)	RF with base DT	97.55%	96.0%	98.96%	96.28%	97.46%
	RF with base LR	93.91%	93.54%	93.95%	93.88%	93.75%
	RF with base AB	91.04%	92.91%	88.63%	93.39%	90.72%
Peripheral Vascular (PVD)	RF with base DT	97.83%	98.0%	86.88%	98.0%	92.11%
	RF with base LR	97.56%	97.9%	71.42%	98.0%	83.33%
	RF with base AB	97.67%	98.0%	78.94%	98.0%	88.23%

up the intrinsic properties of the features measured using univariate statistics. Information Gain and the Chi-square Test are two of the Filter methods. In this research, we have used the Chi-square Test to select the features related to T2-DM. The Chi-square between each feature and the target is calculated, and the number of features with the best Chi-square scores is selected. The Formula for Chi-square is given in Eq. (2), where c is the degrees of freedom, O is the observed value(s), and E is the expected value(s).

$$\chi_c^2 = \sum_{i=1}^{n} \frac{(O_i - E_i)^2}{E_i} \tag{2}$$

- **Data Split:** This step includes splitting the dataset for the ML model into two or more separate sets. Typically, with a two-part split, one part (training dataset) is used to train the ML model, and the other (test dataset) is used to evaluate or test the model. The testing data set is used following training. Usually, the dataset is split into an 80:20 ratio or 70:30 ratio. This

TABLE III. EXISTING COMPLICATIONS

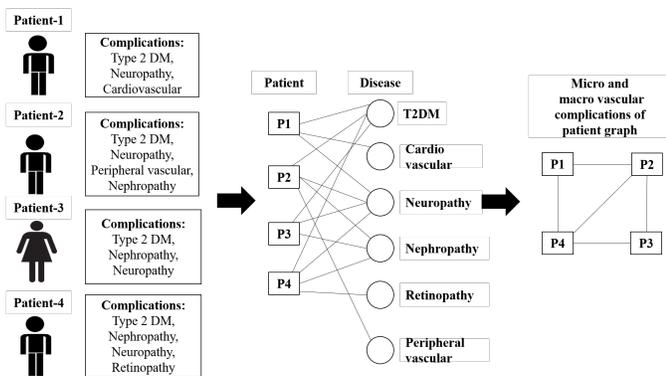
Patient	Existing Complications				
	NEP	NEU	RET	CVD	PVD
A	0	1	0	0	0
B	1	0	1	0	0
C	0	0	0	0	0
D	1	0	1	0	0
E	1	1	0	0	0


Fig. 3. MIV and MAV Complication Network.
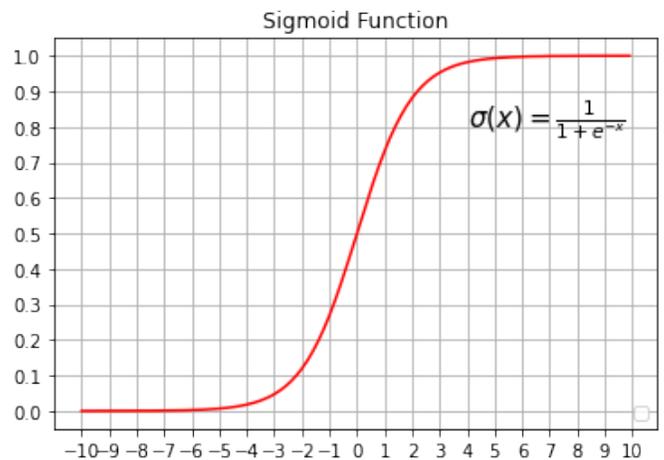

Fig. 4. The Sigmoid Function.

means that 80% or 70% of the data is used for training the model, while the remaining 20% or 30%, is used

Algorithm: Generate_decision_tree. Generate a decision tree from the training tuples of data partition *D*.

Input:

- Data partition, *D*, which is a set of training tuples and their associated class labels;
- *attribute_list*, the set of candidate attributes;
- *Attribute_selection_method*, a procedure to determine the splitting criterion that "best" partitions the data tuples into individual classes. This criterion consists of a *splitting_attribute* and, possibly, either a *split point* or *splitting subset*.

Output: A decision tree.

Method:

(1) create a node *N*;
(2) **if** tuples in *D* are all of the same class, *C* **then**
(3)   return *N* as a leaf node labeled with the class *C*;
(4) **if** *attribute_list* is empty **then**
(5)   return *N* as a leaf node labeled with the majority class in *D*; // majority voting
(6) apply Attribute_selection_method(*D*, *attribute_list*) to find the "best" *splitting_criterion*;
(7) label node *N* with *splitting_criterion*;
(8) **if** *splitting_attribute* is discrete-valued **and**
        multiway splits allowed **then** // not restricted to binary trees
(9)   *attribute_list* ← *attribute_list* − *splitting_attribute*; // remove *splitting_attribute*
(10) **for each** outcome *j* of *splitting_criterion*
        // partition the tuples and grow subtrees for each partition
(11)   let *D_j* be the set of data tuples in *D* satisfying outcome *j*; // a partition
(12)   **if** *D_j* is empty **then**
(13)   attach a leaf labeled with the majority class in *D* to node *N*;
(14)   **else** attach the node returned by **Generate_decision_tree**(*D_j*, *attribute_list*) to node *N*;
     endfor
(15) return *N*;

Fig. 5. Basic DT Algorithm [30].

TABLE IV. PREDICTED COMPLICATIONS

Patient	Proposed model risk predictions				
	NEP	NEU	RET	CVD	PVD
A	Low	Medium	No	No	No
B	Medium	No	Medium	Low	No
C	Low	No	No	No	No
D	Medium	No	Medium	Low	No
E	Medium	Medium	No	Low	No

for testing. Most often, data is separated into three or more sets. With three sets, the additional set is the validation set, which is used to modify the parameters of the learning process.

- **Data Scaling:** This crucial step concludes the data preprocessing phase in ML. It is a technique for converting all independent features of a dataset to the same scale. This allows for faster learning convergence and more uniform influence across all weights. Normalization and Standardization are two commonly used methods for feature scaling.

  - Normalization: This technique is known as Min-Max scaling, in which all independent feature values are changed between 0 and 1, as defined below:

$$X' = \frac{X - X_{min}}{X_{max} - X_{min}} \quad (3)$$

where X_{min} and X_{max} are the minimum and the maximum values of the feature, respectively.

  - Standardization: In this technique, the independent feature values are standardized by removing the mean and scaling to unit variance. The standard score of a sample X is calculated as:

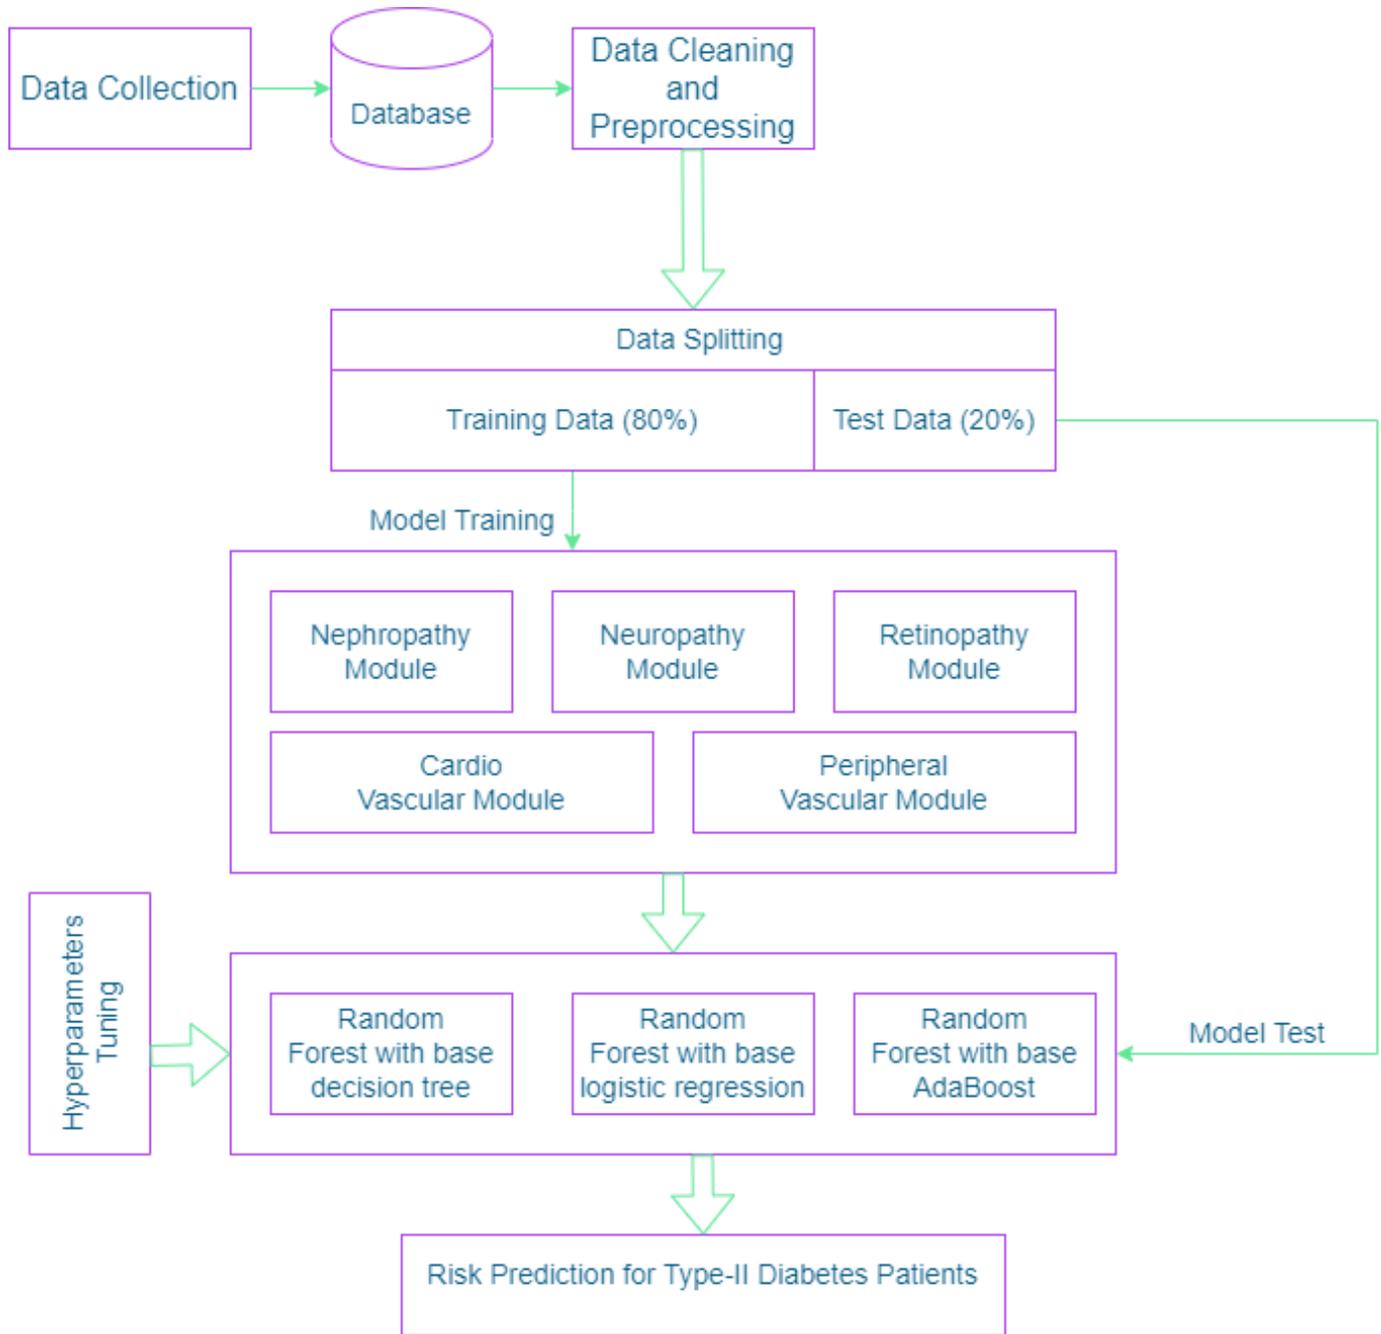
$$X' = \frac{X - \mu}{\sigma} \quad (4)$$


Fig. 6. Proposed Framework.

where μ is the mean of the feature values, and σ is the standard deviation of the feature values.

The data preprocessing procedure can vary slightly according to each dataset, but many of the aforementioned steps are applicable to all situations.

D. ML Models

1) Logistic Regression: Logistic Regression (LR) is a powerful ML algorithm commonly used to solve binary classification problems. It is called after the core function of the method, the logistic function. The logistic function (a.k.a. sigmoid function) has an S-shaped curve that can map any real-valued number to a value between 0 and 1 [33]. The sigmoid function, usually denoted by $\sigma(x)$ is defined as follows:

$$\sigma(x) = \frac{1}{1 + e^{-x}} \tag{5}$$

where e is Euler's number and x is the actual numerical value to be transformed. Fig. 4 shows a plot of the numbers between -10 and 10 transformed into the range 0 and 1 using the sigmoid function. LR, like linear regression, uses an equation as its representation. To predict an output value (y),

- TP (True Positives): Number of times the model correctly predicts positive samples.
- TN (True Negatives): Number of times the model correctly predicts negative samples.
- FN (False Negatives): Number of times the model incorrectly predicts positive samples as negatives.
- FP (False Positives): Number of times the model incorrectly predicts negative samples as positives.

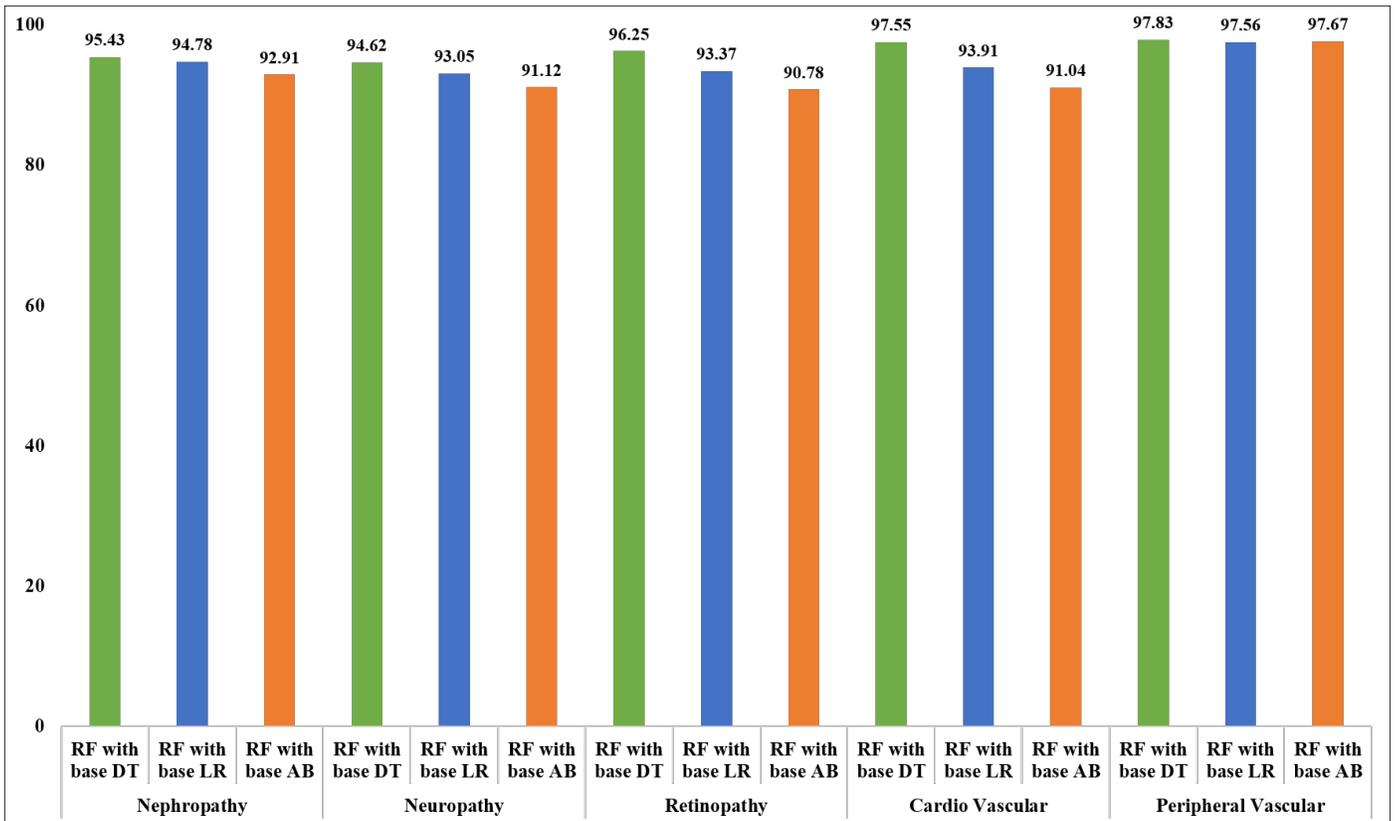

Fig. 13. Accuracy Results for All Complication Modules.

input values (x) are linearly combined using weights values. The output value being modeled is a binary value (0 or 1) rather than a numeric value, which distinguishes it from linear regression. An example LR equation is shown below:

$$y = \frac{1}{1 + e^{-(w_0 + w_1 \times x)}} \quad (6)$$

Where y is the predicted output, w_0 is the bias and w_1 is the weight for the single input value (x). Each column in the dataset has an associated w weight that must be learned from the training dataset. LR predicts the probability of the positive class (e.g., a patient has diabetes). For example, if we're predicting whether or not a patient has diabetes or not based on their age, then the positive class could be diabetic, and the LR model could be written as the probability of being diabetic given a patient's age, or more formally:

$$P(x) = P(y = \text{diabetic} \mid x) \quad (7)$$

To get a clear answer, we can snap the probabilities to a binary class value, such as:

$$
\begin{aligned}
\text{prediction} &= 0 \text{ (non-diabetic)} \text{ IF } p(\text{ diabetic }) < 0.5 \\
\text{prediction} &= 1 \text{ (diabetic)} \text{ IF } p(\text{ diabetic }) \geq 0.5
\end{aligned}
\quad (8)
$$

2) Decision Tree: Decision Tree (DT) algorithm is another popular supervised ML algorithm used for solving both classification and regression problems. The goal of using a DT is to learn simple decision rules from training data to create an efficient model that predicts the class of the target variable [34]. DT is a flowchart-like tree structure in which each leaf node corresponds to a class label, and features are represented on the internal node of the tree. The root node is the topmost node in a tree. The DT can be better understood with the help of the algorithm summarized in Fig. 5.

By adopting the above algorithm to the problem of determining whether an instance belongs to class-0 or class-1, we can construct a decision tree by selecting a root node, internal nodes, and leaf nodes, and then defining the class's splitting criteria. For example, we can select the "glucose" feature to be the root node and based on it and other features such as "systolic BP," "Diastolic BP," "Age," and "BMI," we can construct our tree.

The most challenging aspect of the DT algorithm is selecting The root node or first test attribute based on what we will start splitting the data. It is selected based on statistical measures like Information Gain (IG), Gain Ratio, or Gini Index. In this paper, we used the IG measure. IG helps to measure the reduction of uncertainty of a certain feature. It also helps decide which feature is good as a root node. The calculation of $IG(a)$ shows us the formula for the gain in the general case. Let S denote the dataset to be split by creating a new node. Let's suppose that the attribute a can take m values: $a_1, a_2, \ldots, a_m$, and that p_i is the fraction of the objects in S with $a = a_i$. Then, the information gain of a is:

$$IG(a) = H(S) - \sum_{i=1}^{m} p_i H(S \mid a = a_i) \quad (9)$$

Here $H(s)$ is the Entropy of the dataset, is a function H of probabilities $p_1, p_2, \ldots, p_n$. Entropy can be thought of as the amount of variance in the data. For binary classification problems, the following formula is used to compute Entropy.

$$H(S) = -\sum_{i=1}^{n} p_i \log_2 p_i \quad (10)$$

3) Random Forest: Random Forest (RF) is another popular ML technique used to solve regression and classification problems. RF consists of many decision trees. The 'forest' generated by the random forest algorithm is trained using an ensemble method known as bootstrap aggregation (or bagging for short) [35]. Bagging is a technique that combines the predictions from multiple decision trees to make more accurate predictions than any single model. The model's final output is based on the majority of the predictions if the problem is a classification, or the mean of the predictions if the problem is a regression.

4) AdaBoost: Boosting is an ensemble technique for constructing a strong classifier from a collection of weak classifiers. This is accomplished by first creating a model from the training data, followed by the creation of a second model that attempts to correct the errors in the first model. Models are added until the training dataset is perfectly predicted or until the maximum number of models is reached [36]. AdaBoost, shortened for Adaptive Boosting [37], was the first successful boosting algorithm developed for binary classification problems. Decision trees with one level are the most appropriate and widely used algorithm with AdaBoost because these trees are so short and only have one classification decision. They are commonly known as "decision stumps." Weights are assigned to each instance in the training dataset. The initial weight is set as follows:

$$\text{weight}(x_i) = \frac{1}{M} \quad (11)$$

where x_i is the i'th training instance and M is the number of training instances. To train a single model, a weak classifier is prepared on the training data using the weighted samples. Only binary classification tasks are supported, so each decision stump makes one decision on one input variable and outputs a $+1.0$ or -1.0 value for the first and second class value.

The misclassification rate (E) for the trained model can be calculated as follows:

$$E = \frac{r - M}{M} \quad (12)$$

where r is the number of training instances predicted correctly by the model and M is the total number of the training instances. The opposite of misclassification rate would be accuracy, calculated as:

$$\text{Accuracy} = 1 - E \quad (13)$$

To take into account the weighting of the training instances, the weighted sum of the misclassification rate is computed as:

$$E = \frac{\sum_{i=1}^{n} (w_i \times p_i)}{\sum_{i=1}^{n} w} \quad (14)$$

where w is the weight for training instance i and p_i is the prediction error for training instance i, which is 1

if misclassified and 0 if correctly classified. For the trained model, a stage value is calculated, which provides a weighting for any predictions made by the model. A trained model's stage value s_v is calculated as follows:

$$s_v = \ln\left(\frac{1-E}{E}\right) \qquad (15)$$

The stage weight has the effect of giving more weight or contribution to the final prediction to more accurate models. The training weights are adjusted so that incorrectly predicted instances receive more weight and correctly predicted instances receive less weight. For instance, the weight w of one training instance is updated as follows:

$$w = w \times e^{(s_v \times p)} \qquad (16)$$

E. Proposed T2DC Prediction Model

The proposed framework for predicting the risk levels of MIV and MAV complications among T2-DM patients using the RF-based method is shown in Fig. 6. It is broken down into six major steps: a) gathering data from reliable sources; b) cleaning and preprocessing the data; c) dividing the cleaned data into two sets—a training set (80%) and a testing set (20%); d) training the model with the training set; e) evaluating the model performance of the trained model with various base estimators such as DT, LR, and Adaboost models; and f) tuning the model's hyperparameters to see if its accuracy can be improved.

IV. RESULTS AND DISCUSSIONS

This section presents all of the results obtained by the proposed framework, as well as related discussions.

A. Model Performance Evaluation Metrics

Evaluation of the performance of a classification model is based on the number of test samples that the model correctly and incorrectly predicts. The confusion matrix extracts additional information about the performance of a predictive model. It demonstrates which classes are correctly and incorrectly predicted and what types of errors are made. Fig. 7 shows an illustration of a confusion matrix for a binary classifier. The four classification metrics (TP, FP, FN, TN) are calculated, and the confusion matrix compares the model's predicted value to the actual value. The confusion matrix is not exactly a performance metric, but it is used to calculate important classification metrics like accuracy, precision, recall, specificity, and, most importantly, the f1-score, which are used to evaluate the results.

1) **Accuracy:** It is the fraction of correct predictions made by the model.

$$\text{Accuracy} = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{TN} + \text{FP} + \text{FN}} \times 100\% \qquad (17)$$

2) **Precision:** It is the proportion of true positives to all positive predictions made by the model.

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}} \times 100\% \qquad (18)$$

3) **Recall:** It is the proportion of actual positives correctly identified by the model.

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}} \times 100\% \qquad (19)$$

4) **Specificity:** It is the proportion of actual negatives correctly identified by the model.

$$\text{Specificity} = \frac{\text{TN}}{\text{TN} + \text{FP}} \times 100\% \qquad (20)$$

5) **F1-score:** It is the proportion of actual positives correctly identified by the model.

$$F1\text{-}score = \frac{2 * \text{precision} * \text{recall}}{\text{precision} + \text{recall}} \times 100\% \qquad (21)$$

B. Feature Importance Score

Feature importance is a process that involves calculating the score for the input features for a given model — the scores simply represent the "importance" of each feature. A higher score indicates that the specific feature will have a greater impact on the model used to predict a specific class. This can enhance a predictive model's efficiency and effectiveness on the problem. The feature importance scores on T2-DM complications such as nephropathy, neuropathy, retinopathy, cardio vascular, and peripheral vascular modules of the RF model with different base estimators, DT, AdaBoost, and LR, are shown in Fig. 8 to 12, respectively. It is evident from the figures that BMI and HbA1c are the most significant features in the dataset.

C. Model Evaluation Discussion

Table II represents the evaluation of MIV and MAV complications in T2-DM patients. After evaluating the proposed ML models, the decision tree as a base model with RF provides the best performance in all evaluation metrics. The visualization of the accuracy metric for all complication modules is shown in Fig. 13.

D. Risk Prediction Identification

Table III shows the results of T2-DM patients with existing complications, and Table IV shows the predicted complications of the same patients. The existing complications only represent True (1) or False (0) in regard to NEP, NEU, RET, CVD, and PVD. This type of result is not sufficient to assist doctors in identifying further complications. To overcome this, our proposed model can automatically identify the risk levels with respect to low, medium, and high depending upon the severity of T2-DM complications among patients. For instance, T2-DM patient-A has only one NEU complication in existing data. In contrast, the same instance, when evaluated on the proposed risk prediction model, shows a "low" risk in NEP and a "medium" risk in NEU. This helps healthcare providers make accurate treatment plans for T2-DM patients so they can give them good clinical care.

V. Conclusion

AI and its applications, such as machine learning (ML) in medical diagnosis and healthcare, have shown enormous promise in recent years, both in terms of improving care and alleviating the enormous strains on the healthcare system. ML-based solutions are revolutionizing diabetes care and helping the medical community gain ground in the fight against the disease. The number of people with diabetes who go undiagnosed can be lowered with the help of ML algorithms that allow for accurate early diagnosis. In this research, we have identified MIV and MAV risk levels of T2-DM complications by proposing a T2DC ML-based prediction model. We have used a decision tree as a base estimator with random forest and obtained better accuracy when compared to other base models. The proposed model achieves 95.43%, 94.62%, 96.25%, 97.55%, and 97.83% accuracies for NEP, NEU, RET, CVD, and PVD complications, respectively. The model can be used as a viable aid in clinical decision-making for practitioners and diabetes educators to improve the quality of life of patients. In the future, we will study how T2-DM and related complications affect pregnant women.

Abstract—Computers have evolved over the years, and as the evolution continues, we have been ushered into an era where high-speed internet has made it possible for devices in our homes, hospital, energy, and industry to communicate with each other. This era is known as the Internet of Things (IoT). IoT has several benefits in a country's economy's health, energy, transportation, and agriculture sectors. These enormous benefits, coupled with the computational constraint of IoT devices, make it challenging to deploy enhanced security protocols on them, making IoT devices a target of cyber-attacks. One approach that has been used in traditional computing over the years to fight cyber-attacks is Intrusion Detection System (IDS). However, it is practically impossible to deploy IDS meant for traditional computers in IoT environments because of the computational constraint of these devices. This study proposes a lightweight IDS for IoT devices using an incremental ensemble learning technique. We used Gaussian Naive Bayes and Hoeffding trees to build our incremental ensemble model. The model was then evaluated on the TON IoT dataset. Our proposed model was compared with other proposed state-of-the-art methods and evaluated using the same dataset. The experimental results show that the proposed model achieved an average accuracy of 99.98%. We also evaluated the memory consumption of our model, which showed that our model achieved a lightweight model status of 650.11KB as the highest memory consumption and 122.38KB as the lowest memory consumption.

Keywords—*Cyber-security; ensemble machine learning; incremental machine learning; Internet of Things; intrusion detection; online machine learning*

I. INTRODUCTION

As the evolution of computing technology continues, the ability of things, such as fridges, air-conditioners, medical equipments, and meters among others to communicate has become a reality due to fast communication technologies. A paradigm popularly known as the Internet of Things (IoT) has not only become a household term with smart homes, but it also has numerous uses in energy, agriculture, manufacturing, healthcare, and transportation. There is no doubt that the IoT has many benefits, which is why the number of IoT devices is growing exponentially. According to [1], the number of

IoT devices is estimated to reach 30.9 billion by 2025. The numerous benefits of the IoT ecosystem make it attractive to cyber-attacks. An attack statistic presented by SAM Seamless Network shows that over 1 billion IoT-based attacks happened in 2021 [2]. Although methodologies, such as encryption and secured architecture are progressively being deployed to ensure that IoT devices are secured, the computational constraint of these devices makes it challenging to implement these security measures to their fullest potential. Another approach to securing these devices from cyber-attacks is to detect these attacks before an attacker exploits them. Intrusion Detection Systems have been around for more than four decades, with the development of these IDSs focused on traditional computing systems [3]. They have been among the primary methodologies used to protect computer networks. Vacca [4] defines intrusion detection as the process of detecting activities perpetrated against computer systems by intruders. Over the past 40 years, many breakthroughs have been made in intrusion detection. One of the most significant breakthroughs in this area is the use of machine learning in detecting intrusions. However, with all these breakthroughs, it is practically impossible to deploy traditional computing-based IDS methods in the IoT. The impossibility of deploying these IDSs in IoT systems has been created because of the computational constraints of IoT devices. The constraints have led to several studies being carried out to design IDSs that can be deployed in IoT systems without significantly affecting the computational resources of these devices. Several approaches have been proposed in designing lightweight IDSs for IoT environments. However, these studies fail to either report how these lightweight IDSs are achieved or how much computational resources these proposed approaches consume. For example, [5]–[9] proposed various techniques that are supposed to translate into lightweight IDSs. However, these works either failed to report how these methods translate into lightweight IDS or how much computational resources these proposed methods consume. This study proposes a novel lightweight intrusion detection system using an incremental machine learning approach. The main contributions of this study are as follows:

- Using an incremental machine learning approach to design a lightweight IoT intrusion detection system.

- Measuring the memory consumption of our proposed model.

- The study uses an incremental ensemble approach to achieve improved accuracy.

- The study evaluates the proposed IDS model on an IoT dataset.

The remainder of the paper is structured as follows. Section II discusses the study's background. Section III focuses on works relevant to our study, whereas Sections IV, V and VI focus on the proposed model, experimental evaluation, and conclusion, respectively.

II. BACKGROUND

A. Intrusion Detection System

An intrusion detection system (IDS) is a security device that detects illegal access to data within a networked or computer-based environment in order to threaten the integrity, availability, or confidentiality of the computing device [10], [11]. An IDS's objective is to continuously monitor network traffic and flag any activity that violates the normal usage of the system [12]. According to [13], typically, an IDS consists of sensors, an analysis engine, and some reporting system. Intrusion detection systems can be classified either on how they are deployed or detect illegal activities. From a deployment perspective, an IDS can be classified as distributed, centralized, or hybrid. On the other hand, an IDS can be classified as signature-based, anomaly-based, specification-based, or hybrid. According to [14], signature-based detection is the set of pre-defined rules, such as the sequence of bytes in network traffic that are pre-loaded to trigger an alert when a matched sequence is detected. On the other hand, anomaly detection records the normal behavior of a network and then compares them with the system's current behavior. The authors also explained the specification-based detection method as an approach that uses input specifications designed manually. Finally, hybrid detection methods deploy a combination of signature-based, anomaly-based, and specification-based detection methods to improve accuracy and reduce false positive rates.

1) Ensemble Learning: According to [15], ensemble learning is a machine learning technique that combines the strengths of different machine learning algorithms into a single algorithm. The primary goal of ensemble learning is to improve accuracy by leveraging the strengths of the ensemble learners [16]. There are instances where traditional machine learning models do not achieve high accuracy [17]. Several ensemble-based techniques have been developed over time, but the most popular are bagging, boosting, stacking generalization, and expert mixture [16].

In the preceding paragraphs, we briefly explain the three categories of ensemble learning.

2) Bagging-based Learning: Bagging, short for bootstrap aggregation, is an algorithm that is best suited for problems with a small training dataset. Given a training set S with a cardinality n, the bagging algorithm trains several independent classifiers T. Each of these classifiers are trained using a percentage of N [16] sampling. Linear classifiers such as linear SVM, decision stumps, and single-layer perceptrons are excellent candidates for bagging [16]. Classifiers are trained and then combined using simple majority voting in bagging. Bagging, an abbreviation for bootstrap aggregation, is a method that works well with issues that have a limited training dataset. The bagging algorithm learns several independent classifiers T given a training set S with a cardinality of n. Each of these classifiers is trained using a proportion of N sampling. Linear classifiers like linear SVM, decision stumps, and single-layer perceptrons are great candidates for bagging [16]. In bagging, classifiers are trained and then concatenated using simple majority voting.

3) Boosting-based Learning: An iterative approach can be used to generate a robust classifier from a set of weak classifiers. Although boosting also combines a large number of weak learners through simple majority voting, there is one significant difference between boosting and bagging. Every instance in bagging has an equal chance of being in each dataset used in training. In boosting, on the other hand, the dataset used to train each subsequent model focuses on instances misclassified by the previous model. At any given time, a boosting designed for a binary class problem generates a set of three weak classifiers. The first learning classifier is trained on a random subset of the training data available. A different subset of the original training dataset is used to train the second learning classifier [18].

4) Stack Generalization: Non-trainable combiners are used in bagging and boosting methods. The combination weights in non-trainable combiners are determined after the classifiers have been trained. The combination rule used in non-trainable combiners does not allow determining which member classifier learned from which partition of the feature space [16]. Trainable combiners can be used to solve this problem, and individual ensemble members can be combined using a separate classifier in stacked generalization.

5) Mixture of Experts: A sampling technique is used to train an ensemble of classifiers in a mixture of experts. The classifiers are then combined using a weighted combination rule [19]. Furthermore, a mixture of experts can encompass the selection of algorithms, with each classifier trained to become an expert in a different aspect of the feature space. Individual classifiers are usually not weak since they are trained to become experts.

B. Online/Incremental Machine Learning

Online machine learning, also known as incremental machine learning, is increasingly becoming popular in real-time data streams. According to [20], online algorithms instantaneously build machine learning models after seeing a small portion of the data. This characteristic leads to the inability to undo less optimal decisions made earlier because the data will no longer be available for the algorithm. The concept of machine learning models acquiring knowledge from continuous data without accessing the original data has been applied to domains like intelligent robots, auto-driving, and unmanned aerial vehicles [21]–[23]. According to [24], as reported by [20],, in data stream models infinite stream of data arrives

continuously, and these streams of data are to be processed by systems with resource constraints. The main restriction of data stream models is that memory of these systems are usually small and can only hold a minimal portion of the data stream. Regarding data stream models, only a minimal subset of the data can be kept for instant data analysis [25]. Fig. 1 shows an online machine-learning model using an offline dataset, while Fig. 2 shows the same model using streams of network traffic.

III. Related Work

Throughout this section, we will look at some studies that are relevant to our work. Yang et al. [26] proposed an ensemble framework for intrusion detection systems (IDSs) in IoT environments, focusing primarily on idea drift adaptability. The suggested framework employs a performance-weighted probability averaging ensemble to manage concept drift in IoT anomaly detection. When compared to other cutting-edge approaches, the suggested framework performed better. Even though the author's proposed method took less time to run than the other methods they looked at for their study, they did not look into how the proposed model affected other computing parameters, such as memory.

Jan et al. [5] used a supervised Support Vector Machine (SVM) to detect IoT adversarial attacks. The authors used only the sensor node's packet arrival rate to design the proposed IDS. The accuracy of the proposed IDS showed better performance compared to other models like neural networks, KNN, and decision trees. One of the drawbacks of this study is that it only considered DDoS attacks. Additionally, the authors failed to report how the proposed approach leads to a lightweight IDS. Parameters such as memory consumption and model running time were not reported.

In a similar study, [27] proposed a lightweight IDS for IoT ecosystems using a Deep Belief Network and Genetic Algorithm. According to the study, the proposed system was more accurate than other methods that were looked at for the study. However, the study failed to report how the proposed approach translates to a lightweight model. Moreover, the dataset used for the experimental validation is not an IoT-based dataset. Like in other studies, parameters that are supposed to prove the lightweight status of the proposed method were not considered in the study.

Roy et al. [7] also designed a lightweight IDS for IoT systems using a set of optimization techniques. They used multicollinearity, sampling, and dimensionality reduction to reduce the training data, which resulted in a shorter training time. Like other earlier related works considered in this section, although their proposed approach reduces the training time of the model, the study did not report how much memory the model consumes.

Zhao et al. [8] suggested a network intrusion detection method for IoT devices utilizing a lightweight neural network. To minimize the dimensionality of features, the authors employed a principal component analysis approach. The proposed method was tested using the UNSW-NB15 and Bot-IoT datasets. Although the authors determined that both the ultralight feature extraction network and principal component analysis contributed to the suggested model's lightweight per-

formance, they did not report on the computational complexity of their proposed method.

In order to make a lightweight IDS for IoT systems, [9] said that they used a mix of feature selection techniques on different datasets to make a lightweight IDS algorithm for IoT traffic. However, two datasets used to evaluate their proposed lightweight IDS were non-IoT related. Also, the authors did not talk about how their proposed model would affect the computing power in their experimental environment.

Latif et al. [6] reported using a Dense Random Neural Network to develop a lightweight intrusion detection system for IoT environments. The proposed model was evaluated on the ToN-IoT dataset, and the results show a detection accuracy of 99.14% for binary class classification and 99.05% for multiclass classifications. However, Latif et al. did not report on the computational complexity of their proposed model. A parameter is required to measure the lightness of the proposed model.

Pan et al. [28] also suggested a lightweight, intelligent intrusion detection system (IDS) architecture for wireless sensor networks. The authors used KNN and the sine cosine technique to create their model. The authors reported that combining the above techniques improves classification accuracy and reduces false alarms. However, the authors failed to report how the lightweight model was achieved or what parameters were used to determine the lightweight status of the model.

Reis et al. [29] created an IDS for cyber-physical systems using incremental support vector machines. In their study, a one-class support vector machine was applied to each sensor to retrieve abnormal behaviors. These anomalies are orchestrated as an output of the proposed incremental machine learning model. Although the model proposed by Reis et al. achieved an accuracy higher than 95%, the study did not detail how the proposed method would affect the computational resources of cyber-physical systems.

To reduce the computation overhead, [30], introduced a privacy-preserving pipeline-based intrusion detection for distributed incremental learning that selects unique features using an innovative extraction technique. Current incremental learning techniques are computationally expensive, and the distributed intrusion detection method is used to distribute the load across IoT and edge devices. Theoretical analysis and experiments show that state-of-the-art techniques require less space and time. The study, however, reported on time complexity but not space complexity. Furthermore, the experimental validation dataset is not an IoT-based dataset.

IV. Proposed Model

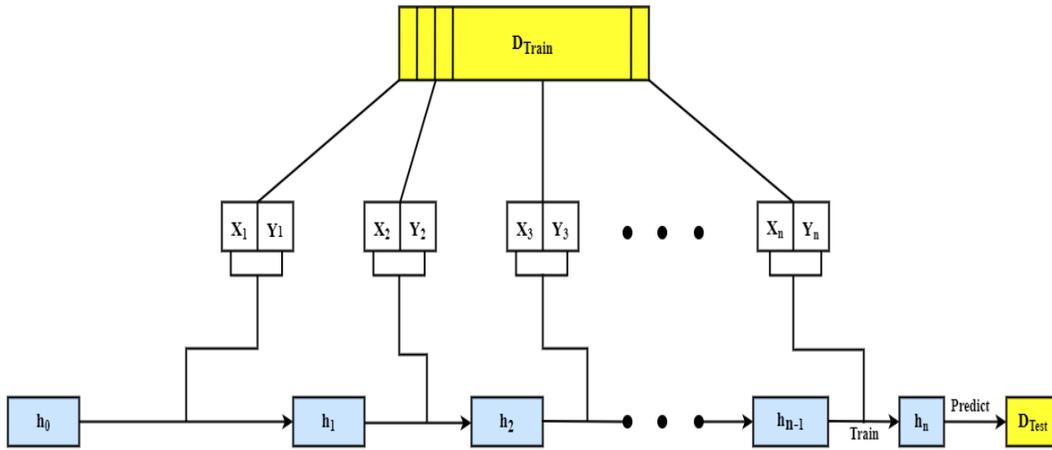
This section details the design and conceptual implementation of our suggested approach. The suggested model is based on a machine learning technique, ensuring the creation of a lightweight IDS model suitable for the IoT environment. The proposed model employs incremental machine learning and data streaming ensemble learning approaches to create a lightweight intrusion detection system for the IoT environment. The proposed model processes network data generated in IoT environments as data streams and train each data stream. After each iteration, the model is updated. Fig. 3 depicts our proposed model.


Fig. 1. Online Machine Learning using Offline Dataset.
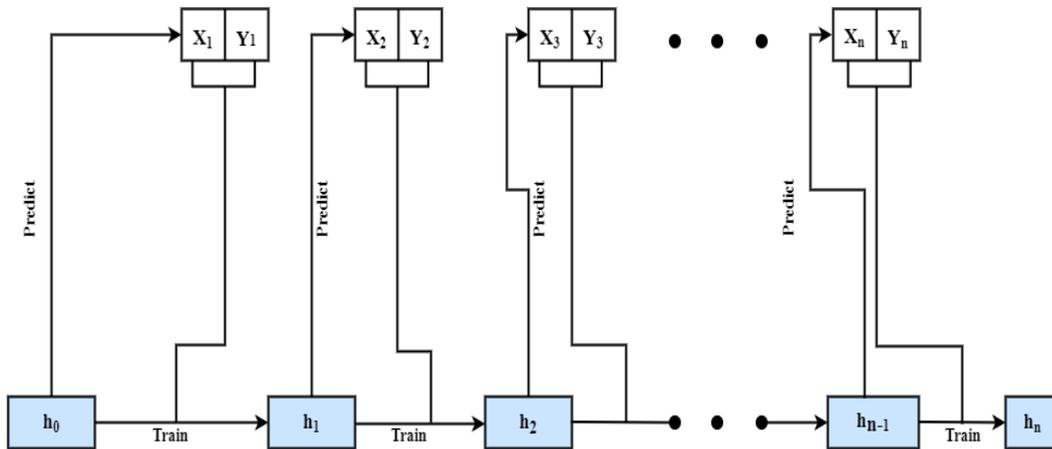

Fig. 2. Online Machine Learning using Data Stream.

1) Pre-Processing: The dataset used to train our proposed model is cleaned at this stage. The pre-processing data approach used in this study includes imputing missing data values and transforming and selecting important features to train our machine learning model. We employed one-hot encoding as one of the techniques to pre-process our data. A single hot encoding transformer will encode all the features provided to it. If a list or set is supplied, this transformer will encode each item in the list or set by composing it with compose.Select command in River; the encoding can apply to a subset of features.

2) Model Training: This study proposes a novel online stacking ensemble machine learning technique using Gaussian Naive Bayes and Hoeffding Tree Classifier. We chose these two machine learning models to build our ensemble learning because we want to achieve the following three objectives

- Design a model that consumes a minimal computational resource (lightweight).
- Building a fast model.
- A model that achieves a high accuracy.

Gaussian Naive Bayes and Hoeffding Tree Classifier are used as the base classifiers of our proposed model; whiles Hoeffding Tree is used as the meta classifier of the proposed model. Each observation of the dataset is read as a stream and is then used to train the base and meta classifier. Each base classifier predicts each stream of data, that is, $X_i Y_i$ which becomes feature input to the meta classifier. The meta classifier (HT) then uses the outputs of the base classifiers to make a better prediction. We chose Hoeffding trees because they learn patterns in data without continuously storing data samples for future reprocessing, and this makes them particularly suitable for use on embedded devices. Similarly, Gaussian NB is quick and flexible and produces highly reliable results. It works well with large amounts of data and requires little training time, and it also improves grading performance by removing insignificant specifications [31], [32].

3) Model Evaluation: The final stage of the model is the model evaluation stage. The proposed model's accuracy, precision, recall, F1, model training time, and memory consumption are all evaluated.

We chose incremental and ensemble machine learning to develop our framework in this work because of the the following

benefits.

1) Network traffic is generated in blocks as a data stream. By using incremental learning on network traffic, models can predict the nature of traffic without having to be trained on large datasets.
2) The computational constraints of IoT devices make loading an entire training dataset into main memory difficult and impractical. Even if the entire training data can fit into the main memory of an IoT device, the device's computational power will be drastically reduced.
3) New data is constantly available because of the sophisticated nature of cyber-attacks. Retraining the model on the entire dataset will be time-consuming and computationally expensive. Because models in online machine learning are trained with data streams, they can quickly learn from new data examples without consuming much computational power.
4) Real-time network traffic is generated, which must be analyzed in real-time to prevent intruders from gaining unauthorized access to devices. Online machine learning has proven to be an effective learning method in real-time environments.
5) Traffic flow is dynamic and constantly changing. Changes in network traffic can impact the predictive performance of machine learning models, referred to as concept drift in machine learning. Models should be able to self-adapt to changes in the relationship between input and output data to handle concept drifts.
6) Most of the time, ensemble methods have produced higher accuracy than the individual models that were used to make them.

Additionally, the use of the above method poses the following limitation.

1) Getting a good tradeoff between accuracy, speed, and minimal resource consumption is going to be a challenge because combining models increases the computational consumption of the final output.

A. Gaussian Naive Bayes

According to [33], the Naive Bayes algorithm is a typical illustration of how generative hypotheses and parameter guesses can facilitate learning. Consider the problem of predicting a label y $\in \{0,1\}$ from a vector of characteristics $\mathbf{X} = (x_1,..., x_d)$, where each x_i is in the range of $\{0,1\}$. The optimal classifier of Bayes is given below

$$h_{Bayes}(\mathbf{X}) = argmaxP[Y = y|X = x], y \in \{0,1\} \quad (1)$$

We need 2^d parameters to define the probability function P[Y = y—X = x], each of which relates to P[Y = 1—X = x] for a given value of y $\in \{0,1\}^d$. This means that when the number of features increases, so does the number of instances necessary. In the Naive Bayes technique, we make the generative assumption that, given the label, the features are independent of one another. To put it another way,

$$P[Y = y|X = x] = \prod_{i=1}^{d} P[Y = y|X = x] \quad (2)$$

The Bayes optimum classifier can be reduced further using this assumption and the Bayes rule:

$$h_{Bayes}(\mathbf{X}) = argmaxP[Y = y] \prod_{i=1}^{d} P[X_i = x_i|Y = y] \quad (3)$$

That is, the set of parameters to estimate has been reduced to 2d +1. In this situation, the generative assumption we made considerably decreased the number of parameters we needed to learn. When the maximum likelihood principle is used to determine out the parameters, the resulting classification model is called the Naive Bayes classifier.

One typical technique to handle continuous attributes in Naive Bayes classification is to use Gaussian distributions to express the probabilities of the features based on the classes. As a result, every attribute is represented as Xi N(, 2) by a Gaussian probability density function (PDF), [34] as reported by [35].

$$X_i \sim N(\mu, \sigma^2) \quad (4)$$

The Gaussian PDF is shaped like a bell and is defined by the equation below where μ is the mean and σ^2 is the variance.

$$N(\mu, \sigma^2)(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2a^2}} \quad (5)$$

B. Hoeffding Tree (HT)

Hulten et al [36] are the first to propose Hoeffding trees. The Hoeffding tree algorithm is a fundamental algorithm for stream data classification. It is an induction of a decision tree algorithm that could learn from enormous data streams if the distributed generating examples remain constant over time. It creates decision trees that are similar to the standard batch learning method. Asymptotically, Hoeffding trees as well as decision trees are connected. The HT technique is based on the basic premise that a modest sample size can frequently be sufficient to identify an optimal splitting feature. The key point to understand here is that classic batch learning algorithms produce decision trees based on attribute splitting. The HT method is mathematically verified to use the Hoeffding bound. To comprehend the significance of the Hoeffding bound, a few assumptions must be made. Let's say we get *N* separate samples of a random variable *r* with a range of *R*, where *r* is a measure of attribute selection. In the case of Hoeffding trees, *r* is information gain, and if we calculate the mean value of r_{mean} for this sample, the Hoeffding limit indicates that the true mean of *r* is at least 1-δ. The primary benefits of the HT algorithm are as follows:

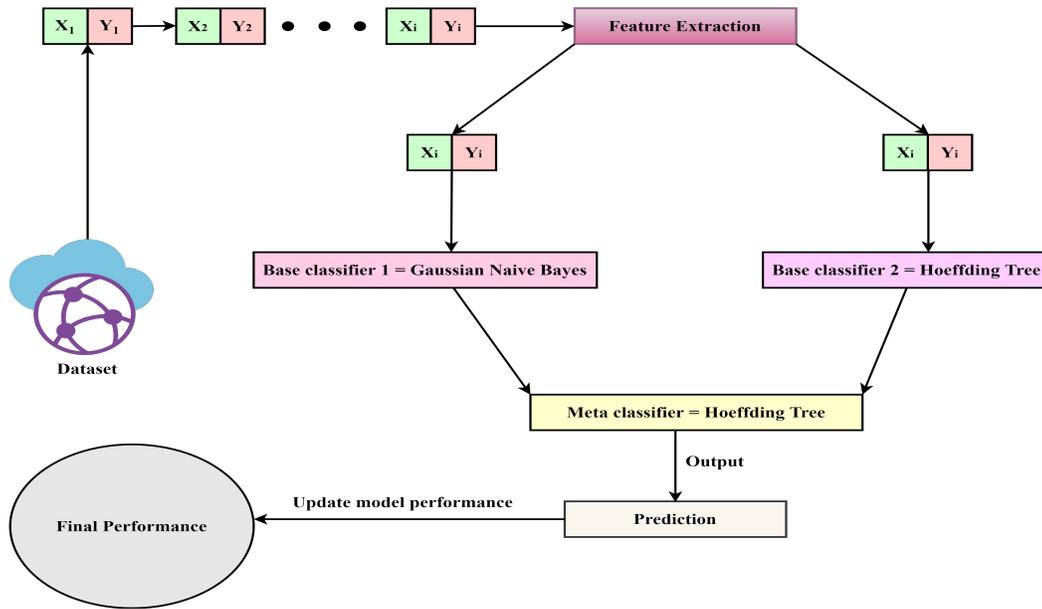
1) it is incremental in nature
2) it achieves high accuracy with small sample size.
3) scans on the same data are never performed.


Fig. 3. Our Proposed Model.

However, Hoeffding Tree has a few disadvantages. The main disadvantage is that HT cannot handle concept drift because the node cannot be changed once it is created. Wang et al [37] described how to deal with concept drift using classifiers. The algorithm devotes a significant amount of time to attributes with nearly identical splitting quality. Furthermore, memory utilization can be further optimized.

$$[!h] \in = \sqrt{\frac{R^2 1 n \frac{1}{\delta}}{2n}} \qquad (6)$$

The algorithm for Hoeffding tree is shown in Algorithm 1.

V. EXPERIMENTAL EVALUATION

A. Experimental Environment

The proposed method was implemented using Python 3.8 with River as our framework for online machine learning. The proposed method was implemented on a MacBook Pro with an M1 chip with 16 GB of RAM. The TON-IoT dataset was used to evaluate the proposed framework. There are several incremental or online streaming libraries that provide machine functionalities. Some of these libraries are Creme, scikit-multiflow, and River. In this study, we choose to build our incremental learning models using River. According to [38], River is a merger of creme and Scikit-multiflow. River is a library that allows continual learning by handling dynamic data streams. We chose River because it includes data transformation methods, learning algorithms, and optimization algorithms. Its distinct data structure lends itself well to streaming data and web application settings.

B. Dataset

According to [39], the TON-IoT dataset was built by the Cyber Range and IoT Las at the University of South Wales.

The dataset has nine (9) types of cyber-attacks. These are Denial of Service (DoS), Distributed Denial of Service (DDoS), ransomware, backdoor, data injection, scanning, Cross-site Scripting (XSS), password cracking, and Man-in-The-Middle (MiTM). The generated data were from seven IoT and IIoT devices: fridge, motion light, garage door, GPS tracker, thermostat, and weather. The fridge dataset has a total of 587076 records; the motion light dataset has 452262 records; the garage door has 591446 records; the GPS tracker produced 595686 records, whiles the thermostat and weather produced 442228 and 650242 records, respectively. The statistics of the dataset used are shown in Tables I and II below.

C. Evaluation Metrics

True positive (V_P): Positive intrusion that is both expected and confirmed.

False positive (U_P): An intrusion that was expected to be positive but ended up turning out to be negative.

True negative (V_N): The intrusion is expected to be negative and confirmed to be negative.

False negative (U_N): The intrusion was expected to be negative, but it turned out to be positive.

1) Accuracy: A model's overall accuracy can be measured by the number of correctly predicted events made by the given model. The formula below computes the total accuracy of the model.

$$Accuracy = \frac{V_P + V_N}{V_P + V_N + U_P + U_N}$$

2) Precision: Precision is found by dividing the total number of positive detections by the number of positive detections that were correctly identified as positive.

Algorithm 1: Hoeffding Tree Algorithm [36]

Input: S is a sequence of examples,
    X is a set of discrete attributes,
    G(.) is a split evaluation function,
    δ is one minus the desired probability of
    choosing the correct attribute at any given
    node

Output: *HT* is a decision tree

  procedure HOEFFDINGTREE(S, X, G, δ)

    Let *HT* be a tree with a single leaf l_1 (the root)

    Let $X_1 = X \cup \{X_\theta\}$

    Let $\bar{G}_1(X_\theta)$ be the $\bar{G}$ obtained by predicting the most frequent class in S

    for *each class Y_k* **do**

      for *each value X_{ij} of each attribute $X_i \in \mathbf{X}$*

    do

        Let $n_{ijk}(l_1) = 0$

      end

    end

    for *each example (X, Y_k) in S* **do**

      Sort (x, y) into a leaf l using HT

      for *each X_{ij} in X ssuch that $X_i \in \mathbf{X}$* **do**

        Increment $n_{ijk}(l)$

      end

    end

    Label *l* with the majority class among the examples seen so far at *l*

    if *the examples seen so far at l are not all of the same class* **then**

    end

    Compute $\bar{G}_l(X_i)$ for each attribute $X_i \in X_l - X_\theta$ using the counts $n_{ijk}(l)$

    Let X_a be the attribute with highest $\bar{G}_l$.

    Let X_b be the attribute with second-highest $\bar{G}_l$.

    Compute $\in$ using Equation 1

    if $\bar{G}_l(X_a) - \bar{G}_l(X_b) > \in$ *and* $X_a \neq X_\theta$, **then**

    end

    Replace *l* by an internal node that splits on X_a.

    For each branch of the split

    Add a new leaf l_m and let $X_m = X - \{X_a\}$.

    Let $G_m(X_\theta)$ be the G obtained by predicting the most frequent class at *l*

    for *each class Y_k and each value X_{ij} of each attribute $X_i \in X_m - \{X_\theta\}$* **do**

    Let $n_{ijk}(lm) = 0$

    end

    return *HT*

  end procedure

$$Precision = \frac{V_P}{V_P + U_P}$$

3) Recall: The recall is defined as the ratio of true positive detections to the number of real abnormal samples.

$$Recall = \frac{V_P}{V_P + U_N}$$

4) F1 Score: The F1 score is the average of precision and recall. The F1-score is determined as the weighted average of precision and recall, taking both the U_P and U_N into consideration.

$$F1 = \frac{2 * Precision * Recall}{Precision + Recall} = \frac{2 * V_P}{2 * V_P + U_P + U_N}$$

5) Memory: The computational constraint of IoT devices makes it difficult and sometimes impossible to run IDS meant for traditional computers on these IoT devices. This calls for developing models that consume minimal memory (lightweight models).

6) Model Running Time: In this evaluation metric, we measure the total time it takes for the proposed model to run.

D. Results

In this section, we present the proposed results and compare them with other state-of-the-art techniques. To begin with, this study compares the results of the proposed model with other state-of-the-art IDS proposed and evaluated with the TON IoT dataset. We decided to limit the state-of-the-art studies that used ToN IoT dataset because we wanted to eliminate biases. In comparing these studies, we considered the category of the TON IoT dataset used in each study, the method proposed by each of the works under consideration, the highest accuracy recorded, and whether the study records the time used to build the model as well as the amount of memory the model consumes. The comparison of our approach with other state-of-the-art IDS for IoT systems is presented in table III. When the authors fail to report a parameter, we indicate it as non-available (N/A). Table III shows that out of the five state-of-the-art IDSs considered in the study, none of them reports on the model or the memory consumption of their proposed technique. Although [40], [41] both report 100% accuracy, our proposed model outperforms the methods proposed in those studies for the following reasons:

1) The accuracy reported in our study is the average accuracy of our proposed model whereas [40], [41] report total accuracy.
2) Our study focused on multi-class classification, whereas [40], [41] focused on binary-class classification.

Table IV compares the accuracy, time, and memory consumption of the models used to build our incremental ensemble technique with our proposed model. Although the time and memory consumption of the individual models are lower than our proposed model, we wanted to propose a model that achieves a trade-off between accuracy, time, and memory consumption. Our proposed model achieved a higher accuracy without significantly increasing the time and memory consumption. The time and memory consumption of the proposed model shows it can run on computationally constrained devices without negatively impacting the computational resources of these devices.

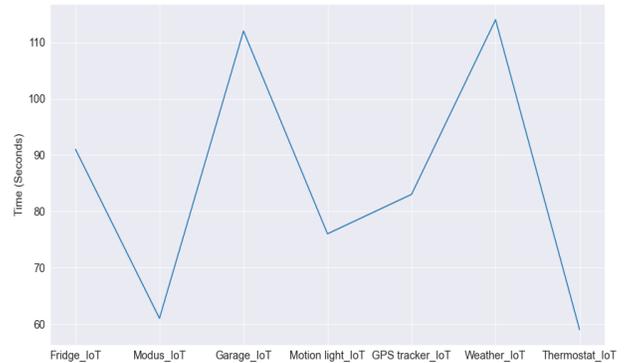
Fig. 4 below shows the output of our proposed model in terms of the time taken to build the model. The results show that our proposed model recorded the least training time of 59 seconds on the thermostat dataset and the highest training time of 114 seconds on the weather IoT dataset. The concept of incremental learning allows our model to learn one stream of data at a time. Therefore, the time used to train the model on a stream of data will be the total observations in the dataset divided by the total model training time. This makes our model very fast irrespective of the size of the dataset.


Fig. 4. Model Training Time of our Model using the TON IoT Dataset.

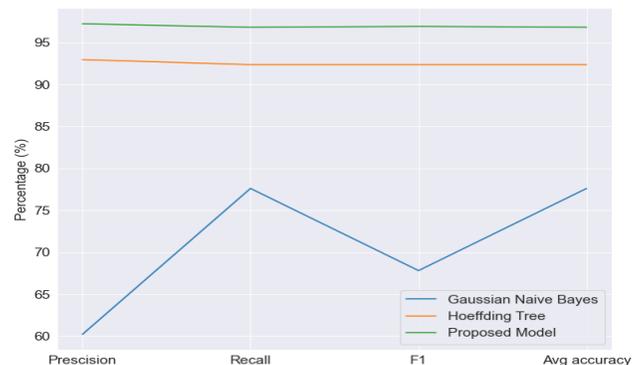
When tested on the modus dataset, our proposed model achieved a superior average accuracy of 96.81%, with precision, recall, and F1 scores of 97.23%, 96.81%, and 96.92%, respectively. The Hoeffding tree had an average accuracy of 92.96%, precision, recall, and F1 scores of 92.36%, 92.36%, and 92.36%, respectively. Using the GPS IoT dataset, the Gaussian NB had an average accuracy of 77.60% and precision, recall, and F1 scores of 60.21%, 77.60%, and 67.81%, respectively. Fig. 5 shows the results of our model when evaluated using the modus IoT dataset.


Fig. 5. Accuracy of Gaussian NB, HT and Proposed Model on Modus Dataset.

Similarly, our proposed model has a superior average accuracy of 99.98% when it was evaluated using the fridge IoT dataset. The proposed model also recorded the same precision, recall, and F1 score value using the same dataset. Hoeffding tree algorithm recorded 98.63%, 98.68%, 98.52%, and 98.52% for precision, recall, F1 score, and average accuracy, respectively. Gaussian NB recorded the lowest average accuracy, an average accuracy of 85.31%. Gaussian NB also recorded the least values for precision, recall, and F1 scores, with 72.8%, 85.31%, and 78.55%, respectively. Fig. 6 illustrates the outcomes of our model when tested against the fridge IoT dataset.

TABLE III. USING THE TON IOT DATASET, WE COMPARED OUR PROPOSED MODEL TO STATE-OF-THE-ART MODELS THAT HAD BEEN TESTED USING THE SAME DATASET

The experimental findings show that our proposed method performed better when tested using the motion IoT dataset. The proposed ensemble model achieved an average accuracy of 99.98% with precision and recall of the same value whiles recording 99.97% for the F1 score. The same dataset revealed that the Hoeffding tree recorded an average accuracy of 92.06% whiles recording a precision, recall, and F1 score of 88.56%, 92.06%, and 89.64%, respectively. The average accuracy, precision, recall, and F1 score recorded by Gaussian NB is 85.86%, 73.73%, 85.86%, and 79.33%, respectively. Fig. 7 depicts the results of our model when tested against the motion IoT dataset.

When tested on the garage IoT dataset, our proposed ensemble model again had the highest precision, recall, F1 score, and average accuracy. Our proposed model recorded an average accuracy of 99.96%, with the same value recorded for precision, recall, and F1 score. Hoeffding tree, on the other hand, recorded a precision, recall, F1 score, and average accuracy of 95.52%, 95.70%, 95.26% and 95.70% respectively. Gaussian Naive Bayes recorded a precision, recall, F1 score, and average accuracy of 73.88%, 85.96%, 79.46%, and 85.96 respectively when it was evaluated using the garage IoT dataset. Fig. 8 shows the results of our model when tested against the garage IoT dataset.

Evaluating our proposed model on the GPS tracker dataset, our model achieved a superior average accuracy of 99.97% with precision, recall, and F1 score of 99.97% each. Hoeffding tree recorded an average accuracy of 98.29% whiles recording a precision, recall, and F1 score of 98.36%, 98.29% and 98.08%, respectively. Evaluating the Gaussian NB using the GPS IoT dataset revealed an average accuracy of 85.20% with precision, recall, and F1 score of 88.26%, 85.20%, and 82.02%, respectively. Fig. 9 shows the results of our model when evaluated using the GPS tracker IoT dataset.

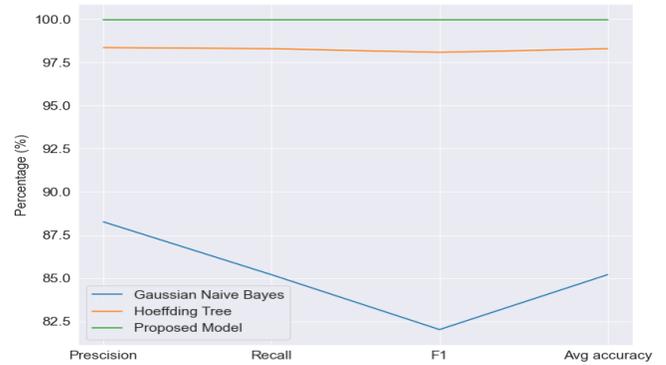

Fig. 9. Accuracy of Gaussian NB, HT and Proposed Model on GPS Tracker Dataset.
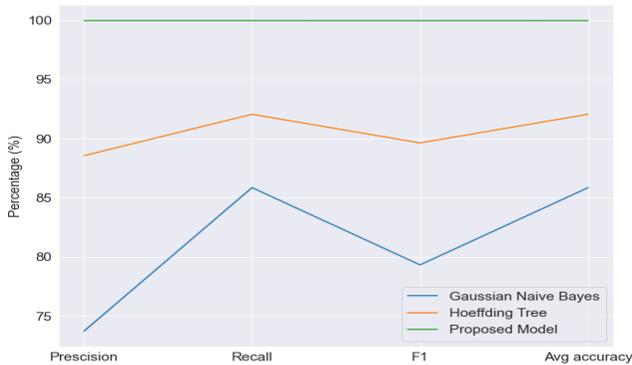

Fig. 7. Accuracy of Gaussian NB, HT and Proposed Model on Motion Dataset.
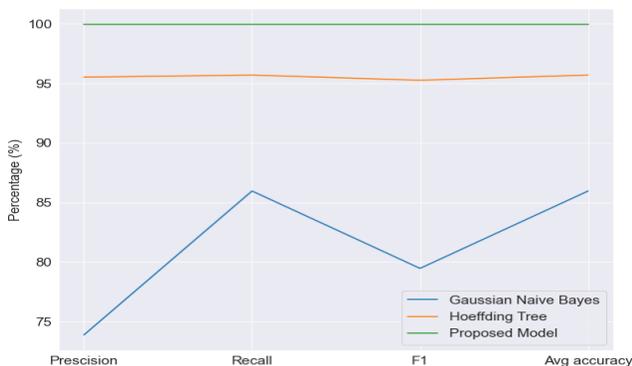

Fig. 8. Accuracy of Gaussian NB, HT and Proposed Model on Garage Dataset.

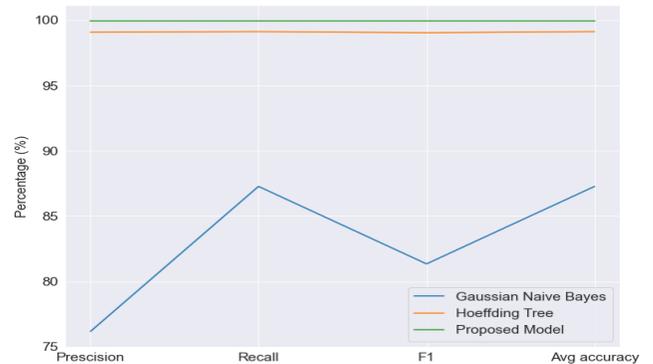
model achieved an average accuracy of 99.94% with precision, recall, and F1 score of 99.94% for each of them, respectively. Gaussian NB showed an average accuracy of 87.27% whiles recording a precision, recall, and F1 score of 76.17%, 87.27%, and 81.34%, respectively. Hoeffding tree showed an average accuracy of 99.12% with precision, recall, and F1 score of 99.07%, 99.12% and 99.03%, respectively. Fig. 10 shows the results of our model when tested against the thermostat IoT dataset.


Fig. 10. Accuracy of Gaussian NB, HT and Proposed Model on the Thermostat Dataset.

We also evaluated our model on the weather IoT dataset, one of the datasets found in the TON IoT dataset. The results show that Gaussian NB recorded precision, recall, F1, and average accuracy of 80.02%, 86.08%, 76.65%, and 86.08%, respectively. On the other hand, the Hoeffding tree recorded precision, recall, F1, and average accuracy of 98.47%, 98.37%, 98.30%, and 98.37%, respectively. However, our proposed ensemble technique recorded an average accuracy of 99.93% with precision, recall, and F1 score of 99.93%, respectively. Fig. 11 illustrates the outcomes of our model when tested against the weather IoT dataset.

The experimental result shows that when our proposed model is evaluated using the thermostat IoT dataset, the

The Fridge IoT dataset recorded the highest consumption of

Fig. 11. Accuracy of Gaussian NB, HT and Proposed Model on Weather Dataset.

650.11KB, whiles the weather IoT dataset recorded the lowest memory consumption of 122.38KB. The results of the memory consumption of the model proposed in this study show that even at the highest memory consumption, the proposed IDS achieves a lightweight status and can potentially run on IoT devices without significantly affecting the available memory of these devices. The memory consumption of our proposed model is shown in Fig. 12.

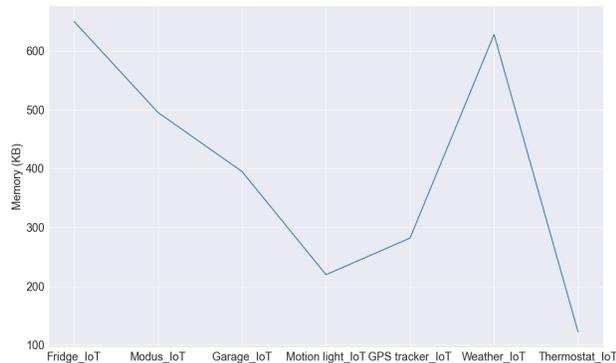
The precision, recall, and F1 score of Gaussian Naive Bayes, Hoeffding tree, and our proposed model on different attack categories are shown in Tables V and VI below.


Fig. 12. Memory Consumption of our Proposed Model on Various Sub-Datasets of TON IoT Dataset

VI. LIMITATION OF THE STUDY

The main limitation of the study is how the proposed method can be used to achieve good accuracy, higher detection speed, and lower resource consumption at the same time. One approach that can be used to overcome this limitation is to deploy the proposed model on a resource-constrained device while fine-tuning the model to achieve a good tradeoff among the parameters mentioned above.

VII. CONCLUSION

The security of the IoT ecosystems is increasingly gaining significant importance due to its numerous applications. The security of IoT systems has gone beyond encryption, authentication, and secured architecture. Recently, much security-based research in IoT systems has been focused on detecting attacks and anomalies in network traffic. However, because of the computational constraints of IoT devices, IDS developed for traditional computing systems cannot be deployed in IoT environments. It is, therefore, expedient to design lightweight IDS that can be deployed on IoT devices. In this view, we used the incremental machine learning technique to design a lightweight IDS for IoT systems using incremental ensemble machine learning algorithms. Our proposed model was evaluated using the TON IoT dataset. The results show that our proposed model achieved a high average accuracy rate of 99.98%. The experimental results show the highest memory consumption at 650.11KB and the lowest at 122.38KB. The experimental result shows that our approach has led to the design of an IDS with a high accuracy rate and a lightweight model that can potentially run on IoT devices. In the future, we plan to evaluate our approach to other IoT-based datasets and deploy our model on an IoT device to evaluate parameters such as CPU usage, memory, and energy consumption. Additionally, future work could consider exploring how concept drifts in these datasets could be handled.

Department of Computer and Information Sciences, Universiti Teknologi PETRONAS, Sri Iskandar, Malaysia[1, 3]
Platinum Software Development Company, Australia[2, 4, 5]

Abstract—**For maintaining sustainable economy, the government of Malaysia is working towards improvising the standards of education in higher education institutes. According to reports, around 32% of enrolled students in Public Universities of Malaysia are unable to graduate on time due to unknown reasons. To ensure more students graduate on time with high quality of education, continuous monitoring of the student is essential. Continual tracking will allow the student as well as the educator to analyze the weak performer at an early stage. Tracking the student performance manually is challenging but with the advancements in information technology, keeping a track of student performance has been relatively easier. Therefore, the fundamental aim of this paper is to present a novel blockchain framework for record keeping and student performance tracking. We name this framework BloSPer (Blockchain Student Performance Tracking System). BloSPer has an edge over the existing systems as current systems face problems of single point of failure and unreliable data. The proposed framework will enable the students and educators to track the performance of the students in a more convenient and transparent manner. Due to this, it will be simpler for them to analyze the reasons of a students' poor performance. Moreover, the data gathered through the system will be more reliable and worthy for data analytics because of tamper resistance provided through blockchain. This will result in much knowledgeable decisions by the institutions regarding improving the performance of each individual candidate.**

Keywords—Blockchain; education; performance tracking; trackability; student data analytics; student monitoring

I. INTRODUCTION

A. Background

For any nation to progress, education plays a significant role and is therefore usually the main focus for most developed countries. This is because the advancement in any sector depends on the level of education. United Nations has listed quality education as the 4th out of 17 Sustainable Development Goals (SDG) for its 2030 agenda. Education has a long-term positive impact on a country's economic growth [1]. Education plays a vital role in Malaysia for building a resilient nation, encouraging the creation of a just society, and maintaining sustainable economic growth [2]. Thus, improvising education sector is one of the major concerns of the Malaysian government nowadays.

According to Malaysian Qualifications Agency (MQA) criteria for higher education has been set through a code of practice that includes, vision, mission and learning outcomes; curriculum design and delivery; student selection and support services; assessment of students; educational resources; continual quality improvement and more. Each institution is evaluated based on the standards to ensure high quality of education. However, the way each institution works towards achievement of those standards varies. Despite of providing high quality of education, demand on predicting student academic performance become more critical to improve the quality of education and assisting the students to achieve a greater performance in their studies [2].

One way that most of the higher education institutions maintain the standards and quality of education is through tracking the student performance in a classroom setting [3][4]. Keeping a record of student performance at regular intervals will enable an interactive learning environment and promote better educational outcomes for the students. Tracking and monitoring the performance of students from time to time throughout the course of an academic semester has a positive impact for both, the students and the educators [5]. This positive impact may include valuable insights to redesign the course for instructors, decisions for improving standards of education, effective intervention of students and collection of valuable data for further analytics processes (if any). The fundamental aim of performance recording and analysis is to ensure better education standards and improved student performance. In order to achieve higher quality education, it is the core responsibility of each individual student and the academic institute to ensure every student achieves expertise in his area of interest. To reach this goal, various tools are needed by the educators to identify students who are at a potential risk of academic failure and adjust their strategies of delivery education meeting the needs of those students. Moreover, it is also very important for students to know the areas that need further focus and hard work. With student performance tracking the educators and students can continually evaluate the effectiveness of teaching and learning environment in the class. The continual monitoring will help them make more informed instructional decisions.

Information technology has made it easy to do and achieve with the recent advancements. The record keeping and management are now shifting to an innovative technology named Blockchain [6]. A blockchain is a distributed ledger i.e. the ledger is spread among all peers in across the network, and each peer holds a copy of the complete ledger [7]. Fundamental features of blockchain include being, i)

distributed, i.e., disseminating the ledger across the network to restrict the tampering of data [8], ii) transparency [9], i.e., authenticity of each transaction is verified by participants via consensus [10] in the network, and iii) immutable [11], i.e., the data cannot be modified/altered. The technology of Blockchain is known to track and trace the data in a more efficient way then the traditional record keeping approaches.

B. Research Gap

Presently, various tools and techniques are being used to monitor [12] the performances of students, and to predict student grades [13]. However, to the best of our knowledge, there's no way of determining the causes of student failure, i.e., if a student is likely to fail, then what reasons are causing this failure. This information is mainly important as it highlights what an individual lacks. In order to ensure each student's academic success, it is important to adjust the learning materials according to their needs. This can be achieved by tracking history of the student. Existing information systems do not have a reliable track of student performance data. Therefore, in this paper, we intend to overcome this gap by using the cutting-edge technology of the blockchain networks [14]. The main contributions of the manuscript, in this regard, are elaborated in upcoming section.

C. Major Contributions

The major contributions of this research article are twofold: 1) the shortcomings of existing student performance tracking systems are discussed and, 2) blockchain based novel framework for student performance tracking system is proposed. This framework will record the performance of the students in a distributed ledger accessible by various stakeholders involved in the process. The transparency and traceability of the blockchain will ensure that the performance indicators are not tampered with and can be tracked as needed. Moreover, since blockchains are immutable, hence the data collected from the proposed framework will be reliable, tamper free and accurate. This data can further be used for data analytics to determine student behaviours in various educational applications.

D. Organization

The organization of rest of the paper is as follows: Section II, describes the state-of-the-art student performance tracking systems available in literature and describes the shortcomings of the existing systems and discusses how blockchain technology can be used to overcome these challenges. Section III enlists the design goals and reasoning behind the proposed design. Section IV entails the proposed framework BloSPer. Section V presents results and discussions of the proposed framework. The paper finally concludes in Section VI, and a few promising future research directions are suggested in Section VII.

II. LITERATURE REVIEW

According to Malaysian Educational Statistics report published by Education Data Sector [15] about 32% of the students enrolled in public universities, fail to graduate on time. Moreover, this report was further analysed, and it was found out that from 2016 and onwards, each year the budget being used on improvising the education sector is substantially increasing. In 2016 actual educational recurrent expenditure was around 40 Million MYR which increased to around 45 Million MYR in 2018. Despite of the substantial increase in the budget being spent on education (public universities only) the literacy rate did not have a considerable improvement. The overall literacy rate in subsequent years only increased by 0.8%. These insights highlight the importance of taking measures to analyze the reasons behind unsatisfactory performance of a student in higher educational institutes.

A. Existing Student Performance Tracking (SPT) Systems

For determining the success and worth of any educational institute, the number of students graduating [16] each year plays an important role. Not only students graduating but, the students graduating with better scores is also significant [17]. Some students, having a higher intellectual ability, are fast learners while others need more time and undivided attention of the instructor. To maintain the quality of education, many institutions use different tools and techniques to track the output of the students. This tracked output helps the educators to accommodate differing needs of students [18]. With the advancements in technology it has been easier for educators to keep a track of student performance using various factors like student attendance, exam, quiz and lab work score, timely submission of assignments [19] and many more. Recording these features can also be used to predict if a student is likely to pass an exam or fail. In [20] a study was conducted to predict the success rate of the candidate in an English exam. Besides that, scores were also predicted with the help of technology. Similar study was presented in [21] where different data mining techniques were used to predict if a student is likely to pass or fail. This kind of analysis is claimed to be useful for higher education institutes as it will help them analyze students at risk to take preventive measures in time. Several other studies [22][23] have also been conducted to try different methods to predict passing or failing of a student in a course. However, these studies fail to track back to the factors causing failure of a student. Although, it is desirable to know the tendency of a student to fail to prevent it in time, but existing systems and technologies are incapable of tracking and finding the flaws each student possess. The identification of these flaws can lead to build a foundation of more useful strategies to enable students cop up with their inabilities or other study related issues.

Keeping the record of student performance is a usual practice in educational institutes all over the world. Tracking plays a significant role in analysing whether the student is learning well or not. Not only it allows monitoring of the students but recording performance and behavioural patterns of students also help data analysts to predict future performance of the students with the help of information technology. This prediction is highly valuable as it helps educational institutes to take measures to improve the performance and learning ability of students [13], thereby uplifting institutional reputation.

B. Challenges in Existing SPT Systems

A lot of work is being done for tracking student performance. However, this work has various challenges and shortcomings in terms of data storage and retrieval that need

to be addressed for more efficient systems and for better learning of students. Some of these challenges are discussed as follows.

1) Lack of traceability: The most common problem with existing record keeping systems is lack of traceability [24][25]. This means that these systems usually depict the overall statistics of the student performance but fail to give a detailed insight on the history of student evaluation as a learner at various levels of study. This history is important as it determines when the student's performance started declining what factors caused it to decline. This information is significant for correct prediction of student future behavior [26]. Moreover, history tracing allows the educators to make more knowledgeable decisions for improving a certain student's learning ability and overall performance.

2) Single point of failure: Existing systems are built on centralized storages [27] [28]. This means that they have a single point of failure [29]. In case of a disaster or loss of data, it will be very difficult and almost impossible to retrieve back the data if backups are not properly kept.

III. CONCEPTUALIZATION OF PROPOSED BLOCKCHAIN BASED STUDENT PERFORMANCE TRACKING SYSTEM (BLOSPER)

A. Design Goals

Based on the problems found in literature with existing student performance tracking systems (as mentioned in previous section), we have devised a few design goals that must be present in the proposed system. These design goals are as follows:

1) The application must be decentralized to avoid any single point of failure.

2) The record of student submissions must be transparent and tamper proof.

3) The performance of each student must be easily trackable.

To accomplish this, we proposed a student performance tracking system based on the novel technology of blockchain networks.

B. Blockchain as a Solution

The idea of blockchain technology was introduced with the advent of bitcoin, popularly known cryptocurrency [14]. The technology eliminates the need of third parties for transactions and has been proven to be more time efficient as compared to the third-party hosted system [15]. Blockchain is a disruptive innovation based on distributed ledger technology. It is responsible for record keeping in a transparent ledger. The transparent distributed ledger makes it very convenient for the user to trackback even the tiniest form of information as all the data is chained into the blocks. Besides ease of tracking data, blockchain also ensures immutability of records. This implies that the once the data has been validated and stored into the blockchain, it cannot be tampered with, hence a blockchain based system is essentially hack proof. Blockchain has a number of benefits that will help the traditional student performance monitoring and tracking systems more efficient and meaningful. Some of these include:

C. Decentralized and Distributed Ledger

Since the data on a blockchain network is distributed among all the participating peers [16] therefore, the need of trusting a designated authority to control and supervise the chain is not needed. This provides a user a complete autonomy over his data. Any student using this system can completely rely on the system for accurate tracking and monitoring without any ambiguities. Moreover, the decentralization of storage [17] ensures that there is a very little to no chance of the data being misplaced. This ensures the integrity and security of the data to any deploying enterprise/institution.

1) Transparency: Another remarkable feature provided by blockchain technology is transparency. Anyone in the network can view the information as per their convenience. This reduces the chances of illegal transactions.

2) Better trackability: The data on blockchains cannot be altered or removed. This signifies that all the data that is present on the blockchain remains there and every new information is linked to the previous corresponding information. This enables the user to trackback the entire history of chained records from the storage. This history can present detailed insights on the performance of students through various events from the beginning of usage of the system. Since all the transactions in the blockchain are timestamped hence the time and data of submission for different assignments and tasks can also be inferred from the records. Such data can be very useful for data analytics and to examine the weak points in student performance that must be targeted for better learning of the student and overall education system.

3) Immutability: Immutability of the data and transactions in blockchain will ensure no student data is tampered with. This enables a greater trust of the stakeholders into the performance tracking system. Moreover, it guarantees that the data used by data analytics for prediction purposes is original and untampered.

Moreover, according to [7] the internet access to educational institutes is getting better with each passing year. This provides a stronger base for blockchains to be implemented without a problem. Therefore, with these wide variety of benefits and ease of internet access, blockchain-based student performance tracking systems can be successfully deployed in educational institutes thereby improving the education standards of the country.

IV. BLOSPER ARCHITECTURE

A. Proposed Framework Components

Continual monitoring and tracking of students' performance is known to increase the efficiency of the students. In this paper, a novel framework for blockchain based student performance tracking (BloSPer) is proposed to keep the record of student performance on a blockchain network. The fundamental aim of this framework is to make

tracking the performance of students easier and more transparent. The traditional student monitoring and tracking systems are unable to trackback and identify the causes of student failure. The proposed framework will trackback to the entire performance history of the students to recognize the causes of performance lag in students. This ensures better strategies are devised to improve student learning ability and overall quality of education of an institution. The overall framework for the proposed BloSPer is shown in Fig. 1. The proposed framework has three major components i.e., User Interface (the front-end), Processing Layer and, Blockchain Layer. The functionality of each component is explained below:

1) User interface: As the name suggests, this component enables the users to interact with the blockchain system for information storage and retrieval. It captures information including login credentials, assignments, and other essential data from end user and sends it to processing layer.

2) Processing layer: This component consists of all the major modules designed for smooth functionality of BloSPer. The modules include i) Login Module, ii) Registration Module, iii) User Management Module, iv) Data Management Module and, v) Data Analytics Module. The data from front-end is received by processing layer and the query is forwarded to the corresponding module. The purpose of each module is elaborated as follows.

a) Login Module (LM): This module is responsible for ensuring if the login credentials entered by a user are authorised to use the system. Once the user is authorised, the module maintains a session so that the user does not need to login for every transaction triggered.

b) Registration Module (RM): The registration module enables the system administrator to register the records of students and instructors. No one can use the system unless administrator registers them using this module.

c) User Management Module (UMM): This module allows the administrator to add and delete the users from the system.

d) Data Management Module (DMM): This module is responsible for management of data, i.e., it enables the users to store the data into the chain and retrieve the authorised information from the blockchain.

e) Data Analytics Module (DAM): The purpose of this module is to download all the data for analytics purposes. These purposes may include predicting student academic performance, analysing instructor behaviour, and so on. However, it should be noted that this module is yet not a part of the implementation, currently it is only being proposed, hence it is colour coded in red to illustrate the difference between this module and the rest of the modules.

3) Blockchain layer: The third component is the blockchain layer. It provides the decentralised support for the proposed framework. Since blockchain itself cannot store

huge multimedia files, hence this layer also provides blockchain compatible, decentralised storage.

B. Stakeholders

There are three kinds of stakeholders involved in the proposed system, i.e., the instructor or educator, the student and the administrative staff as shown in Fig. 2. The role of each stakeholder is described below:

1) Instructor

The main responsibilities of instructor include:

- Self-authorize to be able to use the system.

- Upload scores of exams, assignments, lab work and other tasks submitted by students.

- Track and trace the performance of students.

2) Student

The main responsibilities of students include:

- Self-authorize to be able to use the system.

- Upload assignments, lab work and other tasks assigned by the instructor.

- Track and trace their performance.

3) Administrator

The main responsibilities of students include:

- Self-authorize to be able to use the system.

- Add student data and grant those students the permission to access the system.

C. Features and Functionalities

The various other features the BloSPer offers for end users include the following:

1) Enabling students to upload assignments/tests/lab work and other assessment materials.

2) Enabling instructors/teachers to review the assessment materials uploaded by students and mark those.

3) Enabling instructors/teachers to award reward points to students. Students can further redeem these reward points for accessing paid teaching and learning materials.

4) Enabling institutional administrators to ensure that students and instructors are uploading and reviewing assessment materials on time.

5) Enabling institutional administrators to download reliable data for further data analysis and decision making on improving student performance.

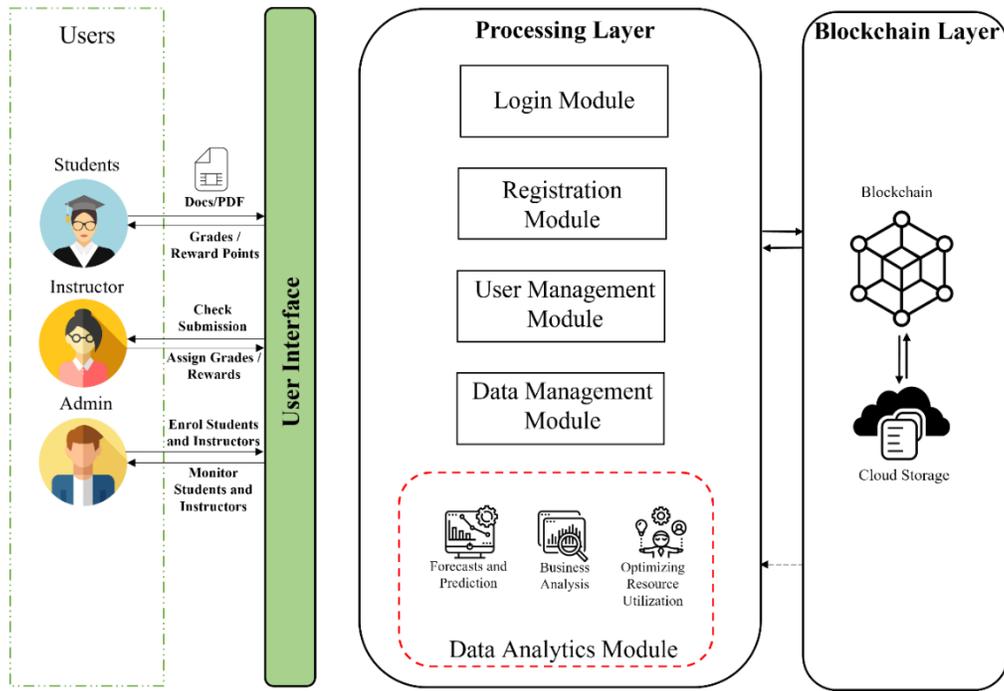
System users need to use DApp to login to the system using their private keys and interact with the data stored on the chain. It can be noted that the framework has a module.


Fig. 1.   Proposed Framework for BloSPer.
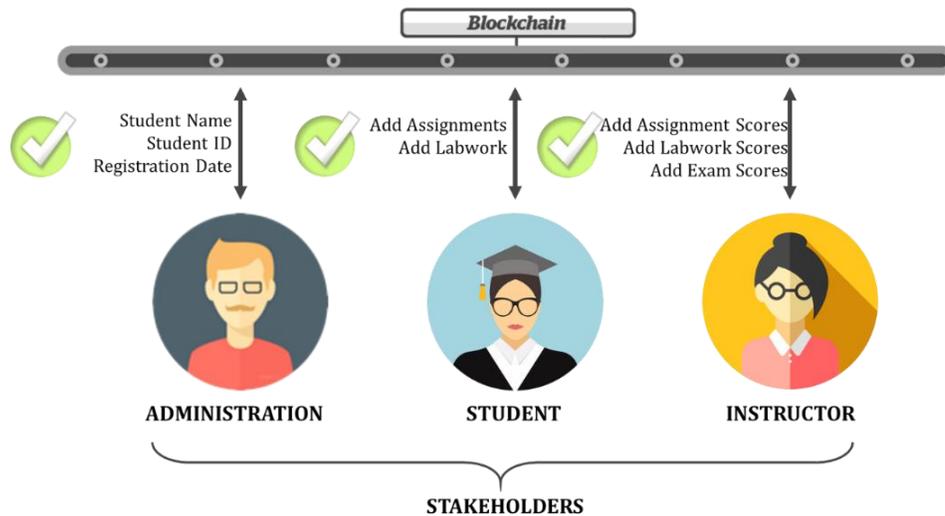

Fig. 2.   Stakeholders in Student Performance Tracking System.

D. Interaction and Transaction Sequence

In this section, we describe how BloSPer transactions are executed and communicated between different stakeholders. A graphical illustration of the system usage is given in Fig. 3. The student will submit his assignment, lab work or other tasks in the form of a transaction in a block. The block must be then validated by all the participating peers in the network. Once the block is validated it is stored into existing blockchain network. Next, the instructor can forward the request for data retrieval. This request will again be validated by participating peers to check if the instructor is authorized to access the data or not. After the request has been validated, the data will be retrieved from the blockchain and sent to the instructor. After reviewing student assignment/lab work, the instructor will insert the relevant grade into the blockchain, which will again be validated by peers and the final data will be stored into the blockchain.

The same procedure will be repeated when student wants to access his grade or when the administrative staff wants to retrieve the data for official purposes.

For using this system, all users are required to identify and authenticate themselves using the private keys received upon registration. Initially, a predefined administrator will login the system. This login request will trigger login () function in LM, from where the LM will authenticate him by matching the user records stored on blockchain. Once the administrator is authorised, he may use the system to register different

participants (i.e., students and teachers/instructors) to use the system, by calling reg(uname, utype) function, where uname refers to the name of the users and utype refers to his role/type (student/teacher). Once the registration module receives the request from admin, it generates public and private keys for the users and returns the same to the admin. Now the student may use these keys to login and submit their assignments. This will trigger the function submit (title, type, desc, teacher)

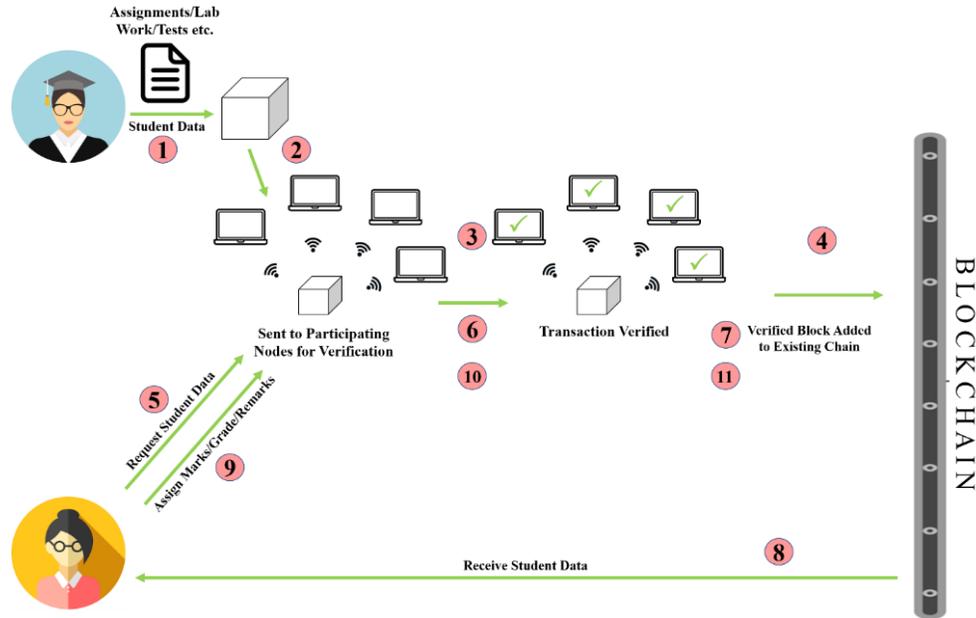
where title refers to assignment title, type refers to the type of file submitted, desc refers to description of the submission and finally teacher refers to the public ID of the instructor that the assignment is submitted to. Once the student has submitted the assignment, the teacher can login to his portal and view the assignment, mark the assignments and monitor student progress. This entire process is shown in Fig. 4.


Fig. 3.   Workflow of Students Performance Tracking Systems.
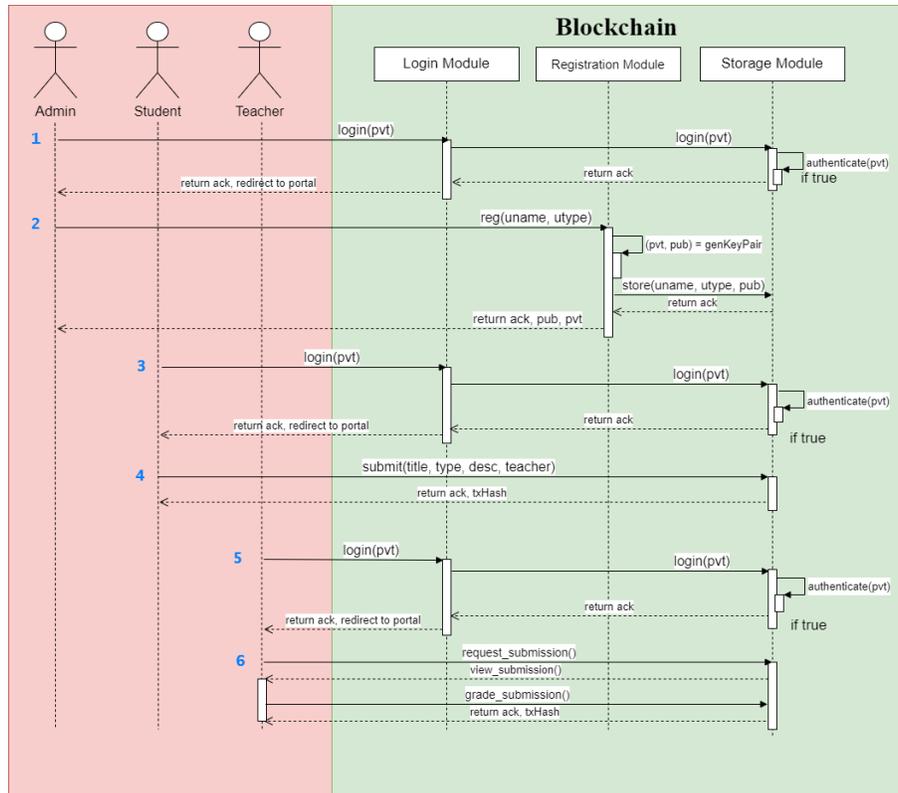

Fig. 4.   Different Types of Transaction Flows in BloSPer.

E. System Architecture

The layered architecture of the proposed system is illustrated in Fig. 5. The proposed framework is divided into four layers: i) Infrastructure Layer, ii) Consensus Layer, iii) Protocol Layer and iv) Application Layer.

The first layer is the infrastructure layer facilitating all the required hardware components for the system including different kinds of nodes (i.e., simple, full, mining), storage and other network facilities. The function of the nodes is to send, receive, store and mine the transactions. Storage in the layer is responsible for storing the updated ledger after each verified transaction is added to the chain.

Followed by infrastructure layer, the proposed architecture consists of consensus layer. A consensus mechanism is an integral part of blockchain networks. It can be defined as a fault-tolerant mechanism that is used in blockchain systems to achieve the necessary agreement on a single data value or a single state of the network among distributed processes or multi-agent systems. Most widely used consensus mechanism include Proof-of-Work (PoW), Proof-of-Stake (PoS), Proof-of-Capacity (PoC), etc. This layer also includes smart contracts which are computer programs consisting of predefined set of rules and agreements among various parties involved in the blockchain network.

The third layer in the proposed architecture is the protocol layer. This layer deals with the protocols that are necessary for a transaction to flow through the network. Whenever a transaction is requested/initiated in a blockchain network, it must first be signed with digital signature of the sender and public key of the receiver. Then the transaction is encrypted using hash functions. This layer is also responsible for handling various protocols required for decentralized data storage.

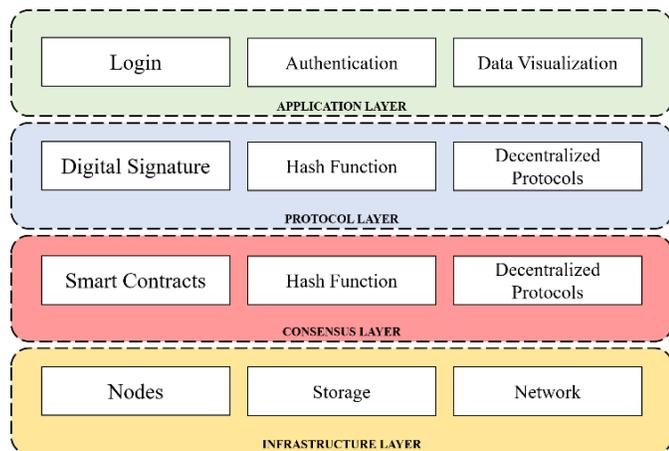
Finally, there is an application layer. The function of application layer is to provide the user an ease of interacting with the data and communication within blockchain. This is a host layer for network application to make the usage of the system more convenient to the stakeholder.


Fig. 5.   Student Performance Tracking System Architecture.

V.   Simulation Results and Discussion

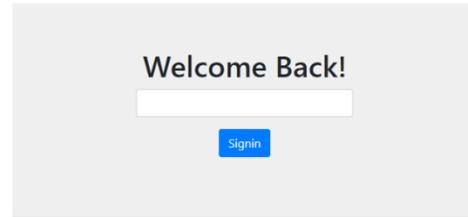
In this section, the simulation results are described and discussed. The experiments are simulated on Intel(R) Core (TM) i7-10510U processor with 8GB RAM and 2304 MHz clock speed. The prototype is implementation using NodeJS programming language and executed using Visual Studio Code. The main screen to use the system is shown in Fig. 6.


Fig. 6.   Welcome Screen of BloSPer.
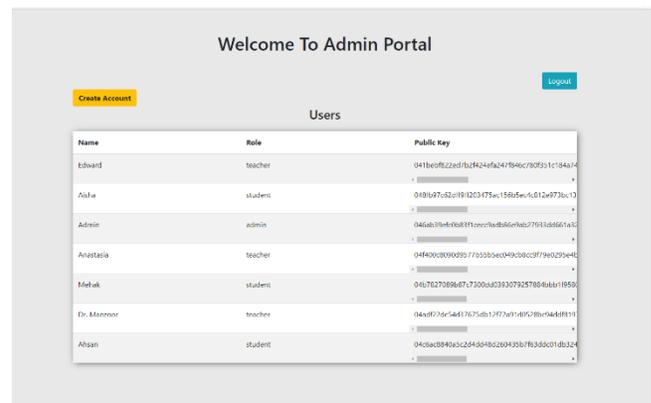

Fig. 7.   Admin Portal.

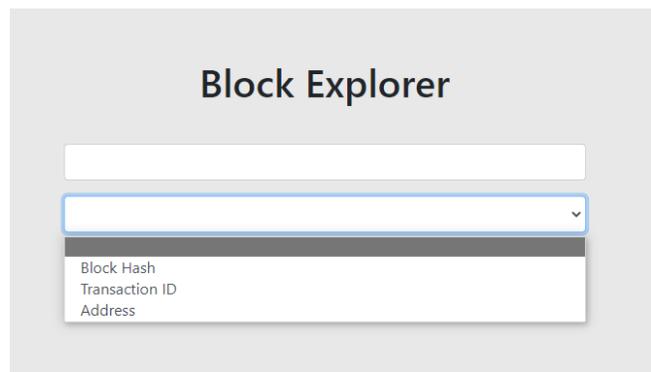
This screen requires the admin to sign in. The information of the admin has already been added to the system. Once the admin logins using his private key, the admin will be redirected to the admin portal as shown in Fig. 7. On the portal, the admin can see all the users of the system, their roles/types and their public keys. Here, the admin has an option of register more students and teachers to the system using create account button. Moreover, the admin portal has an option named "Block Explorer" which will enable the admin to retrieve information about a user, a block, or a transaction by using their corresponding hashes as shown in Fig. 8.


Fig. 8.   Block Explorer – Admin Portal.

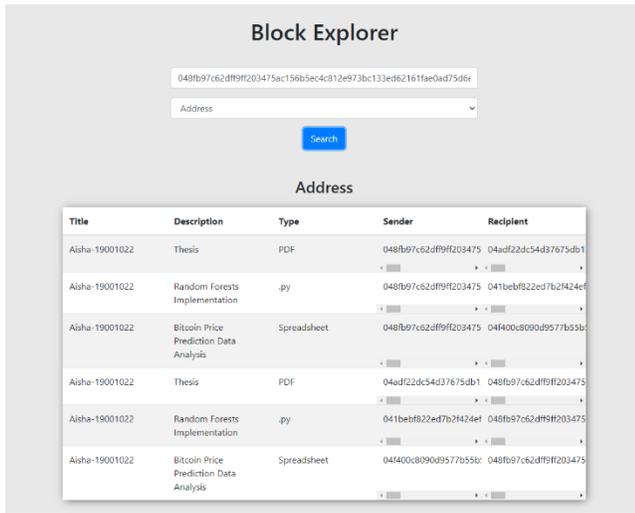
As soon as the admin enters the hash and selects the category that the hash belongs to, the entire information about that hash will be visible to the admin for monitoring purposes as shown in Fig. 9.


Fig. 9. Retrieving user information – Admin Portal.
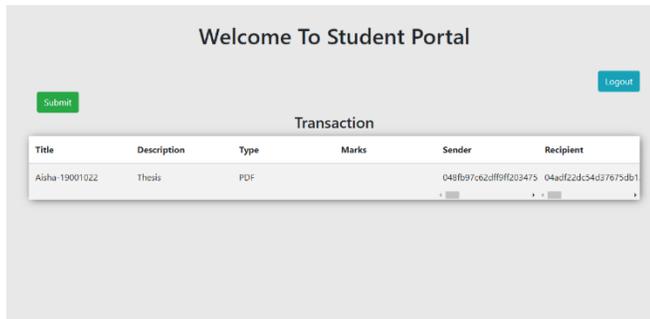

Fig. 10. Student Portal.
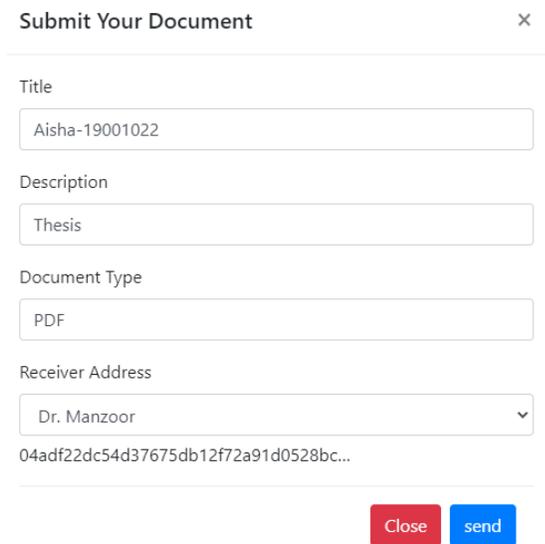

Fig. 11. Task Submission – Student Portal.

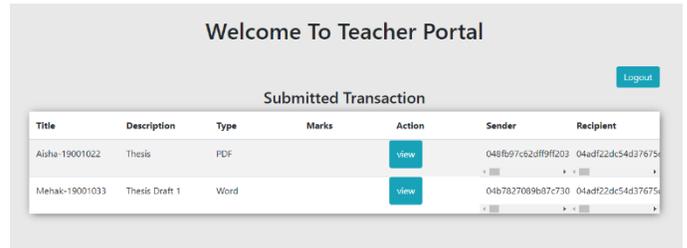
The second stakeholder of the proposed BloSPer is the student. As soon as the student logins, he will be redirected to the student portal as shown in Fig. 10. To add a file, the student must click on submit button, which will open a pop-up window for submission as shown in Fig. 11. At the time of submission, there will be no marks assigned as shown in Fig. 10. Once the student has submitted the work, the teachers can view and mark it on their portal as shown in Fig. 12. and Fig. 13. respectively.


Fig. 12. Viewing Task – Teacher Portal.
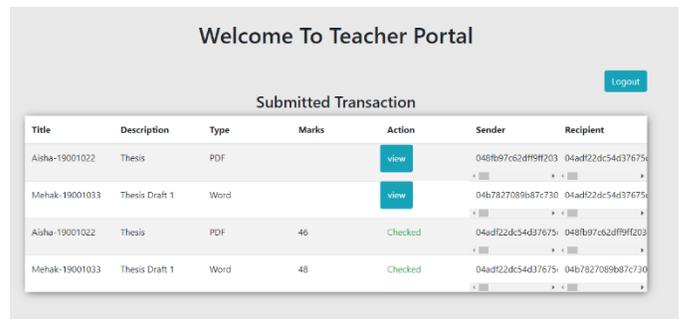

Fig. 13. Marking Task – Teacher Portal.

The data retrieved from the usage of this system will not only provide information regarding student marks but will also describe the student behavior in terms of submission time and other patterns. It will also monitor the behavior of teachers while marking. All this data can further be used to develop insights to improvise student academic performance.

VI. CONCLUSION

High quality education has a great significance for progress and prosperity of any nation. For socio-economic, political and industrial growth and well-being of a country, it is very important for its people to be well learned. Various institutions are striving towards ensuring that their students are well skilled and well trained. To achieve this, these institutions are trying and testing several methods to improve the performance of the students lagging due to unknown reasons. One such widely adopted practice is monitoring and analyzing the performance of students with the help of information technology. Literature shows that there is some remarkable work done in the domain for recording student's past and current behavior and predicting the future performance to improve the quality of education and overall student performance. However, these systems present statistical analysis only. Substantial amount of consideration is not given to trackback to the causes of students' poor performance. Our proposed framework utilizes the features of blockchain to overcome these issues. It provides a platform for

student performance monitoring in a decentralized environment. Due to immutability and trackability of blockchain, the entire history of student performance is stored which cannot be removed or altered. Hence, it provides a clear picture of student's academic standing. Using this information, important actions could be taken in order to optimize and improvise the learning experience for the students.

VII. FUTURE WORK

In this paper, we have presented a novel framework based on innovative technology of blockchain that will not only record student performance but also trace back to the causes of student failure, which is essential to devise better strategies to improve the overall education standard of the institute. However, the given system has some limitations due to time and resource constraints, hence we propose the following future research directions to improvise the study given in this paper:

1) Incentive based learning: Another simple feature could be added to BloSPer where teachers award the students with some reward points based on their good performance. These reward points can later be redeemed to access paid research and study materials, or to apply for certain courses/certifications to further enhance their capabilities.

2) Incorporation of IPFS/CouchDB for multimedia storage: Interplanetary File Storage System or CouchDB are two decentralized storage platforms. These platforms can further be integrated with the proposed system for storing different kinds of multimedia files.

3) Data analytics: The data analytics module in the proposed framework has not been implemented in the tested prototype yet. Hence, the module can be implemented to automatically visualize the data and retrieve insightful information. This is a great promising research direction as it will hugely benefit data analytics industry besides improvising student performance.

Mecca, Saudi Arabia

Abstract—**Hypertension is a major risk factor for cardiovascular morbidity and mortality. It is a condition that increases the high risk of heart, liver, and other diseases. Since hypertension is one of the biggest global public health issues, patients require more interventions to manage their blood pressure. The vast use of mobile phones and applications with medication features has turned a smartphone into a medical device. These tools are helpful for a physician in the treatment of hypertension. Mobile health applications are utilised to manage hypertension at the moment; however, there is a lack of information regarding their efficacy. Smartphones and their applications are evolving quickly hence the rise in the innovation of mobile health applications. Mobile-based applications are helpful in-patient education and reinforce the behaviour through constant reminders, medication, and appointment alarms. The main objective of this study is to determine the impact of mobile health applications on self-management in patients with hypertension and its advantages and disadvantages. We used publications from 2015 and later as a time frame and searched on the first five pages of Google Scholar, JSTOR, Hindawi, PubMed, and ResearchGate. We group all associated terms that might turn up articles on this subject in the search results. The total number of database records that we identified were 213, and the duplicate identified and removed were 117; hence the screened records were 96. The reports excluded based on abstract and title were 31. Articles with full text and have been accessed for final inclusion were 65. The excluded articles were 51, and the studies included in the qualitative analysis were 14.**

Keywords—*Impact; self-management; mHealth; hypertension*

I. INTRODUCTION

Hypertension is a global health challenge in which patients need to be more careful and take more measures to control blood pressure. It is a chronic disease that requires self-management which is the most effective treatment for the patient with hypertension. It is one of the major risks of heart disease, stroke, and renal failure [1]. Despite knowing the fact of the danger of this disease, hypertensive patients do not control their blood pressure [2] . So, it is necessary to encourage them by using smartphone applications.

The arteries in the body are impacted by the prevalent condition of high blood pressure and hypertension. The blood's constant pressure against the artery walls is too high if you have high blood pressure [3]. Worldwide, hypertension is a major contributor to cardiovascular and cerebral events risk and poses a serious threat to public health. With population expansion and aging, it is predicted that more than one in four persons globally have hypertension. A blood pressure reading of 130/80 mm Hg or greater is generally considered hypertension [3]. Hypertension is categorised into four that is normal blood pressure, elevated blood pressure, stage 1 hypertension and stage 2 hypertension [4, 5]. Most people with hypertension do not have symptoms but the few that have experience headaches, nosebleeds and shortness of breath [3].

Mobile application is a type of application software designed to run on a mobile phone, such as a smartphone or tablet PC [6]. Apps are typically small, independent software modules with constrained storage. The mobile applications can be gaming applications, business applications, education applications or travel applications. Mobile applications are developed for Android, IOS and Windows operating systems. Mobile applications are categorised depending on the following factors: the intended users of the app, technology used to develop the app and the expected performance of the application [6].

Mobile health applications have had numerous positive impacts on patients. Mobile health technology, as opposed to a conventional and ineffective telephone connection to doctors and healthcare organisations, allow patients to instantly send secure messages, make appointments, and connect to clinicians 24/7 for telemedicine visits [7]. It is difficult for doctors to keep track of a patient's adherence once they leave the hospital, and with poor medication adherence, the patient's condition can worsen and result in readmission. The mobile health applications will keep track of the patient's medication adherence. The mobile health applications will help in remote monitoring just like home care. The patients will enter data on the mobile applications that will be transmitted to the doctors. This data will include their weight, diet, and blood pressure levels without the need to visit the hospital physically [7]. Mobile health technology means the use of smartphones for health care and self-management [8]. It can integrate everyday life with health care and collects and deliver health services and information in an accessible, convenient, and interactive mode [9]. The use of smartphones and other devices like tablets, and iPad is rapidly increasing. Mobile phones are

important in health as they have become an important platform for using health care applications.

Self-management attempts to give patients with chronic diseases the power to take charge of their care [10]. Mobile health applications have proven to have a positive impact on the level of self-management among patients with chronic conditions. Mobile health applications improve self-management by allowing hypertension patients to record and track their blood pressure levels, diet intake and exercise therapy. Patients with hypertension require self-management on a daily basis because they need to check on their exercise therapy and diet intake [11]. Additionally, several nations have found that increasing self-management is an effective way to lower hypertension [10]. Multiple studies have revealed that remote patient self-monitoring without feedback from healthcare professionals has a negligible impact on lowering blood pressure. The most effective treatment for hypertension is self-management, it concludes the role of patients to manage the symptoms, physical effects, psychosocial, treatment, and changing lifestyle [12]. It is hard to achieve the optimum level of self-management as it needs considerable attention from patients. Therefore, self-management is an important part of healthcare management, as it's important to get patients to

become more involved in managing their blood pressure [4, 13].

II. RESEARCH METHOD

We searched the first five pages of Google Scholar, JSTOR, Hindawi, PubMed, and ResearchGate, with articles published as far back as 2015 as a deadline. We include all relevant terms whose search results can find articles related to this topic. We decided to use an integrated review to determine the impact of mobile applications on patients with hypertension and factors affecting the use of mHealth applications. The review was conducted to establish both the positive and negative impact that mobile health applications have had on the self-management of patients with hypertension. The review was done according to the PRISMA guidelines. The selection and extraction of data were conducted on inclusion and exclusion criteria. The articles that were included were dated from 2015 to 2022 and were concerned with the self-management of hypertension patients.

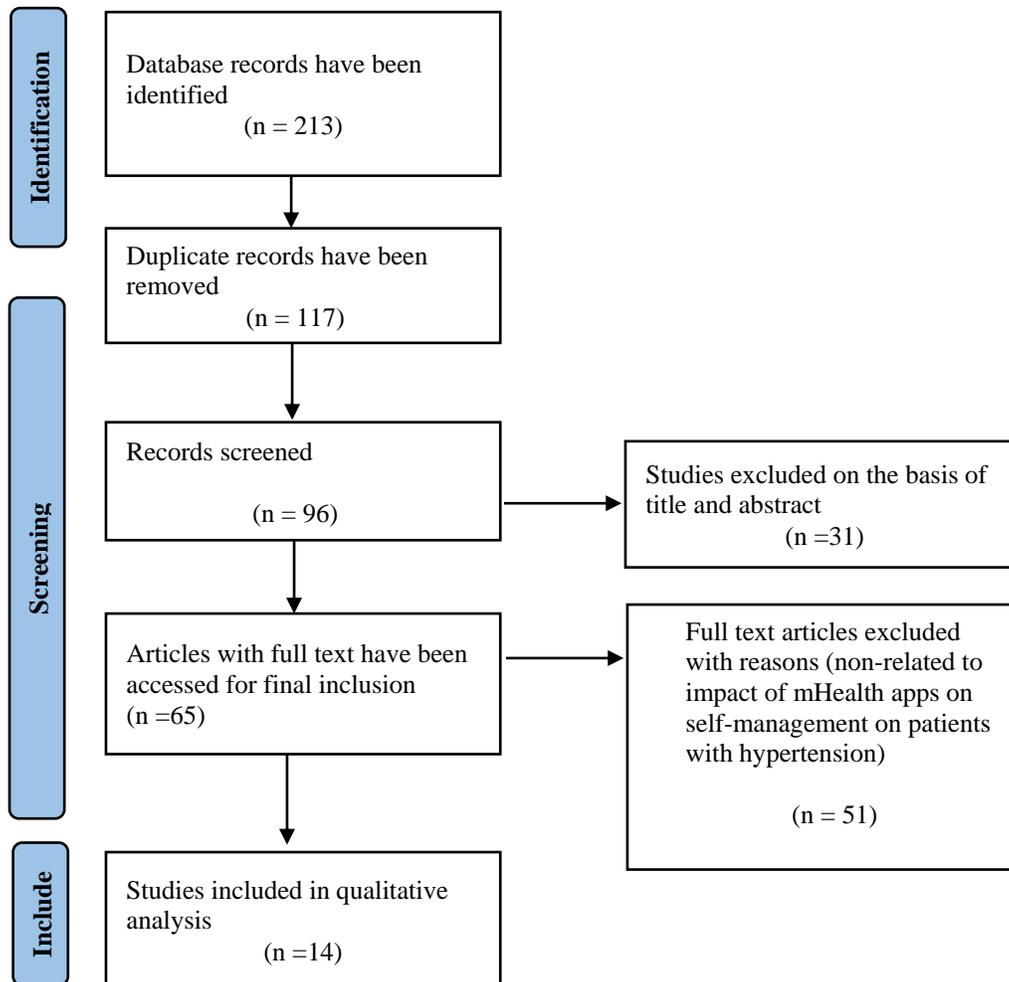
Out of all the 213 records identified, only 14 studies were included in the qualitative analysis (Fig. 1). Some were excluded basis of title and abstract, and others due to reasons related to no topics of self-management and mobile health applications for hypertension patients.


Fig. 1. Prisma Chart for the Investigation.

A. Inclusion Criteria

- The population group in all articles evaluated was 18-79 years.

- The studies were conducted between 2015 and 2022.

B. Exclusion Criteria

- The studies were carried out on less than 18 years and more than 80 years of age.

- The studies were carried out on chronic diseases other than hypertension.

- The studies published in languages other than English were excluded, which likely missed the relevant research.

III. RESULTS AND DISCUSSION

A. Positive Impacts of Mobile Health Applications on Self-Management in Patients with Hypertension

The information monitoring feature for self-care and the app's display, notes and reminders, information access, and information sharing features support the fundamental self-care tactics [3]. Because hypertension patients need to regularly assess their lifestyle, they have found the reminder feature on mobile health applications to be quite beneficial [11, 28]. To remind themselves to take their medications, exercise, check blood pressure, the patients set alarms and reminders. Numerous medications are used to manage hypertension, and not all patients can keep track of when they should take each one. The utilisation of the reminder feature to notify patients when their next appointment is coming is due to the fact that patients occasionally need to see a doctor [28]. Therefore, Reminders have a very positive impact on medication, notification pop up on smartphone screens either to check blood pressure or to take medicines.

Goal setting feature on the mobile application is also helpful because hypertension patients need to check on their weight and food intake daily. By setting a goal of reducing weight and watching their diet on the mobile applications they will be able to achieve their set targets. Moreover, setting goals is a powerful tool for encouraging physical exercise. The goal setting feature allows the patients to set a target and observe their improvements towards achieving their goals. A sedentary lifestyle is closely linked to hypertension. Exercise has been demonstrated to delay the onset of hypertension [29]. Effective blood pressure reduction has been shown to occur with both aerobic and resistance training hence the need for hypertension patients to set a goal of exercising daily. The hypertensive patient can set goals using medical health applications. He can generate a checklist or can use a default list of common goals that have to be achieved or recommended by the physician. Through these applications, hypertensive patients record the achieved goal in progress goals. Mobile health applications can also populate these goals and show overall progress. Achieved or progressed goals can also be linked with calendars and deadlines. Mobile health applications provide tips on one base of these achieved goals [30].

Some applications for mobile health have an educational component that gives more details about the patient's illness and how they may manage it at home. Patients may comprehend the data they input into mobile applications, such as their blood pressure and salt intake, with the aid of the teaching component. The educational function will enable patients to determine whether their condition is improving or declining. There are apps that can give you the contents, including the calories, fat, and sugar, of any specific restaurant item [29]. You may make an informed choice that supports you by rapidly comparing the nutrition facts to your daily objectives. Hypertensive patients also use the educational features of mobile health applications in which applications suggest them food intake, weight management as well as physical activities. These applications are also used to ask a question from a physician or to seek his opinion. The motivational feature of mobile health applications is also very important as it helps people to continue the medication and adherence and finally, they get rid of the disease.

B. Barriers to using Mobile Health Applications on Self-Management for Hypertension Patients

Lack of privacy is one of the major barriers to adoption of mobile health applications. The mobile applications contain patients' crucial information such as their email address, phone number and home address which when a breach occurs the information can be used by cyber criminals for malicious reasons [11, 31].

In addition, usability is a crucial concern for mobile health application systems because it contributes significantly to their success. However, Poor usability is a major obstacle to the widespread use of mobile applications [32]. Therefore, M-health could have unforeseen, detrimental effects if usability is not taken into account, including an increase in medical errors and issues with provider communication [31]. Some applications are very tedious and the data entry process is annoying. Even patients who are familiar with technology found it difficult which is one of the reasons for not using mobile health applications. Numerous mobile health applications are not regulated, which means they may provide consumers inaccurate information and seriously harm their health [29].

Another barrier is the prescription of mobile applications, patients think that only those applications can be beneficial and are recommended by their doctor. Finding an appropriate application is also a barrier to the frequent use of mobile applications. Lack of evidence about the effectiveness of medical health applications is also a barrier, patients demand evidence of whether either application feature is beneficial for hypertension or not [33].

C. Examining the Effects of using Mobile Health Apps for Hypertension Self-Management by Patients in Table I

This study aimed to review the impacts of mobile applications on self-management among patients with hypertension. In this review, 14 studies have been reviewed that were conducted recently between 2015 and 2022. There may be differences in study design however the main crux of these studies was to evaluate the impacts of mobile health applications on self-management in patients with hypertension.

TABLE I.   DETAILS OF ARTICLES INVESTIGATING THE IMPACTS OF MOBILE HEALTH APPLICATIONS ON SELF-MANAGEMENT IN PATIENTS WITH HYPERTENSION BETWEEN 2015 AND 2022

Study (year)	Study title	Aim	Study design
[14]	The Effectiveness of Self-Management of Hypertension in Adults Using Mobile Health.	The goal of this systematic review was to find out how well mHealth helps adults better manage their own hypertension. Blood pressure (BP), blood pressure control, medication management, self-management behaviour, and costs were used to measure the results.	Systematic Review and Meta-Analysis
[15]	Evaluation of the Effectiveness of the Mobile Application on Adherence of Patients with Arterial Hypertension.	The purpose of the study was to evaluate the impact of a mobile application on medication adherence in individuals with documented arterial hypertension.	A multi-centre randomized controlled
[16]	Smartphone Apps to Support Self-Management of Hypertension,	The study's goal is to evaluate and describe all existing applications that aid in self-management of hypertension, as well as to analyses their functionalities.	Review and Content Analysis
[17]	Apps on Google Play Store to assist in self-management of hypertension in Indian context.	The purpose of this research was to examine the analytical and practical features of hypertension self-management apps found in the Google Play Store.	Features analysis study
[18]	Comparing the Acceptance of Mobile Hypertension Apps for Disease Management Among Patients Versus Clinical Use Among Physicians.	The goal of this study is to find out what makes people in German-speaking countries accept mobile hypertension apps for personal use and what makes doctors accept them for clinical use.	Cross-sectional Survey
[19]	Mobile health applications for the management of primary hypertension.	The objective was to evaluate the impact of mobile Health applications on blood pressure control and medication adherence.	A multicenter, randomized, controlled trial
[20]	Chinese Mobile Health APPs for Hypertension Management.	The goals of this study are (a) to provide recommendations for developers in industry and (b) to aid hypertensive patients in selecting suitable APPs by comparing and contrasting the efficacy of hypertension management APPs released in the Chinese market; (c) to gain an understanding of the general circumstances, characteristics, issues, and trends in hypertension management mHealth APPs; and (d) to determine the gaps between products from mainland China and those from outside of mainland China.	A Systematic Evaluation of Usefulness
[21]	Effects of using a mobile health application on the health conditions of patients with arterial hypertension.	To verify the mobile intervention and effects of using a health application on patients with hypertension.	A pilot trial in the context of Brazil's Family Health Strategy
[22]	A content analysis of smartphone-based applications for hypertension management.	This study aims to determine the content of mobile hypertension applications available on Google Play and Apple iTunes.	cross–sectional study
[23]	Impact of a mobile phone app on adherence to treatment regimens among hypertensive patients.	The aim of this study is to investigate the impacts of mobile applications and medication adherence among hypertensive patients.	A randomized clinical trial study
[24]	Effect of an Integrative Mobile Health Intervention in Patients with Hypertension and Diabetes.	The object of this study is to evaluate the use of an integrated mobile application for hypertension, obesity, and blood pressure.	Crossover Study
[25]	The effect of the mobile "blood pressure management application" on hypertension self-management enhancement.	This study assessed the impact of a self-management application on patient adherence to hypertension therapy in context of the increasing use of mobile health in healthcare.	A randomized controlled trial
[26]	The Emerging Role of Mobile-Health Applications in the Management of Hypertension	This study examined the current research on m-health systems and how m-health might impact the management of hypertension.	Study review
[27]	Mobile Health Applications and Medication Adherence of Patients with Hypertension.	The goal of this study is to figure out how health apps impact how people with hypertension take their medicine and what causes those effects.	A systematic Review and Meta-Analysis

These studies have appraised the applications with a combination of functionalities and features, as some were designed for self-monitoring of blood pressure, some to measure blood pressure and other was helpful in log and record updating of a patient. In most studies, participants accepted the applications for blood pressure and self-monitoring. Due to varying places, study designs, and quality of results, it is inconclusive to define the most evident impacts of mobile applications, and which is more effective in lowering blood pressure worldwide. However, it is finalized that applications with more comprehensive functionalities and features were more effective in self-management.

There are different study designs evaluated in this paper, (4/14) studies are randomized control trials, (3/14) are systematic reviews and meta-analysis, (2/14) are cross-sectional surveys and (2/14) are reviews and content analysis whereas other study designs are included in this paper are, features analysis study, pilot trial in the context of Brazil's family health strategy, crossover study. All these studies were on the effectiveness of mobile health applications in patients with hypertension, and many have also assessed the experience and satisfaction with these applications. These are conducted in different environments for different purposes, so there is no standard duration as well as the number of participants.

A systematic review conducted in China to determine the effectiveness of self-management of hypertension patients who use mobile health indicated that mHealth self-management treatments successfully lower blood pressure [14]. Patients with hypertension require self-management regularly. Maintaining blood pressure with medication and avoiding problems are the fundamental therapies for hypertension. Because hypertension is seen as a chronic condition, self-management should be a regular part of the patient's routine. Improvements in self-management behaviour and medication adherence were seen as a result of this review. The mHealth intervention that was the most effective combined personalized messaging with interactive communication and diverse features. With the prevalence of hypertension increasing internationally, mHealth presents a potentially efficient approach for hypertension self-management and control. It is simple to incorporate mHealth into current healthcare systems [14]. Therefore, according to this study, self-management education can increase patients' understanding of hypertension and enable early diagnosis of excessive blood pressure.

A study conducted in the UK to evaluate various mobile applications that support the self-management of hypertension patients and their functions concluded that many mobile health applications but only a few could be considered effective [16]. According to the study, many applications are ineffective because they do not have security measures and do not provide evidence of their effectiveness and usability making it difficult for hypertension patients to determine which mobile health applications are effective [16]. In Brazil, a study was conducted to verify the effects of mHealth applications on arterial hypertension patients. The study indicated that technology use with health information is a development that can benefit hypertension patients' therapeutic plans by promoting better treatment compliance, healthier lifestyle choices, and better health outcomes [21]. mHealth systems help patients manage hypertension in the following ways: setting alarms and reminders for patients to take their medications, linking patients' blood pressure reports to their electronic medical records so that their doctors can check them, providing patients with feedback on their blood pressure tendencies, and acting as point-of-care blood pressure sensors [21]. mHealth apps with alarms and reminders can increase medication compliance, while apps that share ambulatory blood pressure records with patients' doctors can advance patient-health professional communication.

A study conducted in Kazakhstan was aimed at evaluating the effectiveness of mobile health applications on patients diagnosed with arterial hypertension. The study concluded that the mobile health applications did in fact help with patient adherence. However, more research is needed to allow the wider implementation of mobile health applications in healthcare [15]. A study done in India to identify the mobile applications in the Google play store that support self-management for hypertension patients indicated that the applications mainly focused on recording blood pressure and providing statistics and trends and not self-management techniques, hence the need for improvement [17]. Therefore, Developers of hypertension apps should now focus on including additional self-management features.

According to a study conducted in German speaking countries to determine the acceptance of mobile health applications for patients and physicians of hypertension by observing the modes of service and delivery of health services indicated that the expected performance of the applications was the main factor for the acceptance of the mHealth applications [18]. A systematic review done in China to evaluate the effectiveness and usefulness of mobile health applications for hypertension patients concluded that the usefulness of the mobile applications was unsatisfactory hence the need for improvement because there is a rise in the need for mHealth applications for hypertension patients [20].

In Palestine (Gaza Strip), a study was conducted to identify the impact of mobile health applications on adherence to medication on hypertension patients indicated that the applications were indeed effective and reduce cardiovascular mobility and morbidity [23]. A study conducted in South Korea to investigate the effect of using integrated mobile health intervention on patients with hypertension and diabetes indicated that even though the apps body fat and glucose levels they failed to indicate clinical improvement on the patients. The medical information and reminder app was also more appealing to patients than a food diary and fitness monitor [24].

A study conducted in Iran to verify the effect of mobile blood pressure management application on self-management for patients with hypertension indicated that the application is helpful for hypertension patients in developing countries [25]. An analysis is done in France to determine the effectiveness of smartphone-based applications on hypertension management showed that the applications were helpful by recording the patient's blood pressure, heart rate and salt intake. Additionally, Medical app development for HTN, especially medical devices, needs more oversight. [22]. In China a study was conducted to observe the impact of mHealth apps on blood

pressure and medical adherence and the results showed that the mHealth apps helped to lower blood pressure, improve blood pressure control, and medication adherence, all of which can assist to minimise the economic and social burden of hypertension in people [19].

A review conducted to identify the role of mobile health applications on the management of hypertension indicated that improvements in blood pressure outcomes might be achieved through the use of smartphone applications that serve as medication reminders, offer patients with individualised feedback, and provide two-way communication with their healthcare professionals [26]. A study conducted to analyze the impacts of mobile health application on medical adherence of hypertension patients and the underlying factors showed that mobile health applications have a positive impact on medical adherence of hypertension patients and helps improve their conditions [27].

All the above-mentioned studies agreed as a whole that smartphone-based has the potential to manage chronic diseases considerably. The results are in accordance with the impacts of mobile health applications in self-management for patients with hypertension. The results of the application with automatic feedback and recommendation features without involving a physician were more promising in controlling blood pressure. In the same way, the mobile applications in which healthcare products were involved in remotely monitoring the patients with automatic feedback also had a significant impact on blood pressure. It can be assumed that both approaches are effective and beneficiary.

In all the included studies one thing is common hypertensive patients appreciated the features of medical health that have saved their time as compared to traditional ways. They found medical health application valuable if it is simple to use, provide specific and to-the-point recommendations and instructions and share data with their desired individual. Though tracking is the main function, it may distract the patients at the same time.

This study is one of the systematic reviews which explore the impacts of mobile health applications in self-management for patients with hypertension. Lastly, this study might be a roadmap for future studies on this topic.

IV. CONCLUSION

This study determined that mobile health applications are acceptable and assist in controlling and lowering the blood pressure of hypertensive patients. It is also concluded that applications with more comprehensive features and functionalities are more effective. This study also demonstrates its positive impacts and barriers which help the technology giants to design user-friendly applications. In positive impacts, it highlights the most effective impacts, such as reminder, goal setting as well as educational feature of these applications. At the same time, the barrier in patients' perspectives is also highlighted. Implementation of these applications more effectively would help to control the disease which requires self-management and self-monitoring. According to studies, mobile health applications can benefit people with hypertension by keeping track of their diet, salt intake, blood pressure, and heart rate, which can help their condition. The majority of studies showed that mobile health applications had a good effect. To boost the effectiveness of mobile health applications for patients self-managing their hypertension, we advise conducting more research in this area.

IRemember: Memorable CAPTCHA Method for Sighted and Visually Impaired Users

Mrim Alnfiai, Sahar Altalhi, Duaa Alawfi
Information Technology Department
College of Computer Science and Information Technology
Taif University, Taif, Saudi Arabia

Abstract—**A CAPTCHA is used to automatically differentiate between human users and automated software to prevent bots from accessing unauthorized websites. Most proposed CAPTCHAs are not accessible to visually impaired users because of the memorability of the CAPTCHA's numerical digits. Recalling six random spoken digits is a difficult task for any human. Visually impaired users must typically play the audio several times to memorize the spoken digits in the correct order. The authors reviewed existing CAPTCHAs for visually impaired users and concluded that the high cognitive load is more susceptible to response errors due to extensive challenge digits intended for visual users. Thus, the authors proposed a novel method that improves current audio CAPTCHA by enhancing the display of the challenge and improving the memorability of its phraseology. The proposed CAPTCHA presents short common phrases, such as "piece of cake." After hearing or seeing the phrases, the users are required to type the first letter of each word from the presented phrases, such as POC for a piece of cake. The study results of 11 visually impaired users concluded that the memorability and success rate for the IRemember CAPTCHA was 82.72%, compared to the audio CAPTCHA at only 48.18%. It has also demonstrated higher memorability and less workload than the traditional audio method. This research indicates that using common knowledge and experience in the design process for a CAPTCHA method for these users can enhance performance and minimize workload and, hence, error rates.**

Keywords—CAPTCHA; blind users; visually impaired users; memorability; accessibility

I. INTRODUCTION

Today, we can consider web services as the backbone of life, especially since the inception of the COVID-19 pandemic. Many services are provided through web-based applications. The Completely Automated Public Turing test to tell Computers and Humans Apart (CAPTCHA) is used as an authentication protocol. It has become a necessary step for online services, especially ones designed for public use, free usage cost, or registration to the end user. If you use the internet regularly and deal with a web form, you will typically encounter a CAPTCHA test. Being able to utilize the services on these applications is a right for everyone worldwide. A study by the World Health Organization shows that about 217 million people have some kind of visual impairment, and almost 36 million are totally blind [1]. It is also determined that the rate of people with visual impairments will increase because of the population expansion. CAPTCHAs are annoying for humans to solve and can be difficult or impossible to figure out for those with disabilities. CAPTCHAs have to work for all people, disabled or not, because this tool prevents bots and viruses, but people must be able to use them with ease. Therefore, it is essential to develop new technologies that people with visual impairment can effectively use.

CAPTCHA, initially developed in 1997 by Alta Vista, is a test used to determine whether or not the user is human. It is a significant step when dealing with a web form to prevent automatic bots and harmful invasions. It does this by offering tests that humans can pass, but computer programs cannot. The term CAPTCHA was instituted in 2000 by Luis von Ahn, Nicholas J. Hopper and Manuel Blum of Carnegie Mellon University and John Langford of IBM [2]. Essentially, CAPTCHA blocks robot software from submitting fake or misused online requests. It is also used to protect the integrity of online polls by preventing hackers from sending in repeated false responses using robots.

Currently, CAPTCHA is categorized into five main categories: text-based, image-based, video-based, puzzle-based, and audio-based [20], the text-based type being the most widely deployed. Google, Yahoo, and Microsoft websites have deployed text-based CAPTCHAs for years. Many techniques are used for creating text-based CAPTCHAs, such as Gimpy, which provides an arbitrary number of words and displays them in a distorted manner. The EZ-Gimpy technique uses only one word. The Gimpy-r technique uses random distorted letters with a noise background. Simard's HIP CAPTCHA selects random letters and numbers and then uses arcs and colors to distort them [3]. The problem is that text-based CAPTCHAs are not suitable for individuals with visual impairments since they have a hard time remembering letters and typing them.

Image-based CAPTCHAs require users to select matching images or images that don't fit. A Braille display cannot present an image; therefore, a user who needs to use a Braille display cannot solve the challenge. So, if screen reader software could display the CAPTCHA to a blind user that would defeat the purpose of preventing automatic bots and harmful actions since bots would be able to solve the challenge as well. This is a severe limitation of image-based CAPTCHAs, which cannot be used wherever accessibility has to be guaranteed by governmental institutions.

The third category is video-based CAPTCHAs, which rely on typing information from the video that only humans can notice.

Puzzle-based CAPTCHAs have pictures divided into parts with different techniques and ask the user to find the missing part.

Audio-based CAPTCHA is the last category, and that presents an audio recording with a noisy background of a series of letters or numbers [14]. This CAPTCHA helps visually impaired users, but it is difficult to interpret the results. Many studies and schemes have been done in this area to develop it. One of these studies did try to help blind people by not making them type the word. This mechanism is called HearAct CAPTCHA, and it uses a tap or swipe to allow the user to determine if it is a specific letter in a sound-maker name. Users with comprehensive spelling and English vocabulary can solve this challenge. So, remembering how to spell the word is the gist of this type of CAPTCHA [1]. reCAPGen schemes depend on choosing audio clips from old radio programs, podcasts, and YouTube lectures and adding the amount of noise. Noising minimally affects the human ability to solve the generated audio CAPTCHAs [4].

The Last Two Words (LTW) scheme achieves a success rate of 78 percent with sighted users and 81 percent with visually impaired users with an average response time of 15 seconds [5]. These CAPTCHAs exploit the human effort to generate transcriptions for audio files with high accuracy [6]. This scheme relies on remembering the last two words and knowing how to pronounce them, which is difficult for non-native English speakers.

This paper introduces a new technical solution to address visually impaired individuals' challenges in answering CAPTCHA questions. This solution allows browsing and accessing internet content while maintaining website security. Using an approach to help users recall the response to the CAPTCHA question improves the accessibility. It makes solving the CAPTCHA challenge the idea behind audio, improves accessibility, and allows people with visual impairments to solve the CAPTCHA independently. This approach uses common memorable phrases to enable users to memorize the answer quickly without repeating it several times. In this technique, we will use these sentences in the audio CAPTCHA and ask the user to input the first letter of each word. For example, if we use the common phrase, "How are you?" they are required to input the first letter of each word, in this case, "hay." We will display common phrases to enhance the memorability of the CAPTCHA. The length of the phrases must not exceed four words. Developing this new form of CAPTCHA allows visually impaired users to memorize it.

The objectives of the proposed CAPTCHA method are:

1) To overcome the limitations associated with traditional audio CAPTCHA methods for visually impaired users.

2) To build accessible and secure CAPTCHA challenges for both visually impaired and sighted users.

3) To improve memorability for visually impaired users by reducing the mental workload needed to solve the

CAPTCHA and minimizing their cognitive load needed to recall the CAPTCHA digit.

4) To minimize error rate and completion time to solve the challenge.

The contribution of this research is as follows:

- Creating a novel and memorable CAPTCHA method that uses common phrases in creating CAPTCHA challenges, allowing users to respond with few characters to minimize completion time.

- Developing a CAPTCHA method that is memorable and easy to solve for visually impaired individuals.

- Presenting a user study to investigate the performance of the proposed CAPTCHA and measure the accuracy, usability, and cognitive load required to complete the task. Participants solved a set of CAPTCHA challenges during the experiment.

The paper is organized as follows: a review of the CAPTCHA systems previously designed for visually impaired people, an explanation of the IRemember CAPTCHA design, the methodological approach to testing the proposed CAPTCHA method, results, conclusions, and considerations for future research.

II. RELATED WORK

With the spread of the Internet and its technologies, it has become necessary to propose and develop online verification methods, CAPTCHA, and facilitate it to all society members in proportion to their special needs, such as people with autism spectrum disorders [7], learning disabilities [8], and blinds or visual impairment [9]. For Internet users with a visual disability, our target in this research, the audio CAPTCHA overcomes limitations of other CAPTCHA types because it is based on what they hear, not what they see [1].

Human-Interaction Proof, Universally Usable (HIPUU) with both versions [10] and [11] is an audio CAPTCHA designed to overcome the traditional audio CAPTCHA limitations. The task is based on choosing the appropriate word to describe an image from a drop-down list. In addition, an alternative for the image is provided by playing an audio file corresponding to the same image. In this way, the user can choose the preferred media representing CAPTCHA. In version 1, the list contains 15 different choices and some false decoy answers, which makes it vulnerable to brute force attacks because of the small number of choices. However, HIPUU version 2 increases the security level by requiring solving multiple tasks, each with 35 choices and some false decoy answers. In contrast, version 3.0 requires users to type in the solution using a keyboard instead of choosing from the drop-down menu, which is a time-consuming task for visually impaired users. Similarly, SoundsRight [12] is another audio-based CAPTCHA that asks the user to press the space button each time the users hear a particular sound.

In [13], the CAPTCHA is made of a simple text-mathematical problem converted into speech/audio using text to speech (TTS) system. The user has to listen to the question and then answer by only typing the answer as a number. On

the one hand, this method relies on computer limitations to solve numerical spoken questions, but it is challenging to generate a large number of tests. Thus, it is not a practical solution [14]. Similarly, in [15], the authors propose four scenarios of audio CAPTCHA includes: ask users to calculate a running total, count the occurrence of a character in an alphanumeric series, transcribe the alphanumeric characters they heard, and last which is the categories prototype that asks users to count the number of sounds, in a series, that belonged to a specific category. Three out of four designs have increased vulnerability against random guessing attacks, which makes it limited to situations where high security is not critical. HuMan [16] asks the user a question from his/her favorite field and types the answer in a text box. It is easier than the text or image-based CAPTCHAs for blind users, but still has a high probability of spelling mistakes since it requires a full written answer.

In 2021, Mathai et al. improved the existing audio CAPTCHA as they stated that the traditional audio CAPTCHA is complicated to solve by visually impaired users. In their developed method, users hear a distinctive sound, and they are required to count how many times they hear the intended sound. The distinctive sound is a combination of sound, background noise, and music produced using Generative Adversarial Networks to make it difficult for bots to distinguish the answer. The main advantage of this method is allowing users to solve the challenges using numbers. However, it is too complicated and time-consuming to prepare the sound challenges.

Another distinct study where the CAPTCHA method is developed using an OTP-based QR code [17]. Users can decrypt the OTP using a unique key. It is a secure method, but it requires having another phone device to scan the QR code. Noorjahan designed a CAPTCHA method using fingerprints (2019). This method is accessible for visually impaired users, but it requires external hardware to complete the CAPTCHA solving task, which is a fingerprint scanner. Another drawback of this system is that it is applicable to smartphone devices.

HearAct [18] is an audio-based solution that does not require typing text but reaction. The user listens to a sound of what is called a "sound-maker" and answers a spoken question by tapping if the answer is true. Otherwise, swap left or right. The work achieved a success rate of about 82.05%, which is twice as much as the success rate of the traditional audio CAPTCHA and a faster completion time of 55.35 seconds than 65.64 seconds in the traditional audio CAPTCHA.

A recent and related work [19] proposes Machine Learning (ML) model to classify humans from bot behavior. To solve the CAPTCHA task, the user will be asked by audio to draw a simple shape. Then, the cursor movement will be captured and converted to an image and sent to the backend ML model to decide if it was a human or not.

The Generative Adversarial Network (GAN) algorithm is used in [20] to generate music with unique sound samples and a white noise layer. The CAPTCHA challenge asks the user to count the number of unique sounds made by percussion instruments such as drums. This solution simplifies the task for blind or impaired users by requesting to type the answer as

a number. In addition, auto-generation of music and adding the noise layer make it more secure against speech-to-text bots and APIs.

The work [21] is a simple but efficient solution developed to allow visually impaired users to verify their humanity by walking at least five steps. If this step is done successfully, then the user will proceed to enter a username and password. Otherwise, the verification process will fail, and the user will be prevented from accessing the service that he/she wants.

By reviewing these studies and taking in mind the few numbers of research on audio CAPTCHAs and their accessibility and usability for people with vision impairments, the door is opened for more investigation and encouraged more studies to improve the accessibility, memorability, usability, and speed of solving CAPTCHA tasks for blind Internet users. This motivated us to propose a new solution based on commonly spoken phrases to increase memorability and requires entering only the first letter from each word to speed the task for blind or visual impairment users.

III. IREMEMBER CAPTCHA DESIGN

The proposed method is audio and text-based, where users can see or listen to a short common phrase and then identify the beginning letter of each word in the phrases displayed and spoken. The proposed method is built based on the theoretical concept that people can remember phrases better than random and varied letters [22]. The IRemember CAPTCHA features include:

1) Requiring users to listen to the provided phrase.
2) Recognizing the beginning letter of each word in the phrase.
3) Typing only the first letter of each word in the response field.
4) Ability for user to double tap when updating the CAPTCHA challenge.

For example, users will receive a question like, "Please type the first letter in each word in the following phrase." Then, users are required to listen to the given phrase, "How are you?" and to determine the first letter of each word within the phrase. Once users recognize the beginning letters of the phrase, they must type "hay." If users want to update the challenge, they can double tap anywhere on the screen to receive a new challenge (see Fig. 1).

The proposed CAPTCHA differs from existing methods in two ways: the identification stage and solving stage. In the identification stage, users listen to the phrase and are required to recognize the first letter of each word in the phrase. In the solving phase, users can type 3 to four letters that represent the first letter in each word. Doing so will minimize the time spent to solve the CAPTCHA as users have only to type three digits.

To improve the accessibility of CAPTCHA, two sounds are used. The first speaks the CAPTCHA question, "Type the first letter of each word in the phrase," and the second speaks the phrases. This feature can enhance the method's usability and simplify the differentiation between the question and challenge. To minimize cognitive load, the CAPTCHA

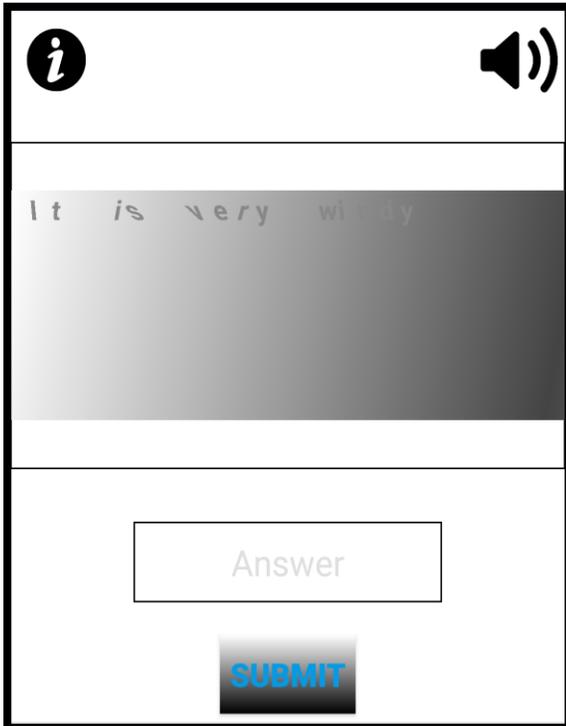
method has one basic CAPTCHA statement, which is "Type the first letter of each word in the CAPTCHA challenge."


Fig. 1. IRemember CAPTCHA Method Interface.

The proposed approach is different from existing methods in both the identification and solving phases. In the initial phase, the challenges are represented as a phrase, which is easier to recall than presenting different letters. In the second phase, users are required only to type a few letters. To enhance security and reduce confusing recognition software, the CAPTCHA method presents the entire phrase that is distorted using text and audio. With this CAPTCHA style, it is easier for users to identify the first letter of each word of the phrase while simultaneously being difficult for the software to determine the letters.

A more secure and accessible CAPTCHA method is provided by developing the proposed CAPTCHA method. The new method will also benefit a wide range of users as it will simultaneously provide visual and audible challenges. Doing so makes CAPTCHA universal and meets usability and accessibility standards. Another valuable benefit of developing IRemember CAPTCHA is creating an accessible and memorable CAPTCHA method that will enable visually impaired individuals to solve CAPTCHA challenges by themselves without asking for assistance from others to pass this stage. By doing so, the visually impaired will be independent and able to access online materials without support. Another critical benefit of this CAPTCHA is minimizing the time spent to complete the challenge and reducing the cognitive load needed to recall the CAPTCHA digits. In addition, developing an easy-to-recall challenge will minimize the error rate and enhance users' satisfaction with the developed method.

The proposed method will be easier for sighted users to solve as they are only required to type the first letter of each word, which is much easier to recognize and type since its only six digits. From the website security perspective, the proposed method will be more secure as it will use different background noise to prevent software recognition and determine the challenge response. As a result, developing this method will provide websites with a more resistant and secure approach to various attacks. It is more confusing for software to recognize the content of a challenge, which is the entire phrase. Additionally, providing different methods for presenting CAPTCHA challenges will improve accessibility for humans as it considers people's disabilities. In general, building accessible CAPTCHA for visually impaired users and other individuals with disabilities prevents the technical barriers they have faced when browsing web pages and enables them to do their online tasks without complications.

A. Selection of Phrases

The authors gathered a set of common phrases or idioms that individuals typically use in their daily lives that are recognizable by general users without requiring too much concentration and mental effort to memorize the given digits. The used phrases were collected from the EnglishSpeak website [22]. In the implementation phase, the authors used 250 common English phrases to build the first version prototype's library.

B. IRemember CAPTCHA Task Complexity

The primary goal of the IRemember CAPTCHA is to create an accessible and memorable method for individuals with no or low vision. The method presents a phrase that contains at least three words to enhance the complexity of the audio CAPTCHA challenge and, thus, the security. In addition, background noise was added to the text and audio clip to make it more challenging for software to recognize the CAPTCHA content.

C. Implementation of IRemember CAPTCHA

The proposed CAPTCHA is implemented on the Android platform. The authors chose to implement the prototype on the Android platform because it is open source and allows designers to integrate available functions with future iterations. In addition, the proposed CAPTCHA can be implemented on other platforms.

IRemember has one interface that presents the challenges of using textual and audible approaches. At the bottom of the challenge, a large text box appears where users can type the requested response. As a result, it is easier for users to locate the answer box, and they can immediately type the response upon hearing the challenge. For example, the users hear the prompt, "Type the first letter of each word in the phrase" with a particular pitch of a sound. Then, the application will immediately present the phrase "Cup of Joe" on a different pitch. After users hear the phrase, they should recognize the first letter of each word (COJ) and type those letters into the response box. If the response is correct, users pass it onto the website's main page; if it is wrong, users receive a new CAPTCHA challenge.

Fig. 1 shows an example of an IRemember CAPTCHA as described above. Then, if users enter an incorrect answer, the CAPTCHA says, "Try again," and users receive a new challenge. Users follow the same steps to solve the additional challenge.

The key features of the audio CAPTCHA file used to implement IRemember CAPTCHA are:

- Common phrases.
- Phrases ranging between three to four words.
- Background noise.
- Challenge duration differs based on phrase length.
- Randomly presented phrase.

D. IRemember CAPTCHA Security

The IRemember CAPTCHA method provides another level of layer after the authentication process for users. It has been implemented to build an accessible approach for people with no vision to enable them to solve the given challenge in a short time with less effort.

In the implementation process of the proposed CAPTCHA, we considered the essential security requirements that make the CAPTCHA method more secure and eligible [23, 24]. The IRemember CAPTCHA is implemented based on these requirements, including distortion levels, challenge type, randomness, time constraints, and size. Most blind users find it extremely difficult to solve a CAPTCHA following a loud background noise or distortion. Thus, according to the HearAct, CAPTCHA challenge type and size are the predominant design factors to consider and have been used to make the IRemember solution secure and accessible. Users receive the whole phrase and need to recognize the first letter of each word in the phrase; doing this makes it very difficult and costly for an automated bot to attack. The addition of background noise makes it complicated and requires time from software bots to provide the answer. Randomness is another IRemember method presented randomly to increase the hardness of distracting the correct response. In addition, time is another approach to restrict the software bots from recognizing the answer. After a short time, the method will generate a new challenge. Adding a specified time frame for answering the CAPTCHA challenge prevents the bots from having time to identify the right answer. Another factor that enhances the security level of a CAPTCHA method is the size and length of the CAPTCHA challenge. The IRemember CAPTCHA method provides phrases that have at least three or four words.

The steps that are required to break or automatically solve the IRemember CAPTCHA method would include the following procedures:

1) Understand the main question (e.g., "Type the first letter of each word in the phrase?"

2) Separate or remove the random noise from the audio content.

3) Convert the spoken phrase into textual format.

4) Extract concepts from the transcribed text and recognize the first letter of each word from the given phrase.

5) Type the answer by analyzing the challenge and specify the response.

Theoretically, the software bots need to transcribe the audio into a textual format in the traditional audio CAPTCHA. However, the software bots need more than three steps to break the IRemember CAPTCHA: removing the background noise, understanding the main question, and determining the first letter of each word in the phrase. These steps make it more challenging to break the CAPTCHA method and require more time.

E. Advantages of IRemember

The proposed CAPTCHA system is easy to solve and reduces the time users will spend typing by only asking for the first letter of each word. This CAPTCHA is unlike the traditional audio CAPTCHA, where users need to type at least six digits for each challenge [25]. Additionally, this CAPTCHA approach is efficient because once users hear the audio challenge and identify the CAPTCHA, they can immediately solve the challenge without any need to hear the audio clip in its entirety. When users identify the phrase, they can type the response and pass the challenge seamlessly.

The most important advantage of the proposed CAPTCHA is that it is simple to recall the response phrases because they are commonly used in everyday life. So, memorizing a phrase is far easier for users than a string of random digits.

IV. METHODOLOGY

This section aims to investigate the usability and memorability of the IRemember CAPTCHA method for visually impaired users. Our methodology focuses on mixed methods to perform measurements. The quantitative method was used to measure solving time and success rate and to clearly determine user experience through a workload (NASA TLX) Subjective Questionnaire. On the other hand, the qualitative method will be used to collect strengths, limitations, and suggestions through interview questions. The performance measures were used to analyze the efficiency and effectiveness of the examined CAPTCHAs. This section explains the user study procedures and the obtained results in detail.

A. Study Goals and Hypotheses

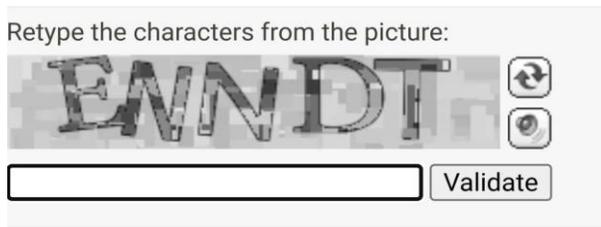
The primary goal of the proposed IRemember CAPTCHA method is to improve memorability as well as maximize the success rate. The main goal of the user study is to analyze the usability and memorability of the proposed method. In particular, we compared our proposed method with the traditional audio CAPTCHA method taken from [25]. The audio CAPTCHA method is an alternative to text-based CAPTCHA, where it speaks out the given digits, and the users are required to memorize it and type it using the keyboard on the answering box (see Fig. 2).


Fig. 2. Common Audio CAPTCHA Method.

The user study hypotheses are:

1) Completing time: The IRemember CAPTCHA can be solved faster than the traditional CAPTCHA due to the easiness of remembering the given challenges and the few numbers of digits that need to bed entered. The IRemember CAPTCHA removes the need to repeat the CAPTCHA challenges several times to memorize the digits limitations of the touchscreen entry method, including locating the location of keys on a touchscreen keyboard.

2) Success rate: The IRemember CAPTCHA will be solved correctly more than the traditional audio CAPTCHA due to the memorability of the given challenges.

3) Workload: The IRemember CAPTCHA will require less workload to complete solving the challenge than the traditional audio CAPTCHA.

B. Participants

To evaluate the proposed CAPTCHA and audio CAPTCHA, eleven participants (six female and five male) were recruited from the Taibh University Accessibility Center and from the Center for Disabled People at Taibh. Participants' ages ranged from 18 to 33 years old and participated in the study voluntarily. All participants were completely blind, have experience using touch screen devices with the support of a screen reader, and were proficient in the English language.

C. Procedure

The study aimed to examine the usability and memorability of two CAPTCHA methods, including IRemember CAPTCHA and the traditional audio CAPTCHA. At the beginning of the experiment, researchers explained the study goals and tasks and described the functionality of both examined CAPTCHAs. They also introduced an overview of the study requirements and study steps and answered participants' queries and provided a clear overview of the study procedures and requirements. After answering participants' questions, they signed a consent form that disclosed that their interaction with the smartphone device while solving CAPTCHA challenges is recorded and their private information is protected. The study contains four main sessions, which are a demographic questionnaire, a training session, a test session, and a Workload Questionnaire.

1) A Demographic questionnaire: To have a clear overview of user experience and performance when using the proposed CAPTCHA method, we collected participants' demographic data, including age, gender, vision level, and touchscreen experience, and English language proficiency.

2) Training session: After collecting participants' demographic data, researchers trained participants on how to solve challenges in both CAPTCHA methods. They were also encouraged to explore both methods and use them for five minutes to ensure they were familiar with the CAPTCHA methods' interfaces. The data from the training session were not included in the study results.

3) Test session: Participants were required to answer 10 CAPTCHA challenges without any assistance or without using other tools to help them record the response to a CAPTCHA question. To avoid order effect, CAPTCHA methods were randomly presented with a 2*2 Latin Square. Challenges for each CAPTCHA method were presented randomly. After listening to a CAPTCHA challenge, participants were requested to speak out the CAPTCHA answer before typing it in order to determine the causes of error when solving a CAPTCHA challenge, whether due to the input method or the difficulty of recalling the given digits. Then, they can type their response. At the end of the test session, participants were required to answer the questionnaires orally.

4) Questionnaires: To measure workload perception [26] for CAPTCHA methods, participants completed the workload questionnaire (NASA TLX) at the end of the study (see Table II). Participants were also asked to identify the strengths and limitations of CAPTCHA methods and recommend any improvements for the memorability aspect. This session took five to ten minutes.

5) Apparatus: We developed a prototype of IRememeber CAPTCHA method on an Android device called Galaxy Nexus phone that has a 4.65-inch-long screen. In the experiment, we asked participants to use the prototype on a portrait mode when solving challenges. In addition, participants were screen recorded when solving CAPTCHA challenges to track the method performance and participants' behavior when interacting with the device. At the end of the experiment, participants were audio recorded to report their answers to the questionnaires.

D. Usability Measurements

Success rate, completing time and the subjective NASA TLX were measured to evaluate the usability and memorability of both CAPTCHA methods.

1) Success rate: The effectiveness (success rate) of the IReamamber CAPTCHA and audio CAPTCHA were evaluated by calculating the challenge completion rate and the number of errors. The total number of challenges completed successfully were divided by the total number of challenges to calculate the CAPTCHA success rate (see Eq. 1).

$$Success\ Rate = \frac{Challenges\ completion\ Successfully}{Total\ number\ of\ Challenges} \qquad (1)$$

2) Completing time: In order to determine the average solving time taken to solve CAPTCHA challenge for each participant, each CAPTCHA challenge was tracked from the start time (the time when Run button was pressed) and and the

completing time (the time when Submit button was pressed). The difference between the completing time and start time determine the solving time, which involves the time spent listening to the challenge and the time spent typing a response.

3) Subjective measure: The Workload NASA TLX questionnaire was used at the end of the study, it contains six factors which are mental demand, physical demand, temporal demand, performance, effort, and frustration (see Table II).

4) Memorability measure: To determine whether participants remember the CAPTCHA content, we asked them to speak out the answer before typing it. In the IRemember CAPTCHA, users cannot repeat listening to the challenge, but in the audio CAPTCHA method, users can repeat several times and then they can speak out their responses.

V. RESULT

The aim of the conducted user study is to evaluate the usability and memorability of the proposed CAPTCHA IRemember. The success rate, speed, user satisfaction, and memorability were computed and discussed in detail in this section.

A. Success Rate

Fig. 3 shows the average success rate of each participant for each CAPTCHA method. The average success rate of the IRemember CAPTCHA method is 81%. Whereas the average success rate for audio CAPTCHA is 48% (see Table I). The results indicate that the success rate for IRemember CAPTCHA is higher and more efficient than the traditional audio CAPTCHA. The results also disclosed that users tend to make more typing errors when using the traditional audio CAPTCHA. Fig. 3 also shows that all participants perform better when solving CAPTCHA challenges using the IRemember CAPTCHA method, which may contribute to the easier recalling of a common phrase than random digits.

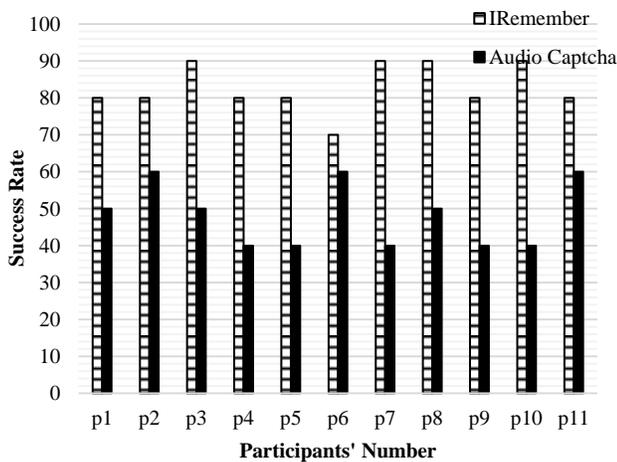
One way ANOVA value shows a significant difference between IRemember and the traditional audio CAPTCHA $(F(1, 21) = 78.47; p < 0.000476)$. The t-test value indicates a significant difference between the success rate for IRemember and the traditional audio CAPTCHA $(p= 0.000476)$.


Fig. 3. Average Success Rates for IRemember and Audio CAPTCHA.

TABLE I.   SUMMARY OF THE RESULTS OF BOTH CAPTCHA METHODS FOR VISUALLY IMPAIRED USERS

Methods	Average success rate (standard)	Average solving time (standard)
Audio CAPTCHA (6 digits)	48.18% (8.73)	138.75 s
IRemember CAPTCHA	82.72% (19.20)	54.96 s

B. Completing Time

Fig. 4 shows the average completing time each participant spent on solving IRemember and Audio CAPTCHAs. 54.36 seconds is the average time participants spent Completing IRemember CAPTCHA, and 137.5 seconds for the traditional audio CAPTCHA. The results reveal that all participants spent more time completing the traditional audio CAPTCHA method than IRemember method. That may be due to the need to listen to the CAPTCHA challenge several times to memorize it, unlike the IRemember CAPTCHA, which can recognize the phrase immediately and do not need to listen to it again.

One way ANOVA value shows a significant difference between IRemember and the traditional audio CAPTCHA $(F(1, 21) = 384.13; p < 0.000261)$. The t-test value indicates a significant difference between the success rate for IRemember and the traditional audio CAPTCHA $(p= 0.000261)$.

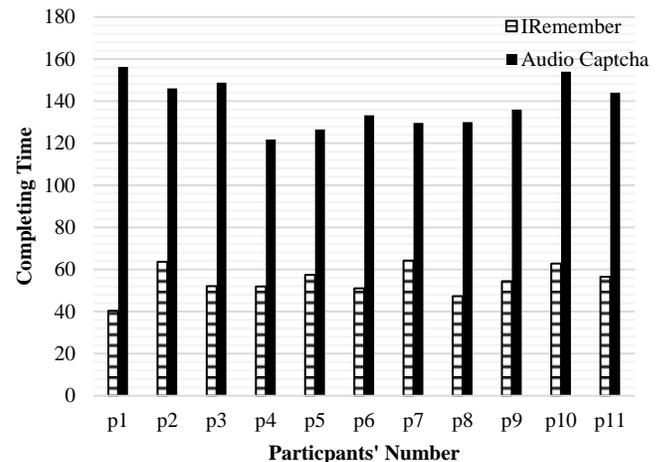
Solving the traditional audio CAPTCHA method requires more time to solve than the IRemember CAPTCHA. This may be due to playing the audio challenges several times to memorize the random digits in the correct order. Unlike IRemember CAPTCHA, the participant recognizes the answer once they hear the common phrase, which eliminates the repetition needs.


Fig. 4. The Average Time each Participant Spent on Solving IRemember and Audio CAPTCHAs.

C. Memorability Response

The difficulty of remembering the CAPTCHA digits of the traditional audio CAPTCHA was the main cause of error and confusion. Solving CAPTCHA requires memorization of the challenged content. Thus, the primary goal of designing the

IRemember CAPTCHA is to enhance remembering the CAPTCHA responses. So, we asked participants to listen to the CAPTCHA challenges and speak out the response before typing it to figure out the cause of the error, whether it is related to recalling the CAPTCHA response or it is related to the use of the input method.

The result shows that most participants were able to remember the response for the IRememeber CAPTCHA correctly (95%). The reason that caused an error at the stage of speaking the answer out was ignoring the preposition word that is in the provided phrase, for example, the phrase "I waited for a while." Most participants ignored the word "for" and only type "Iwaw". However, the main cause of error for the proposed method was the use of the input method that might lead them to double tap a letter which caused entering the letter twice. As a result, the success rate drops to 84% because the input method is not accessible and error-prone [17].

Regarding the traditional audio CAPTCHA, most participants could not remember the given random digits in the correct order, and sometimes they forgot a digit. Additionally, the other causes of error are that when they type their answer, they also make typing errors using the keyboard as they get confused when they listen to the screen reader and recalling what they should type, they got interfered and confused unlike on the proposed method they can just recall the phrase and determine the letter they should type.

D. Workload (NASA TLX) Questionnaire

The workload questionnaire contains six indicators that are applied to measure mental demand, physical demand, temporal demand, performance, effort, and frustration (see Table II). There is a significant difference based on all six aspects for both CAPTCHA methods. The average score of the mental demand indicator is 33.57 for IRemember CAPTCHA and 87.43 for the audio CAPTCHA method, and it shows the largest significant difference between the IRemember CAPTCHA and the audio CAPTCHA ($F_{(1, 21)} = 262.877$, $p < 0.000159$). Because participants need to memorize the random six digits in the correct order, they must listen to the screen reader when it reads the letter under the user's fingers. The Temporal demand is the second highest significant difference between the IRemember CAPTCHA and the audio CAPTCHA ($F_{(1, 21)} = 302.46$, $p < 0.000708$). The average score of the temporal demand indicator is 33.57 for IRemember CAPTCHA and 84.28 for the audio CAPTCHA method. It means there is high time pressure when solving the audio CAPTCHA. The third highest significant difference between the tested CAPTCHA is the frustration indicator; ANOVA result shows that ($F_{(1, 21)} = 84.309$, $p < 0.000893$). Participants reported a frustration rate of 33.57 for IRemember CAPTCHA and 80.71 for audio CAPTCHA. It means participants feel frustrated when solving the traditional audio CAPTCHA. The fourth highest significant difference between tested CAPTCHA is in the effort indicator ($F_{(1, 21)} = 136.7088$, $p < 0.000645$), where the average score of the effort indicator is 42.85 for IRemember CAPTCHA and 85.71 for the audio CAPTCHA method. It means that participants need to accomplish all tasks at one time, such as listening, memorizing the giving challenge, locating the answer box,

locating letters on the keyboard, and locating submitting button. There was also a statistically significant difference between IRemember CAPTCHA and audio CAPTCHA in terms of performance indicators ($F_{(1, 21)} = 132.923$, $p < 0.000754$). The performance score (80) shows that participants were not satisfied with the performance for audio CAPTCHA. Physical demand was also an essential indicator of workload, and the test showed a significant difference between the Physical demand of IRemember CAPTCHA and audio CAPTCHA ($F_{(1, 21)} = 45.375$, $p < 0.000208$). In general, the t.test values reveal a statistically significant difference between IRemember CAPTCHA and audio CAPTCHA in the six indicators of NASA TLX workload (p=0.000760).

Overall, the interpretation of all six indicators is very high for the traditional audio CAPTCHA, where each indicator receives a very high score, which means users are not satisfied with the audio CAPTCHA. On the other hand, the IRemember CAPTCHA receive a score between 30 and 50 which is interpreted as somewhat high, and users might face some usability issue as well when solving the CAPTCHA.

TABLE II.   AVERAGE NASA TLX SCORES FOR IREMEMBER CAPTCHA AND AUDIO CAPTCHA

TLX aspect	IRemember CAPTCHA	Audio CAPTCHA	T-test
Mental demand	33.5714286	87.4285714	0.00029
Physical demand	52.8571429	84.2857143	0.00170
Temporal demand	33.5714286	84.2857143	0.000377
Performance	45.7142857	80	0.000877
Effort	42.8571429	85.7142857	0.000211
Frustration	33.5714286	80.7142857	0.000596
Average of workload	40.3571429	83.7380952	
Interpretation of score	Somewhat high	Very high	

E. Strengths

The fundamental strength of IRemember CAPTCHA is that it is easy to remember and recall the CAPTCHA challenge response as it provides common phrases that users can easily recall what they just heard, whereas the traditional audio CAPTCHA requires users to remember the six digits as well as the sequence of the digits to pass the CAPTCHA challenge. Another strength of the proposed CAPTCHA is that it reduces the need to locate the repeat button to repeat listening to the CAPTCHA several times. It eliminates the need to repeat the CAPTCHA challenges several times to memorize the digits in the correct order. Users hear the CAPTCHA challenge once and begin typing the response based on memorization. It also removes the need for extra movements like locating the playing button or the response box; users need to interact with the screen to respond to the given challenge. In the proposed CAPTCHA, the cursor is directed at the response box to allow users to type their answers straightforwardly without a requirement to locate the response box.

It also provides a universal design as its interface offers both audio and visual interfaces for sighted people with no

vision. The most important point that makes IRemember CAPTCHA accessible for people with no or low vision is that it overcomes the limitation of memorizing the CAPTCHA content and eliminates the need to locate the position of the play button or the update button. These points improve the efficiency of the proposed CAPTCHA where it enhances the success rate because users can easily remember the answer to CAPTCHA questions in the correct order, as well as reducing the time spent responding to a challenge and minimizing the needed efforts to type the response where users can type three or four digits that are extracted from a given phrase. It also minimizes accidentally pressing an unwanted button, which leads to an error and much extra effort. The IRemember CAPTCHA is also easy to learn, and all participants were able to learn how to accomplish its task from the first trial.

F. Limitations

The main limitation of the proposed CAPTCHA and audio CAPTCHA was that the CAPTCHA challenges and questions were provided in English. Non-native speakers might require more time to memorize the given phrases. Thus, they will spend more time responding to the given challenge. To overcome this limitation, the challenges should be introduced based on the user's native language, preferences, and culture to enhance the user experience. Another drawback associated with the traditional audio CAPTCHA is requiring users to memorize the given challenges in order, which is a difficult task for users with no vision as they cannot see the challenge while typing; they need to depend completely on their memory.

G. Suggestions

At the end of the study, participants suggested multiple recommendations to improve the memorability and usability of IRemember CAPTCHA. They recommended allowing users to customize CAPTCHA challenges based on users' suggestions, personalities, culture, language, and region. Doing so, it can make the CAPTCHA challenge easier to remember. Another critical suggestion was to eliminate the need to type the first character from a preposition word and it is short, and it is the main cause of error in the IRemember CAPTCHA. Finally, they suggested integrating the proposed CAPTCHA into different platforms.

VI. DISCUSSION

The IRemember CAPTCHA method outperformed the traditional audio CAPTCHA method. The success rate for the IRemember CAPTCHA method was higher than the traditional audio CAPTCHA. 82.72% was the success rate for the IRemember CAPTCHA, and it was 48.18% for the traditional method. The solving time was lower for the IRemember CAPTCHA, as well as it required less workload when solving its challenges. 55 seconds users spent to solve the IRemember challenge, and they spent 138.75 seconds solving the traditional audio CAPTCHA. According to prior research, the success rate of the traditional audio CAPTCHA is 46% and the completing time to solve the challenge is 65.64s [27, 28]. These findings show that the IRemember CAPTCHA achieved high performance in terms of success rate and solving time. Overall, the IRemember CAPTCHA achieved high performance in terms of success rate and

solving time. Overall, the IRemember CAPTCHA approach is useable and accessible for visually impaired people, making it suitable for implementation as a real-world CAPTCHA in an application.

According to the NASA TLX scale, the IRemember CAPTCHA method requires fewer mental and physical temporal demands than the traditional audio CAPTCHA. The IRemember CAPTCHA requires users to recall the phrase and type the first letter of each word in the phrase. This task is simple and does not cause cognitive overload and memorization efforts. Thus, all users were able to recall the answer once they heard the given phrase. Unlike traditional audio, CAPTCHA requires users to remember six random digits in the correct order; these steps increase cognitive load as well as physical, temporal, and mental demand. Usually, visually impaired users tend to repeat listing to the given challenge trying to memorize the random digits. Thus, it causes a high level of effort, is demanding and is time-consuming [29, 30]. Therefore, the traditional audio CAPTCHA leads to high frustration once the users are required to repeat until memorize the digits as well as locate the repeat button and then the answer box, which needs more effort and mental demand. Whereas the IRemember CAPTCHA is less frustrating and requires less physical and mental effort than the traditional audio CAPTCHA. It eliminates the causes of confusion and the need to memorize the random CAPTCHA digits by allowing users to hear the common phrase and then recognize the intended character.

Findings show that most existing CAPTCHA requires intensive mental and recalling efforts to remember all digits. Unlike the IRemember CAPTCHA method requires less workload efforts [4-16].

Regarding the security of the proposed method, as the study result shows, IRemember CAPTCHA has the same level of security as the traditional audio CAPTCHA. In addition, IRemember CAPTCHA questions are easy to recall by humans and take only a few seconds to listen to the provided phrase and begin typing the answer [31, 32]. However, software bots find it complicated and time-consuming to solve these questions as the software must be able to determine the first character of each word in the phrase and extract the background noise from the CAPTCHA challenge [33].

VII. CONCLUSION

This paper discusses the implementation and evaluation of a novel audio CAPTCHA method called IRemember CAPTCHA. The IRemember CAPTCHA uses various approaches to build an accessible CAPTCHA for an extensive range of users. The proposed method applies a recognition-based CAPTCHA where the user is asked to listen carefully to the given phrase and determine the first letter of each word from the spoken phrase. Then, users are required to type or record the determined first letters. In addition, users can use swiping gestures to repeat the challenge or submit the response. The result of the evaluation study shows that visually impaired users find the IRemember CAPTCHA easy to learn and solve. However, the most important outcome was that the CAPTCHA was easy to remember for users.

In the experiments, the designed CAPTCHA has demonstrated a higher memorability and recall over the traditional audio method. Through experimental analysis, recording the response for the CAPTCHA method is considered a more effective technique than other input mechanisms like typing or gestures in CAPTCHA design. Moreover, the success rate was high, and the error rate was low. The IRemember CAPTCHA challenges take a different amount of time-based on the length of the phrase and the user's ability to type the response and repeat the challenge. The researchers indicated that the IRemember CAPTCHA is a valuable alternative method as it is a memorable and usable mechanism for people with limited abilities.

In the future, there is a need to improve the CAPTCHA usability by allowing personalization and customization of the presented challenges that are most common and known to the end users and is provided in their own language. Further improvements would make CAPTCHA more accessible by taking into account the impact of culture and language to simplify the way of responding to the given challenges. We also need to integrate the proposed CAPTCHA into a website to ensure its effectiveness and efficiency with the existence of different tasks around the CAPTCHA mechanism.

The study's main limitation is that the sample number is few due to the difficulty of finding a large number of users from this kind of sample demographic of the participants used for the study. We recruited only blind users who have good English language. Thus, there is a need to verify the study results by conducting a longitudinal study with more individuals with no or low vision and sighted users as well to see the effectiveness of the proposed method for all users. Finally, conducting a similar study with users with other types of impairments like mental or mobility impairment.

Abstract—One of the most important topics in computational biology is protein secondary structure prediction. Primary, secondary, tertiary, and quaternary structure are the four levels of complexity that can be used to characterize the entire structure of a protein that are totally ordered by the amino acid sequences. The polypeptide backbone of a protein's local configuration is referred to as a secondary structure. In this paper, three prediction algorithms have been proposed which will predict the protein secondary structure based on machine learning. These prediction methods have been improved by the model structure of convolutional neural networks (CNN). The Rectified Linear Units (ReLU) has been used as the activation function. The 2D CNN has been trained with machine learning algorithms, including Support Vector Machine, Naive Bays and Random Forest. The SVM is used to correctly classify the unseen data. Naïve Bays (NB) and Random Forest (RF) are also applied to solve the prediction problems for not only classification problems but also regression problems. The 2D CNN, hybrid of 2D CNN -SVM, CNN-RF and CNN-NB have been proposed in this experiment. These different methods are implemented with the RS126, 25PDB and CB513 dataset. Further, all prediction Q3 accuracy is compared and improved with their datasets.

Keywords—Protein Secondary Structure Prediction (PSSP); Support Vector Machine (SVM); Naive Bays (NB); Random Forest (RF); Convolutional Neural network (CNN)

I. INTRODUCTION

Proteins are the building blocks of amino acid sequences [1] [2]. Generally, there are four types of protein structure's which are primary, secondary, tertiary, and quadratic structure. Secondary structure are the building blocks of the macromolecule structure [1]. Secondary structures can be divided into two categories- the regular and the irregular secondary structures. The regular secondary structure has two types, including α -helices (H) and β-sheet (E) and the irregular secondary structure has more types, including tight

turns, Random coils, Bulges, etc. By using only their basic structure, the PSSP method is a series of bioinformatics technique aimed at predicting the secondary structure of protein sequences or residues[2] [3]. In molecular biology, the most essential and crucial problems are the prediction of the protein secondary structures using machine learning approaches [3]. This proposed work aims to predict the protein secondary structures and come up with a highly accurate solution that would be easily solved by computational biology. The purpose of PSSP is also to categorize the pattern of residues in amino acid sequences as a-helix, B-strand, or coil. To discover the secondary structure of proteins, the researchers must examine hydrogen bonding patterns and geometric limitations, as well as employ the DSSP tool [4]. The prediction of PSSP is done using a variety of machine learning and deep learning techniques[5] [6].

Researchers used a variety of strategies to predict the protein secondary structures in the early years [5][7][8]. Furthermore, compared to the prior years, the prediction accuracy has been improved in this paper. The understanding of protein folding mechanisms are frequently regarded as a crucial objective that will help structural biologists unravel the puzzling connection among the protein sequence, structure, and function. The scientific work will be aided by the ability to estimate protein folding speeds without the requirement for actual experimental study. In this study, the secondary structure prediction is merely enhanced, as it would be challenging to predict the tertiary structure of proteins in the absence of homology.

Convolutional neural network is a form of artificial neural network that is generally used in deep learning for image processing [1][2]. The hidden units of the CNN are frequently the same dimensions or size as the processed data [1]. The data is convolved by the hidden units, which then stored the information from the data. Each hidden unit's information will

*Corresponding Author.

be recorded as a feature map [1] [7]. The number of feature maps that produced equal to the number of hidden units are employed. After that, the pooling stage is performed on the existing feature maps, collecting dense information from them [1][9].

Support vector machine is a machine learning algorithm based on a supervised technique that has been used for different types of classification problems [1]. If a model of SVM is given that the sets of labeled schooling data for each section, it will be enabled to classify the new data. It has been used to analyze the data for not only classification problems but also regression problems. It has also been used to categorize the unlabeled data. The main aim of this is to search hyperplane that can be utilized as a decision surface to close the gap between two classes [1] [10].

Naïve bays is also a supervised machine learning model based on Bays Theorem [3]. Typically, this is a classification technique that predicted with an estimation of independence. Naïve bays model is easy to create and especially applicable to solve the classification problems and huge complex data sets. For that, it can make as a fast prediction [11].

Popular machine learning algorithm, random forest belongs to the supervised approach. This type of algorithm is also applied for both classification as well as regression problems. In RF, each individual tree has been spread as a class prediction and the most voted class can be estimated for prediction and it predicts the final output. It improves the prediction accuracy [12].

In this paper, a prediction method has been represented for the secondary structure of proteins based on CNN and machine learning techniques. In addition, this paper is exploded into six sections. The Section II discusses about the related works. The Section III represents the preliminaries for the proposed models. The Section IV introduces and describes the proposed techniques smoothly. The Section V shows the simulation results. Finally, conclusion is presented in Section VI.

II. RELATED WORK

Vincent Michael Sutanto et al. [1] introduced a hybrid 1-D CNN and SVM for the prediction of protein secondary structures. They fine-tuned CNN and then changed it, therefore, instead of giving an orthogonal label as output, model feature map production. By doing this step, they projected the data into higher levels. They aimed to absorb high dimensional space of SVM as classifier. The modified CNN model created the 3-D array properties as an output and therefore, a conversion must be applied. The modified CNN models used feature maps for the training of SVM models.

Shangxin Xie et al. [10] introduced a new algorithm formed on the increased fuzzy support vector machine (FSVM) for the prediction of secondary structure of proteins. They applied the different classification rules for the prediction. They used this model to improve the fuzzy membership value and prediction accuracy. They implemented this model to derive the approximate optimal division hyperplane in the feature space.

Masood Zamani et al. [13] proposed the evolutionary-based computation method of protein secondary structure classifiers. They evaluated the performance prediction by using the amino acid sequence with the help of the clustering technique. K-means clustering technique is applied to reduce the dimension of the classifier's inputs on sequence component. They also presented PSS classifier stand on genetic programming technique. They evaluated this approach to improve the performance prediction.

Pooja Jain et al. [14] explored the structural classification of protein with the help of supervised learning technique. Firstly, they chose domains for learning the structure classification. This technique considered two types of domains, known and unknown structural classification. They assigned known domains into unknown domains for classification of protein.

Ying Xu et al. [15] proposed a prediction method of secondary structure based on convolutional neural network (CNN) and random forest. After each convolutional layer, Rectified Linear Units (ReLU) activation layer was used to solve the gradient disappearance problems. They used deep CNN to extract the protein features from amino acid sequence. Here, the fully connected layer and SoftMax layer were used to predict the three types of secondary structure (C, H, E).

III. PRELIMINARIES

A. Protein

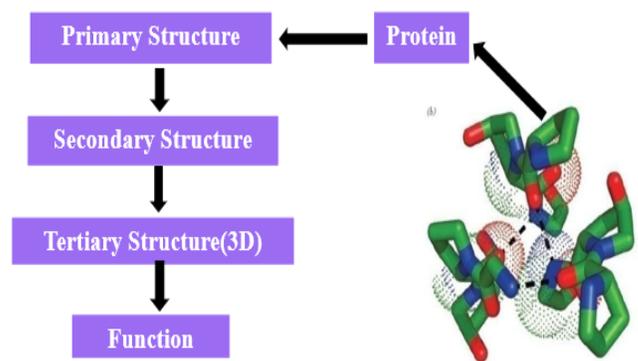
The three-dimensional arrangement of atoms in an amino acid-chain molecule is known as protein structure [16] [17]. Proteins are polymers – especially polypeptides – made up of amino acid sequences, which are the polymer of monomers [16]. Proteins are involved in a wide range of biological processes from accelerating chemical reactions to construct the architecture of all living things [18]. Despite their diverse activities, all proteins are built up of the same twenty amino acid building blocks. The folding of the protein into its unique final form and function is determined by how these twenty amino acids are organized [8][19][20].


Fig. 1. Protein Structure.

Fig. 1 shows the structure of protein and its function.

B. Primary Structure

The sequence of amino acids in a polypeptide chain is known as primary structure [18]. The primary structure of a

protein is described the starting from the amino-terminal (N) end to the carboxyl-terminal (C) end. Ribosomes are the most frequent organelles in cells that perform protein production [21]. Peptides can also be manufactured in the lab. Primary structures of proteins can be sequenced directly or deduced from DNA sequences [18] [20].

C. Secondary Structure

The pattern of hydrogen bonds between the amino hydrogen and carboxyl oxygen atoms in the peptide backbone is technically characterized as a secondary structure [17] [18]. The hydrophobic side chains are those facing inward. A third of every amino acid has hydrophobic properties [17]. There are hydrogen bonds between the two distinct zones (carbonyl & amino groups). Beta sheets are made up of 5–10 amino acids in each region.

Secondary structure, the next level of protein structure, refers to the local folded structures formed inside a polypeptide as a result of interactions between backbone atoms [22]. (It does not involve R group atoms; the backbone only refers to the polypeptide chain away from the R groups.) Helixes and pleated sheets are the two most common types of secondary structures [18][21][23].

D. Tertiary Structure

The term "tertiary structure" refers to the overall three-dimensional structure of a polypeptide. There are various types of polypeptide chains in it. It interacts with R-groups. Polar R-groups are capable of forming hydrogen bonds. Dipole-dipole interactions and hydrophobic interactions play key roles in the three-dimensional structure [8].

E. Convolutional Neural Network (CNN)

The most popular kind of neural network is the convolutional neural network which is used to solve the image processing problems [1]. CNN is divided into two sections: the hidden layers, also known as the feature extraction section, and the classification section. A series of convolutions and pooling operations are carried out by the hidden layers [7]. To create a map, convolution is applied to the input data using a filter or kernel [7][21].The classification parts assign a probability for the object on the image being what the algorithm is predicted. Multilayer perceptron is regularized variants of CNNs. Normally, these networks are fully connected, which means that every neuron in one layer is connected to every neuron in the layer below. It is susceptible to data overfitting because of the network's "full connectivity." By utilizing the hierarchical structure in the data and assembling patterns of increasing complexity using smaller and simpler patterns imprinted in their filters, CNNs develop a new method of regularization [20]. The bottom end of the connectivity and complexity spectrum is where CNNs fall due to this.

Fig. 2 shows the architecture of CNN, including with three input layers, hidden layer section 1 and section 2 (both containing 4 layers) and finally output layer.

F. Convolutional Layer

It is the principal components of CNN. It has a collection of filters or kernels, which are parameters that must be learned

during training. The convolution 2D layer was employed in this investigation. The size of the filters is typically smaller than the size of the image. An activation map is created when each filter is applied to an image. This has the advantage of reducing parameter usage and allowing the convolution kernel to extract features more effectively. The preprocessed protein data with a size of (13, 20) is used as the input data. To obtain the output, the convolution kernel of 3×3 is twisted in steps of 1 from left to right, from top to bottom, from the upper left corner of the data with the input size of (13, 20). If padding is not used, the output size is $(13 - 3 + 1)/ (20 - 3 + 1)$ [7]. The number of parameters is minimized by the CNN feature and considerably the training speed has been enhanced through it. The data is convolved in the same way by 128 convolution kernels, and each convolution kernel extracts features automatically. Different convolution kernels extract picture edge information, shading information, contours, and other image features automatically in the image domain. The model can extract 128 features automatically in theory. Supposing that the convolution kernel's width is ck and the height is dk. The 2D convolutional equation is:

$$m_{i,j} = \begin{bmatrix} n_{i,j} & n_{i+1,j} & \cdots & n_{i+ck,j} \\ n_{i,j+1} & n_{i+1,j+1} & \cdots & n_{i+ck,j+1} \\ n_{i,j+ck} & n_{i+1,j+dk} & \cdots & n_{i+ck,j+dk} \end{bmatrix} \text{[7][15]} \qquad (1)$$

The ReLU is used as the activation function within the model. The ReLU function has the following expression:

$$F(y) = \max (0, y) \text{ [7]} \qquad (2)$$

G. SoftMax Layer

It is mostly used in artificial neural network as the activation function in the output layer. This is used as classification problems where more than two class labels require class membership [9]. The SoftMax layer has been also used in proposed model as the activation function [7].

H. MaxPooling Layer

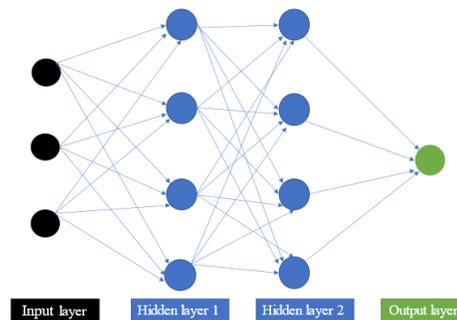
It is a procedure for retrieving features from the convolutional layer that reduces their dimensionality [18]. It offers the advantage of reducing the size of the featured image while maintaining the number of feature maps, allowing for data processing after the convolutional layer is output. Simultaneously, significant feature information is stored, reducing the model's computation complexity and increasing calculation speed. Median and average pooling are two other pooling algorithms. The kernel size of MaxPooling layer is 2×2 [9].


Fig. 2. Convolutional Neural Network.

I. Flatten Layer

It is frequently used to convert multidimensional information into one-dimensional input during the transition from the convolution layer to the fully linked layer. Flattening is the process of converting data into a one-dimensional array for use in the layer below. We flatten the convolutional layer output to create a single, extensive feature vector. The final classification model, sometimes referred to as a fully-connected layer, is connected to it [3].

TABLE I.   POOLED FEATURE MAP AND FLATTENING STEPS

1	1	0	Flattening	1

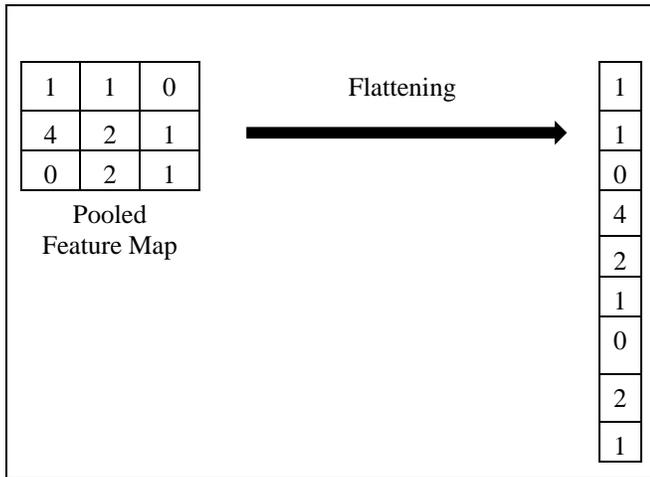
				1
				0
				2
				1


Table I shows that the pooled feature map and flattening steps. The flattening process is used to make a single feature vector and get the next layer.

J. Support Vector Machine (SVM)

It is a type of supervised learning model that analyzes and linearizes data for classification as well as regression in machine learning [18]. SVM algorithm classifies data that is linearly divisible. If it is not linearly divisible, we have to follow the kernel strategy to build decision [24]. This decision program is called support vector. Support Vector uses a subset of training points that makes it efficient in memory [25]. Support vector machine works in following steps:

- Firstly, we have to import the dataset.
- Need to analyze the data.
- Then we have to preprocess the data.
- Split up the dataset.
- Sort out the dataset into training and testing sections.
- Train and test the support vector machine algorithm.
- Build some predictions.
- Finally, compute the accuracy.

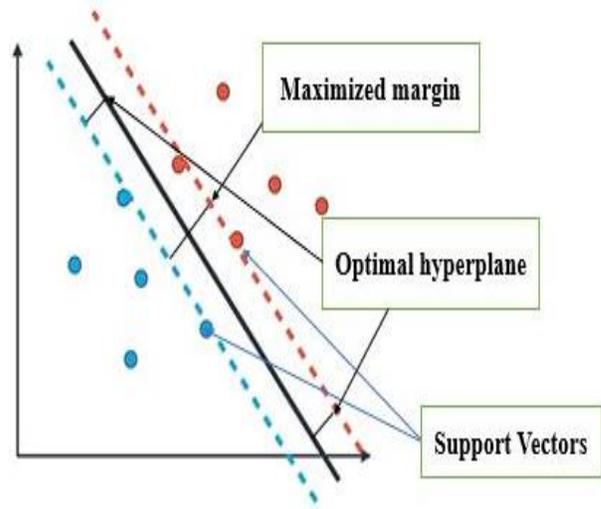
Fig. 3 shows the architecture of SVM. In this figure, a hyperplane with maximized margin is created which refers to the distance between the data points.


Fig. 3.   The Architecture of Support Vector Machine.

K. Naïve Bays (NB)

Naïve bays is a general machine learning strategy that is supervised using Bayes Theorem [3]. It is a statistical classification technique. The basic innocent way is to assume that each feature makes a distinct and equal one for which it is called a "naïve". This is a strong idea for genuine and unrealistic data. This type of conjecture is indicated as class conditional independence. Naïve Bays algorithm works in following steps such as:

Fig. 4 shows the naïve bays classifier. It is one kind of linear classifier. It's named "Naïve" because it assumes that the feature of datasets is mutually independent.

Naïve Bays algorithm works in following steps such as:

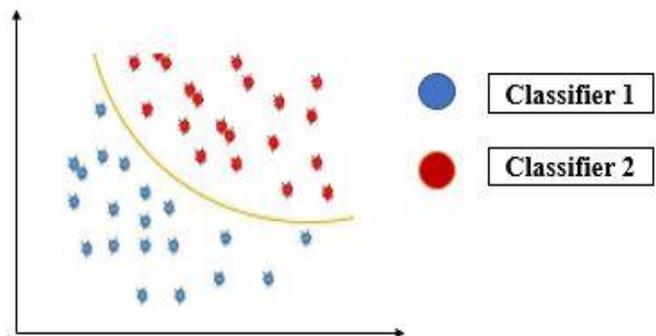
- Divide the class.
- Sum up the dataset.
- Again, sum up data according to class.
- Then calculate density function according to Gaussian Probability.
- Finally compute class probabilities.


Fig. 4.   The Architecture of Naïve Bays Classifier.

L. Random Forest (RF)

Generally, random forest is a simple, supervised learning technique. It is used for not only classification troubles but also regression troubles like support vector algorithm. It can be learned how to classify data randomly. It extracts several samples from the original sample using the bootstrap resampling approach that works by training a large number of decision trees [23]. The RF output is the class chosen by the majority of trees for the classification task [18].

The random forest algorithm can be explained in following steps:

- Import the dataset.

- Choose the random samples.

- Compute the vote for the predictive result. It can be used "Mode" for "Classification" troubles, and also can be used "Mean" for "Regression" troubles.

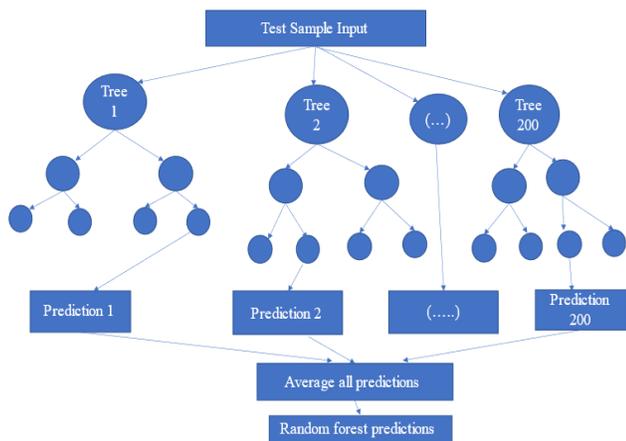
- Ultimately, choose the peak voted value for predictive result. And it is the most precious final prediction.


Fig. 5. The Architecture of Random Forest Classifiers.

Fig. 5 shows the random forest classifier. In this figure, the test sample input is tree root. Random forests generate decision trees from randomly chosen data samples, obtain predictions from each tree, then vote on the best option.

IV. PROPOSED METHOD

In this research, the PSSP method has been proposed based on CNN and machine learning algorithms. 2-D CNN and machine learning algorithms i.e., RF, SVM and NB have been used in this paper. Here, the Rectified Linear Unit (ReLU) has been used as an activation function in 2D-CNN. It has been used after each convolutional layer to solve the gradient disappearance problems. This paper used deep CNN to extract the protein features from the amino acid sequence. The fully connected layer, MaxPooling, flatten and SoftMax layer have been used to predict the three types of secondary structure (C, H, E). Further, the pooling function have been used in these layers. The 2D CNN has been combined and trained with SVM, RF, NB. Secondly, the datasets have been trained and tested with SVM, RF and NB. The 2D CNN, the hybrid of 2D

CNN-SVM, CNN-RF and CNN-NB have been implemented. Finally, the prediction accuracy has been calculated.

Fig. 6 shows the flow diagram of protein secondary structure prediction. Firstly, the input (amino acid sequence) has been processed. Secondly, the Con2D layer has been used. Here, the filter has been changed with the process. The softmax layer has been used as an activation function. Also, the maxpooling and other layers have been used in this process. Further, the 2D-CNN has been combined and trained algorithm such as SVM, RF and NB algorithm. Finally, the secondary structure sequence such as Helix (H), Strand (E) and Coil (C) have been predicted from the amino acid sequence.

Secondary structure prediction datasets.

1) RS126 dataset.
2) CB513 dataset.
3) 25PDB dataset.

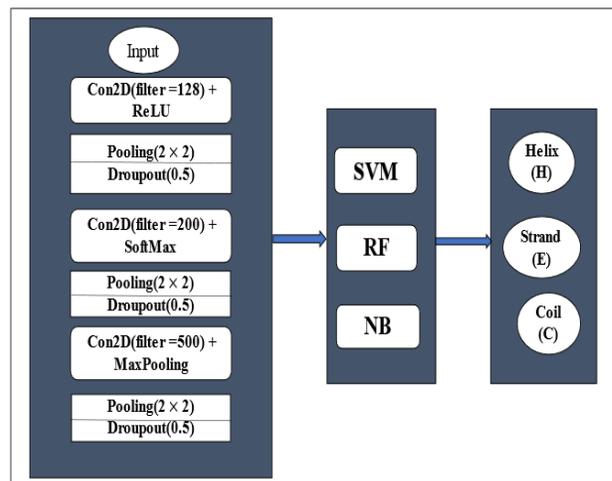
The first and best-known dataset for the PSSP is the RS126 dataset. Electric Sander as well as Rost came up with the concept [26]. It is one of the best non-homologous datasets for predicting the structure of protein [26]. This dataset is applied for the prediction of protein secondary structure. Its maximum carrying capacity is 23,347 residues, and its typical protein sequence length is 185. RS126 is composed of 47% random coil, 21% -sheet, and 32% -helices (H).[25] Furthermore, the CB513 and 25PDB datasets have also been used. The 2-D structure is predicted using the CB513 dataset. This is a crucial dataset that is excellent for enhancing algorithms and forecasting secondary structures. The CB513 dataset was created by Cuff and Barton and contained 513 sequences and 84,107 residues [24]. This kind of dataset is used in this study to enhance the performance of protein secondary structure prediction. One of the biggest datasets is this. Furthermore, it is utilized to classify data and fold the protein structure. Additionally, the 25PDB dataset was included. The PDB dataset's accuracy is better than some other types of datasets in each of the datasets. All protein datasets have been collected from Research Collaboratory for Structural Bioinformation (RCSB).


Fig. 6. The Flowchart of Proposed Model of Protein Secondary Structure Prediction.

TABLE II.   PROTEIN SECONDARY STRUCTURES OF 8 AND 3 CLASSES.[22]

8class symbols	8 class names	3class symbols	3class names
H	α-helix	H	Helix
L	Loop/Irregular	C	Coil/Loop
T	B-Turn	C	Coil/Loop
S	Bend	C	Coil/Loop
G	3_{10}-helix	H	Helix
B	B-bridge	E	Sheet
I	π-helix	H	Helix

Table II shows the protein secondary structure of eight and three classes. According to DSSP (Define Secondary Structure of Proteins), eight class secondary structures are converted to three class of secondary structures of proteins.[19].

Pseudocode 1: CNN [1]

Input: Amino acid sequence

Step 1: Sliding window process

Step 2: ESF ⟶ Extract Shadow Feature

Step 3: Normalize by the ESF

Step 4: Feature, data size 13*20

Step 5: Repeat

Step 6: Forward Propagation

CD ⟶ Convolution2D (ESF)

MP ⟶ MaxPooling 2D (CD)

FC ⟶ Fully Connected (MP)

Class label ⟶ SoftMax (FC)

Class label ⟶ Dense(D)

Class label ⟶ Flatten (F)

Step 7: Backward Propagation

Conduct backward propagation with Adam;

Step 8: Use the trained algorithm with SVM, RF and NB.

Pseudocode 2: SVM

Input: M and n filled with schooling labeled data, $\beta \Leftarrow 0$ or $\beta \Leftarrow$ partially trained support vector machine.

Step 1: P ⟸ some value (20 for example)

Step 2: repeat

Step 3: for all {m_i, n_i}, {m_j, n_j} do

Step 4: optimize β_i and β_j.

Step 5: End for

Step 6: until no changes in β or other element constraint criteria met.

Ensure: Just contain the support vectors ($\beta_i > 0$).

Output: Accuracy prediction.

Pseudocode 3: RF [12] [15]

Step 1: Randomly select the "K" attribute from the total "P" attributes. K < P

Step 2: Calculate the node "r" in the "K" properties by applying the largest partition points.

Step 3: Need to use the greatest split node for splitting the node into daughter mode.

Step 4: Steps are repeated 1 through 3 until the "F" number of node is reached.

Step 5: The forest is created by repeating steps 1 to 4 for "N" number times for to build "N" number of trees.

Pseudocode 4: NB [3]

Input: Training dataset D,

P= ($p_1, p_2, p_3 \ldots p_n$) // value of the predictor variable in testing dataset.

Output: A category of testing dataset.

Step 1: Firstly, read the training dataset D.

Step 2: Secondly, compute the mean deviation and standard deviation of the predictor variables in every group;

Step 3: Repeat. Compute the probability of p_i applying the gauss density equation in every group;

Until the probability of predictor variables ($p_1, p_2, p_3 \ldots \ldots, p_n$) has been computed.

Step 4: Compute the likelihood for every class or group;

Step 6: Finally, get the best likelihood.

V. RESULT ANALYSIS AND DISCUSSION

The Q3 approach was employed in this paper to assess the algorithm's effectiveness. Q3 is used to represent the number of residues and is computed by dividing the number of accurately predicted protein residues by the total number of residues in a known protein's secondary structure sequence.

$$Q_3 = \frac{Q_C + Q_H + Q_E}{Q} \qquad (3)$$

Where Q_C, Q_H and Q_E are the number of accurately predicted protein structural class of C, H and E. The total number of amino acids are denoted by Q [7].

$$Q_j = \frac{Q_k}{Q} \qquad (4)$$

Where,

Q_k represents the total number of amino acid residues. K ∈ {C, H, E}. [7].

Q_C, Q_H and Q_E are used to evaluate the experimental result in this research. The Eq. 4 can be used to calculate the values of Q_C, Q_H and Q_E.

Test sequence:

Original sequence:

Fig. 7.   Prediction from Original Sequence.

Fig. 7 shows the actual structure predicted from the predicted structure and predicted structure predicted from original primary sequence. [Test sequence collected from RS126 dataset].

Table III, IV, V shows the Q_C , Q_H , Q_E and Q_3 accuracy based on RS126, CB513 and PDB25 datasets.

Where Q_C , Q_H and Q_E are used to accurately predict the protein structural class of C, H and E. In these tables, CNN, CNN-SVM, CNN-RF and CNN-Bays methods have been used for the prediction of protein secondary structure. In Q_3 all prediction accuracy, the CNN-SVM method has been achieved the highest prediction accuracy. These achievements are 82.34%, 84.32%, 83.76% based on RS126, CB513 and 25PDB datasets.

Table VI and VII shows the comparison between the previous model and the proposed model. Here, 25PDB and CB513 datasets have been used for the protein secondary structure prediction. It is seen that the previous work of datasets based on the model of CNN-SVM, CNN-RF and CNN-Bays are not satisfactory. The proposed model has improved the performance of protein secondary structure prediction in Q3 accuracy. The CNN-RF, CNN-Bays, CNN and CNN-SVM have been achieved the highest Q3 accuracy of 81.73%, 79.35%, 80.57% and 84.32 based on 25PDB and CB513 datasets which are 2.34%, 2.45%, 1.48%, 2.83% higher than those datasets. It is seen that the proposed model has been achieved the highest prediction Q_3 accuracy than the previous model.

TABLE III.   THE ACCURACY OF RS126 DATASET

Method	Accuracy (%)			
	Q_C	Q_H	Q_E	Q_3
CNN	79.24	76.35	77.43	80.09
CNN-SVM	81.27	78.32	80.35	82.34
CNN-RF	79.76	75.03	78.45	80.24
CNN-Bays	78.20	73.23	75.76	79.27

TABLE IV.   THE ACCURACY OF CB513 DATASET

Method	Accuracy (%)			
	Q_C	Q_H	Q_E	Q_3
CNN	79.54	73.65	77.83	80.35
CNN-SVM	83.08	78.67	81.07	84.32
CNN-RF	78.80	74.09	76.53	79.24
CNN-NB	78.36	74.26	77.34	79.80

TABLE V.   TABLE V. THE ACCURACY OF 25PDB DATASET

Method	Accuracy (%)			
	Q_C	Q_H	Q_E	Q_3
CNN	80.32	74.30	76.04	80.57
CNN-SVM	82.37	75.31	81.09	83.76
CNN-RF	79.05	72.53	74.23	81.73
CNN-NB	77.45	70.63	73.83	79.35

TABLE VI.   THE PERFORMANCE COMPARISON RESULTS BETWEEN THE PREVIOUS AND PROPOSED MODEL

Dataset	Method	Q_3 Accuracy (%)	
		Previous prediction	Proposed prediction
CB513	CNN-SVM	81.49 [1]	84.32
	CNN-RF	-	79.24
	CNN-NB	-	79.80
	CNN	-	80.35

TABLE VII.   THE PERFORMANCE COMPARISON RESULTS BETWEEN THE PREVIOUS AND PROPOSED MODEL

Dataset	Method	Q_3 Accuracy (%)	
		Previous prediction	Proposed prediction
25PDB	CNN	79.09 [15]	80.57
	CNN-RF	79.39 [15]	81.73
	CNN-Bays	76.90 [3]	79.35
	CNN-SVM	-	83.76

VI.   CONCLUSION AND FUTURE WORK

The issue of protein structure prediction must be resolved in the realm of bioinformatics. The protein secondary structure has been utilized in this paper. To understand the protein sequence using CNN and machine learning algorithms was the initial step for solving the PSSP problem. In this work, three identical and separate datasets—25PDB, RS126, and CB513 are used in this study. These datasets are sufficient for solving the problems of prediction. The ReLU layer is used as the activation function (CNN). Further, MaxPooling, SoftMax, dense and flatten layer have been used. The CNN has been integrated with RF, SVM, and NB in this study. The proteins have been categorized using these techniques. These hybrid techniques have successfully overcome the gradient disappearance problems by retaining the significance of

original features data to the maximum extent possible. It is demonstrated that the proposed model has been enabled to capture the long-range interdependencies between the sequence residues. The proposed models reached in high accuracy. The CNN-SVM model has achieved the highest Q3 accuracy of 82.35%, 84.32% and 83.76% on the RS126, CB513 and 25PDB datasets than the previous work. Besides, CNN, CNN-RF and CNN-NB has achieved the highest prediction accuracy. The secondary structure of protein takes part in an important role in protein function and folding. It identifies the similar function where protein sequence varies (only ~50% remote homologies may be identified based on sequence). The proposed method can experimentally perform better than other previous work and this work could be easily understandable by researchers for solving the problem of protein secondary structure prediction. Further, it can help to explain the disease (the effect of mutations and design drugs). As a future scope of research, it would be possible to propose the three-dimensional protein structure prediction using deep learning algorithms.

A Mobility Management Algorithm in the Internet of Things (IoT) for Smart Objects based on Software-Defined Networking (SDN)

Lili Pei

Department of Architectural Engineering
Tangshan Polytechnic College
Tangshan, 063299, China

Abstract—In recent decades, technological advancements have significantly improved people's living standards and given rise to the rapid development of intelligent technologies. The Internet of Things (IoT) is one of the most important research topics worldwide. However, IoT is often comprised of unreliable wireless networks, with hundreds of mobile sensors interconnected. A traditional sensor network typically consists of fixed sensor nodes periodically transmitting data to a pre-determined router. Current applications, however, require sensing devices to be mobile between networks. We need mobility management protocols to manage these mobile nodes to provide uninterrupted service to users. The interactions between the mobile nodes are affected by the loss of signaling messages, increased latency, signaling costs, and energy consumption because of the characteristics of these networks, including constrained memory, processing power, and limited energy source. Hence, developing an algorithm for managing smart devices' mobility on the Internet is necessary. This study proposes an efficient and effective distributed mechanism to manage mobility in IoT devices. Using Software-Defined Networking (SDN) based on the CoAP protocol, the proposed method is intended not only to reduce the signaling cost of messages but also to make mobility management more reliable and simpler.

Keywords—Internet of things (IoT); mobility management; software-defined networking (SDN); CoAP protocol

I. INTRODUCTION

In recent years, Internet of Things (IoT) technology has been used in multiple areas, including health supervision, crisis management, and transportation management. IoT is an information network of physical objects (sensors, machines, devices, etc.) that facilitates communication and cooperation between these objects to reach a specific aim [1-3]. Each device within the IoT can identify, evaluate, and interact with the existing internet infrastructure using its embedded system. In other words, the IoT is a computational concept that can describe a future in which physical objects are connected using the internet and create a network of connections with other objects. In this technology, each entity on the internet is assigned a Unique Identifier (UI) and an Internet Protocol (IP) address through which it can send the data to the designated databases [4-6].

The Internet Engineering Task Force (IETF) has introduced various standards for the interactions between web services and a network of smart objects. For instance, Constrained Application Protocol (CoAP) is an application layer protocol modeled based on the Representational State Transfer (REST) software architectural style that facilitates the communication between the resource-constrained devices and web services within the IoT infrastructure. CoAP is a simple and modified version of the Hypertext Transfer Protocol (HTTP) designed in 2013. In CoAP, two messages are mainly used: Confirmable (CON) to signal secure connections and Non-Confirmable (NON) to signal regular connections. When receiving the CON message, the receiver sends an acknowledgment message to indicate that the message was received correctly. If the acknowledgment message is not received, the CON message is sent out again after a specific time. Therefore, this format provides the ability to resend messages which, in turn, creates an atmosphere of trust within the entire network. Fig. 1 demonstrates the CoAP retransmission mechanism. Chun et al. [7] introduced an algorithm for retransmission management based on the CoAP retransmission mechanism that incorporates the features and message formats of CoAP.

Software-Defined Networking (SDN) has three layers: the infrastructure layer (data plane), the control layer (control plane), and the application layer [8]. The infrastructure layer, also known as the data plane, consists of the packet delivery elements (routers and switches). The control layer is the logical architecture of the software that sets out the delivery codes for the elements within the infrastructure layer while managing the networking and routing tasks. Separating the data and control planes enables the network operator to control the network behavior from the top down. The application layer manages the applications within the network. Software-Defined Networking (SDN) introduces the technology of a centralized network controller that increases network scalability and flexibility by separating the control and data planes. Zhou and Zhang [9] introduce a host-based method that uses SDN technology to improve mobile IP and manage filtering and routing. The problem with this method is that it requires a hostname and IP address change. Furthermore, Raza et al. [10] introduced a network-based retransmission method that sets out an OpenFlow-based Proxy Mobile IPv6 (PMIPv6) protocol. This method separates the signaling control route from the communication data path. However, using Mobile Nodes (MN)

to send Router Solicitation (RS) messages and using the network to send Router Advertisement (RA) messages leads to significant delays within the system. Furthermore, this method uses an IP tunnel instead of an OpenFlow, which requires more network overhead. Chen et al. [11] introduced an SDN-based retransmission protocol that decreases the retransmission timeout. In this method, network switches occur in parallel and simultaneously with layer two switches. At the same time, active currents are delivered to all possible target channels. Network switch configuration takes place through an optimal track method.

Unfortunately, most IP-based standard Transmission Control Protocols (TCPs) are incompatible with IoT infrastructure [12, 13]. IoT structure consists of hundreds of interconnected mobile sensor nodes. Since these sensors have constrained memory, processing ability, computing ability, and energy resources, they introduce multiple challenges to the system that can impact delay-sensitive applications. On the other hand, most standard TCPs, such as Mobile IPv6 (MIPv6), have significant signaling overhead for tunneling and binding. That is why they impose a significant processing overhead on the network [14, 15]. Within the IoT ecosystem, mobile sensor

nodes should be able to deliver the analyzed data to the remote user periodically. As a result, IoT requires a new protocol to control transmission that can meet the various needs of the system based on mobile sensors' features while operating on a constrained energy and sleep mode. In this study, to come up with a solution for this problem, instead of using IP-based standard TCPs, CoAP and SDN-based TCPs are used since they introduce an effective transmission control mechanism for mobile sensor nodes while decreasing signaling costs.

To get a clear overview of the research, short descriptions of the structure of the research paper are summarized as follows:

- Section II: In this section, the details of the proposed solution for managing the mobile nodes of the resource-constrained in the IoT will be examined.

- Section III: This section will evaluate and compare the proposed solution with previous methods in this field.

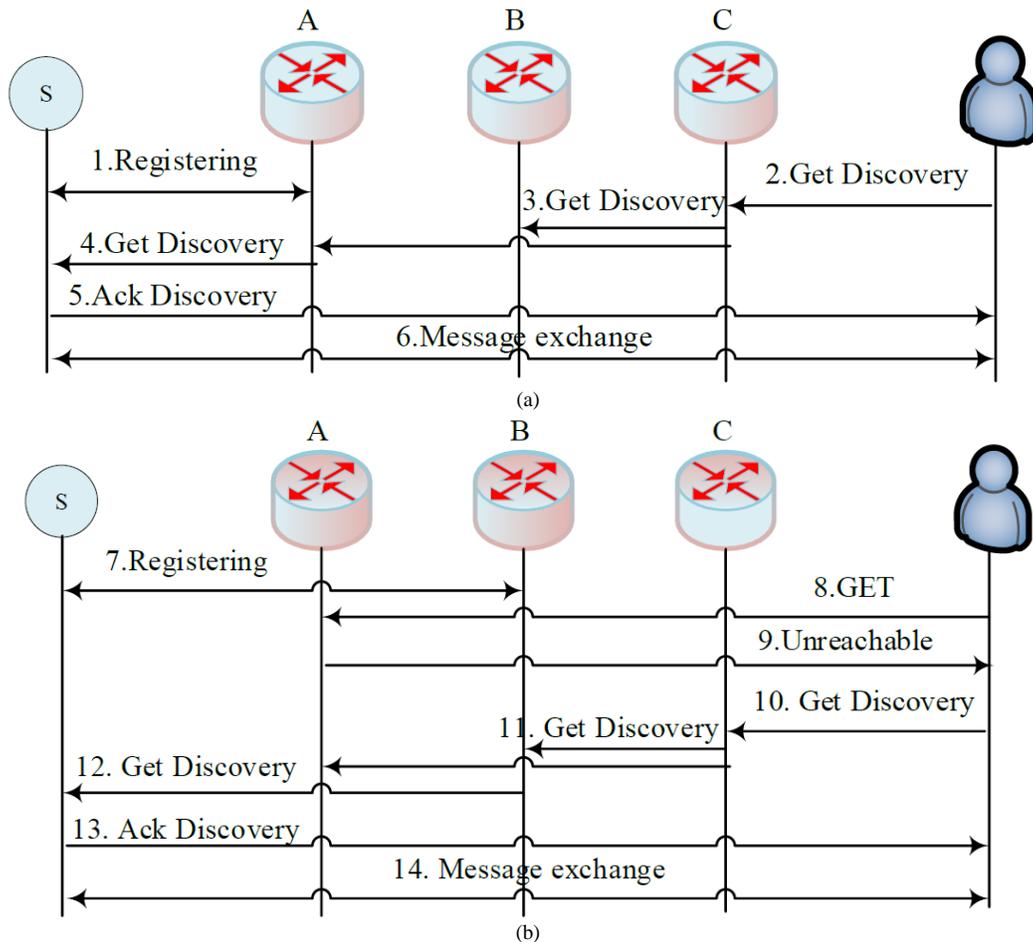
- Section IV: In this section, the summary and conclusion of the results will be presented.


Fig. 1.   CoAP Retransmission Mechanism: (a) Before Retransmission, (b) After Retransmission.

II. PROPOSED SDN-BASED TRANSMISSION CONTROL ALGORITHM

A. Intra-Domain and Inter-Domain Transmission

Fig. 3 demonstrates what transpired before and after the Intra-Domain transmission. The order of the exchanged messages and their related reactions are included in the following:

- Phase 1: Mobile Node (MN) service network delivers the "weak signal" message to the controller.

- Phase 2: After receiving the "weak signal" message, the controller examines the transmission protocol of all neighboring networks to identify the host channels. Then, all the active currents receive the mobile nodes from the current manager and compute the number of routes needed for multicasting.

- Phase 3: After computing the routes, the manager delivers the current change messages to adjust routing tables in the associated networks.

- Phase 4: CoAP-based Mobile Node, while entering a domain, by exchanging the Power-On Self-Test (POST) message, records its IP address within the network and receives an acknowledgment message.

- Phase 5: The network informs the controller of a new mobile sensor connection and sends the mobile sensor's IP address within the report to the controller.

- Phase 6: After receiving the network's message, the controller sends the current change messages to the host networks to eliminate the unnecessary currents.

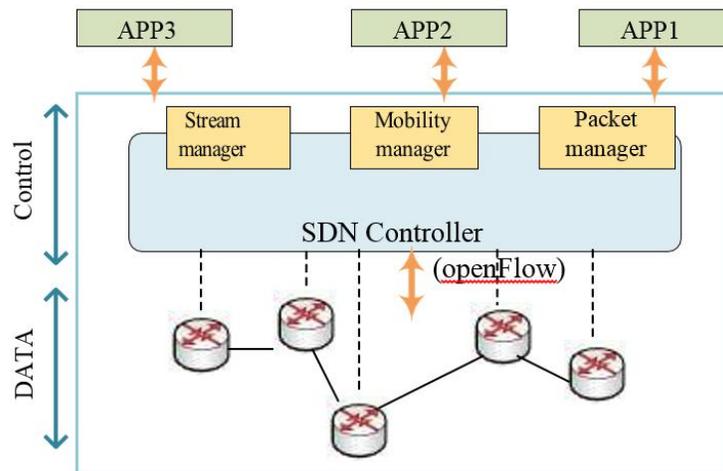
Fig. 4 demonstrates the order of the exchanged messages in inter-domain transmissions. As demonstrated in Fig. 4, Phases 1, 2, and 3 in this method are similar to intra-domain transmission. The source controller sends out the pre-transmission request to the location server. The location server identifies host networks and sends requests to their domain controllers. When the host network's controller receives the request, it estimates the pre-transmission route and sets out the current tables. In the final phase, by delivering the address report, the target network informs the controller of a new node connection within its domain. The controller transmits the update message to the location server. The location server updates the new location of the mobile sensor node. It sends out the transmission report to Primary Site Controller (PSC). After receiving the report, the controller eliminates the information related to the transmitted mobile node and the extra currents. Fig. 2 shows the SDN controller architecture in the IoT.


Fig. 2. SDN Controller Architecture in the IoT.
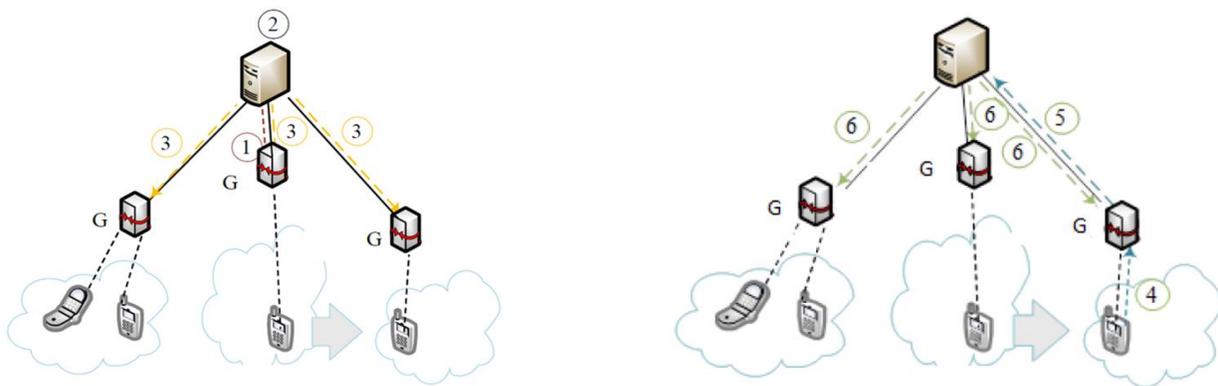

Fig. 3. Intra-Domain Transmission: a) Intra-Domain Pre-Transmission, b) Completed Intra-Domain Transmission.
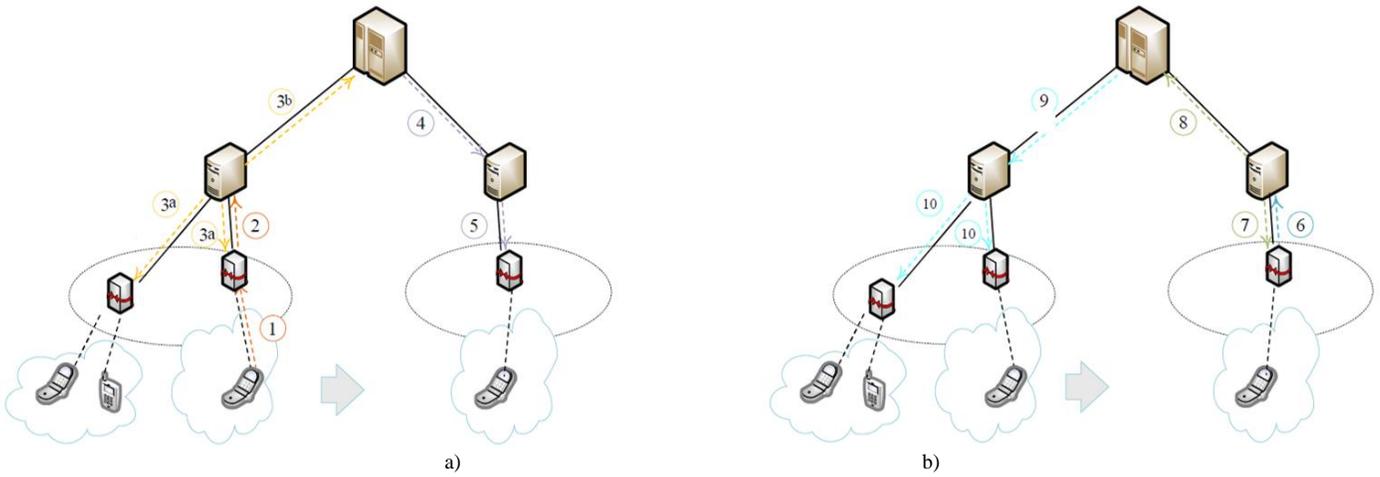

Fig. 4.   Inter-Domain Transmission: a) Inter-Domain Pre-Transmission, b) Completed Inter-Domain Transmission.

B. Transmission Delay and Signaling Costs Analysis

CoAP provides End-to-End Security using CON messages and a Stop-and-Wait Automatic Repeat Request (ARQ) mechanism. If the mobile node does not receive an ACK for its CoAP Confirmable Message (CON) within a specific time, it retransmits the same CON.

Based on the calculations done in [7], the packet loss ratio in the wireless transmission is calculated through the following equation:

$$P = 1 - (1 - S)^{2m} \qquad (1)$$

In which S is the sampling error and m is the packet length.

The Packet Error Rate (PER) in the application layer is calculated through the following equation:

$$E = P^{c+1} \qquad (2)$$

In which c equates to the maximum number of retransmissions in the MAC layer.

When it comes to packet segmentation in CoAP, Packet Error Rate is calculated by:

$$E_s = \sum_{i=1}^{s} E \times (1 - P)^{i-1} \qquad (3)$$

The maximum number of packages is 12.

The probability of message delivery for i times of P_R retransmission of a CoAP message using the s packet is estimated through the following formula:

$$P_R^i = (1 - E_s) \times E_s^i \qquad (4)$$

Therefore, the average retransmission time for each CoAP message is:

$$E(R) = \sum_{i=0}^{m-1} i \times P_R^i + (m-1) \times E_s^m \qquad (5)$$

in which m is the maximum count of message retransmission that the internet-connected system can approve.

If m is the maximum number of message retransmission, then the probability of a CoAP message not being delivered is E_s^{m+1} and the probability of its successful transmission is $\tau = 1 - E_s^{m+1}$. Since n sensors are competing with each other

to transmit the messages within the channel, the probability of having at least one successful transmission in each time slot is:

$$P_s = 1 - (1 - \tau)^n \qquad (6)$$

Therefore, the possibility of successful transmission within a channel provided that only one sensor transmits the message is calculated by the following formula:

$$P_{succ} = \frac{n\tau (1-\tau)^{n-1}}{1-(1-\tau)^n} \qquad (7)$$

At this point, while taking into account Round Trip Time (RTT) and the time required for receiving the Acknowledgment report for each message (T_{ACK}), we calculated the delayed signaling messages in CoAP, which is estimated at:

$$D = \sum_{i=0}^{m-1} P_R^i \times (RTT + T_{ACK}) + E_s^m \times T_{ACK} \qquad (8)$$

RTT is the time from the point of message transmission to the point of receiving a response estimated through the following equation:

$$RTT = \alpha \times old\ RTT + (1 - \alpha) \times new\ RTT \qquad (9)$$

In this equation, α is always between 0 and 1.

Finally, the signaling costs can be estimated from the following formula while taking into account the Packet Length (Lp) and Packet Arrival Rate:

$$C_p = \lambda_s \times L_p \times D \qquad (10)$$

In which λ_s is the packet arrival rate, Lp is the Packet Length, and D is the packet transmission delay.

III.   RESULTS AND DATA ANALYSIS

In this study, we used the two methods of mathematical simulation and analysis to examine the effectiveness of the proposed algorithm. In the simulation method, the study is based on the grounds that it matches the circumstances in real-life situations and operational networks as much as possible. There are various simulators, including OMNet++, NS, and Opnet. Opnet is one of the most powerful and popular simulators that many researchers use to simulate their proposed models. To examine the effectiveness of the proposed

algorithm, we implemented it in the Opnet simulator to compare it with the algorithm introduced by Chun et al. [7]. We used Matlab software to analyze the derived mathematical models.

A. Evaluation Criteria

The proposed algorithm should be assessed based on the basic algorithm to examine its performance of the proposed algorithm. To examine algorithm efficiency, some parameters should be studied that are included in the following:

- Signaling Latency: the time it takes for a signaling message to be transmitted and received indicates the signaling Latency.

- End-to-End Delay: the time it takes to send a request and receive its response is the end-to-end Delay. End-to-End Delay consists of signaling time, request transmission time within the link, and the time required to receive the Acknowledgment message and its response.

- Traffic Load: this parameter indicates the number of packets transmitted within the network at any time.

- Throughput: the average data packet successfully transmitted within the network is called network throughput. Network throughput is typically measured in bits per second or packets per second. In this study, the packet's network throughput is measured per second.

- Signaling Cost: The average costs of the exchanged signaling messages are measured based on the packet length and link latency.

Successful Transmission Probability Rate: successful transmission probability rate is measured by dividing the number of packets that were transmitted successfully within the channels by the total number of packets.

B. Results of the Proposed Algorithm Analysis

Within the IoT ecosystem, retransmission delay and the packet loss ratio are two of the most significant factors in evaluating the transmission algorithm. Channel delay and error rates are calculated by the formula introduced in the previous section. In this part of the study, we implemented Matlab's resulting correlations and calculated the transmission delay and signaling costs. To examine the system's efficiency, we provided networks of sensors that have n mobile sensors connected to the internet using a network. Networks support the OpenFlow protocol through which they connect to the controller.

On the other hand, the networks are connected to the sensor nodes using CON messages in CoAP. The parameters used in this analysis are similar to the ones used by Makaya and Pierre [16] in Table I. The bandwidth of the wireless network and the wired network are 250 kilobits per second and 10 megabits per second, respectively.

TABLE I. THE PARAMETERS USED IN THIS STUDY

Parameter	Value
Wireless link latency	15 ms
Wired link latency	2 ms
Wired bandwidth	10 Mbps
Wireless bandwidth	250 kbps
Average node speed	10 m/s

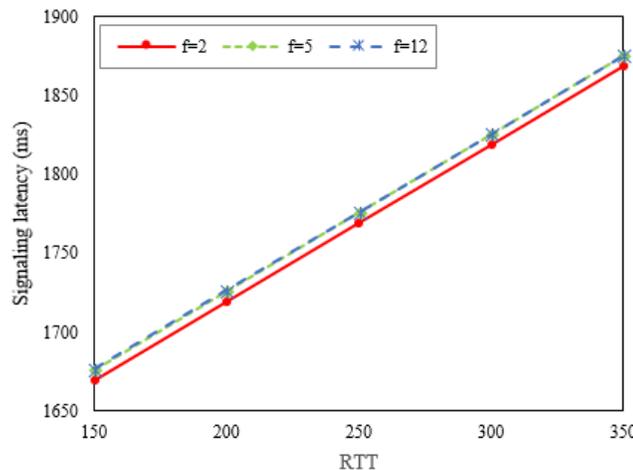
Fig. 5 demonstrates how RTT affects signaling message latency. As demonstrated in Fig. 5, transmission delay increases signaling latency. However, the Quality of Service (QoS) requirements' impact on signaling latency depends on the internet packet types (IP packet or CoAP packet) and the number of parts within each packet. Fig. 5 demonstrates that small network packets impose fewer network delays than the packets that contain more parts. This parameter begins to increase in network packets that have more parts. That is to say, for more extensive data packets, latency occurs mainly because of the traffic competition in the channel and not because of the multitude of packet parts.


Fig. 5. Signaling Latency Caused by Round Trip Time (RTT) Variations.

Fig. 6 demonstrates signaling costs based on the variation in entry rates. As demonstrated in Fig. 6, when entry rates increase, signaling costs increase, as well. The competition between the nodes for packet transmission within the channel increases the number of packet retransmissions within the channel, which, in turn, raises signaling costs.

The probability of successful transmission based on the number of sensor nodes within the network is demonstrated in Fig. 7. As demonstrated in Fig. 7, the successful transmission rate decreases with increased sensors within the network. This parameter can positively impact the retransmission rate and signaling costs.

C. Proposed Algorithm Simulation

In this study section, we introduce the structure of the simulation modeling of the M-CoSDN transmission mechanisms. An Opnet simulator was employed in this study for simulation modeling. Furthermore, this study provides a comparative analysis of the M-CoSDN proposed algorithm and the algorithm proposed by Chun et al. [7].

Fig. 8 demonstrates the network topology of the inter-domain simulation mainly used in transmission management studies. A 200×200 Wireless Sensor Network (WSN) with a range of 50 meters was chosen for this study. Each trajectory covers around 20 meters. A specific packet is introduced for each exchanged message during the signaling process. A specific packet based on the protocol format was introduced for the controller's response, acknowledgment, and current messages. In this study, the average incoming request time is not changed and is calculated every two milliseconds. Therefore, the incoming requests are transmitted to the controller every two milliseconds.

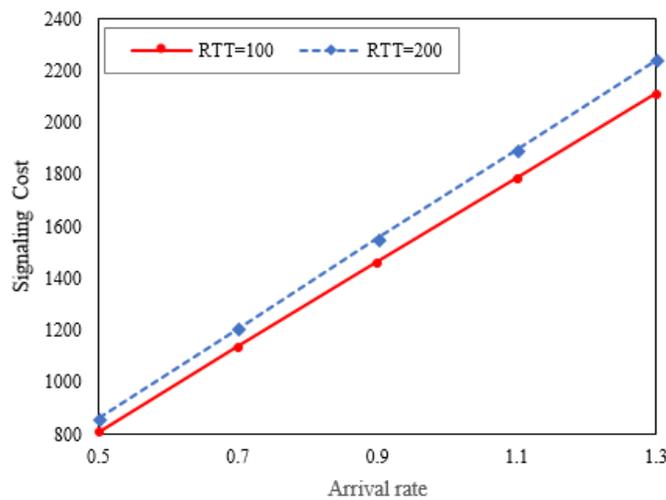
Fig. 9 demonstrates the End-to-End Delay within M-CoSDN proposed algorithm and the basic algorithm. As predicted, End-to-End Delay within the proposed algorithm is much lower than the basic algorithm. Using a central controller for transmission control that transmits current messages and controls the network's topology and sensors accelerates transmission. That is why the proposed algorithm detects a few delays.


Fig. 6. Signaling Costs Caused by Increasing Entry Rates.
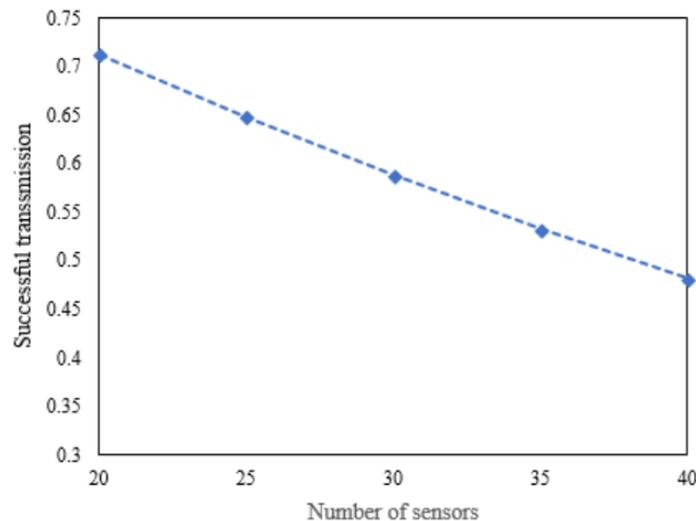

Fig. 7. Successful Transmission Probability within the Channel is Caused by Variance in the Number of Sensor Nodes.
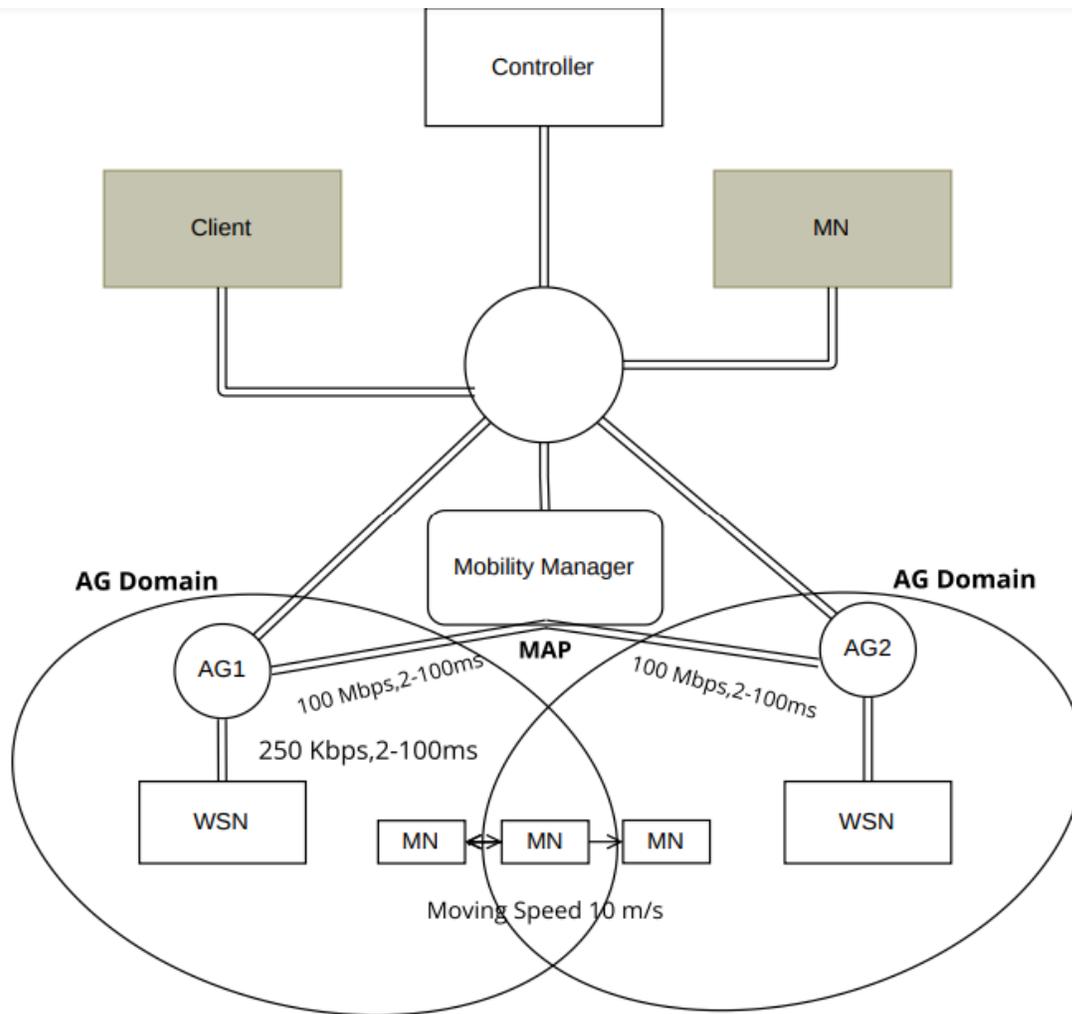

Fig. 8. Network Topology and Simulation Parameters.
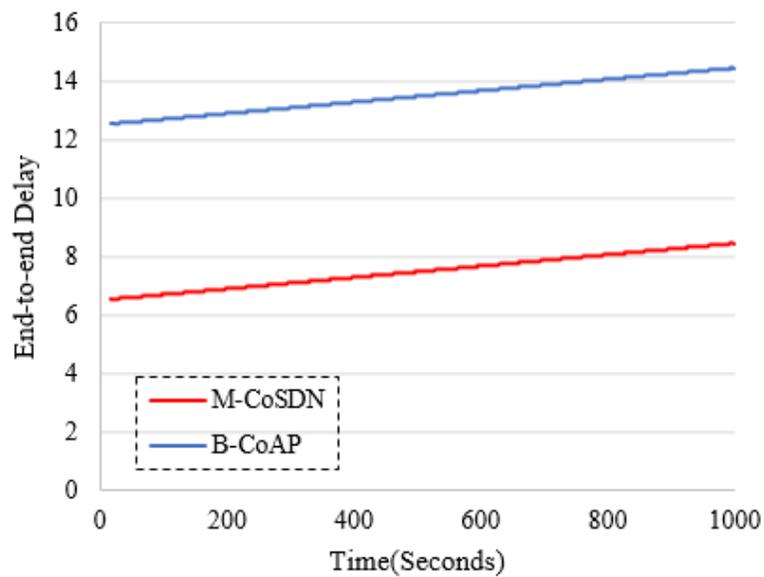

Fig. 9. End-to-End Delay within the Proposed and the basis Algorithm.

Within the basic algorithm, during mobile sensor nodes transmission, the user receives a 'Destination Inaccessibility Message' that informs him of the ongoing transmission. Then, the user finds the node's location through the retransmission of the source discovery message. This process leads to transmission delays. While within the proposed model, the mobile sensor node informs the controller of the domain change using the network. Therefore, the controller can reduce the delays to a bare minimum by updating the current tables and sending them to the network routes. Increasing the simulation time contributes to more delays within both algorithms. The increasing traffic load and transmitted packets within the network cause queuing delays in nodes and other network entities. That is why the End-to-End Delay is bound to increase with time.

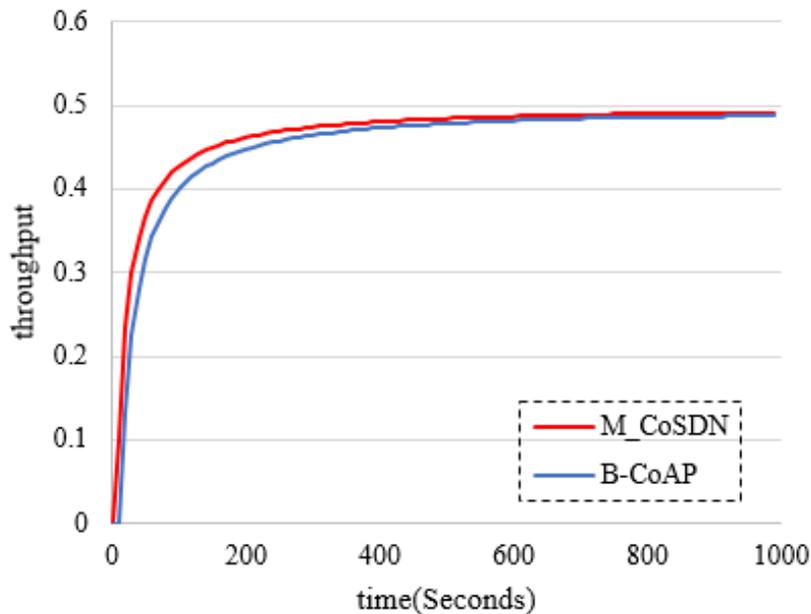
Fig. 10 compares network throughput within the two models. In this study, we defined network throughput as the number of successful requests divided by the total number of requests. As observed in Fig. 10, the network throughput in the proposed model is higher than the basic algorithm. The number of signaling messages transmitted between the two entities that might cause delays or collisions within the channel contribute to the higher network throughput in the proposed model. At the beginning of the simulation phase, network throughput was increasing at a high pace. However, with the increasing network traffic loads that cause collisions and errors within the channel, network throughput is decreased at a moderated pace. Therefore, network throughput is dependent on the channel type, errors, and network traffic load.


Fig. 11 demonstrates the network traffic load within the proposed and basic algorithms. As demonstrated in Fig. 11, in the basic algorithm, because of the repeated source discovery within each transmission, the exchanged traffic load increases. As predicted, increasing the simulation time leads to an increased network traffic load in the basic algorithm compared with the proposed algorithm that follows a higher positive slope. Traffic load increase, in turn, leads to increased delays and packet loss within the network. Therefore, network traffic load can impact network throughput and overall productivity.

In this part of the research, we have conducted a study on inter-domain routing. To do so, we have used two different domains controlled by two controllers within the network topology. Furthermore, a new entity called 'location server' is added to the network that records the data related to all network sensor nodes. First, the network's End-to-End Delay is studied (Fig. 12).

It is observed that inter-domain routing imposes more delays than intra-domain routing. However, by comparing Fig. 12 with Fig. 9, it is observed that inter-domain routing within the proposed model imposes much fewer delays than the basic algorithm. Both networks produce the same traffic load (Fig. 13) since both timeouts and delays are the same.

Fig. 14 demonstrates that inter-domain network throughput is slightly less than intra-domain network throughput. Increased packet delay and packet collisions in the network route decrease the number of successful requests, which, in turn, causes a slight decrease in inter-domain network throughput compared with intra-domain network throughput.

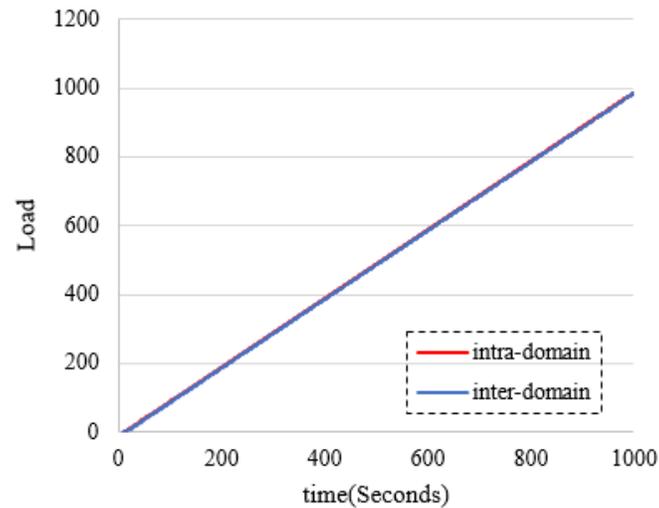

Fig. 13. Network Traffic Load.
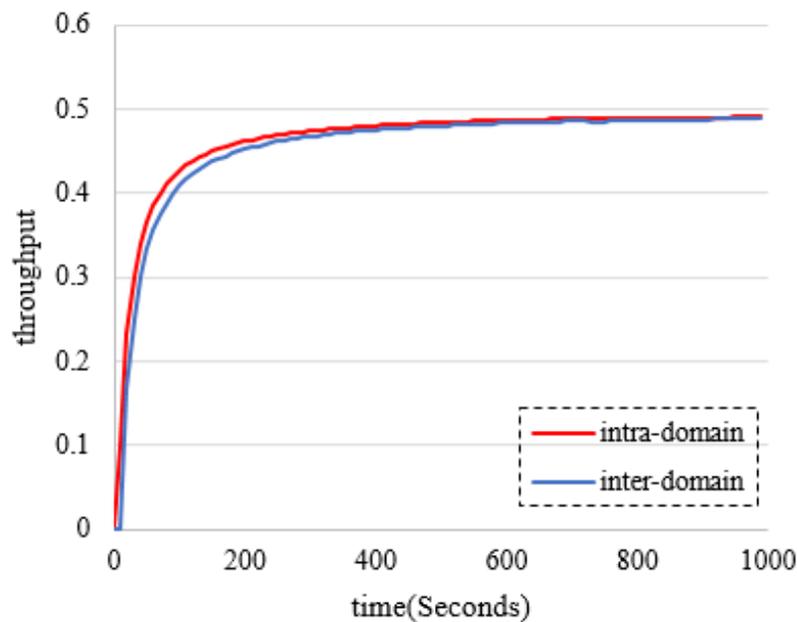

Fig. 14. Two Scenarios for Network throughput.

IV. CONCLUSION

IoT is a concept that connects multiple devices. The purpose of IoT is to facilitate human life and information exchange. IoT has multiple applications that can impact multiple aspects of human life, including personal, business, and industrial sectors. To increase network flexibility and reduce the costs of sensor nodes' transmission, we need to take a practical approach to the sensor nodes' transmission control. Because of the specific structure, infrastructure, and features of IoT, standard TCPs will not be of use. Therefore, it is essential to introduce a protocol based on the specific features of the IoT.

In this study, a secure M-CoSDN transmission model is introduced that would decrease signaling latency and costs in the IoT ecosystem. The proposed model uses SDN technology to impose centralized control on mobile sensor nodes within the network. CoAP CON messages are used to introduce a secure transmission model. Multicast transmission prevents packet loss and transmission delay for mobile sensors. The efficiency analysis results of the proposed algorithm indicate that it is far more effective than other models.

SPAMID-PAIR: A Novel Indonesian Post–Comment Pairs Dataset Containing Emoji

Antonius Rachmat Chrismanto[1], Anny Kartika Sari[2]*, Yohanes Suyanto[3]

Department of Computer Science and Electronics, Faculty of Matematics and Natural Science, Universitas Gadjah Mada[1,2,3]
Faculty of Information Technology, Universitas Kristen Duta Wacana, Yogyakarta, Indonesia[1]

Abstract—The detection of spam content is an important task especially in social media. It has become a topic to be continuously studied in Natural Language Processing (NLP) area in the last few years. However, limited data sets are available for this research topic because most researchers collect the data by themselves and make it private. Moreover, most available data sets only provide the post content without considering the comment content. This data becomes a limitation because the post-comment pair is needed when determining the context of a comment from a particular post. The context may contribute to the decision of whether a comment is a spam or not. The scarcity of non-English data sets, including Indonesian, is also another issue. To solve these problems, the authors introduce SPAMID-PAIR, a novel post-comment pair data set collected from Instagram (IG) in Indonesian. It is collected from selected 13 Indonesian actress/actor accounts, each of which has more than 15 million followers. It contains 72874 pairs of data. This data set has been annotated with spam/non-spam labels in Unicode (UTF-8) text format. The data also includes a lot of emojis/emoticons from IG. To test the baseline performance, the data is tested with some machine learning methods using several scenarios and achieves good performance. This dataset aims to be used for the replicable experiment in spam content detection on social media and other tasks in the NLP area.

Keywords—Dataset; natural language processing; spam detection; spamid-pair; post-comment pairs

I. INTRODUCTION

Research on text analysis, especially in context-based detection/classification problems, is increasingly important because of the higher need for system automation. A labeled dataset is needed for supervised text classification to be used as machine learning data. Unfortunately, the datasets for text classification are mainly in English. Other languages (Turki [1], Bangla [2], Chinese [3], Arab [4], and Morocco [5]), including Indonesian, are rare enough [6], [7].

Datasets for text classification can be divided into two types: single-text classification and paired-text classification. Some examples of single-text classification datasets are news classification, sentiment classification, hoax classification, spam, topic classification, and emotion text classification. Examples for paired text classification are text entailment classification, duplicate question classification, text pair similarity classification, including spam comment classification based on a particular post on the social media. One of the challenges in the NLP area is how to understand the context to gets the meaning. Context understanding can also be applied to spam comment detection based on its post by detecting the comment's relevance. If the comment is not related/relavance to its post, it is likely to be categorized as spam. To detect spam comments, machine learning methods require training datasets that can be used according to the context, such as in the context of the language, that are still rare.

The motivation of this research is to overcome the datasets scarcity in Indonesian for the text pairs classification to get the context between two texts in pairs correctly. The authors have collected the dataset for spam comment detection based on social media posts. This dataset is taken from Instagram (IG) based on selected 13 public Indonesian artists/actors inspired by [8], [9]. Each of the public Indonesian artists/actors has more than 15 million followers. Each row of this dataset consists of a post and comments text pair called SPAMID-PAIR[1]. SPAMID-PAIR contains 72874 pairs of posts and comments and breaks down into 53837 non-spam data and 19037 spam data.

This article introduces the SPAMID-PAIR dataset, a novel dataset collected, labeled, validated, and used as training data for spam comment detection based on their posts with several machine learning methods. This dataset is intended to contribute as one of the Indonesian datasets in NLP for text pair classification problems based on the context. The SPAMID-PAIR dataset has an advantage because it contains symbols, special characters, and emojis that are widely available in social media posts and comment texts. This dataset is useful for NLP research because most researchers discard emojis in their classification techniques. Some examples are news article classification [10], Twitter without emoji [11], spam comments from the blog [12], Twitter (removed emoji) [13], SMS and Twitter without emoji [14], Twitter without emoji [15], Youtube comment without emoji [16], video spam comment without emoji [17], Youtube comment without emoji [18]. The emoji is essential because most social media users use emojis to express their feelings, such as to support/deny, show sympathy, joy, sadness, and anger. The emojis in the dataset is needed for research in some fields that learn through emoji expression. This dataset uses the UTF-8 format for post and comment data, so both emojis can be used in emoji pairs expression research.

The contribution of this paper is two-fold; first, the novel SPAMID-PAIR dataset, and second, several machine learning algorithms will be used to implement the supervised text-pair classification using this dataset using the F1 score. This paper is written as follows, firstly, the introduction of SPAMID-PAIR and its purpose. Secondly, the related works of the Indonesian NLP dataset, the experiments and results using this dataset, and finally, the conclusion.

II. Related Works

Datasets are the primary data source in machine/computer learning. Various machine learning and deep learning techniques are in dire need of data sources for system learning. But in reality, not all public datasets are available, especially in Natural Language Processing (NLP). Even though learning datasets in NLP are quite widely available in English, such as IMDB Dataset [19]–[21], SMS Spam UCI [22], FLAIR [23], [24], Twitter Spam [25], [26], YouTube Comments [15], PeerRead [27], and Huggingface Community Datasets [28]. Still, there are few public datasets in other languages, especially Indonesian.

IndoNLU [6] is one of two dataset sources in the field of Natural Language Understanding (NLU) for 12 main tasks that have been attempted to be collected in collaboration with universities and industry. IndoLEM [29], as the second source, is a dataset source in NLP for seven main tasks (post tagging, named entity recognition, parsing, sentiment analysis, summarization, and word prediction). IndoLEM, the second, provides datasets, Indonesian Fasttext, and BERT pre-trained that can be used for other tasks. To the best of our knowledge, unfortunately, for the case of the semantic task in detecting spam comments in social media based on the context of the post in pairs, it has not been found. This article introduces SPAMID-PAIR to enrich the Indonesian NLP dataset collection in spam comment detection based on its post context, which has not been done before.

Spam text detection on social media is mostly done on Twitter [11], [13], [14], [15]. Twitter has a structure that is not in the posts and comments pair structure. Otherwise, Youtube, Facebook, and Instagram are examples of social media with posts and comments pair structures. However, the detection of spam comments in previous studies was not based on paying attention to the post. The previous research used some popular machine learning methods. Septiandri and Wibisono use Naïve Bayes, SVM, and XGBoost to detect spam comments from Instagram, and SVM outperformed the others [30]. Zhang uses the Random Forest to detect Instagram spam posts and achieve good [31]. Research [32] investigated 11 state-of-the-art machine learning methods in text classification using 71 datasets and obtained that Stochastic Gradient Boosting, SVM, and Random Forest were the best methods compared to the others. That research can be used as a reference for the best machine learning in classification.

III. Research Method

This research uses the following steps: data acquisition, dataset construction, data profiling, annotation/labeling, pre-processing, feature extraction/generation, ML algorithm implementation, and evaluation. These stages can be seen in

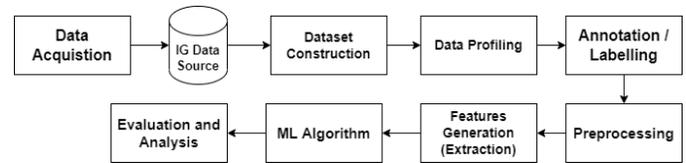
Fig. 1, while a more detailed explanation is in the following sub-chapters.


Fig. 1.   The Research Method.

A. Data Acquisition

In the data acquisition stage, IG was chosen because 1) IG has a lot of spam comments, especially on Indonesian public figure accounts [33], [34]. 2) Posting and commenting on IG is in pairs suitable for the pair dataset; 3) IG has a lot of non-formal posts and comments, and it also contains a lot of emojis; 4) IG does not have a spam filtering feature in Indonesian yet. For comparison, on Twitter (TW), a tweet is a post, but replies from other users must always use a mention tag, so the form of the reply is not a comment. The reply data is equivalent to the tweet, not as a child node. On Facebook (FB), a user can create a status/post, and others can comment on it. But on FB, the situation tends to be more formal/serious, so it does not contain much spam and emojis. Nowadays, IG is a famous social media with many young IG users; not as serious and formal as FB.

Comparing three leading social media existing today, e.g., IG, TW, dan FB, IG is the best choice for collecting datasets for spam detection. IG is widely used by public figures such as politicians, artists/actors, and well-known people. Very limited datasets are available in languages other than English and Chinese, especially Indonesian [6], making collecting this dataset more critical. The SPAMID-PAIR dataset from IG contains post-comment pairs from 13 Indonesian artists/actors with more than 15 million followers without stating their account names. It is expected that researchers in the NLP field can use this dataset to replicate research and use it as the dataset reference in the topic of spam detection using various algorithms.

The SPAMID-PAIR dataset was retrieved using several tools such as Instaloader and Chrome Selenium Python driver. For the first planning, the data is taken from the 50 most recent posts, and 120 most recent comments are taken from each post. Hence, it was estimated that 78000 data could be collected. However, the data is not as planned in reality because some posts do not have as many comments as expected. The dataset was collected in September 2020, and after data retrieval was completed, 72874 pairs of post and comment data were obtained, which are ready for further processing.

Table I displays all the artists/actor's usernames used in the SPAMID-PAIR dataset. SPAMID-PAIR contains 72874 pairs of posts and comments and breaks down into 53837 non-spam data (73.87%) and 19037 spam data (26.13%). Details of the number of spam and non-spam labels per artist/actor are highlighted in Table II, analyzed using Python Pandas. Table II also shows that the IG ID 24239929 only has 103 data because the user recently had disabled comments, so the data could not be retrieved anymore. Spam comments are detected in all 13

IG users chosen with varying percentages. The SPAMID-PAIR dataset consists of 11 fields and is available in Excel format (.xlsx) and comma-separated value (CSV) with UTF-8 encoding, as described per field in Table III.

TABLE I. THE 13 PUBLIC FIGURES USED IN THE SPAMID-PAIR DATASET WITH MORE THAN 15 MILLION FOLLOWERS (PER DECEMBER 2021)

Account ID	Followers (millions)
1918078581	54.3
522969993	47.4

Total	53837	19037			72874

Table IV shows that the number of emojis in this dataset reaches 68%, and the number of emojis in the spam category is higher than in the non-spam category. Table V shows detailed data related to emoji statistics in the dataset. Fig. 2 illustrates the distribution of emoji in the SPAMID-PAIR dataset per IG artist ID and tells us how the emoji is related to the spam or non-spam label. Fig. 3 shows some correlation between some attributes of the SPAMID-PAIR dataset. First, it shows a correlation between the length of comments and spam labels. There is also a correlation between the length of comments and the number of emojis. Lastly, there is a correlation between the length of comments and the post length.

TABLE III. DESCRIPTION OF ATTRIBUTES IN THE SPAMID-PAIR DATASET

Attribute	Description
igid	Account ID
comment	Comment on a post
post	Post from an account ID
emoji	Whether the data contains emojis or not (1 or 0)
spam	Whether the data is spam or not (1 or 0)
lengthcomment	The character length of the comment
lengthpost	The character length of the post
countemojicomment	Number of emoji symbol characters in comments
countemojicommentuniq	Number of emoji symbol characters in comments (unique)
countemojipost	Number of emoji symbol characters in posts
countemojipostuniq	Number of emoji symbol characters in the post (unique)

TABLE IV. NUMBER OF EMOJIS IN THE SPAMID-PAIR DATASET

Category	Count	Percentage (%)
Non-Emoji	22710	31,16
Emoji	50164	68,83

TABLE V. NUMBER OF EMOJI IN THE SPAMID-PAIR DATASET PER ACCOUNT ID

Account ID	Count of Non-Emoji	Count of Emoji	% Non-Emoji	% Emoji	Sub Total
4934196	2085	4731	30,59	69,41	6816

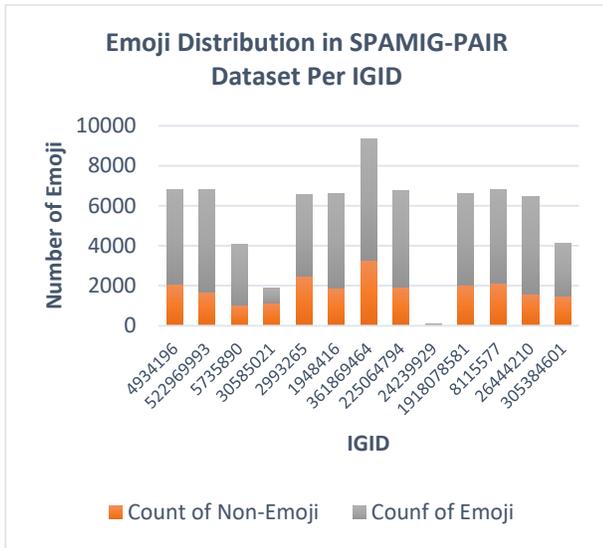
SPAMID-PAIR dataset profile generally has an average comment length of 34.23 characters and an average post length of 252.03 characters. The highest number of emojis (non-unique) in a comment is 359 emojis, and the highest number of unique emojis is 112. In the post data, the highest number of emojis (non-unique) is 32 emojis, and the highest number of unique emojis is 14. Complete statistical details of the comment and post data can be seen in Table VI. The maximum length of the comment is 386, and the post is 3938.


Fig. 2.   Distribution of Emoji in the SPAMID-PAIR Dataset.
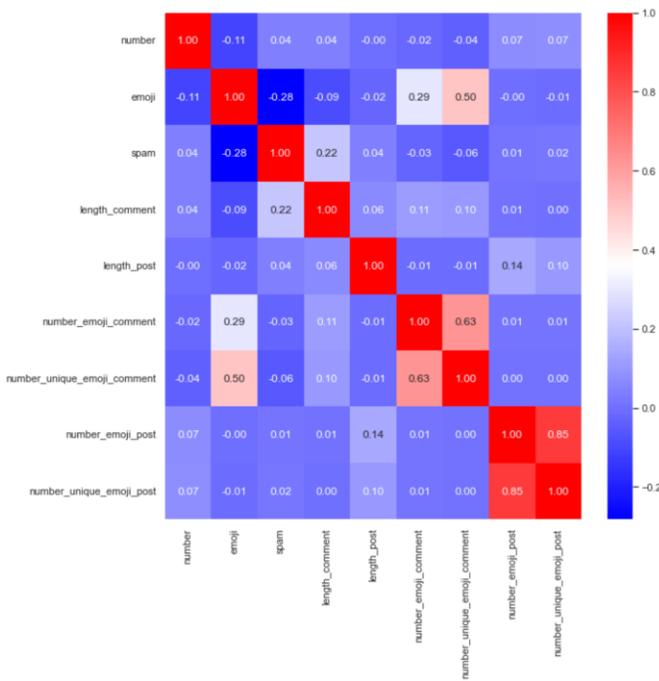

Fig. 3.   Attributes Correlation in the SPAMID-PAIR Dataset.

B. Data Profiling and Labelling

After the dataset has been collected, the next step is data profiling, labeling, and validation. Labeling gives each data a "spam" or "not spam" label. The "spam" criterion is given if the post and comment data, text data, or emojis are irrelevant. On the other hand, the "not spam" criteria will be given if the post and comment data are relevant. Two Indonesian labelers carried out the labeling process. Before starting the labeling process, a joint briefing was held between the two native Indonesian labelers to create a common perception of the meaning of "spam" and "non-spam" labels. After that, labeling was done using an excel formatted dataset that was given to each labeler, and there was one additional column, "label,"

which would be filled with "spam" or "not spam" by each labeler manually. The final label was determined by the final agreement of the two labelers. Based on the Kappa score, the result is the "almost perfect" category with a Kappa score of 0.95, proving that the labeling agreement between the two annotators was relatively easy. The difficulty arises when the comment contains only an emoji, and it is difficult to determine its meaning. However, it can be overcome by looking at the consistency of the type of emoji and the type of "positive" emoji used. Suppose the emojis use "positive" emojis such as expressions of joy, enthusiasm, support, and love. In that case, the label is a high possibility of "not spam." Otherwise, if the post content tends to be "positive" and the comment content tends to be "negative," it is labeled as "spam." Examples of labeling results for data labeled as "spam" and "not spam" can be seen in Table VII.

TABLE VI.   STATISTICAL INFORMATION ON COMMENTS AND POSTS DATA IN THE SPAMID-PAIR DATASET

Statistics of Comments	Average	Max	Statistics of Post	Average	Max
Number of sentences	1,1	29	Number of sentences	2,88	45
Number of characters	34,25	212	Number of characters	2,52	3938
Number of whitespaces	4,4	386	Number of whitespaces	33,13	570
Number of words	4,8	384	Number of words	35,33	602
Number of numbers (as a whole)	0,2	72	Number of numbers (as a whole)	1,1	35
Number of punctuations	1,1	213	Number of punctuations	10,52	192
Number of date format	0,00013	1	Number of date format	0,000618	1

TABLE VII.   EXAMPLE OF LABELING RESULTS

Comment	Post	Label	Reason
😣😣😣😣 😣💧💧💧 💧💧💧💧	Can't argue with the clan 😎! Entertainment Inc presents u @USER. Watch the full version on my video	Spam	The comment contains only emojis that are not consistent, "sad and hot" at the same time about the new post video
cantik bangettt😩🖤 (in English: veryyy pretty 😩🖤)	🌸 Outfits custom @USER Styling @USER Makeup @USER Hair @USER Photographer @USER	Not spam	The comment reply a post about how pretty an artist is because the post shows how beautiful the artist in an outfit

After the labeling had been completed and re-validated, a data profiling step was carried out to determine additional data from the dataset using Python NLP Profiler. It analyses whether there are emojis or not in the posts or comments. It does statistical analysis on the number of sentences, the number of characters, the number of whitespaces, the number of words, the number of words in the form of numbers, and the number of signs. It also reads and counts the number date

format. Data profiling is used to determine the characteristics of the data and assist in determining the appropriate pre-processing steps later.

C. Pre-processing

The pre-processing process consists of the following steps:

1) Generating manual features such as the length, the number of emojis, the number of unique emojis, the number of digits, the number of hashtags, the number of mentions, the number of uppercase letters, the number of special chars, and the number of links.

2) Changing letters to lowercase.

3) Removing spaces and characters that appear excessively.

4) Removing certain punctuation marks unrelated to hashtags, emails, mentions, and URLs.

5) Doing simple normalization as follow:

    a) Repeated words normalization (such as "pergi2" to "pergi-pergi").

    b) Slang words normalization using a dictionary.

    c) Email, hashtag, number, mention to specific TAG (USER, ANGKA, EMAIL, MENTION)

    d) Abbreviation normalization using a dictionary.

    e) Some minor spelling corrections using a dictionary.

6) Performing stopwords removal (using combined stopwords from standard and stopwords generated from the dataset based on their frequency).

7) Performing stemming using the Sastrawi Python library.

8) Saving the final output and passing it to the model.

IV. EXPERIMENTS AND DISCUSSION FOR BASELINE PERFORMANCE

The testing was carried out using the ML method (Nave Bayes, Complement Naïve Bayes, Decision Tree, and Multi-Layer Perceptron) [32], which was partially or fully implemented using the Python Scikit Learn library (Sklearn). The test scenario was carried out in two forms: a dataset with emoji in symbols and emoji in the text. Pre-processing uses tokenization, Indonesian stopwords, and simple normalization and uses the n-gram TF-IDF features, i.e., 1-gram and 2-gram. Table VIII shows the experiment scenario using the machine learning methods. The dataset splits into 80% training data and 20% testing data. The evaluation score used F-measure (F1) with a score between 0-1. The measurement matrix uses the F1 score with 80% training data and 20% testing.

The authors use Naïve Bayes (NB) with an alpha value of 0.01 and other parameters defaulted from sklearn. Complement Naïve Bayes (CNB) was used in the second experiment, which was expected to overcome datasets whose classes are not balanced. Both methods were used as representatives of the probability classifier. The Decision Tree (DT) method was also used, representing the classifier tree with the random_state parameter set and the information gain using the Gini index. Finally, an artificial neural network-based classification method was used: a multi-layer perceptron with a limited

iteration of 300. The F-measure (F1 score) was chosen for the performance evaluation because the F1 score value represents a combination of recall and precision values and can also be used in the unbalanced dataset.

Moreover, the accuracy value alone is inappropriate for the SPAMID-PAIR dataset with an unbalanced number of classes. Table X shows the results of the experimental scenarios using the methods. Fig. 4 to 10 display the confusion matrixes of the models, while Fig. 11 and 12 show ROC curves of the models in testing data. From the confusion matrix in Fig 4(a) and 4(b) (EmojiSymbol NB), all the true positives are higher than the others (true negative, false positive, and false negative). The ability to detect spam comments is good enough, but it also can be seen that the accuracy is better on not-spam comments than on spam comment labels. Fig. 5(a) and 5(b) (EmojiText NB) show that the F1 score is higher than the EmojiSymbol, although the true positives are lower than the EmojiSymbol. From this result, the EmojiText performs better because it can detect spam comment properly in a balanced dataset. Fig. 6(a) and 6(b) (EmojiSymbol CNB) show that the F1 score (based on true positive, true negative, false positive, and false negative) is better than the NB method. CNB works better because it can complement the weight of an unbalanced dataset [34]. Fig. 7(a) and 7(b) (EmojiText CNB) show that the CNB in text format outperforms the NB in EmojiSymbol and EmojiText. Fig. 8(a), 8(b), 9(a), and 9(b) shows the performance of the DT method that also has better F1 in EmojiText but not for the EmojiSymbol. Decision Tree can handle the emoji symbol well. The last, in Fig. 10(a) and 10(b), it can be seen that the confusion matrix shows that MLP (a traditional neural network) has close F1 score to NB and CNB but trains slower than them. But, based on Fig. 11(a) and 11(b), it can be seen that EmojiText in MLP works the best from the other methods.

The authors also extract a list of emojis categorized as 'spam' and 'not spam' based on the SPAMID-PAIR dataset. It can be seen in Table IX. It can be seen that list of spam emojis is more than not spam emojis. The intersection between them is also quite a lot, and the emoji only used in the "not spam" category contain very reasonable emojis (clear emoji meaning). Still, on the other hand, the emoji used only in the "spam" category is quite a lot and very random emojis (not clear emoji meaning).

TABLE VIII. THE TESTING SCENARIO ON SPAMID-PAIR USING THE MACHINE LEARNING METHODS

Test Scenario Using Machine Learning Methods		
Emoji Symbol	Pre-processing: tokenization, stopwords, normalization, stemming, feature: TF-IDF 1 gram and 2 gram	Methods: Naïve Bayes (NB) (alpha: 0.01), Complement Naïve Bayes (CNB) (alpha: 0.01, norm: true), Decision Tree (DT) (random_state: 42, gain: Gini), Multi-layer Perceptron (MLP) (random_state: 42, max_iter: 300)
Emoji in Text	Pre-processing: tokenization, stopwords, normalization, stemming, feature: TF-IDF 1 gram and 2 gram	Methods: Naïve Bayes (NB) (alpha: 0.01), Complement Naïve Bayes (CNB) (alpha: 0.01, norm: true), Decision Tree (DT) (random_state: 42, gain: Gini), Multi-Layer Perceptron (MLP) (random_state: 42, max_iter: 300)

TABLE IX.   EMOJI LIST (SPAM AND NOT SPAM), INTERSECTION, AND DIFFERENCE IN THE SPAMID-PAIR DATASET

List of Emojis	Category

Fig. 13. ROC Curve of (a) EmojiText1GramTFIDF (NB, CNB, DT, MLP) and (b) EmojiText2GramTFIDF (NB, CNB, DT, MLP)

The results in Table X prove that the SPAMID-PAIR dataset is a dataset that can be used in Indonesian text classification experiments originating from social media. In Fig. 4 to Fig. 10, all the confusion matrixes of the models use 14.573 (20%) data testing. From Table X and Fig. 4 to Fig 12, It can be seen that CNB and MLP are superior to NB and DT. Fig. 13 shows the ROC curve, which explains that the area of the ROC curve in 13(a) is higher than in 13(b). The EmojiText1Gram is better than the EmojiText2Gram because the TFIDF vectors from 1gram have a better weight representing the text's characteristics. The traditional ML can only achieve an F1 score in the range of 0,72-0,78, but a multi-layer perceptron can achieve an F1 score of 0,8. It promises that these results can be improved, such as with the pair context classification approach [35]. Hopefully, this dataset can also be used in other related research and enrich the Indonesian dataset collection, which is still rare. This dataset is also important because it contains pairs of posts and comments that can be related and used in problem sentence pair classification in Indonesian.

V. CONCLUSION

This research collected post and comment pairs data from 13 selected Indonesian public figures (artists) / public accounts with more than 15 million followers. Two persons labeled all pair data as an expert in 72874 data. The dataset is called SPAMID-PAIR, containing post-comment pairs and label in Unicode text (UTF-8) text containing emojis. The dataset does not include any account information except the ID number. Unlike the other existing sentence pair datasets, the SPAMID-PAIR dataset is specifically used to determine the context between comments and posts that have never been collected in a large enough dataset. The objective of this dataset is as the primary data source in machine learning, especially in the NLP area, for spam comments detection based on the post context. This dataset is intended as one of the Indonesian language datasets that also contains many emoji symbols from social media so that it can be used to understand human expressions using emojis.

SPAMID-PAIR proved that it could be used as a training dataset to detect spam comments based on its post. From the experimental research using some ML methods, it can be seen that ML can only achieve an F1 score in the range of 0,72-0,78, but a multi-layer perceptron (MLP) can achieve an F1 score of 0,8. It significantly promises that these results can be improved in future works. The limitation of this dataset is it includes imbalanced data between not spam and spam categories. This dataset can also be enhanced in the future.

Cedarwood Quality Classification using SVM Classifier and Convolutional Neural Network (CNN)

Muhammad Ary Murti[1], Casi Setianingsih[2], Eka Kusumawardhani[3], Renal Farhan[4]

School of Electrical Engineering, Telkom University, Bandung, Indonesia[1, 2, 4]
Department of Electrical Engineering, Universitas Tanjungpura, Pontianak, Indonesia[3]

Abstract—**Cedarwood is one of the most sought-after materials since it can be used to create a wide variety of household appliances. Other than its unique aroma, the product's quality is the most important selling attribute. Fiber patterns allow for a qualitative categorization of this wood. Traditionally, workers in the wood-processing business have relied solely on their eyesight to sort materials into several categories. As a result, there will be discrepancies in precision and efficiency, which will hurt the reputation of the regional wood sector. The answer to this issue is machine learning. In this study, we compare the performance of two different cedarwood quality classification systems where both systems use different machine learning methods namely Support Vector Machine (SVM) and Convolutional Neural Network (CNN). Each system will be sent images captured with a Logitech Brio 4K equipped with a joystick and ultrasonic sensors, labeled as belonging to one of five cedar classes (A, B, C, D, or E). In the initial method to learn the wood's pattern and texture, the Histogram of Oriented Gradient (HOG) will be used to identify the material. Meanwhile, the classification method uses a Support Vector Machine (SVM) which will be compared to find the best accuracy and time computation. The first system's experiment achieves 90 percent accuracy with a computation time of 1.40 seconds. For the second, we use a Convolutional Neural Network, a deep learning technique, to classify cedarwood (CNN). Extraction of features occurs in the convolution, activation, and pooling layers. Experimental results demonstrated a considerable enhancement, with an accuracy of 97% and a prediction speed of 0.56 seconds.**

Keywords—Cedarwood classification; convolutional neural network (CNN); HoG feature; SVM classification

I. INTRODUCTION

When it comes to exterior, interior, and home appliance needs, cedarwood is one of the most popularly purchased light wood processing materials. This is not without good reason, the resin content contained in Cedarwood will emit a very fragrant odor, the goal of which is to expel the terms that will eat the wood composition [1]. Cedarwood also has a very high level of resistance to mold because it belongs to the group of hardwoods which incidentally has dense pores so that moist water does not easily enter and cause mold. That is why the quality of cedar is the main point of concern [2]. Like wood in general, cedarwood also has a variety of qualities depending on the factors of sawing and the age of the tree, so these quality factors can be classified directly by paying attention to the color, texture, and pattern of the fiber [3], [4].

Many businesses that deal with processed wood still perform classification by hand, using just their eyes and gut

reactions to determine how many items are alike. Compliance with observations is only indicated as a percentage (50-60%) in that matter [5]. Therefore, it is challenging to avoid the issue of ambiguity and misclassification within each category. The legitimacy of Indonesia's processed wood sector is threatened by subjective standards of accuracy and production time [6]. In light of this, the field of machine learning offers a means of addressing and ultimately resolving these issues. Local wood industries can use machine learning to create uniform wood classes, allowing for reliable automatic classification [7].

The implementation of machine learning to create uniform wood classes, it can use two deep learning approaches into the cedarwood quality categorization system. Support Vector Machine (SVM) and Convolutional Neural Network (CNN) will be utilized to automatically capture and predict when wood enters the categorization area. These approaches will be directly integrated with the small conveyor, Controller, and Logitech Brio 4K webcam. Cedarwood quality data from Classes A through E is employed, and an automated feature extraction process is carried out with a total of 16 layers in CNN and in SVM. The Histogram of Oriented Gradient is then used to determine the grain pattern and texture of the wood during recognition.

II. RELATED WORK

Widespread use of machine learning theory emerged during the era of the 4.0 Industrial Revolution, which also paid close attention to technical advancements. As a result, its implementation in the wood industry is quite probable [8] [9]. Over the years, many types of wood classification systems have been developed, such as wood classification based on PCA, 2DPCA, (2D) PCA and LDA [10], the second method is the Classification of Coconut Wood Quality based on Gray Level Co-Occurrence matric [11], and the third method is the Species Identification of Wooden Material using Convolutional Neural Network [12]. However, in the first method, the highest implementation accuracy was only 86.67% and even then, it had to be tested on a different sample, besides the feature extraction and identification process requires a good dataset structure to obtain a good system performance. In the second method Based on Gray Level Co-Occurrence Matrices, the highest accuracy obtained is only 78.82% so that it still requires a feature selection strategy to improve its performance. Then in the third method which classifies fir, pine, and fir wood with various CNN architectures used, the highest accuracy is 99.4%. However, this classification method can only identify the type of wood in certain parts and cannot make the identification of the whole wood being tested if it is

done in real-time, so pre-processing is still needed to perfect the research.

III. RESEARCH METHODOLOGY

In this research, the CNN and SVM-based cedarwood classification system is broken down into three distinct phases: Acquisition, training, and categorization of images, as well as indication systems. In the first phase, an ultrasonic sensor is used to identify the presence of wood on the conveyor path, and the resulting input signal is used for auto-capture. The Controller relays the signal to the server using serial communication. When the server receives the command, the Logitech brio 4k webcam is activated to take a picture for use in the training and classification process. The second stage is responsible for machine learning and categorizing the collected images through the use of the convolution, activation, and max-pooling layers.

An indicator system made up of five LED lights of varying colors, each of which represents a different category of wood, shows the results of the second stage of learning. The following are the three working states of the cedarwood quality classification system illustrated in Fig. 1.

All process of sending commands between the device controller and the server is done using the serial communication method with a data rate of 8 bits per second. The detection and prediction code that the system has processed must first be converted into binary forms so that the data transmission process can be easily carried out in series.

A. Image Acquisition Process

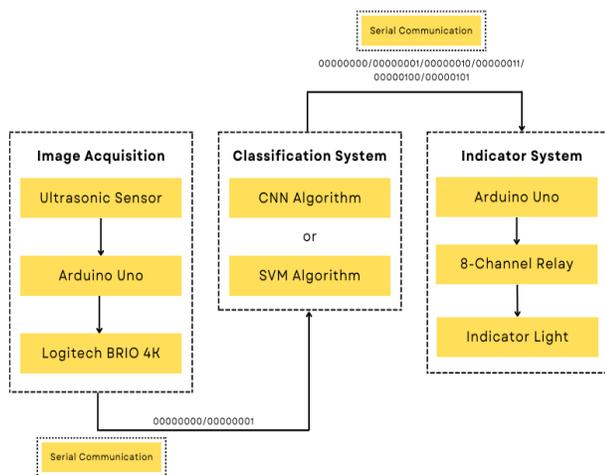
Image acquisition is one of the subsystems directly related to the process of automatically capturing images when scanning wood. The sensor is placed horizontally next to the direction of the conveyor belt rate to detect wood when it passes by. When wood is detected, the capturing image will be performed by a webcam mounted in the sky of the acquisition box. This section functions as a data gateway between hardware and software on the server.


Fig. 1. Block Diagram of Classification System.
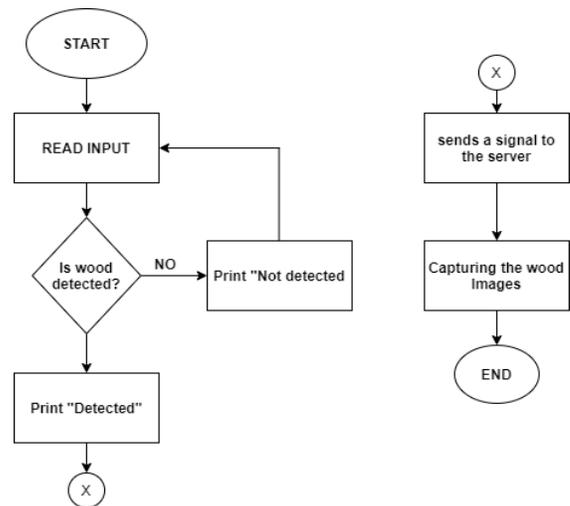

Fig. 2. Flowchart of Images Acquisition Process.

Fig. 2 is a flowchart diagram of the image acquisition process used to give the camera commands to carry out image capture tasks that are integrated between the Controller and the server with serial communication mode. Upon receiving a signal from the HC-SR04 proximity sensor that is incorporated with the Controller, the server will instruct the Logitech brio 4K to automatically capture the cedarwood runs on the conveyor track. The image is captured in a black, matte, 27.6 x 23.6 x 30 cm acquisition box lit from above by LED strips emitting 723 lux. The resulting image has a 640x480 pixel resolution and the following features of the wood used.

Images of cedarwood captured at a zoomed-in percentage of 130%, with a black backdrop, brightness of 26, Contrast of 24, and camera focus of 14 are displayed in Table I.

TABLE I. CHARACTERISTICS OF CEDARWOOD IN EACH CLASS

Class	Fig	Description
A		Magnificently straight fiber, with a distance so short that it is barely perceptible, is the hallmark of this technology.
B		There are a lot of fibers, they're all straight and rather thick, and you can see the separation between them.
C		The space between the fibers is considerable, and there are also some transverse fibers visible.
D		Fiber-to-fiber spacing and transverse pattern are easily visible.
E		Extremely transparent fiber; random fiber patterns are typically not straight.

B. Training and Classification Process

In this section, the image has been baptized and stored on the server, then pre-processing is done to match the

classification architecture used. After a match between the image's dimensions and architecture, the image classification process is carried out using the CNN and SVM methods.

1) Convolutional Neural Network (CNN) Method

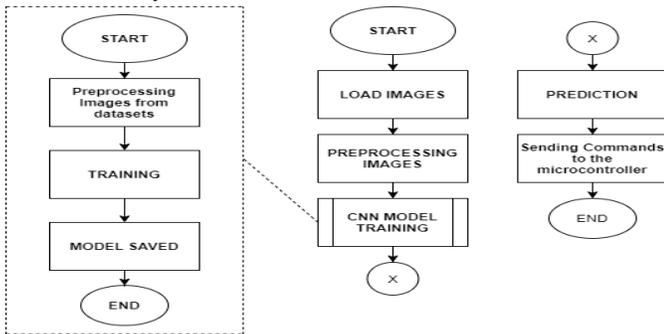
a) Feature Extraction: Fig. 3 explains the data processing up to sending commands to the microcontroller. The left is a classification process of wood images captured and stored in a server. On the right is a training process for the Convolutional Neural Network method to get the best classification model used in the system's classification. The first layer of the convolutional neural network design will be fed with the image acquired during the acquisition phase. But first, it needs to go through some pre-processing to ensure that the image and layer have compatible dimensions [13]. The CNN architecture VGG-16 technique is used in the wood classification system. VGG16 is used because it's considered a type of CNN, one of the most advanced computer vision models. VGG16 is an object detection and classification algorithm that can classify 1000 images of 1000 different categories with 92.7% accuracy. It is one of the most widely used algorithms for image classification and is easy to use with transfer learning. It uses a square picture with dimensions of 224 by 224 by 3 pixels as the suitability parameter. Up until the point of delivering commands to the microcontroller, the data processing is described in detail. The left is a classification process of wood images captured and stored in a server. On the right is a training process for the Convolutional Neural Network method to get the best classification model that will be used in the classification of the system. The acquired image will be used as input for the CNN architecture's first layer. However, prior to doing that, the image must be pre-processed so that its dimensions match those of the layer.


Fig. 3. Flowchart of Training and Classification Process using CNN Method.

In the CNN architecture VGG-16 algorithm [14] employed in the wood classification system, the parameter of appropriateness is a square-shaped image with dimensions of 224 x 224 x 3 pixels.

$$Rz = \frac{P(q,r) + P(q+1,r) + p(q,r+1) + p(q+1,r+1)}{4} \quad (1)$$

Based on Eq. 1, the image will be resized to be smaller, as in Fig. 4. However, so that the original rectangular image can be resized into a new rectangular image, it is necessary to do an additional process by improving the image's aspect ratio or adding padding to the new image to be resized. The step for resizing the image will affect the accuracy of the classification [15]. Also Adding padding can be done in three ways [16]:

- Inserting a zero value at the edge of the dimension.

- A max value at the edge of the dimension.

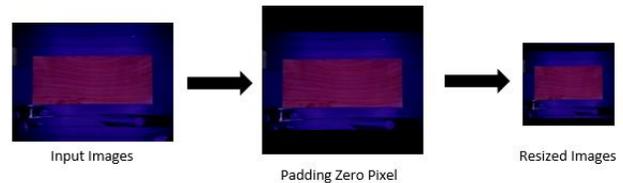
- Inserting the same value as the image at the edge of the new dimension.


Fig. 4. Resizing Rectangle into Square Images.

A feature extraction technique is carried out to capture features in each wood class after the input image is found to be a match for the first layer of a convolutional neural network. The 2D convolution operation comes at the beginning of the feature extraction procedure. The convolution layer is the initial feature-extracting layer in the CNN architecture, and it does so by convolving the input of a square-resolution picture with a filter, also known as a kernel [17]. In a broad sense, we might say that this 2D convolution procedure uses the sliding window idea to calculate its weight [18].

$$(y, x) = \sum_{p=-m2}^{m2} \sum_{q=-n2}^{n2} h(p + m2 + 1, q + n2 + 1) f(y - p, x - q) \quad (2)$$

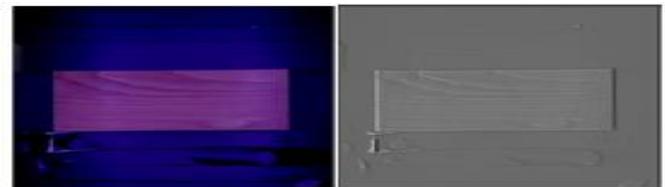
If we apply the above equation, we get the following representation of the convolution's final image:


Fig. 5. Visualization of Convolution Layer.

One of the 3 x 3 pixel filters/kernels used in the convolution layer's 2D convolution operations is shown in color in Fig. 5. The study found that 64 features might be used on the first convolution layer when using input dimensions of $224 \times 224 \times 3$. Then, the convolutional layer's output is turned on, which is the second part of the feature extraction procedure. One component of CNN architecture, the activation layer, can prevent vanishing gradients and speed up the convergence process during training [19]. As an activation function, ReLu will swap out negative pixel outputs for zeros without touching the original pixel values [20]. The corresponding mathematical expressions are as follows:

$$ReLu = max\,(y, 0) \quad (3)$$

A new image will be created that is shown in Fig. 6 by plugging the above algorithm into the convolutional layer's output.

Fig. 6. Visibility of the Activation Layer.

Most of the pixels in the final image produced by the above activation are zero, and hence the image is predominantly black. It will shed lighter on the characteristics and make it easier to calculate data for use in either training or testing. Using a pooling layer as the last stage in feature extraction. The pooling layer is the final stage of feature extraction, and its job is to select the most informative aspects of the activation function at the output layer [21]. It aims to simplify features and accelerate computing time. The challenge is to implement the equation to do down sampling on each pixel of the image:

$$Pooling = max(y, 0) \qquad (4)$$

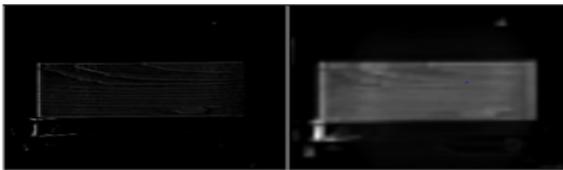
Feature clarity can be achieved using the down sampling method, as seen in Fig. 7. Reduce the size of individual pixels to reduce the time needed to classify data in the fully linked layer. The Fully Connected Layer is a Multilayer Perceptron (MLP) that makes use of the softmax activation function.


Fig. 7. Visualization of Pooling Layer.

b) Training Process: In this stage, the final probability is computed using the extracted feature. Fully connected layer is an MLP that uses the softmax activation function. It is the responsibility of this layer to take the extracted feature and process it so that the final probability is obtained. This layer also does categorization by selecting the weighted product of the highest value of the flattened results. Using the following simple equation, weight values will be refined until the fewest losses are incurred:

$$W'^l_{n,m} = W^l_{n,m} - \eta \frac{\partial L}{\partial W^l_{n,m}} \qquad (5)$$

As such, a loss value of zero represents the best possible categorization likelihood. As used here, "weight" refers to a property of the objects being categorized. Once losses are zero, the following computation will be used to discontinue updating weight:

$$Loss\ Function = \sum_{k=1}^{n}(Y - \overline{Y})^2 \qquad (6)$$

c) Classification Process: For the record, the multiclass system relies on the Softmax Classifier Function to properly label each class before making a final prediction. One type of function activation is the Softmax classifier. In a multiclass classification problem, the softmax function must be used in the output layer [22]. It's utilized in MLP, and its values range from zero to one, with the overall probability adding up to one [23]. It is undoubtedly essential to evaluate a class prediction

on a machine-learning model because, with a softmax classifier, users will quickly know the level of confidence in the system to make predictions [24]. Sometimes the system predicts classes correctly with a confidence level below 50%, while the system predicts wood classes correctly with a confidence level above 50%. Every chance of a multiclass event occurring with a value of one is expressed in the following equation.

$$fj(y) = \frac{e^{y_i}}{\sum_k e^{y_k}} \qquad (7)$$

For each jth member in the class output vector, the function's result is displayed using the fj notation. For classification purposes, the training model provides the hypothesis y as the argument to the Softmax function.

2) Support Vector Machine (SVM) Method

a) Pre-Processing: During the SVM classification procedure, the acquired image will be converted to grayscale and scaled to 427 x 240 pixels. Several tests utilizing three image sizes, including the original size of 1280 x 720 pixels, 640 x 360 pixels, 427 x 240 pixels, and 320 x 180 pixels, are required. The results demonstrated that the 427 x 240 pixels have an accuracy of 100 percent and a computation time of 3.08 seconds. After determining the optimal size for image capture, the photographs will be converted to grayscale. The straightforward equation for converting RGB to grayscale is as follows [25], [26]:

$$Gray = (Red * 0.3 + Green * 0.59 + Blue * 0.11) \qquad (8)$$

With this equation, the image could be transformed into grayscale (see Fig. 8):

Fig. 8. Grayscale Conversion Image.

b) Feature Extraction: HOG features are the next step. Here, we apply 1-D centering to determine the point of the discrete derivative mask in the x and y directions to compute the gradient value [24] (see Eq. 9 and 10).

$$L_x(r, c) = l(r, c + 1) - l(r, c - 1) \qquad (9)$$

$$L_y(r, c) = l(r, c + 1) - l(r, c - 1) \qquad (10)$$

The equation for the gradient's magnitude is as follows:

$$\mu = \sqrt{lx^2 + ly^2} \qquad (11)$$

Furthermore, gradient orientation is given by:

$$\theta = \tan^{-1} \frac{ly^2}{lx^2} \qquad (12)$$

Bin grouping based on spatial orientation is the next step. The goal of this procedure is totally votes and provide a histogram of cellular activity. To determine the image's overall orientation, each pixel will be assigned to the nearest bin between 0 and 180 degrees. As a next step, the HOG descriptor is used to convert the cellular and histogram data to a vector

space normalization. Using the L2-Hys norm, the block normalization is carried out as follows as the final step:

$$b = \frac{b}{\sqrt{|b|^2 + \varepsilon^2}} \qquad (13)$$

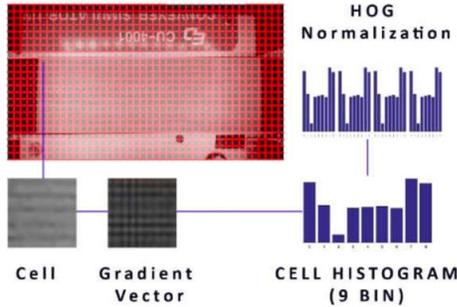
The limit of renormalization is b = 0.2. The Feature used to implement this HOG is depicted in Fig. 9.


Fig. 9.   Feature Process of HOG to Identify the Wood.

For this experiment, we will partition the detection window of 427 × 240 pixels into 966 chunks, 42 in width and 23 in height. There are four cells in each block, and each cell's histogram has 36 values spread out across nine bins. This increases the total size of the vector to 42 blocks across by 15 blocks vertically by 4 cells/block by 9 bins/histogram, or 22,680 values. The *.csv file format can take this final vector as input.

c) Classification Process

As a final stage, we employ a Support Vector Machine. The goal of this process is to assign a category to each photograph. In addition, SVMs enhance the picture of each class by employing hyperplanes or discriminatory boundaries. The margin at the maximal hyperplane point is used to choose the optimal hyperplane. We can express the linear classification hyperplane as [27]:

$$f_{svm}(x) = \sum i \in N a_i y_i K(x_i, x) + b \qquad (14)$$

$$class = \begin{cases} 1, & f_{svm}(x) \geq 0 \\ -1, & others \end{cases} \qquad (15)$$

C. Indicator System

This section is the last working state of the system that will be created, where the Command that comes from the classification results becomes an input to the microcontroller to function the installed plant, namely the indicator lights with five different colors.

The flowchart above in Fig. 10 shows the last working state in the wood classification system starting from receiving commands sent from the server by the serial communication method to the microcontroller, which will give the state high to each lamp with a relay intermediary. When the prediction results state that the test wood is class A wood, the server will give an Arduino command with the serial communication method to contact the relay so that it becomes NC and makes the red light turn on. Likewise, on the results of other conditions, a similar process will be carried out according to

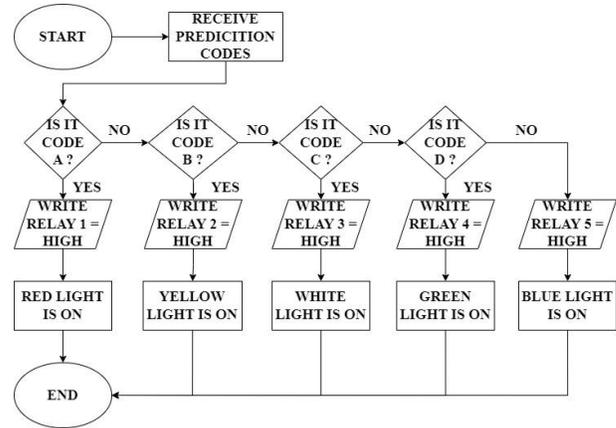
the predicted wood class— LED lights are employed as the indicator and will light up in response to data from the server. Signals will be transmitted via serial communication to an Arduino that will then activate relays and LED lights as expected. Signals that are transmitted as coded signals based on the classification of the wood, with the following stipulations: Light color codes: "A" for red, "B" for yellow, "C" for white, "D" for green, and "E" for blue.


Fig. 10.   Flowchart of Indicator System.

IV.   RESULT AND DISCUSSION

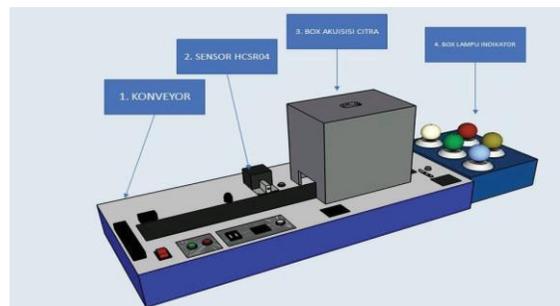
The algorithm utilized by the cedarwood classification system is a CNN and SVM written in Python with the Open CV library. Up to 50 boards of the cedarwood utilized as testing material were examined. The dimensions of the wood for classes A, B, and D are 18.3x6.2x0.45 cm, while the measurements for classes C and E are 18.3x7.6x0.45 cm. The cedarwood training dataset reached 2,830 instances due to data enhancement using a condition that involves rotating through 180 degrees and flipping under the conveyor condition. This section provides an overview of the system. Fig. 11 is the overall design of the system that implemented. The system consists of nine pieces of hardware use like conveyors, ultrasonic sensors, laptop that use for server, Arduino uno, image acquisition boxes, webcams, led strips, indicator lights, and 8 channel of relays.


Fig. 11.   Integrated System with Plant.

A. Observation of Data Distribution Effect Result

Observation of data distribution is done to find the most optimal model when the training process on the computer occurs. The augmented dataset is divided into four distribution variations which are illustrated in Table II.

TABLE II.   DATA DISTRIBUTION VARIATIONS

Data Distribution	Training Data	Test Data	Total Datasets
60 : 40	1710	1140	2850
70 : 30	1995	855	2850
80 : 20	2280	570	2850
90 : 10	2565	285	2850

The goal of the data distribution experiment is to evaluate the system's performance in terms of the distribution of the input data using wood from datasets that were chosen at random depending on each class, the experiment was run 20 times, ten times from the front view and ten times from the back perspective, with the following findings from both CNN and SVM.

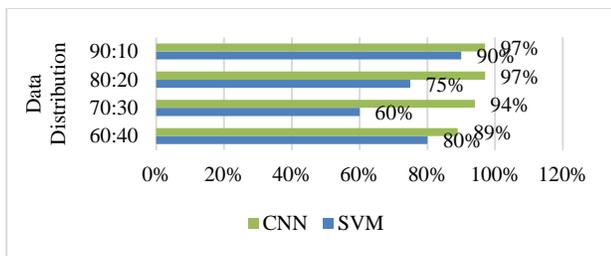
The experiment result shown in Fig. 12 shows that the 90:10 dataset experiment is the best accuracy in both SVM and CNN methods. It indicates that as the proportion of training data increases, the system will generalize more object attributes of each class, also data variability is more important than the testing data, and identification will be better when the training dataset is more significant than the testing data. So, the 90:10 dataset will be used as the parameter for the next following experiment of both methods.


Fig. 12. Data Distribution Experiment Result.

B. Experimental Result of System using SVM Method

There are three experiments carried out to know the system's performance using the SVM method:

- The test angle for the camera position.
- The parameters for the HoG test.
- The parameters for the SVM test.

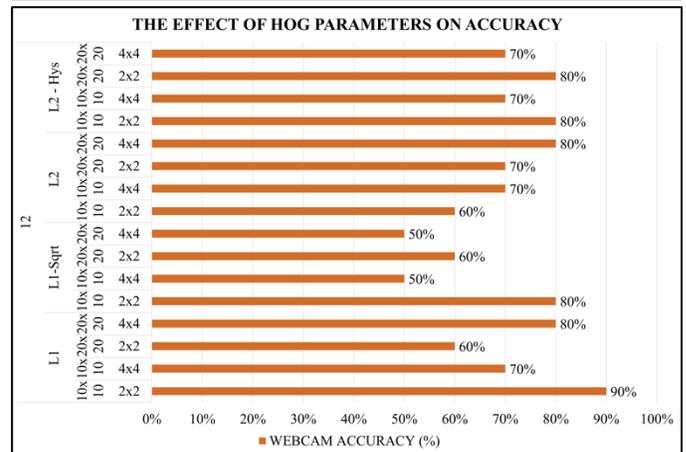
The first experiment involves changing the angle of the camera position test. The goal of this experiment was to find the best camera angle for this system. On the camera's surface, five angle sites will be established: Five degrees to the right, ten degrees to the right, zero degrees, five degrees to the left, and ten degrees to the left. As a result, the findings are shown in Table III.

Table III demonstrates that a 90 percent success rate can be attained with a camera positioned at a zero-degree angle. Similarly, time computation is important but not always a constrained-range issue. The conveyor belt serves as the background for the training dataset consisting of wood fibers. It will be impacted by the system for it to detect the things. Predicated on the work of Sahki et al. [28], His article concerning HOG-based Fast person detection utilized a two-folder training database from the INRIA pedestrian database.

Each folder contains both "post" and "neg" photos. Negative training or test photos, such as a park, ocean, cityscape, etc., are included in the neg post, while the positive training or test photographs centered on a person with their left-right reflections are included in the post. These conditions may facilitate recognition of the object in a different position inside the image. It might be concluded that 0 degrees Celsius will be employed in this experiment.

TABLE III.   OVERALL RESULT OF ANGLE CAMERA EXPERIMENT

	Right Side		0°	Left Side	
	+10°	+5°		+5°	+10°
Accuracy	0	30	90	40	10
Duration (s)	1.61	1.45	1.58	1.61	1.61

The second experiment is a test of HOG parameters to determine the optimal orientation, block norm, pixel/pixel, and block/pixel parameters. Fig. 13 and 14 depict the outcome of the experiment involving the modification of each HOG indicator. There are several methods for computing precision and time. The ideal parameter for this test is 100% with a computation length of 2 seconds, pixel/cell 10 x 10, and cell block 2 x 2. The cells/block indicator shows that each 2x2 is more essential than a 4 x 4. That data points to a 2 x 2 layout being preferable to a 4 x 4 one in this system. This result is shown in Fig. 13.


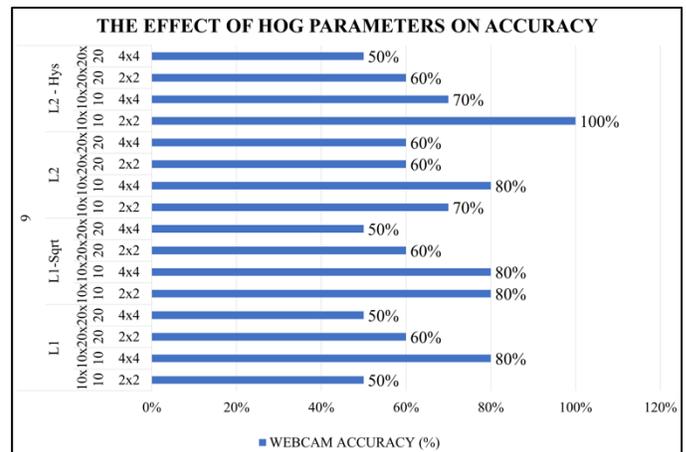


Fig. 13. The Accuracy Rate of HOG Feature (%).

In addition, for the pixel-per-pixel indicator, 10x10 is superior to 20 x 20, indicating that the gradient produces greater detail and precision. In addition, the Block value prevents images from having excessive brightness and contrast. This technique is ideal for controlling cells per 2-by-2 block and pixels every 10-by-10 pixel. Next, the indicator for the block norm has a variable value; it has not yet been affected. Block normalization minimizes brightness and contrast variations in an image depending on neighboring gradient cells. By dividing each vector element by its vector length, it aims to preserve the image's luminance and contrast [29]. The result is shown in Fig. 14.

Last is orientation; the average accuracy of the nine orientation values is 66% for a total of nine values. It indicates that the accuracy is less than 12 orientations. The 12 orientation value has an average performance of 70%. Therefore, if the system employs a greater orientation value, the optimum analysis for picture detail and gradient value will be compromised. It is possible to determine that orientation 9, block norm L2-Hys, pixel/cell 10 x 10, and cell block 2 x 2 are optimal for this system and provide the highest performance rate.

kernel type parameters. The outcome of this experiment is depicted in Fig. 15 and 16.

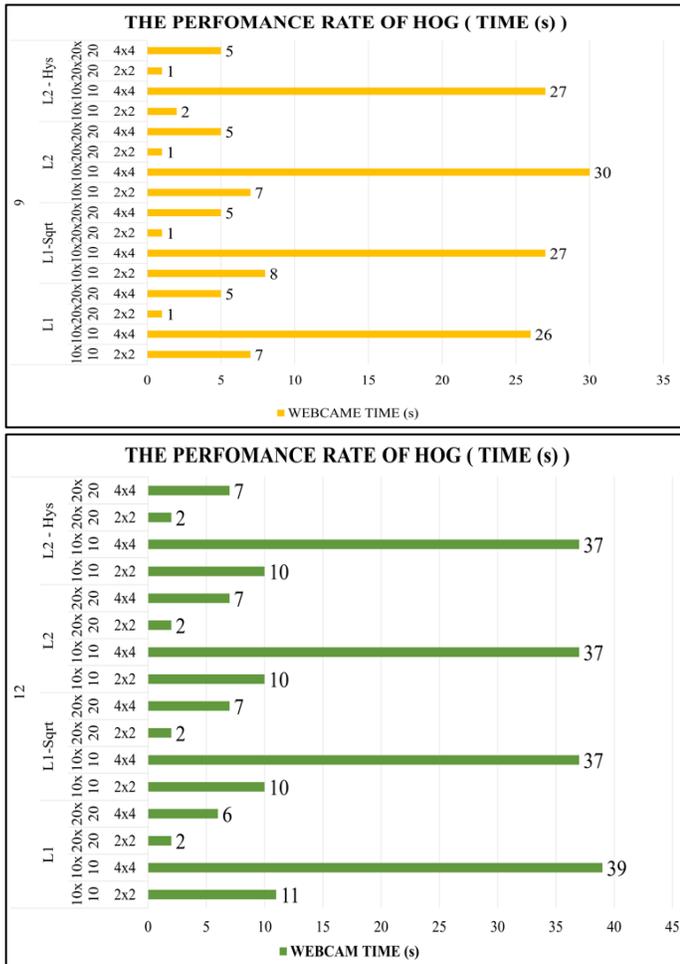
Fig. 15 and 16 shows that the linear kernel with a one-versus-rest multiclass produced the best performance rate at 1.40 seconds for 90% accuracy. One-to-one accuracy in the radial basis function kernel resulted in the least accurate solution. The highest accuracy can be achieved in this system by using a linear kernel. Due to the database creation process, the image array will become flatter. This implies that the data from each column-major column of the picture array has been moved to a single row or flattened into a 1-D iterator through the array. This database has been converted to text format, with column one indicating the categorization type and columns two through the end carrying picture codes. The soft margin cost function is controlled by a parameter called C or gamma, which controls the effect of each support vector. This process involves trading error penalty for stability. Text-classification-appropriate kernels include linear kernels. Radial Basis Function (RBF) is a nonlinear sample on a higher-dimensional space. In contrast to the linear kernel, it can handle situations when the relationship between class labels and attributes is nonlinear. Nonlinear kernels, such as a polynomial kernel, offer advantages over linear and RBF kernels in terms of speed and accuracy. Since the best performance rate and time for the C = 1 condition using multiclass OVR and a linear kernel are 90% and 1.40 seconds, respectively, this suggests that a linear kernel could be used in this situation.


Fig. 14. Time Computation Rate of HOG Feature (s)

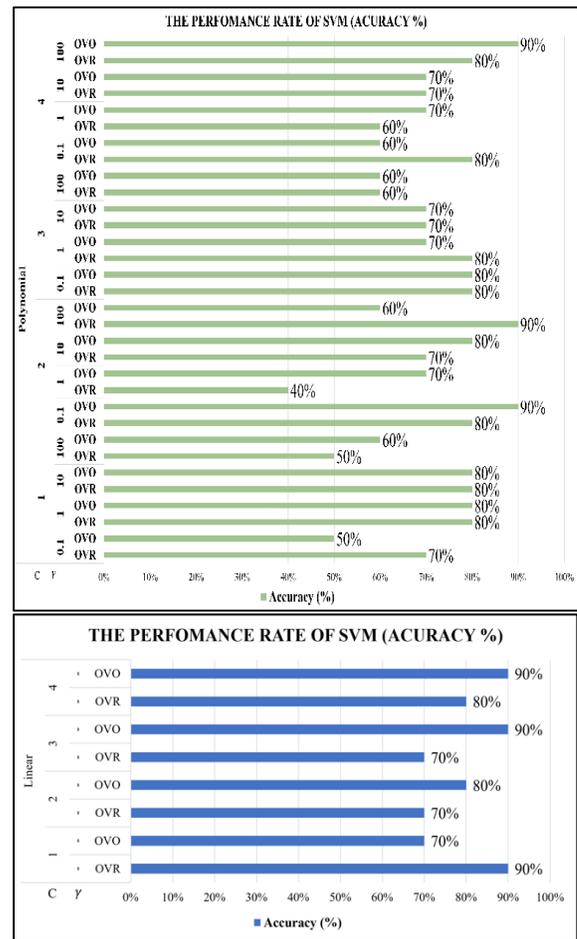
In this section, the objective of the third experiment is to determine the multiclass type, gamma, and c value, optimal


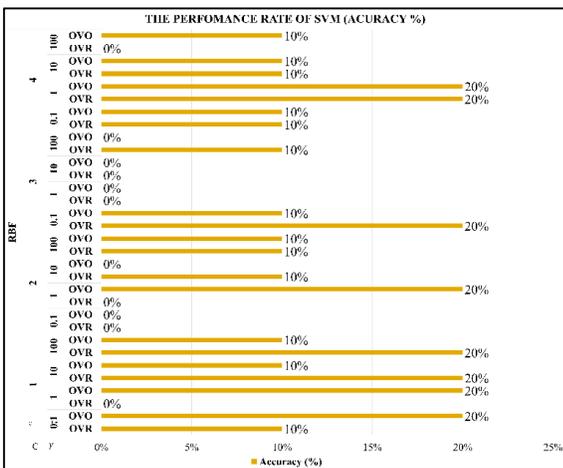


Fig. 15. The Accuracy Rate of SVM (%).
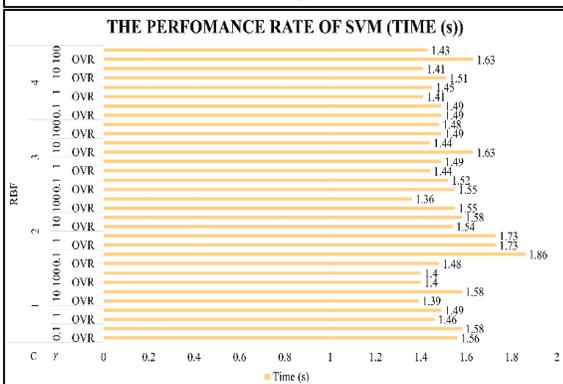

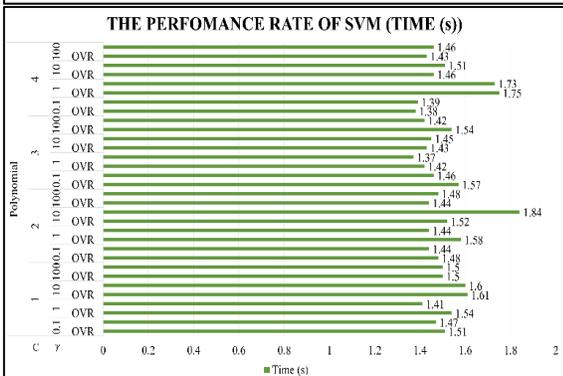

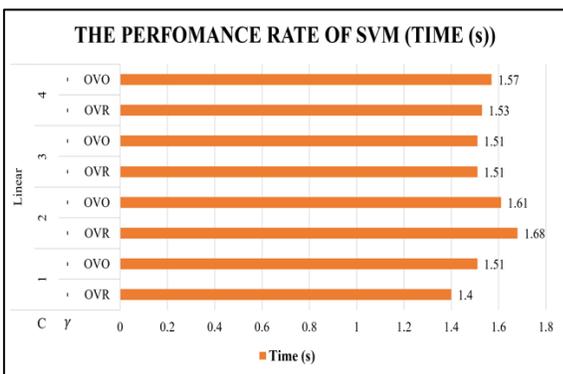

Fig. 16. The Time Computation Rate of SVM (s).

C. *Experimental Result of CNN Method*

To evaluate the performance of the wood classification system using the CNN method training parameter test, which includes observations on number of epochs, batch size, learning rate, and optimizer the CNN training parameter test trials must be conducted. The following Table IV is a scan of CNN algorithm parameter observations.

TABLE IV. CNN TRAINING PARAMETERS

No	CNN Training Parameters			
	Learning Rate	Batch Size	Epoch	Optimizer
1	0.001	8	1	Adam
2	0.0001	16	5	Rmsprop
3	0.00001	32	10	Adagrad
4	0.000001	64	15	SGD

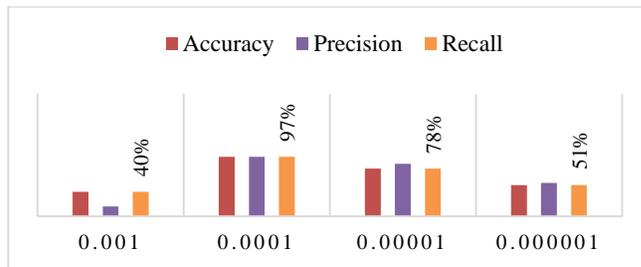
The experiments will be conducted by modifying the Table III parameters. The subsequent experiment evaluates the learning rate as a CNN training parameter. The goal is to measure how quickly the system converges on the global minimum point, where performance is maximized. When the system reaches the greatest levels of accuracy, precision, and recall with variations in the learning rate of 0.000001, 0.00001, 0.0001, and 0.001, then the conditions have been met. Fig. 17 displays the outcomes of the tests.


Fig. 17. Observation of Learning Rate Effect.

Fig. 18. Optimization of the Predicted Results from each Learning Rate.

Based on Fig. 17 and 18, which depict the system's hopeful attitude toward the expected object, the system's ideal learning rate is 0.0001. A learning rate of 0.001 is deemed excessively high, as it causes the system to diverge. The alternative is that

training accuracy does not improve as quickly as with a learning rate of 0.000001 since the system cannot reach the global region of minima due to the rapid rise in weight and numerous errors throughout the rebuilding process. The system rejects the input as being too low. Therefore, the length of the step reaches the minimal global area, yielding inferior accuracy, because the iterative step for updating the weight is quite small.

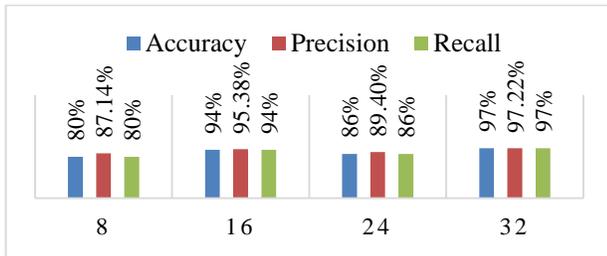
The second experiment of CNN training batch size analyzes the optimal test-time learning rate. Finding the optimal model for generalizing features and speeding the training process for wooden items is the objective. The observed batch sizes are 8, 24, and 32, as shown in Fig. 19, which depicts the experimental outcomes.


Fig. 19. Observation of Batch Size Effect.
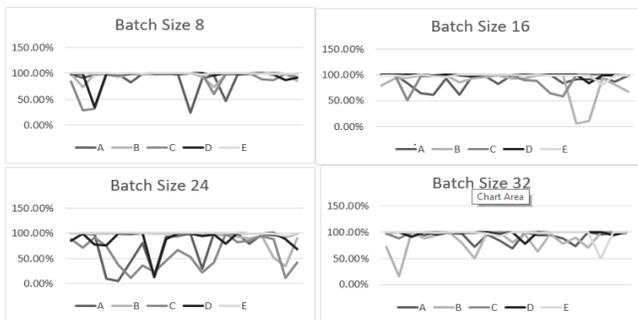

Fig. 20. Optimization of the Predicted Results from each Batch Size.

According to Fig. 19 and 20, the best batch size for a learning rate of 0.0001 is 32. A batch size that is too big can reduce accuracy since changing the weight per batch can result in errors. However, if the batch size is too small, the lengthy training period and system workload will increase. For this reason, it is absolutely necessary to adjust the learning rate parameters in accordance with the batch size in order to obtain precision and the optimum amount of training time [30].

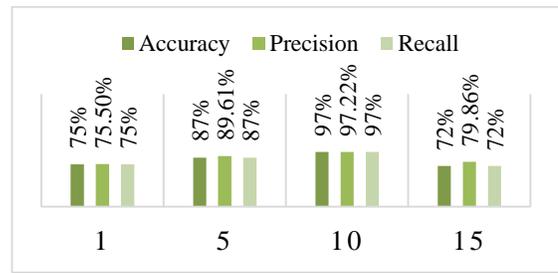
Considering the best parameters from previous experiments, the number of epochs is the subject of the third experiment of CNN training parameters. This test is designed to identify the system with the best performance, one that is neither underfitted nor overfitted. 1, 5, 10, and 15 epochs are utilized, with the performance characteristics depicted in Fig. 21.


Fig. 21. Observation of Epoch Effect.

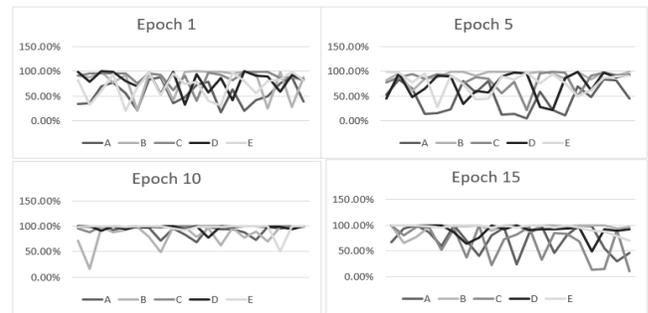
Experimentally, training with ten epochs yields the best performance as it can see in Fig. 22. A training cycle for all datasets is one epoch. Too few epochs will induce underfitting in the model we are training, hence the resultant accuracy is typically subpar. In contrast, if there are too many epochs, the training model may become overfit. Consequently, the system is less capable of generalizing the characteristics of the first new timber system site.


Fig. 22. Optimization of the Predicted Results from each Epoch.

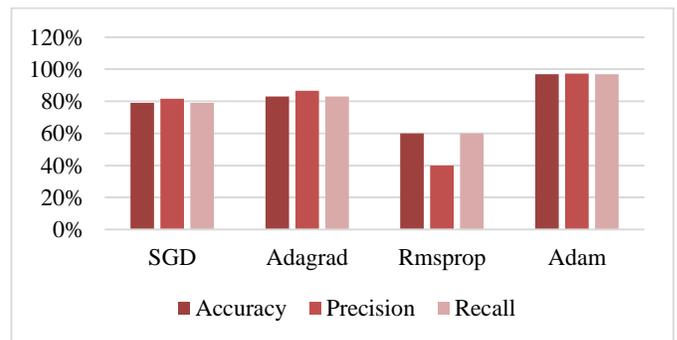
The fourth CNN training parameter is the optimizer, which requires consideration of the preceding three experiment parameters. The optimizer is intimately connected to the system's ability to lower the value of losses and find the most effective actions to reach the global lowest point. The observed optimizer algorithms are SGD, adagrad, rmsprop, and adam, with test results depicted in the Fig. 23.


Fig. 23. Observation of Optimizer Effect.
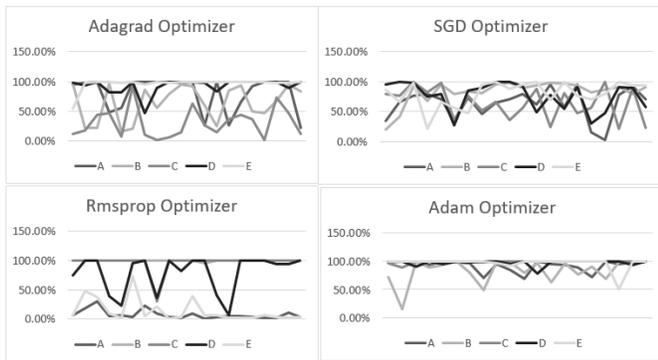

Fig. 24. Optimization of the Predicted Results from each Optimizers.

Based on Fig. 23 and 24, Adam Optimizer provides the most ideal performance. Adam is the most recent optimizer based on the notion of integrating SGD with momentum and rmsprop to tune the learning rate for each system network weight.

V. CONCLUSION

In conclusion, this research shows that a cedarwood classification system based on the CNN and SVM approach correctly recognized five wood classes using the features listed in Table I. SVM's classification output revealed that this system's performance rate is 90%, with a computation time of 1.40 seconds. The value derived from the experiment using the difference in the data set consists of 90% training data and 10% test data. In addition, the camera's angular position is 0°. Utilizing a linear kernel and one-versus-rest multiclass, the SVM classifier used in this study was useful. This condition easily categorizes and identifies the texture and fiber pattern of cedar. In contrast, the CNN improved the system's performance to 97% accuracy with an average computation time of 0.5472s. The value is calculated by comparing training and testing data distributions of 90:10, CNN training parameters of 0.0001, batch size of 32, epoch of 10, adaptive moment estimate as an optimizer and 723 lux of light intensity. It reveals that CNN is a significantly more effective method for image classification than SVM classification utilizing the HOG Feature.

Abstract—**Due to the advancement and easy accessibility to computer and internet technology, network security has become vulnerable to hacker threats. Ransomware is a frequently used malware in cyber-attacks to trick the victim users to expose sensitive and private information to the attackers. Consequently, victims may not be able to access their data any longer until they pay a ransom for stolen files or data. Different methods have been introduced to overcome these issues. It is evident through an extensive literature review that some lexical features are not always sufficient to detect categories of malicious URLs. This paper proposes a model to detect Ransomware using machine and deep learning approaches. This model was introduced as a novel feature for classification using the idea that starts with "https://www." This feature was not considered in the earlier papers on malicious URLs identification. In addition, this paper introduced a novel dataset that consists of 405,836 records. Two main experiments were carried out utilizing malicious URL features to defend Ransomware using the proposed dataset. Moreover, to enhance and optimize the experimental accuracy, various hyper-parameters were tested on the same dataset to define the optimal factors of every method. According to the comparative and experimental results of the applied classification techniques, the proposed model achieved the best performance at 99.8% accuracy rate for detecting malicious URLs using machine and deep learning.**

Keywords—Machine learning; ransomware; URL classification; malicious URLs; deep learning

I. INTRODUCTION

Over the past few years, the growth of ransomware has become an uncontrolled cyber problem and highly profitable criminal business. Ransomware attacks are primarily performed using malicious Uniform Resource Locators (URLs) [1]. On May 7, 2021, Colonial Pipeline [2], an American oil pipeline system that originates in Houston, Texas, suffered a ransomware cyberattack that hit computerized facilities managing the pipeline.

In response, Colonial Pipeline Company stopped all of the pipeline's operations to contain the attack. Colonial Pipeline

paid the demanded ransom (75 bitcoin or $4.4 million) within several hours after the attack. The attackers then sent Colonial Pipeline a software application to restore their network, although it was slow. This example illustrates how problematic Ransomware can be. Therefore, it becomes a necessity to know more about Ransomware [3].

There are essentially two types of ransomware: locker and crypto-ransomware. Locker ransomware works by blocking the victim from arriving at their files by denying access to computing resources, such as locking the desktop or preventing the victim from logging in and, demanding a ransom to regain access to the system. Crypto-Ransomware encrypts all data on the target system until the victim pays the ransom via the Bitcoin currency and obtains the decryption key from the hacker. Some kinds of crypto-ransomware can progressively erase files or release them to the public if the victim declines to pay the ransom on time. Recent ransomware families are essentially based on this type. It can have disastrous effects, primarily on corporate and government agencies, if they do not have a backup to restore the system to the state before the attack. Following the installs of the crypto-ransomware installs on the target system, it can noiselessly search for essential files based on their extensions and starts encrypting them. Then the ransomware will search for files on the local hard disk, the external hard disk, and in the network shares. Many crypto-ransomware users make sure that the files cannot be restored from the backup by totally deleting the backup. Usually, there are three main ways that ransomware can attack a system. They can get it infected, then takes over the files.

The first common way is through browsing the web. The malicious websites usually install the exploit kit to take over the machine and install additional malicious software such as ransomware. The other even more common way is through emails. Emails become a very demanding business tool. Email, more specifically, has two different vectors within itself. It may contain a malicious web link. That is sent within the email message that people click assuming that they are directed to a safe web page location. The second common way

in which an email can affect us is with malicious attachments sent directly in the email body. Once it opens, it can take control over the entire system. The third common way is through free software or games. Most of the free software found on the Internet is malicious software developed by hackers, disguised as legitimate software to access systems. Based on the said, it is necessary to notify the user that some URLs direct users to a malicious website before accessing it. Though numerous cybersecurity techniques defences are developed against Ransomware URLs, the nature of the security still requires further research to improve the entire system. As a remedial response to Ransomware threats, the present paper proposes a model to detect and track malicious URLs using machine learning classifiers and deep learning approaches. To enhance and secure the efficiency of our model, a novel dataset called Ransomware Detection Dataset (RDD) has been introduced. RDD is available for the public on the git hub website [4].

The proposed model achieved a high performance in terms of accuracy using both MCLs and DL, securing 99% and 99% respectively. In addition, through the discussion and analysis of numerous identity algorithms, malicious URLs detection systems were used to identify different forms of known phishing and to examine the appearance of dangerous URLs in websites.

The contribution of this paper can be briefed as follows:

- Proposed a model to detect and track malicious URLs using machine and deep learning approaches.

- Proposed a new feature used in identifying malicious and benign classification using the idea starting with "https://www.

- Introduced a novel dataset containing 405,836 rows of a URL to classify webpages as Malicious or Benign called Ransomware Detection Dataset (RDD) [4]

- Compared performance of the proposed model with that of MLCs and DL approaches.

- Proposed detection algorithms that enhance accuracy in classifying malicious and benign website applications via optimizing URL features and selecting optimal factors for every method.

- Examine three loss functions (Binary Crossentropy,Hinge, and Mean Squared Error respectively) on the RDD using three optimizers (Adam,SGD, and ADAgard).

The rest of this paper is structured as follows: Section II has to do with a brief review of related works; Section III describes the research approach, feature extraction and classifications algorithms; methods and materials will be explained in Section IV; experiments, results and discussion will be presented in Section V; Section VI concludes the paper and provides suggestions for future work.

II. RELATED WORK

To improve accuracy and faster detection, numerous methods have been introduced for malicious URLs detection.

Recently, research has shown that many detection methods can resist the increasingly diverse hackering threats. Popular techniques used for malicious URL detection are machine learning/deep learning-based detection, blacklist-based detection and, heuristic rules-based detection. Blacklist based approach utilizes a massive list of malicious URLs that can be created from numerous sources manually or programmatically. Many commercial products build blacklists utilizing user proprietary and their feedbacks mechanisms to detect malicious URLs [5] and [6], like WOT Web of Trust [7], McAfee's SiteAdvisor [8], Cisco IronPort Web Reputation [9], and Trend Micro Web Reputation Query Online System [10]. On the other hand, diverse websites supply blacklist applications, such as: PhishTank [11], jwSpamSpy [12] and DNS-BH [13]. Although blacklist technique gives faster and low false positive detection, it has some drawbacks. The newly generated malicious URLs are not detected, so the database of blacklisted URL requires timely and frequent updates. As the result, researchers using the heuristic rule-based detection method to overcome this issue, in which generalized rules are used for malicious URL detection. These rules are based on features extracted from the datasets [14]. The limitations of this method are the mapping of weightage to the rules and, the threshold value may be modified based on datasets, it becomes unclear how to fix threshold value for each rule [15].

Later, the machine learning approach has been used in several methods to classify malicious URLs. It operates on two stages: first, extraction of the dataset features and training the model; then, training is used for testing. The best advantage of this technique is that the generated model can automatically assign the weightage of selected features and detect the malicious URL, including newly generated malicious URLs. A survey on malicious URL recognition via machine learning was presented by Doyen et al. in [16]. It scans the cons and pros of various methods used in malicious URLs Authors Suppressed Due to Excessive Length identification literature. Practically, the features utilized in machine learning approach are classified into four broad categories: host-based features, popularity features, content-based features and lexical features. Author in [17] presented a multiclass classification method to identify the malicious URL. It considers 18 hos-based features, 34 content related features and 63 lexical features. Recently, Djaballah et al. [18] presented a new work to recognize the malicious URL in social network such as twitter. In that work, three machine-learning techniques were used namely Random forest, SVM and Logistic Regression for the experiments, giving 5.51%, 93.43% and 90.28% accuracy rate respectively. In [19], the researchers suggested a technique for malicious website detection which utilizes various feature selection methods and diverse machine learning techniques with PCA such as RF, NN, bagging, KNN, NB, and SVM were used for experiments. In [20], the authors presented a method of choosing the optimal features using Chi-Square and ANOVA F-value to detect phish URL. The light weighted technique that uses only a fewer number of lexical features for malicious URL detection was introduced in [14].

III. PROPOSED APPROACH

This paper aims to explore how a URL is identified as malicious or benign by using only its associated URLs lexical features quickly and accurately. This work works on build a URL classifier to predict whether a URL is malicious or benign with a very high degree of recall and precision. When the user sends a DNS (Domain Name System) request, it will be sent first to our URL classifier. If the URL is Benign, then the DNS request will be sent to the DNS server. And in case the URL is malicious, then DNS requests will be dropped and not forwarded to the DNS server.

IV. METHODS AND MATERIALS

This section presents the methods and phases of the proposed model. There are four phases in the presented detection architecture. They are data collection, feature extraction, classification, and model evaluation as shown in Fig. 1.

A. Data Collection

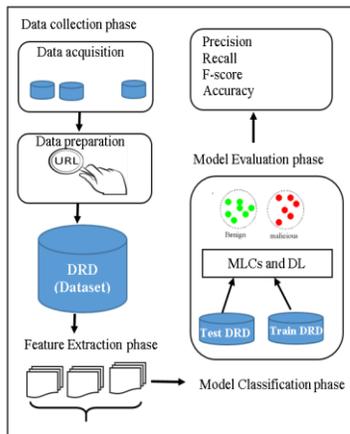
This is the input phase on the mode. Processing and preparing datasets are critical stages. However, getting sizeable balanced data is one of the potential challenges. The efficiency and performance of the system essentially depend on them. The importance of this issue appears when the model deals with imbalanced data that will cause a bias towards predicting the larger class, and on the other hand, may ignore the smaller class altogether. Therefore, one of the challenges that this work is handling a sizeable balanced dataset. Consequently, the dataset was collected from six different Kaggle resources [21, 22, 23, 24, 25] to create an extensive balanced dataset. This effort acquired a total of 405,836 URLs, 202918 benign and 202918 malicious. At the end of this phase, the dataset has been built.


Fig. 1.   Model Architecture.

B. Features Extraction

This is the second phase of the model. It receives input from the first phase. The reliable and discriminative feature is significant for achieving high-performance machine learning classification. The criteria of attributes are essential to present the crucial characteristics of the malicious URL. It should be noted that in the Feature extraction phase, there are three main steps: the length of the feature, count feature, and binary

feature. These steps are performed using the work developed in the open-source code, which Siddharth Kumar provides in [23]. The output of this phase is the features extracted from the URLs. These features are used in the next phase which is classification.

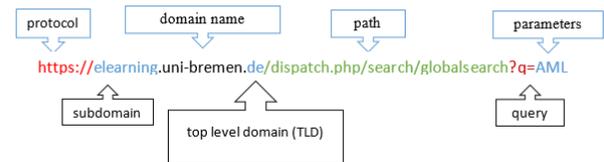
What is a URL? To understand attackers' strategy, firstly, the reader must know the basic components of a URL. The basic structure of a URL is depicted in a URL is typically made up of six or seven components. First is the Protocol, which is used to access resources on the Internet. It could be Hypertext Transfer Protocol Secure (HTTPS) or the less secured HTTP. The other components are subdomain, domain name, top-level domain, path, query, and parameters, as shown in Fig. 2.


Fig. 2.   URLs Components.

Features Score Initially, this work specified 17 most common lexical features. Since all extracted features are not always suitable for classification, the quality and effectiveness of each lexical feature was examined by testing and training the classifier with each feature group separately. The results are illustrated in Table I.

TABLE I.   FEATURES SCORE

Feature	Score	Feature	Score
Start with https://www	0.9978527	count=	0.546040
count-https	0.980527	count?	0.545931
count-www	0.924533	path length	0.516274
ld length	0.723060	use of ip	0.513758
hostname length	0.681407	count-digits	0.510565
count-http	0.666719	count@	0.510015
count.	0.605214	count%	0.498175
count dir	0.552626	fd length	0.484810
count-	0.549475	count-letters	0.473917

A compelling feature selection will enhance the classifier ability of the model with low computational complexity that reduces the storage consumption and execution time.

Ranking analysis help to find the optimal feature. The effect of prominent features on recognizing accuracy will be addressed in the following:

- Counting HTTPS The first and most crucial feature found was the count-https. The count of HTTPS was calculated in all URLs in the dataset. It has been observed that all benign URLs (202918) use the HTTPS protocols. On the other side, most of the malicious URLs (195014) do not use HTTPS protocols, making this feature one of the best features for training our classifier.

- Counting www The second most essential feature is count-www in which the frequency of www was

counted in all URLs in the dataset. It has been observed that almost all benign URLs (202739) use www whereas most of the Malicious URLs (172290) do not have www.

- Start with https://www Counting https is an essential feature since most malicious URLs do not use HTTPS. However, the problem with this feature in previous work is that it just counts how much time it acquires. It does not take into account the location of the HTTPS. While testing, it was noticed that the result got many false positives because many malicious URLs used HTTPS in the middle of the URL. To solve this problem, this research introduced a new feature called Start with https://www. It is a binary feature that returns one if the URL starts with https://www. And returns zero otherwise. This feature will enhance the classifier ability of the model (i.e., reach an accuracy of 99.78%) with low computational complexity that reduces the storage consumption and execution time. This feature is newly selected and extracted in this paper.

To represent URLs detection issues mathematically. Let us define a function space [26, 27] as:

$$F : u \rightarrow \{0, 1\}$$

Where u represent the URLs. Note that the function is assumed to take values in {0, 1}. Meanwhile, g(u) represents the values of every feature.

$$(F \circ g)(u) = F(g(u)) = F([f1, f2, \dots, f19])$$

$$= \{1\ malicious\ \ 0\ Benign\ \}$$

where g(u) has three operations $\{counting\ compute length\ Boolean\ \}$ and [f1, f2, ..., f19] represents the value of every features.

C. Classification Process

In the third phase, the classification process is carried out by using the most common MLCs and DL approaches used scholarly [28, 29]. In MCLs, the most common classifiers used are the Random Forest, Gradient Boosting Classifier, Neural Net,poly SVM, Decision Tree, AdaBoost, Nearest Neighbors, Stochastic Gradient Descent (SGD), Naive Bayes, and QDA. The general overview of the machine learning classification process is shown in Fig. 3. In deep learning models architecture as shown in Fig. 4, two deep neural networks ANN and LSTM mode are applied. In both experiments, the dataset is divided 30% for training and 70% for testing.

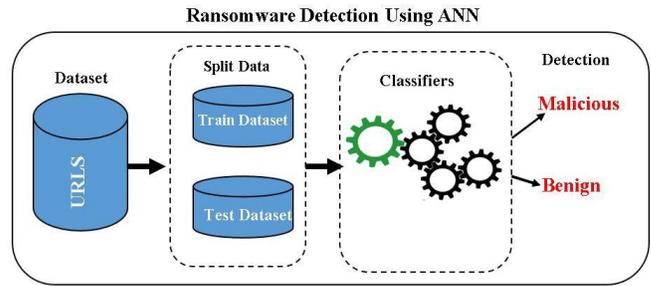
The model performance has been evaluated based on the most common methods using a confusion matrix. For all experiments, the unified performance indicators such as accuracy, precision, recall, and F1 were used to evaluate the performance of the model as represented in the following mathematical formula.


Fig. 3. Overview of Machine Learning Classification Process.
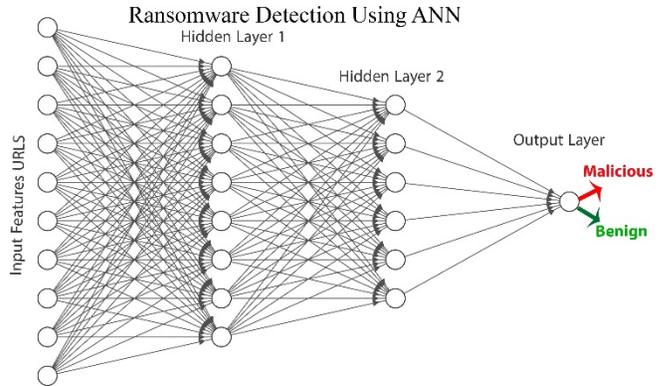

Fig. 4. Deep Neural Networks Architecture.

D. Model Evaluation

The model evaluation has been used in the most popular accuracy measure called confusion matrix to calculate accuracy, precision, recall and, the F1 Score that use in [30].

- Accuracy: measures how much of the data are labeled correctly

$$Accuracy = \frac{T\ P\ + T\ N}{T\ P\ + T\ N + F\ P\ + F\ N}$$

- Precision (specificity): it estimates how many identified targets are indeed relevant (real targets)

$$Specificity = \frac{T\ P}{T\ P\ + F\ P} = \frac{true\ positive}{no.\ of\ predicted\ positive}$$

- Recall (Sensitivity): it measures how good it is at identifying the positive cases.

$$Sensitivity = \frac{T\ P}{T\ P\ + F\ N} = \frac{true\ positive}{no.\ of\ actual\ positive}$$

- F1 Score: F1 is the function of Precision and Recall.

$$F1 = 2\ x\ \frac{Precision\ x\ Recall}{Precision\ +\ Recall}$$

V. RESULTS AND DISCUSSION

This section discusses the experimental results of the proposed model which were used to detect malicious URLs. These experiments are categorized according to their processing architecture; the machine learning experiments and deep learning approach experiments.

A. Machine Learning Experiments

This section presents and demonstrates the results of the experiments of most popular classifiers used in our model [28, 29]. The experiments evaluated in this section used a confusion matrix to show the detection performance of the models. After creating the large balance dataset and extracting features, the implementation of the model is completed in two stages. In the first stage, all the features were used to train the models. In the second stage, we tested the adoption of the presented model with new lexical feature, namely, Start with https://www. This feature enhanced the classifier ability of the model (i.e., reaching an accuracy of 99.78%) with low computational complexity that reduced storage consumption and execution time. For all experiments, 75% of the dataset was utilized for training and 25% for testing. It should be noted that for Preprocessing, Classification, Dimensional reduction, Model selection, and evaluation Scikit-learn (sklearn) library has been used. To find the best parameter values, the GridSearchCV, provided by sklearn, has been used. The results of the experiments are shown in Tables I and II.

TABLE II. EVALUATION METRICS

Sr. No.	Classification Algorithm	Accuracy	precision	recall	f1-score
1	Random Forest	0.998115	0.9999	0.996	0.9981
2	GradientBoosting Classifier	0.99809	0.9997	0.997	0.9981
3	Neural Net	0.997967	0.9996	0.996	0.998
4	poly SVM	0.997893	0.9997	0.996	0.9979
5	Decision Tree	0.997893	0.9996	0.996	0.9979
6	AdaBoost	0.997893	0.9998	0.996	0.9979
7	Nearest Neighbors	0.997856	0.9994	0.996	0.9979
8	Stochastic Gradient Descent (SGD)	0.997647	0.9998	0.996	0.9976
9	Naive Bayes	0.995232	0.9953	0.995	0.9952
10	QDA	0.935577	0.9944	0.876	0.9316

B. Deep Learning Experiment

This section presents the results of the deep neural network experiment built on the basis of a Multi-layer Perceptron. Two Deep learning models were applied. They are an artificial neural network (ANN) and long short-term memory (LSTM). All the experiments were executed using Keras by Jupyter platform. In the ANN experiment, the model consists of five layers of one input layer, three hidden layers, and one output layer. The input layer consists of seventeen input dimensions. The features and activation function is "Relu" and the output are 256 neurons. The three hidden layers consist of 256, 128, 64 neurons, and the activation function is "Relu" with a drop out of 30%, while the output layer consists of a single layer

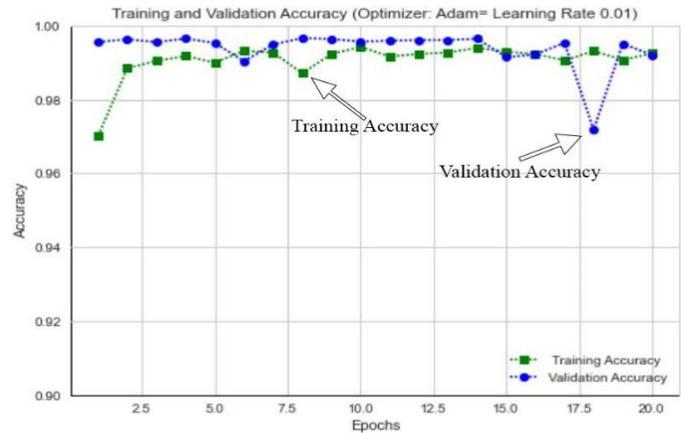
with "sigmoid" as the activation function. The loss function used in the testing stage was binary crossentropy while three optimizers were used. They are: Adam, ADAgard, and SGD in which the learning rate was recorded at 0.01, 0.001 and 0.0001. Both training and testing for the models were applied, and the dataset was divided into 70% for training, and 30% for testing utilizing Adam optimizer with the three categories of the learning rate. In training and validation, the model achieved a high-performance rate of 99.16% in terms of accuracy while for validation it achieved 98.10%. Twenty epochs were included, and the batch size was 64. The loss function noticeably decreased. The model accuracy of ANN for learning rates of 0.01, 0.001, and 0.0001 are shown in Fig. 5 to 7 for training and validation.


Fig. 5. Model Accuracy for Validation and Testing using Adam Optimizer (LR 0.01).

While loss function for testing and validation is shown in Fig. 8 to 10. The best accuracy rate has been recorded using a learning transfer of 0.0001.

Fig. 14. Loss of Validation and Testing using ADAgard Optimizer.

Fig. 15. Model Accuracy for Validation and Testing using LSTM.

In the LSTM experiment, the model consists of three layers. They are the input layer, LSTM layers, and output layer. In the input layer, the model receives a training dataset of features as an input dimension with 'Relu' activation function including 128 neurons.

In the second and third layers of LSTM, the number of neurons is 64, 32 respectively. The activation function is "Relu" for both layers. The dataset was divided into 70% for training and 30% for testing. In the training, the model reached a performance rate of 99.76% in terms of accuracy with twenty epochs using 'Adam' optimizer with a learning rate of 0.0001 and the validation reached to 99.66% is shown in Fig. 15. The loss function of validation and testing is "binary-cross entropy" which decreased with each training epoch is shown in Fig. 16.

Fig. 16. Loss of Validation and Testing using LSTM.

VI.   CONCLUSION

The study explored the possibility of distinguishing benign and malicious URLs by using machine learning classification algorithms. A new feature was proposed for classifying and identifying malicious and benign using the idea of start with https://www. Experimental results using this feature were found significant. To evaluate the proposed feature, a sizeable balanced dataset has been created with a total of 405,836 URLs, 202918 benign, and 202918 malicious. Machine learning classifiers and deep learning approaches were applied, particularly ANN and LSTM. The proposed approach

gave a high classification accuracy rate of 99.81%, and a very high degree of classification precision at 99.99%. In the future, more focused research on modeling URL detection can be made to cope with the most sophisticated cyber-attack techniques.

Evaluation of Online Teaching in the Covid Period using Learning Analytics

Jolana Gubalova

Department of Quantitative Methods and Information Systems
Faculty of Economics, Matej Bel University
Banská Bystrica, Slovakia

Abstract—**The article compares education at the Faculty of Economics Matej Bel University before the pandemic and during the coronavirus pandemic. At the same time, it tries to outline what the education will look like after this situation is over. It finds out how the situation during the corona affected the education of economists and to what extent the changes it brought will be preserved in the future. The comparison of face-to-face and distance learning in 2019 and 2020 was made. This is because teaching in 2019 was carried out in a "classic", face-to-face manner, and on the contrary, in 2020, after the closure of schools in March 2020, teaching at Matej Bel University was carried out only distance online method. To get the best possible view of the researched topic, several research methods were used: the examination of the LMS Moodle with using of various Learning Analytics tools and Questionnaire Research. The results showed that face-to-face education before the Covid pandemic and after this pandemic will no longer be the same because distance online education will also cause changes in face-to-face education in the post-pandemic period. Questionnaire research showed that up to 78% of part-time students and 61% of full-time students would like their study program to use elements of distance education in full-time study as well. Since this is a large group of students, their opinion will be considered in the future when fully returning to face-to-face teaching.**

Keywords—Distance online learning; learning management system; moodle; collaboration platform microsoft teams

I. INTRODUCTION

The COVID-19 pandemic in Slovakia is part of the global pandemic of this infectious disease. The first case was confirmed in our country on March 6, 2020. From March 16, 2020, schools were closed and at the same time a state of emergency began to apply, which lasted with smaller or larger breaks until February 22, 2022. However, the state of emergency remains in force. The pandemic caused a revolution in education at all levels of schools, including university education. It also significantly influenced the education of economists at Matej Bel University (MBU) in Banská Bystrica. Before the pandemic, it was a classic face-to-face education, which was carried out either in large lecture rooms or specialized ones, e.g., computer classrooms.

The Matej Bel Virtual University portal is available at MBU, based on the LMS Moodle, from 2012.

Moodle is a free software, a learning management system providing a platform for e-learning, and it helps the various educators considerably in conceptualizing the various courses, course structures and curriculum thus facilitating interaction with online students [19].

Teachers use LMS (Learning Management System) to publish teaching materials in courses for individual subjects and to communicate with students, but not everyone had used this occasion in the past. Various communication platforms were also sporadically used - e.g., Skype, Zoom, Google Hangouts, etc. for communication, mainly with external students. Some teachers went further and prepared multimedia teaching materials for students - e.g., video sequences with the solution of tasks in the Camtasia Studio program, which they published as part of courses in LMS Moodle or in YouTube. Therefore, after the outbreak of the pandemic and the complete transition to distance online education, they had no problem quickly adapting to the new situation, when all teaching was moved to the online space. After the state of emergency was established, every teacher had the obligation to teach online with the support of the communication platform MS Teams, which was introduced as a unified platform for the entire university according to the previously prepared schedule for face-to-face teaching [20]. They also had to publish their teaching materials for subjects in courses in LMS Moodle. Invaluable help in these difficult times was provided by the MBU Institute of Automation and Communication, which organized courses for teachers who needed to learn/improve their work with LMS Moodle and MS Teams.

The exam period also took place online with the support of LMS Moodle and MS Teams. Most of the exam dates looked like this: students logged into MS Teams, where they had a channel ready for the test and had to turn on their webcam. At the same time, they signed up for the subject course in LMS Moodle, where they had a test with tasks prepared. They downloaded file with tasks to the desktop and, after processing, uploaded them to the storage in the LMS Moodle. In addition, many tests were also prepared directly in LMS Moodle through the Test activity.

The article compares the features of face-to-face and distance online education and their suitability for university students with support of Learning Analytics tools and questionnaire research.

Learning Analytics is a research area that focuses on the use of quantitative methods in learning research in and outside of the virtual environment [2]. The first definition of Learning Analytics was published by G. Siemens (on his blog) in 2010,

which was used in a modified form at the 1st international conference focused on Learning Analytics in 2011. Learning analytics is the measurement, collection, analysis, and reporting of data about learners and their contexts, for purposes of understanding and optimizing learning and the environments in which it occurs [3].

But it's not just access to data that helps us make smarter decisions, it's the way we analyze it. That's why it's important to understand the four levels of analytics: descriptive, diagnostic, predictive and prescriptive [22].

A. Descriptive Analytics

Descriptive (also known as observation and reporting) is the most basic level of analysis. This includes compiling reports and presenting what has happened in the past.

B. Diagnostic Analytics

Diagnostic analytics is where we get to the why. We move beyond an observation and get to the "what" that is making it happen. This is where the ability to ask questions about the data and tie those questions back to objectives is most important.

C. Predictive Analytics

Predictive analytics allows to predict different decisions, test them for success, find areas of weakness, make more predictions—and so forth. This flow allows institutions to see how the first three levels can work together. Predictive analytics involves technologies like machine learning, algorithms, and artificial intelligence, which gives it power because this is where the data science comes in.

D. Prescriptive Analytics

Prescriptive analytics exist at a very advanced level and is the most powerful and final phase, and truly encompasses the "why" of analytics. It's when the data itself prescribes what should be done. Data-driven decision making is tied most closely to predictive and prescriptive analytics, even though these are the most advanced.

All four levels create the puzzle of analytics: describe, diagnose, predict, prescribe. When all four work together, we can truly succeed with a data and analytical strategy.

II. LITERATURE REVIEW

A significant number of authors are engaged in research focused on the use of LMS Moodle with various type of plug-ins to improve the quality of teaching, especially in the Covid period. A greater number of authors use Learning Analysis tools for this purpose. Their work was a springboard for our research.

M. C. S. Manzanares at al. used a module UBU Monitor in Learning Management System for monitoring and detecting students at risk of dropping out during a lockdown caused by COVID-19 [6].

R. Kuo et al. designs a Moodle plug-in that not only can visualize students' learning behavior patterns from the log but also can cluster students into different groups based on their behavior patterns. The annotations made by the teacher can be a support for researchers to further analyze and design

mechanism and algorithm to automatically recognize and identify a student's characteristics and conditions like learning styles, preferences, at-risk, and potential required assistances via the features extracted from a learning pattern and notify the teacher or administrative staff automatically [7].

Research's aim of [8] is to compare Moodle LMS usage before, during and after the first wave of COVID-19 pandemic, what resources and activities were used and what future tendencies have come from this scenario. Results show a huge growth of the LMS platform usage during the first wave and an increase afterwards, showing that teachers and students behaviors have changed, and technologies can complement traditional on premises classes, improving teaching and learning methods.

The study [9] illustrates the development of a learning analytics dashboard that can improve learning outcomes for educators and students.

The work [10] reinforces that local educational data analysis is feasible, opens new ways of analyzing data without data transfer to third parties while generating debate around the "local technologies first" approach adoption.

Learning management systems (LMSs) that incorporate hypermedia Smart Tutoring Systems and personalized student feedback can increase self-regulated learning, motivation, and effective learning. LMS with hypermedia Smart Tutoring Systems in Moodle increased the effectiveness of student learning outcomes, above all in the individual quiz-type tests. It also facilitated personalized learning and respect for the individual pace of student-learning [11].

Paper [12] presents an empirical study and related activity system analysis regarding the implementation and use of Moodle specifically, and learning management systems in general, in problem-based learning. The research involved an exploration of the characteristics that defined use of Moodle at a Danish university, the reasons why Moodle was or was not used in specific contexts and the way in which Moodle use was perceived by students. The investigation uncovered several reasons for the lack of focus on problem-based learning in Moodle structures and content and explored them through the contradictions identified within the activity systems and between the double contextual frame surrounding the interacting activity system.

Study [13] sought to determine the impact of using Moodle in teaching university courses on students' future anxiety and psychological happiness. It shows that implementing Moodle technology into teaching had a positive impact in reducing future anxiety and increasing psychological happiness among university students.

Paper [14] presents research work conducted at the University in Sri Lanka, to solve facilitate students learning in fully online and blended learning environments using Learning Analytics. The system was designed as a Moodle Plugin. As a result of the system, students could track their current progress and performance compared to the peers, which helps to improve their motivation to engage more in the course. Also, the increased engagement in the course enhances the student's self-confidence since the student can see

continuous improvement of his/her progress and performance which in turn improves the student's grades.

Qualitative case study [16] explores the perceptions and experiences of embedded experts in a global learning community that occurred over a 12-year period. The study was designed using the Online Collaborative Learning Framework developed by the authors in 2006. The goal of the study was to provide a nuanced understanding of embedded experts in online discussion that engage in real world issues related to today's diverse and digital classrooms. From the thematic analysis of the data, the following three implications emerged: Purposeful selection of technology; orientation and supports for the experts; and design of an organic environment that fosters the development of community including embedded experts.

The study [17] examines the effects of interactive and learning structures enabled by different Learning Management Systems (LMS) on satisfaction and learner engagement in online courses. An LMS can support or hinder active engagement, meaningful connections between segments of the course, easy communication, and formative feedback by making it easier or more difficult for faculty to communicate course requirements, provide open-ended feedback, and place course elements that are used together contiguous to one another.

Drawing on design experience of developing learning analytics and inducting others into its use, the article [18] presents a model that researchers have used to address five key challenges they have encountered. In developing this model, they recommend: a focus on impact on learning through augmentation of existing practice; the centrality of tasks in implementing learning analytics for impact on learning; the commensurate centrality of learning in evaluating learning analytics; inclusion of co-design approaches in implementing learning analytics across sites; and an attention to both social and technical infrastructure.

The paper [28] examines how training support and LMS readiness factors influence the capability of faculty to adopt e-learning and student perceived benefits. The results reveal that training support and LMS readiness have a positive influence on the faculty's capability to adopt e-learning, which leads to enhancing students' perceived benefits. By identifying the factors that influence e-learning adoption, universities can provide enhanced e-learning services to students and support faculty through providing adequate training and powerful e-learning platform.

III. METHODOLOGY

The comparison of face-to-face and distance online education was carried out for years 2019 and 2020. The reason was the teaching in 2019 took place "classically", face-to-face, and on the contrary, in 2020, after the schools closed on 16/03/2020, teaching continued solely online. The year 2021 was different from this point of view and there was an irregular alternation of face-to-face and distance education depending on the current pandemic situation, and therefore it is not suitable for our research.

To get the best possible view of the researched topic, we combine a few research methods:

1) The examination of the LMS Moodle (version 3.11.8) with using of Learning Analytics tools:

a) Google Analytics,

b) Data analysis from the MySQL Standard Edition Database System (Data storage of LMS Moodle),

2) Questionnaire research.

During the data processing we followed the recommendations given in the sources [1], [4], [5], [15], [23].

Google Analytics is a website traffic analysis application that provides real-time statistics and analysis of user interaction with the website. Google analytics enables website owners to analyze their visitors, with the objective of interpreting and optimizing website's performance [21]. In this research, we use Google Analytics to explore data from LMS Moodle at MBU.

By default, LMS Moodle at MBU uses the relational database system MySQL (version 8.0.29) for data storage. Given that, we planned to prepare SQL queries in MS SQL Server 2019, we first converted the data from MySQL to MS SQL Server, using the tool MS SQL Server Migration Assistant for MySQL (SSMA) [26], [27].

SQL Server Migration Assistant (SSMA) is a free supported tool from Microsoft that simplifies database migration process from MySQL to SQL Server. SSMA automates all aspects of migration including migration assessment analysis, schema and SQL statement conversion, data migration as well as migration testing. This download includes a GUI client-based application to manage migration process. A separate extension pack will install functionalities in SQL Server to emulate MySQL features not natively supported in SQL Server [24].

We have more user experience with MS SQL Server than with MySQL, which is why we are more comfortable working with it. We used the Microsoft SQL Server Management Studio graphical interface to communicate with SQL Server.

SQL Server Management Studio (SSMS) is an integrated environment for managing any SQL infrastructure. SSMS provides tools to configure, monitor, and administer instances of SQL Server and databases [25].

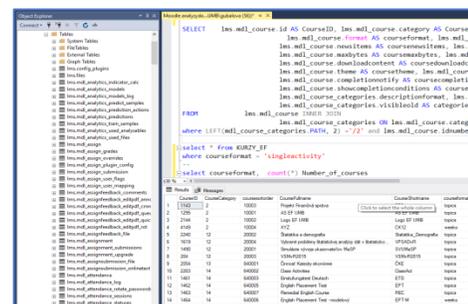
The investigated database consisted of more than 460 tables and its size was 9.36 GB and its preview is in the Fig. 1.


Fig. 1. The Moodle Database in the SSMS Tool.

IV. RESULTS AND DISCUSSION

The research of the LMS Moodle at MBU with support of Google Analytics tools shows how the number of users in LMS Moodle increased during the pandemic in 2020, compared to the previous year 2019, when "classic" face-to-face teaching was taking place.

As shown in Fig. 2, the curves had an approximately same course until March 2020. The turning point occurred on March 16, 2020, after the declaration of a state of emergency and the closing of schools, when teaching was fully moved into the online space and continued in this mode until the end of 2020.

The number of users in 2020 increased by 118.21% compared to the previous year 2019, and the number of new users increased by up to 132.08%. The number of sessions more than doubled - 210.67%. The number of sessions per user increased by 42.13%, and on the contrary, the number of exits - Bounce Rate decreased (-16.19%). The total number of displayed pages (Pageviews) increased almost 3.5 times (342.37%), while the average number of pages viewed by users during one session (Pages/Session) increased by 42.39% and the average duration of one session (Avg. Session Duration) increased by 42.13%.

The enormous increase in users results in higher hardware and software requirements for LMS and next learning-related systems to be reckoned with in similar crisis situations.

During both monitored years, users worked with LMS Moodle most often with the support of these browsers. Based on Fig. 3 we state that most sessions were made through the multi-platform Chrome browser - 69.63%. Another 10.89% of sessions were made through the Safari browser for the operating system Mac OS X and for Windows. The third in the order is the Firefox browser with a 7.88% share. It is followed by Edge with a share of 3.64%, which also has the lowest Bounce Rate - 18.13%. A slightly higher Bounce Rate have Firefox (19.27%) and Chrome (23.04%).

Browser	Acquisition			Behavior		
	Users	New Users	Sessions	Bounce Rate	Pages / Session	Avg. Session Duration
	405,354 % of Total: 100.00% (405,354)	402,380 % of Total: 100.06% (402,138)	3,274,375 % of Total: 100.00% (3,274,375)	24.02% Avg for View: 24.02% (0.00%)	8.45 Avg for View: 8.45 (0.00%)	00:07:38 Avg for View: 00:07:38 (0.00%)
1. Chrome	230,108 (56.98%)	229,388 (57.01%)	2,280,059 (69.63%)	23.04%	8.43	00:07:44

Fig. 3. Browsers Overview in LMS Moodle via Google Analytics Tools (Jan. 1, 2019 – Dec. 31, 2020).

The Pages/Session indicator is the highest for Firefox (10.92), followed by Edge (10.51) and Internet Explorer (8.86) with Chrome (8.43). These browsers also have the highest Avg. Session Duration in this order: Firefox (00:09:59), Edge (00:09:47), Opera (00:07:46) and Chrome (00:07:44). Therefore, we note that these browsers are most used for online study and should be given more attention. Electronic learning materials available over the web (e.g., in LMS Moodle) should be adapted mainly to these browsers.

Other browsers for mobile devices (Samsung Internet, Safari (in-app), Android WebView or Mozilla Compatible Agent) are used to search for information in LMS Moodle, but not for e-learning because of their small screen. There is no need to prepare e-learning materials tailored to these browsers.

Fig. 4 shows the Devices Overview in LMS Moodle in the examined period.

Fig. 2. Audience Overview in LMS Moodle via Google Analytics Tools (Jan 1, 2020 – Dec 31, 2020, Compared to: Jan. 1, - Dec. 31, 2019).

Device Category	Acquisition			Behavior		
	Users	New Users	Sessions	Bounce Rate	Pages / Session	Avg. Session Duration
	405,354 % of Total: 100.00% (405,354)	402,380 % of Total: 100.06% (402,138)	3,274,375 % of Total: 100.00% (3,274,375)	24.02% Avg for View: 24.02% (0.00%)	8.45 Avg for View: 8.45 (0.00%)	00:07:38 Avg for View: 00:07:38 (0.00%)
1. desktop	222,699 (55.17%)	222,786 (55.37%)	2,497,557 (76.28%)	19.47%	9.44	00:08:55
2. mobile	175,643 (43.51%)	174,268 (43.31%)	760,057 (23.21%)	38.60%	5.23	00:03:28
3. tablet	5,346 (1.32%)	5,326 (1.32%)	16,761 (0.51%)	40.77%	5.78	00:04:40

Fig. 4. Devices Overview in LMS Moodle via Google Analytics Tools (Jan. 1, 2019 – Dec. 31, 2020).

We note that 76.28% of all sessions were made from desktop devices. The relatively high share of mobile devices (23.21%) was a surprise, so we will focus on it in the next analysis (Fig. 5). Tablets with a share of 0.51% represent rarely used devices.

The most widespread mobile platform is represented by Android-fcm (2360 devices), followed by iOS-fcm (2222), Android (265) and iOS (125).

```
SELECT [PLATFORM], COUNT(*) NUMBER_OF_DEVICES

9	2020	2082
10	2021	1131
11	2022	11

Fig. 6. Comparison of the Number of Newly Created Courses in LMS Moodle in Individual Years.

We note that the number of newly created courses increased more than five times in the pandemic year 2020 (2082) compared to the previous year 2019 (411). Next, we analyze their formats in more detail in the Fig. 7.

We constate that the biggest increase (26 times) occurred in the format Collapse Topics (topcoll), but its share in the total number of course formats is minor (1.2%). By researching courses with this format, we found that the reason for choosing this type of format was the large number of sections with learning materials that needed to be expanded or collapsed for clarity. The second highest increase (15 times) was recorded by the Single Activity format, but its share is also minor (0.7%). Teachers used it to present one study obligation - e.g., term paper, case study or seminar paper. The Topics format follows with a 7.37-fold increase and a 46% share of the total number of course formats. The lowest increase occurred in the case of the Weeks format (3.88 times), which still dominated with its 52% share in the number of course formats. During the pandemic, course creators chose the Topics format more often than in the past.

6	2017	27
7	2018	21
8	2019	15
9	2020	1136

Fig. 8. Comparison of the Number of Newly Created Quizzes in LMS Moodle in Individual Years.

Therefore, at the beginning of the pandemic, the LMS Moodle portal collapsed under the onslaught of testing activities. The schedule had to be prepared in such a way that several testing activities did not take place at the same time. The limit was max. 250 test users simultaneously.

Fig. 9 presents that in 2020 there was also a 26-fold increase in the number of Questionnaires, compared to 2019. By researching in the LMS Moodle, we found out that it was mainly about surveys of satisfaction with teaching, finding suitable dates for an exams or defense of seminar papers by students.

```

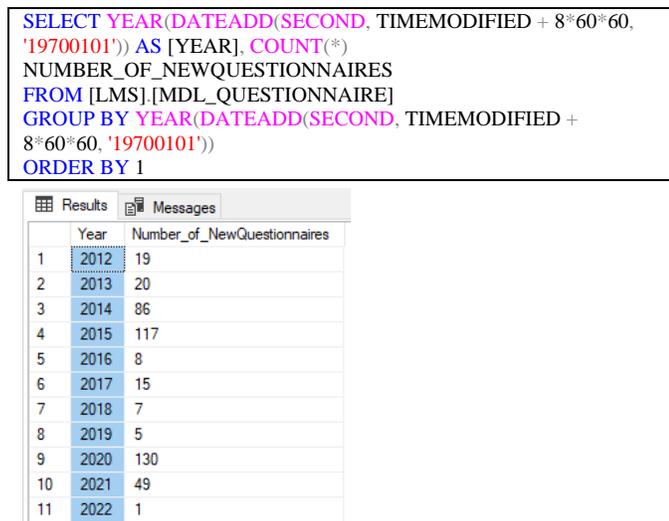
8	2019	5
9	2020	130
10	2021	49
11	2022	1


Fig. 9. Comparison of the Number of Newly Created Questionnaires in LMS Moodle in Individual Years.

After the end of the winter term, during the month of February 2021, we prepared an anonymous questionnaire in LMS Moodle for students, regarding the evaluation of the progress and organization of online teaching at Faculty of Economics MBU. There were 231 students (respondents) – 202 full-time and 29 externals, answered the questionnaire.

The questions Q1 - Q5 were aimed at surveying satisfaction with distance online education and utilized a five-point Likert scale (1-Very dissatisfied, 2- Rather dissatisfied, 3-Neutral, 4- Rather satisfied, 5-Very satisfied). For the analysis, a Likert score of 1-2 was regarded as a negative response, 4-5 as a positive response and 3 as a neutral response. The Likert scores for the questions Q1 - Q5 are presented in Table I.

We constate that the highest satisfaction was with the collaboration platform MS Teams (4.31), educational support of LMS Moodle (4.28) and with studying at Faculty of Economics MBU generally (4.05).

TABLE I. LIKERT SCORES FOR QUESTIONS Q1 – Q5

	How satisfied are/were you:	Likert Scores
Q1	with studying at Faculty of Economics MBU?	4.05
Q2	with the process and organization of distance online education in year 2020?”	3.90
Q3	with educational support of LMS Moodle	4.28
Q4	with the provision of teaching through collaboration platform MS Teams	4.31
Q5	with e-learning materials from teachers	3.14

Q7 investigated how students prefer individual forms of lectures with using of five-point Likert scale (1- I don't prefer it at all, 2- I don't prefer it, 3- neutral attitude, 4- I prefer it, 5- I strongly prefer it).

TABLE II. LIKERT SCORES – EVALUATION OF LECTURES

	Form of lectures	Likert Scores
L1	Publication of study materials in the LMS	4.82
L2	Online video lectures with recording	4.82
L3	Off-line video lectures (video recordings)	4.75
L4	Audio recording to the published presentation	3.25
L5	Online video lectures without recording	3.05

Based on the results in Table II, we conclude that students prefer persistent forms of lectures for which there is a record and to which they can return in the future if necessary.

Q8: “In what form were the lectures carried out?”

TABLE III. FORM OF LECTURES IN THE MONITORED PERIOD

Form of Lectures	Very Often & Often	Less Often & Not at all	I don't know
L1 - Publication of study materials in the LMS	79.65%	12.12%	8.23%
L5 - Online video lectures without recording	79.22%	12.55%	8.23%
L2 - Online video lectures with recording	28.14%	63.64%	8.23%
L4 - Audio recording to the published presentation	8.23%	83.55%	8.23%
L3 - Off-line video lectures (video recordings)	7.79%	83.98%	8.23%

It follows from Table III that in period of online teaching, lectures were very often provided to students in the form of publishing in LMS Moodle, the second most common form was “online video lectures without recording” and, to a much lesser extent – “online video lectures with recording”.

Q9 investigated which individual forms of seminars/exercises students prefer with using of five-point Likert scale (1- I don't prefer it at all, 2- I don't prefer it, 3- neutral attitude, 4- I prefer it, 5- I strongly prefer it).

According to Table IV, students prefer persistent forms of Seminars/Exercises (with recording).

TABLE IV. FORM OF SEMINARS/EXERCISES IN THE MONITORED PERIOD

x	Form of Seminars/Exercises	Likert Scores
S1	Online video seminars with recording	4.82
S3	Off-line video seminars (video recordings)	4.55
S4	Online video seminars without recording	3.35
S2	Assignments you could consult with teacher	3.25
S5	Published assignments with solution procedure	3.20
S7	Writing term papers/case studies/projects, etc.	3.16
S6	Posted assignments with results only	2,56

Q7: "In what form were the seminars/exercises carried out?"

TABLE V. FORM OF SEMINARS/EXERCISES IN THE MONITORED PERIOD

Form of Seminars/Exercises	Very Often & Often	Less Often & Not at all	I don't know
S4 – Onlin e video seminars without recording	75.76%	16.02%	8.23%
S7- Writing term papers/case studies/projects, etc.	57.58%	34.20%	8.23%
S2 - Assignments you could consult with teacher	50.22%	41.56%	8.23%
S5 - Published assignments with solution procedure	35.50%	56.28%	8.23%
S1- Online video seminars with recording	27.27%	64.50%	8.23%
S6 - Posted assignments with results only	21.65%	70.13%	8.23%
S3 - Off-line video seminars (video recordings)	9.96%	81.82%	8.23%

Table V presents that during online teaching, the seminars/exercises were carried out particularly in form of "online video exercises without recording", at second position

was "Writing term papers/case studies/projects" and at third position "Assignments you could consult with teacher".

The answers to questions Q8, Q9 and Q10 differed significantly for full-time and external (part-time) students, so we evaluate them separately.

Q8: "I acquired comparable knowledge as during face-to-face teaching."

Q9: "The method of evaluating subjects took into account the specifics of distance education."

Q10: "There is a lack of live contact with the teacher (the teacher usually sends texts and assignments; students send completed assignments)."

As for the answers, students could choose from the options: Majority of subjects, Minority of subjects, I don't know.

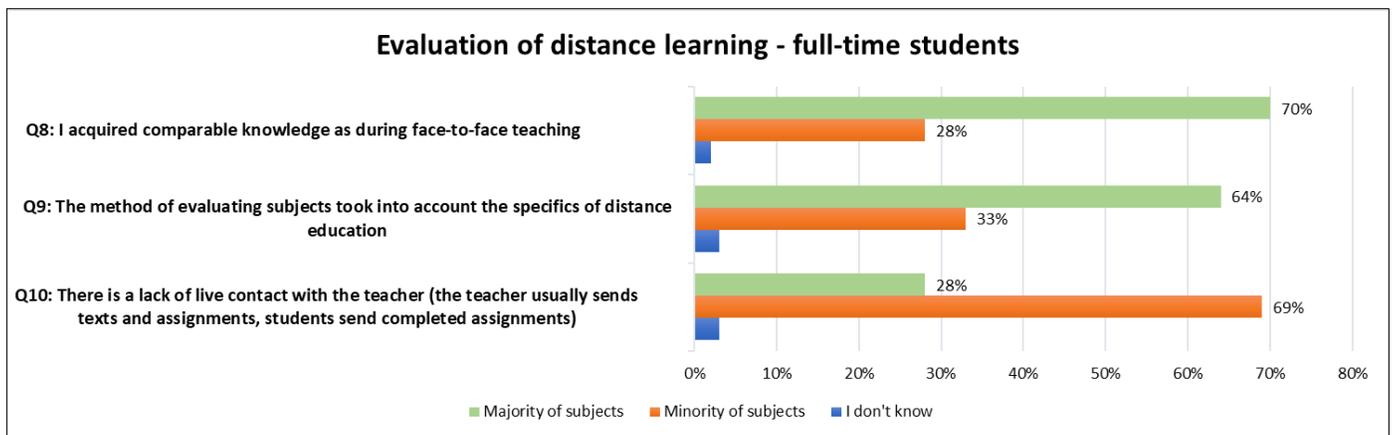
Based on the Fig. 10 and Fig. 11, we conclude that distance learning is perceived more positively by external students. It is also because the main way of their education in the past was self-study. The Covid era brought them a benefit in the form of a large amount of e-learning teaching materials and better support in LMS Moodle and MS Teams.


Fig. 10. Questions Q8, Q9, Q10 - Answers of Full-time Students.
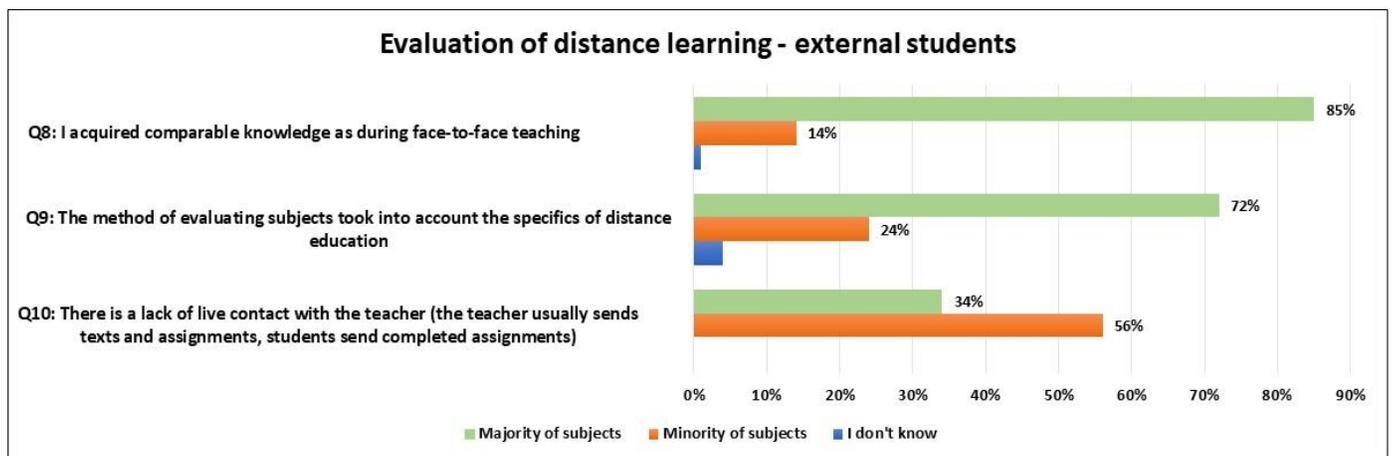

Fig. 11. Questions Q8, Q9, Q10 - Answers of External Students.

TABLE VI. ADVANTAGES AND DISADVANTAGES OF DISTANCE LEARNING

Advantages:	Disadvantages:
1 reduction of travel and accommodation costs (students could use the saved time for longer sleep, self-study or sports activities), 2 the opportunity to learn in the home comfort, 3 the possibility of education even with a weaker illness, 4 the possibility to replay the learning activity from the record, 5 the possibility to use new information and communication technologies in education, 6 there is no need to look for someone to supervise the children, as was the case with full-time studies (in case of external students).	1 absence of social contact with teachers and classmates, 2 inability to maintain long-term attention when working with a PC, 3 lack of motivation to study, procrastination, 4 health problems (e.g. vision impairment, back pain), 5 increased demands on technology, technical problems, especially poor internet connection on the part of students, 6 inability to understand the subject matter as in face-to-face studies, 7 less movement, 8 during online classes they can eat, look at their mobile phone, etc. When a person is in a comfortable environment, it is easy to lose focus, 9 external distractions (family, pets, couriers, housework).

Q11: "Even after the pandemic, my study program should use elements of distance education". We note that 78% of external (part-time) students and 61% of full-time students agreed with this statement.

Q12: Prepare list the advantages of the distance learning method from your point of view. Table V lists the most frequently mentioned advantages and disadvantages.

Questionnaire research showed that up to 78% of part-time students and 61% of full-time students would like their study program to use elements of distance education in full-time study as well. Since this is a large group of students, we will take their opinion into account in the future when fully returning to face-to-face teaching.

Based on the results of the research, we declare the following recommendations for face-to-face education in the post-Covid period:

- In time of building university information systems for e-learning (e.g., Learning Management Systems, Communication Platforms), emphasize their expandability and scalability (the system's ability to advantageously use additional resources such as processors, memory, or disk space) in case of need.

- To adapt the prepared e-learning teaching materials to the most used internet browsers and desktops.

- To enable students who cannot participate in face-to-face teaching (e.g., due to a minor illness) to participate in it online, via a communication platform - the so-called hybrid method of teaching.

- To prepare records from educational events (lectures, seminars/exercises) so that students can return to them in the future, e.g., when preparing for the exam.

- To provide external students with the option of participating in classes either face-to-face or online (and not only in the case of e.g., illness).

- Regularly implement training for teachers, focused on working with modern information and communication technologies (ICT), which are applied in teaching, so that the next pandemic or similar event does not catch them unprepared.

- To organize trainings of effective work with ICT for teachers and students.

V. CONCLUSION

The article deals with the comparison of face-to-face education and distance online education in Covid period. In frame of research, we combine a few research methods: the examination of the LMS Moodle with using of Learning Analytics tools: Google Analytics, Data analysis from the MySQL Standard Edition Database System and Questionnaire research.

The results showed that face-to-face education before the Covid pandemic and after this pandemic will no longer be the same because distance online education will also cause changes in face-to-face education in the post-pandemic period.

Future research is planned to determine the extent to which these recommendations will be implemented in the UMB environment and what their impact on education will be.

Multi-Feature Extraction Method of Power Customer's Portrait based on Knowledge Map and Label Extraction

Wentao Liu*, Liang Ji

Big Data Center of State Grid Corporation Limited

Beijing 100053, China

Abstract—In order to realize the visualization of power customer characteristics and better provide power services for power customers, a multi-feature extraction method of power customer's portrait based on knowledge map and label extraction is studied. The power customer's portrait construction model is designed, which uses the knowledge map construction link to collect the power customer related data from the power system official website and database, and clean and convert the data; In the multi-feature analysis section, natural language processing technology is used to analyze the characteristics of power customers through Chinese word segmentation, vocabulary weight determination and emotion calculation; Based on the feature analysis results, the portrait label is extracted to generate the power customer's portrait. The power customer's portrait is used to realize the application of power customer's feature visualization, power customer recommendation, power customer evaluation and so on. The experimental results show that this method can effectively construct the knowledge map of power customers, accurately extract the characteristics of power customers, generate labels, and realize the visualization of power customer's portraits.

Keywords—Knowledge map; label extraction; power customer's portrait; multi-feature extraction; natural language processing; feature visualization

I. INTRODUCTION

At present, China's power grid has retained nearly 500 million customer data, which come from data collected by power grid energy meters, customer telephone service system data, power grid management data, etc. [1]. Based on these data, using big data analysis technology to analyze power customers, we can build a multi-level and multi-dimensional power customer's portrait [2]. The customer portrait can help relevant personnel quickly and accurately identify and recognize customers, and formulate targeted, refined and personalized service plans by quantifying sensitivity, so as to improve service quality and service efficiency [3].

The current research on portraits can be roughly divided into two categories according to the different objects of the portraits: one is the user portraits of scientific and technological experts, library users, website users and other characters, which are mainly used to recommend content to the research objects and improve the experience of the research objects; The other is the portrait of non-human things such as cities and books [4], which is mainly used to provide information services for groups other than the research object based on the portrait of things. Among them, the research on user portrait is relatively more extensive, and has been extended to various fields for different application scenarios. A lot of research has been done on the generation methods of user portraits at home and abroad. Wang and Zhu et al. used user portraits sharing representative opinions to predict emotion, and considered the impact of different characteristics of user groups on emotion analysis from three aspects: attribute characteristics, interest characteristics and emotional expertise [5]. Guo and Wei et al. used user portraits to automatically obtain user behavior data in web server logs in a big data environment by using a collection system; used PrefixSpan algorithm to build user portrait model, establish user behavior feature labels through frequent sequence mining, and realize abnormal feature extraction [6]. Chicaiza et al. used knowledge maps to build user portraits, and designed a recommendation system based on user portraits to achieve a good recommendation function [7].When the above three methods process massive power customer data, it is difficult to achieve rapid data extraction, and to provide better power service, and the application value is not high. Based on the previous research results, the multi-feature extraction method of power customer's portrait based on knowledge map and label extraction is studied. Knowledge atlas aims to describe the entities in the objective world we know and the direct relationships between entities in a structured form. It provides a better way to summarize and manage massive data in the Internet. The application of knowledge map is a good thing for the semantic search of the Internet. It plays an absolute role in promoting the development of semantic search. At the same time, it also shows its special and amazing ability in intelligent question answering. In the era of big data, knowledge map will have its place. Big data is the foundation and knowledge map is the tool. Combined with deep learning, it will develop better and better. Based on the analysis of user characteristics, tag extraction abstracts user portraits into user-friendly or computer-readable labels. The label has generality and condenses the key information in user characteristics. The content of user portrait labels is diverse, which can be words, phrases or concepts. The visualization methods of labels can be vectors, description charts and label clouds. Through the full analysis of user features and the accurate extraction of labels, we can achieve a deeper characterization of user portraits. By accurately constructing the power customer's

portrait, we can better provide power services for power customers.

II. MATERIALS AND METHODS

A. *Construction of Power Customer's Portrait*

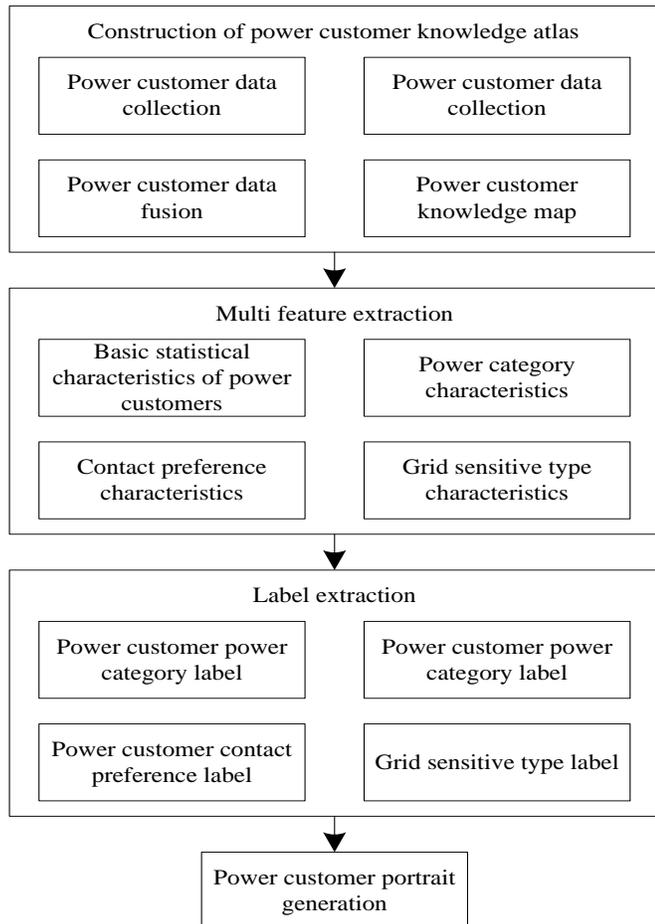
In the context of big data, single data cannot fully reveal the characteristics of things, and the decision support services are insufficient and incomplete. Multi-source big data can describe things from different perspectives. Data complement and cross verify each other, breaking the "data island" [8]. Based on the understanding and elaboration of domestic and foreign scholars on the concept of power customer's portrait, it is considered that power customer's portrait refers to a model that can describe and characterize the features of power customers from different dimensions after abstracting and summarizing the basic statistical characteristics of power customers, power category characteristics, contact preference characteristics, power grid sensitive type characteristics and other characteristics from multi-source big data. On this basis, a model based on power customer's portrait is proposed, as shown in Fig. 1.


Fig. 1. Power Customer's Portrait Construction Model.

The power customer's portrait construction model can be roughly divided into three links: knowledge map construction, multi-feature analysis and portrait label extraction.

The knowledge map construction link collects relevant data of power customers from the power system official website, encyclopedia website and literature database; Data cleaning, data specification, data integration, data conversion and other data processing work are carried out for the relevant data of power customers. In the step of data fusion, the relevant data of power customers obtained after processing are stored according to the basic statistical characteristics of power customers, the characteristics of power categories, the characteristics of good contacts, the characteristics of power grid sensitive types and other categories to realize data processing; Multi-feature analysis links analyze the characteristics of power customers; Based on the feature analysis results, the portrait label is extracted to generate the power customer's portrait. The power customer's portrait is used to realize the application of power customer's feature visualization, power customer's recommendation, power customer's evaluation and so on.

B. *Construction of Power Customer's Knowledge Map*

The data extraction and processing of power customers in the process of building the knowledge map of power customers is to collect the relevant data of power customers from the power system website, encyclopedia website and relevant structured knowledge base, and build the original tourism route database.

The perfection of the construction of power customer's knowledge map directly affects the quality of the generation results of power customer's portraits [9]. Therefore, it is necessary to collect relevant data in the official website of the power system, encyclopedia websites and literature databases, and analyze the collected data through big data technology to determine that it meets the construction standard of knowledge map. On this basis, the collected power customer's related data is analyzed with the current existing data [10], and the data that meets the threshold standard is defined as valid data, which is stored in the original database.

Fig. 2 shows the construction process of power customer's knowledge map. The construction process of power customer's knowledge map can be roughly divided into four links:

1) Power customer data collection: The main function of this link is to collect relevant data of power customer's entities in various websites, and realize noise elimination through the preprocessing process in the data crawling process. On this basis, based on the differences of data types (structured, semi-structured and unstructured), the collected data are stored and processed, and the power customer entity database is constructed.

2) Power customer data extraction: The main function of this link is to use the data extraction model to extract different data needed to build the power customer's knowledge map from all kinds of data collected.

3) Power customer data fusion: The main function of this link is to use thesaurus to fuse the extracted data, and in this process, to complete the elimination of entity / attribute ambiguity and synonymous relationship merging [11].

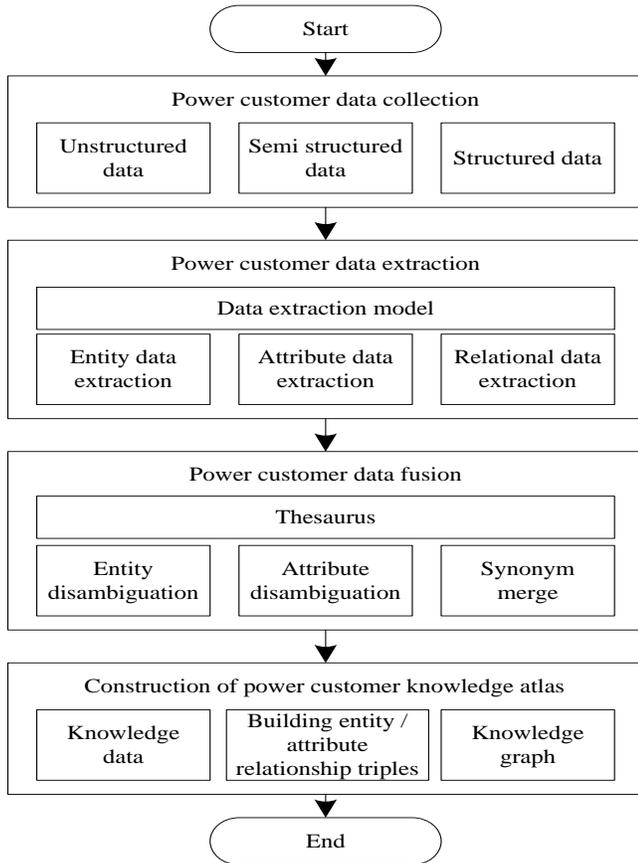
4) Construction of power customer knowledge map: The main function of this link is to use the fused data to generate entity / attribute / relationship triples, so as to finally complete the construction of power customer knowledge map.


Fig. 2.   Construction Process of Power Customer Knowledge Map.

In the data extraction process, a timestamp incremental data extraction model based on variable window is used, which depends on the given time window for incremental data extraction. It is normal to assume that exceptions occur in the process of data extraction, and the occurrence of exceptions often leads to the inconsistency between the target table data and the source system data. To solve this problem, before incremental data extraction, it firstly gives two time windows (source time window and target time window, which are respectively used to extract data from various websites and power customer entity databases), then uses the given time window to extract corresponding data from various websites and power customer entity databases, and finally de-duplicates these data to produce the final result set. Considering the impact of abnormal occurrence on the consistency of power customer data in the process of power customer data extraction [12], it is necessary to use the data maintenance lead time to make minor adjustments to the given time

window before power customer data extraction. Here, the formal definition of timestamp incremental data extraction model with variable window is given:

$$M = \left(S_R, d_s, gmt, \Delta t, T_W, O_P, clean, d_u \right) \tag{1}$$

In equation (1), S_R is an n-tuple, $S = \left(s_1, s_2, \cdots, s_n \right)$ represents n data sources; d_s refers to the information database table of power customer, which requires an attribute column that marks the storage time of records; gmt represents the maximum value of the warehousing time of the data obtained from table d_s; Δt refers to the lead time of power user's data maintenance, which is used to adjust the size of the time window. T_W represents the time window information required for data extraction, T_W can be represented by a binary $T_W = \left(T_{W,S}, T_{W,T} \right)$, where $T_{W,S}$ represents the source time window and $T_{W,T}$ represents the target time window. In model M, the determination of $T_{W,S}$ and $T_{W,T}$ in T_W is very important to ensure the data consistency between the source system and the power customer's information database, especially when the data extraction process is started again after an exception occurs in the data extraction process, the determination of $T_{W,S}$ in T_W is directly related to whether the data that cannot be extracted due to the exception can be extracted. O_P refers to the operation defined on the data source, O_P is also a multivariate group, and the dimension of tuples is related to the operation defined on the data source, such as $O_P = \left(INNERJOIN_{s_1-s_2}, \cdots \right)$, which means that the power user data extracted from data source s_1 and data source s_2 will be internally connected. $clean$ represents a simple cleaning operation for the power user data extracted from S_R, that is, to remove the redundant time field value (the non-minimum data warehousing time of each record from S_R); d_u means to de duplicate the power user data extracted from S_R and d_s.

The working process of incremental data extraction model based on variable time window is described as follows:

1) Perform gmt operation on the target database table d_s to obtain the maximum value $\max Time$ of the storage time of power user data in d_s;

2) Set the value of the start time node of data extraction in $T_{W,S}$ and $T_{W,T}$ time windows to $\max Time$ respectively, and then adjust the time windows $T_{W,S}$ and $T_{W,T}$ according to the given data maintenance lead time to obtain $T_{W,S}{}'$ and $T_{W,T}{}'$;

3) Take $T_{W,S}{}'$ as the new time window, extract the data from the power user data source $S_{R,i}$, and operate the extracted power user data O_P, and then make $clean$ operation to remove the redundant time field values in the data to obtain the result set $tempRS\_S_R$;

4) Then take $T_{W,T}{}'$ as the target time window, extract the power user data from d_s, and get the result set $tempRS\_d_s$;

5) Perform d_u operation on $tempRS\_S_R$ and $tempRS\_d_s$ to obtain the final result set;

6) Load the final result set into d_s.

C. Multi-feature Extraction based on Natural Language Processing Technology

Multi-feature extraction of power grid sensitive customer's portrait under natural language technology, that is, using the methods of word segmentation, word vector conversion and word weight calculation in natural language processing technology to extract the features in the power grid sensitive customer's portrait label.

1) Chinese word segmentation: Letting the computer understand the label text information is the basis of multi-feature extraction of sensitive customer's portrait in power grid. There are a large number of Chinese words in the label text translated from Chinese. When using computer tools to comprehensively analyze the text information of portrait labels, the more common statistical word segmentation method is usually used [13] to preprocess the text information of portrait labels of power grid sensitive customers.

The N-ary grammar model in the statistical analysis method is selected. The conditions for the establishment of this model are: the production of the N-th word is affected by the first N-1-th word; There is no correlation with other words except this word and the N-1-th word; The probability of a whole sentence in the label text is the product of the production rates of different words in the sentence. Using the N-ary grammar model to judge the scientificity of the word segmentation plan is based on the probability value of the sequence of N words [14]. For example, suppose a sentence Y in the label text of power grid sensitive customer's portrait has two word segmentation plans, which are defined as Y_1 and Y_2 respectively, and the detailed process of word segmentation processing using the N-ary grammar model is as follows:

a) If the word order in Y is $C^{(1)}, C^{(2)}, C^{(3)}, \cdots, C^{(n)}$, it is expressed as $Y_1 = \left\{ C_1^{(1)}, C_1^{(2)}, C_1^{(3)}, \cdots, C_1^{(n)} \right\}$ and $Y_2 = \left\{ C_2^{(1)}, C_2^{(2)}, C_2^{(3)}, \cdots, C_2^{(n)} \right\}$ respectively.

b) The joint probability distribution expression of Y_1 and Y_2 is:

$$P(Y_m) = P\left(R_m^{(1)}\right) \times P\left(C_m^{(2)} \middle| C_m^{(1)}\right) \times P\left(C_m^{(3)} \middle| C_m^{(1)} C_m^{(2)}\right)$$
$$\times \cdots \times P\left(C_m^{(n)} \middle| C_m^{(1)} C_m^{(2)} \cdots C_m^{(n-1)}\right) \tag{2}$$

In equation (2), $P\left(C_m^{(n)} \middle| C_m^{(1)} C_m^{(2)} \cdots C_m^{(n-1)}\right)$, $P\left(C_m^{(n)}\right)$ and $P\left(C_m^{(n)} \middle| C_m^{(n-1)}\right) C_m^{(n)}$ respectively represent the joint probability distribution of sentence Y_m, the probability of word and the basis of word $C_m^{(n-1)}$. Through the public corpus, we can determine the probability of corresponding words, and then we can determine $P\left(C_m^{(n)}\right)$ and $P\left(C_m^{(n)} \middle| C_m^{(n-1)}\right)$.

c) The $P(Y_1)$ probability value is compared with the $P(Y_2)$ probability value, and the higher probability value is the correct word segmentation plan of the label text sentence T of power customer's portrait. After the word segmentation plan is determined, word vector conversion is performed on the label text.

2) Determination of vocabulary weight: Different words form sentences, and different sentences form the label text of the sensitive customer's portrait in power grid. The importance of each word in different label texts is different, and the importance of the same word in different label texts is also different. Therefore, the determination of vocabulary weight is very important for the extraction of multiple features of the sensitive customer's portrait in power grid. Statistical knowledge is used to determine the vocabulary weights that have been transformed into vectors in the text of sensitive customer's portrait labels in power grid, that is, the vocabulary weights are determined according to the text statistical information such as word frequency [15]. The above statistical process is based on Shannon's informatics theory: assuming that a certain word in all texts has a high word frequency, its information entropy is small; On the contrary, the lower the word frequency of a word in all texts is, the greater the information entropy is, that is, the inverse relationship between the word frequency and its information entropy.

As a typical information retrieval and data mining weighting technology, the term frequency-inverse document frequency (TF-IDF) algorithm can act on the vocabulary weight determination of the label text of the sensitive customer portrait in power grid [16], which is conducive to extracting the characteristic vocabulary in the label text information and realizing the multi-feature extraction of the power grid sensitive customer's portrait. The calculation process of TF-IDF algorithm is as follows, in which equation (3) and equation (4) calculate word frequency and inverse text frequency index respectively.

$$F_{i,j} = \frac{x_{i,j}}{\sum_k x_{k,j}} \times \ell$$

(3)

$$DF_i = \log \frac{T}{j : r_i \in t_j} \times \ell$$

(4)

$$F - DF = F_{i,j} \times DF_i \times \ell$$

(5)

In the above equation, $x_{i,j}$ and $\sum_k x_{k,j}$ respectively represent the occurrence frequency of word i in the power customer's portrait label text t_j and the total number of words in t_j; $|T|$ and $\left|\left\{ j : r_i \in t_j \right\}\right|$ respectively represent the number of all tagged texts in the corpus and the number of all tagged texts containing the word r_i in the corpus; ℓ represents the correction factor. Equation (3) is multiplied by equation (4), that is, equation (5) can exclude the vocabulary commonly existing in the text of power customer's portrait labels, and retain the vocabulary that can reflect a certain feature.

3) Emotion calculation: Using the feature words retained after the vocabulary weight is determined, the sentence emotion in the image label text of power grid sensitive customers can be determined. When determining sentence emotion based on vocabulary level, in order to ensure the efficiency of emotion determination, feature dimensionality reduction needs to be implemented, which will cause a large loss of feature words and lead to the deviation of emotion determination results. In order to avoid such problems, the Latent Dirichlet Allocation (LDA) model is used to determine the sentence emotion in the label text of the sensitive customer's portrait in power grid [17].

$T = \left\{ t_1, t_2, \cdots, t_T \right\}$ and $t_i = \left\{ y_1^i, y_2^i, \cdots, y_k^i \right\}$ are used to represent the text set of the power customer's portrait label and the sentence set in the text t_i respectively, so $T = \left\{ y_1, y_2, \cdots, y_N \right\}$ can be used to describe T as the set of all sentences in t_i, where N represents the number of all sentences in D.

The model of T is constructed by using LDA model. After parameter estimation, the distribution of sentences on characteristic topics and the distribution of characteristic topics on vocabulary are obtained respectively [18], and expressed by $\rho(\phi|\alpha)$ and $\rho(w_n|\phi,\partial)$, where ϕ, α and ∂ represent vectors, k-dimensional Dirichlet parameters and a $k \times v$ matrix respectively. Based on $\rho(\phi|\alpha)$ and $\rho(w_n|\phi,\partial)$, the multi-feature extraction of power customer's portrait is carried out. The specific process is as follows.

4) Density features: describe the maximum number of sentences with emotional words in the sentence, expressed by density (S).

5) Range features: describe the number of words in the sentence, expressed by range (S).

6) Quantitative features: describe the number of emotional words, expressed by the number (S).

7) Polarity features: q and $p_o(q)$ are used to represent emotional words and their polarity respectively. After calculation, it can determine the polarity of the sentence as:

$$p_o - s(S) = \sum_{i=1}^{count(S)} p_o(q_i) \times \beta$$

(6)

Where β is any constant.

8) Degree features: assuming the degree of q is $e_x(q)$, the degree of the sentence after calculation is:

$$e_x \_ s(q) = \max_{i=1,count(S)} e_x(q_i) \times \beta \tag{7}$$

Through Chinese word segmentation, vocabulary weight determination and emotion calculation, the basic statistical features of power customers, power category features, contact preference features and power grid sensitive type features are extracted. According to the feature extraction results, the basic statistical labels of power customers' portraits, power category labels, contact preference labels and power grid sensitive type labels are extracted.

D. Label Extraction and Portrait Generation of Power Customer's Portrait

1) Basic statistical label extraction of power customer's portrait.

$$D_e = \langle B_a, E_d, W_o, C_o \rangle \tag{8}$$

Where, B_a refers to the basic information of power customers, including name, gender and date of birth; E_d refers to the education experience of power customers, including education background, graduation college and graduation time; W_o refers to the work experience of power customers; C_o refers to the contact information of power customers, including office phone, mobile phone, email and personal web address.

2) Electricity category label extraction of power customer

$$S_p = \langle s_1, s_2, s_3, \ldots, s_n \rangle \tag{9}$$

Where, s refers to the power category feature word extracted from the power consumption data of power customers.

3) Contact preference label extraction of power customer

$$I_n = \{(t_1, tf_1), (t_2, tf_2), (t_3, tf_3), \ldots, (t_n, tf_n)\} \tag{10}$$

Where, t refers to the keyword in the contact preference of power customers, and tf_n refers to the number of times the preference word appears.

4) Extraction of grid sensitive type label

$$l_a = \langle l_{a,T}, R_d, R_{di} \rangle \tag{11}$$

Where, $l_{a,T}$ is the node label in the grid use partnership of power customer, R_d is the contribution of power customer d in the power grid use partnership, and R_{di} is the weight of the correlation between power customer d and power customer i.

Power customer's portrait is a label combination model of multi-dimensional and multi-level power customer [19]. According to the type of relevant data of power customers, it can define a vector space to represent the power customer's portrait [20]:

$$d = D_e, S_p, I_n, l_a \tag{12}$$

III. EXPERIMENTAL RESULTS

A. Experimental Environment

In order to verify the application effect of the multi-feature extraction method of power customer's portrait based on knowledge map and label extraction studied in this paper in the actual application process, the open data set of 2020 "Customer portrait" competition is taken as the experimental object, which includes the power use data of millions of grid customers in a province in 2019. This paper determines three types of information, a total of 12 fields (Table I) for the experiment.

The experimental environment is as follows: the server and client exist in the same computer, and the computer processor, memory and operating system are (Intel)i9-9900KF core eight core CPU, 8 GB memory and Windows 8 operating system respectively.

TABLE I. DESCRIPTION OF EXPERIMENTAL DATA

Experimental information category	Number of fields	Content description
Power system work order information	6	Name, gender, contact information, contact address, customer nature, etc
Registration form information	3	Business hall, store, communication reasons, etc
Data acquisition information of power meter	7	High energy consumption type, electricity fee guarantee type, total electricity consumption, paid in amount, payment, etc

B. Construction Results of Power Customer's Knowledge Map

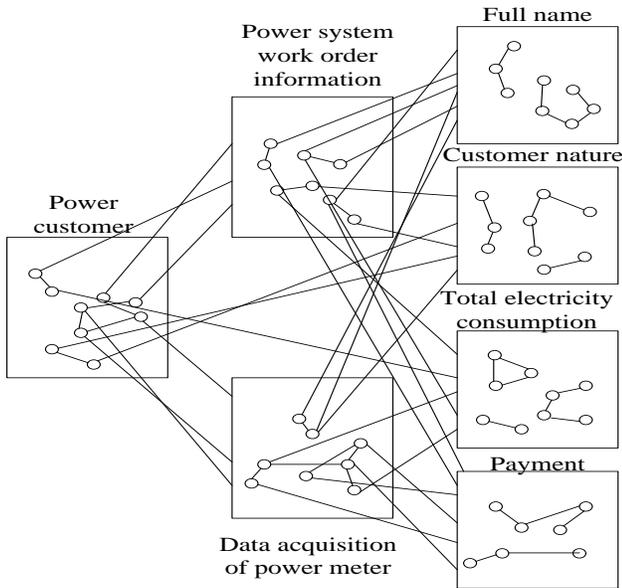
The construction of power customer's knowledge map is the basis of power customer's portrait generation. According to the experimental data, the proposed method is used to build the customer knowledge map. Fig. 3 shows the customer knowledge ontology model built by this method.


Fig. 3.   Experiment Object Knowledge Ontology Model.

The knowledge ontology model of power customer shown in Fig. 3 contains the work order information of the power system of the power customer and the data collection information of the power meter, in which the name, customer nature, total electricity consumption and payment are the low redundancy entity summaries generated by the proposed method. The different kinds of data contained in the body of knowledge come from experimental data.

C. Multi-feature Extraction Test of Power Customer

The multi-feature extraction of power customers is the most critical and time-consuming link in the generation of power customer's portraits. Therefore, the multi-feature extraction test of power customers is mainly analyzed from two aspects: extraction accuracy and extraction efficiency.

In the process of extracting accuracy test, we mainly use accuracy, precision rate, recall rate and F1 value as evaluation indicators to evaluate the effect of experimental feature extraction.

According to the combination of the actual feature extraction results of the experimental object and the extraction results of the proposed method, the real examples, false positive examples, true negative examples and false negative examples are defined. The confusion matrix of the feature extraction results during the experiment is shown in Table II.

TABLE II.   CONFUSION MATRIX OF FEATURE EXTRACTION RESULTS

Actual feature extraction results		Positive example	Counterexample
This method extracts the knot	Positive example	True example	False positive cases
	Counterexample	False counterexample	True counterexample

As the most critical and widely used evaluation index in the process of multi-feature extraction of power customers, accuracy can be understood as the proportion of the correct number of samples for feature extraction in the number of text samples of all power customers' portraits, and its expression is:

$$\text{Accuracy} = \frac{\text{ture positive example+false negative example}}{\substack{\text{ture positive example+false negative example+}\\ \text{ture negative example+false positive example}}} \quad (13)$$

The index describing the correct extraction probability of feature extraction into the positive example is the precision rate, and its expression is:

$$\text{Precision rate} = \frac{\text{ture positive example}}{\text{ture positive example+false positive example}} \quad (14)$$

The index describing the probability that the features in the positive example are correctly extracted is recall rate, which is expressed as:

$$\text{Recall rate} = \frac{\text{ture positive example}}{\text{ture positive example+false negative example}} \quad (15)$$

The harmonic mean of precision and recall is defined as F1 value, and its expression is:

$$\text{F1} = \frac{2 \times \text{ture positive example}}{\substack{2 \times \text{ture positive example−false positive example+}\\ \text{ture negative example+false negative example}}} \quad (16)$$

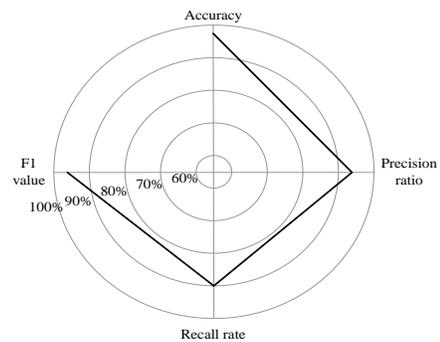
Among the above four indicators, there is an inverse relationship between recall rate and precision rat, that is, the higher the recall rate in the proposed method is, the lower the precision rate is. According to the prediction parameters of feature extraction, the evaluation results of multi-feature extraction of this method are obtained, as shown in Fig. 4.


Fig. 4.   Performance Analysis of Multi-feature Extraction Results.

By analyzing Fig. 4, we can see that the comprehensive performance of the four index evaluation results of the proposed method has certain advantages, indicating that the multi-feature extraction effect of this method is good.

In order to test the feature extraction efficiency of the proposed method under the condition of different sample numbers, the number of feature texts to be extracted in the experiment is set to 1000, 3000, 5000 and 10000 respectively, and the time consumed by the proposed method under different text numbers is compared. The results are shown in Table III.

TABLE III.   NALYSIS OF MULTI-FEATURE EXTRACTION EFFICIENCY OF THIS METHOD

Elapsed time /s	Number of power customer information texts / piece			
	1000	3000	5000	10000
Chinese participle	6.33	18.97	54.16	97.85
Vocabulary weight determination	2.53	8.04	18.35	26.45
Affective computing	0.86	0.96	1.22	1.31

It can be seen from Table III that the time used for text emotion calculation is relatively short when the method is used to process the power customer information text. When the sample size is 10000, the running time is less than 1.31s; It takes a long time for Chinese word segmentation. When the sample size is 10000, the running time is about 97.85s, and it grows in gradient with the gradual increase of the number of power customer portrait label texts. Among them, the time consumed by this method in Chinese word segmentation and the determination of vocabulary weight fluctuates significantly, specifically in a linear rising state; The time consumed by emotional calculation fluctuates slightly. Since the determination of Chinese word segmentation and vocabulary weight is only conducted once in the initial stage, the impact of the above two steps on the subsequent feature extraction process is not significant. The experimental results show that the increase in the number of power customer portraits has no significant impact on the efficiency of multi feature extraction, indicating that the method is suitable for power grid big data environment.

D. Label Extraction Results

Different data sources such as power system registration form information, power system customer telephone system work order and power meter information collection are the data sources of label design of power customer's portrait. These data sources generally have the characteristics of massive, multi-directional and multi-dimensional content, high dispersion, non-uniform format and so on. To extract labels from these data sources, data association analysis and preprocessing should be carried out first. For example, by analyzing the customer information, guarantee information and charge control information in the power grid customer data, we can fully understand the attribute data of relevant types of power grid customers; By analyzing the work order information of the customer's telephone system, the actual electricity charge collection information, the electricity charge collection information, etc., we can understand the customer behavior data of the power grid. Only after fully understanding the data, it is convenient to extract the characteristics. Because the relevant data of the same power customer exists in different data tables, that is, there are several data of the same customer in different data tables, in order to better describe the power customer's portrait, it is necessary to integrate the multi-dimensional information of the power customer, and form the portrait label of the power customer based on the multi-feature extraction results of the power customer. The label structure is shown in Table IV.

TABLE IV.   POWER CUSTOMER LABEL EXTRACTION RESULTS

Label name	Label details
Basic statistics of power customer's portrait	Age
	Gender
	Industry
	Income
	Contact information
	Contact address
	Town / village
	Customer nature
Power customer power category	Important type
	High energy consumption type
	Multi power type
	Special line variant
	Electricity charge guarantee type
	Prepaid controlled
Power customer contact preferences	Store business hall
	Network business hall
	Terminal
	APP
	Telephone system
Grid sensitive type	Non sensitive
	Class A sensitivity
	Class B sensitivity
	Class C sensitivity
	Class D sensitivity

By analyzing Table IV, we can get that the labels in the relevant information of power customers can be extracted comprehensively and accurately by using the proposed method based on the multi-feature extraction results of power customers.

E. Visualization of Power Customer's Portrait

This paper uses Tagul to realize the visualization of power customer's portrait, imports the label of power customer's portrait into Tagul, and sets the size of the label according to the weight of the tag. The weight of each label in each label of power customers is set to 0.2, and the product of the frequency of each label in this feature and the feature weight are taken as the weight of the label. Because there may be the same label in several features, this paper adds the weight of the same label as the total weight of the label, and makes the power customer's portrait of "Li Boming", as shown in Fig. 5.

According to Fig. 5, it can get the portrait results of the power customer "Li Boming". According to this portrait, it can get the power customers who are more similar to the portrait of the power customer "Li Boming". On this basis, we can provide recommendations for these power customers who are more similar to "Li Boming", improve the allocation efficiency of power application resources, and bring more convenient power consumption experience and more effective power supply services to power customers.

IV. CONCLUSION

In this paper, a multi-feature extraction method based on knowledge atlas and label extraction is proposed, and experimental research is carried out on this basis. In this paper, a multi feature extraction method based on knowledge atlas and label extraction is proposed, and experimental research is carried out on this basis. This method can realize the multi feature extraction of power users, and the calculation efficiency is high. When the sample size is less than 10000, the time for emotion calculation is less than 1.31s, the time for Chinese word segmentation is less than 97.85s, and the time for vocabulary measurement is less than 26.45s, which has certain research value. The innovation of this method lies in:

1) A construction model of power customer's portraits based on knowledge map and label extraction is proposed, and the extracted labels are used to calculate the similarity between power customer's portraits, which provides a research idea for personalized service recommendation and accurate power supply services to power customers through the similarity of power customer's portraits.

2) It combs the data sources, main contents, data types and collection methods of building power customer's portraits. By integrating multi-source data, it depicts the characteristics of power customers as people who enjoy power services in the actual power application process from a more comprehensive perspective, enriches the connotation of power customer's portraits, presents power customer's portraits in a visual way, and promotes the innovative development of smart power.

However, there are some limitations in the research of this paper. In the future, two main works will be carried out: expanding the sample to the data of all power customers, further enriching and constructing the group of power customer's portraits; using PLSI, LDA, BTM and other data mining methods in topic mining to mine information in unstructured text data in various forms.

Abstract—**Recently, education has changed from physical learning to online and hybrid learning. Furthermore, the outbreak of COVID-19 makes them more significant. An online learning management system (LMS) is one of the most prevalent approaches to online and distance learning. The acceptance of the students towards the LMS is significant and it can give either bad or good responses to ensure the success of LMS. However, the Universiti Tun Hussein Onn Malaysia (UTHM) has not yet implemented any study to examine their LMS. The Unified Theory of Acceptance and Usage of Technology (UTAUT2) model is used in this study to investigate students' Behavioral Intention and Use Behavior when using the LMS in UTHM. This study also introduces a new construct in UTAUT2 named Online Learning Value. 376 respondents took part in this survey. Descriptive Statistics, Reliability Analysis, Pearson Correlation Coefficient, and Multiple Linear Regression analysis were all used to analyze survey data. The outcome of this research is Performance Expectancy ($\beta=0.129$, $p=0.014$), Hedonic Motivation ($\beta=0.221$, $p=0.000$), Online Learning Value ($\beta=0.109$, $p=0.036$) and Habit ($\beta=0.513$, $p=0.000$) has influence on students' intention to use LMS. Besides that, Facilitating Conditions ($\beta=0.481$, $p=0.000$) are the most important factors in students' use behavior toward the LMS followed by Habit ($\beta=0.343$, $p=0.000$) and Behavioral Intention ($\beta=0.239$, $p=0.000$). By utilizing the UTAUT2 model, the constructs of technology acceptance related to students' adoption of LMS have been identified and may become a reference to the stakeholders for future enhancement.**

Keywords—*Online learning management system; technology acceptance; unified theory of acceptance and usage of technology 2; online learning value*

I. INTRODUCTION

Currently, almost all universities in Malaysia rely on their online learning management system (LMS) to support academic activities including teaching and learning. Besides, online learning has become the best solution for students and lecturers in academic activities during the COVID-19 worldwide outbreak. The pandemic has forced changes in new normal academic activities where the institutions have the potential to build their own LMS [1]. The LMS is considered one of the best approaches toward online learning [2], [3] which provides benefits to the students and lecturers where it provides unlimited access to the learning materials, can track student progress and performance from assessment activities, organize the sources into the same shared data center, collaboration and discussion, and provides a different experience for both students and lecturers [4].

The use of LMS also is convenient and can boost students' efficiency throughout the process of teaching and learning because this system is compatible with any device, such as a smartphone or laptop [5]–[7]. Hence, students can gain knowledge and information by joining the learning management system that has been provided by the university at anytime and anywhere. There are many campuses that had been developed and used their own LMS including Universiti Tun Hussein Onn Malaysia (UTHM) [8].

In UTHM, an online LMS named Author has been implemented and was used before the COVID-19 pandemic as a mixed or blended learning tool. This LMS has been the primary tool for instruction and learning throughout recent years. However, the acceptance and usage of LMS in UTHM have not been empirically investigated. Due to the recent increases in the usage of LMS, it is valuable to understand and distinguish the factors that influence students' acceptance of LMS usage. Therefore, this research is important to examine the variables influencing students' Use Behavior as well as their Behavioral Intention of using the LMS. The study's research question is structured as shown in the following Table I.

TABLE I. RESEARCH QUESTIONS

No.	Research Questions
RQ1	What are the factors influencing UTHM students' behavioural intention and use behaviour towards using the LMS?
RQ2	Which main variables influence students' use behaviour towards using the LMS in UTHM?
RQ3	Does online learning value construct influence students' behavioural intention toward using the LMS in UTHM?

This paper is arranged as follows: The subsequent part will go through relevant research, namely the UTAUT2 model used in this study. Afterwards, the following section presents the research method where one new variable of UTAUT2 is proposed. Following that, the research's findings and analyses will be discussed. Finally, we address the conclusion and future works in this study.

II. RELATED WORKS

In order to obtain fewer risks during the adoption of new technology, many theories and models have been developed by previous researchers according to technology acceptance and usage.

A. Models Related to Technology Acceptance and Usage

There are eight user acceptance models: the Theory of Reason Action (TRA), the Technology Acceptance Model (TAM), the Motivational Model (MM), the Theory of Planned Behavior (TPB), the Combined TAM and TPB (C-TAM-TPB), the Model of PC Utilization (MPCU), the Innovation Diffusion Theory (IDT), and the Social Cognitive Theory (SCT). These models were then combined into a new framework called as the Unified Theory of Acceptance and Use of Technology (UTAUT)[9]. The UTAUT model is a well-improved model that can explain the technology acceptance behavior as it combines the eight models (TRA, TAM, MM, TPB, C-TAM-TPB, MPCU, IDT, and SCT) to form the determinants of behavioral intention and use behavior towards technology [10]. In this study, we utilized the UTAUT2 model, an expanded version of UTAUT, to investigate student acceptance of online LMS at UTHM. The UTAUT2 model focuses on the individual perspective of technology adoption compared to the UTAUT model. Therefore, this model will give a better understanding of technology acceptance by users.

The constructs in the UTAUT model are Performance Expectancy, Effort Expectancy, Social Influence, and Facilitating Conditions. An expanded edition of the UTAUT model with additional constructs and relationships was proposed to give an effective acceptance model in the consumer use context [11]. The added constructs in the UTAUT2 model are Hedonic Motivation, Price Value, and Habit. We proposed the Online Learning Value construct as an extension of the UTAUT2 in this study. This construct was classified into two types: dependent variables and independent variables. Use Behavior and Behavioral Intention are the dependent variables, whereas the independent variables are Performance Expectancy, Effort Expectancy, Social Influence, Facilitating Conditions, Hedonic Motivation, Online Learning Value, and Habit.

Use Behavior explains the constancy of the technology usage and the degree to which technology may improve a user's knowledge and skills[12]. Use Behavior also is referred to the level of technology use among students such as their use of mobile devices as learning aids [13].

The adherence of the user to keep using the system and how long the user intends to use the system is referred to as Behavioral Intention [12]. Furthermore, Behavioral Intention is the extent to which students expect to utilize technology such as smartphones in their studies and how long they will continue to do so [13]. Also, it can be referred to person's willingness to engage in a specific behavior [14]. Behavioral Intention also is described as individuals' intents to replace traditional methods with the new systems in the future [15].

Performance Expectation is the degree to which an individual believes that their work performance would be improved when utilizing a system [9]. It is also specified as the expectation of performance improvement due to the use of technology [16]. Similarly in education, it is also defined as the extent of a belief that their performance in academics will be improved by using LMS [17].

The level of easiness associated with the application of a system is characterized as Effort Expectancy [9]. Therefore, the student's level of education and information technologies knowledge will not involve any kind of physical or mental exertion in the usage of technologies in their studies [13]. It is also mentioned that the perceived easiness of using LMS is considered Effort Expectancy [18].

The degree to which an individual considers that essential persons think they have to utilize technology is referred to as Social Influence [9]. Furthermore, the degree to which students believe that important persons, such as colleagues, friends, and university lecturers, think they must apply technologies such as smartphones in their studies is also referred to as Social Influence [13]. Next, the social impact is the belief that others' perspectives on utilizing online learning management systems are essential for instructional activities [18].

The amount to which someone believes that the adoption of technology comes with technological and organizational infrastructure is referred to as the Facilitating Conditions [9]. It also refers to the tools and assistance available for using technology [16]. Facilitating Conditions also is defined as students' belief that technology like smartphones can be used by students as supplemental learning tools in their coursework since there is adequate organizational and technical infrastructure [13].

Hedonic Motivation is described as happiness or joy brought on by technology [11]. It is also described as the perceived enjoyment acquired when using LMS in the education sector [18]. Previous studies also stated that within the framework of mobile learning adoption and usage, Hedonic Motivation is referred to envisioned as a sense of enjoyment [16].

Habit is defined as a human action that is repeatable due to knowledge [11]. Habit also is referred to the extent to which the student uses the online learning management system platform automatically [18]. Previous studies also mentioned that the extent to which a user feels their technology usage is automatic or instilled is referred to as habit [16].

Learning Value is referring to an intellectual exchange among the alleged advantages of the applications and the period and effort spent on utilizing them [19]. Learning Value also is related to the student's learning achievement by using a smart campus [20].

B. Students' Acceptance towards Technology Adoption in Campus using UTAUT2

There are many adoptions of technology on campuses to provide better life experiences to the campus community, especially students. As such, research has been made to study student acceptance of technology adoption on campus by using the UTAUT2 model. Table II provides an overview of related studies regarding to the students' acceptance towards technology in campus.

TABLE II.   SUMMARY OF RELATED WORKS

Author & Year	Domain of Measure	Variables	Results
Ali et al. (2016) [21]	Factors influencing how well students in hospitality and tourism institutions embrace and use computer-based collaborative classrooms	Performance expectancy, effort expectancy, social influence, facilitating conditions, price value, hedonic motivation, habit	The admission of pupils is significantly influenced by all the elements. The way that students utilize technology is determined by their intention, their habits, and the facilitating conditions that are in place.
Farooq et al. (2017) [22]	Relationship between the UTAUT2's current notions of personal innovativeness (PI), intention, and use behavior regarding lecture capture systems (LCS)	Performance expectancy, effort expectancy, social influence, facilitating conditions, price value, hedonic motivation, habit, personal innovativeness	The acceptability and usage of LCS by students is significantly influenced by all variables.
Arain *et al.* (2019) [16]	Factors influence mobile learning acceptance in context of higher education	Performance expectancy, hedonic motivation, habit, ubiquity, satisfaction, information quality, system quality, appearance quality, effort expectancy, facilitating conditions, social influence	Performance expectancy, hedonic motivation, habit, ubiquity, satisfaction have the significant impact on students' behavioral intention. Information quality, system quality and appearance quality have significant impact on satisfaction of the students. Effort expectancy, facilitating conditions and social influence does not have significant impact on students' behavioral intention towards mobile learning acceptance.
Samsudeen, & Mohamed (2019) [15]	Factors that affect how university students in Sri Lanka intention and use behavior when using e-learning systems	Performance expectancy, effort expectancy, social influence, hedonic motivation, facilitating conditions, work life quality, internet experience	Students' behavioral intentions are extensively influenced by performance expectancy, effort expectancy, social influence, work life quality, internet experience and hedonic motivation. The LMS usage is influenced by behavioral intention and facilitating conditions.
Sharif et al. (2019) [20]	Combining the UTAUT2 and Task Technology Fit (TTF) model to analyze behavioral intention while adopting learning management systems.	Social influence, facilitating conditions, hedonic motivation, learning value, habit, performance expectancy, effort expectancy, task characteristics, technology characteristics.	The acceptance of LMS is significantly influenced by social influence, facilitating conditions, hedonic motivation, learning value and habit. However, the intention to employ a LMS is not significantly impacted by performance expectancy and effort expectancy. TTF will motivate students as well as influences user-friendliness and performance.

Based on the UTAUT2 model, variables influencing hospitality and tourism students' acceptance and use of classroom technology are explained by Ali et al. [21]. According to the study, performance expectancy, effort expectancy, social influence, facilitating conditions, price value, hedonic motivation, and habit all have a substantial impact on student acceptance. Furthermore, students' use behavior differs depending on their intention to use and their habit of using classrooms technology, as well as the facilitating conditions accessible to the students.

Next, pivotal correlation between existing constructs of UTAUT2, personal innovativeness (PI) as the new variables extends in UTAUT2, intention and use behavior towards lecture capture systems (LCS) presented by Farooq et al. [22]. The studies also revealed that student acceptance and usage of LCS are significantly influenced by performance expectancy, effort expectancy, social influence, facilitating conditions, price value, hedonic motivation, and habit. Personal innovativeness, a new variable included to the UTAUT2 model, was also found to have a substantial positive influence on student acceptance and usage of LCS. It has a large influence on students' intention and use behavior toward the LCS.

Sharif et al. [20] integrate the UTAUT2 and the Task Technology Fit (TTF) model, to describe individuals' behavioral intention to embrace learning management. The findings revealed that social influence, facilitating conditions, hedonic motivation, learning value, and habit had a substantial impact on the acceptability of the LMS in the UTAUT2 model. However, there was no significant influence of performance expectancy or effort expectancy on the desire to use a LMS. Furthermore, the TTF has an impact on user-friendliness and performance in addition to motivating student adoption of the system. Hence, the relationship between UTAUT2 and TTF will provide advanced performance and effort expectancy when students use the technology based on a match between its characteristics and the task's requirements.

III. PROPOSED METHODOLOGY

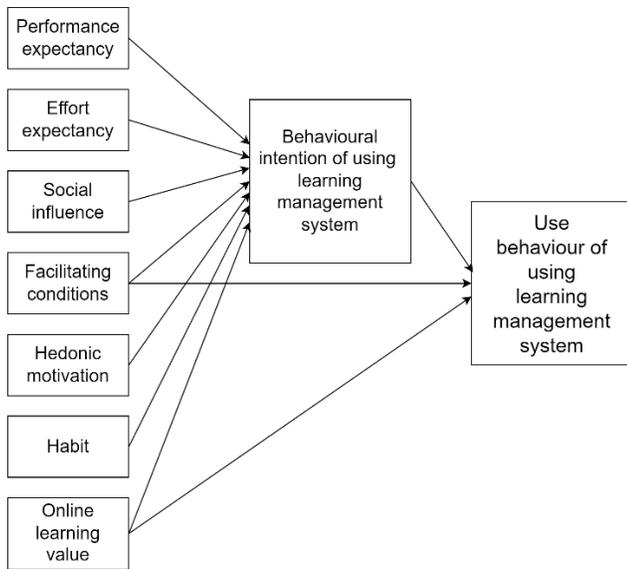
The UTAUT2 model was used to design a questionnaire in accordance with the recommendations from authors of earlier research [13], [20] to study student acceptance of using the LMS in UTHM. The research model employed in this work is depicted in the following Fig. 1.


Fig. 1. Extended UTAUT2 Research Model.

A. Questionnaire Design

Generally, this study was conducted by distributing the questionnaire through an online survey to the participants. The respondents for this study are UTHM students as we need to study the acceptance of LMS among UTHM students. The questionnaire consists of two parts comprising the demographic and UTAUT2 variables. An online tool known as Google Forms was used as a mode of survey delivery. These items were measured using a five-point Likert scale, ranging from "strongly agree" to "strongly disagree" [11].

Table III shows the list of measurement items included in the questionnaire which was derived from prior research. The total number of measurement items produced for this study were 30. The measurement item codes of PE1-PE3, EE1-EE4, SI1-SI3, FC1-FC4, HM1-HM3, HT1-HT3, and BI1-BI3 have been modified from Venkatesh et al. [11]. The measurement item codes of OLV1-OLV3 were modified from Ain et al. [23] while the measurement item codes of USE1-USE4 were adapted from Nikolopoulou et al. [13]. Each of these measurement items has been tailored to the perspective of this study.

B. Pilot Study

Table IV shows Cronbach's alpha results for every construct in Pilot Study from 43 respondents. According to the findings, all of the constructs have Cronbach's alpha values more than 0.70, which is deemed good [24]. Thus, the questionnaire was considered reliable to proceed with the actual study.

C. Data Collection

In order to reach the respondents, a link to the questionnaires was shared with them via social media, including Twitter, Instagram, and WhatsApp. The questionnaire link remained active until the targeted sample size has been reached. The data then were collected and analyzed using SPSS software.

TABLE III.   LIST OF MEASUREMENT ITEMS

Item Code	Question
PE1	I find that using a learning management system is beneficial to my learning.
PE2	Using a learning management system allows me to complete tasks faster.
PE3	Using a learning management system improves my understanding of my courses.
EE1	It is simple for me to learn how to use a learning management system.
EE2	My interaction with the learning management system is simple and straightforward.
EE3	I found the learning management system to be simple to use.
EE4	It is easy for me to become skillful at using learning management system.
SI1	People who are significant to me believe that I should use the learning management system.
SI2	People that have an impact on my behavior believe that I should use a learning management system.
SI3	People whose opinions I appreciate advise me to use the learning management system.
FC1	I have the necessary resources to use the learning management system.
FC2	I have the essential knowledge to use the learning management system.
FC3	Other technologies that I use are compatible with the learning management system.
FC4	I can seek support from others once I am having difficulty utilizing the learning management system.
HM1	It is fun to use a learning management system.
HM2	It is enjoyable to use a learning management system.
HM3	It is very entertaining while using learning management system.
OLV1	Learning using a learning management system is more valuable than the time and effort invested.
OLV2	The learning management system enables me to share my knowledge rapidly and easily with others in less time.
OLV3	The learning management system allows me to expand my knowledge and regulate my achievement.
HT1	Using a learning management system has become a habit for me.
HT2	I'm hooked on using the learning management system.
HT3	I must utilize the learning management system.
BI1	In the future, I intend to continue utilizing the learning management system.
BI2	In my daily life, I will continuously attempt to use a learning management system.
BI3	I want to make extensive use of the learning management system.
USE1	I regularly use learning management system in my studies.
USE2	Learning management system usage is a pleasant experience.
USE3	I am now using a learning management system to help me with my academics.
USE4	I spend a lot of time using a learning management system during my studies.

TABLE IV.   CRONBACH'S ALPHA COEFFICIENT

Construct	Cronbach's Alpha	Number of Items
Performance expectancy	0.942	3
Effort expectancy	0.974	4
Social influence	0.961	3
Facilitating conditions	0.969	4
Hedonic motivation	0.978	3
Habit	0.927	3
Online Learning value	0.971	3
Behavioral intention	0.972	3
Use behavior	0.977	4

The sample size for this study was obtained by applying Adam's sample size calculation [25]. The calculation is applicable to be used in determining the optimum sample size at all levels of confidence for both continuous and categorical variables. Equation (1) shows the sample size formula by Adam [25].

$$n = \frac{N}{1 + N\varepsilon^2} \tag{1}$$

Where.

n is the minimum size of returned samples.

N is the size of population.

ε is the adjust margin of error [$\varepsilon = (\frac{\rho e}{t})$].

e is the degree of precision given as a proportion.

ρ is the number of standard deviations that would encompass all feasible range values.

t is the t-value for the chosen alpha level of confidence.

According to Adam [25], the ρ value recommended for continuous variables is four and for categorical variables is two, whereas according to Krejcie & Morgan [26], the e value recommended for continuous variables is 0.03 and 0.05 for categorical variables. Besides, there are three confidence levels which are 90% confidence level with a 10% chance to be wrong, 95% confidence level with a 5% chance to be wrong, and 99% confidence level. The population size of UTHM students includes 13,895 students. The ρ value calculated in this formula is two, while the e value used in this formula is 0.05. The 95% confidence level was used in this study because the 90% confidence level would be narrower, and the 99% confidence level would be wider. Thus, the t-value calculated in this formula is 1.96. Adam [25] stated that a minimal required sample size for categorical variables for a population size of 10,000 is 370 and for continuous variables is 260. Based on the calculation, the minimum returned sample size required for this study is 374 (2.7%) respondents.

IV. DATA ANALYSIS AND RESULTS

Descriptive Statistics, Pearson's Correlation Coefficient, and Multiple Linear Regression were used to analyze the data in this study. Each of it will be presented in the following sections.

A. Descriptive Statistic

To summarize the data from the demographic section, a descriptive analysis was performed. Table V shows the demographic analysis.

TABLE V.   DEMOGRAPHIC ANALYSIS

Items	Category	Frequency	Percentage (%)
Gender	Male	161	48.82
	Female	215	57.18
Age	Below 20	130	34.57
	21-30	246	65.43
	31-40	-	-
	41-50	-	-
	>50	-	-
Faculty	FKAAB	18	4.79
	FKEE	14	3.72
	FKMP	28	7.45
	FPTP	31	8.24
	FPTV	26	6.91
	FSKTM	187	49.73
	FAST	16	4.26
	FTK	10	2.66
	PPD	46	12.23
Last Time Using	A days ago	332	88.30
	A weeks ago	18	4.79
	A months ago	14	3.72
	A years ago	12	3.19
How Often Using	Once every week	8	2.13
	2-3 times each week	60	15.96
	Always	282	75.00
	Rarely	26	6.91

The total number of questionnaires filled by the respondents after the data preparation was 376 consisting of 161 males and 215 females, representing a proportion of 42.82% and 57.18% respectively. Additionally, most responders fall within the age range of 21-30 years old with a percentage of 65.43%, followed by the age below 20 years old with a percentage of 34.57%. The results of this survey, which covered nine faculties, show that the Faculty of Computer Science and Information Technology (FSKTM) provided half of the replies, with a total of 187 respondents. Also, most of the respondents used LMS days ago with a percentage of 88.30%, while the least respondents used LMS years ago with a percentage of 3.19%. Lastly, most of the respondents are always using a LMS with a percentage of 75%, while the minority of the respondents use a LMS once a week with a percentage of 2.13%. In this regard, most of the students often use LMS because it has been fully used by the academic staff as a medium in the teaching and learning process instead of

using other systems or applications related to online learning platforms.

Construct	Measurement Item	Mean	Std. Deviation
Performance Expectancy	PE1	2.54	1.377
	PE2	2.63	1.283
	PE3	2.81	1.152
Effort Expectancy	EE1	2.46	1.397
	EE2	2.53	1.358
	EE3	2.44	1.441
	EE4	2.53	1.433
Social Influence	SI1	2.76	1.195
	SI2	2.86	1.158
	SI3	2.85	1.166
Facilitating Conditions	FC1	2.62	1.289
	FC2	2.52	1.338
	FC3	2.61	1.338
	FC4	2.67	1.343
Hedonic Motivation	HM1	2.71	1.197
	HM2	2.73	1.167
	HM3	2.81	1.156
Online Learning Value	OLV1	2.78	1.139
	OLV2	2.79	1.187
	OLV3	2.72	1.154
Habit	HT1	2.65	1.383
	HT2	3.16	1.152
	HT3	2.82	1.248
Behavioral Intention	BI1	2.73	1.179
	BI2	2.90	1.119
	BI3	2.83	1.160
Use Behavior	USE1	2.48	1.403
	USE2	2.64	1.214
	USE3	2.58	1.290
	USE4	2.78	1.300

Table VI shows the average and Standard Deviation (SD) for each measurement item. Based on the table, the mean value ranges from 2.44 to 3.16, which indicates that the center of the data is within the range of Likert scale between "agree" and "not sure". The standard deviation for each measurement item also shows that the data were spread out closely to the mean.

B. Analysis of Pearson Correlation Coefficient

Table VII shows the Pearson correlation coefficient analysis result. The Pearson correlation coefficient was utilized to evaluate the linear relationship between the independent and dependent variables. A value of 0 implies there is no link between the two variables, a value of +1 suggests there is a strong relationship, and a value of -1 indicates there is a weak association [27].

The multicollinearity in the data can be detected by determining the correlation matrix, tolerance value, and variance inflation factor (VIF). If the correlation coefficient in Pearson's correlation does not exceed 0.90, then the data do not have any multicollinearity problem [28]. Also, Table VII illustrates that all variable's correlation values do not exceed 0.90; as a result, there is no multicollinearity in the data. Additionally, Multicollinearity in the data may be recognized if the tolerance value is less than 0.10 and the variance inflation factor (VIF) value is more than 10 [29]. According to the study, all tolerance levels above 0.10, and all VIF values were under 10. This shows that the data do not have any multicollinearity problem.

C. Analysis of Multiple Linear Regression

Multiple linear regression analysis was conducted to measure the significance of two or more independent variables with the dependent variables. The following equation shows the multiple linear regression formula used in this study.

$$\hat{y} = \beta_0 + \beta_1 x_1 + \beta_1 x_1 + \cdots + +\beta_k x_k \qquad (2)$$

where,

$\hat{y}$ is the dependent variable.

x_k is the independent variable.

β_0 $\beta_0 = \bar{y} - \beta_1 \bar{x}_1 + \beta_2 \bar{x}_2$

$\beta_1 = \dfrac{[(\sum x_2{}^2)(\sum x_1 y) - (\sum x_1 x_2)(\sum x_2 y)]}{[(\sum x_1{}^2)(\sum x_2{}^2) - (\sum x_1 x_2)^2]}$

$\beta_2 = \dfrac{[(\sum x_1{}^2)(\sum x_2 y) - (\sum x_1 x_2)(\sum x_1 y)]}{[(\sum x_1{}^2)(\sum x_2{}^2) - (\sum x_1 x_2)^2]}$

Using SPSS software, multiple linear regression analysis was conducted to assess the significance of two or more independent variables in relation to the dependent variables of behavioral intention and use behavior.

We changed R Square in the model summary for the first dependent variable, Behavioral Intention, to estimate the total variability proportion in the dependent variable explained by the independent variables [30]. The modified R Square value was 0.752, indicating that the independent factors explain 75.2 percent of the variability in behavioral intention to utilize the LMS. This implies that the research model might be utilized to

explain the variables influencing students' behavioral intention to use the LMS. Table VIII shows an analysis of the multiple linear regression for the Behavioral Intention.

TABLE VIII. MULTIPLE LINEAR REGRESSION : BEHAVIORAL INTENTION

Independent Variable	Coefficient β	p-value
Performance Expectancy	0.129	0.014
Effort Expectancy	-0.032	0.515
Social Influence	0.037	0.369
Facilitating Conditions	0.013	0.812
Hedonic Motivation	0.221	0.000
Online Learning Value	0.109	0.036
Habit	0.513	0.000

The ANOVA table's Sig. column displays the p-value. The dependent variable may be predicted by the model if the p-value is less than 0.05. According to the results of the ANOVA, the p-value was 0.000, which is less than 0.05. As a result, there is significant evidence that the model is beneficial in understanding the factors influencing students' intentions to use LMS and that the independent variables can predict students' Behavioral Intention.

The coefficient β is used to identify the strength of each independent variable towards Behavioral Intention. This means that changes by one unit in the independent variable that keeps other independent variables constant can determine the number of changes in independent variables [31]. Habit has the highest coefficient β value with 0.513. As a result, this factor has the biggest influence on students' Behavioral Intention to use the LMS which means that when students keep using the learning management system, it will influence their habit to use the LMS.

Furthermore, the p-value should be less than 0.05 for the variables to be significant. Evidently, Performance Expectancy, Hedonic Motivation, Online Learning Value, and Habit each has a p-value under 0.05. As a result, each of these variables affects the dependent variable. When the student also enjoy using the learning management system, it will influence their intention to use the LMS as we can see hedonic motivation is the second important factor that influence student's behavioral intention towards LMS. Furthermore, when the students keep using the LMS, they recognize that LMS help them in their learning performance as in this study the performance expectancy is the third important factor. As the LMS assist in their learning performance, they tend to explore more on the benefits of the learning management system. This means that the learning value that is obtain by using the LMS will influence students' intention to use the LMS.

In the meanwhile, the p-values for effort expectancy, social influence, and facilitating conditions were all more than 0.05. This shows that each of these factors does not influence the dependent variable. The facilitating conditions that are provided and the ease of use by using the LMS does not significantly influence their behavioral intention to use the LMS. Students also do not intent to use the LMS by

depending on others opinion. As a result, none of these indicators can predict students' behavioral intention to use the LMS at UTHM.

For the Use Behavior, the output shows that the value of adjusted R Square was 0.798; hence, 79.8% of the variability in the students' Use Behavior towards the learning management system is explained by the independent variables. This also means that the research model may be used to describe the factors influencing students' Use Behavior in the learning management system.

TABLE IX. MULTIPLE LINEAR REGRESSION: USE BEHAVIOR

Independent Variable	Coefficient β	p-value
Facilitating Conditions	0.481	0.000
Habit	0.343	0.000
Behavioural Intention	0.239	0.000

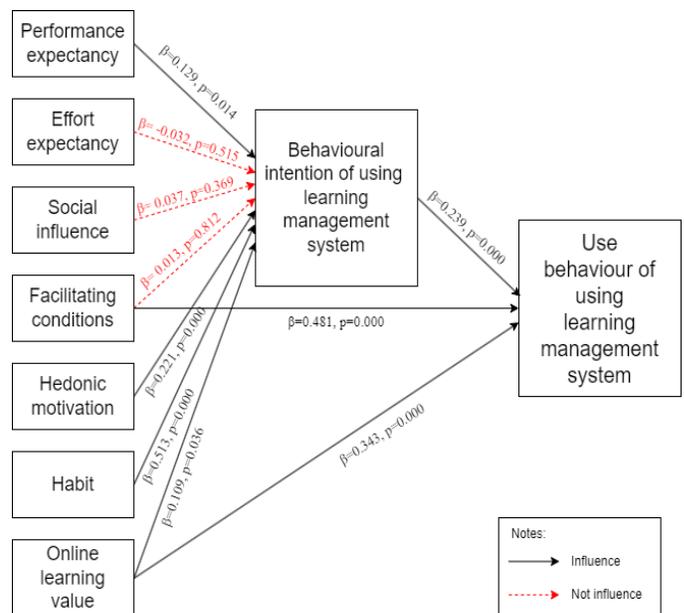
Table IX shows the coefficient β and the p-value for the multiple linear regression analysis of the dependent variable: Use Behavior. Facilitating Conditions yielded a higher coefficient β value of 0.481. This means that this factor has the strongest effect on students' Use Behavior toward the LMS. Furthermore, the p-value should be less than 0.05 for the variables to be significant. Evidently, Facilitating Conditions, Habit, and Behavioral Intention all have p-values of less than 0.05. Hence, each factor influences the dependent variable. The result also shows that behavioral intention has the least coefficient β which means that their intention to use the LMS did not fully influence their use of LMS. However, because the students must continue to use the LMS, it has become a habit for them. As a result, habit has emerged as the second most significant element influencing student LMS usage behavior. Fig. 2 shows the research model after analysis.


Fig. 2. Research Model after Analysis Result.

Overall, the results have shown that performance expectancy, hedonic motivation, habit, and online learning value are the significant factors that influence students' intention to use LMS, whereas facilitating conditions, habit, and behavioral intention are the significant factors that influence students' use behavior towards LMS.

V. CONCLUSION AND FUTURE WORKS

This study is focused on the acceptance of UTHM students of their online learning management system based on the UTAUT2 model. A detailed explanation on the use of the UTAUT2 model and the background information related to this study has been provided. The proposed methodology also has been discussed. Then the data analysis and results has been presented using Descriptive Analysis, Pearson's Correlation and Multiple Linear Regression. The objectives of this study have been achieved.

Firstly, from the results, the factors that have the most influence on UTHM students' behavioral intentions toward using the LMS are Performance Expectancy, Hedonic Motivation, Online Learning Value, and Habit. Also, we may infer from the results that students think implementing a learning management system would improve their academic achievement. Next, students have fun and joy derived from using the LMS. Furthermore, students dedicated their time and effort to using the LMS and the perceived value that they get from using the LMS. Lastly, students used the LMS automatically and become habitual in their learning process.

Secondly, the outcome also demonstrates that Habit, Behavioral Intention, and Facilitating Conditions are the elements that affect UTHM students' Use Behavior when using LMS. From the results, we conclude that having access to a few sources and assistance boosts students' intention to utilize the LMS, making it the most important factor influencing students' LMS Use Behavior. The next reason why students use the LMS is Habit, and it is the final element that has the least impact on how students use the LMS is whether they want to keep using it to further their education.

Thirdly, Online Learning Value construct was proposed as the new variable in the UTAUT2 model to study students' behavioral intention toward the LMS in UTHM. The result from Table VIII shows that the Online Learning Value construct (β =0.109, p=0.036) also is a significant factor in determining students' behavioral intention toward using the LMS in UTHM.

Several recommendations for future works based on the findings of this study can be explored. Currently, this study only focuses on the variables stated in the UTAUT2 model along with the new construct which is Online Learning Value. Other variables may be explored to identify other factors that can influence student acceptance of using LMS in UTHM. This may further give insight to LMS administrator and developer to enhance the LMS in UTHM. Also, choosing other stakeholders such as academic staff and administrators for the acceptance of the LMS also can be done in the future. This work is also important considering that other stakeholders' acceptance may also play an important part in the LMS's success.

Abstract—Video information processing is one of the most important application areas in research and to solve in various pre-processing issues. The pre-processing issues such as unstable video frame rates or capture angle, noisy data and large size of the video data prevent the researchers to apply information retrieval or categorization algorithms. The video data itself plays a vital role in various areas. This work aims to solve the motion stabilization, noise reduction and key frame extraction, without losing the information and in reduced time. The work results into 66% reduction in key frame extraction and nearly 6 ns time for complete video data processing.

Keywords—Information loss preventive; mean angle measure; key frame extraction; moving average; dynamic thresholding

I. INTRODUCTION

Key-frame extraction from first-person vision (FPV) is a fundamental tool for highlighting and memorizing meaningful moments from a person's life. Selecting pivotal frames is challenging when using head-mounted FPV cameras due to the scene's inherent uncertainty. Because of the inherent instability of head-mounted cameras, FPV footage is noisier than TPV footage. In order to extract key frames, most algorithms consider TPV scenes to be static. Extraction of key frames from noisy first-person-view videos is still in its infancy. While human motion is ubiquitous in daily life, most key-frame fractionation algorithms rely on information from first-person videos. FPV videos rely heavily on motion capture integrated with visual scenes due to the rapid nature of scene transitions. The authors of this study propose a new key-frame extraction technique for FPV videos to attenuate background noise and identify potentially important events. Both the sparse-based and graph-based multi-sensor integration models proposed for key-frame extraction perform well on the shared space. Experiments with multiple datasets support the claim that the proposed key-frame extraction techniques enhance "extraction precision and coverage of entire video sequences" [1].

When applied to dynamic regions of interest, video SAR can enhance automatic retrieval of information. Extracting key frames from a video efficiently processes large amounts of data. Background subtraction using computer vision is suggested for automatic key-frame selection in Video SAR scattering. Key frames for scattering in Video SAR are revealed by a universal parameterization model. To differentiate the scattering key-frame state of transient persistence and disappearance, we propose the use of the "sub aperture energy gradient (SEG) and a modified statistical and knowledge-based object tracker (MSAKBOT)". Multitemporal video sequences are no match for the proposed SEG-MSAKBOT method, which evaluates pelting key frames in a more comprehensive and adaptable manner. Experimental findings and performance evaluation on two actual airborne Video SAR datasets with coherent integration angles [2].

VSUMM is widely used for processing large amounts of video information. Frames that best capture the essence of a video's subject are chosen by VSUMM. A novel framework is proposed for elucidating content and motion to solve these problems. A cross - functional and cross motion curve is created by Capsules Net, which has been taught to extract spatiotemporal information. Next, we propose an approach to automatically extract individual shots from continuous video feeds by analyzing their sensitivity to a variety of transition effects. Key-frame patterns in under shots can be selected using a self-attention model, key static images can be chosen for video content categorization, and optical movements can be calculated for video motion summarization. Results from experiments show that the method achieves competitive results [3].

An essential part of video retrieval is the extraction of key frames. For videos with multiple scenes and actions, the current state of the art in key frame extraction falls short. This article proposes a model for image saliency extraction that is aided by deep prior information. The paper proposes a saliency extraction algorithm to find important details in a given image. Here we describe a novel approach to finding the most important moments in a video. In this article, we build an image-integrated model of visual attention to track a combination of multiple bottom-level features and the skin color confidence map of the target. Extraction of the moving targets. The algorithm has been shown to effectively grasp pedestrian information in moving videos and provide samples of motion targets for post-processing [4] based on experimental results.

The rest of the work is organized such as in the Section – II, III and IV the foundational methods for motion stabilization, noise reduction and key frame extractions are discussed, further based on the baseline methods, the recent research improvements are discussed in the Section – V, further the persistent research problems are discussed in the Section – VI and based on the analysis of the problem, the proposed solutions are discussed in Section – VII and Section VIII, the obtained results from the proposed solutions are discussed in the Section – IX and again compared with the other benchmarked algorithms in Section – X. The research presents the conclusion in the Section – XI.

II. Foundational Method for Motion Stabilization

Firstly, in this section of the work, the baseline method for motion stabilization is analyzed. The process for motion stabilization is highly crucial as the unstable video data influences the decisions during video stabilization process.

Assuming that, the complete video data is V [] and each frame is denoted as f_i. Then, for n number of total frames, the relation can be formulated as,

$$V[] = <f_1, f_2, f_3 .... f_n> \tag{1}$$

Further, assuming that the function ϕ is an arbitrary function to extract the dimension, $d_X[]$ and angle of video capture, a_X from the frames. Thus, this can be furnished as,

$$\phi\{f_X\} \Rightarrow [d[]_X, a_X] \tag{2}$$

Thus, for two independent frames, as f_i and f_j, the formulation can be realized as,

$$\phi\{f_i\} \Rightarrow [d[]_i, a_i] \tag{3}$$

$$\phi\{f_j\} \Rightarrow [d[]_j, a_j] \tag{4}$$

The detection of the unstable video can be detected if the following condition appears in any two consecutive frames as,

$$a_i \neq a_j \tag{5}$$

During such situations, the baseline method recommends calculating the mean angle, a_{Mean} of the total video and further change the angle of the unstable frames with the mean angle. This can be realized as,

$$a_{Mean} \Leftarrow mean\{\sum_{i=1}^{n} a_i\} \tag{6}$$

And further replace with the existing angles, as,

$$a_i \leftarrow a_{Mean} \tag{7}$$

$$a_j \leftarrow a_{Mean} \tag{8}$$

Regardless to mention, the base line method has seen many improvements in recent times. The improvements are discussed in the further section of this work.

III. Foundational Method for Noise Reduction

Secondly, in this section of the work, the baseline method for noise reduction is analyzed. The noise reduction is yet another highly important task before processing the video data for information extraction. Any noisy video data can wrongly influence the decision-making tasks during the processing of the video data.

The baseline method for noise reduction or removal process is furnished here. After realizing the Eq. 1, assuming that, λ is an arbitrary function to extract the size of the pixel information, s_X and list of objects with details, $obj_X[]$ from each frame. This can be formulated as,

$$\lambda\{f_X\} \Rightarrow [s_X, obj_X[]] \tag{9}$$

The baseline method demonstrates that, the extraction of similar frames, F[], with similar objects is the initial step towards the noise reduction as,

$$F[] \Leftarrow \prod_{obj_X[]=V[i].obj_i[]} V[i] \tag{10}$$

Now assuming that two frames, fi and fj are part of F[] set and contain similar number of objects. Hence, the information size, s_i and s_j, must be same. If the information sizes are different, then it is natural to realize that the frames contain noise as per the baseline method. As,

$$iff \ s_i \neq s_j$$
$$then, s_i \ \& \ s_j \Rightarrow Noise \tag{11}$$

Further, the baseline method indicates to replace the pixel information of the noisy frames with the mean information, S_{Mean} from the similar frames. As,

$$s_i \Leftarrow Mean\{\sum_{k=1}^{Length\{F[]\}} F[k]\} \tag{12}$$

$$s_j \Leftarrow Mean\{\sum_{k=1}^{Length\{F[]\}} F[k]\} \tag{13}$$

Regardless to mention, that the base line method has seen many improvements in recent times. The improvements are discussed in the further section of this work.

IV. Foundational Method for Key Frame Extraction

Thirdly, in this section of the work, the baseline method for the key frame extraction is furnished. The video information processing is a highly time complex process in general and to reduce the time complexity of the processing algorithms, the researchers have adapted to method to reduce the size of the video data without losing the critical information from the data. This process is identified as key frame extraction process.

The baseline method indicates, that the total video data must be broken into set of frames, F[], based on a given time threshold as,

$$F[] = \frac{d}{dt}V[] \qquad (14)$$

Further, the key frame extraction process, as per the baseline method, is very simple. The consecutive frames contain different information must be considered as key frames, KF[]. This can be formulated as,

$$KF[] \Leftarrow \prod_{F[i] \neq F[i+1]} F[] \qquad (15)$$

The terminating condition for such methods is that the length of the extracted key frame set must be less than the total video data as,

$$Length\{KF[]\} \; \Box \;\; Length\{V[]\} \qquad (16)$$

Regardless to mention, that the base line method has seen many improvements in recent times. The improvements are discussed in the further section of this work.

V. RECENT RESEARCH REVIEWS

After realizing the baseline methods, in this section of the work, the recent research improvements over the baseline methods are discussed.

To address the problems of miss-election and misselection due to poor video key frame detection, Z. Wang et al. [5] propose an algorithm based on motion vectors to locate the crucial frames in a video. Using the sum of the entropy of the difference between adjacent frames and the entropy of the image in two dimensions, we can quantify frames. Second, the lens boundary can be obtained with the help of statistical tools. ViBe is an algorithm that can recognize the object in the foreground of a video and extract transformation features that are not affected by the size of the image. The motion vector is found by first segmenting two consecutive frames, and then matching those segments block by block. The video's level of motion is reflected in the magnitude of the motion vector, allowing us to identify "active and inactive motion" regions. Video frames are compared using a predetermined formula to determine which regions of frames are most similar, and then video frames are extracted from those regions. Video findings with rich motion information are improved by the proposed detection algorithm, as demonstrated by experimental results. The outcomes of VR key frame extraction are also analyzed in this article.

Determining whether or not a video frame was intentionally deleted or altered, is a crucial part of video forensics. Existing methods are unable to process videos with varying levels of motion. Interfering frames are ignored by these methods. C. Feng et al. [6] aim to develop an interference-free, motion-adaptive forensic technique. Researchers analyze statistically the frames that interfere with one another, like moved I-frames to pinpoint the frames that should be removed (FDPs). The adaptability of the fluctuation feature to various levels of motion is enhanced by the elimination of intra-predictions. The improvement is quantified with the aid of moving window detectors. We propose a post-processing technique to eliminate jarring transitions in brightness, focus, and frame rate. When applied to videos with varying motion intensities and interfering frames, the algorithm has a true positive rate of 90% and a false alarm rate of 0.3%. The proposed technique has potential applications in video forensics.

CRC mortality rates can be lowered through early diagnosis. Polyps are the first stage of cancer. Disease diagnosis and comprehension require analysis of the most crucial endoscopy frames. Sasmal et al. [7] use deep learning to select laparoscopic video key-frames. This technique employs transfer learning due to the scarcity of high-quality polyp depth maps. During an endoscopy, many images are taken. Discarding frames from an endoscopic video that are of poor quality or have no diagnostic value is necessary for making a clinical diagnosis. Key-frame selection is suggested using polyp depth information. This method intelligently chooses key-frames by analyzing the significance of edges, punctuation, and other image features. So that the surgeon can separate the polyp from the mucosa layer, a real-time 3D image of the polyp's surface is provided. Polyps can be more easily pinpointed with the aid of depth maps.

Recognizing anomalies in video footage, which is necessary for uses such as surveillance, is not easy. The state-of-the-art methods for detecting video anomalies typically rely on deep rebuilding models, but their results fall short because there isn't enough of a difference between the reconstruction errors for normal and anomalous video frames to fully optimize the models. Anomaly detection using frame predictions shows promise. Unsupervised content anomaly detection was proposed by X. Wang et al. [8] using frame prediction. To deal with semantically informative objects and regions of varying scales and to capture spatial-temporal dependencies in everyday videos, the proposed method employs a "multipath ConvGRU-based frame prediction" network. In order to lessen the impact of ambient noise, training lowers tolerance for it. The proposed method achieves better results than the current state-of-the-art approaches.

To achieve a higher frame rate in videos, interpolation is used to synthesize new frames between the existing ones. Existing techniques rely on pairing adjacent frames to create intermediate frames, but they struggle with issues like high-velocity motion, occlusion, and blurring. In order to make the most of the spatial and temporal data at their disposal, H. Zhang et al. [9] proposed "a multi-frame pyramid refinement network". There are three technical advancements that would benefit the proposed network. The first step is the proposal of a coarse-to-fine framework for improving optical flows across multiple frames. Estimates can be made for both large-scale motion and occlusion. Second, spatial and temporal context is unearthed, and texture is restored. Third, we use perceptual loss in multiple steps to keep the finer details of the intermediate frames intact. For interpolation between multiple frames, this technique can be used. Overall, 80K frame groups are used in the training process. The method has been shown to outperform state-of-the-art methods and handle challenging cases on multiple independent datasets.

H. Bhuyan et al. [10] extract the key frames from the dance video and the motion frames from the video itself. New,

easy, and efficient, the localization method is suggested. The basic structure of KFs varies depending on the dance style and the dancer. It's not easy to establish a universal threshold for movement that applies to all dancers and performances. The threshold was previously determined using iterative methods.

W. Zhang et al. [11] investigated spatio-temporal video super-resolution. The researchers first propose a cross-frame transformer-based network for end-to-end spatio-temporal video super-resolution. To reconstruct high resolution and frame rate results from coarse to fine, the researchers propose "a multi-level residual reconstruction module" that makes use of the maximum similarity and similarity coefficient matrices produced by the cross-frame transformer. Compared to the standard two-stage network, this method has fewer training parameters while providing improved performance.

The process of "video object extraction (VOE)" identifies and isolates region of interest from a video. To solve the issues of imprecise foreground object extraction and superfluous small-scale motion interference, Y. Guo et al. [12] proposed a novel VOE approach based on "spatiotemporal consistency saliency" detection. The proposed method's main innovation is comprised of three parts: first, the spatiotemporal gradient field (SGF) is built a tempor Experiments on the public video saliency data sets ViSal and SegtrackV2 demonstrate efficiently and accurately identify the salient object in a video sequence.

Semantic sections of a video are extracted using video segmentation, with each segment corresponding to a user-defined concept. The goal of the user has not been taken into account in previous research on video segmentation. With dimension reduction and temporal clustering, X. Peng et al. [13] present a "two-stage user-guided video segmentation" framework. During dimension reduction, coarse-grained features are extracted using ImageNet. During the temporal clustering phase dimensionally, reduced frames is used to segment videos on the time domain based on the user's intended viewing path. To better understand videos, users can employ hierarchical clustering to divide them into smaller, more manageable chunks.

To facilitate the retrieval, it takes advantage of the fact that certain video-related image features tend to exhibit temporal correlations. Key frame identification and key area localization are made possible through the use of video imprint representation. The video imprint tensor is created in the framework developed by Z. Gao et al. [14] by removing redundancy across frames with a specialized feature alignment module. The proposed reasoning network employs a memory-inspired attention mechanism. The latent structure of the reasoning network identifies key frames from the video imprint that can be used to reconstruct the sequence of events. Event retrieval is enhanced over the state-of-the-art techniques thanks to the "compact video representation aggregated from the video" imprint.

Observing moving objects is made possible thanks to video satellite's ability to produce rich actionable information. Time resolution is more important than spatial clarity in video satellite images. The quality of video satellite images is greatly enhanced by super-resolution. "Video satellite image SR reconstruction" was proposed by Z. He et al. [15]. Oftenest calculates the LR optical flow from multiple image frames. Next, an upnet is constructed to enhance the resolution of the input frame and the LR optical flow. Motion compensation is executed in accordance with HR optical flows. Through the use of the HR cube's compensation, the ARLnet produces SR results.

Intelligent service robots with video analysis capabilities are used for complex computing in the cloud. To monitoring human activity, intelligent service robots' film in a continuous loop. "Action classification, recognition, abnormal event detection, and crowd emotion sensing" all require action extraction from unrestricted continuous video. With three components—spatial location estimation, temporal action path searching, and spatial-temporal action compensation. H. Guo et al. [16] proposed a novel approach for action extraction in unconstrained continuous video. It is possible to pinpoint one's location based on a person's outward appearance and their motion. Then, considering missed sightings and false alarms, the results of the spatial action proposal are used to formulate the space - time action trail scanning as an optimal probability model. "The researchers advocate for and demonstrate the convergence of the "Markov Chain Monte Carlo" algorithm.

Because of developments in video and image processing, video tampering forensics is extremely difficult to conduct. Object reduction video forgery requires the use of passive forensics techniques, which are crucial in the courtroom. The "spatial rich model (SRM) and 3D convolution (C3D)" were the basis for the proposal of a spatiotemporal trident network by Q. Yang et al. [17], which is used to extract tampering traces from video. It can enhance the detection and identification of tampered regions, and it has three distinct branches. The "spatiotemporal trident network" served as inspiration for the development of a time-based detector and a space-based locator for locating instances of video manipulation. The temporal detector used 3D convolutional neural networks (CNNs) with three different types of encoders and decoders. C3D-ResNet12 was developed as the spatial locator's encoder. The loss functions of both algorithms were optimized by the researchers.

The future of the space information network will rely heavily on satellite video because of the dynamic information it provides on large spatial and temporal scales. This study employs a two-stream approach to extract EOI from satellite video scenes. Still images, such as scenes, are captured in each frame of a satellite video, while the order of these frames is what establishes motion. In light of these details, we propose a brand new two-stream EOI detection framework. One stream uses AlexNet to pull static spatial data from satellite videos, while the other uses local trajectories analysis to pull data on motion. Before anything else, the video scene is cut up into spatial-temporal patches where EOI and non-EOI regions are labelled. The next step is to take the 3-D satellite video cubes from the event scene patches and extract the trajectories. Finally, this weak-supervision trajectory classification problem is solved by sparse dictionary learning. The experimental outcomes demonstrate the efficacy of the two-stream method in EOI detection and its potential utility in "satellite video analysis" and comprehension. The approach

taken by Y. Gu et al. [18] is superior to current video analysis models.

CNNs can dehaze individual images, as discovered by W. Ren et al. [19]. Scientists investigate the feasibility of using a network to defog video footage. Dehazing a video can make use of the wealth of data available in adjacent frames. Based on the estimated transmission map, a haze-free scene model is created. Since the semantic information of a scene is a powerful prior for image restoration, the team suggests using "global semantic prior to regularize the transmission" maps, making the estimated maps continuous only between objects and smooth within each object. To train this network, scientists generate synthetic hazy and clear videos. Scientists have demonstrated that the features of this dataset can clear up haze in videos of outdoor scenes.

For supervised video summarization, W. Zhu et al. [20] proposed DSNet. Anchors are used and ignored by DSNet. While the anchor-based approach eliminates pre-defined temporal proposals and predicts importance scores and segment locations, the anchor-free approach in contrast to preexisting supervised video summarization techniques, the interest detection framework makes an initial attempt to exploit temporal consistency. Before extracting their long-range temporal features for location regression and importance prediction, researchers in the anchor-based approach. Segments are assigned as positive or negative to ensure the summary is accurate and comprehensive. The anchor-free method directly predicts the significance of video frames and segments, sidestepping the drawbacks of temporal proposals. This framework is compatible with existing supervised video summarization tools. Scientists evaluate both anchor-based and anchor-free methods on SumMe and TVSum. Both the anchor-based and anchor-free strategies have been verified by experiments.

Object recognition is the mainstay of computer vision. There is hope in the use of correlation filters. Because each target is so small and the target and background are so similar, the "kernel correlation filter (KCF) tracker" has trouble keeping up with moving objects in satellite videos. To better locate objects in satellite footage, B. Du et al. [21] suggested combining the KCF tracker with a three-frame-difference algorithm. For a robust tracker, it is suggested to combine the KCF tracker with the three-frame-difference algorithm. Three satellite videos demonstrate the superiority of the proposed method, as demonstrated by the researchers.

Further, based on the recent research improvements, in the next section of this work, the persistent research problems are furnished.

VI. PROBLEM FORMULATION – MATHEMATICAL MODEL

After the understanding of the baseline methods and detailed analysis of the recent research outcomes, in this section, the persistent research problems are discussed.

Firstly, the problem of information loss due to the change of angle for video stabilization is discussed.

Continuing from Eq. 3 and 4, assuming that, due to the change of the angle with a_X, the frames f_i and f_j, are expected

to change the dimensions from $d_i[]$ and $d_j[]$ to $d_X[]$. Naturally, which are different from the original dimensions. This can be realized as,

$$d_i[H_i, W_i] \neq d_X[H_X, W_X] \tag{17}$$

$$d_j[H_j, W_j] \neq d_X[H_X, W_X] \tag{18}$$

Where H and W are the height and width respectively also, it is natural to realize that, if the new dimensions are less than the original dimensions, then the information loss is non-preventable. As,

$$iff \ H_i > H_X \ Or \ W_i > W_X$$
$$Then, \lambda(f_i) > \lambda(f_i') \tag{19}$$

Where, f' is the modified frame after the motion angle change. Hence, it is natural to observe the information loss due to the angle change as per the traditional existing methods.

Secondly, the problem of undetected object mismatch during the noise reduction is realized.

The second issue with the traditional existing methods are to be realized with a condition that, the shape and number of the objects are same, however the position of the objects are different. This can be realized from Eq. 9. Assuming that, two frame f_i and f_j contain the set of objects in the frame as $obj_i[]$ and $obj_j[]$. As,

$$\lambda\{f_i\} \Rightarrow [s_i, obj_i[]] \tag{20}$$

$$\lambda\{f_j\} \Rightarrow [s_j, obj_j[]] \tag{21}$$

Here, the objects in the respective frames are same and the size of the frames are also same as,

$$s_i = s_j \tag{22}$$

$$obj_i[] = obj_j[] \tag{23}$$

Nonetheless, the positions of the objects are different as,

$$obj_i[k].(H, W) \neq obj_j[k].(H, W) \tag{24}$$

Thus, naturally, the information from the frames is also not equal. As,

$$\varpi\{f_i\} \neq \varpi\{f_j\} \tag{25}$$

Where, ϖ is an arbitrary function to extract knowledge from the video frame. Henceforth, the loss of object unique locations over in the noisy frames will be lost as per the Eq. 13.

Finally, the problem of higher time complexity during the key frame extraction is analyzed. As per the initial assumptions, the total number of frames in the video data is "n" and as per the Eq. 15, the total time complexity, T, can be formulated as,

$$T = n*(n-1) \tag{26}$$

Or,

$$T = n^2 \tag{27}$$

Which implies,

$$T(n) = O(n^2) \tag{28}$$

And, during a situation of $n \rightarrow High$, naturally, $T(n) \rightarrow Very\ High$. Thus, this problem also must be addressed.

Further, the proposed solutions to these identified research problems are furnished in the next section of this work.

VII. PROPOSED SOLUTIONS

After the detailed analysis of the problems with baseline methods and the recent improvements observed to the baseline methods, in this section of the work, proposed methods are furnished here.

Firstly, the proposed video stabilization method without the information loss is realized. The initial process is to identify the variation of the angles in each frame. Using Eq. 2, extracting all the angles from each frame and build the angle collection, A[], as,

$$A[] = \prod V[].a \tag{29}$$

Further calculate the mean angle, A_{Mean} from the angle collection as,

$$A_{Mean} \Leftarrow Mean\{\sum_{i=1}^{n} A[i]\} \tag{30}$$

Further, build another set of frames, FA[], where two consecutive frames angle is different as,

$$FA[] \Leftarrow \prod_{a_i \neq a_j} F[] \tag{31}$$

Further, apply the mean angle to the FA[] collection frames and check the number of frames, where information loss is observed. As,

$$FA[].a \Leftarrow A_{Mean}$$
$$iff\ \lambda(FA[i]) > \lambda(FA'[i]) \tag{32}$$
$$then, C[] \Leftarrow FA[i]$$

Where, C[] is collection of frames, where after motion stabilization information is lost. Now, if for the maximum number of frames information loss is observed, then the mean angle must be recalculated. As,

$$iff\ length\{C[]\} \approx length(FA[])$$
$$then, A_{Mean} \Leftarrow Max\{FA[].a\} \tag{33}$$

The proposed method indicates to repeat the process until $length\{C[]\} \rightarrow 0$. Henceforth, the loss of information is almost reduced to zero.

Secondly, the proposed noise reduction method with object information persistent and background separation is furnished.

The proposed method indicates to separate the background and foreground information from each frame. Assuming that, X is an arbitrary function to perform the separation task, then the following model can be formulated,

$$\Delta\{f_x\} \Rightarrow \{f_x.FG, f_x.BG\} \tag{34}$$

Further, build the set of frames, K[][], with similar background and similar foreground as,

$$K[][] \Leftarrow \prod_{f_x.FG=F[].FG, f_x.BG=F[].BG} F[] \tag{35}$$

The mean value of the information extracted from the K[][] collection for the background, BG_{Mean}, foreground, FG_{Mean}, must be calculate to substitute for the noisy frames. As,

$$BG_{Mean} = Mean\{\sum_{i=1, j=1}^{length\{K[][]\}, n} \lambda\{K[i][j].BG\}\} \tag{36}$$

$$FG_{Mean} = Mean\{\sum_{i=1, j=1}^{length\{K[][]\}, n} \lambda\{K[i][j].FG\}\} \tag{37}$$

Once the mean values are calculated, then the pixel value information must be replaced with the mean values. Hence, continuing from Eq. 15.

$$f_x.BG \Leftarrow BG_{Mean} \tag{38}$$

$$f_x.FG \Leftarrow FG_{Mean} \tag{39}$$

Hence, now the frames with similar object positions and similar background information can be denoised without missing the specific objects information.

Finally, the proposed variable threshold based key frame extraction method is realized.

The concept of the variable threshold used here is primarily to indicate that as the video information changes frame by frame, thus the selection of the key frames also must be decided dynamically. Hence this proposed method indicates to calculate the keyframe selection method using moving average of the threshold.

Continuing from the Eq. 9 and Eq. 14, the threshold, TH, for the information frame must be calculated as,

$$TH \Leftarrow \lambda\{f_i\} \tag{40}$$

and, further,

$$KF[] \Leftarrow \prod_{F[i].TH > Mean\{\sum_{i=1}^{n} TH(i)\}} F[] \tag{41}$$

Hence, this proposed key frame extraction process reduces the time complexity to O(n) as the mean value calculation is an iterative process along with the same steps of key frame extraction.

Further, based on the proposed methods, in the next section of this work, the proposed algorithms are furnished along with the proposed framework.

VIII. PROPOSED ALGORITHMS AND FRAMEWORKS

After the finalization of the proposed mathematical models in the previous section of this work, in this section, the proposed algorithms based on the mathematical models are presented.

Firstly, the Information Loss Preventive Video Stabilization using Mean Angle Measure (ILP-VS-MAM) Algorithm is discussed.

Algorithm - I: Information Loss Preventive Video Stabilization using Mean Angle Measure (**ILP-VS-MAM**) Algorithm

---

Input:
Video data as V[]

Output:
Motion Stabilized Video data as V1[]

Process:
Step - 1. Read the total video data as V[]
Step - 2. For every frame in V[] as V[i]
    a. Extract the angle as A[i] using Eq. 2.
    b. If A[i] != A[i-1]
    c. Then, C[j] = V[i]
Step - 3. For every element in V[] as V[k]
    a. Calculate the mean angle as MA from A[]
    b. Apply V[k].A = MA and generate V_Temp[i]
    c. If V_Temp[k] contains less information then V[k] using Eq. 32
    d. Then, remove A[k] and C[k] = 0
    e. Else, V1[k] = V[k]
    f. Stop if Length((C[]) = =0)
Step - 4. Return V1[]

In order to prevent visual quality loss, video stabilization technology minimizes unintentional jitters and shakes of an object capturing equipment without affecting moving subjects or purposeful camera panning. This is especially important for handheld imaging devices because of how much more susceptible they are to vibrations. Unwanted changes in camera position led to unstable image sequences, but controlled movement commonly generate unstable images.

Secondly, the Noise Reduction using Object Separation and Background Normalization (NR-OS-BN) Algorithm is discussed.

Algorithm - II: Noise Reduction using Object Separation and Background Normalization (**NR-OS-BN**) Algorithm

---

Input:
Motion Stabilized Video data as V1[]

Output:
Noise Reduced Video data as V2[]

Process:
Step - 1. Read the total video data as V1[]
Step - 2. For every frame in V1[] as V1[i]
    a. Extract the Background as BG[i]
    b. Extract the Foreground as FG[i]
Step - 3. Calculate the BG_Mean and FG_Mean from BG[] and FG[]
Step - 4. For each information set in BG[] as BG[k]
    a. If BG[k] == BG[k+1] and FG[k] == FG[i+1]
    b. Then, K[][]= V1[k]
Step - 5. For each element in K[][] as K[j][]
    a. If K[j][].BG > BG_Mean and K[j][].FG > FG_Mean
    b. Then,
        i. K[j][].BG = BG_Mean and K[j][].FG = FG_Mean
        ii. V2[]=K[j][]
Step - 6. Return V2[]

The process of reducing noise from a signal is known as noise reduction. Both audio and picture noise reduction methods exist. Algorithms for noise reduction may slightly skew the signal. As with common-mode rejection ratio, noise rejection refers to a circuit's capacity to separate an undesirable signal component from the desired signal component.

Finally, the Key Frame extraction using Moving Average Dynamic Thresholding (KFE-MA-DT) Algorithm is discussed.

Algorithm - III: Key Frame extraction using Moving Average Dynamic Thresholding (**KFE-MA-DT**) Algorithm

---

Input:
Noise Reduced Video data as V2[]

Output:
Reduced Key Frame set as KF[]

Process:
Step - 1. Read the total video data as V2[]
Step - 2. For each frame in V2[] as V2[p]
    a. Extract the frame threshold as TH[p]
    b. Calculate the Mean Threshold as MT using Eq. 41
    c. If TH[p] > MT
    d. Then, KF[r] = V2[p]
    e. Else, Discard the frame
Step - 3. Return KF[]

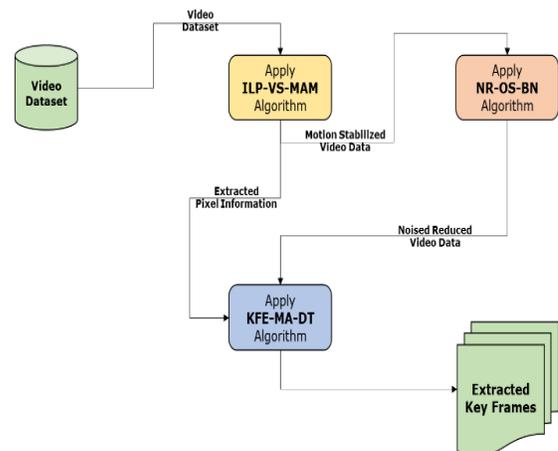
Further, based on the proposed algorithms, the framework to automate the process is furnished [Fig. 1].


Fig. 1.   Proposed Framework.

Furthermore, in the next section of this work, the obtained results are discussed.

IX. RESULTS AND DISCUSSIONS

After the detailed discussions on problems and proposed solutions, in this section of the work, the obtained results are discussed. Firstly, the dataset information is furnished [Table I].

TABLE I. DATASET INFORMATION [22]

Attributes	Number (#)
Number of Videos	1900
Average number of Frames	7247
Number of Categories	8

The number of samples in the dataset are 1900, however due to representation purposes, only 10 samples are listed. Secondly, the video data stabilization outcomes are furnished [Table II].

TABLE II. VIDEO MOTION STABILIZATION OUTCOMES

Dataset ID	Before Processing		Dataset ID	After Processing		Dataset ID
	Mean Heights	Mean Width		Mean Heights	Mean Width	
1	240	320	1	240	320	1
2	240	320	2	240	320	2
3	240	320	3	240	320	3
4	240	320	4	240	320	4
5	240	320	5	240	320	5
6	240	320	6	240	320	6
7	240	320	7	240	320	7
8	240	320	8	240	320	8
9	240	320	9	240	320	9
10	240	320	1	292	292	2

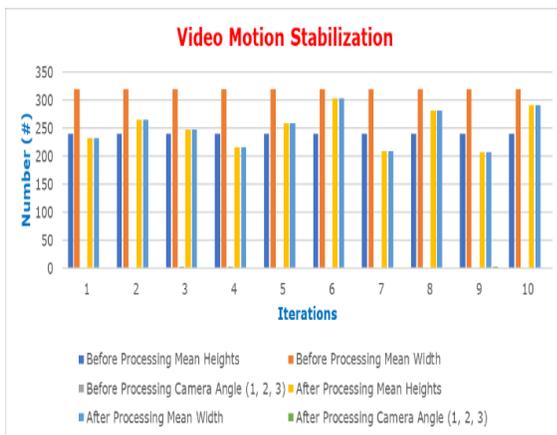
It is natural to realize that, due to the change of camera angle for each frame, the images are converted to a square image frame and the camera angles are justified. The same results are visualized graphically here [Fig. 2].


Fig. 2. Video Motion Stabilization Outcomes.

For a single video data, few frame-by-frame analysis are furnished here [Table III].

TABLE III. SINGLE VIDEO FRAME-BY-FRAME ANALYSIS

Dataset ID	Before Processing				After Processing			
	Mean Heights	Mean Width	Camera Angle (1, 2, 3)	FPS	Mean Heights	Mean Width	Camera Angle (1, 2, 3)	FPS
1	240	320	3	10	265	229	2	10
	240	320	3	10	259	269	3	10
	240	320	3	10	212	251	2	10
	240	320	3	10	282	186	1	10
	240	320	3	10	293	173	2	10
	240	320	3	10	276	114	2	10
	240	320	3	10	201	247	2	10
	240	320	3	10	293	235	3	10
	240	320	3	10	131	175	2	10
	240	320	3	10	248	168	2	10

Thirdly, the analysis of the noise reduction process is analyzed [Table IV].

TABLE IV. VIDEO MOTION STABILIZATION OUTCOMES

Dataset ID	Mean Initial Noise (dB)	Mean Reduced Noise (dB)	Time (ns)
1	5.7684727	2.7311466	1.722
2	4.3735304	1.9569633	7.556
3	5.286506	3.096948	7.395
4	4.7074976	2.7789779	7.110
5	4.768707	2.8522859	3.160
6	4.387303	2.6379135	9.517
7	4.337146	2.4204903	6.397
8	3.9589996	2.2259648	8.053
9	3.7900214	2.1423862	1.512
10	3.7343879	2.0677133	6.911

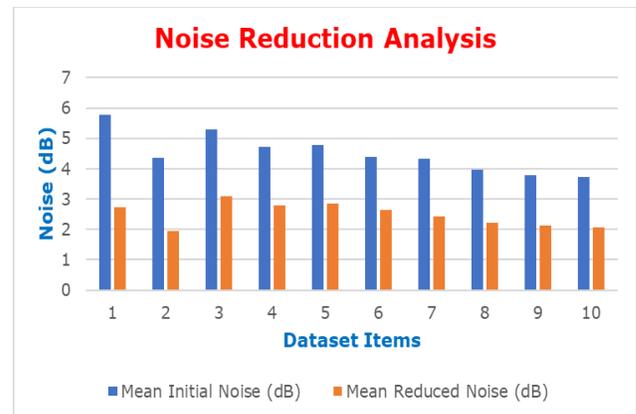
Thus, it is natural to realize that the noise reduction [Fig. 3] with a minimal time complexity [Fig. 4] is achieved.


Fig. 3. Noise Reduction Analysis.
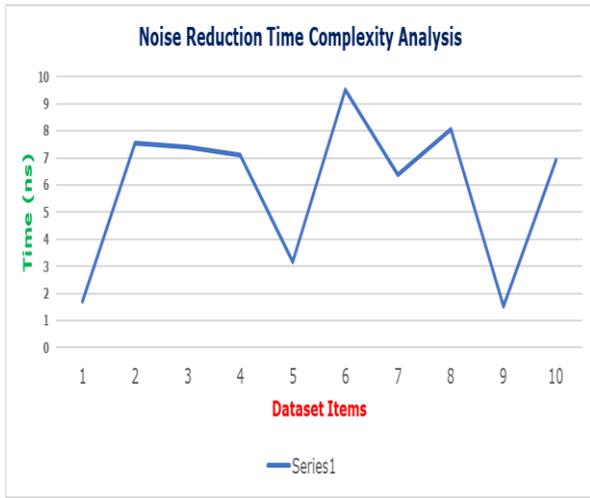

Fig. 4.   Noise Reduction Time Complexity Analysis.

Finally, the key frame extraction outcomes are analyzed [Table V].

TABLE V.   KEY FRAME EXTRACTION ANALYSIS

Dataset ID	Initial Number of Frames	Number of Key Frames	Adaptive Threshold	Time (ns)
1	150	119	90456	8.788
2	61	56	96709	4.229
3	181	83	98426	6.131
4	141	32	99201	7.822
5	131	61	94871	3.244
6	81	16	95059	6.798
7	151	148	95206	5.393
8	71	64	91944	6.577
9	111	61	90952	7.671
10	151	72	90036	2.254

Henceforth, the reduction in terms of key frames [Fig. 5] is clearly visible with finite number of iterations, which again reflects in the minimal time complexity [Fig. 6].

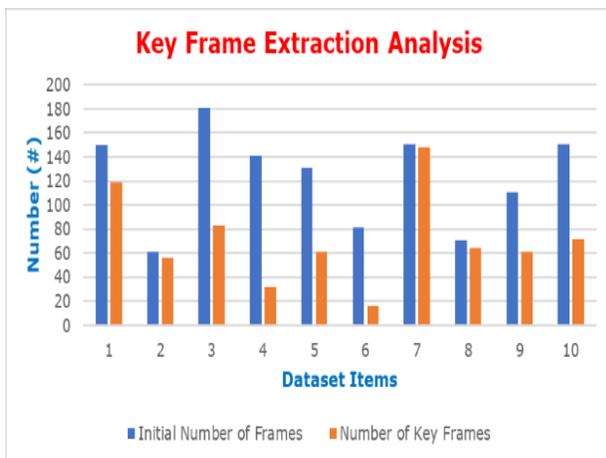
Fig. 5.   Key Frame Extraction Analysis.


Fig. 6.   Key Frame Extraction Time Complexity Analysis.

Henceforth, with the complete confirmation of the achieved results discussed in this section of the work, in the next section the obtained results are compared with other parallel research works.

X.   COMPARATIVE ANALYSIS

After the detailed discussion on the proposed solutions, algorithms and the results, this section of the work, is dedicated to summarizing the outcomes and further compare with significant parallel research works [Table VI].

TABLE VI.   COMPARATIVE ANALYSIS

Author, Year	Proposed Method	Key Frame Reduction (mean) (%)	Model Complexity	Time Complexity (mean) (ns)
Y. Zhang et. al. [2], 2020	Key Frame Extraction	49%	$O(n^2)$	9.58
P. Sasmal et. al. [7], 2021	Key Frame Extraction	51%	$O(n^2)$	7.55
X. Wang et. al.[8], 2022	Key Frame Extraction	63%	$O(n^2)$	7.85
Proposed Method	Motion Stabilization, Noise Reduction, Key Frame Extraction	65%	$O(n)$	5.89

It is natural to realize that the proposed method has outperformed the parallel research works. Henceforth, in the next section of the work, the research conclusion is presented.

XI. CONCLUSION

Over the past decade, research into video information processing has been one of the most concentrated efforts, with many studies focusing on pre-processing concerns. Researchers are unable to use information retrieval or categorization algorithms due to pre-processing problems such as inconsistent video frame rates or collection angles, noisy data, and enormous file sizes. Due to the popularity of using video as a means of presenting information, addressing these

issues is equally crucial. The purpose of this study is to automate the processes of motion stabilization, noise reduction, and key frame extraction so that these tasks can be completed in less time and with fewer losses of information. This work initially applies the Information Loss Preventive Video Stabilization using Mean Angle Measure (ILP-VS-MAM) Algorithm to stabilize the motion across the frames, secondly applies the Noise Reduction using Object Separation and Background Normalization (NR-OS-BN) Algorithm to reduce the noise from each frame and from the overall video data and finally, applies the Key Frame extraction using Moving Average Dynamic Thresholding (KFE-MA-DT) Algorithm to extract the minimal amount of key frames with reduced time to complete all the processes. The study leads in a 66% reduction in key frame extraction time and a duration of roughly 6 ns for processing all of the video data.

A Review on Approaches in Arabic Chatbot for Open and Closed Domain Dialog

Abraheem Mohammed Sulayman Alsubayhay[1], Md Sah Hj Salam[2], Farhan Bin Mohamed[3]

School of Computing, Faculty of Engineering, Universiti Teknologi Malaysia (UTM), Johour, Malaysia

Abstract—**A Chatbot is a computer program which facilitates human-to-human communication between an artificial agent and humans. The Arabic language unlike the other languages has been used in Natural Language Processing in relatively fewer works owing to the lack of corpus along with the complexity of the language which has a number of dialects extending across various countries across the world. In the current scenario, little research has been conducted in the case of Arabic chatbots. This study presents a review about the existing literature on Arabic chatbot studies to determine knowledge gaps and suggests areas that require additional study and research. Additionally, this research observes that all relevant research relies on pattern matching or AIML techniques. The searching process was conducted utilizing keywords like 'utterance' 'chatbot', 'ArabChat', 'chat agent', 'dialogue', 'interactive agent', 'chatterbot', 'conversational robot', 'artificial conversational', and 'conversational agent'. Further the study deals with the existing studies and the various approaches in Open and Closed domain dialog system and their working in the case of Arabic Chatbots. The study identified a severe lack of studies on Arabic chatbots, and it was observed that the majority of those studies were retrieval-based or rule-based.**

Keywords—Arabic chatbot; artificial intelligence; arabchat; human-machine interaction; conversational agent

I. INTRODUCTION

Artificial Intelligence (AI) research works like natural language processing (NLP) aids in developing new software solutions in computer science. One of them is the Chatbot or Chatterbot which is a high-intelligence technology. It was created to increase human-computer interaction by simulating a true human conversation by the use of diverse technologies and computer applications. Numerous areas of life, including customer support and companions for mental health, have seen extensive usage of chatbots. Arabic language chatbots powered by NLP and AI have been relatively rare because of the Arabic language complexity, despite advances in attaining human-like interactions. NLP advances are more readily accessible to computing resources and the communication techniques have facilitated the chatbot's rapid growth and deployment in several industries. One of the earliest systems of dialogue is Eliza which was created in 1966. Later, Weizenbaum created the ELIZA chatbot to mimic a psychotherapist[1]. PARRY attempted to imitate a paranoid agent in 1971[2], ALICE (Artificial Linguistic Internet Computer Entity) established by Wallace in 1995[3], inspired by ELIZA. They were created to mimic human behaviour in a text-based discussion and to pass the Turing Test within a certain domain.

A. Research Problem

The literature review reveals the chatbot development goals range from specific to wide range. In particular domains, such as healthcare, education, and industry, Chatbots primarily focused on specific topics. Thus, this paper aims to summarize classic, modern and dialect Chatbots for Arabic language. The work comprises of chatbots from close domain as well as open domain. Though English is the most frequently used language for chatbots, the technology has extended to other languages as well. Lack of Arabic corpuses has led to the reduced utilization of the language in several natural language processing technologies like chatbots. Moreover, the complexity of the Arabic language like rich morphology, higher intent of ambiguity, frequent orthographic variants and the number of dialects are also the reason behind the reduced usage of Arabic in Natural Language Processing.

B. Research Question

What are the techniques utilized to overcome the existing researches?

What are the keywords utilized in this study for searching process?

What are the purposes of open and closed domain dialog system?

C. Research Objectives

The study utilized Pattern matching and an AIML technique which documents the chatbots that interacted with users while speaking Arabic. The searching process was conducted utilizing keywords like 'utterance' 'chatbot', 'ArabChat', 'chat agent', 'dialogue', 'interactive agent', 'chatterbot', 'conversational robot', 'artificial conversational', and 'conversational agent'. The closed domain is used in situations where the amount of information needed to produce an appropriate response to an input is restricted. Similar to human conversation, the open domain will grow over time to support multiple conversation domains

D. Research Significance

The purpose of this study is to analyse the body of literature on Arabic chatbot studies, identify knowledge gaps, and suggest areas for further investigation. Additionally, this research notes that pattern matching or AIML approaches are used in every pertinent research. The study also discusses previous research and different Open and Closed domain dialogue system methodologies, as well as how they apply to Arabic chatbots. The study found a severe paucity of research

on Arabic chatbots and found that most of the research was retrieval - or rule-based.

The standard orthographic representation of Arabic not only determines the intended pronunciation of a written word in the language but also sets a special diacritic which is required to indicate the corresponding pronunciation. Various diacritics produce different kinds of words with different possible meanings for the same spelling form. In the case of most genres of written Arabic, however, these diacritics are usually omitted, resulting in an extensive ambiguity in the case of pronunciation and even meaning (in some cases). Even though native learners can typically infer the desired meaning as well as intonation from the sense, Arabic is frequently difficult to analyse automatically. While native speakers can quickly recognise the intended purpose and intonation from the background context, automated Arabic processing is often hindered by the lack of diacritics [4]. The subject of this paper is 'Arabic Chatbots'. The well-established approaches in closed and open domain dialogue system for Arabic language and the Chatbot applications are available for research in Arabic are numerous in number which are studied to a certain extent.

II. BACKGROUND

The Chatter Bot's system design comprises three main components:

- Chat Interface - It is the component that communicates with users directly. Its primary role is to take in chat text as from users, pre-process them, and then send it to the Knowledge Engine and Conversation Engine for processing. It then relays chat text again to the users after receiving input from engines. It features a number of sub modules that make this work easier.

- Knowledge Engine - The variety of topics, which fall inside the purview of the chatbot's conversation are organized in the Knowledge Engine's Topic Hash Table. Every topic covers a wide range of information relevant to the specific domain being used. A series of contextual maps are used to encrypt specific data about every topic item in the hash table. Various goal fulfillment maps have been now used to realize the context maps.

- Conversation Engine - Based on the pre-coded criteria with in goal-fulfillment mappings chosen by the Knowledge Engine; moreover, the Conversation Engine component regulates the conversation path. This controls how the dialogue moves forward [3].

In Artificial Intelligence-Based Systems, machine learning algorithms are frequently utilized to generate replies to the input of the user. Since this system is primarily based on machine learning techniques, it is regarded to be more efficient than rule-based systems. Artificial intelligence-based systems can be categorized into two types[5]. They are:

- Retrieval-based model.

- Generative-based model [2].

Retrieval-based chatbots benefit from providing knowledgeable and fluent answers; they use response selection algorithms to find the appropriate reply for the present discussion from a repository [3]. According to Wang et al., most of the researches on retrieval-based chatbots emphasize on answer assortment of single-turn dialogues which take into account the most recent input message [4]. This kind of chatbot is well suited for use in domain-specific conversational systems [2]. According to Arfan Ahmed et al., scoping review, most of the chatbots are developed based on retrieval-based model [49]. Despite the fact that there are many chatbots in use today, Arabic-language chatbots are rather rare. Furthermore, compared to chatbots for other languages, Arabic chatbots have become less sophisticated. Moreover, the research suggested that extensive generative-based models, input and output modes, and NLP-based Arabic chatbots must be developed by researchers.

The generative learning model is a knowledge-based unsupervised learning paradigm. Large volumes of conversational information can be used by generative-based chatbots to start a new discussion. The generative-based model can combine different learning methods, such as supervised learning, adversarial learning, unsupervised learning, and reinforcement learning. Some trials and investigations were started when Wittrock first presented the sub-model in 1974 [6]. The system is trained so that it can create a reply in the process of a new query. While the Support Vector Machine (SVM) method generates output based on stated rules or database matching, a vast amount of data for training is used by generative model. The system then tries to produce newer replies in response to a new inquiry.

A. Dialogue System

A dialogue seems to be a discussion between two or more entities, whether they are artificial or human. Human-human conversation and human-computer conversation are the two main areas of dialogue studies. The latter participates in a dialogue system, a computerised system its aim is to converse in natural language with people. The development of dialogue systems nowadays includes graphic, spoken, written, and multimodal platforms. The systems which are adapted for the purpose of on-the-job learning are the dialogue frameworks. They have the ability to communicate with the users and ensure that proper feedbacks are received for further advancements[8]. Dialogue Systems are studied in a number of papers[4, 8-13].

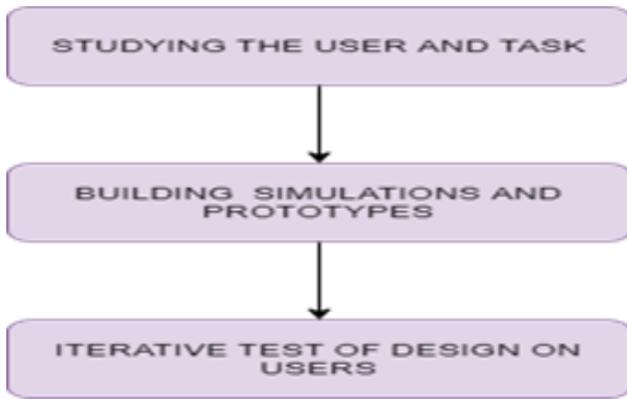
1) Dialogue system design: As compared to the other speech and language processing domains, the user holds a great part in the dialogue systems. This makes it closely inclined to Human-Computer Interaction (HCI). The term Voice Strategy is used to describe the error messages, dialogue strategies and prompts. It follows the principles which is user-centred[15].The first of the principles is the studying the user and task concerned. Similarly, after the process, building of simulations and prototypes must be done followed by an iterative testing of the design on the users. The step by interpretation is shown in the form of a Fig. 1 as shown.


Fig. 1.   Steps in Dialogue System Design.

*2) Classification of dialogue systems.*The dialogue systems' classification is an important aspect of all the research papers involved[4, 9, 16-18]. The Dialogue systems are basically divided into two types[14]. It is shown in the Fig. 2.

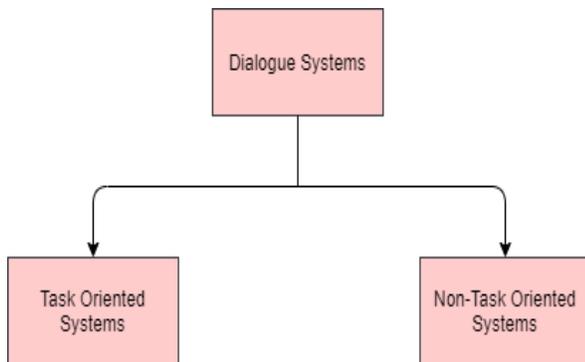
- Task-Oriented and
- Non-Task Oriented/ Chatbots.


Fig. 2.   Types of Dialogue Systems.

According to (Gao et al., 2019; Zhang et al., 2020) the conversational systems are classified into three main types as shown in Fig. 3. They are

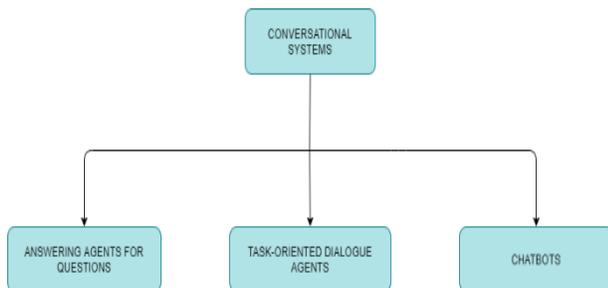
- Answering Agents for questions.
- Task-Oriented Dialogue Agents.
- Chatbots.


Fig. 3.   Classification of Conversational Systems.

The classification of Dialog system has been studied by many researchers. Lee and Dernoncourt studied the recurrent and convolutional neural network with regard to preceding short texts. In the case of dialog prediction it achieves results based upon three different datasets. The model though produces predictions and performance of better quality, it is restricted to the sequential model it uses(Lee and Dernoncourt, 2016). The study makes it very evident that the Dialogue system seems to be an excellent instrument for user communication with any programme. This is a useful tool that can be employed with a variety of gadgets, including smartphones, PCs, and telephones. It might be a useful tool for helping users navigate websites that deal with topics like stock transactions, online shopping, information search, remote banking, route planning, etc.

B. Chat bots: An Overview

The human lives are integrated with Artificial Intelligence and this is evident from the creation of intelligent software as well as hardware along with the analysis of the same. One of them is the work of Himanshu and Rizwan who studied the mental model in Human Computer Interaction[19]. It has the capability to understand multiple languages of humans through the technology of NLP[20]. The functioning of AI systems were studied in[20], the turning tests and the concerned problems thereby redefining the machine intelligence. The importance of the work relies on its discussion over businesses like e-commerce and the other related domains. A much more detailed working of the chatbot system with the language processing system is needed in the work[21].

Chatbots can be categorized into Rule-Based or Corpus-Based systems, which are discussed as follows:

3) Rule-based chatbots: The Rule-based Chatbots or the Decision Tree Bots work based upon a series of well-defined rules or principle. A sample conversation of a Rule-based Chatbot is shown in Fig. 4. Conversations are mapped out by these chatbots in order to lay out a plan meeting the expectation of the customer and the chatbots must respond. Some of the famous rule based chatbots are ELIZA and PARRY[22].

4) Corpus-based chatbots: The Corpus-based Chatbots unlike the rule based chatbos mine the human-human conversation. A sample conversation of a Corpus-based chatbot is discussed by various researchers in one of his papers on spoken dialogue systems[18]. It is shown in Fig. 5. One of the advantages of using them is they are not based on framed out rules. Hence they require huge amounts of data for training[23].

General intent Chatbot's knowledge base must have been small, simple, and user-friendly to understand. Despite the fact that certain of the commercial solutions have only recently appeared, advancements must be done to discover a standard method for creating Chatbots.

The majority of corpus-based chatbots respond to user turns in contexts either utilising retrieval techniques (employing information retrieval to find a reply from a corpus,

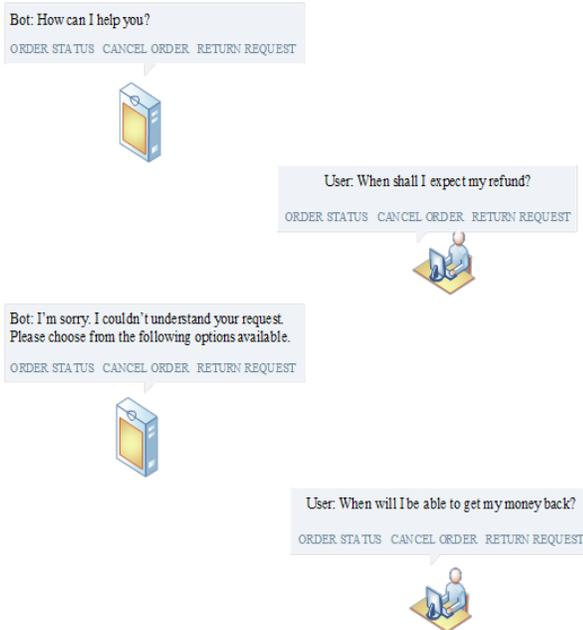
which is suitable provided the dialogue contexts) or generation techniques (employing a language prototype or encoder-decoder to produce the reply provided the dialogue contexts). For interactions that are brief enough to fit into a particular model's frame, systems typically produce a solitary respond turn that is acceptable given the entirety of the dialogue up to that point. They are frequently referred to as response generation algorithms for this purpose. Thus, corpus-based chatbot methods borrow from question answering framework methods, which also emphasise single replies while disregarding longer-term conversational objectives.


Fig. 4. Sample Conversation of Genius.

Fig. 5. Conversation of a Corpus based Chatbot.

A part of the research survey, databases of different literatures were used similar to the literature review of any paper[24]. The bibliography was compiled using widely referenced computer science resources such as Google Scholar, IEEE, Science Direct, Springer, and ACM. The searching process was conducted utilizing keywords like 'utterance' 'chatbot', 'ArabChat', 'chat agent', 'dialogue', 'interactive agent', 'chatterbot', 'conversational robot', 'artificial conversational', and 'conversational agent'. Papers were collected in the years ranging between 2004 and 2021 and reviewed based on their title and abstract, omitting those that did not demonstrate an Arabic chatbot implementation, which has been from the Google Scholar, Springer libraries, and IEEE. Studies documenting chatbots that interacted with users while speaking Arabic were considered in this investigation, irrespective of the users' categories, input and output methods, platforms, or topic of interaction. Nevertheless, chatbots that have been managed by a human operator were not included in this study.

III. RELATED WORK OF ARABIC CHATBOT

Despite the fact that Arabic chatbot implementations have been built, little research has been done on them. Al-Haj Bot, El-Kahwagy, Msa3ed, Theyabi, Rammas, and other services that offer Arabic chatbot applications created for commercial use seem to be some instances of the former. Additionally, there have been platforms like Watson by Telegram Bot, Messenger Bot via Facebook, IBM, and PandoraBot that offer creators coding assistance. Due to the paucity of published studies on these systems and apps, it was difficult to conduct a fair analysis and comparison. This study's objective is to showcase cutting-edge Arabic chatbot investigation. The Arabic language is classified into three dialects:

- Classical Arabic - Old Written type.

- Modern Standard Arabic (MSA) – The commonly used type.

- Dialectal Arabic – The dialect of natives across various regions.

Since the Middle Ages, the language's written form has deviated from dialectic Arabic. Although Modern Standard Arabic is basically written, the regional dialects are frequently used in spoken communication and daily interactions. In contrast to MSA, the dialects lack written grammatical rules and have their own morphology, syntax, and phonetics [4]. Chatbots are often created using either generative or retrieval-based methods. While retrieval-based methods profit from relevant and eloquent replies, generative approaches can produce additional relevant replies that wouldn't have surfaced in the corpus [25]. Pattern matching is a common technique for constructing the conversational agent in a retrieval-based model. In question-and-answer chatbots, where the machine compares the inputs to a specified framework and creates a reply, pattern matching has been most frequently used. Additionally, chatbots can have either brief interactions (one reply is generated for each Q&A session) or lengthy interactions (large number of data exchanged throughout interactions). Chatbots might be open (i.e., strive to serve various sorts of communication on various topics) or closed (i.e., fulfill a specific goal or topic; the information necessary for output answer is restricted) [49]. Chatbots have been

further splitted into two subcategories predicated on their domain of usage. They are:

- Closed domain.

- Open domain.

A. Closed Domain

The closed domain is used in situations where the amount of information needed to produce an appropriate response to an input is restricted. The creation of the ArabChat has taken a significant amount of time and effort. Table I shows a list of the closed conversation chatbots that has been discussed. In [26] Brini, Ellouze, Mesfar, and Belguith suggest the Question-Answering System for Arabic Language (QASAL) as an Arabic Question-Answering (Q-A) framework. A natural language question typed in Modern Standard Arabic (MSA) is provided to QASAL, which then outputs the best possible response. The system consists of three subsystems: a question assessment module, a text retrieval subsystem, and a reply extracting subsystem. These three components were processed using the language development tools known as the NooJ Platform. The content of the Quran restricts the conversation's scope. The foundations of the chatbot database are therefore retrieval-based. The group of the greatest crucial terms from the "Ayhas" that indeed java implementation pulls restricts the chatbot's interactivity and responses. The dialogue is brief since the chatbot responds to single user input with a single response.

Shawar demonstrates the usage of a chatbot in accessing Arabic Web Question Answering (QA) corpus without resorting to advanced natural language processing or inference. Java application was developed for converting textual corpus to AIML[27] chatbot linguistic model format, and the chatbot dataset was retrieved from multiple sources. Since it is impossible to predict regardless of whether a client will query the ALICE information base with the same queries, the standard file has been built using the initial and most important word techniques. Users could use Spanish, English, and Arabic to engage FAQ chatbot platforms. A modest collection of 412 Arabic QA spanning five themes was also created from a variety of Web sites, including fasting and its linked health concerns, women and their reproductive wellness, dental care, blood illnesses like diabetic and cholesterol, and donating blood. Additionally, the user submits a textual query in MSA to the chatbot regarding one of the available domains, and the chatbot responds with the appropriate response[28] [29]. The user enters a text inquiry in MSA regarding one of the allowed domains, as well as the chatbot responds with the appropriate response even without usage of complicated NLP. The text corpus has also been converted using Java software to produce the explosive and standard AIML documents. The queries and responses that occur in the corpus are contained in the binary file. The utilization of the usual file ensures that the customer's query is translated to the relevant query kept in the information base. Additionally, the file is constructed utilising the first word as well as most important word method. The most important word seems to be the least common in the query, while the first word serves as a classifier for the query. After tokenizing the query, the latter is accomplished by creating a list of frequently asked questions. The terms in the query, together with respective frequencies, are included in the created list. The method then takes the two least common terms from the list—which are also the two most prominent words—and uses them as keywords to connect the inquiry to a response. The most crucial word strategy was used to boost the anticipated output's rate. The chatbot was evaluated with fifteen questions, with a success rate of 93 percent. The primary disadvantage of this paradigm is that if the structure of the question is in an altered form in the knowledge base, then what will be stored, then the replies of the chatbot will be an incorrect one. The chatbot doesn't employ a heuristic to choose the appropriate response but instead relies on a direct retrieval mechanism. Additionally, when the Arabic query is rewritten in its original form, one of two things occurs: either no response is generated, or a similar but erroneous response is obtained. Moreover, a success rate of 93 percent is unjustifiable when using a sample of only fifteen questions.

Abdullah [4] implements an approach known as Pattern Matching. Abdullah CITS has been basically an Arabic Conversational Intelligent Tutoring System (CITS) which educates about 10 to 12 fundamental Islamic concepts. This online system is capable of communicating with MSA students. These pupils are given a series of questions and then addressed their responses in Classical Arabic, citing evidence from the Hadith and Quran or the traditions and sayings of the Prophet Muhammed of Islam. The system communicates with pupils via pictures and sound effects, and it is capable of determining a student's level of expertise and guiding the dialogue. Abdullah CITS is capable of distinguishing between a user's questions and responses. A comprehension base with subject-specific data, a communicative agent coding language for providing tutorial conversations to trainees, and a tutorial comprehension base for assessing every student's abilities of subject-specific insight make up the system, which uses a Pattern Matching method [30].

A. Shawar and E. Atwell published one of the early studies on Arabic chatbot applications [31]. They communicated with the ALICE chatbot (Artificial Linguistic Internet Computer Entity). Here, the techniques of Machine learning (ML) were employed to create an Arabic chatbot that receives input of the user in Arabic and answers with Quranic quotes. The Quran is comprised of 'Ayahs' or 6236 verses and 114 'Surahs', or collections of verses. The user provides the Arabic words with 'Tashkil' or diacritics in the form of phonetic guidance. The chatbot then responds by searching the Quran for "Ayahs," containing the user's comments. Since Quran text is not conversational, Java software was designed to establish a learning mechanism. The learning process is guided by the Ayah, the most critical word in the AIML file and prototype's "Ayha" category. The Java software creates an AIML file in Arabic. The chatbot dataset origins are retrieval-based. However, feedback from Arabic evaluators indicates that entering vowels in Arabic words is difficult. Another argument that does not satisfy users is the random selection of an object from the list; if the word(s) is repeated in more than one Ayya, one is chosen randomly. They also found that not all words have a response related to the least frequently used word technique. The content of the Quran also limits the

dataset; hence this is a retrieval-based model. This project aims to demonstrate how the ALICE chatbot has evolved to learn from non-conversational content. The chatbot's ability to engage and respond is constrained by the set of "Ayhas" words, which the java programme has identified as being the most important.

Hijjawi, Bandar [32] develops ArabChat, the first version of Chatbot of Arabic. ArabChat is a web-based conversational agent system. The chatbot conversation is Arabic task-oriented, and it was created to support students at Jordan's Applied Science University. Pattern Matching is used to manage user conversations in the system for creating the Arabic Conversational Agent (ArabChat). The hybrid rule mechanism and the user classification approach were used to solve issues in the first version of ArabChat.

ArabChat Mobile [33] is a mobile-based conversational agent which serves as a student counselor at Amman's Applied Science University based on ArabChat's original code[32]. It is a streamlined Android version of ArabChat. The ArabChat CA and Mobile ArabChat system are rule-based CAs that include a scripting language, a temporal memory, an information container brain, a scripting engine, and a user interface. Additionally, the Mobile ArabChat employs the Pattern Matching PM method to handle Arabic textual chats. Although users in Arab nations suffer several obstacles, including poor and inconsistent internet connections and limited capacity, this program operates despite these limitations. Mobile ArabChat employed a pattern matching method predicated on text. In terms of its programming engines, programming language, as well as knowledge repository, this architecture is similar to ArabChat. 96 percent of customers concur that utilizing Mobile ArabChat on a smart phone is preferable to doing so on a computer. On the other hand, mobile ArabChat requires internet connection for working. This result may appear satisfactory at first glance, but for the most reliable results, manual analysis of the Mobile ArabChat logs is required. The outcome revealed that 83.2 percent of the inputs corresponded to the anticipated outcome. However, Mobile ArabChat requires an internet connection to function.

In [34] an Arabic interaction platform or conversational interface is presented by Moubaiddin, Shalbak, Hammo, and Obeid. It is intended to communicate with hotel guests and generate responses about booking hotel rooms and other operations. The technology makes use of text-based human language conversation. The two key components in this architecture are the analyzer and the dialogue controller. They have chosen to use the Government and Binding (GB) theory to construct a GB-based analyzer [35]. Users can bargain a desired appointment, as well as question about the rooms and amenities offered by the hotel. They report the findings of an actual study that involved 500 participants who've been total newcomers to the method. The system was to be used by the customers, who have been then asked to score the conversations as "extremely bad," "bad," "moderate," "good," or "extremely good." 92.3 % of the conversations received "good" or "extremely good" ratings, making up 66.92 percentage of the total. The usage of an Arabic conversation system to solve the issue of participatory Arabic dialogues is

supported by these outcomes. The system, which allows users to make hotel reservations using written Arabic text, could be improved. The system does not employ a morphological analyzer to provide important word characteristics such as clitics, number, and gender. Additional criteria for including more phrase patterns and other grammatical elements, including subject-verb alignment on numbers and gender, aren't also included.

Al-Ajmi, A. H., & Al-Twairesh, N. suggest a hybrid rule-based/data-driven method in [36] for a text-based flight booking DS ability of handling consumer utterances. The suggested DS was developed using the natural language interface Wit.ai. The Wizard of Oz technique was used to establish the conversation flow, and crowdsourced training samples were used to develop the DS intents and entities. The evaluation outcomes indicate that the designed system has been capable of comprehending user words and self-feeding effectively. They proposed a hybrid method to data science development that addresses the difficulty of establishing a data science system with limited training data. Furthermore, they designed a DS that utilises a hybrid method to fulfil flight booking tasks by leveraging current DS programming frameworks. Additionally, they evaluated the method in two steps to ascertain the DS's capacity for self-feeding. They use a pipeline architecture methodology and a combination of rule-based and data-driven methodologies. Users can text-book airline tickets in Arabic using this method. According to the assessment results, the suggested methodology was a quick and easy way to book tickets as users gained experience. As more information about member booking times was provided, the system learned. Effectiveness of the DS was severely hampered by the lack of training examples, which researchers tried to lessen by giving the DS self-feeding capacities. They did not, however, imitate real-world flight booking systems. In addition, they did not integrate their DS with an existing reservation system. Although the total experience of ordering a flight ticket via the created flight booking DS was favourable, 52 per cent of participants reported having difficulties comprehending Telegram commands, believing they needed to restart the discussion in order to begin booking. As a result of the misunderstanding, the orders' explanation message is displayed. Additionally, there are no buttons or a greeting message to send following the description of the commands. Another issue was that their system did not notify the user when to begin the booking.

Hijjawi, Bandar [37] and Hijjawi, Bandar [38] developed a previous research project called ArabChat. ArabChat closed domain in Jordan's Applied Science University was chosen as a knowledge point guide for their innate Arabic students in the chat. They use a hybrid rule mechanism as well as a user classification approach. After that, the revisions were included in the final output. The utterance classification function makes an attempt to distinguish between utterances that are and are not inquiries. It accomplishes keyword matching by supplementing the pattern of the question-based rule with additional keywords. The second function is Hybrid Rule, which is concerned with responding to and dealing with an utterance that encompasses multiple themes. Manual examination generated more precise results and shown

performance enhancement, even if ArabChat provided a Ratio of Matched Utterances to the Total (RMUT) outcome that was more precise than the enhanced one brought about by unintellectual users. While carefully reviewing logs, Improved ArabChat correctly processes 82% of phrases with two subjects, and this proportion decreases as the amount of items in the phrase increases. Al Humoud and Al Wazrah [7] claim that is manually classifying utterances reveal a large proportion of query-based phrases because of three factors: the area chosen, the users' demands, which lead them to ask rather than discuss, and the complexity of scripting multiple rules.

TABLE I.   SHOWS A LIST OF THE CLOSED CONVERSATION CHATBOTS

Author	Language	Domain	Approach
Shawar, B. A., & Atwell, E 2004	English/ classical Arabic	Closed (Quran book)	AIML

LANA was developed to help autistic children with Autism Spectrum Disorder (ASD) aged 10-16 years old learn more effectively by adapting Visual Auditory Kinaesthetic (VAK) learning styles. They have a basic understanding of the mechanics of Arabic writing and can use MSA to teach them science topics. For kids with ASD, conventional education is challenging since the teacher can't cater to the requirements of every single student. Using pattern matching as well as a short text similarity method, LANA seems to be equivalent to Abdullah CITS (Arabic Conversational Intelligent Tutoring Sys-tem), but still it endorses a wide range of learning genres, such as visual, hearing, and proprioceptive. This allows kids to practise training skills autonomously predicated on their unique needs [39].

In [40] created "Nabiha," a chatbot that can converse with King Saud University Information Technology (IT) students employing the Saudi Arabia language. Nabiha is accessible on Twitter, web, and Android, among other platforms. As an academic adviser, the Nabiha can converse with students and answer their questions about the IT department's courses or their academic achievement at KSU. Thirteen students practice the Nabiha chatbot and offer replies via a survey to ensure the chatbot's usefulness. Twitter have tried Android and web technologies because its textual area only supports a limited number of characters. Several learners who were asked to envision who Nabiha was thought of her as a professional in the IT division, whereas others thought of her as a graduate candidate with substantial training. Nabiha is a robot, according to only one human. The AIML files were created by converting the readable text from the corpus into AIML format using a java program. Nabiha chatbot was launched on the Pandorabots platform after ALIM files were generated, and it was later integrated with Android, Twitter, and the Web. However, even though the dataset contained 1104 categories, Nabiha still needs to be enhanced. HTML tags have an issue, and some sentences are incompatible with Twitter's text area scale, which is very large.

Bendjamaa and Nora proposed a discussion method based on Quranic ontology. The ontology under consideration comprises Quranic chapters and verses and each Quranic term, its origin, and lemma. The system is an Arabic-language natural language communication system. The user's input must be processed first, followed by segmentation, and finally by establishing a semantic route. Additionally, a module is required to access the ontology and retrieve the data. The system admits as input an Arabic spelling string (arrived by the client). This project, which was developed in Java, was implemented using the CoreNLP plugin. Its purpose is to make Islamic knowledge more participatory. The performance, however, is either in Arabic or English, depending on the ontology and the response to the inquiry. If an Arabic version of the answer is available, the output will be in Arabic; otherwise, it will be in English [41]. Although this project permits easy admit to Qur'anic data, it needs to add more querying functionalities. As a result, it does not help a lot of non-Arabic speakers. Syntactic mistakes in the inquiry are some other problems that are not addressed. Additionally, it does not extensively cover Islamic scholarship and legal sources.

B. Open Domain

Similar to human conversation, the open domain will grow over time to support multiple conversation domains.[42] Makatchev and co-authors Hala discusses a bilingual (English

and Arabic) robot administrator at Qatar's Carnegie Mellon University. The investigators compare Hala's English conversation vocabulary to that of a comparable monolingual robotic on the campuses of Carnegie Mellon University in Pittsburgh to verify the installation of Hala (named "Tank"). Hala's purpose is to provide information on campus directions, weather, and area events and respond to inquiries about her personal life. A rule-based conversation manager, which consists of an information base with prepared statements and criteria that trigger responses in English as well as Arabic, has been used by the robot to interact with people. The English information base currently has a much wider range of topics covered. In addition to Hala's spoken answer, a text appears on the monitor next to her image.

IbnSina [43, 44] is a dual-language conversational robot capable of communicating Arabic and English. The user controls it via text or voice inputs. The IbnSina robot responds with audio output in the language specified by the user. The IbnSina robot develops human-to-human contact discourse by utilizing Wikipedia and a locally stored Quran database. As a result, the Chabot of the IbnSina robot can address a wide variety of subjects. As a result, it responds to general inquiries by translating terms, providing online resources, or referring to books stored in its database. Additionally, it warns the user when certain pieces of information are missing or incorrectly spelled. As a result, IbnSina's approach to dialogue is open and extensive. However, because it relies on the information that has already been described in the database to react with the proper output, it does not produce new responses. The IbnSina dialogue system is built on object-oriented methods like the Quran class and Wikipedia class, which permit the robot to respond with the required response, as well as the chatterbot class, which allows for simple discussion and user query responses. Additionally, a chatterbot module has been developed that responds to human input.

In [32] and [45] the ArabChat's effectiveness was increased by differentiating between statements that contained questions and those that did not by classifying Arabic phrases as conversation activities predicated on structural traits found in Arabic function phrases. To study the approaches for categorizing statements into inquiries and non-inquiries using function words, a database of statements has been compiled from diverse sources. These sites were chosen to reflect various issues in the Arabic language, including politics, religion, sports education, and business. 1000 statements make up the resultant database, known as the "CA Database" (500 queries and 500 non-queries). The artificial non-inquiry phrases and the indirect inquiry, in contrast side, were absent from the "CA Database." As the first step in creating the ArabChat categorization method, the "CA Database" was loaded into a ML toolkit for categorization and rule creation. Researchers chose WEKA (Waikato Environment for Information Analysis) as that of the ML toolbox because of its open-source nature. The outcome reveals that 73.56 percent of the inputs corresponded to the anticipated output.

However, ArabChat requires a technique that distinguishes between query-based and non-query-based statements that resolves the same rule. This is because each utterance type (query-based and non-query-based) requires a unique response, even though they target the same rule. Additionally, the number of predefined patterns per rule increases, reducing ArabChat's ability to respond with appropriate responses. Additionally, there is the requirement for a technique that deals with utterances discussing various themes, which necessitates the firing of several rules (each rule has one topic). Finally, it is beneficial to keep the number of required patterns to write to a minimum.

The authors introduce "BOTTA," an Arabic dialect chatbot, in[46]. BOTTA seems to be a communication partner that mimics friendly human interaction by speaking Egyptian Arabic (Cairene). BOTTA is the first Arabic-language chatbot in the world. BOTTA strives to be the Rosie of Arabic dialects; Rosie is a chatbot that communicates in English. BOTTA was created using artificial intelligence and is now available on the Pandorabots platform. The information base of BOTTA has been made up of set data contains themed terms and phrases,, mapping documents storing pairings of linked words and sentences, and AIML documents containing categories including its replies to user inputs. Additionally, the BOTTA chatbot collects essential information about the user during each discussion via questions, resulting in an open dialogue due to the chatbot's ability to react to various topics. It is constructed based on a retrieval-based paradigm. It uses a retrieval-based approach rather than adding new answers or updating the information base. It makes use of algorithms to select a suitable response from a range of pre-written ones. Furthermore, before answering properly, the chatbot doesn't perform text normalisation on the user input. When performing orthographic changes, it also fixes common spelling errors in user input. By employing this technique, BOTTA has been able to fix 85.1% of typical spelling mistakes in Arabic typing. Three people also put BOTTA towards the test. One Levantine Arabic person and two native Egyptian Arabic learners make up the total, which does not meet the requirements for a passing grade.

The authors of [47] give the Arabic Reading Comprehension Dataset (ARCD), which contains 1,395 questions posed by crowd workers on Wikipedia articles, as well as a machine translation of the Stanford Question Answering Dataset (Arabic-SQuAD). The system for open-domain question answering in Arabic (SOQAL) is composed of two components: (1) a document retrieval component that utilizes the hierarchical TF-IDF approach, and (2) a neural reading comprehension component that utilizes the pre-trained bidirectional transformer BERT [24]. Their ARCD trials demonstrate the efficiency of their methodology, with their BERT-based reader attaining a 61.3 F1 score and their open-domain system SOQAL attaining a 27.6 F1 score. However, this approach should increase the size of ARCD. Additionally, this work is not focused on paragraph selection but rather on improving the end-to-end system.

To construct a CA in the Arabic Gulf dialect, T. Alshareef and M. A. Siddiqui used a deep-learning architecture dubbed the Seq2Seq neural network. They framed the CA problem as a machine translation task and trained and evaluated the model using post–reply to tweets. They employed the Bilingual Examination Understudy (BLEU) scores and professional reviewers to assess how pre-trained encoders affected a

convolutional neural network's efficiency. The model fared better than earlier deep learning systems since it was trained on more databases and in more languages [48]. The method has attained the BLEU score as 25.1. However, they do not concentrate on the mechanism for developing a baseline against which this work can be compared. Additionally, when doing the automatic measurement, BLEU, it is necessary to compare the result to many references, as each sentence does not have a single accurate response. Table II shows the table type styles. To improve the model's ability to engage in fluent discourse (i.e., a dialogue with numerous turns), rather than simply reacting to a single remark.

TABLE II. TABLE TYPE STYLES

According to the evaluated papers, retrieval-based modeling is used in all of the work that has been done on Arabic chatbot implementations. In other words, the information pool from AIML documents, databases, or web pages is what the chatbot answers are built on. The key finding of this study is the scarcity of Arabic chatbot literature. Most chatbots were built using a rule-based model. This once more demonstrates how little Arabic is used in more sophisticated systems. Because of the language intricacy, Arabic NLP has been developing more slowly than other languages. Relatively fewer Arabic chatbots use NLP methods. Future research might likely concentrate on figuring out the best way to combine many approaches to chatbot development in order to maximize the usefulness of each approach, even the most straightforward.

IV. DISCUSSION

According to the evaluated papers, retrieval-based modelling is used in all of the work that has been done on Arabic chatbot applications. In other words, the data pool from AIML files, databases, or web pages is what the chatbot responses are built on. It may restrict the chatbot's functionality and usability. Additionally, it should be noted that all relevant work relies on AIML or pattern matching techniques. This could result in 1) a tiny dataset for the chatbot as well as a limitation to closed domains. 2) Limits the chatbot's response to the user, in which the right answer can only be obtained if the user's input fits the chatbot database. Additionally, one of the causes Arabic chatbots in the literature lack certain features is due to the intricacy of Arabic grammar and user errors in spelling and grammar, which explains why there aren't many Arabic chatbot programmes available in both text and speech.

V. CONCLUSION

A review on the available Arabic chatbots is done in the study. The papers collected were basically divided into two categories based on the form of chatbot conversation or interaction as closed and open domain. Because of the complexity of the language and the lack of Arabic Corpuses, the available chatbots in the language is low compared to that of English and hence limited papers are available for the research. This study discovered the dearth of researches on Arabic chatbots and among those works, it is found that the major part of the available literature is retrieval-based or rule-based. Furthermore, the majority of the Arabic Dialog Systems discussed earlier is text-based and employ a rule or pattern-matching technique. Only a fewer of them have developed enhanced system functionality through the use of Short Text Similarity in conjunction with a rule-based approach. Additionally, it has been suggested[30] that the pattern matching approach is preferred despite its limitations due to the difficulties associated with developing Dialog Systems in Arabic. Future studies should perhaps focus on determining the optimal way to integrate many ways to chatbot development in order to maximise the utility of each method, even the simplest.

Facial Emotion Detection using Convolutional Neural Network

Pooja Bagane, Shaasvata Vishal, Rohit Raj, Tanushree Ganorkar, Riya

Department of Computer Science and Engineering, Symbiosis Institute of Technology (SIT), Pune, India

Abstract—Non-verbal specialized strategies, e.g. look, eye development, and motions are utilized in numerous uses of human-PC connection, among them facial feeling is generally utilized as it conveys the enthusiastic states and sensations of people. In the machine learning calculation, a few significant separated highlights are utilized for displaying the face. As a result, it won't get a high accuracy rate for acknowledging that the highlights rely on prior knowledge. Convolutional Neural Network (CNN) has created this work for acknowledgment of facial feeling appearance. Looks assume an essential part in nonverbal correspondence which shows up because of the inner sensations of an individual that thinks about the countenances. This paper has utilized the calculation to distinguish features of a face such as eyes, nose, etc. This paper identified feelings from the mouth, and eyes. This paper will be proposed as a viable method for distinguishing outrage, hatred, disdain, dread, bliss, misery, and shock. These are the seven feelings from the front-facing facial picture of people. The final result gives us an accuracy of 63% on the CNN model and 85% on the ResNet Model.

Keywords—Feature extraction; convolutional neural network; resnet; emotion recognition; emotion detection; facial recognition

I. INTRODUCTION

For ideal human-PC interfaces (HCI) would likely want that equipment to produce usable and safe systems [1]. This examination is definitely about how precisely PCs could distinguish feelings correctly from the distinct sensors. This try-out has been applied as a cosmetic picture as a new medium to follow human inclination [2]. Seven important feelings are most inclusive to men and women. Specifically, unbiased, mad, disdain, dread, happy, miserable, and impact and these vital feelings can always be perceived from a new human's look. This specific examination proposes a new compelling way for figuring out unbiased, cheerful, gloomy, and shocking these kinds of four feelings by front-facing cosmetic inclination. During many previous years, different techniques have been proposed for feeling acknowledgment. Numerous calculations were recommended to foster framework applications that can identify feelings well indeed [3]. PC applications could better convey by changing reactions as per the enthusiastic condition of human clients in different connections. The feeling of an individual is not set in stone by discourse or his face or even one's signal [4]. The work introduced in this paper investigates the acknowledgment of looks from the face. Concerning feeling suggestion, the customary procedures ordinarily consider another face picture that is perceived coming from your information picture, and facial broken expressions or accomplishments as a rule are

seen from the specific face regions. Just after that novel space and normal qualities are disengaged out of their facial helpings. At last dependent on the secluded attributes a classifier, with respect to example, the Keras index, sporadic forest, is typically ready to supply affirmations results.

Each of our facial thoughts is expressed through account activation of specific systems of facial muscles. These are sporadic, subtly complex alarms in an expression that frequently contains a wealth of data [5]. Through facial sentiment recognition, we are able to assess the effects that content and services have on the audience/users. We used a machine learning model like CNN to achieve these aims [6].

The essential motive of this research is to discover facial feelings. Emotion recognition will be a significant step in identifying many thoughts on the face. Through face emotion recognition, all of us can gauge the effects content materials and services bestow on users. The opportunity that devices can interpret human beings' emotions is exactly what motivated us to generate this particular research.

Convolutional Neural Network is one type of Deep Learning algorithm which is used for working with images and videos. Images are used as inputs, and the system collects their features before categorizing those using previously learned features. The various filters available in the model help extract features at each layer such as edges, and shapes (vertical, horizontal, round), and combine them all to be used as identification for the image.

The CNN model works in mostly two stages:

Feature Extraction – The phase where filters and layers work for extracting information from the images to be passed on to the next layer for classification.

Classification – Classifying the images based on the target variable is carried out.

In Section II, we describe the literature review followed by the methodology and model specifications in Section III that have been implemented in this paper. Moving forward we have discussed the outcome of our model in Section IV and have concluded that in Section V.

II. LITERATURE REVIEW

1) Bartlett et al. carried out the initial work that outlines a method to complete the task [7]. The goal of the article was to develop a system that could automatically identify frontal faces in video streams and categorize the emotions those faces were expressing based on their facial expressions [8]. The

article defined facial expressions as expressing happiness, sorrow, surprise, contempt, fear, rage, or neutral emotions.

2) With the help of the Radial Basis Function network (RBFN) for classification and Fisher's Linear Discriminant (FLD), Singular Value Decomposition (SVD), for feature selection, an algorithm for identifying a person's emotional state through facial expressions like anger, disgust, and happiness is demonstrated. It attempts to represent the face analytically in order for the feature vector can be input into a classifier. The system's overall success mostly hinges on the accurate recognition of the face or specific facial features like the eyes, brows, and lips [9].

3) Authors proposed to use of a revolutionary EEG-based emotion recognition method. This method uses multi-channel EEG data to examine the usage of three-Dimensional Convolutional Neural Networks (3D-CNN) for emotion identification. The proposed 3D-CNN approach's performance is improved by the data augmentation step. And using the multi-channel EEG signals as the data input for the proposed 3D-CNN model, a 3D data representation is created [10].

4) The VGG Net architecture was adopted by Yousif Khaireddin and Zhuofa Chen, who tuned its hyperparameters and experimented with other optimization techniques. To their experience, the model does not require additional training data to attain state-of-the-art single-network accuracy of 73.28% on FER2013 [11].

5) The initial step of visual processing, the encoding of facial features, and the decoding of facial expression connotation can all be considered as stages in the process of facial emotion identification, which was seen in schizophrenia patients [12].

6) In their study, M. Kalpana Chowdary, D. Jude Hemanth, and Tu N. Nguyen discuss the use of transfer learning techniques to recognise emotions. Pre-trained Resnet50, vgg19, Inception V3, and Mobile Net networks were employed in this study. After removing the completely connected layers from the pre-trained ConvNets, their own fully connected layers that are appropriate for the number of instructions in our task were added. The CK + database was used to conduct the experiment [13].

7) The technology of convolutional neural network model is used in an effective deep learning technique for face emotion detection to classify emotions from facial photographs and accurately identify age and gender from facial expressions [14].

8) A pre-trained DCNN model is adopted by replacing its dense higher layer(s) compatible with FER in one study's proposal for very Deep Convolution Neural Network (DCNN) modelling through Transfer Learning (TL) technique. The model is then tweaked using facial emotion data. A new approach is shown, which leads to a progressive increase in the model's accuracy by first tweaking each of the pre-trained DCNN blocks individually, after training the dense layer(s). Eight alternative pre-trained DCNN models (VGG-16, VGG-19, ResNet-18, ResNet-34, ResNet-50, ResNet-152, Inception-v3, and DenseNet-161) as well as the well-known KDEF and JAFFE facial image datasets are used to verify the proposed FER system [15].

9) A pre-trained DCNN model is adopted by replacing its dense higher layer(s) compatible with FER in one study's proposal for very Deep Convolution Neural Network (DCNN) modelling through Transfer Learning (TL) technique. The model is then tweaked using facial emotion data. A new approach is shown, which leads to a progressive increase in the model's accuracy by first tweaking each of the pre-trained DCNN blocks individually, after training the dense layer(s). Eight alternative pre-trained DCNN models (VGG-16, VGG-19, ResNet-18, ResNet-34, ResNet-50, ResNet-152, Inception-v3, and DenseNet-161) as well as the well-known KDEF and JAFFE facial image datasets are used to verify the proposed FER system [16].

10) The authors of the cited paper have suggested a two-tower CNN architecture to categorize images into seven fundamental types of emotion in light of the significance of edges in an image. In addition to the other tower, the planned CNN contains a tower called the edge-tower, which has a more straightforward architectural design and employs edge pictures as inputs [17].

III. METHODOLOGY AND MODEL SPECIFICATIONS

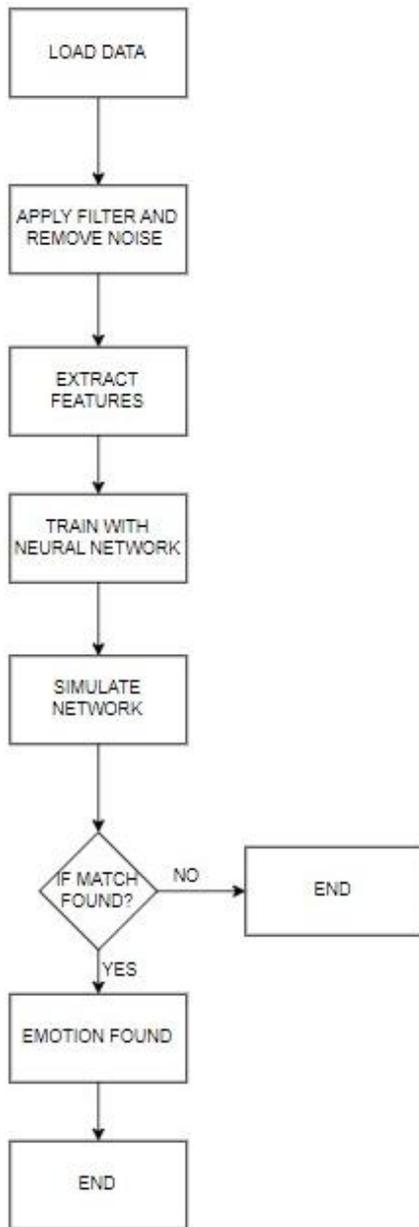
This activity looks at the ongoing challenge facing machine learning and the whole program is part of the training. The location where the system should educate using real-time individual face replies to data. For example, if the system has to discover a furious face the very first system must learn about an angry face and if the program should see a happy face, then the first program should get acquainted with a happy face. To precede a program with these types of emotions, a retraining method was used. Retraining data is then collected from surveys and people. The most difficult part of the program was the iterating component out of various other components of the system. Machine learning works as an advanced tool to analyze data from a wide range of expertise and slow motion [18]. This gives you the ability to get more accurate emotions [19] and provides real-time feedback. The machine did not hold out for a future result, not to be preserved. With the help of modern personal computers, neoteric data exploration techniques can examine thousands of data quickly and save several hours [20].

Other than that, using and installing such programs is very costly. Properly covered, it will withstand a high deal of adverse situations. This work offended the common and possible framework of emotional data mining to verify emotional patterns with the use of machine learning. This kind of paper proposes software based on typically the in-depth reading style and emotional conception of computer eyesight. This proposed approach uses the CNN algorithm in this document. This has triggered a much even more advanced approach as compared to the one which observed only seven feelings about CNN [21].

CNN Implementation: Convolutional Neural Network is one type of Deep Learning algorithm which is used for

working with images and videos. Images are used as inputs, and the system collects their features before categorizing those using previously learned features [22]. The various filters available in the model help extract features at each layer such as edges, and shapes (vertical, horizontal, round), and combine them all to be used as identification for the image [23].

The CNN model works in mostly two stages as seen in Fig. 1:

Feature Extraction – The phase where filters and layers work for extracting information from the images to be passed on to the next layer for classification [24].


Classification – Classifying the images based on the target variable is carried out.

CNN Algorithm: The convolution neural network works by taking input images and assigning them weights and biases according to the importance of the objects identified. Here, we take the Facial Emotion Recognition 2013 dataset available publicly as our input data. Various pre-processing of input data is carried out as converting the images to grayscale, resizing them, reshaping the data, etc. The data is then divided into training and testing sets for model implementation. Various accuracy parameters are then taken into consideration for checking model performance and prediction.

1) ResNet implementation: Residual Networks, or ResNet, learn residual functions with reference to the layer inputs, instead of learning unreferenced functions. The residual is the amount or number by which you have to change your prediction to meet the actual value. Rather than skipping every few stacked layers directly, to fit a desired underlying mapping, residual nets let these layers fit a residual mapping. Residual blocks are stacked on top of each other to form a network. The model ResNet-50 has fifty layers using these blocks.

To produce classification results, ResNet-50 first performs a convolution operation on the input, then it applies residual blocks, and finally, it applies a full connection operation. CNNs typically end with fully connected (FC) layers that summarize the characteristics of the preceding connected layers [25]. The Fully Connected layer can be viewed as feature weighting and uses earlier convolution and pooling as feature engineering, local amplification, and local feature extraction.

The structure of the Fully Connected layer is a way to quickly learn the non-linear combinations of advanced attributes generated by the convolutional layer. The layer learns a possible non-linear function. First, the image, which has been converted into a suitable format, is flattened into column vectors and fed back to the feed-forward neural network. Every training iteration uses flattened data. In this approach, the model is able to discriminate between some low-level aspects in the image and the image's main features, classifying those using methods like SoftMax [26]. The categorization outcomes for the seven expressions are output here.

2) ResNet Algorithm: The ResNets work on the principle of building deeper networks compared to other existing network architectures and simultaneously finding an optimized number of layers to negate the vanishing gradient problem. Here, we take the Facial Emotion Recognition 2013 dataset available publicly as our input data. Various pre-processing of input data is carried out as converting the images to grayscale, resizing them, reshaping the data, etc. The data is then divided into training and testing sets for model implementation. The model works on a 50-layer deep residual neural network that stacks residual blocks on top of each other. Various accuracy parameters are then taken into consideration for checking model performance and prediction performance.

IV. RESULTS

The very first challenge that we faced here was the smaller number of images in the dataset for emotions like disgust and fear. As a result of this, the model would be biased towards the emotions that have a larger number of images while training. Machine learning algorithms work well with datasets having a large number of segments and information. Image data generator helps deal with this by creating augmented images by making some modifications to the images in the form of flipping or rotating at various angles.

A. CNN Result

The model used by us here uses a convolution neural network (CNN) where we work by classifying images according to the emotion that it represents [27]. This is done with the help of feature extraction and various layers of the model such as max pool and dense [28]. The dropout layers help decrease the complexity of the models. This model is helpful in classifying the images with an accuracy level of approximately 62%. This however is not useful and very accurate so we try handling this problem with the help of transfer learning [29]. We can see the prediction outcome in Fig. 3.

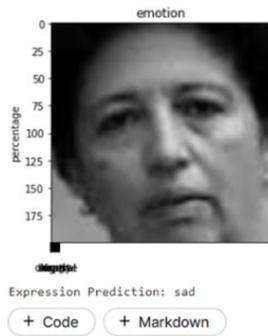
In Fig. 4, we see how accurately our model performs by plotting the loss and accuracy metrics for the training and validation datasets. The loss that occurs, can be seen as decreasing as we increase the number of epochs the model iterates over. The accuracy for the model can be seen increasing as the model learns and the validation data accuracy can be seen as that of training i.e., 62%.


Fig. 3.   Expression Predicted: Sad.

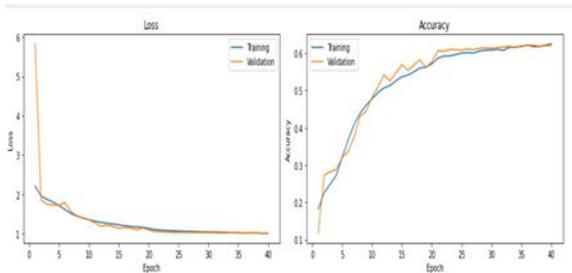
Fig. 4.   Loss and Accuracy.

B. ResNet Result

Transfer learning involves the use of pre-trained models or information that is already stored and with the help of it we train new models. It helps in the reduction of time complexity as well as space complexity. We have chosen Resnet50 as the transfer learning model to solve our problem. Resnet50 makes use of its pre-existing information for feature extraction in determining emotions [30]. The model is then fine-tuned on different parameters and is able to reach an accuracy of 85% for both training and validation data. With an AUC score of approximately 70%, the model using Resnet50 seems to be more promising as compared to CNN. We can see the prediction outcome in Fig. 5.

In Fig. 6, we see how accurately our ResNet model performs by plotting the loss and accuracy metrics for the training and validation datasets. The loss that occurs, can be seen as decreasing as we increase the number of epochs the model iterates over. The losses for validation data can also be seen as decreasing. The accuracy for the model can be seen increasing as the model learns and the validation data accuracy can be seen as that to training after finetuning as well to reach around 85%.

Fig. 5.   Expression Predicted: Neutral.

Fig. 6.   History of Accuracy and History of Loss.


V.   CONCLUSION

A seasoned human can often identify another human's thoughts by inspecting and searching his/her face. Yet, machines are becoming more intelligent day by day as we are moving towards more advancements. Machines with capacities for acting similar to humans are introduced. Machines are being trained to behave on behalf of human opinion. Alternatively, if machines can identify the sentiment, it can prevent lots of incidents too. Data exploration can facilitate appropriate expression patterns by allowing machines to find an action more like humans with additional proficiency and error-free computation sentiment.

We have discussed a method for expression recognition in static pictures in this paper. In order to develop this emotion analysis system, CNN and Haarcascade were used for feature selection, and CNN and ResNet models for classification. This study uses average values generated from training samples to identify emotional expressions on human faces. We tested the system's ability to recognize the photographs and correctly interpret the expressions from the images.

Research on Sentiment Analysis Algorithm for Comments on Online Ideological and Political Courses

Xiang Zhang[1]

Guizhou University of Traditional Chinese Medicine
Guiyang, Guizhou 550025, China

Xiaobo Qin[2]

Guiyang University
Guiyang, Guizhou 550005, China

Abstract—The online course teaching platform provides a more accessible and open teaching environment for teachers and students. The sentiment tendency reflected in the online course comments becomes an essential basis for teachers to adjust the course and students to choose the course. This paper combined two deep learning algorithms, i.e., a convolutional neural network (CNN) algorithm and a long short-term memory (LSTM) algorithm, to identify and analyze the emotional tendency of comments on online ideological and political courses. Moreover, the CNN+LSTM-based sentiment analysis algorithm was simulated in MATLAB software. The influence of the text vectorization method on the recognition performance of the CNN+LSTM algorithm was tested; then, it was compared with support vector machine (SVM) and LSTM algorithms, and the comments on online ideological and political courses were analyzed. The results showed that the recognition performance of the CNN+LSTM-based sentiment analysis algorithm adopting the Word2vec text vectorization method was better than that adopting the one-hot text vectorization method; the recognition performance of the CNN+LSTM algorithm was the best, the LSTM algorithm was the second, and the SVM algorithm was the worst in terms of the performance of recognizing the sentiment of comment texts; 86.36% of the selected comments on ideological and political courses contained positive sentiment, and 13.64% contained negative sentiment. Relevant suggestions were given based on the negative comments.

Keywords—Online courses; comment; sentiment tendency; long short-term memory

I. INTRODUCTION

Education is an important cause of social development, and good education can provide more excellent talents for society and further promote the benign development of society [1]. Students are still in the stage of shaping their value system. The information they can receive at that stage is mixed, and the existence of the Internet has exacerbated this process [2]. Once the information has a negative impact on student's value system, it will seriously affect their future growth. Therefore, in addition to learning the necessary knowledge, students need to establish the correct value system through ideological and political education [3]. Traditional classroom ideological and political education aims to popularize education and is student-oriented. Although there are excellent teachers who can take into account the personalized training of different students in classroom teaching, the number of excellent teachers is limited; moreover, as the fixed time and place of traditional classroom

education is fixed, students only do homework after school hours [4]. With the development of Internet technology, online teaching platforms have emerged, which are not bound by time and place compared with traditional classroom teaching. In general, the teaching resources provided by the platform are pre-uploaded teaching texts and recorded videos [5], and the platform users can browse and learn anytime and anywhere. Online teaching also has shortcomings. Firstly, the lack of direct interaction between teachers and students makes it difficult for teachers to get feedback. Secondly, students are the main subjects when choosing teaching resources, and the diversity of teaching resources in the platform makes it difficult for students to make effective choices [6]. The comments on teaching resources in the platform can alleviate the shortcomings mentioned above to a certain extent. Teachers can correct the problems of their courses according to the emotional preferences of the comments, and students can make preliminary judgments on teaching resources [7]. However, since there are hundreds of comments for a course and even more comments when comparing different courses, it is difficult to collect and organize the comments by manual means alone. In order to quickly collect and process the sentiment tendencies of online course comments to assist instructors and students, intelligent algorithms are needed to process the comment texts. Intelligent algorithms can analyze the sentiment in the comment area under online ideological and political courses efficiently. Students can select courses based on the tendency of sentiment distribution in the comment area, while teachers can improve courses based on it. This paper studied the sentiment analysis algorithm for analyzing the sentiment tendency of comments on online ideological and political courses, which combines two deep learning algorithms, the convolutional neural network (CNN) algorithm and long short-term memory (LSTM). The CNN algorithm obtained the local and global features of the comment text, and then the sentiment tendency was calculated by the LSTM based on the comment text features extracted by the CNN. Finally, the CNN+LSTM algorithm was compared with support vector machine (SVM) and LSTM algorithms.

II. LITERATURE REVIEW

Related studies are as follows. Yasmina et al. [8] used an unsupervised machine learning algorithm to classify sentiment based on a corpus of data constructed using YouTube comments. They used a point-by-point mutual information

metric to calculate the similarity of the sentiment to every target sentiment and found that the algorithm had a global accuracy of 92.75%. Atmaja et al. [9] recognized sentiment in natural language by fusing acoustic and text networks using a support vector machine (SVM). The experimental results showed that this two-stage late-fusion approach achieved higher performance than any one-stage processing. Bernhard et al. [10] proposed sent2affect, a tailored form of transfer learning for affective computing. The results showed that recurrent neural network (RNN) and transfer learning consistently outperformed traditional machine learning. Zhi et al. [11] proposed an application framework and design of an intelligent system for emotion recognition and topic mining, aiming at intelligent and personalized learning analysis for Massive Open Online Courses (MOOC). The system could predict the popularity of every course and obtain emotional topic feedback about the course content so that teachers could analyze and improve their teaching strategies. It could also obtain the emotional topic feedback platform support of the relevant course topic so that administrators could improve user experience in the platform. Jin et al. [12] proposed a hybrid deep neural network model for Chinese text sentiment recognition to identify the sentiment tendency of Chinese medical reviews. The results showed that the model was able to obtain better text features than the reference model and had a text classification accuracy of 99%. Pan et al. [13] proposed an emotion recognition algorithm based on synchronized time comments as the basis for video clip recommendation and found that the model could effectively analyze the complex emotions of different types of text information.

III. METHODS

A. Basic Process of the CNN+LSTM Algorithm

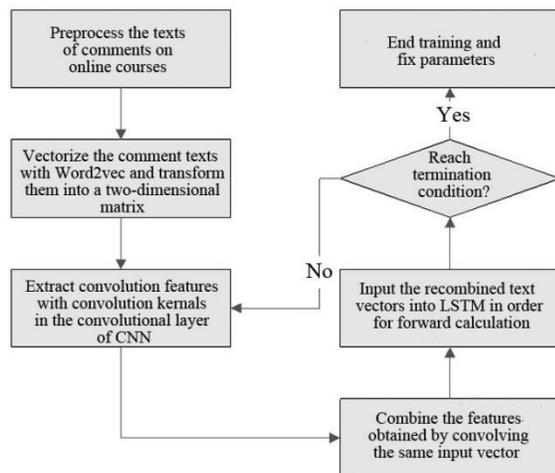
This paper analyzed the sentiment in the comments of online courses with the CNN and LSTM algorithms [14]. The CNN algorithm was used to extract features from comment texts. The LSTM algorithm analyzed the sentiment in the extracted features based on its feature of capable of contacting the context. The flow of the combined algorithm is shown in Fig. 1.


Fig. 1. Training Process of the CNN+LSTM-Based Sentiment Analysis Algorithm for Comments on Online Ideological and Political Courses.

1) The comment text about online ideological and political courses is pre-processed by denoising, filtering, and word segmentation [15]. Denoising refers to removing meaningless characters such as numbers and punctuation from the comment text; filtering means removing comments that are irrelevant to the course topic with a clustering algorithm; word segmentation means dividing sentences into phrases or words [16] for later text vectorization.

2) The pre-processed comment text is vectorized to transform natural language into a text vector that computers can understand. The skip-gram model [17] in Word2vec is used for text vectorization. The dimensionality of the text vector is determined according to the computational requirements, and usually, the larger the dimensionality, the more accurate the distribution of semantic features of the words that the vector can reflect, but the more difficult the computation. Then, the vectorized text is transformed into a two-dimensional matrix. Taking a five-dimensional text vector as an example, it is assumed that there are only four words in the short comment. The two-dimensional matrix of the text vector of the comment is shown in Fig. 2, where every row represents a five-dimensional text vector of one word.

3) After transforming the text vector of the comment into a two-dimensional matrix, the text vector of the comment is regarded as an image, and every dimensional vector of words is regarded as a pixel point in the image. The two-dimensional matrix is input into the CNN, and plural convolution kernels slide on the two-dimensional matrix in a certain step length in the convolutional layer, and convolution operation is performed using the convolution kernel in every slide [18]. The convolution formula is:

$$Y_i = f(X_i \otimes W_i + b_i),$$
(1)

where Y_i is the convolutional output eigenvalue of the i-th convolutional kernel, X_i is the input vector of the i-th convolutional kernel, W_i is the weight of the i-th convolutional kernel, and b_i is the bias of the i-th convolutional kernel.

4) Several convolutional characteristic faces of the two-dimensional matrix are obtained by the convolutional operation of the CNN convolutional layer. The characteristic part obtained by convolving the same input vector is selected from the convolutional characteristic faces extracted by every convolutional kernel and joined in rows to obtain a new vector [19].

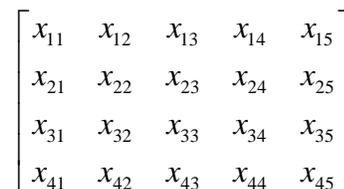
$$
\begin{bmatrix}
x_{11} & x_{12} & x_{13} & x_{14} & x_{15} \\
x_{21} & x_{22} & x_{23} & x_{24} & x_{25} \\
x_{31} & x_{32} & x_{33} & x_{34} & x_{35} \\
x_{41} & x_{42} & x_{43} & x_{44} & x_{45}
\end{bmatrix}
$$


Fig. 2. Schematic Diagram of the Two-Dimensional Matrix of Text Vectors.

5) The new combined vector obtained is input to the LSTM for forward computation by the input gate, forgetting gate, and output gate [20]. The equations are as follows:

$$\begin{cases} i_t = g(\omega_i \cdot [h_{t-1}, x_t] + b_i) \\ \tilde{C}_t = \tanh(\omega_C \cdot [h_{t-1}, x_t] + b_C) \\ C_t = f_t \cdot C_{t-1} + i_t \cdot \tilde{C}_t \\ f_t = g(\omega_f \cdot [h_{t-1}, x_t] + b_f) \\ o_t = g(\omega_o \cdot [h_{t-1}, x_t] + b_o) \\ h_t = o_t \cdot \tanh(C_t) \end{cases}, \qquad (2)$$

where the current cell input is x_t, the previous hidden layer state is h_{t-1}, the last cell state is C_{t-1}, i_t is the proportion that determines the newly added information that can be remembered, $\tilde{C}_t$ is the cell state of the newly added information, C_t is the current cell state after the new information is added, ω_i and ω_t are the corresponding weights [21], b_i and b_C are the corresponding biases, f_t is the weight of the information not to be forgotten in C_{t-1}, ω_f is the corresponding weight, b_f is the corresponding bias, o_t is the proportion that determines the final output information volume, and h_t is the final output or the next hidden state[22]. The output result of the output gate of the LSTM is calculated using the softmax function [23] in the fully connected layer to obtain the sentiment classification result.

The actual results obtained from the forward calculation are compared with the expected results of the training samples. Cross-entropy is used to calculate the error between them. Then, whether the training of the algorithm reaches the termination conditions, including the number of iterations reaching the set number and the error converging to the set range, is determined. If the algorithm reaches the termination condition, the training will be stopped, and the algorithm's parameters will be fixed; if the algorithm does not reach the termination condition, the parameters in the algorithm will be adjusted reversely, and then it returns to step *3)*.

B. Simulation Experiment on the CNN+LSTM Algorithm

1) Experimental Data and Setup

The comment text data used in the experiment came from the China University MOOC website. Twelve thousand comments were crawled from the comment area of ideological and political courses using crawler software. After identification, the emotional tendency of these comments was divided into positive and negative, and their numbers were close. Then, 60% of the comments were used as training samples, and the remaining 40% was used as testing samples.

The parameters of the CNN+LSTM-based sentiment analysis algorithm [24] are as follows. The dimension number of the Word2vec vector for vectorizing the comment text was set as 100. The parameters of the CNN part are as follows. There was a convolutional layer with 64 convolutional kernels.

The specification of every convolutional kernel was 2×100, and the moving step length of the convolutional kernel was 1. The specification of the input data in the input layer, i.e., the size of the two-dimensional matrix, was $M \times 100$, where M is the maximum number of the segmented words. The parameters of the LSTM part are as follows. There were 64 hidden neurons. The weights were initialized using glotot_normal. The bias was set as 0. Training stopped after a maximum of 1,000 iterations.

In order to further verify the effectiveness of the CNN+LSTM algorithm, it was compared with a machine learning algorithm, SVM, and a deep learning algorithm, LSTM, by experiments. As to the relevant parameters of the SVM algorithm, the sigmoid function was used as the kernel function, and the penalty parameter was set as 1. The relevant parameters of the LSTM algorithm were the same as the LSTM part of the CNN+LSTM algorithm.

2) Experimental Project

a) The Impact of Comment Text Vectorization Methods on Sentiment Analysis Algorithms

The Word2vec method was used to vectorize the comment text, but the one-hot method was also applicable in addition to this method. The CNN+LSTM algorithm used the one-hot method and the Word2vec method, respectively, and the recognition performance of sentiment analysis algorithms under these two text vectorization methods was compared.

b) Performance Differences between Different Sentiment Analysis Algorithms

All three sentiment analysis algorithms used the Word2vec method for text vectorization. Then, they were trained using the same training set and tested by the same training set.

The evaluation indexes used to compare the performance were precision [25], recall rate, and F-value, which were calculated by the following formulas:

$$\begin{cases} P = \dfrac{TP}{TP + FP} \\ R = \dfrac{TP}{TP + FN} \\ F = \dfrac{2PR}{P + R} \end{cases}, \qquad (3)$$

where P is the precision, R is the recall rate, F is a combination of the precision and recall rate, TP is the number of positive samples that are predicted as positive, FP is the number of negative samples that are predicted as positive, and FN is the number of positive samples that are predicted as negative.

(3) Analysis of comments on online ideological and political courses with the validated sentiment analysis algorithm

The CNN+LSTM-based sentiment analysis algorithm performed sentiment analysis on online ideological and political courses on the Chinese University MOOC website.

The top ten ideological and political courses with the highest number of plays were selected from the corresponding classification in the MOOC platform. Comments on these ten courses were crawled using crawler software. The sentiment analysis algorithm identified the sentiment classification of the collected comments, and relevant course improvement suggestions were given based on the negative comments.

IV. RESULTS

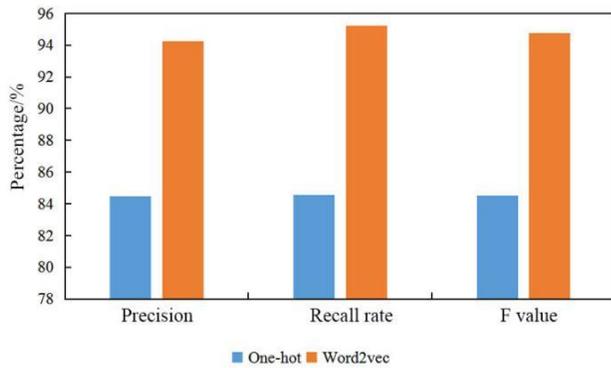
Fig. 3 shows the recognition performance of the CNN+LSTM sentiment analysis algorithm under different text vectorization methods. It was seen from Fig. 3 that the sentiment analysis algorithm using the one-hot method for text vectorization had a precision of 84.48%, a recall rate of 84.57%, and an F-value of 84.52%; the sentiment analysis algorithm using Word2vec for text vectorization had a precision of 94.26%, a recall rate of 95.24%, and an F-value of 94.75%. The comparison of the performance between the algorithms under the two text vectorization methods revealed that the sentiment analysis algorithm using Word2vec had a more excellent sentiment recognition performance.


Fig. 3. Recognition Performance of the CNN+LSTM Sentiment Analysis Algorithm under Different Text Vectorization Methods.

Fig. 4 shows the comparison of the recognition performance of three sentiment analysis algorithms, SVM, LSTM, and CNN+LSTM algorithms. It was noticed in Fig. 4 that the precision, recall rate, and F-value of the SVM algorithm were 77.36%, 76.58%, and 76.97%, respectively; the precision, recall rate, and F-value of LSTM were 90.12%, 89.63%, and 89.87%; the precision, recall rate, and F-value of the CNN+LSTM algorithm was 94.26%, 95.24%, and 94.75%, respectively. It was intuitively seen that the SVM algorithm had the worst recognition performance, the LSTM algorithm had the medium performance, and the CNN+LSTM algorithm performed the best.

Fig. 5 shows the results of sentiment identification using the CNN+LSTM-based algorithm for the ten comments selected from the comment section of ideological and political courses. It was seen from Fig. 5 that 86.36% of the comments in the comment section contained positive sentiment and 13.64 % contained negative sentiment. For students, positive comments can help them understand the advantages of the course, while negative comments can make students view the online ideological and political course as objectively as possible; for teachers, positive comments can encourage teachers, but more

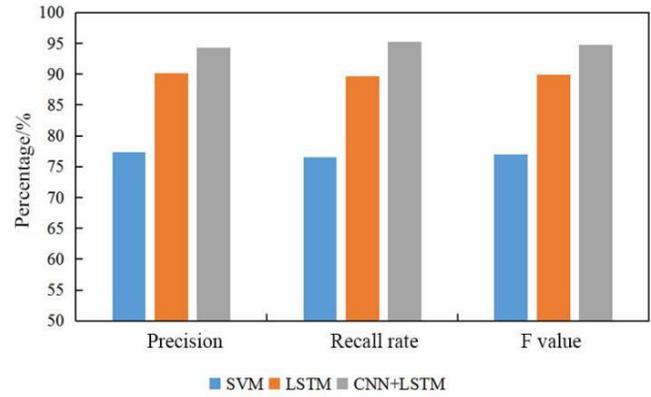
importantly, negative comments can help them search for defects in online ideological and political courses and make better improvements. Due to space limitation, this paper only presented some comments containing negative sentiment and the corresponding key negative words, as shown in Table I. It was seen that users' negative comments on online ideological and political courses were "boring content," "lack discipline in online courses," "lack of interactivity in online ideological and political courses," "one-size-fits-all," etc.


Fig. 4. Recognition Performance of Three Sentiment Analysis Algorithms.
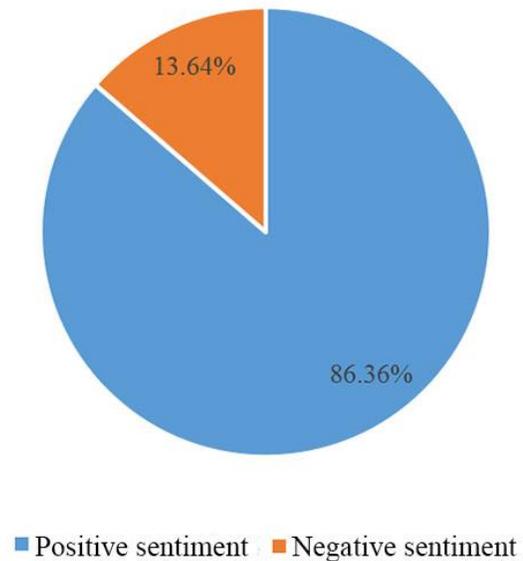

Fig. 5. Sentiment Recognition Results of Comments on Online Ideological and Political Courses by the CNN+LSTM-Based Sentiment Analysis Algorithm.

TABLE I. SOME NEGATIVE COMMENTS AND THEIR KEY NEGATIVE WORDS

Part of the original texts of some negative comments	Key negative words
The course content is straightforward and boring	Boring content
Online courses lack discipline, and students have low autonomy	Lack discipline
Lack of interactivity between teacher and students in online courses	Lack of interactivity

V. Discussion

Online teaching courses are gradually increasing with the popularity of the Internet. Compared with traditional offline teaching courses, online teaching courses have advantages of not constrained by time and space and a higher degree of autonomy for students. However, online teaching courses also have disadvantages such as difficulties in teacher-student interaction and students' difficulties in choosing due to the variety of teaching resources in the platform. The platforms where online teaching course resources are located often have comment areas. These comments on online courses can, to a certain extent, alleviate the problems of communication difficulties and diversification of choices for teachers and students, but the number of comments in the comment areas is so large that it is difficult for them to quickly obtain the emotional tendency from these comments. In order to solve the above problems, this paper combined two deep learning algorithms, CNN and LSTM, and then used them for sentiment analysis of online course reviews. In the simulation experiment, the effects of different text vectorization methods on the CNN+LSTM algorithm were tested, and it was compared with SVM and LSTM algorithms. Finally, the CNN+LSTM algorithm was applied to the actual MOOC platform to recognize the sentiment of comments in ten online ideological and political course comment areas in the platform. The final experimental results have shown in the last section.

The CNN+LSTM algorithm that adopted Word2vec performed better in sentiment recognition than the CNN+LSTM algorithm that adopted the one-hot method. The reason was analyzed. The one-hot method sets the length of the text vector according to the total number of words in the coding dictionary. The position of the word to be transformed in the dictionary determines that its corresponding position in the vector is one and the other positions are zero. This method is simple and intuitive, but in practice, the number of words in the dictionary is huge, resulting in a high dimensionality of the text vector, and only one position in the text vector is 1, making the text vector very sparse, so the algorithm wastes much computational power when training. In addition, the one-hot method encodes the words independently and does not contact the context. The Word2vec method vectorizes words by mapping them into a word space. Semantically similar words are clustered, i.e., the distribution expression of words is realized based on the context. In this paper, the skip-gram model of the Word2vec method predicted the probability distribution of the context based on the intermediate word and used it as its vector representation. Compared with the one-hot method, Word2vec made full use of the context of the words to be transformed and used a smaller word space dimension, so the sentiment analysis algorithm using Word2vec was better in terms of recognition performance.

The results of the comparative experiment on SVM, LSTM, and CNN+LSTM algorithms showed that the CNN+LSTM algorithm had better sentiment recognition performance. The reason is as follows. The SVM algorithm used the kernel function to map the text vector to a high-dimensional space, then searched for the hyperplane that could divide the space in the high-dimensional space, and used the hyperplane to classify the comment text. The SVM algorithm was still difficult to fit completely though it used the high-dimensional mapping of kernel functions to linearize the nonlinear laws in the text as much as possible. The LSTM algorithm is a derivative of the RNN algorithm. The activation function in the hidden layer effectively fit the nonlinear law, and the LSTM algorithm contacted the context based on the historical information, so its recognition performance was much stronger than the SVM algorithm. The CNN+LSTM algorithm is a combination of CNN and LSTM algorithms. The convolutional kernel of the CNN algorithm extracted local features from text vectors, and then the features were reorganized in text order. The LSTM algorithm identified the sentiment from the reorganized text features. The local features provided by the CNN algorithm made up for the defect that the LSTM algorithm could not utilize local features; thus, the CNN+LSTM algorithm was better than the LSTM algorithm in recognition.

The results of the sentiment recognition of the ten comment areas in the actual MOOC platform using the CNN+LSTM algorithm showed that most of the comments were positive. The following suggestions are given according to the negative comments in the comment areas.

1) Teachers should not use too many text descriptions when making online ideological and political courses but can combine teaching contents with pictures and videos.

2) For the lack of discipline when students take online courses, teachers can assist by setting hard targets and focusing on cultivating autonomy in the daily teaching process.

3) Teachers can enhance the interactivity of online ideological and political courses through the live streaming function in the MOOC platform.

VI. Conclusion

This paper combined two deep learning algorithms, CNN and LSTM algorithms, to identify and analyze the sentiment tendency of comments on online ideological and political courses and then simulated the CNN+LSTM-based algorithm in MATLAB software to test the recognition performance difference under two different text vectorization methods, one-hot and Word2vec methods. The following results are obtained. Moreover, the CNN+LSTM-based algorithm was compared with SVM and LSTM algorithms, and the comments on online ideological and political courses were also analyzed. The following results are obtained. The CNN+LSTM sentiment analysis algorithm using Word2vec for text vectorization had better sentiment recognition performance than the algorithm using the one-hot method. The SVM algorithm had the worst recognition performance, the LSTM algorithm had the medium performance, and the CNN+LSTM algorithm had the best performance. 86.36% of the selected comments on the ideological and political courses contained positive sentiment, and 13.64% contained negative sentiment. Relevant suggestions were given based on the negative comments.

Why do Women Volunteer More than Men? Gender and its Role in Voluntary Citizen Reporting Applications Usage and Adoption

Muna M. Alhammad

Management Information System Dept

King Saud University

Riyadh, Saudi Arabia

Abstract—By researching why citizens are eager to participate in citizen reporting applications, this study contributes to the understanding of citizen-government interaction in open government. Self-determination theory, gender role theory, and social role theory were employed to evaluate the impact of various motivational factors on individual behavioural intentions to participate in citizen reporting applications, as well as the role of gender in moderating their effects. The model was quantitatively tested by collecting 499 responses through a questionnaire from citizens who had previously utilized citizen reporting applications. The model was validated using partial least squares. The findings reveal that social responsibility, output quality, self-concern, and revenge are the motivational antecedents that have the most influence on individuals' motivation to participate in citizen reporting applications managing to explain 65.9% of behavioural intention variances. Social responsibility is the most significant driver when compared to the others. The study also revealed that gender differences moderate the impact of social responsibility and revenge on user involvement in citizen reporting apps. The current study adds to the existing literature on citizen reporting adoption and usage by examining the motivational factors that affect citizens' engagement across multiple contexts and evaluating the effect of gender in moderating the influence of social responsibility and revenge. Government institutions need to consider gender differences when designing their citizen reporting applications and their associated marketing campaigns.

I. INTRODUCTION

Transparent public information, participatory decision-making procedures, and innovative platform-based forms of collaborative activities are examples of government efforts to strengthen citizen-government connections [1]. Crowdsourcing applications are one form of open government initiative that aims to accomplish a task by soliciting of external community contributions via an online platform [2]. Crowdsourcing involves two types of actors: individuals or organizations seeking assistance in carrying out tasks and solving problems, and crowd members who offer their services as a contribution [3]. Citizen reporting applications are one type of crowdsourcing application that aims to incorporate citizen participation in reporting incidents to develop public services. Originally, it was mainly used to report infrastructure issues in specific regions through the utilization of geolocation technology [4]. Citizen reporting applications are now being employed for several purposes, such as reporting environmental disasters, controlling pandemic outbreaks [5], and reporting commercial or security incidents.

Many publications on citizen reporting focus on either reviewing the structural concept of citizen reporting applications, such as the study of Linders [6], or concentrate on the ultimate design of citizen reporting applications, such as the study of Lönn, et al. [7]. Few studies were found investigating motivational factors behind citizens' willingness to voluntarily engage in citizen reporting activities in a specific context. Wijnhoven, et al. [8] investigated various motivational factors behind users' willingness to engage in open government, which includes citizen reporting applications as one variant of the open government initiative. Although the study is useful in giving general insight about factors motivating citizens to participate, it only studies citizens' hypothetical interest in participating as the majority of the survey respondents did not actually use this kind of application before. Therefore, further studies are needed to confirm their results using a representative sample. Abu-Tayeh, et al. [4] studied the impacts of two drivers, i.e., self-concern and other-orientation, on citizens' actual participation in citizen reporting applications in the context of smart cities. Although the study found these factors to be significant, the validity of their findings is limited to the context of reporting issues and damages related to the infrastructure in Zurich, which cannot be generalized to other contexts. Alhammad, et al. [9] studies the motivational factors behind citizens' engagement in citizen reporting applications to report commercial incidents. They found that self-concern, revenge, and output quality play significant roles in users' engagement. However, their study was limited to the context of only reporting commercial incidents. Motivational factors behind citizens' willingness to engage in citizens' reporting applications related to different contexts, such as reporting commercial, health, or security issues and violations, remain unstudied. In addition, there is a scarcity of empirical research on studying gender differences when studying what motivates application users to dedicate time and resources to assisting

governments through their participation in citizen reporting applications.

Gender has a significant impact on how people organize their identities and how they interact with different stimuli surrounding them [10]. When it comes to personality, men and women are very different [11]. Common standards for men encourage rivalry, independence, status striving, and toughness, but women are expected to be caring, communal, and modest, rather than controlling, aggressive, dominant, or stubborn [12]. In the context of individuals' engagement in citizen reporting applications, Abu-Tayeh, et al. [4] found that gender is related to the number of reports. In particular, men were found to contribute substantially more frequently to the citizen reporting applications compared to women. This implies that the incentive to participate in citizen reporting is not distributed equally among genders. However, no previous studies investigated the role of gender in moderating the relationships between antecedents of motivations and individuals' engagement in citizen reporting applications. Gender is potentially important to our understanding of user acceptance of citizen reporting since it could play an important role in determining how users make their decisions about adopting and using such applications.

Hence, in order to bridge the gaps in the contemporary literature on citizen reporting applications stated above, the present study aims to investigate gender differences in the overlooked context of studying the impact of motivational factors behind the use of citizen reporting applications. In light of this, this research will employ the self-determination theory to elicit the main reasons that enhance citizens' participation in citizen reporting applications. The theory will be expanded to consider factors impacting users' intrinsic and extrinsic motivations to participate, as well as gender as a moderator factor. As such, this paper contributes to enhancing our understanding of the motivational factors behind citizens' participation in such applications, which are increasingly being used as part of many open government initiatives.

The reminders of this paper are organized as follows: the following section continues a review of relevant literature about citizen sourcing and reporting applications with reviewing the motivations behind citizen reporting behaviour. Next, the model and hypothesis development are presented, followed by the research methodology used in this research. We then continue with presenting the analysis and results. The final section discusses the results and concludes the study.

II. Literature Review

A. Citizens Sourcing and Reporting Applications

Three components of crowdsourcing, as identified by [13], are interacting to bring about the rise of a "collective intelligence system": the organization, the crowd, and the platform, which are represented in the context of this study by the government, citizens, and technology, respectively [14]. Crowdsourcing is sometimes called as 'citizen-sourcing' or 'citizen-reporting' in the context of open governments, as considered in this study [15]. Citizen reporting applications allow citizens to share information directly with the concerned governmental agencies via web-based or mobile platforms [4].

By offering this kind of applications, citizens can play an important role in providing situational awareness by sharing information with the government [6]. Governments can then employ the information gathered through these applications to enhance the quality of public services. Therefore, the goal of governments usage of citizen sourcing is to co-produce knowledge with citizens while the government remains fully responsible for carrying out its activities.

Evidence shows that government agencies are capable of utilizing citizen reporting applications to improve public services at a lower cost, carry out policy innovations, and boost public engagement [16]. Therefore, several governments have developed citizen reporting applications for different purposes. For example, in Switzerland, the "FixMyStreet" application allows citizens residing in Zurich to report issues regarding the infrastructure of the city to local authorities [4]. The Portuguese government has also developed a mobile application, "Citzens@City", that allows citizens to report city-related problems, such as potholes, poor road lighting, or the lack of accessibility of wheelchairs for people with disabilities, to the local authority. Citizens can easily download the application and use it to report the problem, which is categorized by a subject, description, location, and optional picture of the spot [17]. Additionally, the Saudi government has also created a set of national citizen reporting applications such as "Kulluna Amn" (which translates to "We are All Safe") to enable citizens to report security incidents, and "Balagh" (which translates to "report app"), to enables customers to report any commercial violations.

In order for these applications to be effective, citizens must be encouraged to participate in and engage with them. These apps will not provide the intended benefits unless citizens participate. As a result, this article will discuss the motivators that drive user participation and engagement in citizen reporting systems.

B. Motivations and Citizens Engagement in Citizen Reporting Applications

The motivation for human behaviour is one of the most important current subjects in psychology. Motivation stems from the dynamic relationship that occurs between an individual and their environment, which causes certain behaviours to occur [18]. Motivation is more than just the basic concept of motive, which remains relatively steady throughout an individual's lifespan. Motivation is primarily about the interaction between an individual's personal motives and a setting that may spark positive behaviour [19, 20].

Even though motivation is present in all activities, the effect and orientation of these drives vary. Motivation is grouped into three types according to the Self-Determination Theory (SDT) [21]: extrinsic motivations, intrinsic motivations, and amotivation. From an extrinsic motivation perspective, individuals' behaviour is driven through the use of external sources such as attaining better/more valuable outcomes or gaining reward [21]. On the other side, from an intrinsic motivation perspective, individual behaviour is self-driven, and the motivation comes from internal drives within the individuals themselves. Individuals' core values and interests are examples of intrinsic motivations, rather than the

value of the activity itself. Enjoyment and happiness, though important, are not the primary motivations for choosing to perform certain behaviour [22]. According to Waterman [23], only positive subjective states should be considered part of intrinsic motivation, whereas activities that are more related to hedonic enjoyment should be labelled as "hedonic motivation". Waterman [23], therefore, emphasised the importance that the term "intrinsic motivation" be redefined to relate specifically to activities that involve both eudaimonia and hedonic motivation. Lastly, from the amotivation perspective, amotivated people do not appear to have particular aims and goals, and they do not appear to approach their goals in a systematic manner [24]. They are not motivated either internally or externally [25].

In the context of this study, it is essential for governments to know what motivates citizens to engage and participate in citizen reporting applications especially as this kind of engagement is completely voluntary behaviour. Citizens are not obligated to participate and report observed incidents. In fact, citizens using this kind of application work as voluntary sensors to report issues and share knowledge with governments to help them perform their jobs and provide better services. Lin [26] examined the motivations behind individuals' participation in voluntary knowledge sharing within an organization. The study examined extrinsic motivations (i.e., expected organizational rewards and reciprocal benefits) and intrinsic motivations (i.e., knowledge self-efficacy, and enjoyment in helping others) as key factors influencing individuals' intentions to share knowledge. The results show that three motivational factors (i.e., reciprocal benefits, knowledge self-efficacy, and enjoyment in helping others) are significantly associated with an individual's intention to share knowledge. However, expected organizational rewards do not significantly influence individuals' behavioural intentions toward knowledge-sharing. Thapa, et al. [27] found that citizens with relevant expertise are self-motivated and have the courage and sense of responsibility to collaborate and engage in their field of expertise. They also found that rewards, though working as incentives, are not essential to ensure citizens' engagement in reporting applications. Another study conducted by Schmidthuber, et al. [1] found that the level of citizen motivation to engage in citizen reporting applications varies based on the types of users, i.e., proactive, interactive, and passive types of users. The study also found that citizens who always report offline tend to be more likely to report incidents online using citizen reporting applications. This indicates that regardless of the channel of reporting, citizens' motivations and personalities play a significant role in their willingness to report to the government. Additionally, Abu-Tayeh, et al. [4] studied the motivational factors behind citizens' engagement to use the "Zueri wie neu" application (which translates to "FixMyStreet") in the city of Zurich, Switzerland. The study indicates that both self-concern and other-orientation motivate citizens to voluntarily support the government by reporting incidents related to infrastructure using this platform, though self-concern is a slightly stronger driver. According to Alam, et al. [2], intrinsic motivations that are related to personal interest, fun, and community service are the main drivers for individuals' participation in voluntary crowdsourcing

applications and they only impact users short-term engagement. On the other hand, individuals' extrinsic motivations, such as recognition and rewards, are what actually drive long-term engagement. However, by reviewing other relevant studies in the field [8, 9, 28], one can indicate that both intrinsic and extrinsic motivational categories are to varying degrees, responsible for human behaviour.

In this study, amotivation, intrinsic and extrinsic motivations, and their antecedents will be considered as the main predictors of citizen participation in the citizen reporting application. Individual differences, particularly gender differences, will also be taken into account as they are theorized to moderate different relationships within models studying information system adoption in general [29].

III. HYPOTHESES AND MODEL DEVELOPMENT

The self-determination theory (SDT) is feasible in the context of this investigation. It will be used to investigate the motivating elements that drive user adoption and engagement in citizen reporting applications (see Fig. 1). The SDT theory can be expanded to include aspects that may elicit both intrinsic and extrinsic motivations, influencing an individual's behavioural intention to use such apps. Extrinsic motivation is driven by the user's perceptions of usefulness and benefits that will be gained from using an application [29, 30]. On the other hand, intrinsic motivation is driven by the user's perceptions of satisfaction and pleasure when performing a behaviour [31, 32]. This sense of pleasure motivates citizens to help and support the government by voluntarily reporting incidents in online citizen reporting applications [33]. Interestingly, Van der Heijden [34] found that although both types of motivation are significant predictors, antecedents of intrinsic motivation are stronger determinants of an individual's behaviour and intention to perform certain tasks compared to antecedents of extrinsic motivation. Psychological research found that a higher level of intrinsic motivation leads to users' inclination to dedicate more time to perform the task due to the self-satisfaction feeling they experience while performing the behaviour [21]. However, both types of motivations have been verified in the literature to be a strong incentive for users to participate in crowdsourcing projects and open government initiatives [8, 9, 27, 35]. Hence, this leads to the following hypotheses:

H1: Intrinsic motivation will positively impact users' behavioural intention to use citizen reporting applications.

H2: Extrinsic motivation will positively impact users' behavioural intention to use citizen reporting applications.

Amotivation must also be included in order to completely comprehend human behaviour [21]. Amotivation, which refers to the lack of motivation to perform certain activities, is a good predictor of human behaviour. According to Deci and Ryan [36], individuals are experiencing the amotivation state if they believe there is a lack of consistency between their behaviour and its outcomes, or when they feel incompetent and out of control [36]. Legault, et al. [37] further illustrate that amotivation is a result of an individual's feeling of lack of ability, the difficulty of the work, task characteristics, and the value derived from executing the task. Amotivated people

may feel fragmented or detached from their actions and, as a result, expend little effort or energy in carrying out assigned tasks. Such people will consider their behaviour as being beyond their control. Therefore, as individuals that are unmotivated simply do not demonstrate a willingness to participate in an activity, we hypothesis that:

H3: Amotivation will negatively impact users' behavioural intentions to use citizen reporting applications.

A. Antecedents of Intrinsic Motivation in Citizens Reporting Applications

Engagement in citizen reporting applications is in part driven by antecedents of intrinsic motivation, as the majority of citizen reporting applications are voluntary and users are typically not rewarded for their participation [38]. Based on the reviewed literature, the main antecedents of intrinsic motivation that are considered in this study are settling an issue related to self-concern or satisfying the feeling of revenge.

According to [22], revenge initiate a feeling of pleasure resulting from the relief of a painful tension. Although revenge is considered inappropriate and discouraged in modern society [39], it remains an emotionally and politically powerful force in society [40]. Revenge forms an intrinsic motive that drive individuals to take actions to relief the dissatisfaction feeling [41]. [42] found that customer retaliation entails a customer causing harm to a company in exchange for perceived losses committed by the company. Additionally, [43] has found that a vengeance motive (a strong desire to cause damage) increases the chance of "tangible" revenge behaviour. The emphasis on a desire for vengeance is vital since users are not always able to translate their desire into acts [44]. Citizen's sourcing applications, which allow citizens to report incidents, empower citizens and open an opportunity for citizens to report incidents that harm them directly. Hence, it offers a way for satisfying the revenge feeling. Therefore, the desire for revenge will motivate citizens to participate in citizens sourcing applications. In light of this, we hypothesis that:

H4: Revenge will positively impact users' intrinsic motivation towards using citizen reporting applications.

According to [4], self-concern is a strong intrinsic motivator for citizen reporting engagement. Self-concern is defined as the inclination to form one's behaviour with respect to the craving to secure and improve one's self-interest. Citizens may engage in citizen reporting applications in the hope of solving their own issues and get the most personal benefits from the platform [8]. An example of this is when the users are reporting an incident that impacts them personally. On the other hand, when self-concern is the main motive for using the platform, self-concern can be raised by setting higher aspirations [45]. In addition, several other studies [1, 9, 46, 47] found that self-concern is a significant predictor of citizens' participation in crowdsourcing projects, which include citizen reporting applications. Drawing on these studies, we hypothesis the following:

H5: Self-concern will positively impact users' intrinsic motivation towards using citizen reporting applications.

B. Antecedents of Extrinsic Motivation in Citizens Reporting Applications

Extrinsic motivation is behaviour that is instigated by external benefits such as monetary rewards, promotions, and other tangible rewards. Citizens' participation in the citizen's sourcing application is influenced in part by extrinsic motivational factors such as having a sense of and appreciation for social responsibility, expecting rewards, or receiving better service quality as a result of reporting an incident. Literature shows that this kind of motivation is thought of as a significant stimulus for adopting and using information systems in general [29, 48-50].

In the context of citizen reporting applications, [4] found that other-orientation (aka social responsibility) is a significant extrinsic motivational driver of citizen reporting engagement. Other-orientation is defined as the attempt to help others by reporting their issues to the government with the aim of solving their problems. In this case, altruistic motivation is the driving force behind citizens' voluntary engagement to use this kind of collaboration platform [51]. [46] study revealed that the main reason for individuals' participation in open-source platforms is the desire to help others. According to [1], individuals who are altruistic and interested in helping their community engage in more citizen sourcing activities more frequently compared to others. Caring and having love for the community initiate an altruistic motivation to engage in crowdsourcing projects [52]. However, feeling obligated to participate in order to be a good community member can occur [53]. In many cultural settings, especially those characterised as being collectivistic, social standing is determined by what one gives away rather than what one owns [54]. Hence, intensifying the obligation feeling can raise citizens' extrinsic motivation to participate as well as their direct willingness to engage in citizens reporting applications. Therefore, we hypothesis the following:

H6: Social responsibility will positively impact users' extrinsic motivation towards using citizen reporting applications.

H7: Social responsibility will positively impact users' behavioural intentions towards using the citizen reporting application.

The second antecedent of extrinsic motivation to be considered in this research is output quality. The second version of technology acceptance model (TAM2) posits that output quality is a determinant of users' perceptions of a system's usefulness [30]. This construct refers to the performance related consequences of doing the task [55]. Venkatesh and Davis [30] suggest that output quality judgments take the form of a profitability test, "in which, given a choice set containing multiple relevant systems, one would be inclined to choose a system that delivers the highest output quality" (pp.192). Citizens are more likely to participate in government citizen reporting applications if the system's expected output quality is high. In other studies by Winkler, et al. [56] and , Alhammad, et al. [9] they find that output quality takes on greater importance than any other variables related to extrinsic motivation. In light of the aforementioned, we derive the following hypothesis.

H8: Output quality will positively impact users' extrinsic motivation towards using citizen reporting applications.

Crowdsourcing research also discovered that reward and prizes were especially important in determining citizens' behaviour to participate in crowdsourcing, including citizen reporting applications [35, 57]. Monetary rewards can increase participants' willingness to report to the government as many participants treat crowdsourcing applications as a kind of employment [35]. According to Garcia Martinez and Walton [58], increasing the monetary compensation can attract more participants and therefore increase the success of the crowdsourcing project. In non-government crowdsourcing projects, such as Amazon Mechanical Turk, studies show that more than half of the crowd dedicates about eight hours to work on the platform as an additional source of income [57]. Another study conducted by Assegaff et al. (2016) found that if employees believe they can obtain organizational rewards for sharing their knowledge, they will be more willing to use virtual communities of practice (VCoPs) and to share their knowledge. In the context of the public sector, the U.S. Office of Management and Budget in 2009 encouraged the use of prizes and rewards to encourage citizen participation in open government initiatives [59]. This is because offering rewards and prizes initiates incentives and motives for citizens to participate and increases the chance of project success. On the other hand, while offering excessive tangible rewards increases participants' extrinsic motivations, it may weaken their intrinsic motivation [18]. This is known as the "over-justification" effect phenomenon. To simplify, it explains that if the behaviour is already intrinsically rewarding, offering extrinsic motivation will eliminate the enjoyment gained from performing it. Rewards as an extrinsic motivation should be offered when an individual needs to perform an unpleasant task. Therefore, government sectors should evaluate the right rewards to be offered for individuals participating in crowdfunding projects. As most of the offered citizen reporting applications do not incorporate enjoyment factors into their design, it would be expected that rewards would play a positive role in citizens' motivation and willingness to participate in this kind of project. Hence, in this study, we hypothesis the following:

H9: Rewards will positively impact users' extrinsic motivation towards using citizen reporting applications.

C. The Moderating Role of Gender

In the context of the proposed model, gender role theory [60] and social role theory [61] are employed to establish gender's differences as a moderator in the proposed model. According to these theories, gender differences are likely to moderate the impact of social responsibility and revenge. Literature demonstrates that gender differences exist when it comes to caring for other people and the environment, with women being more caring, concerned about environmental issues, and having more environmentally friendly ideas and beliefs [62]. Females not only care about environmental degradation and climate change, but they also maintain the awareness and abilities necessary to discover local solutions [63]. The authors in [64] stated that females, in general, are interested in acquiring and cultivating social behaviors such as

helping and caring for others. Revenge, on the other hand, is more associated with males than females, as females mostly assume a submissive attitude and avoid aggression and retaliation, whereas men are encouraged to demonstrate violent behaviours and seek revenge [65, 66]. [67] found that men had more vengeance dreams than women, whereas women thought vengeance was pointless. Hence, this study will hypothesis that:

H10: Gender moderates the relationship between social responsibility and users' behavioural intentions towards using citizen reporting applications.

H11: Gender moderates the relationship between revenge and users' intrinsic motivation towards using citizen reporting

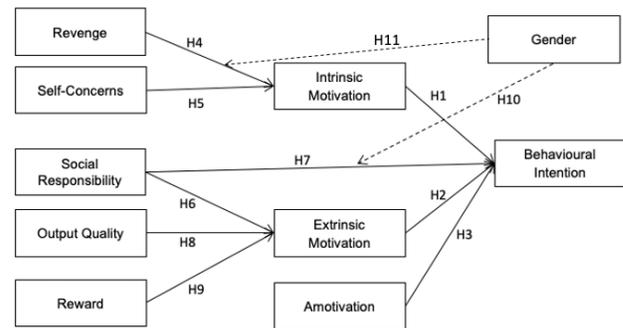
These hypotheses are presented comprehensively in a proposed model shown in Fig. 1.


Fig. 1. Proposed Model.

IV. RESEARCH METHODOLOGY

A. Sample and Data Collection

The purpose of this empirical study is to investigate the direct effect of motivational factors on citizen participation in citizen reporting applications. It also intends to investigate the moderating effect of gender on some of the proposed relationships. To test the proposed hypotheses, this study applies the questionnaire survey method, which is a widely accepted method for model testing in the field of information systems [68]. A closed-ended structured questionnaire was designed using the SmartSurvey website. Trap questions were used to identify unengaged responses. The questionnaire was pilot-tested in order to assess its correctness, meaningfulness, and clarity. Specifically, 50 respondents participated in the pilot study before administering the survey to the targeted audience to certify the face validity of the applied measurement items. A slight refinement was made based on their feedback. After ensuring the quality of the questionnaire, the survey link was distributed to 1000 individuals living in Saudi Arabia through online channels such as emails, WhatsApp, and social media accounts. Only the respondents who had previously used one of the available citizen reporting applications were allowed to participate. After removing duplicate responses and unengaged responses, a total of 499 valid responses were received for analysis. Table I shows the demographic information of the respondents.

TABLE I.   RESPONDENTS DEMOGRAPHIC INFORMATION (N = 499)

Variable	Value	Frequency	Percentage
Age	Under 18	18	3.6 %
	18-24	72	14.43 %
	25-34	134	26.85 %
	35-54	237	47.49 %
	Over 55	38	7.62 %
Gender	Male	124	24.85 %
	Female	375	75.15 %
Educational level	High school	96	19.24 %
	Bachelor degree	328	65.73 %
	Master degree	48	9.62 %
	PhD.	11	2.2 %
	Other	16	3.2 %

B. Measurements

All of the items used in this study were derived from previously validated items and changed to match the goal of this study (see Table II). Behavioural intention and intrinsic and extrinsic motivation measurement items were adapted from [50] and [29]. Amotivation was measured using items adapted from [69]. Self-concern was measured using items adapted from [4] while social responsibility was measured using items adapted from both [4] and [1]. Items measuring rewards were adapted from [8]. Output quality measurement items were adapted from [55] and [29]. For revenge, measurement items, which were originally developed by [70] and adapted by [44], were used after alteration to suit the context of this study. All of measurement items were measured and operationalised using a five-point Likert scale ranging from strongly disagree (1) to strongly agree (5). The questionnaire was in English and translated into Arabic to ensure respondents understood the questions. Three experts used back translation to validate the translation's accuracy.

TABLE II.   MEASUREMENT ITEMS

VBs	Items	Source
Behavioural Intention	BI1: I am considering using this app to report incidents. BI2: I would seriously contemplate using this app. BI3: It is likely that I am going to use this app. BI4: I am likely to make future reports using this app.	Adapted from [50] and [29]
Extrinsic motivation	EM1: I find using this application useful. EM2: Using this application enables me to report incidents more efficiently. EM3: I can forward my concerns to local government directly.	
Intrinsic motivation	IM1: I participate in this application because I think that this participation is interesting. IM2: I participate in this application because this participation is fun IM3: I participate in this application because I feel good when doing this reporting	
Amotivation	AM1: There may be good reasons to do this activity, but personally I don't see any AM2: I do this activity but I am not sure if it is worth it	Adapted from [69].

output quality	OQ1: The use of this application will improve the quality of provided services. OQ2: The use of this application will contribute to the development of offered services. OQ3: Using this application will enhance the overall quality and efficiency of the provided services.	Adapted from [55]
Reward	RW1: My willingness to participate in this application would increase if there were monetary rewards RW2: I will really like to participate in this application if I would receive monetary rewards in return for my knowledge sharing.	Adapted from [8]
Revenge	RV1: My feeling of anger towards violators pushes me to use the application and report them RV2: I use this app to publicize the practices of violators and punish them. RV3: I submit a complaint via the application to avenge violators	Adapted from [70]
Self-concern	SC1: I took part in "Balag" because I could report problems that concerned me personally. SC2: I took part in "Balag" because I could report problems that prevented me from fulfilling my needs SC5: I participate in this application because I believe that this kind of reporting is important for me	Adapted from [4]
Social responsibilities	SR1: I took part in Balag application because it gives me the opportunity to protect others from fraud. SR2: I took part in this application because I could help the community by doing so. SR3: I want to contribute to the development of the services provided in my city by using this application. SR4: I would feel bad about myself if I don't share information about commercial violations with the relevant authorities. SR5: I participate in this application because I feel that this is something that I have to do it for the society.	Adapted from both [4] and [1]

V.   DATA ANALYSIS AND RESULTS

The study uses the partial least squares structure equation Modelling (PLS-SEM) method to analyse the collected data due to its ability to validate the measurement and test structural models at the same time. PLS is a comprehensive variance-based structural equation modelling for analysing skewed non-multinormal distribution, and its variance-based approach is more averse to overestimating relationships between constructs compared to the common SEM [71]. The PLS is also useful for analysing complex models with multiple constructs [72, 73]. Therefore, PLS was the ideal method to be used in this study due to the relative complexity of the proposed model. The analysis was done using the SmartPLS 4 for Mac OSX to examine the measurement and structural models.

A. Measurement Model

To validate the measurement model, the reliability and validity of the measurement model are evaluated. Table II shows that all of the measurement items show a good level of factor loading ranging from 0.560 to 0.963 which exceeds the minimum acceptable value of 0.5 [74]. Two measurement items, one from amotivation and one from reward, had to be removed because their factor loading values were less than 0.5. All of the items were loaded to their relevant construct than on any other constructs with the t-values showing significant results (p < 0.001). Therefore, these items were maintained for the analysis. In addition, to assess the

reliability of the maintained measurement items, Cronbach's alpha (α) and composite reliability (CR) were applied. The Cronbach's alpha (α) values for most of the constructs were above 0.7 which indicates a good internal consistency level of each construct [75]. Amotivation and revenge have slightly lower reliability level with Cronbach's alpha (α) values of 0.663 and 0.617 respectively. However, these Cronbach's alpha (α) values still exceed the minimum threshold value of 0.6 [76] and demonstrates an acceptable level. Composite reliability (CR) values of all of the constructs are above the recommended value of 0.7 [77]. Hence, all the constructs demonstrate acceptable internal consistency.

TABLE III.   THE MEASUREMENT MODEL STATISTICS

Variable	Items	Loading	T-value	α	CR	AVE
Behavioural Intention	BI1	0.841	47.041	0.867	0.909	0.715
	BI2	0.854	43.247			
	BI3	0.839	39.678			
	BI4	0.850	55.164			
Amotivation	AM1	0.917	18.233	0.663	0.773	0.636
	AM2	0.657	5.702			
Extrinsic motivation	EM1	0.832	52.969	0.750	0.856	0.665
	EM2	0.807	31.543			
	EM3	0.809	30.046			
Intrinsic motivation	IM1	0.769	22.409	0.721	0.834	0.626
	IM2	0.786	25.439			
	IM3	0.818	45.401			
output quality	OQ1	0.871	64.121	0.824	0.895	0.739
	OQ2	0.840	32.563			
	OQ3	0.867	53.018			
Reward	RW1	0.963	3.054	0.811	0.702	0.570
	RW2	0.560	1.274			
Revenge	RV1	0.786	27.894	0.617	0.797	0.567
	RV2	0.765	27.240			
	RV3	0.707	20.702			
Self-concern	SC1	0.749	24.626	0.721	0.824	0.541
	SC2	0.640	13.936			
	SC3	0.759	29.309			
	SC4	0.786	29.174			
Social responsibilities	SR1	0.825	34.577	0.861	0.900	0.643
	SR2	0.804	38.671			
	SR3	0.786	28.045			
	SR4.	0.762	32.847			
	SR5	0.830	33.293			

To assess the convergent validity of the constructs, the average variance extracted (AVE) was calculated. Table III shows that all of the constructs have an AVE above the recommended value of 0.5 [78] showing satisfactory convergent validity. On the other hand, discriminant validity was also assessed using the criterion of Fornell and Larcker [79] where the square root of AVE is calculated. Table IV shows that the square root of AVE for each construct is greater than its correlation with the other constructs, indicating that the measurement items used meet the discriminate validity conditions. Additionally, the Heterotrait-Monotrait ratio of correlations (HTMT), which is a new method for assessing the discriminant validity of the measurement model, was also assessed. Table V indicates that the HTMT values for each of the two distinct constructs in the proposed model are less than one. Thus, based on the HTMT criterion [80], discriminant validity is achieved, and the structural model can be evaluated.

TABLE IV.   DISCRIMINANT VALIDITY: SQUARE ROOT OF AVE (FORNELL-LARCKER CRITERION)

Variables	AM	BI	EM	IM	OQ	RV	RW	SC	SR
Amotivation	**0.798**

B. Structural Model Assessment

The second step is to analyse the structural model to test the proposed hypotheses and the theoretically established path. The bootstrapping procedure with 5000 samples set on PLS was used to obtain the path coefficients. The significance level was set to 5% to determine the significance levels for each of the path coefficients. The squared multiple correlation (R^2)

and significance of paths were used to assess the predictive power of the model and test the proposed hypotheses. The R^2 of extrinsic motivation is 0.652 which implies that social responsibilities, output quality, and rewards are able to explain the variance in extrinsic motivation by 65.2%. Likewise, revenge and self-concern are able to explain 42% of the variance of intrinsic motivation (R^2 = 0.42). The multi-mediation model explains 65.9% of behavioural intention variances. The results indicate that the proposed model has good predictive power, as all of the R^2 values are greater than the specified threshold value of 0.1 (Falk & Miller, 1992). In addition, the model fit was evaluated using SRMR, which, according to Henseler, et al. [81], can be used to avoid model misspecification. The SRMR value was 0.093, which is less than the required threshold value of 0.1, suggesting satisfactory model fit [71].

After assessing the proposed model's goodness of fit, hypotheses were evaluated to determine the significance of the identified relationships. As hypothesised in H1, H2, H3, and H7, intrinsic motivation (β = 0.122, t = 3.806, p < 0.001), extrinsic motivation (β = 0.213, t = 3.213, p < 0.005), amotivation (β = -0.045, t = 1.714, p < 0.05), and social responsibility (β = 0.812, t = 6.360, p < 0.001) exhibit significant impact on behavioural intention. As expected, intrinsic motivation, extrinsic motivation, and social responsibility all have a positive impact on behavioural intention, with social reasonability having the highest impact on variance, while amotivation has a negative impact. Therefore, H1, H2, H3, and H7 are supported. In addition, H4 and H5 evaluate whether revenge and self-concern have a significant positive impact on intrinsic motivation. The results indict that revenge (β = 0.278, t = 5.971, p < 0.001) and self-concern (β = 0.435, t = 9.369, p < 0.001) positively influence intrinsic motivation, thus validating H4 and H5. Additionally, extrinsic motivation is found to be positively influenced by social responsibilities (β = 0.494, t = 9.984, p < 0.001) and output quality (β = 0.354, t = 7.058, p < 0.001) with the social responsibility having the highest impact, supporting H6 and H8. Rewording, on the other hand, was found to have no effect on extrinsic motivation (β = 0.031, t = 0.790, p > 0.05), rejecting H9.

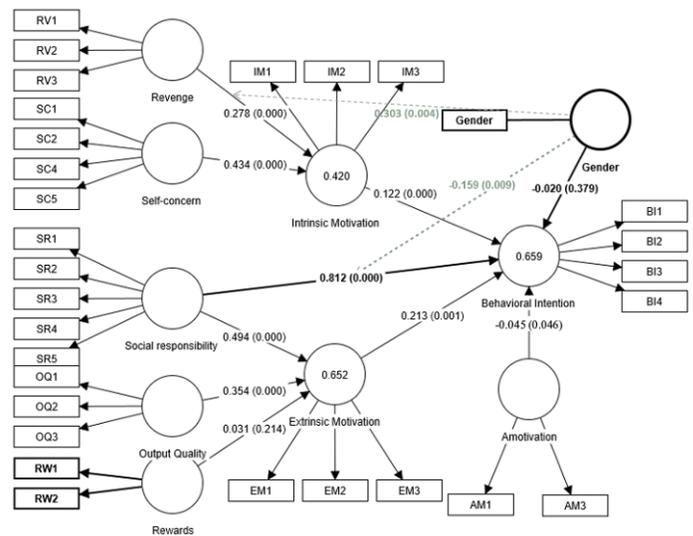
For the moderate relationships, the results demonstrate that gender moderates the relationship between social responsibility and behavioural intention. At (β = -0.159, t = 2.132, p < 0.01), this relationship is statistically significant. Thus, H10 is supported. Furthermore, it moderates the relationship between revenge and intrinsic motivation, which is statistically significant at (β = 0.303, t = 2.918, p < 0.005); thereby supporting H11. Fig. 2 depicts the results of the structural model, and Table VI shows the hypotheses test results.


Fig. 2. The Results of the Empirical Study.

TABLE VI. OVERVIEW OF THE HYPOTHESES TEST RESULTS

H	Hypotheses	β	SD	T-value	P-Values	5.00%	95.00%	Supported / not supported
H1	Intrinsic Motivation → Behavioural Intention	0.122	0.034	3.806	0.000	0.074	0.189	supported

H11	Revenge*Gender → Intrinsic Motivation	0.303	0.104	2.918	0.004	0.088	0.493	supported

VI. DISCUSSION AND IMPLICATIONS

As mentioned earlier, the aim of this study is to examine the motivational factors behind the usage of citizen reporting applications and investigate the role of gender differences in moderating the proposed relationships. The statistical analysis indicates that both intrinsic and extrinsic motivations positively influence individuals' behavioural intention, with extrinsic motivation being the highest predictor. On the other hand, amotivation, as expected, was found to negatively influence individuals' behavioural intentions. Surprisingly, these findings support the current and efficacy of the three types of motivations identified in self-determination theory [21]. Individuals experiencing a low amount of self-determination (amotivation) are less likely to engage in the citizen reporting applications, whereas individuals having a high amount of self-determination (intrinsic or extrinsic motivation) are more likely to participate. Several awareness efforts should be launched by government organizations to raise citizens' understanding of the benefits of their collaboration and participation in the use of citizen reporting applications. Hence, enhancing their self-determination level.

Self-concern and revenge are found to significantly influence individuals' intrinsic motivation, with self-concern being more influential. The significant impact of self-concern is consistent with previous research findings such as Abu-Tayeh, et al. [4], Schmidthuber, et al. [1], Alhammad, et al. [9], Wu, et al. [46], Oreg and Nov [47]. It stands to reason that citizens will report concerns that directly affect them in order to solve their own problems and meet their own demands. Individuals that are preoccupied with self-concern are proven to be more persistent contributors. Similarly, when an individual feels vengeance, it increases his/her self-determination level to impose harm on the offender. By offering citizen reporting applications to report incidences in a variety of fields, the government provides a means for individuals to express their rage without causing physical harm. Interestingly, the results show that revenge boosts men's willingness to harm the offender as compared to women, who are less prone to revenge. This corresponds to the personal attributes of men and women highlighted in the gender role theory [60] and the social role theory [61]. It also supports Mullins, et al. [65] illustration that females are more submissive and tend to avoid aggression and reprisal, whereas men, in several cultures, are raised to engage in violent behavior and seek vengeance.

Extrinsic motivation was found to be significantly impacted by social responsibility. Social responsibility is not only the strongest predictor of extrinsic motivation, but it is also the strongest direct predictor of an individual's behavioural intentions to use citizen reporting applications. This result is in line with the findings of Abu-Tayeh, et al. [4] and Schmidthuber, et al. [1]. Hence, the impact of social responsibility should not be underestimated. Altruistic people often go above and beyond in order to serve others and protect their community. The government should promote collectivism's social principles in order to create a loving community that looks out for one another. Creating such a community will boost the number of people who participate in citizen reporting applications. Furthermore, while women were found to have a higher sense of social responsibility than men, the impact of social responsibility principles in driving men to participate in citizen reporting applications was considerably sharper compared to women, where the impact is steady. This could be because men have a strong sense of duty and dedication when they believe in something [60]. Additionally, the majority of women, according to the analysis, have a greater level of social responsibility and actively participate in citizen reporting applications, making the analysis of this variable less sensitive to covariance analysis.

Output quality was also found to significantly impact extrinsic motivation. Many citizens participate in citizen reporting applications with the hope that they will receive better public services and an improved environment. Several technology acceptance theories, such as TAM2 [30] and UTAUT [48], emphasise the role of output quality in determining user acceptance of technology. The government should report on its progress as a result of citizen participation in citizen reporting applications. If citizens who participate cannot see the outcomes of their reporting, they may be reluctant to take part again.

Although many studies [35, 57] emphasised the importance of rewards in increasing individuals' willingness to perform certain tasks, rewards were not found to influence citizens' extrinsic motivation. The finding, though not expected, is not surprising, as some studies (e.g. Deci, et al. [18]) found that reward might produce negative consequences by weakening participants' intrinsic motivation. Hence, offering rewards will not intensify citizens' motivation to participate. Rewards should only be offered in citizen reporting applications if the reporting process is unpleasant and will not result in a benefit for the reporter or his/her community.

The current study makes numerous contributions to the recent literature. For example, the current study adds to the existing citizen reporting adoption and usage literature by investigating the motivational factors that influence citizens' engagement across multiple contexts, whereas the majority of previous studies have focused on citizen reporting adoption and usage in a single context. Furthermore, it investigates the impact of amotivation on users' behavioural intentions to use citizen reporting applications, which has not previously been investigated to the best of the author's knowledge. Similarly, the current study is the first to add considerably to the existing citizen reporting literature by studying the role of gender in moderating the influence of social responsibility and revenge.

VII. CONCLUSION

We conclude that extrinsic motivation, internal motivation, and amotivation all influence citizen involvement in citizen reporting applications. According to our findings, the motivating antecedents that strongly influence individuals' motivation to participate in citizen reporting applications are social responsibility, output quality, self-concern, and revenge. When compared to other drivers, social responsibility is the most powerful. The study also discovered that there are gender differences that influence the relationship between social responsibility and citizens' behavioural intentions, as well as

the relationship between revenge and intrinsic motivation. Future research should look into the function of other socioeconomic characteristics in moderating the observed motivational factors and their impact on individuals' behavioural intentions to participate in citizen reporting applications.

Laboratory of Sciences and Technologies of Information and Education, STCED Research Team, FSBM, Hassan II University of Casablanca, Morocco[1,2,3,4,5]

Higher Institute of Nursing and Health Technology Professions Casablanca-Settat, Morocco Street Faidouzi Mohamed, 20250 Casablanca, Morocco[2]

Abstract—**This study aims to reveal the existence of a relationship between the visuospatial capacity of pupils with a specialization in physics, with high educational performance, and the capacity for E-learning. To achieve the study, we used the Wechsler intelligence test of cognitive ability. Our sample is composed of 204 adolescents, whose average age is 15 years, 12 months, and 11 days, with a standard deviation of 00 years, 1 month and 19 days. The selection criterion was based on the general results and specifically the physics science mark. The results of the study showed the existence of a significant relationship between visuospatial ability and scientific thinking, and statistically significant homogeneity attributed to specialization in visuospatial ability and creative thinking.**

Keywords—Visuospatial; e-learning; physics; intelligence

I. INTRODUCTION

For more than two thousand years, psychological studies have been interested in mental abilities and have occupied a prominent place among cognitive psychologists because of the importance of this topic in the professional, academic and social life of an individual. Mental abilities are of great importance in guiding the individual to studies appropriate to his abilities and preparing him to integrate into it, something that will allow him to know his faculties. The holder of high mechanical ability is qualified to study mechanical engineering with distinction, the holder of high linguistic ability is qualified to study linguistics with distinction, and the holder of distinguished ability to understand mathematical problems is qualified to study successfully engineering and mathematics [1]. Indeed, spatial visual ability has a significant impact on pupils, as it develops their mental abilities, and helps them to understand study material and solve problems they face from different method, so as to raise their level of success [2]. This visuo-spatial ability is defined as the ability to represent and transform non-linguistic symbolic information [3]. Spatial visual ability requires the ability to mentally rotate models, as well as short-term visual memory, in addition to a series of sequential operations [4].

A lot of studies indicate the relationship between visuospatial ability, performance, and academic achievement, and have shown the superior performance of high-performing pupils in measures of visuospatial ability. Various studies have also shown that academic performance and success in many subjects is associated with high visuospatial ability. Studies indicate that the visuospatial ability of pupils when solving mathematical problems is related to their abilities for academic achievement, [5].

Some experimental research shows the importance of the role of visuospatial experience in the development of mental abilities, and the importance of visuospatial experience in explaining the differences between individuals in abilities [6]. A study indicates that movement and displacement in the environment is one of the most important sources of learning visuospatial skills [7], which reinforces the role of the environment in abilities development.

Visuospatial experience can be acquired through academic specialization, and this is confirmed by a study that found that pupils with math and engineering backgrounds go on to study science and engineering in college and succeed in advantages than others. They did a long way in shortening many visuospatial concepts and thinking about their performance, compared to others that still need exposure to experiences to improve that performance [8]. This confirms that differences in pupils' visuospatial abilities date to their earliest school and extracurricular experiences [9]. The study specify that shape visualization abilities increase whenever pupils are exposed to appropriate experiences, in which the teacher plays a major role [10].

Intelligence tests are the best tests for measuring visuospatial ability, however it is rare in our environment that this skill is studied, or indeed measured, before pupils choose the best academic orientation. As a result, many pupils who fail visuospatial skills may complete their studies in fields that require such skills, such as science and technology, or vice versa, where pupils who have visuospatial skills complete their studies in fields such as than languages. It doesn't depend on the high school, but also on the university course.

Intelligence is one of the important factors that help the pupil achieve success. The most intelligent pupils are more capable than others of learning and acquiring the experiences provided by the environment [11] [12] [13] [14].

Pupils with learning difficulties are considered a heterogeneous group, whether in terms of intelligence or achievement in academic subjects. In terms of intelligence for Moroccan pupils, some pupils' intelligence is average, and others' intelligence is above average; This means that they possess mental abilities that help them to learn what their ordinary peers are learning while making some necessary

adaptations, especially in the teaching methods used in their education, which is reflected in their development in university research [15] [16] [17]. Thus, the use of techniques and electronic media in learning requires skills and tasks on the part of the learner such as the quality of knowledge of E-learning, where visuospatial intelligence exceeds the capabilities required for successful learning. E-Learning in period of COVID, is among the causes of this study, since learning was online where many new educational technologies were applied, which makes E-Learning possible, such as visual digital media that makes teaching effective. The visuospatial interaction of the learner with electronic media is the first to control performance and academic success.

This study is the first in Morocco, this research work aims to research the types of abilities via a cognitive and E-learning test with pupils with a scientific orientation, physics option, who excel in performance and academic success. The results of this study will provide on the one hand to researchers and specialists a theoretical basis on the role of visuospatial intelligence in the success of E-learning, on the other hand to evaluate educational programs which aim the development of abilities and the skills of his pupils.

II. METHOD

A. Participants

Our sample is composed of many adolescents' pupils from the Physics Option in the scientific common trunk in the city of Safi in Morocco. The number of pupils who participated in our survey was 204 pupils with a mean age is 15 years 12 months 11 days with a standard deviation of 00 years 1 month 19 days which corresponds to a very important period in a person's life, when the child undergoes a range of changes, such as physical, emotional, social, cognitive, perceptual, and other developments. The study included the same number of participants of both sexes.

B. Material

In order to calculate Visuospatial ability, two subtests of a cognitive test were choice from the Wechsler Intelligence Scale for Children and Adolescents. The Visuospatial intelligence scale is calculated by both the Cubes and Visual Puzzles subtests. The Visuospatial Intelligence Scale subtests were administered individually during vacant hours. The administration of the scale was carried out by the use of the cubes and the images in the booklet of stimuli which calculates the Visuospatial intelligence. The attribution and rating were carried out according to the procedure of the administration and rating manual [18] [19]. The questionnaire given to pupils includes questions on the social and cultural environment of the family as well as the visual and auditory problems which the pupils could suffer.

C. Data Collection and Analysis

The overall raw scores obtained after running each subtest were transmitted for unlimited correction online to Q-global instead of manual conversion, which requires more time and may lead to miscalculations. The final results were obtained in the form of Standard Scores and Composite Scores. In order to analyse the study data, the program Statistical Package for

Social Sciences (SPSS version 25) was used for research of reliability, statistical descriptive and t-test results.

D. Socio-Economic Status and Level of Education

The cultural characteristics of the social environment of the participants include the level of education of the child and his parents which reflect on the social level of the families of the participants. The study conducted represents the Moroccan public school which suffers from the absence of children from the high earning class and the absence of children from an integrated family educational environment, in terms of the presence of a high level of education. The level of parental education is very low, and all participants haven't a telephone or a computer, at least one member of their family have a telephone that can be connected to the internet.

III. RESULTS

Pupils participating in this study get an average Composite Score equal to the theoretical average in visuospatial intelligence of 100.43, with a standard deviation half of the theoretical average of 8.98. Thus, girls' pupils and boys' pupils get equal marks.

Concerning the ranking of the results studies, we note that important number of the participating pupils amounted to 65.70% on average, 19.60% of the participating pupils on average strong, and 14.70% of the participating pupils on average weak. The reliability measured by Cronbach's alpha in this test was 0.860.

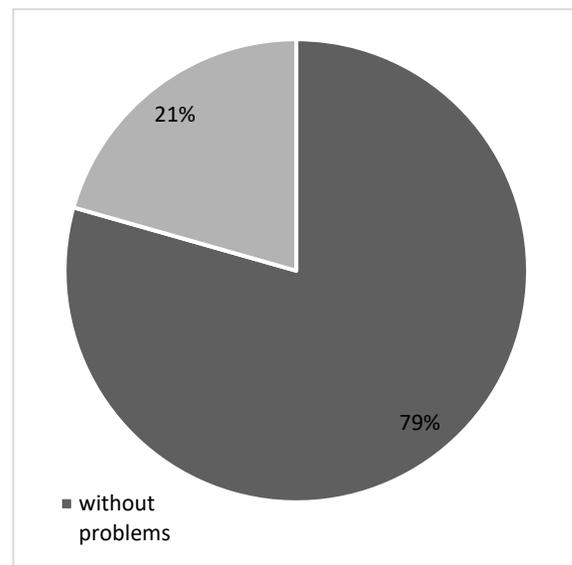
The average and the standard deviations of the standard marks of the two subtests Cubes and Visual Puzzles which builds the visuospatial intelligence are successively with the theoretical average. The Cubes subtest average is 10.01 with a standard deviation of 1.86, also the Visual Puzzles subtest average is 10.22 with a standard deviation of 2.33.


Fig. 1. Percentage of Pupils with Problems among All Participants.

A fifth of the participants indicated in the questionnaire that they suffer from hearing or visual disorders or both Fig. 1. The percentage of girl's pupils and boys' pupils participating in this

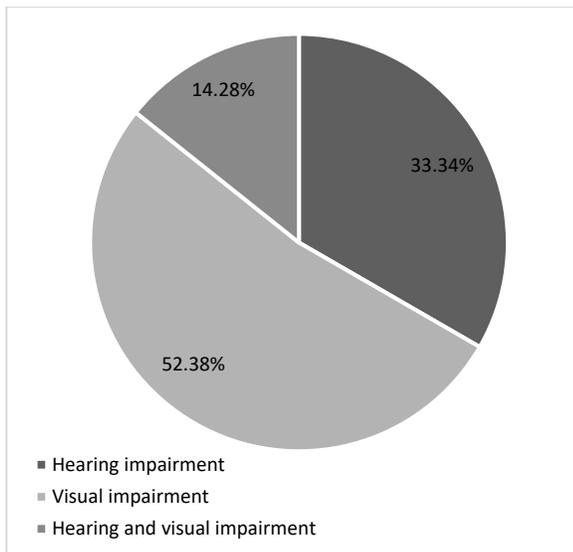
study is equal, but the percentage of girls who report suffering from a hearing or visual disorders or both is 22%, and 78% do not suffer from any disorders.


Fig. 2. Percentage of Pupils with Hearing or Visual Disorders or Both.

Fig. 2 shows the percentage of pupils with hearing or visual disorders or both. A half of pupils who have disorders confirmed having visual disorders. While a third of pupil's report having a hearing disorder. The lowest percentage are pupils who have hearing and visual disorders.

According to gender, the large percentage of female who suffer from problems 45.45%, and this percentage concerns female who have visual problems, followed by a percentage of 36.36% of female who report that they have visual problems, hearing problems; the low percentage of 18.18% is among female reported that they have hearing and visual problems. A large percentage of male who have problems is 60%, is linked to male who have vision problems, with a percentage of 30% of male who suffer from hearing problems, the 10% of male reported that they have hearing and visual problems.

TABLE I. CORRELATIONS BETWEEN VISUOSPATIAL INTELLIGENCE SCORES AND DEVELOPMENTAL AND COGNITIVE IMPAIRMENT FACTORS

Factor	r	p
The quality of family earnings	-0,240	0,015
The quality of the family's level of education	0,244	0,013
Submission to the preschool period	0,167	0,093
Got at least one phone in the family	0,326	0,001
Got at least one computer in the family	0,474	0,000
Participate in e-learning (the Covid-19 pandemic)	0,540	0,000
Desire for E-learning	0,339	0,000

The correlation between visuospatial intelligence scores and participation in e-learning (Covid-19) is the highest according to the Table I which presents the correlation between visuospatial intelligence scores and the seven factors. The high correlation is followed by the correlation between the availability of electronic communication tools such as computer and telephone and visuospatial intelligence. The desire for e-learning is also great. Social and educational factors are also important.

IV. DISCUSSION

Hybrid learning remains a promising technological approach that reduced the existing difference in a disrupted world, the covid 19 pandemic brought different constraints and changed the voices maintained for normal life. However, the success of the E-Learning process depends on a set of skills and cognitive abilities of the learners. Visuospatial intelligence is no longer considered one of the components of the intelligence quotient of each individual but also an essential component to complete one's learning. The study indicates that the results are equal between the female and male gender, this result explains that the programs don't distinguish between two genders in terms of preparation, and that the teachers treat their pupils equally regardless of their gender, and this treatment is reflected in their performance in examinations and general tests [20][21].

In general, the average theoretical visuospatial intelligence is one hundred. The results of this study indicate that the participants received a composite average score equal to the theoretical average of 100.43, it's superior to all intelligence studies in Morocco [22]. This result is between M=99.1 and M=105.6 in the study which conducted in America twice over a same sample belonging to the same age group as the study sample [23]. The average result derived from the theoretical standard and the results of various studies conducted in the United States is concord with the results obtained. The situation of 1,607 Caucasian child with 830 girls and 777 boys aged 6 to 16, with a Visuospatial of 103.49 and a standard deviation of 14.46 (girls with M=102.97 and SD= 13.85; boys with M=104.05 and SD=15.12). Two other studies reveal average inferior. The first concerns 409 African - American child: 221 girls and 188 boys, aged 6 to 16, with a Visuospatial of 90.69 and a standard deviation of 13.71 (girls with M=90.95 and SD=13.67; boys with M= 90.39 SD = 13.76). The second study concerns 621 Hispanic child: 313 girls and 308 boys, from 6 to 16 years old, with a Visuospatial of 97.17 and a standard deviation of 13.41 (girls with M = 95.83 SD = 12.75; boys with M = 98.54 and SD = 14.09) [24]. The difference in study results can be explained by the nature of the development of minds and the use of imagination while they ponder, analyse and reflect on school subjects, in addition to the nature of schools and cultural level and social of parents.

Despite cultural differences and demographic characteristics, the results obtained in our study show similarities with most studies. It's important to emphasize that the samples of American studies serving as a point of comparison with our study, differ from the samples of our study from the point of view of the educational composition of the parents (holders of a bachelor's degree or more), which very logically leads, a set of social and economic privileges for their children [25].

The Moroccan pupils are science pupils, which suggests why they excelled in the test which is due to family orientation and continuous educational development since childhood, unlike pupils who tend to acquire languages, who perform less well on tests.

Suggestion of interventions in the curriculum is necessary to become more adapt to pupil, through the development of

curricula that contain activities that develop visuospatial ability with the diversification of teaching strategies to include both visuospatial methods, and not limited to traditional methods of presenting subject. Using visuospatial skills help pupils find multiple solutions to the same problem during their studies which leads to an improvement in their level of creative thinking and achievement.

The results of the present study indicate that there is a correlation between the development of visuospatial intelligence of participants, and the rate of their participation in E-learning. Also, the acquired spatial visual skills reflected in academic achievement and contribute to the acquisition of learning skills at an early age, have relatively eliminated the comparison between the social and economic privileges of the Moroccan and American learner.

V. CONCLUSION

Based on the results of the research, where spatial ability isn't affected by gender, it can be concluded that public school pupils who excel in the physics course have a high level of spatial ability and that they have a higher level in demonstrating their spatial capability. This is due to the development of their abilities due to the early experiences they are exposed to inside and outside of school, which affects academic achievement. It also shows the strength of the correlation between E-learning and spatial ability, which is reflected in the quality of nature of instructional orientation for this sample, as well as fat status in performance and academic achievement based on e-learning.

VI. RECOMMENDATION

The pupils participating in this study have very good academic performance. Didactic aids to increase and develop the visuospatial skills of all pupils may include providing activities to support visuospatial strengths, activities that build creative structures, provide many educational digital games, and support visuospatial strengths, provide visuospatial activities; encourage the child to engage in visual-spatial tasks, such as putting together puzzles; creating maps; drawing or playing with construction toys. Provide visual learning opportunities to help understand and remember new ideas. When new information is presented in the classroom, visual aids should be presented to supplement the content presented orally. This means decreasing or increasing the number of visual displays with manipulatives, drawings, diagrams, and charts may overwhelm the pupil. It is necessary to explain in words, all new skills and concepts, graphics and visual tasks.

Mobile Devices Supporting People with Special Needs

Tihomir Stefanov, Silviya Varbanova, Milena Stefanova
Department of Mathematics and Informatics
University of Veliko Tarnovo
Veliko Tarnovo, Bulgaria

Abstract—**Over the years, various devices designed for people with special needs have been used for a while and then replaced with modern devices to make everyday life easier. The development of mobile devices is especially improved today and through them different everyday activities are facilitated, not only by people with special needs. The purpose of this paper is to present some of the modern mobile devices with an analysis of their operating systems, functionalities, applications and design. Based on the research, their usability for both sighted and visually and hearing-impaired users is described. Attention is paid to the preferences formed among users when using specialized applications developed for mobile devices. Based on a survey of specific target user groups, the paper provides summary results to support the thesis on the importance of the facilities, offered by modern mobile devices.**

Keywords—Mobile devices; mobile operating systems; Android; iOS; special needs; visually impaired; hearing impaired; e-learning

I. INTRODUCTION

The last few years have seen increased use of mobile devices by users of all ages to accomplish a variety of tasks [2]. In the recent past, their main purpose has been solely for communication. Today, however, using smartphones and tablets, people around the world not only communicate with each other, but work and play by sending and receiving information of all kinds, quickly and easily. It is not yet possible to draw an accurate conclusion as to what percentage of users have completely replaced PCs and laptops with smartphones, and in some professional fields, this is already a fact.

Nowadays, there is an increased interest of people of different nationalities and with diverse health status in professions related to programming and IT. This has contributed to the updating of curricula at universities to include new courses in computer science. The use of computer techniques is particularly important for the laboratory lessons in these subjects. In a number of educational establishments, there are also some students with special needs, which determines the implementation of modern ways and devices in order to provide better and more effective learning. However, not all teachers receive specialized training in teaching the blind or hearing impaired, and the implementation of new ways and the integration of a variety of devices would support the educational process.

The study aims to observe the learning process in leading computer courses for students with visual or hearing impairments. Learning, when supported by the use of smartphones and tablets provides alternative solutions for the hearing impaired or visually impaired – such as special educational tools within a real learning environment or a learning resource center [12].

In our country over the past decade, there has been an increased use of mobile devices and apps among people with special needs, including those who are blind or hard of hearing. The size and weight of the devices are of particular importance for these user groups, especially in daily carrying and use anytime and anywhere possible.

Comparing today's devices with those of ten years ago, there has been a significant change in the external design and the replacement push-button keypads with touch screen displays, which is both a convenience and a drawback for some user groups [13]. Older users have used button keyboards in the past, and touch screens today. Younger users have grown up with mainly modern devices with touch functions

II. RELATED WORK

It took less than a century to advance technology in the areas of hardware and software, and to replace John Atanasoff's large-scale computer with Steve Jobs' smartphone. Over the years, the Internet has established itself as the primary medium for searching, storing and sending data. Users visit leading websites and social networks on a daily basis. The World Wide Web has become popular and has encompassed users' lives completely, not only in their work but also in their leisure time.

This has led to the development, testing and optimization of various applications for computer and mobile devices by specialists in computer companies. The demand for laptops and computers designed for different activities – for office or home, professional, gaming, multimedia has increased. However, there is a preference for the use of smartphones or tablets among 'different' users, namely those with special needs.

According to the World Health Organization, nearly 2.2 million people are visually impaired worldwide. It is particularly important for them to navigate and move around safely, both in open and in unfamiliar indoor spaces [8]. Navigating corridors, sidewalks, stairways, and narrow walkways makes it difficult for the blind. After years of research, navigation aids and systems for mobile devices such as GPS systems have been developed to replace 3D printed maps with protruding dots or magnetic boards [10].

With the development and deployment of voice assistants such as Siri for Apple, Alexa for Amazon, Cortana for Microsoft, Assistant for Google and others, visually impaired

users are greatly facilitated. They now have the ability to do a variety of activities not only through computers, but also through smartphones. Especially when searching for literary resources. In this regard, libraries in educational institutions and localities could provide library services and materials through specialized applications for mobile devices, in order to facilitate their use by the blind [6].

Regarding reading and writing texts, blind people can use Braille in several different ways: with a Braille typewriter or tablet, via a computer or a mobile device [9]. Applying Braille to read and understand text has been the only traditional way for the blind to receive information in the recent past [18]. According to Radulov, however, learning it was an easier process than applying it [16]. Today, braille keyboards and braille tablets greatly facilitate the use of devices as priority tools of accessing needed information [14].

The application of innovative technologies is important for the quality of the learning process among general groups, which include both able-bodied and students with special needs. Usually students with problems are given fewer assignments as they fail to cope and slow down the learning process. Specialized applications have been developed to help them and the teachers to facilitate the learning process of the tasks [3]. The Scrum methodology is one of the most suitable ways to implement software development management, as the purpose of this methodology is to work together and adapt to changes that occur within the project. The application developed within the research of Boza-Chua, Gabriel-Gonzales and Andrade-Arenas, targets students with visual impairment in order to improve the quality of teaching for student teachers [3].

In recent years, due to various reasons, the number of people with hearing problems in the World has been increasing. Currently, there are about 120,000 people with hearing impairment in Bulgaria. In the future, it is expected that one in ten will have some degree of hearing impairment. Everyone with a hearing impairment also has the right to be perceived as healthy. They should be given the opportunity to be educated and to work regardless of the difficulties they face. To communicate with each other, these users use a special language called sign language based on the dactylic alphabet. There are around 25,000 sign language speakers in Bulgaria.

Surveys conducted with users on a predefined or random topic in conversation, and with a trained associate have found that users who made the call without a mobile device were more reliable. However, for people with special needs, the results were different – it was found that through the mobile device they perceived the information better due to mimic gestures [7].

One of the main requirements for admission of students to the University is to pass an entrance examination. However, many higher education institutions do not have the facilities to conduct entrance examinations for visually or hearing impaired people. The need for tools to enable them to perform optimally in the entrance examination are important. To this end, the implementation of web applications that could provide online application capabilities is needed. These applications could

also be beneficial for any of the ongoing examinations during the training [4].

The provision of resource support and out-of-class and learning activities through mobile devices is also supportive of the hearing impaired and is widely applicable in Asia. With the help of resource teachers, pupils and students with hearing impairment are motivated to participate in the learning process and activity. Last but not least, the assistance provided by a parent or relative in the home environment is also of particular importance for improving learning efficiency [17].

In the learning process, the hearing impaired people need proper communication regardless of their age, social status and nationality. Specialized applications are being developed to recognize terms from different languages. The added learning features in these applications are designed to intensively train users in the use of sign language. This can be achieved by voice recognition of words or by typing the words in the selected spoken language. Next, the application displays the appropriate written language images. The research of Setiawardhana, Hakkun and Baharuddin is aimed at developing an Android-based application that directly interprets the sign language, provided by the sign language, into written speech. The translation process starts from hand detection using Opencv and translation of hand signals with K-NN classification [17].

In life, these users often use social networks and video conferencing to communicate with each other. They use the language of the deaf to transmit and perceive information. For convenience, through mobile phones and the Internet, they can exchange information anywhere, anytime.

III. ANALYSIS OF POPULAR MOBILE OPERATING SYSTEMS

New phone models developed in recent years feature not only convenient designs, but also improved versions of both operating systems and software applications. This has led to an increase in users replacing desktops and laptops with modern phones. Improvements in new smartphones are directly aimed at helping people with special needs, and many apps have been developed to help these users in due course.

Just ten years ago, the fact that blind people could use computers, tablets and smartphones was not accepted. Today, visual impairments are no barrier to this, given that blind people perform important work, learning and mobility tasks using their mobile phones. The built-in accessibility features available in smartphones make the process much easier [15]. For example, for getting around, reading emails, online shopping, banking or booking, listening to music. Screen readers such as VoiceOver, TalkBack are also used for the services listed. Blind people can also perceive images accompanied by descriptions through them. Can also successfully use speech-to-text functions when sending messages [5].

Years ago, the popular mobile operating systems were Symbian, Palm, Windows Phone and BlackBerry. The leading operating systems current in modern mobile devices are Android, iOS, and Harmony OS. In this report, only the capabilities of the first two will be discussed, due to the minimal spread of the Harmony OS in Bulgaria at the moment.

In modern smartphones, the 'Accessibility' mode includes options related to screen readers and display settings such as screen magnification, pronunciation of on-screen elements, voice reading, volume up. These features are particularly useful for people with special needs.

A. Features of iOS 16

In iOS, facial recognition of people is implemented through the built-in camera application, which is also helpful for visually impaired users. iOS was originally introduced in 2007, with built-in features to help people with special needs available with the very first versions. Although it supports as many popular languages such as English, Spanish, German, for many years, it has not offered a Bulgarian version.

Localization for Bulgaria was first introduced on September 7, 2022, and the new iOS-16 download became available to users on September 12, 2022 [1]. This version is backwards compatible with all Apple phones – since the iPhone 8, which was introduced in September 2017. This allows people with special needs to take advantage of the opportunity provided without needing devices in the high price range.

In Fig. 1, functionalities of OS are shown in separate groups – for the hearing impaired, visually impaired and physically limited, respectively. The 'VoiceOver' feature speaks out items on the screen and provides helpful hints, where it can also be controlled using simple gestures. On initial activation of this feature, a wealth of detailed information is presented which is useful to the disabled user and their social assistant. Customization includes the ability to set the voice, pronunciation, tone and speed of utterance from the device. For convenience, the additional option of recognizing the phone owner's voice is also provided. The mobile OS also offers Bluetooth connectivity to Braille devices.

Fig. 1.   Functionalities of iOS 6 for People with Special Needs.

Partially sight impaired users are provided by: the ability to zoom the screen, increase text size, adjust color schemes, negative and black and white mode. Hearing impaired people offer the possibility to connect with hearing aids via Bluetooth and a sound recognition option. In the 'Audio/Visual' menu, settings for Mono Audio, Notifications, 'LED Flash for Alerts'

and 'warnings' are collated. In addition, the smartphone supports and adds subtitles and captions for user ease.

The Physical and Motor section includes 'Touch', 'Face ID & Attention', 'Switch Control', 'Voice Control', 'Control Nearby Device' and 'Apple TV Remote'. This section adds options for specific keyboard and side button settings on the device. With all the above-mentioned conveniences of iOS 16 for users, the use of Siri voice assistant can be added, which, however, does not yet support the Bulgarian language.

B. Features of Android 12

The first version of Android was introduced at the end of 2007, with the first T-Mobile G1 (HTC Dream) device running it being introduced in October 2008. In just a few years, Android became the most mainstream OS for mobile devices [23]. Unlike devices at the high end of the price spectrum running iOS, Android is affordable for users with minimal financial means. Another advantage of the Android mobile OS, besides being free, is that every smartphone manufacturer is licensed to use it. The first version of the operating system localized in Bulgarian was Android 2.3 Gingerbread, introduced in 2010.

The menu for people with special needs is located in the 'Accessibility' section (Fig. 2.). It includes 'Recommended for You', 'Visibility Enhancement' and 'Hearing Enhancement', 'Interaction and dexterity', 'TalkBack'.

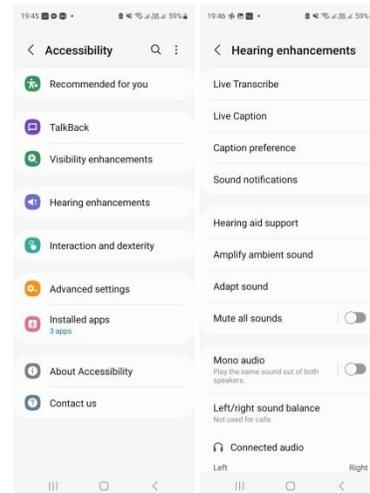
The TalkBack feature provides speech feedback so the device can be used without looking at the screen. Apart from this feature, visibility enhancement settings are available in Android, which include high contrast theme, fonts, button coloring, animation removal, color inversion.


Fig. 2.   The Menu in Android 12 for People with Special Needs.

For the hearing impaired, there are personalization options that cover quickly "finding the relevant written symbols of speech sounds", sound notifications, hearing aid support, amplification of external noise, muting of all sounds, left/right sound balance. Unlike iOS, no option has been added in Android to adapt the device to recognize the user's voice. The Physical Restrictions and Movements section houses options for voice control, answering and ending calls, touch duration,

and more. English Android users are facilitated with Google's voice assistant, but only when setting commands in their native language. Full localization of Google Assistant in Bulgarian is not yet available. In addition to the capabilities of the mobile OS, smartphones extend their functions for people with disabilities through dozens of specialized applications. A more extensive exploration of their capabilities would be a topic for future work.

IV. MOBILE APPLICATIONS TO SUPPORT STUDENTS IN CODE DEVELOPMENT

The use of mobile devices to carry out various daily tasks is almost inevitable in today's information society. Integrating modern technologies and devices into the learning process of students and pupils is important. The inclusion of mobile devices as an aid to learning also greatly facilitates people with special needs, especially those who are hearing or visually impaired. Thanks to this, access to educational resources is becoming a reality for an increasing number of such learners [12]. Recent years have seen increased use of the Android operating system in combination with specialized applications for creating programming code and the ability for beginners to write source code in popular programming and markup languages, scripting languages, and layout.

Leading subjects such as Computer Science, Information Technology, Web Technology, Internet Programming in Higher Education and Schools are categorized as complex. The formation of algorithmic thinking and code design and implementation habits by learners, especially those with special needs, requires time, guidance and persistence. To provide the ability to input the code in markup languages, scripting languages, layout styles such as HTML, JavaScript, CSS, PHP and other technologies, specialized text editors are needed for both desktop and mobile devices. In terms of functionality, they have options for quick debugging, automatically adding code or working with more than one file at a time, and existing customization options in terms of themes. The main task of students is to adapt to using these editors as a medium for writing and reading code. Only then, they could independently implement codes according to predefined criteria.

As a practical experience, it can start with easier tasks involving tagging, basic elements such as headings, paragraphs, images, links, buttons, forms, and more. Moving on to the layout of the elements using styles and defining their dynamics. The idea is to gradually build practical skills in using popular text editors for mobile and desktop devices.

During classes, a common practice in recent years is for students to use their personal mobile devices to write programming code as well. Screens of the two of the mobile applications used for this purpose are presented on Fig. 3.

Fig. 3.   Screens of Web Master's HTML Editor Lite and Droid Edit.

Some of the popular mobile applications for writing programming code are:

- *Web Master's HTML editor Lite* – popular and easy to use editor for Android. Provides the ability to write codes in HTML, CSS, PHP, and JavaScript [22].

- *Droid Edit* – intended for Android analogue of the NotePad++ editor for Windows supporting not only HTML, PHP, CSS, JavaScript, but also C++, C#, Java, Python [20].

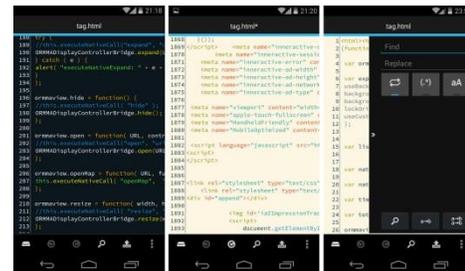
- *AnWriter* – widely applicable editor, shown on Fig. 4. with the ability to enter codes in jQuery, Angular, Bootstrap, SQL, LateX [19].


Fig. 4.   AnWriter Mobile App Screens.

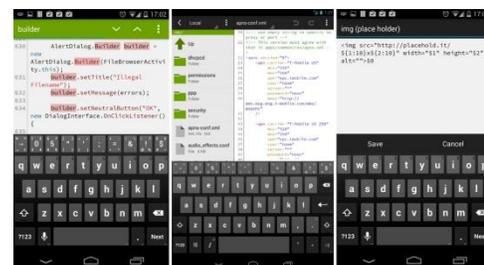
- *Quoda CODE Editor* – specialized editor (Fig. 5.) for programming languages such as Haskell, Lisp, HTML, C#, C++, Ruby, Python, SQL, XML [21, 22].


Fig. 5.   Quoda CODE Editor, Supporting Functional Programming Too.

V. MOBILE DEVICES AND THEIR ROLE IN EDUCATION

Every blind person has the right to adequate education. However, not all blind people in Bulgaria and around the world have the opportunity to complete their studies. One important factor is the need for appropriate technological tools. Based on studies carried out involving both blind students from Latin America and their parent-assistants, applications for mobile devices have been developed to improve their social life and promote their education. The study points to the design of applications for developing computer games, even by the blind themselves, as a good practice [3].

Until recently, it was impossible to use the phones in educational institutions. In recent years, however, there have been cardinal changes that have gradually necessitated the use of mobile devices by both teachers and learners [2]. The need for quick access to electronic resources has led to their increased use.

During the pandemic of Covid-19, e-learning established itself as an alternative form of attendance in many countries around the world. Everyone involved in online learning – teachers, students, pupils, even parents – had to work in virtual classrooms, which took considerable time to adapt to. Through mobile devices, all learners are greatly facilitated – including those with special needs – when they need to access electronic resources for reading, editing, sending and archiving theoretical information or practical assignments [11].

Schools and universities have made a rapid transition to electronic platforms and this has resulted in the need for students to have the appropriate computer equipment and devices for greater ease of communication. Gradually, their use has become established in almost every discipline. A variety of disciplines focusing on different areas are being taught in leading universities in the country and often programming, web design, multimedia, giving basic knowledge in the IT field are more preferred by the learners.

In recent years, more and more people with special needs are completing their higher education. The fact that mobile devices are finding application in the learning process, which facilitates the perception of information by these groups of users, contributes to this. In the Faculty of Mathematics and Informatics at the St Cyril and St Methodius University of Veliko Tarnovo, the leading specialties in the Bachelor's degree are Computer Science, Informatics, and Software Engineering. Students of these specialties receive the necessary knowledge from qualified university lecturers and experts from computer companies. The faculty also trains students with special needs who successfully complete their education, regardless of whether they are hearing impaired or visually impaired.

The problems encountered during the E-learning of students with hearing impairments were mainly related to the perception of voice information. On the other hand, the provision of electronic resources by lecturers in the form of text files and multimedia presentations contributed to overcoming such difficulties.

VI. MOBILE DEVICES AND THEIR USE IN ACCOMPLISHING SPECIFIC TASKS

For the implementation of specific tasks, the considered editors for smartphones can be used by the visually and hearing impaired without significant difficulties.

For the purpose of the study, in some of the laboratory classes of the leading courses in the Faculty of Mathematics and Informatics, students were given three sample problems with the aim of deriving results related to the topic of this paper, which are summarized in Table I. Both able-bodied students and students with visual and hearing impairments were included as user groups.

The following tasks, described below, were set to be completed within two to four class periods.

First Task: to implement a web page (portfolio) including personal information about a student using the web technologies, scripting languages, markup languages and layout using a personal mobile device and an online text editor. Web page to include elements such as images, headings, paragraphs, buttons, navigation, forms.

The time to complete the assignment is two class periods. As a result, the number of students who completed the task according to the criteria set for its implementation is summarized. The assignment is provided for a group of 10 to 15 students. In completing this assignment, students use a text editor for HTML and CSS of their choice. Some of the more famous editors for Android are presented next section of the report.

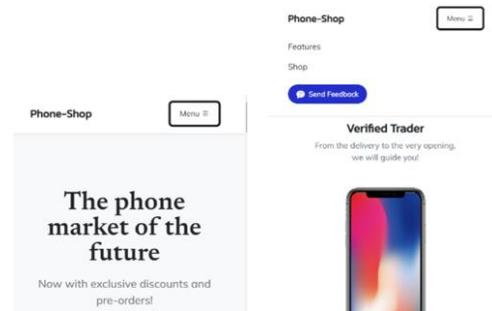
In the 'UX/UI Design' classes, students develop prototypes using modern web technologies such as HTML 5.0, CSS 3, Java Script, TypeScript, Bootstrap 4, JQuery, React, AngularJS, and others. The applications being developed are for educational purposes and are not yet available online. One of the conceptual projects is a website for selling mobile devices for all users, including blind and hearing impaired people. The project is designed for both desktop screens and mobile devices (Fig. 6).


Fig. 6.   Design of the Developed Website for Mobile Devices.

The student integrated an embedded audio file reader into the project homepage, the code for which is presented in Fig. 7. A user-friendly and easily reachable navigation of the website has been achieved, which also offers a contact form.

```
<audio id="features" src="./audio/features.mp3"></audio>
<audio id="intuitive-audio" src="./audio/intuitive-solution.mp3"></audio>
<audio id="jump-shop-audio" src="./audio/jump-to-shop.mp3"></audio>
<audio id="phone-market-audio" src="./audio/phone-market-of-the-future.wav"></audio>

<audio id="verified-trader" src="./audio/verified-trader.mp3"></audio>
```

Fig. 7.   Part of the Source Code of the Created Audio File Reader.

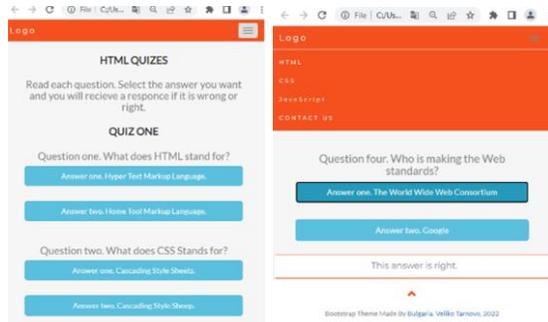
Another of the student projects is a web-based quiz application designed for blind users and implemented for both desktop systems and mobile devices (Fig. 8.).


Fig. 8.   Screenshots from the Mobile Version of the Developed Application.

In the tests made, blind users easily and quickly adapted to the information presented in the application. When viewed with the Google Chrome browser and the Screen Reader turned on, the reader tells out the text part and thus made it easier for blind users to get the content of each page. When viewed with browsers such as Opera, Avast Secure Browser, Firefox, a pre-configured NVDA or JAWS voice reader is required. The template project is a Web Technology related quiz and includes two key questions and the option for two answers. When one of the answers is selected, its correctness is displayed at the bottom of the page. Two functions implemented in JavaScript verify the received answers (Fig. 9.).

```
<script>
function rightAnswer() {
  document.getElementById("foo").innerHTML = "This answer is right.";
  document.getElementById("foo").focus();
}
function wrongAnswer() {
  document.getElementById("foo").innerHTML = "This answer is wrong.";
  document.getElementById("foo").focus();
}
</script>
```

Fig. 9.   The Function Code is Implemented using JavaScript.

Task Two: Each student should familiarize themselves with the curriculum of a given discipline through the E-student system. For this purpose, a personal mobile device should be used.

The guiding criterion for the task is to apply the UX/UI design principle for the number of clicks (up to three times).

As a result of the task performance, the number of students who successfully comply with the set principle is counted – on the first and second visit to the system, respectively. The task is assigned in groups of 10 to 15 students. The number of students who completed the assignment according to the guidelines is reported as the result.

Task Three: Implement an online market research and simulation of a product or service purchase, optionally via a mobile device or computer, using existing websites.

The task is set in a group of 10 to 15 students. Students who completed the task using the pre-set criteria of using a mobile device, laptop or desktop system are scored. Students' opinion on which device they would prefer in a repeat market research for online purchase is recorded, with 72.73% choosing their personal mobile device over a laptop or desktop system.

A summary of the results is presented in the following Table I.

TABLE I.   TASKS ASSIGNED COMPLETED BY STUDENTS

Student's results	Task 1	Task 2		Task 3	
	One solution	*1st option*	*2nd option*	*1st option*	*2nd option*
Users with special needs	3	1	2	3	2
Regular users	47	96+36	125	117	98

VII.   CONCLUSION

The idea of this report is not only to promote modern devices, their functionalities, purposes and applications, but also to present the opportunities for some specific groups of users to use them as an aid. In everyday life, education, science and work, people with special needs experience communication difficulties in perceiving and transmitting information that should not be a barrier to their current and future development.

The design of assistive applications for mobile phones is the subject of research, analysis and testing, and implementation in the future, in order to support visually impaired users. People with hearing impairments find it difficult to perceive 'talking' information such as music, news, and multimedia information. However, the perception of textual information in the form of emails, subtitles and messages facilitate communication and data perception.

Screen readers have been developed for the visually impaired to make it easier for them to use mobile devices. Blind people cannot perceive visual information; rather they 'listen fast'. For the hearing impaired, the perception of 'talking' information is partial or impossible. They adapt to perceiving visual information. Regardless of whether the disorder is congenital or acquired, it results in impaired motor, visual and auditory functions.

According to Stephen Hawking, the ability of people to integrate to changes is important. This applies in full force to all people with and without special needs. As the main task of devices is to serve them.

Vision based 3D Object Detection using Deep Learning: Methods with Challenges and Applications towards Future Directions

A F M Saifuddin Saif[1]
School of Engineering
Aalto University
Finland

Zainal Rasyid Mahayuddin[2]
Faculty of Information Science and Technology
Universiti Kebangsaan Malaysia
Selangor, Malaysia

Abstract—For autonomous intelligent systems, 3D object detection can act as a basis for decision making by providing information such as object's size, position and direction to perceive information about surrounding environment. Successful application using robust 3D object detection can hugely impact robotic industry, augmented and virtual reality sectors in the context of Fourth Industrial Revolution (IR4.0). Recently, deep learning has become potential approach for 3D object detection to learn powerful semantic object features for various tasks, i.e., depth map construction, segmentation and classification. As a result, exponential development in the growth of potential methods is observed in recent years. Although, good number of potential efforts have been made to address 3D object detection, a depth and critical review from different viewpoints is still lacking. As a result, comparison among various methods remains challenging which is important to select method for particular application. Based on strong heterogeneity in previous methods, this research aims to alleviate, analyze and systematize related existing research based on challenges and methodologies from different viewpoints to guide future development and evaluation by bridging the gaps using various sensors, i.e., cameras, LiDAR and Pseudo-LiDAR. At first, this research illustrates critical analysis on existing sophisticated methods by identifying six significant key areas based on current scenarios, challenges, and significant problems to be addressed for solution. Next, this research presents strict comprehensive analysis for validating 3D object detection methods based on eight authoritative 3D detection benchmark datasets depending on the size of the datasets and eight validation matrices. Finally, valuable insights of existing challenges are presented for future directions. Overall extensive review proposed in this research can contribute significantly to embark further investigation in multimodal 3D object detection.

Keywords—3D object detection; deep learning; vision; depth map; point cloud

I. INTRODUCTION

3D object detection provides precise representation of objects in the format of semantically meaningful 3D bounding boxes. 3D object detection aims to categorize and localize objects from various sensors data, i.e., monocular and stereo cameras [1, 2], LiDAR point clouds [3], to understand the 3D visual world and associated semantic labels for objects in 3D scenes, has attracted increasing attention from vision community. In addition, advances of deep learning facilitate the rapid progress of 3D object detection indicates strong application demands which can serve numerous applications, i.e., robotics, autonomous driving, augmented reality, virtual reality, robot navigation, enabling systems to understand their environment and react accordingly. As a result, there has been a surge of interest for developing improved 3D object detection pipeline. Although current methods show impressive performance despite the facts that various problems form different viewpoints were observed and illustrated by this research.

This research identified four major approaches along with deep neural networks for 3D object detection, i.e., monocular images, stereo images, LiDAR and Pseudo LiDAR based approaches. 3D object detection from monocular frames is a fertile research area due to potentially vast impact, ubiquity of cameras, low expense, easy implicated solution with one camera [4]. However, estimation of depth from single monocular images is an ill-posed inverse problem causes accuracy of 3D detection from only monocular images is lower than that from LiDAR or stereo images [2, 5]. In addition, loss of significant information during calibration is another reason for degraded performance on the same 3D object detection benchmarks comparing with LiDAR and stereo methods. Advances of deep neural network facilitate immensely the progress of 3D object detection using LiDAR and stereo based methods. The inclusion of depth information allows capturing the three-dimensional structure of the object's environment, is a key feature for ensuring robustness while maintaining high accuracy. Modern LiDAR acquisition sensors provide meaningful information not only for avoiding imminent collisions, but also to perceive the environment as good as image-based data and even surpass it under poor lighting conditions. For stereo images, calibration issues between two camera rigs [6] and occupation of more pixels for nearby objects than far way objects during perspective projection are considered as major challenges. Besides, high cost of LiDAR sensor encourages researchers to look for alternatives such as Pseudo LiDAR based approaches. In this context, Pseudo LiDAR based approaches uses pre-trained depth network to compute an intermediate point cloud representation to mimic LiDAR data and then fed to a 3D detection network [7]. The strength of Pseudo LiDAR based approaches is that they monotonically improve with depth estimation quality although for long distance object Pseudo

LiDAR approaches could not provide expected detection outcome. However, accountability of the depth estimation is the prime gap between Pseudo-LiDAR and LiDAR based 3D object detection. In this context, simpler end-to-end monocular 3D detectors shows strong promise as an option where lack of same scalability from unsupervised pre-training for their one stage nature is the main drawbacks in this context. Besides, existing datasets for validating 3D object detection was not generalized well for different weather conditions and geographical locations, i.e., any method trained on Waymo datasets [8] suffer from dramatic performance drop on KITTI dataset [1]. Therefore, approaches to effectively adaptive 3D object detection method are highly demanded for practical applications where environment varies significantly. In this context, recent success for various 3D object methods mostly depends on larger datasets of 3D scenes where annotations are done carefully and remains as main bottleneck in the context of available datasets.

In summary, the contributions of this work are:

1) Six key areas are identified to analysis existing 3D object detection methods from different viewpoints to guide future development and evaluation by bridging the gaps using various sensors, i.e., cameras, LiDAR and Pseudo- LiDAR.

2) This research demonstrates extensive experimental analysis based on existing research depending on three major aspects, i.e., comprehensive insights on hardware and software, analysis and challenges of using six datasets with details specification, illustration of eight performance metrics required for validation of 3D object detection methods.

3) Based on comprehensive previous research investigation on existing 3D object detection methods, six key observations are elaborated for improving future 3D object detection methods.

II. BACKGROUND

3D object detection methods mostly depend on four types of input pattern, i.e., monocular image, stereo image, LiDAR point cloud and pseudo-LiDAR signal. Research in [9] also used monocular RGB images as input and mapped image features into an orthographic 3D space by describing deep learning architecture for estimating 3D bounding boxes. They performed front-end feature extractor to extract features from monocular RGB images to form 3D features space and the transformation from 2D features maps to 3D features map was termed as Orthographic Feature Transform (OFT). However, validation on large variations of scales and distances could provide real time usage of their proposed method. Research in [10] used monocular RGB images as input to predict 3D human locations by learning data ambiguity without supervision which leads to predict confidence intervals with point estimation. They used Laplace loss to model Aleatoric Uncertainty and multivariate Gaussians to model Epistemic Uncertainty. However, loss of multiview visual characteristics and spatial structure characteristics from 2D human poses for 3D localization might be the reason for low accuracy compared with other research results.

Research in [1] used stereo data as input to produce set of 3D object proposals which run through convolutional neural network for high quality 3D object detection. Their proposed method generated 3D proposals using energy minimization function to encode object size priors, context of ground plane and features for depth information. However, they used 3D integral images which are not suitable for real time 3D object detection. Research in [4] used stereo data to predict sparse key point for estimating 3D bounding box. They proposed Stereo R-CNN to improve overall performance. However, recent advancement of R-CNN like Faster R-CNN should be implicated to justify the effectiveness of their proposed method. Research in [2] used stereo imagery as input to estimate depth using convolutional neural net (CNN) [11] to compute point clouds. They used proposal generation problem as inference in Markov Random Field (MRF) to encode high density in the point cloud. However, overall performance of their proposed method depends on accurate depth estimation.

Research in [2] used LiDAR point cloud and RGB images as input to generate 3D proposals and projected them to multiple views for feature extraction. They used region-based fusion network to deeply integrate Multiview information for classification of 3D proposals. However, region based fusion network works-based region using convolutional neural network [12] requires more computation overheads for real time detection. In addition, LiDAR sensor is expensive whereas optical camera could be a potential alternative for their proposed method. Research in [7] generated 3D proposal by using raw point cloud instead of generating proposals from RGB image or projecting point cloud to bird's view or voxels. They used PointNet++ to learn point-wise features for describing the raw point clouds which later used for foreground point cloud segmentation. However, for sparse convolutions, alternative point-cloud network structures, such as VoxelNet could be investigated as their backbone network. Research in [13] used RGBD data as input for raw point clouds and proposed framework for RGB-D data-based 3D object detection called Frustum PointNets. Their frustum region is based on 2D region proposal indicates that no 3D object will be detected without 2D region proposal or 2D detection. However, aggregation of image feature after extracting features using based on their backbone network could improve overall 3D object detection performance. Although, point clouds can provide detailed geometry and capture 3D structure of the scene, on the other hand, point clouds are irregular, which cannot be processed by powerful deep learning models, such as convolutional neural networks directly [14]. Research in [5] used both monocular images and stereo images and estimated depth and disparity for monocular and stereo images respectively to generate point clouds. They proposed two step approach by first extracting dense pixel depth from stereo or monocular imagery followed by back-projecting pixels into a 3D point cloud to view the representation as pseudo-LiDAR signal. However, for long distance objects pseudo-LiDAR signal could not provide expected detection results comparing with short distance objects.

III.　ANALYSIS OF METHODS BASED ON SIX ASPECTS

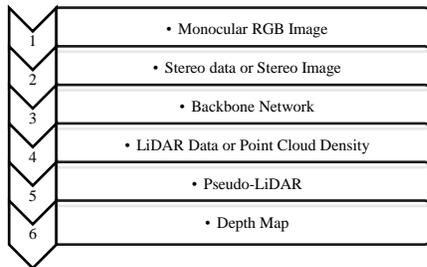
This research identified six significant key areas to analysis existing methods for 3D object detection mentioned in Fig. 1 and comprehensively illustrated in the next subsequent sections.


Fig. 1.　Six Key Areas to Analysis Existing Methods for 3D Object Detection.

A. Monocular rgb Images

Although 3D point cloud extracted from LiDAR provides superior performance, previously less effective alternative was monocular RGB images that were collected from single view RGB image as input for monocular 3D object detection [15]. Usage of monocular RGB images can facilitate domain adaptation for multimodal big data management and significantly aids for 3D model retrieval and classification when compared with multiview image sets [16]. Research in [4] used a single monocular image to generate class specific object proposals to run through standard CNN pipelines for 3D object detection. However, they assumed that objects should be on a ground plane which makes the overall proposed methodology uncomfortable to be used for other mediums such as detection from UAV, UGV or Krane. Research in [10] used monocular RGB images to tackle ill-posed problem of 3D human localization. They used Laplace distribution to address ambiguity by predicting confidence intervals of 3D bounding boxes. However, they used 2D human poses for 3D localization which might be the reason for low accuracy compared with other research results.

Research in [5] used both monocular and stereo images to mimic LiDAR signal and depth map constructions using the Pseudo-Signal hence called Pseudo-LiDAR and provided a milestone instead of using LiDAR sensor for point cloud generation. However, Pseudo-LiDAR approach required additional post processing steps due to the range issue of objects from the source of the camera platform.

If these pose processing can be eradicated, then Pseudo-LiDAR can be considered as a potential option to generate point cloud and depth map. Research in [9] used orthographic feature transforms from monocular image as part of an end-to-end deep learning architecture to map image-based features into an orthographic 3D space. However, fruitful experimentation on large variations of scales and distances can provide real time usage of their proposed method. There are several challenges exists for using monocular images for 3D object detection, i.e., significant information loss, object pose inconsistency, complex background of monocular images [16], accurate depth information [6]. Monocular images lose significant information during calibration such as multiview

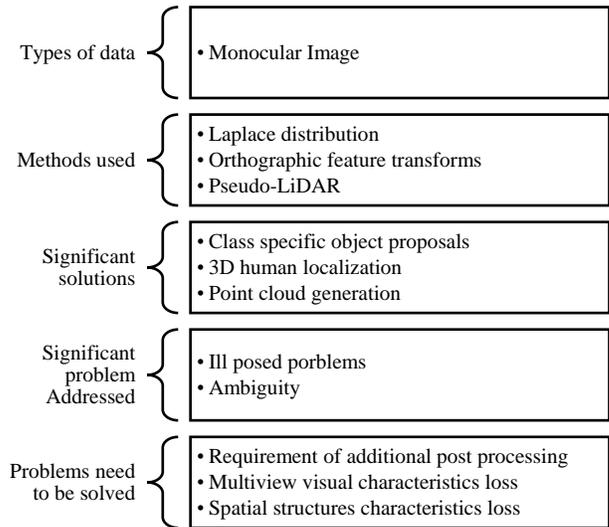
visual characteristics and spatial structure characteristics. Overall scenarios of using monocular images are mentioned in Fig. 2.


Fig. 2.　Scenarios of using Monocular RGB Images for 3D Object Detection.

B. Stereo rgb Images

Stereo cameras work in a manner like human binocular vision which is cost less and have higher resolutions for which they have gathered significant attention in academia and industry [17]. Disparity cues are provided by stereo images to enable better depth estimation compared to monocular images [18]. Research in [1] exploited stereo imagery for high quality 3D object proposals using energy minimization function to encode object size, localization of objects on the depth informed features to reason free space, point cloud densities and distance to the ground. They used CNN to exploit depth information for regressing 3D bounding box coordinates and object pose. However, they used 3D integral images which might cause additional computational cost during training. Research in [4] used stereo R-CNN for detecting associated objects in the stereo images. To achieve the aim, they proposed a 3D box estimator to exploit stereo box key points and dense region-based photometric alignment method to improve 3D object localization accuracy. However, due to later advancement of R-CNN like Faster R-CNN could be better option to investigate in their proposed method. Research in [5] proposed a twostep approach using stereo imagery data, i.e., estimation of depth map from stereo and usage of existing LiDAR-based 3D object detection pipelines. Although they used both monocular and stereo images, it is not clear based on the elaboration whether they used combined depth maps for both types of images or not. Research in [2] used contextual models by exploiting stereo information by reasoning and placing in 3D proposals in the form of 3D bounding boxes. Although, they implicated their proposed method for autonomous driving, they claimed better performance on other object classes such as Cyclist and Pedestrians. Several other shortcomings for using stereo images are observed by this research although stereo image based detection shown promising results, i.e. calibration issues between two camera rigs [2], memory expensive 3D cost

volume learning in image space due to the image's high resolution and requirement of additional dimension for features [18], depth estimation in image space while downstream detection is performed in 3D space [18], existence of many pixels among nearby objects due to perspective projection than faraway objects which lead to biased depth estimation with degraded long-range detection performance [18], dependency on anchor-based 2D detectors with association approach [17].

For stereo images, in image space, 3D cost volume learning is costly in memory due to high computation and extra dimension of the features. Besides, previous lest computation time for one frame was 0.5 seconds which can be challenging for critical applications such as collision avoidance [17, 20, 21]. Besides, in stereo images, depth estimation is performed in 2D image space whereas detection tasks take place in 3D space. Existence of more pixels in nearby objects than faraway objects due to perspective projection led to imbalance biased depth map. Overall scenarios of using stereo images are mentioned in Fig. 3.

C. LiDAR Data/ Point Cloud Density

Research in [1] extended 3D object proposal with class independent variant and neural network to grab both appearance and depth features. Later, they used point clouds obtained via LiDAR followed by giving comparison of the stereo, LIDAR and hybrid settings. However, class specific module they proposed, needs further elaboration to justify their claim. Research in [3] used sensory-fusion framework to take both LiDAR point cloud and RGB images as input. They encoded sparse 3D point cloud for compact multiview representation.

Types of data	• Stereo Image
Methods used	• Energy minimization function • Stereo R-CNN • Depth map estimation • Contextual models
Significant solutions	• Improved 3D Object localization accuracy • Depth map estimation
Problems need to be solved	• Additional computational cost • Biased depth map • Dependancy on anchor based 2D detectors • High image resolution and extra dimension

Fig. 3. Scenarios of using Stereo Images for 3D Object Detection.

Their proposed deep learning network was composed of two subnetworks, i.e., one for 3D object proposal generation and other one for multiview features fusion. For multiple views and interactions between intermediary layers they used deep fusion schemes to combine these two parts. However, region based fusion network works-based region using

convolutional neural network requires more computation overheads for real time detection. In addition, LiDAR sensor is expensive whereas optical camera could be a potential alternative for their proposed method. Research in [4] used raw point cloud for generating small number of high-quality 3D proposals via segmenting the point clouds of the whole scene into foreground points and background. They performed 3D box refinement later by combing local spatial features with global semantic features [22] for each point cloud. However, later version of RCNN such as Fast RCNN and Faster RCNN could be aligned later to find the suitability of the proposed method with most recent deep learning architectures in case of using CNN for raw point cloud achieved from LiDAR.

D. Pseudo-LiDAR Generation

Previous LiDAR methods formulated LiDAR point cloud as point [7], pillar [23] and voxel representation [29,30]. Despite the remarkable performance of these methods, LiDAR sensors are expensive sensor and for the far distance, LiDAR sensor-based detection can potentially make 3D object detection tasks difficult which initiate the need for some approaches to mimic LiDAR point cloud due to high accuracy called Pseudo-LiDAR based point cloud representation. Research in [26] proposed self-supervised learning schemes by mimicking latent spatial features representation based on point-based module. However, their proposed method depends on 2D-3D detection pairs. Accurate depth map is one of the key challenges for 3D object detection from monocular image as lack of prior information is the main issue and eradicated recently by deep learning approaches [25, 27]. By constructing robust depth map, Pseudo-LiDAR point cloud can be constructed to mimic LiDAR point cloud based on pre-calibrated intrinsic camera parameters [28,29]. However, heavy computation is the bottleneck for this research. Research in [30] generated pseudo-ground without the need of LiDAR point clouds by proposing a statistical shape model to address the challenge of disparity annotations in training. However, for monocular 3D object detection, disparity map generation will not be possible for their proposed method. In addition, their proposed research depends on shape analysis which may provide poor performance in case of obstacles such as shadow. Research in [31] combined 2D object detection with Pseudo-LiDAR point cloud data generated from stereo images to investigate the boost of performance with existing six different 3D object detectors. However, distance calculation for their proposed method can be costly. Besides, they did not investigate high consistency issue for the point clouds generated by Pseudo-LiDAR approach. Research in [32] constructed a pseudo-LiDAR feature volume (PLUME) to estimate depth map and 3D object detection in 3D metric space. The main purpose for their proposed PLUME is to avoid biased depth estimation with degraded long-range detection for stereo images. However, for low light and extreme weather conditions, their proposed method may encounter due to the need of accurate depth map estimation.

E. Depth Map

Recent algorithms for stereo depth estimation can produce surprisingly accurate depth maps [33]. However, inferring depth of pedestrians from monocular images is a fundamentally ill-posed problem [10]. This additional

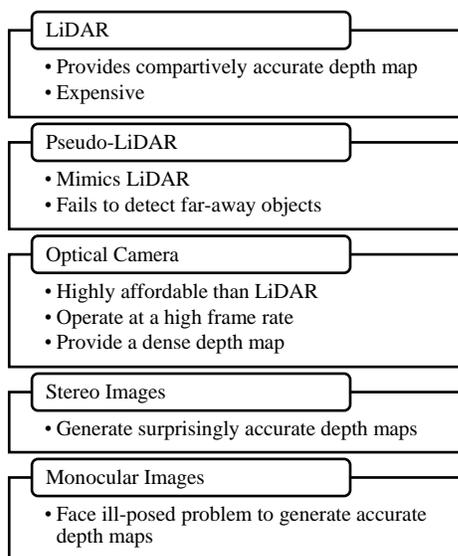
challenge is due to human variation of height. If every pedestrian has the same height, there would be no ambiguity [10]. LiDAR point clouds has been dominated approach in the existing research for 3D object detection due to the availability of accurate depth map [3, 13, 34, 35, 36, 37, 38, 39]. However, performance of image-only methods lacks in absolute depth information of LiDAR. In this context, optical cameras are highly affordable than LiDAR, operate at a high frame rate, and provide a dense depth map rather than 64 or 128 sparse rotating laser beams that LiDAR signal is inherently limited to [5]. Research in [40] proposed first study for estimating depth map in outdoor environments where they combined single RGB image and LiDAR point cloud. However, due to large learning network, powerful architectures for training were needed to use their proposed method. Research in [5] converted estimated depth map from stereo or monocular imagery into a 3D point cloud referred to as pseudo-LiDAR as it mimics the LiDAR signal. Then they took the advantage of existing LiDAR-based 3D object detection pipelines [13, 34] to train directly on the pseudo-LiDAR representation using deep convolutional neural networks to obtain unprecedented increase in accuracy of image-based 3D object detection algorithms. However, usage of LiDAR based method may not be suitable for other image-based classifier for overall 3D object detection. Besides, their proposed pseudo-LiDAR fails to detect far-away objects precisely due to inaccurate depth estimation. Research in [10] detected 2D joints using PifPaf and used MonoDepth [41] to estimate depth for a set of 9 pixels around each key point followed by consideration of minimum depth as their reference value. Later, they calculated distance from normalized image coordinates of the centre of the bounding box using the estimated minimum depth rather than using the average one. However, their proposed method needs further investigation for monocular image as their method worked only for stereo images. Overall scenarios for depth map estimation using different sensors and images are shown in Fig. 4.


Fig. 4. Overall Scenario for Depth Map Estimation using Different Sensors and Types of Images.

F. Backbone Network

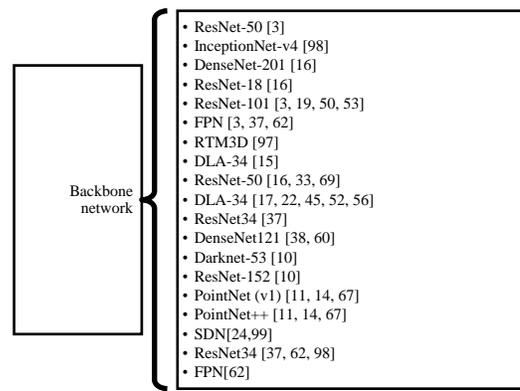
For 3D object detection various backbone networks has been used for feature representation shown in Fig. 5. Research in [42] preferred image features in ResNet-101 [4, 17, 43] for block 1 to maintain a high spatial resolution and avoid redundancy of same features. However, ResNet as backbone network contains too many layers and are not very efficient [4]. Darknet-53 [44] as a backbone network are used with fewer floating-point operations and more speed. Darknet-53 is better than ResNet-101 and 1.5× faster. In addition, Darknet-53 has similar performance to ResNet-152 and is 2× faster. Darknet-53 also achieves the highest measured floating-point operations per second which means the network structure better utilizes the GPU, making it more efficient to evaluate and thus faster.


Fig. 5. Backbone Networks for 3D Object Detection.

Research in [13] used PointNet (v1) and PointNet++ (v2) backbone due to much cleaner in design. While out of the scope for their work, sensor fusion in terms with aggregation of image feature for 3D object detection after extracting features using PointNet (v1) and PointNet++ could further improve their results. Research in [7] extracted point-wise features encoded by PointNet++ as backbone point cloud network, they appended one segmentation head for estimating the foreground mask and one box regression head for generating 3D proposals. However, alternative point-cloud network structures, such as VoxelNet with sparse convolutions could be investigated as their backbone network. Research in [16] used ResNet-50 as the backbone for feature extraction followed by a fully connected neural network [45] with one or two hidden layers. The number of hidden nodes is tuned with 64, 100, 128, and 192 to generate the candidate results which cause additional processing due to too many layers. Research in [63] used SDN [46] as backbone network to estimate dense depth map and fine-tuned on the KITTI datasets. However, their predicted depth was not accurate enough since the ground truth is very sparse. Research in [47] used ResNet34 [48, 49] with Feature Pyramid Network (FPN) [48] as backbone network. They replaced BatchNorm+ReLU layers with the synchronized version of InPlaceABN activated with LeakyReLU with negative slope 0.01 as proposed in [50] to

free up a significant amount of GPU memory for scaling up the batch size or input resolution. However, top down and bottom-up features fusion in feature pyramid network might create additional processing due to combine ResNet34 and FPN. Existing methods mostly used ResNet-50 as the backbone network for both monocular and stereo images due to contain too many layers [4]. InceptionNet-v4 [49] was previously used for visual feature extraction, however, in case of 3D models for multiview mages, InceptionNet-v4 needs to be further investigated for 3D object detection overall pipeline. DenseNet-201 [16] was used to extract the visual features of monocular images and ResNet-18 [16] was for multiview feature extraction of 3-D models. However, combination two backbone network at two different phases, may increase overall computational overheads. In case of monocular images and multiview fusion, four key aspects can ensure efficient use of backbone network for 3D object detection mentioned in Fig. 6 [16].

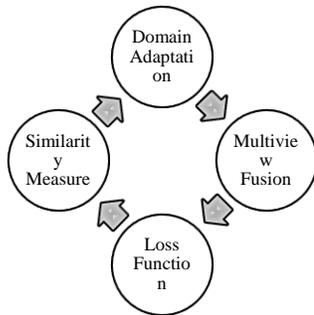
Domain adaptation is the first concerns for backbone network to be used with any method or strategy to solve cross domain problem. In this context, improved datasets developed with the concerns about cross domain ease the task for backbone network. For monocular and multiview aspects different fusion strategies for multiview views are needed for the extracted features using backbone network, such as pooling, concatenation. As monocular images lose multiview visual characteristic and spatial structure characteristic causes significant information loss, various function needs to be designed during features learning process. Efficient implication of the above three aspects helps for efficient pair wise similarity measurement.


Fig. 6. Four Key Aspects for Efficient Use of Backbone Network for 3D Object Detection.

IV. REVIEW ON EXPERIMENTAL ANALYSIS

A. Hardwares and Software Specification for Experimentation

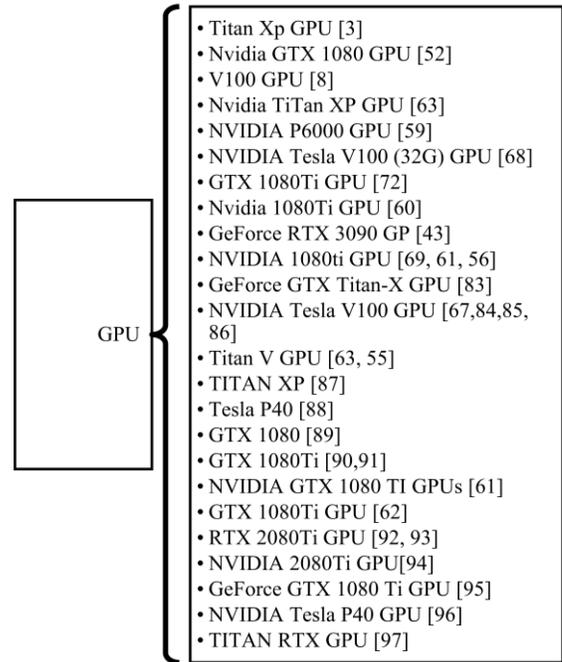
Previously researcher used sensors such as Grayscale cameras [51], optical cameras [5], color cameras [51] and LiDAR like Velodyne HDL-64E LIDAR [5, 51] for own datasets development for validating 3D object detection evaluation. For training, various GPUs were used mentioned in Fig. 7. PyTorch machine learning framework [42, 52, 53, 54, 55, 56] have been mostly used by existing research.


Fig. 7. GPUs Used in Previous Research.

B. Datasets

Domain gaps for different datasets depend on object size, weather condition, specific locations, and orientation [57]. Overall gaps can be categorized in to two categories mentioned below.

1) Content gap such as object, weather condition due to locations during data capture depending on time.

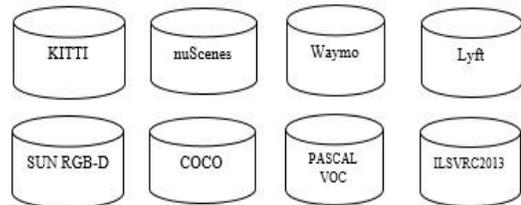
2) Point distribution gap owing to different LiDAR types such as number of beam ways, beam range, vertical inclination, horizontal and vertical angularity estimation of LiDAR. Existing datasets used for 3D object detection purpose are mentioned in Fig. 8.


Fig. 8. Datasets for 3D Object Detection.

1) KITTI dataset: KITTI is the most used dataset for 3D object detection. However, existing datasets such as nuScenes, Waymo, Lyft, SUN RGB-D, COCO, PASCAL VOC and ILSVRC2013 shown in Fig. 8 has been used by the research for more robust validation.

The KITTI 3D dataset [58, 59] is the most used benchmark in the 3D object detection task and it provides left camera images, calibration files, annotations for 3D detection [45].

KITTI datasets are the widely used benchmark for validating 3D object detection includes 2D object detection, Average Orientation Similarity (AOS), Bird's Eye View (BEV) [13, 60, 61]. Samples in KITTI datasets include 3D point clouds, images and Camera-LiDAR calibration data [52]. Images in KITTI datasets are captured in the same city using same camera [10]. 3D bounding boxes for various object classes are provided in KITTI datasets which includes cars, vans, trucks, pedestrians and cyclists labelled manually in 3D point clouds depending on calibrated camera's information [62]. Number of training and test images or point clouds in KITTI datasets are 7481 and 7518 images respectively containing three classes, i.e., car, pedestrian and cyclist [1,2, 8, 42, 52, 54, 60, 61, 63, 64, 65, 66, 75]. Each class is annoted by camera Field of Vision (FOV) with the 3D bounding boxes [64]. Evaluation for each class depends into three categories, i.e., easy, moderate, hard according three aspects, i.e., object size, occlusion state and maximum truncation levels of objects [10, 42, 53, 55]. For ranking the completion of the methods, moderate category is used in the benchmark [2]. Easy object is indicated with minimum pixel height as 40px within 28m as vehicles correspondence. Besides, 25px are the limit for moderate and hard level objects within minimum distance of 47m [62].

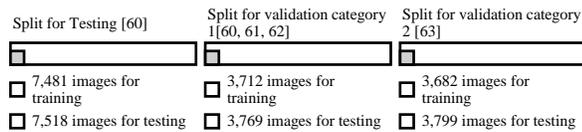
In another way, there are three commonly used data splits in the KITTI dataset, i.e., split for testing, validation category 1, and validation category 2 mentioned in Fig. 9.


Fig. 9. Split of Images for Training and Testing in KITTI Datasets.

In KITTI datasets, object detection validation is estimated mostly through average precision (AP) and IOU (Intersection over union) with threshold 0.7 for car class [8, 53, 42, 67, 62], 0.5 for pedestrian [60, 67, 62] and 0.5 for cyclist [60, 67, 62]. Six illustrative factors for using KITTI datasets is shown in Fig. 10.

In addition, this research identified ten challenges to use KITTI dataset mentioned in Fig. 11 although KITTI dataset is the commonly used dataset for 3D object detection performance validation.

2) nuScenes dataset: nuScenes dataset contains 1000 segments of 20 seconds each for 3D object detection where 750, 150 and 150 segments for training, validation and testing, respectively [10, 68, 69, 57, 70]. Annotation rate is 2Hz for which 28k, 6k and 6k annotated frames are available in these datasets for training, validation and testing respectively. This dataset contains more classes comparing with KITTI datasets which is 10 and evaluation metrics are mean average precision and nuScenes detection score (NDS) [68]. BEV center distance is the true positive metric for this dataset instead of IoU which is another significant difference with KITTI

datasets. However, camera extrinsic information is not also available in this dataset like in KITTI datasets [69].

Fig. 10. Six Illustrative Factors to use KITTI Datasets for 3D Object Detection.

Fig. 11. Ten Challenges to use KITTI Datasets for 3D Object Detection Validation Performance.

3) Waymo dataset: Waymo Open Dataset is more recently released datasets consists of 798 training sequences and 202 validation sequences [8, 53, 71, 42, 72, 57]. Waymo dataset provides object labels in the full 360◦ field of view with a multi-camera rig which is the advantage over KITTI and NuSceneses dataset. However, Waymo dataset includes only 150 test sequences without ground truth data. In addition, there is no published depth results on Waymo open dataset [15].

In addition, with KITTI, nuScenes and Lyft datasets, for 3D object detection other datasets such Lyft [68, 57], PASCAL VOC [73, 74], ILSVRC2013 [73, 74] dataset was previously used for validation. However, these datasets use different annotation rules for validation, i.e., large number of objects outside the road were not annotated for validation.

C. Validation Metrics

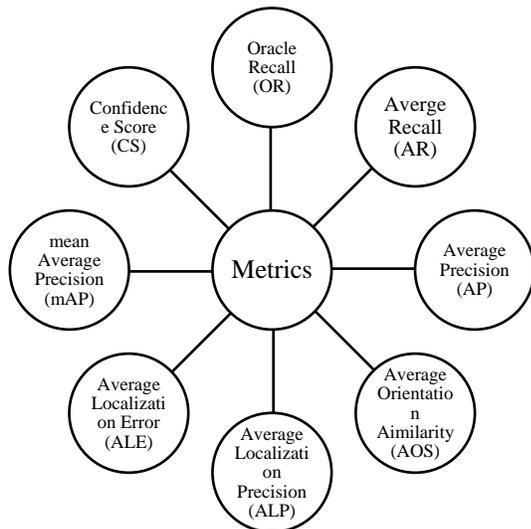
Overall framework for 3D object detection has been validated based on two tasks, i.e., object detection and then object detection with orientation estimation [75,103]. To validate accurate object detection, Average Precision (AP) metric was used by most of the existing research, Average Orientation Similarity (AOS) was used mostly for object detection and orientation estimation. The true positive metric is based on 2D/3D IoU. This research identified eight major performance metrics for validating any method for 3D object detection mentioned in Fig. 12.


Fig. 12. Major Eight Performance Metrics for Validation for 3D Object Detection.

1) Oracle Recall: Oracle recall computes the percentage of the recalled ground truth objects to receive recall rate [75, 2, 76, 104,105]. For certain threshold, if at least one proposal overlaps with IoU, then ground truth object is said to be recalled [1]. Recall is measured for both 2D bounding box and later for 3D bounding box for overall performance.

2) Average Recall (AR): For 3D object detection performance, Average Recall (AR) [32] is highly correlated metrics that needs to be measured for both 2D bounding box and 3D bounding box for overall performance [1,4,75,32]. For

stereo AR metrics, Average Recall needs to be measured for both left and right images [3].

3) Average Precision (AP): For various sampled points, average precision (AP) extracts average value of precision at various recall threshold values [62].

In other words, Average Precision (AP) indicates the average precision value for recall over 0 to 1. For precision and recall, ideal value is 1 [62]. However, for the real time scenarios, any method is assumed to be good enough if the precision and recall metrics gets closer to 1. In this context, this research observed that there is a trade-off between precision and recall, i.e. if more optimizations can be done on precision, recall gets lower, oppositely if recall can be improved, precision value becomes lower. So, this research recommends to balance at the point of fixing threshold point. Average Precision (AP) is used for 2D and 3D object detection for both monocular and stereo images [1, 4, 8, 53, 62, 63,75,77, 83,102]. Like AR, stereo AP metric needs to be evaluated for both on left and right images.

4) Average Orientation Similarity (AOS): Average Orientation Similarity (AOS) indicates perfect prediction between 0 and 1 [1,2, 75]. For 3D object detection, AOS has been used for orientation estimation task for 2D object detection performance towards 3D object detection [75, 15].

5) Average Localization Precision (ALP) [1,10]: Average precision and recall are the requirement to calculate Average Localization Precision (ALP) which can be computed similarly to AP except that 3D localization precision needs to be replaced in pace of bounding box overlap [1]. In other words, ALP provides a prediction to be correct depending on the error between predicted distance and ground truth is smaller than threshold [10]. In this context, predicted 3D location is to be correct if the distance to the ground truth 3D location is smaller than certain threshold [1].

6) Average Localization Error (ALE) [10]: For misaligned bounding box, Average Localization Error (ALE) is estimated from the target category [10]. In other words, ALE provides variation of the actual and estimated value of each location in the localization process.

7) mean Average Precision (mAP): mean Average Precision (mAP) is calculated from Average Precision (AP) from all classes for the IoU thresholds depending on various problems scenario [42,78, 101].

8) Confidence Score: Confidence score indicates the optimum threshold to categorize false positives to ensure the predicted bounding box contains minimum standard score and often used for model performance evaluation [19,79,106]. Non optimal settings for any proposed model requires more minimized confidence score for precise bounding box detection for 3D object detection. 3D box confidence estimation for 3D object detection realized by the previous research. Research in [80] calculated 3D IoU from the predicted 3D box and ground truth involves 3D object dimensions. Research in [47] used 3D box loss to represent 3D detection. Research in [81] introduced self-balancing

confidence loss for generating confidence score from relatively achievable samples. However, all these methods considered loss function for confidence score. To overcome this problem, research in [82] considered the relationship between 3D objects and associated 2D boxes to decompose confidence mechanisms. However, in case of weak transformation for 2D to 3D, their proposed confidence decomposition may result in weakness for their proposed methodology. Research in [10] addressed ill posed problems for predicting confidence intervals to account aleatoric and epistemic uncertainties. They estimated pose to obtain 2D joints which later were used as input to feedforward network and output the 3D location along with a confidence interval. However, their proposed method is suited only for small training data [100]. Research in [83] propagated information from the labelled to unlabeled training set in the form of pseudo-labels contains significant noise for which they introduced confidence-based filtering mechanism for 3D object detection. Their confidence proposals were based on predicted objectless and class probability to filter low quality pseudo labels. However, their proposed confidence intervals depend on category specific thresholds.

V. Observations and Future Research Directions

1) There is a tradeoff between precision and recall, i.e. if more optimizations can be done on precision, recall gets lower, oppositely if recall can be improved, precision value becomes lower. So, this research recommends to balance at the point of fixing threshold point for IoU.

2) Design of experiments should cover practical 3D domain adaptation scenarios mentioned below:

a) Adaptation from label rich domains to label insufficient domains,

b) Adaptation across domains with different data collection locations and time (e.g., Waymo → KITTI, nuScenes → KITTI), and

c) Adaptation across domains with a different number of the LiDAR beams (i.e., Waymo → nuScenes and nuScenes → KITTI). Therefore, domain adaptive evaluation needs to be done for validating 3D object detection models on the following four adaptation tasks: Waymo → KITTI, Waymo → Lyft, Waymo → nuScenes and nuScenes → KITTI.

3) Some ill-posed settings that is not suitable for evaluation needs to rule out. For example, KITTI datasets lacks in ring view annotations (less practical) and Lyft uses very different annotation rules (i.e., many objects outside the road are not annotated).

4) Comparing with stereo images, monocular images lose multiview visual characteristic and spatial structure characteristic causes significant information loss demands for robust depth construction for 3D object detection which can lead to 3D localization.

5) Due to the significant visual gap between object-centric images (various texture with complex background) and multiview images of 3-D models (gray model appearance with clean background), monocular and stereo image-based 3D object detection toward localization or tacking domain adaptation is a challenging task requires further investigation. In lieu of current existing datasets, development of novel dataset for object centric monocular and stereo image based is required to advocate the use of 3D object detection towards 3D localization for real world applications. In this context, few possible query images should be the primary key which can be the significant implication for domain adaptation for overall 3D object detection pipeline.

6) To choose the appropriate backbone network depending on problem specific 3D object detection, appropriate fusion strategies need to be designed in lieu of robust loss function to ensure efficient similarity measurement for final classification tasks of 3D object detection.

VI. Conclusion

3D object detection is the basis of many autonomous intelligent applications. This research demonstrates comprehensive and critical reviews on existing 3D object detection methods using RGB images and other fusion based detection methodology based on LiDAR and Pseudo-LiDAR. Some existing methods detected objects with 2D bounding box to recognize position of the objects which is not sufficient for perfect autonomous system. Therefore, predicting 3D object's position is similarly important as determining the 2D position of object in the image. In this research, sensor modality for the overall review is categorized in four types, i.e., monocular image, stereo image, point clouds obtained from LiDAR and Pseudo-LiDAR and fusion of both where advantages and disadvantages were addressed for each type. Depth summary with relative challenges for eight datasets are critically highlighted by this research. In this context, KITTI benchmark are not suitable for monocular methods for 3D object detection due to lack of depth information and prevents accurate 3D positioning which encourages to use maximum number of datasets to ensure robustness for any 3D object detection method. Besides, comprehensive details for eight evaluation metrics are illustrated to evaluate 3D object detection methods. This research observed that 3D object detection is not matured as 2D object due to large gap existing between them. Existing methods still did not achieve the benchmark performance for real time autonomous applications initiates the need for fast and reliable 3D object detection system for wide range of real time applications. Besides, recent trend for using point cloud processing was observed by this research provides effective solution for 3D object detection but LiDAR is an expensive sensor and further geometrical relationship needs to be discovered among points. Besides, some fusion based methods, i.e., RGB images either with LiDAR point cloud or depth images from RGB-D data could not confirm their superiority than other methods in multimodal datasets to ensure robust validation which indicates that more focus is needed to develop multimodal methods for 3D object detection. In addition, lack of large scale annotated training data, more datasets and fusion methods are expected in near future for indoor and outdoor scenarios to form a unified 3D object detection framework. From this study, this research remarks that 3D object detection has

gained many successes, but remains as potential and fertile research problem which requires more exploration. Demonstrated critical review by this research is expected to serve as a supportive significant reference and forms an important endorsement to the related research community.

Emotion Estimation Method with Mel-frequency Spectrum, Voice Power Level and Pitch Frequency of Human Voices through CNN Learning Processes

Taiga Haruta[1], Mariko Oda[2], Kohei Arai[3]

Graduate School of Engineering, Kurume Institute of Technology, Kurume City, Japan[1, 2]

Applied AI-Research Laboratory, Kurume Institute of Technology, Kurume City, Japan and Saga University[3]

Abstract—**Emotion estimation method with Mel-frequency spectrum, voice power level and pitch frequency of human voices through CNN (Convolutional Neural Network) learning processes is proposed. Usually, frequency spectra are used for emotion estimation. The proposed method utilizes not only Mel-frequency spectrum, but also voice pressure level (voice power level) and pitch frequency to improve emotion estimation accuracy. These components are used through CNN learning processes using training samples which are provided by Keio University (emotional speech corpus) together with our own training samples which are collected by our students in emotion estimation processes. In these processes, the target emotion is divided into two categories, confident and non-confident. Through experiments, it is found that the proposed method is superior to the traditional method with only Mel-frequency by 15%.**

Keywords—*e-Learning; emotion estimation; Mel-frequency spectrum; fundamental frequency (pitch frequency); sound pressure level (voice power level)*

I. INTRODUCTION

Since the spread of the new coronavirus, many schools have introduced e-learning, a learning system using information and communication technology (ICT) that allows students to study independently.

Unlike regular classes for many students, e-learning has the advantage that a history is kept for everyone, and learning can proceed according to the student's level of proficiency. However, self-study through e-learning is generally a challenge for students to maintain their motivation to learn. Children and students with intellectual disabilities need psychological support advice beside the disabled child and support to change the questions according to the learner's situation.

Because of "Annual Report on Government Measures for Persons with Disabilities (Summary) 2020", the total number of mentally retarded persons under the age of 18 is 225,000 [1]. In the Covid-19 pandemic, we believe it is necessary to develop an e-Learning system that considers disabilities to realize "fair, individualized, and optimized learning that leaves no one behind" for a diverse group of children.

As a result of speech change by emotion, it has a significant effect on the continuous speech estimation engine. These effects are caused by the fact that the acoustic models of speech estimation engines currently in general use are designed

assuming calm speech. It is necessary to take measures such as switching the acoustic model every time.

Emotion estimation from speech can be divided into methods that use information obtained from the utterance content (context), that is, methods that perform speech estimation and use the results, and methods that use signal processing methods such as prosody, amplitude, and stress. However, it has already been mentioned that the former is difficult to use as the first stage of a large-vocabulary continuous speech estimation system in terms of computational complexity. Therefore, in order to actually estimate emotions, it is realistic to use the latter method of extracting features from emotional speech and estimating emotions. Methods using neural networks and methods using discriminant analysis are conceivable for estimating emotions using the extracted feature values.

It is important that the feature values used in this method reflect the differences between emotions well, and various feature values have been studied so far. It appears in three aspects: prosodic structure such as frequency and formant frequency, amplitude structure such as sentence stress and accent, and temporal structure such as sentence length. After the speech data is transformed into data in the frequency domain by Discrete Fourier Transformation (DFT), it is then subjected to inverse DFT by taking the logarithm. The basic idea of this fundamental frequency extraction method is to select a certain number in descending order and connect these peaks smoothly by Dynamic Programming (DP).

Although the traditional methods for emotion estimation use a combination among the aforementioned features, the most commonly used feature is frequency components (processed from them), and has long been utilized in speech recognition research [2], also the estimation accuracy is not all good. In order to improve the accuracy, the feature combination among frequency components (Mel-Frequency), voice pressure level and pitch frequency is proposed in this paper. One of the targeted applications of the proposed emotion estimation method is a confidence level estimation of students through remote lectures. Actually, interactive lighting using voice emotion recognition is actually being studied [3]. The final goal of this study is the development of learning support system which Artificial Intelligence (AI) plays the role of teacher to understand the learner's emotions and prompt their self-discipline learning. This paper makes clear how can

we determine whether they are confident in their answers from their utterances during learning.

The related research works are described in the following section. After that, the proposed method for emotion estimation with voices is described followed by experiments. Then conclusion is described with some discussions.

II. Related Research Works

Although voice recognition is now world widely available, recognition performance is not good enough for normal conversations. For instance, voice recognition performance of the typical Hidden Markov Model: HMM based method [4] (this is referred to the conventional voice recognition hereafter) with the feature of Formant is less than 50 % when the signal to noise ratio is below 5dB. In other words, voice recognition performance is totally affected by noise. In normal conversation among us, not only voice but also mouth movement is used for recognitions. Mouth movement video analysis makes voice recognition much better performance. The lip-reading method is for improvement of voice recognition performance.

Usually, Hidden Markov Model based method or neural network-based method is used for voice recognitions as well as optical flow [5]-[12] based analysis of the mouth movement videos. Forward direction (from the past to the future) of optical flow is usually used for mouth movement analysis. Voice recognition performance can be improved by adding backward direction (from the future to the past) of optical flow for correction of voice recognition errors through a confirmation of recognized results. In this process, two voice elements are treated as a unit for the proposed backward optical flow. The conventional forward direction of optical flow recognizes by voice element by voice element, though. In order to make sure the recognized results, two voice elements are much easier and efficient manner. This is because transient between voice element and voice element is so important for voice recognitions. This is the basic idea of the proposed lip-reading method.

As for the voice recognition methods, there are the following related research works,

E-learning system which allows students' confidence level evaluation with their voice when they answer to the questions during achievement tests is developed [13]. On the other hand, voice recognition method with mouth movement videos based on forward and backward optical flow is proposed and validated [14]. Mobile device based personalized equalizer for improving hearing capability of human voices for elderly persons is developed and realized [15]. Meanwhile, hearing aid method by equalizing frequency response of phoneme extracted from human voice is proposed and validated [16].

English pronunciation practice system using voice and video recognitions based on optical flow is developed and validated [17]. The eye based domestic helper robot allowing patient to be self-services through voice communications is also developed and validated its usefulness [18].

As mentioned in the previous section, speech features are essential for speech recognition. Recently, in the frequency component, Mel frequency magnitude coefficient was able to recognize emotions with up to 95.25% accuracy on a multi-class support vector machine [19].

Also, Unsupervised feature selection combining Gammatone Cepstral Coefficients (GTCC) and Power Normalized Cepstral Coefficients (PNCC) is used as speech features to recognize emotion from speech in the presence of various noises if the signal-to-noise ratio from -5 dB to 20 dB is 15 dB or higher [20].

After extracting some statistical features from the fundamental frequencies, we applied different AI methods to examine and study whether they have information about the speaker's emotional state, and found that 89.74% for two emotions, 76.14% for a set of three emotions, and 62.99% for a set of four emotions equal accuracy has been achieved [21].

III. Proposed Method

A. Method Configuration

As mentioned above in introduction section, three features combination, frequency components (Mel-Frequency), voice pressure level and pitch frequencywhich are extracted from the studnets voices and from the speech corpus is used in the emotion estimaion. Jupyter notebook provided by anaconda is used. The programming language used is Python. The following Deep Learning used in the emotion estimation, Convolution Neural Network: CNN + Rectified Linear Unit: ReLu + CNN + ReLu + Pooling + CNN + ReLu + CNN + ReLu + Pooling + CNN + ReLu + CNN + ReLu + Pooling + Fully Connected Layers.

B. Voice Data for Deep Learning

There are two datasets of training samples. One is voice data produced by 17 students of Kurume Institute of Technology to verbally answer "yes" or "no" to 20 questions which are shown in Fig. 1(a) in Japanese, including current events, riddles, and simple calculation problems, and used voice data recorded from their voices.

We also used Keio-ESD[1] [22], a speech corpus provided by the Speech Resources Consortium of the National Institute of Informatics, to perform a binary classification of the recorded speech into positive and negative categories.

C. Feature Extraction

This time, a comparison was made between a model trained with the Mel-frequency spectrogram alone and a model trained with the fundamental frequency and sound pressure level in addition to it. Therefore, each feature was extracted using Python programming, and the numerical data was stored in csv format and then in a Numpy array.

The resulting Mel-frequency spectrograms, fundamental frequencies, and sound pressure levels were scaled differently for each feature, so the scales were aligned by standardizing the data.

---

[1] Keio-ESD: Keio University Japanese Emotional Speech Database, http://research.nii.ac.jp/src/index.html, A set of human speech with vocal emotion spoken by a Japanese male speaker and a set of artificial speech that were synthesized by a system that had been developed using the subset of this database for training.

In addition, the number of feature data is proportional to the voice time. This is because the feature data itself is time series data. Therefore, all students recording data was trimmed every 0.5 seconds. In addition, the number of features for each of the 1 voice was matched to the fundamental frequency with the lowest number of features extracted. This is because if the number of features is not aligned, there will be a bias toward the features with the highest number of features during training. Fig. 1(b) is one of the audio waveform data recorded this time. Fig. 1(c) is the Mel-frequency spectrogram extracted from Fig. 1(b). Fig. 1(d) is the fundamental frequency extracted from Fig. 1(b). Fig. 1(e) is the sound pressure level extracted from Fig. 1(b), respectively.

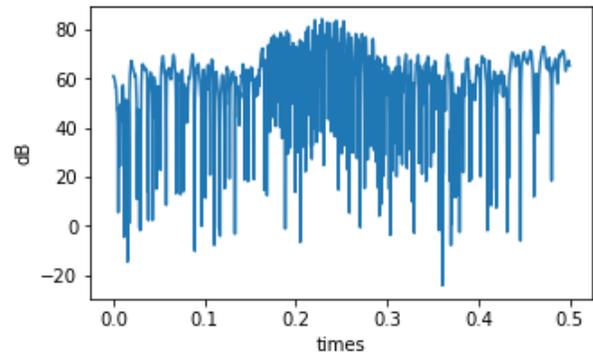
(d) The fundamental frequency extracted from Fig. 1(b)


(e) The sound pressure level extracted from Fig. 1(b)

Fig. 1. A Portion of the Training Samples Extracted from the Students' Voices.

D. Preparation for Supervised Learning and Learning Model

The speech corpus "Keio-ESD" contains 20 words with 47 different emotions. Among those, we labelled 12 positives: "pleasure", "kind", "gentle", "tolerance", "glad", "admiration", "pride", "love", "satisfaction", "expectation", "happiness", and "like". Then we labelled 12 negatives: "repugnance", "complaint", "disappointment", "sorrowful", "fear", "indifferent", "lamentation", "boredom", "dislike", "Nope." "dejection", and "anxiety". We used the speech for the emotions "expectation," "happiness," "like," "Nope." "Dejection", and "anxiety" as test data and the speech data for the other emotions as training data. However, we did not use the last 20% of the recorded data for training but used it as validation data to measure the goodness of the model parameters after each training.

As for the students' confidence classification of the recorded data, they were asked to answer in advance their confidence after their answers. We then used the recorded data of 13 of the 17 students in our study data as training data. We then used the recordings of the remaining four individuals as test data. We did not use these data for the last 20% of recordings but used them as validation data too.

We used the Function API for CNN with Keras to build our learning model. We trained the Keio-ESD emotion classification 200 times and the student confidence classification 20 times, then evaluated each test data set and compared the results.

IV. EXPERIEMNTAL RESULTS

A. Binary Classification of Emotional Speech Corpus into Positive and Negative

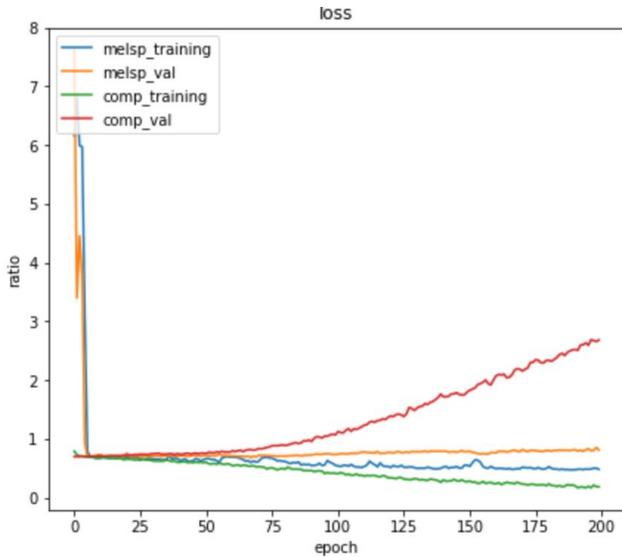
As for the binary classification of speech into positive and negative for the emotional speech corpus, Fig. 2 shows the transition graph of the loss function for each epoch.


Fig. 2. The Loss Function of Binary Classification of Emotional Speech Corpus into Positive and Negative.

The vertical axis shows the percentage, and the horizontal axis shows the number of epochs. The precedents are discussed below:

- "melsp_training" shows the result of training with only the training data of the Mel-frequency spectrogram in the input layer.

- "melsp_val" shows the results that were checked against the validation data of the Mel-frequency spectrogram after each study.

- "comp_training" shows the result of training with only the training data of the Mel-frequency spectrogram, fundamental frequency, and sound pressure level in the input layer.

- "comp_val" shows the results that were checked against the validation data of the Mel-frequency spectrogram fundamental frequency, and sound pressure level after each study.

Figures are basically rounded to two decimal places.

Regarding the loss function, it was quite large immediately after the Mel-frequency spectrogram was put in the input layer, but after each epoch, melsp_training and melsp_val converged around 0.48 and 0.81, respectively. Concerning comp_training and comp_val, comp_training eventually converged around 0.18, comp_val eventually converged around 2.68.

Fig. 3 is a graph of the percentage of accuracy. With regard to the training data, both melsp_training and comp_training showed an upward trend with each epoch. Finally,

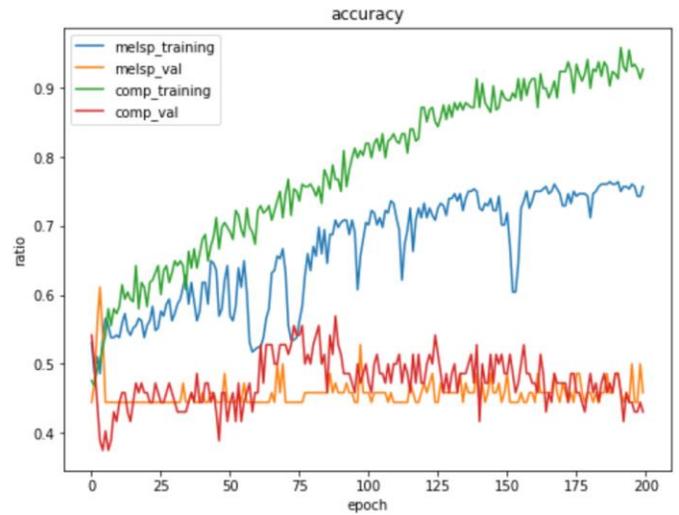
melsp_training and comp_val showed 0.76 and 0.93, respectively. In other words, comp_training is about 16% better at learning than melsp_training. As for the validation data, the melsp_val and comp_val finally converged to 0.46 and 0.43, respectively.


Fig. 3. The Accuracy of Binary Classification of Emotional Speech Corpus into Positive and Negative.

B. Confidence Classification of the Student Recorded Data

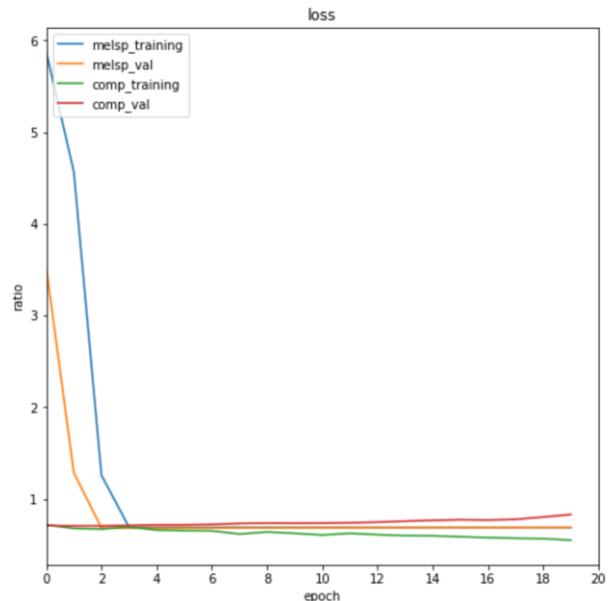
Fig. 4 is the loss function, and Fig. 5 is the accuracy. Regarding the loss function, as in the previous page, the values of the loss functions for melsp_training and melsp_data were quite large, but after the fourth training, they showed values below 1 and finally converged to 0.69. Regarding the validation data, comp_training eventually converged to 0.55 and comp_val converged to 0.83. comp_val exceeded melsp_val by binary classification of emotional speech corpus into positive and negative same amount.


Fig. 4. The Loss Function of Confidence Classification of Student Recorded Data.
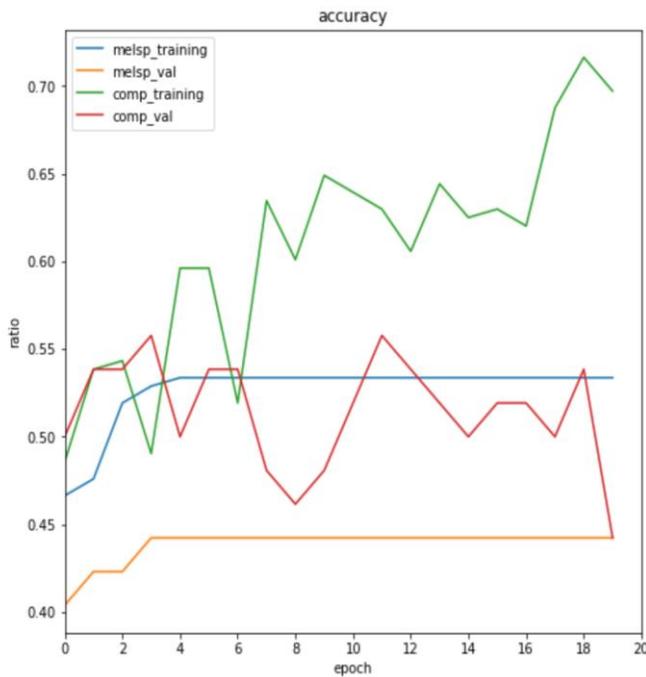

Fig. 5. The Accuracy of Confidence Classification of Student Recorded Data.

With respect to the accuracy, the value of melsp_training remained unchanged from 0.53 after the fifth training, and comp_training increased from 0.49 at the first training to a final value of 0.70. The value of melsp_val also remained unchanged from the fifth study and finally converged to 0.44. Comp_val showed a large difference in the percentage of correct responses from epoch to epoch and finally converged to 0.44.

C. Evaluation with Test Data

We finally evaluated models trained only on the Mel-frequency spectrogram, plus the fundamental frequency and sound pressure level, on test data for each classification. The table of it is Table I and Table II.

TABLE I. EVALUATION WITH TEST DATA (KEIO-ESD)

Binary classification of emotional speech corpus into positive and negative	
Test 1 loss function	1.765992283821106
Test 2 loss function	2.4016263484954834
Test1 accuracy	0.5083333253860474
Test2 accuracy	0.5333333611488342

TABLE II. EVALUATION WITH TEST DATA (CONFIDENCE CLASSIFICATION)

Confidence classification of the student recorded data	
Test 1 loss function	0.6947100162506104
Test 2 loss function	0.7546933889389038
Test1 accuracy	0.48750001192092896
Test2 accuracy	0.637499988079071

Note that Test 1 in the following table shows the results of evaluating the model with only the Mel-frequency spectrogram in the input layer, and Test 2 shows the results of evaluating the model trained with the Mel-frequency spectrogram, fundamental frequency, and sound pressure level.

The loss function for Keio-ESD's emotional voice classification was much higher than 1 for both Test 1 and Test 2, with a difference of about 0.64, while the loss function for the student's confidence classification was also lower than 1, and the difference in the loss function was about 0.06, indicating that the difference between the two functions had narrowed.

On the other hand, Test 2 outperformed Test 1 in both accuracies, with a 15% improvement in accuracy, especially in the classification of students' self-confidence.

V. CONCLUSION

In this study, to develop a learning support system for physically challenged children that applies speech and emotion recognition, which is an applied technology of AI, we attempted to discriminate the confidence of the respondent's speech using deep learning and to classify the emotion of the emotional speech corpus into two emotion values. In this connection, we constructed a model in which only the Mel-frequency spectrogram was learned as the speech feature charge, firstly. Then, not only Mel-frequency spectrum, but also another two types of models were learned: fundamental frequency and sound pressure level. A comparison of the change in the percentage of correct responses between the two models showed that using a model trained with three types of features improved accuracy by up to about 15%. Therefore, it may say that the proposed method is superior to the conventional method with only Mel-frequency spectrum by 15%.

FUTURE RESEARCH WORKS

Further investigation has to be made for improving voice-based emotion recognition accuracy with further experiments by the other testers. The other features related to voice recognition have to be added to the proposed method for improving the recognition accuracy.

AUTHORS' PROFILE

Taiga Haruta: He received BE degree in 2022. He also receives the Kurume Institute of Technology President's Award. He is now working on AI-applied e-Learning research and voice recognition in Master's Program at Kurume Institute of Technology.

Mariko Oda: She graduated from the Faculty of Engineering, Saga University in 1992, and completed her master's and doctoral studies at the Graduate School of Engineering, Saga University in 1994 and 2012, respectively. She received Ph.D(Engineering) from Saga University in 2012. She also received the IPSJ Kyushu Section Newcomer Incentive Award.In 1994, she became an assistant professor at the department of engineering in Kurume Institute of Technology; in 2001, a lecturer ; from 2012 to 2014, an associate professor at the same institute; from 2014, an associate professor at Hagoromo university of International studies; from 2017 to 2020, a professor at the Department of Media studies, Hagoromo university of International studies. In 2020, she was appointed Deputy Director and Professor of the Applied of AI Research Institute at Kurume Institute of Technology. She has been in this position up to the present.She is currently working on applied AI research in the fields of education.

Kohei Arai: He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January 1979 to March 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post-Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science in April 1990. He is now an Emeritus Professor of Saga University since 2014. He was a council member for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA since 1998 and is an Adjunct Professor of Nishi-Kyushu University as well as Kurume Institute of Technology/AI Application Laboratory since 2021. He also is Vice Chairman of the Science Commission "A" of ICSU/COSPAR since 2008 then he is now award committee member of ICSU/COSPAR. He wrote 77 books and published 678 journal papers as well as 550 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Mister of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. http://teagis.ip.is.saga-u.ac.jp/index.html

Cybersecurity in Deep Learning Techniques: Detecting Network Attacks

Abstract—**Deep learning techniques have been found to be useful in a variety of fields. Cybersecurity is one such area. In cybersecurity, both Machine Learning and Deep Learning classification algorithms can be used to monitor and prevent network attacks. Additionally, it can be utilized to identify system irregularities that may signal an ongoing attack. Cybersecurity experts can utilize machine learning and deep learning to help make systems safer. Eleven classification techniques, including eight machine learning algorithms (Decision Tree, Random Forest, and Gradient Boosting) and one statistical technique, were employed to examine the popular HTTP DATASET CSIC 2010. (K-Means). Along with XGBoost, AdaBoost, Multilayer Perceptrons, and Voting, three deep learning algorithms are Convolutional Neural Network (CNN), Long Short-Term Memory (LSTM), and LSTM plus CNN. To evaluate the performance of such models, precision, accuracy, f1-score, and recall are often used metrics. The results showed that when comparing the three deep learning algorithms by the aforementioned metrics, the LSTM with CNN produced the best performance outcomes in this paper. These findings will show that our use of this algorithm allows us to detect multiple attacks and defend against any external or internal threat to the network.**

Keywords—HTTP DATASET CSIC 2010; deep learning; cybersecurity attacks; detection attacks; network attacks

I. INTRODUCTION

Cybersecurity (Cyber_Security) [1] protects computers, servers, and networks from intrusion, theft, and other forms of harm to their data, hardware, and software, as well as from interruptions in service or misuse of the resources they provide. Our reliance on computers, the Internet, and wireless network standards like Bluetooth and Wi-Fi, as well as the proliferation of "smart" devices like smartphones, televisions, and the myriad other devices that make up the Internet of things, have all contributed to the Internet of Things growing significance (IOT) [1]. Due to the complication of its political application and technological implementation, cybersecurity is one of the greatest issues of the twenty-first century. The system's key objectives are dependable operation, integrity of data, and safeguarding of sensitive information. Due to the complication of its political application and technological implementation, cybersecurity is one of the greatest issues of the twenty-first century. The system's key objectives are dependable operation, intact data, and the security of sensitive information [2].

A cyber-attack is any hostile attempt to hack an IT system or its users in order to gain unauthorized access to the system's data or information [3]. Cyber attackers are often crooks looking to profit financially from the attack in the great majority of instances. In other cases, the intention is to stop operations by preventing users from accessing IT systems or destroying physical equipment [3]. State agents or cybercriminals working for them are frequently involved in state-sponsored cybercrime. Cyberattacks can be wide in scope, impacting a number of businesses across several regions and nations, or they can be directed at specific companies or persons [4]. Targeted attacks frequently expand beyond their intended targets, posing a threat to all firms. A state-sponsored strike against Ukrainian banks and utilities most likely caused the global NotPetya outbreak in June 2017. The clean-up achieved the desired effect on Ukraine, but it also had a worldwide impact, costing almost $10 billion in IT system recovery and lost productivity, according to publications documenting the cleanup [2, 3, and 4].

Deep learning can be classified as a sort of machine learning. Research into algorithms is crucial to the growth and development of this discipline. Deep learning employs artificial neural networks created to simulate human cognitive processes, whereas machine learning focuses on generalization and empirical data. Until recently, the available computational power limited the complexity of neural networks [5]. Systems in the cybersecurity sector may use deep learning to recognize and learn from patterns in order to foil future attacks and adapt to evolving adversarial tactics. It can improve the speed with which cybersecurity teams respond to actual attacks and mitigate risks [5]. Because it reduces the amount of time spent on routine tasks, it allows businesses to better allocate their resources. In conclusion, deep learning can make cybersecurity easier, more preventative, cheaper, and more effective [4, 5]. However, this will only be possible if the data that drives machine learning provides an accurate depiction of the setting. As the adage goes, "if you put garbage in, you'll get garbage out." [5].

The following are some key takeaways from this paper that outline its contribution:

1) This thesis makes use of a publicly available dataset pertinent to the topic at hand, allowing a wide range of classification algorithms to be put to use.

2) This category includes deep learning and machine learning. Building a robust model to recognize different network assaults utilizing a variety of machine learning and deep learning methods.

Examining the ability of each method to distinguish between the numerous network assaults that have been documented in the dataset. Several classification techniques, including machine learning and deep learning algorithms, are applied to a well-known network intrusion dataset in this study in order to determine whether or not each sample is typical and to identify attacks that are not typical. The remainder of this study is organized as follows: The second component of this paper provides a bibliography of relevant archival materials for this investigation. The methods employed are thoroughly detailed in Section III. Some examples are provided to illustrate the results in Section IV. Section V presents our conclusion and suggestions for future research.

II. RELATED WORK

Several authors applied machine learning algorithms in the cybersecurity field to detect different types of attacks based on real-time datasets or existing datasets from several resources. Kim et al. [6] using a Convolutional Neural Network (CNN) with long short-term memory (LSTM) and a Deep Neural Network (DNN), the sample was identified as normal or abnormal (DNN). They used the 61,065 instances and 16 features from the HTTP DATASET CSIC 2010 that were classified as either normal (36,000 samples) or anomalous (25,065 samples). The results demonstrated that the CNN equipped with LSTM was 91.54 percent accurate. Vartouni et al. [7] used a novel algorithm known as a Stacked Auto-Encoder to determine whether the sample was typical or out of the ordinary. They used the 61,065 instances and 16 features from the HTTP DATASET CSIC 2010 that were classified as either normal (36,000 samples) or anomalous (25,065 samples). According to the findings, the Stacked Auto-Encoder was able to achieve an accuracy of 88.32 percent.

Betarte et al. [8] The sample was classified as normal or abnormal using three distinct machine learning techniques: Random Forest, K-Nearest Neighbors (K-NN) with a k value of three, and Support Vector Machine (SVM). They utilized the HTTP DATASET CSIC 2010 dataset for their analysis, which covers normal (36,000 samples) and abnormal (61,065 cases) categories (25,065 samples). Compared to the other methods, Random Forest achieved 91.54 percent more accuracy. Tuan et al. [9] examined their five machine learning techniques using the common dataset UNSW-NB15, which includes numerous types of network assaults.

This dataset consists of nine separate attack types (DoS, Reconnaissance, Backdoor, Fuzzers, Analysis, Exploits, Worms, Shellcode, and Generic) and common attacks (44 characteristics). The machine learning algorithms are SVM, ANN, Naive Bayes (NB), and Unsupervised Learning (USML). Using this dataset, they demonstrated the USML's high degree of precision (94.78 percent). Anwer et al. [10] used four machine learning techniques to detect malicious network traffic based on a well-known dataset. They used a popular cybersecurity dataset named NSL-KDD that has 148,517 samples divided into training (125,973) and testing (22,544) datasets. There are a total of five classes in this dataset, split evenly between normal attacks and non-normal attacks, with subclasses within each subclass. For example, DoS attacks (Smurf, Back, Land, Processstable, Neptune, Pod, Apache2, Udpstorm, Worm, Teardrop) and R2L attacks (Xsnoop, Guess Password, Named, Ftp write, Phf, Multihop, Imap, Warezmaster, Warezclient, Snmpgetattack, Spy, Xlock, Snmpguess, Httptunnel, Sendmail) are all in existence. Machine learning algorithms include things like the Support Vector Machine (SVM), Gradient Boosted Decision Trees (GBDT), and Random Forest (RF). These algorithms were evaluated on four fronts: accuracy, specificity, training time, and prediction time. The 85.34 percent accuracy achieved by RF was the highest of any of the tested algorithms.

Su et al. [11] presented the BAT model, a deep learning technique for spotting hostile network infiltration. Utilization of the NSL-KDD dataset, which is commonly utilized in the investigation of network intrusion. The same number of data points were used for training and testing, totaling 125,973 points (22,544). Each of the five classes in this dataset is further subdivided into two additional groups: normal attacks and non-normal attacks. To name just a few examples, there are denial-of-service (DoS) attacks (Smurf, Back, Land, Processstable, Neptune, Pod, Apache2, Udpstorm, Worm, Teardrop), reconnaissance-to-leak (R2L) attacks (Xsnoop, Guess Password, Named, Ftp write, Phf, Multihop, Imap, Warezmaster, Warezclient, Snmpgetattack, Spy, Xlock The intrusion detection accuracy of this model was 84.25%.

Xu et al. [12] proposed a new model based on a five-layer autoencoder (AE) that is more adept at detecting network anomalies. Because of its prominence in the realm of network assault, the NSL KDD dataset was deployed. The same number of data points were used for training and testing, totaling 125,973 points (22,544). Each of this dataset's five classifications is then separated into two additional groups: normal attacks and non-normal attacks. There are denial-of-service (DoS) assaults (Smurf, Back, Land, Processstable, Neptune, Worm, Pod, Apache2, UDPstorm, and others). Teardrop), reconnaissance-to-leak (R2L) attacks (Xsnoop, Guess Password, Named, Ftp write, Phf, Multihop, Imap, Warezmaster, Warezclient, Snmpgetattack, Spy, Xlock), and reconnaissance-to-attack (R2A) attacks (Xsnoop, Guess Password, Named, Ftp write, Phf, Multihop, I. The study demonstrated that the model's accuracy in identifying intrusions is 90.61 percent.

Kavitha et al. [13] presented a new technique for network intrusion detection based on One Class Support Vector Machine (OCSVM). They utilized the popular NSL-KDD dataset, which consists of a total of 148,517 samples split evenly between a training set of 125,973 samples and a testing set of 22,544 samples. This dataset has a total of five classes, evenly divided between normal and non-normal attacks, with subclasses inside each subclass. New technique for network intrusion detection based on One Class Support Vector Machine (OCSVM). They utilized the popular NSL-KDD dataset, which consists of a total of 148,517 samples split evenly between a training set of 125,973 samples and a testing

set of 22,544 samples. This dataset has a total of five classes, evenly divided between normal and non-normal attacks, with subclasses inside each subclass. To name just a few examples, there are denial-of-service (DoS) attacks (Smurf, Back, Land, Processtable, Neptune, Pod, Apache2, Udpstorm, Worm, Teardrop), reconnaissance-to-leak (R2L) attacks (Xsnoop, Guess Password, Named, Ftp write, Phf, Multihop, Imap, Warezmaster, Warezclient, Snmpgetattack, Spy, Xlock. The model was found to be 81.29 percent accurate when used for intrusion detection.

Ferriyan et al. [14] developed several machine learning models for detecting cyberattacks, and used a new dataset called ALLFLOWMETER HIKARI2021. Background, Benign, Bruteforce, Bruteforce-XML, Probing, and XMRIGCC CryptoMiner are the six types of attacks represented among the 555,278 instances and 86 features extracted by Zeek [https://zeek.org/] in this dataset. The normal attacks include Bruteforce, Bruteforce-XML, Probing, and XMRIGCC CryptoMiner, while the malicious attacks include Background and Benign. KNN, SVM, RF, and MultiLayer Perceptron are the ML models to use (MLP). They demonstrated that these models can achieve detection accuracy of roughly 0.99 percent as shown in Table I.

III. PROPOSED METHODOLOGY

Fig. 1 depicts the proposed strategy utilized in this study to identify threats in a wide variety of cybersecurity datasets. The subsequent sections demonstrate how the proposed method operates in practice.

A. Dataset Description

In this study, we utilized the widely-used and exhaustive HTTP DATASET CSIC 2010 dataset, which comprises a variety of cyberattack kinds. The types of cyberattacks, the total number of Instances in the respective datasets, and the total number of characteristics are detailed in Table II.

Our department's online store's traffic is logged in the HTTP dataset CSIC 2010 for analysis. Registering with this web app requires the input of personal data, and once registered, users can make purchases from a cart interface. Due to the fact that it is a Spanish-language website, the collected information may contain some Latin characters [15]. In the dataset, 36,000 requests are legitimate, while another 25,000 were created fraudulently by bots. Threats like cross-site scripting, CRLF injection, server-side inclusion, parameter manipulation, and SQL injection are all part of the package. There have been successful web detection experiments using this dataset [15]. Fig. 2 depicts the frequency of attacks on the HTTP dataset CSIC 2010, while Table III details the characteristics of this dataset.

B. Preparing Dataset

In order to apply different deep learning algorithms to each dataset, we encode their non-numerical properties into numerical features using a standard method [16]. Label Encoder is a technique for converting data that isn't numerical into a form that computers can understand by assigning each value a number starting at zero [16]. All the features in this dataset are categories, so we need to transform them into numbers. We used the Hold out method to divide the data set. As a result, in our experiments, we use only 0.20 percent of the total dataset for evaluation purposes, while the remaining 0.80 percent serves as training data.

C. Classification Algorithms

In this paper, we detail the detection procedure and the classification algorithms that enabled it. Some machine learning and deep learning formula examples are provided.

TABLE II. INFORMATION OF CYBERSECURITY DATASETS

Dataset Name	No. of Instances	No. of Features	Cybersecurity Attacks

1) Machine learning algorithms: After preparing the dataset, it is fitted to seven machine learning algorithms, each with a test size of 0.1, in order to detect the aforementioned cybersecurity attacks. This was accomplished by utilizing a hold-out approach to divide the dataset into training and testing datasets, with 0.9% of the total datasets acting as training datasets and 0.1% serving as testing datasets. Multiple machine learning models are constructed utilizing the training dataset, and their efficacy is assessed utilizing the testing dataset.

- Random Forest Algorithm (RF)

Random forests, an ensemble supervised learning method, trains many decision trees to perform regression and classification. The most commonly selected class by trees is the one that is expected to be the solution to classification problems. When it comes to regression jobs, we give you the typical prediction from all of our trees [17]. Overfitting the training set is a common problem for decision trees; random decision forests are capable of mitigating this effect. Therefore, we utilize the Random Forest classifier to categorize each cyber-attack dataset [18, 19]. Due to the discontinuous nature of our experiment's label, we employed a random forest of the classification variety with the following parameters: n_estimators (number of decision trees) = 100, max_features = sqrt, max_depth = None, random_state = 42.

- Decision Tree Algorithm (DT)

Decision Tree is a supervised machine learning system that, similar to people, makes decisions based on predefined criteria. [20]. The fields of data mining, statistics, and machine learning all use decision tree learning (or induction of decision trees) as a method of predictive modeling [21]. The use of a decision tree, it goes from observing a sample (representing the trunk) to drawing conclusions about the sample's target value (representing the leaves, which are attack types) [22].

Classification trees are a type of tree model where the target variable is discrete, and where the "leaves" represent the different types of attacks and the "branches" represent characteristics of the dataset that aid in predicting class labels [23, 24]. One type of decision tree, called a regression tree, has a continuous objective variable (typically real numbers) [23]. One of the most well-known machine learning algorithms, decision trees are prized for their clarity and ease of use. Using a Decision Tree with a classification type was necessary due to the discrete nature of the label in our experiment. These are the parameters we used for DT: criterion = gini and random_state = 42.

- Multilayer Perceptron Algorithm (MLP)

The feedforward artificial neural network is based on the multilayer perceptron (MLP). Many-layer Perceptron Networks (MLPs) are a type of feedforward artificial neural network (ANN) that can also be thought of as "deep neural networks" (with threshold activation). Decision Tree is a supervised machine learning system that, similar to people, makes decisions based on predefined criteria [20].

Data mining, statistics, and machine learning all use decision tree learning as a technique for predictive modeling (or induction of decision trees) [21]. The use of a decision tree Input, hidden, and output layers are the three types of node layers an MLP needs to operate. Except for the input nodes, all other nodes are neurons with nonlinear activation functions. [25, 26]. As part of its training process, MLP uses backpropagation, a supervised learning method. An MLP differs from a linear perceptron because to its several layers and non-linear activation. It can distinguish between data that can be cleanly categorised and data that cannot [27]. Since our experiment's label is discrete, we used an MLP of the classification variety; the corresponding MLP parameters were as follows: activation = relu and random_state = 42.

- eXtreme Gradient Boosting Algorithm (XGBoost)

Shortened to "XGBoost," Extreme Gradient Boosting is a popular method for both classification and regression. Gradient boosting has been parallelized and optimized [28]. Through the use of parallelization, the training time for the boosting process can be cut in half. As an alternative to training a single optimal model on the entire dataset, we train hundreds of models on different subsets of the dataset [28]. Afterwards, have a vote to determine which model did the best (as in traditional approaches). As opposed to more traditional gradient boosting methods, XGBoost often yields better results [29]. The Python implementation provides access to numerous hidden characteristics that can be changed to increase accuracy and precision [30].

This algorithm's overarching goal is to strengthen weak learners (decision trees) so they can generate the final prediction label (the weighted average of each weak classifier's predictions) [30]. Among the many notable features of the XGBoost [28, 29, 30] are: The model is 1) parallelized, meaning it can run in parallel on multiple CPU cores. 2) Regularization, XGBoost offers a variety of regularisation penalties to prevent overfitting. A properly trained model can successfully generalize thanks to

regularizations with penalties that improve training. XGBoost can recognize and learn from non-linear patterns in data. 3) it's possible to use cross-validation right now because it's built in. 4) XGBoost's ability to run on distributed servers and clusters like Hadoop and Spark makes it possible to manage massive amounts of data. C++, Java, Python, and Julia are just some of the supported programming languages. Because the label in our experiment is discrete, we utilised this approach with classification type. The XGBoost parameters we used are as follows:

colsample_bylevel = 1, learning_rate = 0.1, gamma = 0, n_estimators = 100, and random_state = 42.

- AdaBoost Algorithm

Adaptive boosting, or the statistical classification meta-algorithm AdaBoost, is an example of such a program. It complements a variety of learning strategies to boost efficiency and effectiveness. In a boosted classifier, the final output is a weighted sum of the outputs of other learning algorithms, or "weak learners" [31]. AdaBoost is adaptive because it adjusts subsequent weak learners to prioritize instances that earlier classifiers incorrectly labeled. It has the potential to be more resistant to the overfitting problem than other learning algorithms. Even if individual learners perform badly, the model as a whole will eventually converge on a highly effective learner if and only if it outperforms random guessing [32]. Combining powerful base learners, such as deep decision trees, with AdaBoost has been shown to work well to create a more accurate model [33]. It is common practice to use AdaBoost to combine weak base learners (such as decision stumps). While some learners may perform poorly, the model as a whole will eventually converge to a highly effective learner if and only if it can outperform random guessing [32]. Combining powerful base learners, such as deep decision trees, with AdaBoost has been shown to work well to create a more accurate model [33]. It is common practice to use AdaBoost to combine weak base learners (such as decision stumps).

Most learning algorithms are better suited to certain problem classes than others, and the optimal performance of an algorithm on a dataset depends on a wide range of tuning parameters and settings. Since it employs decision trees as weak learners, AdaBoost has been deemed by many to be the best out-of-the-box classifier [31, 32, 33]. AdaBoost, when combined with decision tree learning, employs information obtained at each stage about the relative "hardness" of each training sample to instruct subsequent trees to prioritize the most difficult-to-classify samples [33]. Because the label was discrete, we employed AdaBoost with classification-type training data in our experiment. Our final GB settings are as follows: algorithm = SAMME.R, learning_rate = 1.0, n_estimators = 50 and random_state = 42.

- Gradient Boosting Algorithm (GB)

Classification and regression are just two examples of the many applications of the machine learning technique known as "gradient boosting." It provides a predictive model in the form of a series of decision trees, which are in general unreliable [34]. Using a technique called gradient boosting, we

can combine the strengths of multiple less-effective learners (decision trees) into a single, more robust one. In this setting, individual decision trees are inefficient learners [35]. Each successive tree in the line is linked to the one before it and functions to correct the defect of the one before it in the chain. Boosting algorithms require extensive training time but provide high accuracy thanks to this causal connection. Statistic learning favors models with a slower learning rate [34, 35].

The following are our final GB settings: As the model improves, each new member of the group of slow learners can be accommodated within the residuals of the previous stage. The final model synthesizes insights from all three to create a robust learner. The residuals are calculated by using a loss function. For instance, in classification, mean square error (MSE) can be used, and in regression, logarithmic loss (log loss) is employed. No alterations occur when a new tree is added to the model.

The residuals of the existing model fit well with the additional decision tree [34, 35, and 36]. We used a GB with categorization type because our experiment's label is discrete. Here are our preferences for configuring GB: subsample= 1.0, learning_rate = 0.1, criterion= friedman_mse, n_estimators = 100, and random_state = 42.

- Voting Algorithm

As stated by [37], an ensemble machine learning model known as a "voting classifier" forecasts a class based on the likelihood that the output (class) corresponds to the target class. The only thing it does is add the results of each classifier that was fed into the voting classifier to predict which output class will receive the greatest number of votes [38]. Instead of building and analysing numerous specialised models, we propose a single model that trains on many models and predicts output based on the total number of votes for each output class. There are two voting processes. [39, 40] that are compatible with Voting Classifier. The projected output class with the most votes, and thus the highest likelihood of being predicted by each classifier, is the one chosen by "hard voting," as described in (1). The second method is known as "soft voting," and it involves basing the forecast on the output class rather than a majority vote.

Given the dichotomous nature of the labels in our experiment, we opted for voting with classification, setting the parameters as follows: estimators = DT, RF, and XGB, and voting type = hard.

2) Deep learning algorithms: Once the dataset is ready, it is possible to use three deep learning algorithms to identify cybersecurity attacks using the dataset. There are three methods: LSTM, CNN, and LSTM combined with CNN.

- Long Short-Term Memory (LSTM) Algorithm

Long Short-Term Memory (LSTM) neural networks are used in the fields of deep learning and artificial intelligence. Because the LSTM can develop itself through feedback connections, it has a distinct advantage over traditional feedforward neural networks. Long Short-Term Memory (LSTM) neural networks are used in the fields of deep

learning and artificial intelligence. Because the LSTM can develop itself through feedback connections, it has a distinct advantage over traditional feedforward neural networks. This recurrent neural network can analyse complete data sequences in addition to individual data points (such as photos, speech or video). LSTM has demonstrated success in the fields of healthcare, video game creation, healthcare analytics, and networked, unsegmented handwriting recognition. The longest short-term memory (LSTM) model of neural networks has been the subject of the most research over the past 100 years [41]. The remaining components of a typical LSTM unit are made up of cells, input gates, output gates, and forget gates. The values stored inside the cell can be retained there indefinitely, and the flow of data entering and leaving the cell is controlled by the cell's three gates. [41, 42]. LSTM networks are excellent for jobs involving the categorization, processing, and prediction of time series data because delays of variable lengths may exist between significant occurrences in a time series. Since the training of standard RNNs can result in the vanishing gradient problem, long short-term memory (LSTMs) was created as a solution. Because it is less sensitive to gap length, LSTM outperforms RNNs, hidden Markov models, and other sequence learning strategies. [42].

Fig. 3 depicts the two layers of the LSTM architecture that we employed: 1) a Bi-LSTM layer made up of an LSTM layer, 64 units, and relu as the activation function; and 2) a dense layer made up of a single unit and sigmoid as the activation function.

- Convolutional Neural Network (CNN) Algorithm

Visual imaging evaluation typically makes use of an ANN class called a convolutional neural network (CNN, or ConvNet). Feature maps, which are translation-equivariant responses generated by convolution kernels or filters based on their shared-weight design and slide along input features, CNNs are also known as artificial neural networks that are shift- or space-invariant (SIANN). Contrary to common opinion, the majority of convolutional neural networks down sample the input, they do not translate invariantly. They are used in natural language processing, picture and video recognition, brain-computer interfaces, classification, segmentation, recommender systems, medical image analysis, and financial time series [43].

The structure of the visual cortex of animals served as inspiration for the development of convolutional networks. In particular, a cortical cell will only respond to stimuli that fall within the cell's receptive field [44]. All of the visible world is covered by the partially overlapping receptive fields of many neurons. Comparatively, CNNs require much less pre-processing than other image classification methods. The implication is that, unlike conventional methods, the network figures out how to optimize the filters (or kernels) on its own. First and foremost, feature extraction doesn't need any context or human input [43, 44].

The five-layered LSTM architecture utilized in our experiment is depicted in Fig. 4. Two Conv1Ds with the following parameters are provided: 128-element filters, three-element kernels, the same amount of padding, and the relu activation function. There are a total of three layers, including two max pooling layers and one dense layer containing one unit and a sigmoid activation function.

IV. RESULTS AND DISCUSSION

Based on four evaluation metrics, this section summarizes the experimental findings for each cybersecurity dataset for each deep learning method.

A. Evaluation Metrics

There are several assessment measures to examine the machine learning algorithms that were utilized, includes f1-score, recall, accuracy, and precision [45]. These metrics' formulas are as follows where:

- TP: The outcome is a true positive when the algorithm accurately predicts the positive class.

- TN: When the algorithm correctly predicts the negative class, the result is said to be "True Negative."

- FP: False positive results occur when the algorithm forecasts the positive class incorrectly.

- FN: A False Negative result occurs when the algorithm guesses the negative class incorrectly.

1) Accuracy: The ratio of correctly predicted samples to total samples, which is just a ratio of correctly predicted samples to total samples, is the most evident performance metric.

$$Accuracy = \frac{TP+TN}{TP + TN + FP + FN} \tag{1}$$

2) Precision: is the proportion of positively anticipated tweets that actually occurred to all positively predicted samples.

$$Precision = \frac{TP}{TP+FP} \tag{2}$$

3) Recall: is the ratio of positive samples that were accurately predicted to those that were generally forecast to be positive samples.

$$Recall = \frac{TP}{TP+FN} \tag{3}$$

4) F1-score: consider the weighted average of Precision and Recall.

$$F1\text{-}score = 2 * \frac{Precision * Recall}{Precision + Recall} \tag{4}$$

B. Machine Learning Results

Table IV and Fig. 6 provide effectiveness measurements for the used machine learning techniques (precision, accuracy, f1-score, and recall). Voting and DT classifiers perform superiorly when it comes to the detection attack technique.

C. Deep Learning Results

The aforementioned three deep learning approaches were implemented with the following parameters: accuracy as the evaluation metric, binary cross entropy as the loss function, Adam as the optimizer function, 15 epochs as the number of training sessions, and 128 as the batch size. Table V and Fig. 7 exhibit the experimental outcomes for various methods. Each algorithm's performance is measured by four different criteria: accuracy, f1-score, recall, and precision:

LSTM: 0.93, 0.96, 0.87, and 0.91.

CNN: 0.92, 0.93, 0.88, and 0.91.

LSTM with CNN: 0.995, 1.0, 0.99, and 0.995.

The LSTM with CNN gave the best performance results, which means that this algorithm can detect these attacks efficiently and effectively compared with LSTM and CNN.

TABLE IV.   BINARY CLASSIFICATION PERFORMANCE RESULTS

Models	Accuracy	Precision	Recall	F1-score
DT	0.894056	0.878958	0.864066	0.871448
RF	0.879974	0.857993	0.852246	0.85511
GB	0.829376	0.733313	0.92632	0.818593

V. Conclusion and Future Work

Eleven classification techniques, including three deep learning approaches [long short-term memory, convolutional neural networks, and long short-term memory + convolutional neural networks] [Decision Tree, Random Forest, Gradient Boosting, XGBoost, AdaBoost, Multilayer Perceptron, and Voting] were used in this study to identify suspicious assaults. Correctly predicted sample ratio is the most straightforward performance metric, as it is simply the predicted sample ratio. Using the Label Encoder method, we transformed the dataset from text to numbers. Algorithms are evaluated using the f1-score, along with precision, accuracy, and recall. In terms of detecting assaults, the LSTM with CNN outperformed the other models with scores of 0.995, 1.0, 0.99, and 0.995 for accuracy, precision, and recall, respectively. In this test, DT and voting classifiers outperformed the top machine learning methods. The results imply that a range of assault kinds can be detected using machine learning and deep learning. In a future study, we intend to assess the efficacy of these algorithms on a distinct dataset. In addition, we plan to implement ML, ML models, and DL approaches in our practice.

Kingdom of Saudi Arabia

Abstract—**Virtual Tourism (VT) is a booming business with potential perspectives in the entertainment and financial industry. Due to travel restrictions, safety concerns, and expensive travelling the younger generation is showing interest in virtual tourism instead of traditional tourism. However, virtual tourism does not financially benefit the service providers as compared to traditional tourism stakeholders. An online system is essential to provide a central point of access to various tourism sites along with usage, permission, and payment control. In this paper, a secure blockchain-based broker service for users and content providers is proposed, which allows tourism sites to announce their virtual tours and provide accessibility and accountability. Meanwhile, it enables users to register, subscribe, access, and be billed according to their usage. The permission control module ensures authentication and authorization, while the usage control provides accountability to the predefined service level agreement. The transactions are stored on the blockchain to ensure the integrity of data and smart contracts are used to ensure automatic usage and permission control. An implementation on Hyperledger Fabric is provided as a proof of concept with performance measurements as a case study.**

Keywords—*Virtual tourism; permission control; usage control; access control; blockchain*

I. INTRODUCTION

The imaginative ability of the human mind can be perceived and experienced by the latest Virtual Reality Technologies [1]. People can visualize and interact with virtual objects in a realistic or enhanced environment. They can build and experience their imaginative environment, which allows them to live, roam, and interact in an ideal, purpose-built world. In general, it is not easy to define the limits of the human imagination, but with the cutting-edge technology of computer-based systems [2], it is possible to create human-inspired imaginary worlds. With the development of technology, the imagination of the virtual world can be diversified from the real world to provide a more realistic experience.

Industry 4.0's arsenal accompanies one of the most promising technologies, Virtual Reality, which is one of the modern technologies in the current generation that yielded a rising market for VR application development. The extensive advancements in VR and other mixed realities have considerably changed experiences in different areas of interest. The implications and uses of these technologies are broad and are being actively used to boost the level of experiences of clients. The massive adoption of these technologies is found in healthcare departments [3] [4], education sectors [5] [6], manufacturing and logistics [7], smart cities [8], Museum [9] [10], social media [11], etc. In retail, virtual reality enables products to be visualized in 3D for consumers [13] [12] that ultimately leads to customer satisfaction and maximum sales.

One of the breakthrough applications of VR in recent times is Virtual Tourism [16], which enables a tourist to explore nature, attractions, destinations, ruins, buildings, and other travel destinations without physical interactions. The immersive experience is provided by the emerging technologies of VR and remote sensing. Virtual tours may include 360-degree view, guided tour of the virtual and augmented world, and video tours of remote destinations, which provides the ability to interact with and experience the art, nature, culture, or ancient ruins [14]. Worldwide, the VT industry was worth USD five Billion in 2021 and it is anticipated to reach USD 24 Billion in 2022 [15], as shown in Fig. 1.

VT provides a cheap replicate, motivation, and a marketing pretense for the tourism industry [16]. Due to the recent coronavirus pandemic (global pandemic), social distancing was recommended that made people's daily lives a bit boring with monotonous experiences. VT enables tourism experiences within the boundaries and guidelines of epidemic restrictions. Users can use specialized equipment from the comfort of their homes to create immersive experiences in virtual or real environments. Another benefit of VT is that it preserves cultural and natural heritage in environments vulnerable to tourist visitation and urbanization [17].

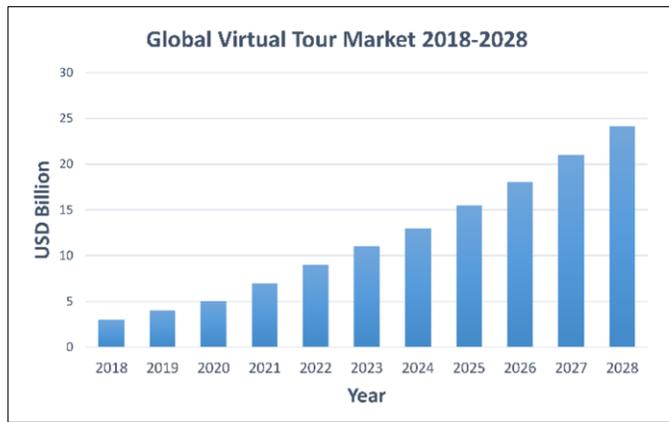
VT is enabled by VR/AR/MR technologies and applications. Without the implementation and support of the right tools, this promising industry cannot develop and thrive [16]. At one end, the virtual and augmented content is created using 3D cameras, scene modelling and composition, and image rendering using computer graphics; while at the extreme end, display technologies with embedded tracking technologies are used to provide an immersive experience to the user. The realistic experience of the user is the selling point of these virtual tours. The availability of tours as online or computer-based services requires accountability for permission, rights, access, and usage to ensure justified financial benefits for the service and content providers. Without this accountability and billing model, the services are not financially feasible.


Fig. 1.   Market Growth of Virtual Tourism [15].
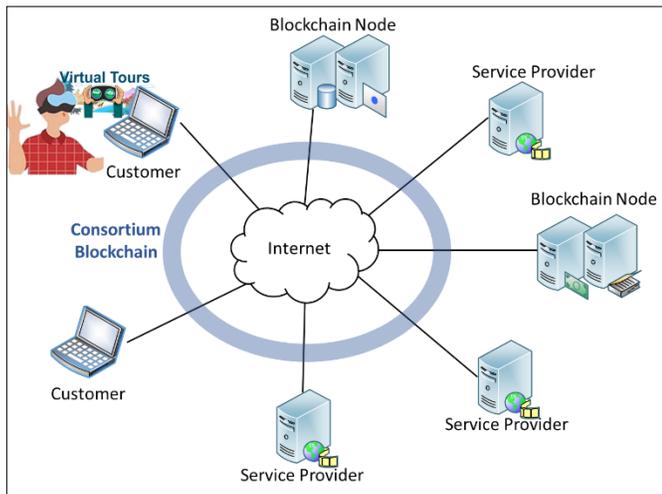

Fig. 2.   The Blockchain based Content Distribution System using a Consortium of Blockchain Nodes, and Registered Service Providers and Customers.

To facilitate the virtual tourism industry and its customers, this paper presents an online system that provides a consortium blockchain-based decentralized access to various tourism sites and content providers, as shown in Fig. 2. Along with the permanent nodes of the blockchain, service providers and customers can become members of the blockchain, which maintains usage, permission, and payment control. It allows the tourism sites to announce their virtual tours and provides accessibility and accountability, at the same time, allows users to register, subscribe, access, and be billed according to their usage. The permission control module ensures authentication and authorization, while the usage control provides accountability and billing. The transactions are stored on the blockchain to ensure the integrity of data and smart contracts are used to ensure automatic usage and permission control.

The rest of the paper is structured as follows. Section II discusses the literature review. Section III presents the proposed blockchain-based permission and usage control system. Section IV presents the implementation details on Hyperledger fabric and evaluation of the system and Section V concludes the paper and provides future directions.

II.   RELATED WORK

VT is used by various industries from museums to ancient ruins and from universities to stadiums. VT is an efficient marketing edge that any business can rely on for expanding clientage and market penetration.   Tourism agencies use virtual tours for marketing their destinations and attractions. According to a survey in 2017 by TIG Global, 50% of tourists base their selection of a destination on virtual tours [18]. A study by Google in 2015, identified a 50% increase in online interest and a 40% increase in booking reservations [19]. According to Panomatics' statistics, 75% of potential buyers consider virtual tours as a major factor in their purchasing decision [20]. Another study found that among the students of culture, 80% of people go to virtual exhibits, museums, and classes for further education [21]. The online event industry, which is a subcategory of virtual tourism, is identified to grow by $2.3 trillion in 2026 [22].

Many websites and portals on the Internet provide virtual tours to various destinations, such as museums [9], architectures [23] [26], [28], underwater explores [24], archaeological sites [25] [27], monuments [29], Holy sites [30] [31], and remote locations [32] [33]. From the couch of your living room, you can party in Ibiza, be alone in the clouds in a hot air balloon, dive with fishes in the Georgia Aquarium, fly over the skies of Paris; and much more [34].

However, most of these sites are using VT for marketing purposes only. As the boom of VT expands, more and more people will prefer virtual tourism over traditional tourism [16]. For making the system financially feasible, a content distribution system is required, which provides all the tours at a single portal, to allow authentication, authorization, accountability, and payment facilities along with security and trust. Such a content distribution system for VT is missing; however, research has already been done for permission, access, and usage control.

In [35], the authors have reviewed various access control systems and identified the challenges and opportunities. They have recommended the use of blockchain for developing an access control system with decentralized trust. Kishigami et al. have proposed a decentralized blockchain-based digital content distribution system along with a prototype application [36]. It uses a digital currency-based payment system; however, a usage control system is missing. Maesa et al. have proposed an access control system, which uses blockchain to publish the policies expressing the right to access a resource and to allow the distributed transfer of such rights among users. The system provides distributed auditing and prevents fraudulent transactions. It is deployed on the Bitcoin blockchain [37]. In [38], the same team has proposed the use of blockchain technologies to implement the traditional access control system to achieve better auditability.

Khan et al. have proposed an extended usage control model known as DistU (Distributed Usage Control), which considers all possible access control models required by a business for permissioned blockchain frameworks [39]. The detailed mechanism of DistU is provided in [40]. Khan et al. also presented an extension to the UCON model in [42].   Their model is an extension of the UCON model developed by Park

and Sandhu [41]. UCON is the most generalized usability control system with work based on pre-defined attributes, conditions, and obligations. It uses a set of policies for maintaining usage before, during, and after access is granted to a user.

The main contribution of this work is a comprehensive and purpose-built permission and usage control for virtual tourism cases, in which the customers can register into the system, subscribe to and visit the virtual tours, and pay for services in a trusted environment. At the same time, the service provider can financially benefit from the virtual tours.

The proposed system is also a derivation of the UCON model, in which the model has been modified according to the requirements based on the customer as a consumer of the service, virtual tours as the service and tourist cites as the service providers. Along with the usage control of UCON, the access and permission control systems have been embedded for the completeness of the solution. A working system on top of a consortium blockchain using the Hyperledger Fabric as a proof of concept has also been proposed. The next section provides the detail of the proposed system.

III. BLOCKCHAIN-BASED PERMISSION AND USAGE CONTROL

To enable content streaming for virtual tourism, a comprehensive system has been proposed, which allows users to register, maintain their accounts and subscriptions, and handle bills. For tourism agencies and service providers, it supports content provision, billing itineraries, and service management. It also enables secure and trusted permission, rights, and usage control using blockchain technologies. Fig. 3 shows the modules available in the proposed system and the following sections discuss the details of each module.

A. Membership

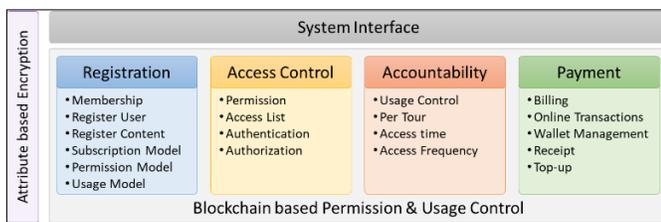
The system is developed on a permission blockchain, therefore only the members are allowed to enter the system. A new user must register into the system by creating an account through a valid email address, contact, and financial details, which enable the system to charge or/and remit the user for the services. There are mainly two types of users: customers and service providers. On registering into the system, a user is created in the blockchain's couch DB, which serves as a distributed database, while the certification authority creates security credentials for authentication and maintaining the confidentiality of the data. In this section, the various participants and entities involved in the system, and their interactions are defined.


Fig. 3. Modular Diagram of the Proposed Blockchain-based Permission and Usage Control System.

Definition 1: A customer is defined in the system as an active member (ui), such that ui ∈ U, while U specifies the set of customers with attributes: identity (id), credentials (ci), set of subscribed tours (Ti), wallet (wi), and states Σ and A.

$$u_i \in U(id, c, T, w, \Sigma, A) \qquad (1)$$

Where, Σ is the state of user (customer or service provider) as signed-in, signed-out, granted, or denied. A is a set of states for the customer against the set of subscribed tours. The state value can be initial, subscribed, requested, accessing, or denied.

Definition 2: A Service Provider (ri) is also a user in the system, (ri), such that ri ∈ R, while R specifies the set of service providers with attributes: identity (id), credentials (ci), set of provided tours (Ti), wallet (wi), and state Σ. A service provider can create/provide a set of Tours (Ti).

$$r_i \in R(id, c, T, w, A) \qquad (2)$$

Upon arrival into the system, a user must sign-in to the system with its id and credentials. A membership function *(Ψ)* checks a user (u_i/r_i) against corresponding credentials (c_i) to allow or deny an entry into the system by updating the state *Σ*.

$$\Sigma(u_i): \Psi(u_i, c_i) \qquad (3)$$

The membership model provides authentication in the system by defining who can access and enter into the system.

B. Content Registration

The content provided by the service provider to the customers is in the form of virtual tours. A customer can view and experience the virtual tour as per the subscription and is charged according to the subscription rate, which is paid through an associated wallet.

Definition 3: A tour is defined as a service consumed by the user (u) and provided by the service provider (r). It is denoted by t such that t ∈ T (id, r, β, ρ, τ, U).

Where, *r* is the service provider of the tour, *β* is the subscription fee, *ρ* is the usage rate per frequency of access, *τ* is the usage rate per time of access, and *U* is the set of users subscribed to consume that resource.

A service provider ri can enter a tour tj into the system if the state is signed-in. An online portal allows the service provider to manage her/his tours in terms of editing information, subscription rates, content, narration, etc. A tour has various attributes such as id, location, subscription rates, viewer's rating and reviews, historical information, content, narration, information and details, and list of attractions, etc., out of which the mandatory tuple is defined in definition 3. After a successful signed-in into the system, the service provider can add tours along with their details and media files, which are saved in a distributed database. After a service provider creates a tour, it is assigned an id and associated with that service provider. The function O(r, t) checks if the service provider ri is the owner of the tour ti, based on which the system permits the service provider to edit the tour or deny access.

C. Subscription

The subscription model defines which user and service provider can access and edit/manage which tours respectively. It enables authorization in the system.

After a customer (u_i) has successfully signed into the system, the customer can enlist the tours available in the system. The customer can search the tours based on various categories such as id, location, subscription rate, viewer's rating, etc. From the available list of tours, a customer can subscribe to the tour given that the subscription condition is fulfilled, which checks if there is enough amount in the customer's wallet to pay the subscription fee against the selected tour:

$$\Delta : w(u_i) \geq \beta(t_j) \tag{4}$$

Where u_i is the customer, t_j is the selected tour, $w(u_i)$ is the amount in the wallet of customer u_i, and β is the subscription fee for the tour t_j, and Δ is the subscription status.

- If Δ = allow (1), then tj is inserted into the set of Ti for customer ui.

$$T_i(u_i) \leftarrow t_j, \text{ or } t_j \in T_i(u_i) \tag{5}$$

At the same time, for the tour t_j, u_i will be inserted in its set of subscribed users U_j.

$$U_j(t_j) \leftarrow u_i, \text{ or } u_i \in U_j(T_j) \tag{6}$$

- If Δ = deny (0), then the customer ui is informed that his wallet (wi) does not have the required amount to subscribe to the tour tj.

Θ(ui, tj) is the subscription function that checks for a user's (ui) access to a tour (tj), which can be initial, subscribed, requested, accessing, or denied. The state is maintained in aj, where aj $\in$ Ai for ui.

D. Access and Permission Control

Permission control has two stages. The first stage is for the entry into the system for the users (authentication), while the second stage is for permitting users to access only their owned and subscribed contents (authorization). When a user logs-in to the system, the permission control checks corresponding credentials (id and password) to ensure a user is allowed in the system, based on which it permits or denies access. Ψ(ui, ci) is the membership function that checks user ui against user credentials ci to grant or deny entry into the system.

$$\Psi(\alpha i, c i) \rightarrow \Sigma(\alpha i) = \{granted, denied\}, \text{ where:} \tag{7}$$

$$Role\ (\alpha) = \begin{cases} customer, & \alpha \in U \\ service\ provider, & \alpha \in R \end{cases} \tag{8}$$

In case of access is denied, the user is advised to register into the system. When a customer registers successfully, a customer entry is created and added to the set of Customers *U*:

$$U \leftarrow u_i\ (id_i, c_i, T_i, w_i, \Sigma_i, A_i) \tag{9}$$

When a service provider registers successfully, an entry is created and added to the set of Service Providers *R*:

$$R \leftarrow r_i\ (id_i, c_i, T_i, w_i, A_i) \tag{10}$$

The second stage of permission control is used when a customer tries to view one of the tours. The permission control uses the subscription model to check if a customer is authorized to access the said tour. Similarly, when a service provider is trying to edit/manage the tour, the permission model checks the ownership.

Θ(ui, tj) is the subscription function that checks if a customer ui is subscribed to a tour tj to granted or denied access to the tour tj. The state is maintained in the set Ai. Similarly, Θ(ri, tj) checks if a service provider ri is the owner of a tour tj to granted or denied access to the tour tj. The state is maintained in the set Ai.

E. Usage Control

The usage control maintains accountability in the system by calculating the use of the service by each customer and ensures that the user does not exploit the system by excessing the usage defined for the said content. After the permission control grants access to the customer to view the tour/content, the usage control is activated. Usage control maintains a state of access for each user accessing a tour t_i. However, in the case of a service provider accessing pre-owned tours, the usage control is not activated.

Usage control used two functions to calculate the usage of the content/tour (t_j) for a customer (u_i). $\Xi(u_i, t_j)$ calculate the usage in terms of time; as the amount of time the customer u_i has accessed the tour t_j. While $\Pi(u_i, t_j)$ calculates the usage in terms of frequency, as how many times the tours t_j was accessed by user u_i.

For each tour t_j the service provider adds a rate ρ_j that is used to calculate the usage in terms of access time and rate τ_j, which determines how many times a tour is accessed. This approach is used to calculate the billed amount ($Q(u_i)$) for the customer (u_i), which is debited from the wallet of the customer u_i, and credited into the service provider r_k, who owns the tour t_j. These two usage parameters are designed to give flexibility to the service provider to charge its customer. If the service provider wants to charge the customers based on how many times the user accesses the system only, then a non-zero value is provided to τ_j and a zero value is provided to ρ_j. On the other hand, when the charge is based on the time of access only, then a zero value is provided to τ_j and a non-zero value is provided to ρ_j.

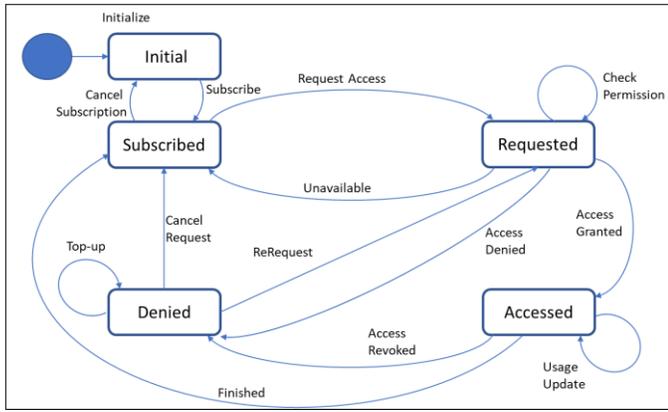
When the customer is allowed to access the tour and allowed by the permission control, the state of the tour for that customer is changed to 'requested.' After that, the usage control first checks the balance in the wallet of the user and if the value of τj is non-zero, then the user is allowed access only if the user has a balance of more than τj. In that case, the state for the tour is changed to accessing. If there is not enough balance, then the state is changed to 'denied' and the user is informed about the lack of balance. The change of state is visualized in Fig. 4. In case the value for τj is zero, then the condition in step 3C1 in Algorithm 1 is true and the customer would only be charged based on λ(ui), which is the amount of time in seconds.


Fig. 4. The State-Model Diagram of the Usage Control Model, which Monitors the usage of a Tour by a Customer and Ensures that the user has enough Balance to Keep viewing the Tour.

Similarly, the usage control monitors and calculates the usage based on the time using equation (11) and deducts the amount from the wallet using equations (12), (13), and (14), respectively.

$$\Xi(u_i. t_j) = \rho_j \times \lambda(u_i) \tag{11}$$

$$\Pi(u_i. t_j) = \tau_j \times \nu(u_i), \tag{12}$$

$$Q(u_i) = \Xi(u_i. t_j) + \Pi(u_i. t_j) \tag{13}$$

$$w(r_k) = w(r_k) + Q(u_i) \tag{14}$$

Where, $\nu(u_i)$ is the number of times a tour (t_j) is accessed by the customer (u_i) and $\lambda(u_i)$ is the time (how long) for which the tour (t_j) is accessed by the customer (u_i).

Once the amount is lower than the threshold (which is zero in most cases), then the usage control will revoke the access of tj for the user (ui) and change the state to denied.

$$\Delta: w(u_i) = w(u_i) - \Xi(u_i. t_j), \text{ where } \Delta: w(u_i) \geq 0 \tag{15}$$

- If Δ = allow (1), then ui keeps accessing the tour tj and aj = {accessing}

- If Δ = deny (0), then tj access for ui is revoked and aj = {denied}

The customer is informed in the system about the revoked access and given an option to top-up her/his account by crediting the balance to the account through the manage account section of the portal. Afterward, the customer can send a re-request for the content/tour, which change the state to 'requested.' The usage control checks the condition (given in equation 15), if the result is 'allow', then the state is changed back to accessing and the tour is continued for the user. At any time, when the customer selects to cancel the access to the tour, the system stops the access and changes the state back to 'subscribed.' This whole process is outlined in Algorithm 1 and the flowchart in Fig. 5 for better understanding.

Algorithm 1: Customer accessing a Tour; Permission and Usage Control

1. System enlists the available tours based on id and location,
2. Customer u_i selects a tour t_j to view
3. Permission Control checks subscription
   if $u_i.a(t_j) = $ **subscribed**
   a. *Permission = Allowed*
   b. state(t_j) = **requested**
   c. **if** $w(u_i) \geq \nu(u_i)$ //(deduct usage based on number of access)
      1. $w(u_i) = w(u_i) - \tau_j * \nu(u_i)$,
      else
      i. **inform** user "*Not enough balance to view the tour*"
      ii. state(t_j) = **subscribed**
      iii. **goto** step 1
      end if
   else (**if** not **subscribed**)
      subscribe tour t_j
   a. Check for the subscription fee
      if $w(u_i) \geq \beta_j$
      i. $u_i.a(t_j) = $ **subscribed**
      ii. $w(u_i) = w(u_i) - \beta_j$ //(deduct subscription fee)
      iii. **goto** step 3
      else
      i. **deny** request (*Permission = Not Allowed*)
      ii. **end**
      end if
   end if
4. Grant Access to the Tour, state(t_j) = **accessing**
5. **while** state(t_j) = **accessing**
   a. **if** *user.action = Cancel Tour*
      i. state(t_j) = **subscribed**
      ii. **end** //Stop Access to the tour
      end if
   b. **monitor** Usage Control, $\lambda(u_i)$ = time in seconds for how long the customer u_i is accessing the tour t_j
   c. **calculate** time usage: $\Xi(u_i. t_j) = \rho_j \times \lambda(u_i)$, // Debit the wallet and check for available balance
   d. $w(u_i) = w(u_i) - \Xi_{i,j}$
   e. **if** $w(u_i) < 0$
      i. **revoke** access

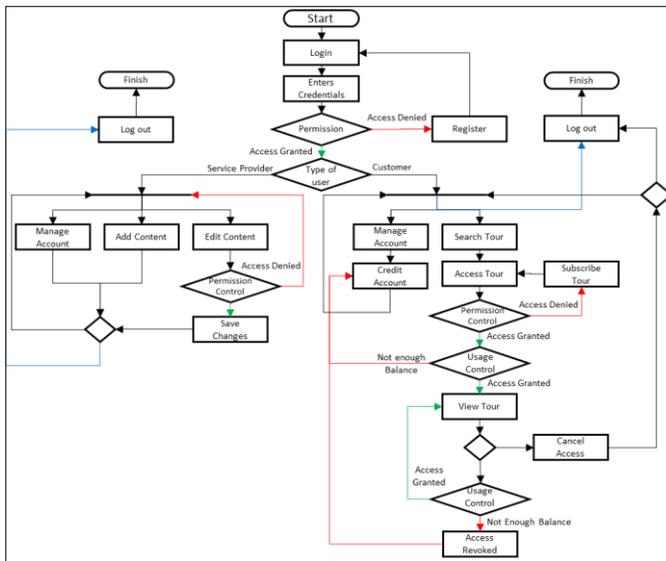
      vi. **else if** *user.action = Topup Account* AND $w(u_i) \geq \Xi_{i,j}$
         a. Action = *ReRequest*
         b. goto step 5.e.iv
         else
         a. **goto** step 5.e.iii
         end if
      end if
6. **end while**


Fig. 5. The Flowchart Depiction of Algorithm 1, Showing the Permission and usage Control.

Fig. 6. Member and Content Registration Steps for the Service Provider on the Consortium Blockchain.

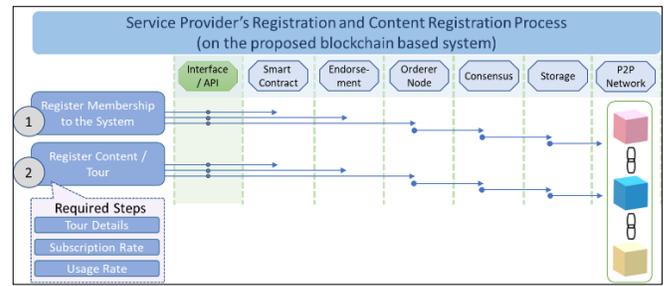
Fig. 7. Permission and Usage Control Model on Top of the Consortium Blockchain.

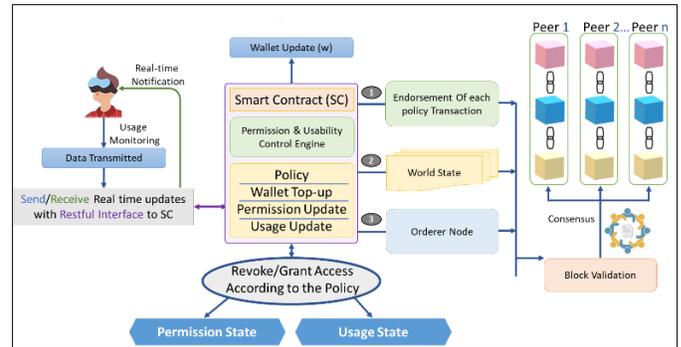
IV. IMPLEMENTATION AND EVALUATION

The proposed usage and permission control system is based on the concept of consortium blockchain, where some permanent nodes are part of the blockchain, and other nodes can register for membership and become part of the blockchain. As shown in Fig. 2, for making the tours available for the customer without needing a centralized server, the service providers can register as a member and then register their content on the blockchain. Similarly, customers can become members and can search for and access the tours. Fig. 6 shows the registration activity for the service provider on the blockchain, verified by various nodes.

Due to its inherent properties, the blockchain provides distributed trust among customers and service providers. Content distribution and financial transactions can be implemented securely on the blockchain. Using smart contracts, the usage and permission control can implement the policies and makes sure that authentication, authorization, and accountability are maintained.

Fig. 7 shows the working of the permission and usage control system on top of the blockchain network A user can register on the blockchain as a member, then search and subscribe for various tours by paying the subscription fee. Afterward, the user can view the tours. The permission control maintains a permission state against a user accessing a tour. It checks the customer's permission to access the said tour and allows or denies the customer based on permission rights.

Similarly, during the access, the usage control maintains the usage state. It monitors the frequency and time of view for the customer against a tour. The system calculates the bill and makes sure that the customer has enough balance in the associated wallet. Accordingly, the usage control can revoke (or grant) access to the customer with a notification.




F. Implementation of Blockchain

The following text details the configuration of the testbed created to verify the permission and usage control model presented in the previous section. The proposed system is implemented on Hyperledger Fabric 1.4 designed as a consortium blockchain, with two permanent nodes and three service provider nodes, and two customer nodes. In the end, the performance evaluation of the consortium blockchain is presented in terms of the throughput and the latency of the system. However, first, a small introduction to blockchain technologies is given, along with the motivation for using the Hyperledger Fabric.

1) Blockchain technologies: The earlier blockchains, such as bitcoin, etc., face challenges with energy consumption and speed due to their public nature. On the other hand, modern blockchains have been developed as private or consortium concepts, to help overcome these limitations and provide practical value for other business uses and applications. The top modern blockchain frameworks are R3 Corda, Hyperledger, and Ethereum. Some of the modern blockchain frameworks are discussed below:

2) IBM Blockchain: IBM Blockchain is a private, decentralized blockchain network that has been the most successful with enterprise clients as it links into enterprise cloud and legacy technologies more seamlessly than is possible in other decentralized networks. The developer tool was designed to be flexible, functional, and customizable with a user-friendly interface to simplify critical tasks, such as setting up, testing, and rapidly deploying smart contracts [43].

3) R3 Corda: R3 Corda [44] is a distributed ledger platform that uses a novel consensus mechanism in which transactions are cryptographically linked but does not periodically batch multiple transactions into a block. It processes all transactions in real-time, which makes it superior in performance. However, R3 declared it as a blockchain and not a blockchain at the same time, as some large companies have observed implementation constraints and is deemed not suitable for consortium blockchains.

4) Ethereum: Ethereum [48] is one of the oldest and most established blockchain platforms. It provides a truly decentralized blockchain that is comparable to the Bitcoin blockchain network. It enables true decentralization with support for smart contracts. Its key weaknesses include slow processing times and higher transaction processing costs compared to other platforms.

5) HydraChain: Hydrachain blockchain platform [45] is an extension to the Ethereum platform that supports the development of a permissioned distributed ledger. Therefore, the tools for developing smart contracts and decentralized apps are same as the Ethereum; however, the issues of Ethereum are also present.

6) Quorum: Quorum [46] is a customized version of Ethereum developed by the financial services company JPMorgan. It has been optimized to support high-speed transactions between institutions such as banks and insurance companies on a private blockchain. It also adds various privacy enhancements to Ethereum to improve support for regulations. It supports confidentiality and privacy for all transactions using smart contracts. Quorum has lower throughput at higher load and experiment results suggest an increase in transaction latency with regard to reading and writing operations.

7) IOTA: IOTA [47] is a blockchain platform designed specifically for IoT blockchain applications, which uses a directed acyclic graph to store transactions on its ledger, motivated by potentially higher scalability over blockchain-based distributed ledgers. IOTA achieves consensus through a coordinator node, operated by the IOTA Foundation. It is not a strict blockchain solution due to the coordinator serving as a central control feature, which goes against the idea of blockchain as "distributed ledger technology".

8) Hyperledger Fabric [49]: Hyperledger Fabric provides a collection of tools to create permissioned blockchain applications. It is engineered with distributed ledger as the core concept. It supports components that can be plugged into a modular architecture, which works well in private and permissioned blockchain deployments, which improves security and speed. An open smart contract model that can support various data models is also provided.

After the comparative analysis of these modern blockchain frameworks, it is concluded that Hyperledger Fabric, due to its prominent features, was inspired to be selected as the number one candidate for the implementation of the proposed system.

Now, a brief overview of the various components of the Hyperledger is presented in the following subsection.

G. Setup of Hyperledger Components

As a proof of concept, the proposed system is implemented as a consortium blockchain using Hyperledger fabric with the essential components, such as certificate authority, working as a membership service provider, orderer node, anchor node, committer nodes, endorser nodes, etc., carrying out the transactions, creating blocks of transactions, implementing the consensus algorithm, and saving them on the shared ledger, as shown in Fig. 8. The discussion about these components, their roles, and their implementation on Hyperledger fabric are discussed in the following sub-section.

1) Certificate authority: The job of the Certification Authority (CS) is to provide secure communication between the blockchain nodes, authenticate the users, and ensure the integrity and confidentiality of the data. It effectively works as the Membership Service Provider (MSP) that provides access to the peer nodes (blockchain nodes, customers, and service providers) in the system, creates digital certificates along with pairs of private and public keys for encryption and decryption of the messages, ensure trust, and enable registration for the new users. Each peer has its own identity given by a membership services provider (MSP), which authenticates each peer to its channel peers and services.

2) Channel: Channels are used to provide communication between the peer nodes of the blockchain consortium to conduct private and confidential transactions. A channel constitutes of. Each transaction on the network is executed on a channel, which constitutes authenticated and authorized members, anchor nodes, the shared ledger, smart contracts or chaincode, and orderer nodes.

3) Smart Contract: Smart Contracts, also called chaincode in Hyperledger fabric, are responsible for processing transaction requests and determining whether transactions are valid by executing policies. These could be third-party applications connected to the blockchain network, or chaincode can be written in Go, JavaScript (node.js), and eventually other programming languages, such as Java through Restful interfaces. The chaincode implements the logic of the usage and permission control and validates the login defined through the policies.

4) Validation of system chaincode: Validated System Chain-Code (VSCC) instigates the source of transaction in the blockchain, validates each transaction signed by peer nodes, and ensures the endorsement of the transaction is performed by enough member nodes.

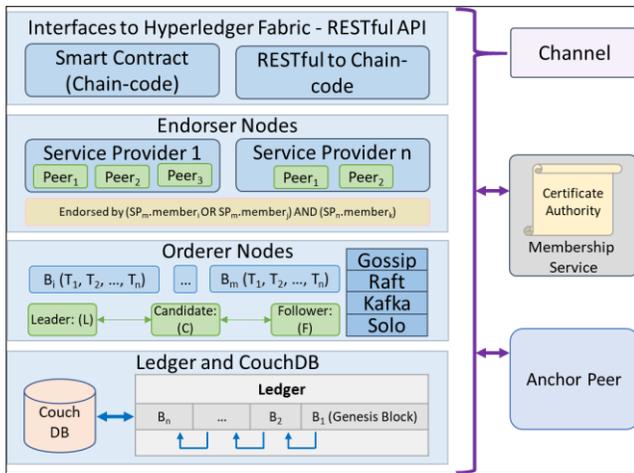
5) Anchor peer: The anchor peers are responsible for providing communication between the members of various organizations, such as service providers, permanent nodes of the consortium blockchain, and customer nodes. It uses the gossip protocol that identifies other available member peers, disseminates ledger data across peers on a channel, and brings new peers up to date quickly.


Fig. 8. The Modular Diagram of the Deployed Hyperledger with Various Internal Components.

6) Endorsement policy: The endorsement policy is implemented to ensure that before adding details of transactions into the ledger, the details are first signed by predetermined peers. Every chaincode has an endorsement policy that specifies the set of peers on the channel that must execute the chaincode and vouch for the outcome of the execution for a transaction to be considered valid. To launch different transactions from the smart contract, the multiple interface interaction is ensured through RestAPI.

7) Consensus: There are three main steps of consensus in Hyperledger Fabric. First is the endorsement, which is driven by the policy upon which the members endorse a transaction. Second is ordering, in which the endorsed transactions are arranged in an order to be committed to the ledger. Third is validation which takes a block of ordered transactions and validates the correctness of the results, including checking endorsement policy. A number of consensus mechanisms were opted for and tested among RAFT, Kafka, and Solo; however, in terms of efficiency, Raft has proven to be much better.

8) Byzantine Fault Tolerance (BFT): BFT is a simple consensus mechanism in which every node has to vote. Each node represents a blockchain ledger (Kafka divides these ledgers into clusters on each node to make searching easy). They need to reach a consensus on the current state of the network. This means a good number of the participating nodes have to reach a decision and execute an identical action to avoid failures. The algorithm is Crash Free, which means even if some nodes fail to vote, the algorithm will not crash.

The endorser node in the blockchain consortium endorses every single transaction performed related to the aforementioned activities i.e. the new members joining the system, and transactions related to funds deposited in favor of the service provider. Once the endorsement is performed, the next operation is carried out which is termed ordering. During the ordering process, all endorsed transactions are executed to form a block. That is passed through a validate node that performs validation of the created blocks. Once the blocks are validated, they are approved via a consensus mechanism. A

number of consensus mechanisms exist; however, in this implementation scenario, the default consensus mechanism of Hyperledger Fabric, Raft is used. Raft has a network of nodes that function to update the blockchain ledger. Raft was selected because it is fault-tolerant, in case of a node failure, and efficient as compared to Kafka and Solo. In addition, Raft conducts an election among the nodes for electing a leader in the blockchain network.

Once Raft opts for the leader, the endorser sends the block to the leader which actually ensures data state synchronization among members of the blockchain consortium. Ultimately, the ledger state is updated, synchronized, and trusted.

H. Performance Analysis Results

This paper, in particular, incorporates features with regard to usage control, access control, and permission control for customers associated with the Tours. In order to measure and evaluate the prototype implementation with regard to the latency and throughput of the proposed system, a testbed environment was created that only processes transactions related to usage control and permission control.

The testbed is implemented on two virtual processors of Intel Xeon server as the permanent nodes of the consortium blockchain, along with eight-gigabyte memory. The two nodes are connected through a gigabit ethernet connection. IBM chaincode's fabric-load-gen tool is used with various test cases with varying latencies and endorsement policies. The generated transactions are configured as both read and write by using load-generating scripts. The latency is calculated as the delay in completing a whole transaction, including endorsement time, broadcasting time and commit and validation time. The delay introduced by the orderer nodes is also included, while the number of transactions executed per second is used to calculate the throughput of the system.

Fig. 9 and 10 depict Hyperledger performance over different block sizes, the latencies (Fig. 9) and throughput (Fig. 10) of the transactions for different transaction arrival rates, and the effect of various endorsement policies with various transaction arrival rates. The linear increment in the throughput can be seen in Fig. 10, according to the increase in the rate of incoming transactions. It can be observed that after 150 tps, this linear increase is limited due to the saturation point. The saturation point is presented in Fig. 8. This saturation is mainly due to the three computationally intensive operations of policy validation, which are (1) x.509 certificate identity validation, which involves reconstruction of the certificate from the received serialized byte stream; (2) validation of the identity by the membership service provider and, (3) verification of the digital signature to authenticate the transaction. The size of the block gets bigger as the number of endorsements is increased with each transaction, which includes encoding and decoding of x.509 certificates.

The testbed is configured using Hyperledger Fabric 1.4 which employs Raft consensus. Raft produces more acceptable performance results as compared to other versions of the Hyperledger Fabric. These results support the idea of blockchain-based permission and usage control mechanisms for decentralized content distribution in virtual tourism.

V.   CONCLUSION

To facilitate the virtual tourism industry and its customers, this paper presents an online system that provides a consortium blockchain-based decentralized access to various tourism sites and content providers. Along with the permanent nodes of the blockchain, service providers and customers can become members of the blockchain, which maintains usage, permission, and payment control. It allows the tourism sites to announce their virtual tours and provides accessibility and accountability, at the same time, allows users to register, subscribe, access, and be billed according to their usage. The permission control module ensures authentication and authorization, while the usage control provides accountability and billing. The transactions are stored on the blockchain to ensure the integrity of the data and smart contracts are used to ensure automatic usage and permission control. An implementation on Hyperledger Fabric is provided as a proof of concept with performance measurements as the evaluation.

In the future, permission and rights controls can be enabled for the shared objects in a collaborated virtual reality, where various users can create their virtual objects, enter historical facts, create milestones, and frequently asked questions (FAQs) in the virtual tours. Through this, the users can control and permit who can access their virtual assets. Similarly, reviews and experiences could be added to a virtual tour with the control in the hands of the service provider.

A Fast Multicore-based Window Entropy Algorithm

Suha S.A. Shokr, Hazem M. Bahig

Information and Computer Science Department, College of Computer Science and Engineering
University of Ha'il, Ha'il 81481, Saudi Arabia

Abstract—Malware analysis is a major challenge in cybersecurity due to the regular appearance of new malware and its effect in cyberspace. The existing tools for malware analysis enable reverse engineering to understand the origin, purpose, attributes, and potential consequences of malicious software. An entropy method is one of the techniques used to analyze and detect malware, which is defined as a measure of information encoded in a series of values based upon the probability of those values appearing. The window entropy algorithm is one of the methods that can be applied to calculate entropy values in an effective manner. However, it requires a significant amount of time when the size of the file is large. In this paper, we solve this problem in two ways. The first way of improvement is determining the best window size that leads to minimizing the running time of the window entropy algorithm. The second way of improvement is by parallelizing the window entropy algorithm on a multicore system. The experimental studies using artificial data show that the improved sequential algorithm can reduce the window entropy method's running time by 79% on an average. Also, the proposed parallel algorithm outperforms the modified sequential algorithm by 77% and has super-linear speed up.

Keywords—Entropy; window method; malware analysis; parallel algorithm; multicore

I. INTRODUCTION

With increased internet use, social media, and data sharing, users must better secure themselves to protect vulnerable information. One of the dangerous software that faces the user is malware.

Malware is a set of instructions that run on a computer, specifically designed to harm the user or the target system by making the system do something that an attacker wants it to do, like steal personal information, delete files, commit fraud, or steal software serial numbers. Moreover, new malware is registered periodically, posing a challenge to cybersecurity efforts. Malware remains one of the most potent threats in cyberspace, despite significant advances in cyber security mechanisms and their ongoing evolution.

Different kinds of malware (e.g., viruses, bots, rootkit, backdoors) can be distributed via various channels, transmitted, and used in various techniques to perform malicious operations [1].

The process of analyzing the malware (with and without execution) is called malware analysis. The main objectives of analyzing malware are to study malicious software's origin, purpose, attributes, and potential impact.

A large number of malware analysis techniques have been proposed. These techniques can be classified into two main categories [2]: static and dynamic. The main difference between static and dynamic analysis is the examination of the malware with or without running it. The two categories contain many malware detection techniques such as signature-based, specification-based, behavioral-based, and heuristic-based [3]. One of the techniques used in malware analysis is the running window entropy (RWE) method, where the entropy is a measure of information encoded in a series of values based upon the probability of those values appearing [1].

The entropy method has been used in many applications such that malware detection [4], lung sound classification [5], gender violence classification [6], Arabic text classification [7], image steganography [8], and sediments quality evaluation [9].

For analyzing malware using entropy algorithm, there are many research papers have been proposed such as [10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28].

Lyda and Hamrock [15] analyzed malware utilizing structural entropy, which employs a skip value to ignore the entropy calculation at each index. McMillan and Garman [21] obtained the same result utilizing a statistical decision concept using malware entropy information.

Sorokin [26] proposed a method based on dividing the file into segments and then applying a discrete wavelet transform (DWT) to the structural entropy to compare the segments of the input file. Baysa et al. [11] used the same strategy to identify the malware changes. The method was implemented on binary files, and there was no need to perform any preprocessing to detect the malware.

Bat-Erdene et al. [12] used the entropy method to detect unknown packers. The method is based on representing the entropy value as a symbolic aggregate approximation (SAX) and measuring the symbol's similarity in the SAX sequence. The accuracy of this method on the tested data is 95%. Radkani et al. [25] suggested a new method to detect metamorphic malware based on entropy and dissimilarity measures. The drawback of this method is the measurement limitation, which is based on the opcode (operation code) frequency.

Jones and Wang [19] suggested a method to reduce the running time of the RWE algorithm. The method is based on removing a nested "for" loop from the old version of the algorithm. The same authors [20] used the entropy concept to extract the feature set used in machine learning algorithms.

Menéndez et al. [22] introduced a new concept called entropy time series to detect malware. The technique uses a time series to represent an entropy signature. Then, the

technique applies wavelet analysis to a file's entropy to obtain a simplified signature. The main advantage of this strategy is reducing the running time of malware analysis.

In light of the previous discussions about the use of entropy in malware analysis, the main question of the research is: how to reduce the running time of the entropy method when the size of the file is large?

This paper has focus on the RWE algorithm because the window method is one of the strategies used in different fields, such as [29, 30], to reduce the running time. This study aims to demonstrate the effect of changing the window size on the RWE algorithm in terms of running time. In addition, the paper explores if there is a common window size that reduces the running time of the RWE algorithm for all malware samples and look at ways to optimize the RWE algorithm's running time. Finally, how to parallelize the sequential algorithm to reduce the running time.

The remainder of this paper is organized as follows. Section II gives briefly the foundation concepts of the RWE algorithm. In Section III, the modified RWE algorithm in terms of execution time is given. The second improvement for RWE algorithm using a multicore system is given in Section IV. The experiments and their analysis for the proposed algorithms on artificial data are given in Section V. Finally, the conclusion and open question are given in Section VI.

II. RUNNING WINDOW ENTROPY METHOD

In this section, we briefly give the main concept of entropy in subsection A. In subsection B, we give the main idea and steps of the RWE method that are used to calculate the entropy values of the malware sample.

A. Entropy Concept

Shannon [1] introduced the concept of entropy in information theory to measure the degree of randomness in a data set. The general formula for Shannon entropy is given by

$$H(X)= -\sum_{x \in \Sigma} p(x) \log p(x) \qquad (1)$$

where

- X is a discrete random variable and has values belonging to the alphabet Σ,

- Σ is the alphabetic domain of the malware sample, and

- $p(x)$ is the probability distribution of the value x and has a value belonging to the range [0, 1].

In information theory, it is essential to recognize that more relevant information is present in the data when the entropy value is higher than when it is lower. This means that a higher entropy value denotes more randomness and useful, unpredictable information.

B. Running Window Entropy Method

Given a malware sample D of size n as $D=(d_1, d_2, d_3, \dots , d_n)$. The RWE algorithm, is a method based on dividing sample D as continuous overlap windows, each window of size w. A window of size w that starts at index i in the data D represents as follows.

$$W_i =(d_i, d_{i+1}, d_{i+2}, \dots , d_{i+w-1}), \qquad (2)$$

where $1 \leq i \leq n-w+1$.

Since the malware sample represents a sequence of bytes, each byte ranges from 0 to 255. Therefore, the entropy for W_i can be calculated as follows:

$$H_i=H(W_i)= -\sum_{0 \leq k \leq 255} p(k) \log p(k) \qquad (3)$$

where $p(k)$ is the probability of byte k within W_i and is equal to the total number of the byte k (symbol) within W_i, t_k, to the size of the window; i.e. $p(k)=t_k/w$.

In the case of the byte, k, does not appear in the window W_i, then $t_k =0$ and the method ignores the log $p(k)$ value because the logarithm of zero value is undefined.

Therefore, the malware sample after applying the RWE algorithm represents a sequence of values.

$$H =(H_1, H_2, H_3, \dots , H_{n-w+1}) \qquad (4)$$

The algorithm uses two arrays:

- H is an array of size n-w+1 and the value of H_i represents the entropy value for the window number i, $1 \leq i \leq n-w+1$.

- t is an array of size 256 and the value of $t(j)$ represents the total number of the byte j in a certain window.

The RWE algorithm consists of n-w+1 iterations, $1 \leq i \leq n-w+1$, as follows:

Step 1: Initialize the array t with zero.

Step 2: Compute $t(j)$ for each symbol in the window W_i by incrementing $t(j)$ with 1, where $0 \leq j \leq w-1$.

Step 3: Calculate the entropy, *e*, of the window W_i using (3) if $t(j) \neq 0$ and $0 < j < 256$.

Step 4: Calculate $H_i=e/K$, where K=8.

The reason for taking the value of K equal to 8 is the values of (3) between 0 and 8.

III. IMPROVED RWE METHOD

In this section, we introduce two comments on the RWE algorithm, then modify the RWE algorithm.

The first comment on the RWE algorithm is that the window size was selected experimentally from 256 to 2048 as in [19]. No experimental studies have addressed the effect of window size when w<256 or w>2048. What is the effect of these values of w on the RWE algorithm? Does the same behavior occur if we start from a window size equal to 4?

The second comment on the RWE algorithm is that when the size of window is less than 256, why do we take the summation of (3) from 0 to 255? Can we propose a fast method to calculate H_i?

For the second comment, we propose a modification on RWE algorithm as follows. If the value of w is less than 256, then we can compute (3) as follows.

$$H_i=H(W_i)= -\sum_{k \in W_i} p(k) \log p(k) \qquad (5)$$

The difference between (3) and (5) is the boundaries of the summation that are taken over the term p(k) log p(k).

The following steps computes the value of H_i as follows.

- Compute t(j) for each symbol in the window W_i by increment t(j) with 1, where $1 \leq j \leq w$.

- For each symbol (byte) in the window W_i do the following: if t(j) $\neq 0$ then update the value of the entropy, *e*, for the j-th symbol of window W_i and set t(j) equal to 0.

The reason for setting t(j)=0 after updating the entropy is that the symbol (byte) j may exist many times in the window W_i. Setting the value of t(j)=0, will remove the step of initializing the array t for each new iteration.

The steps of the modified window entropy method, MRWE, are given in Algorithm 1.

Algorithm 1: Modified Running Window Entropy (MRWE)

Input: Malware sample D of size n, window size w, K=8

1.   If w<256 then
2.   Initialize t with 0
3.   For i=1 to n-w+1 do
4.   For j=0 to w-1 do
5. $t(d_{i+j}) = t(d_{i+j})+1$
6.   End for
7.   e=0
8.   For j=0 to w-1 do
9.   If $t(d_{i+j}) \neq 0$ then
10. $e=e-(t(d_{i+j})/w*\log(t(d_{i+j})/w))$
11. $t(d_{i+j})=0$
12.   End if
13.   End for
14.   H(i)=e/K
15.   End for
16.   Else
17.   For i=1 to n-w+1 do
18.   For j=0 to w-1 do
19. $t(d_{i+j}) = t(d_{i+j})+1$
20.   End for
21.   e=0
22.   For j=0 to 256 do
23.   If t(j)$\neq 0$ then
24. $e=e-(t(j)/w*\log(t(j)/w))$
25.   End if
26.   End for
27.   H(i)=e/K
28.   End for
29.   End if

Output: Entropy values H=($H_1,H_2,...,H_{n-w+1}$)

Note that the first comment will be discussed in the experimental section.

IV. PARALLELIZING MRWE ALGORITHM

In this section, the parallelization of the MRWE algorithm (similarly RWE algorithm) on a parallel shared memory model is discussed. The parallel model consists of multi-

processors/multi-threads that can be communicate via a global memory.

The idea of parallelizing MRWE, PMRWE, is based on dividing the input array D into t subarrays. Each subarray, $D_i=(d_{(i-1)\alpha+1}, d_{(i-1)\alpha+2}, d_{(i-1)\alpha+3},..., d_{i\alpha})$, consists of α elements approximately, where $\alpha= (n-w+1)/t$ and $1 \leq i \leq n/t$. The value of numerator of α represents the number of windows in D. Then each thread, t_i, works on the subarray D_i to compute the entropy of this part. Each thread generates α entropy values, each value represents the entropy value for a window in D_i.

All the threads work on their subarray simultaneously. This means that no shared data between the threads. The complete pseudocode for PMRWE algorithm is given in Algorithm 2.

Algorithm 2: Parallel MRWE (PMRWE)

Input: Malware sample D of size n, window size w, K=8, and t threads.

1. $\alpha= (n-w+1)/t$
2.   If w<256 then
3.   Initialize t with 0
4.   For b=1 to t Do Parallel
5.   For i=1 to α do
6.   For j=0 to w-1 do
7. $t(d_{(b-1)\alpha+i+j}) = t(d_{(b-1)\alpha+i+j})+1$
8.   End for
9.   e=0
10.   For j=0 to w-1 do
11.   If $t(d_{(b-1)\alpha+i+j}) \neq 0$ then
12. $e=e-(t(d_{(b-1)\alpha+i+j})/w*\log(t(d_{(b-1)\alpha+i+j})/w))$
13. $t(d_{(b-1)\alpha+i+j})=0$
14.   End if
15.   End for
16.   H((b-1)α+i)=e/K
17.   End for
18.   End for parallel
19.   Else
20.   For b=1 to t Do Parallel
21.   For i=1 to n-w+1 do
22.   For j=0 to w-1 do
23. $t(d_{(b-1)\alpha+i+j}) = t(d_{(b-1)\alpha+i+j})+1$
24.   End for
25.   e=0
26.   For j=0 to 256 do
27.   If t(j)$\neq 0$ then
28. $e=e-(t(j)/w*\log(t(j)/w))$
29.   End if
30.   End for
31.   H(i)=e/K
32.   End for
33.   End for parallel

Output: Entropy values H=($H_1,H_2,...,H_{n-w+1}$)

V. EXPERIMENTAL STUDIES

The aim of this section is to study experimentally all proposed algorithms, sequential and parallel, and compare them with the original algorithm. The section consists of three

subsections. In the first subsection, we describe briefly the platform specifications and data set used in the implementation. The sequential and parallel comparisons are providing in the second and third subsections, respectively.

A. Platform Specifications and Data

All algorithms, RWE, MRWE, PRWE, and PMRWE, have been implemented using the programming language Python. The Python code for the RWE algorithm exist in [17]. All methods run on a machine of type Intel Core i7 with 8 logical processors speeds 3.1 GHz. The machine is able to run eight threads concurrently. The machine worked under the Windows operating system.

For sequential comparison, the running time of each sequential algorithm is measured by fixing n and w first. Then, generate a malware sample of size n and run the algorithms ten times on the malware sample. This process is repeated 20 times for different malware samples. Finally, the average time for all instances, i.e., the average of 200 runs, is calculated. The running time is measured in seconds.

The data sizes of malware samples are 1k, 2k, 4k, 8k, 16k, and 32k, whereas the window size is w=4, 8, 16, 32, …., and n/2.

For parallel comparison, the number of threads used in the comparison are 2, 4, and 8. The data sizes for malware samples are ½ MB, 1 MB, 2 MB, 4 MB, and 8 MB. The value of w is equal to w_{min}, where w_{min} is the size of window that minimize MRWE algorithm. The value of w_{min} is calculated experimentally in the second subsection.

B. Sequential Comparison

In this subsection, we study the two algorithms, RWE and MRWE, experimentally for two goals. The first goal is to answer the first comment mentioned in the previous section: what is the effect of changing the value of the window, w, on the RWE and MRWE? The second goal is: which value of w leads to minimal time for the method?

The results of running the two methods are shown in Fig. 1. From the analysis of the subfigures in Fig. 1, the behaviors of the two methods is divided into three ranges based on w as follows.

Case 1: w in the range [4,32]. In this case, the following observation were made.

- The running time for the MRWE is less time than the RWE in the case of w=4, 8, 16, and 32 for all values of n.

- The difference between the two running times for MRWE and RWE decreases with increasing the value of w.

- The improvement percentages of MRWE compared to RWE are shown in Table I. The average percentage of improvements are 79%, 66%, 45%, and 20% for w=4, 8, 16, 32, respectively.

Case 2: w in the range [64,256[. In this case, the following observation were made.

- The running time for the RWE is less than the MRWE algorithm in the case of w=64 and 128 for all values of n.

- The difference between the two methods when w=64 is very small and approximately equal to 5%.

- When w=128, the RWE algorithm improves the MRWE algorithm by 25% on average.

Case 3: w in the range [256, n]. In this case, the two methods are equal because the two methods use the same strategy.

From the observations of the three cases, we conclude that the MRWE algorithm can be achieve the minimal time when the window size is small.

TABLE I. PERCENTAGE OF IMPROVEMENTS FOR MRWE

n	w			
	4	8	16	32
1k	79.49%	66.14%	44.95%	20.05%
2k	79.19%	66.79%	45.83%	19.57%
4k	79.86%	66.45%	45.84%	20.29%
8k	79.29%	65.77%	45.77%	20.02%
16k	79.75%	66.06%	45.75%	20.57%
32k	79.06%	65.40%	45.83%	19.52%

C. Parallel Comparison

The results of running the two parallel algorithms, PRWE and PMRWE, on a multicore system using 2, 4, and 8 threads are shown in Fig. 2. The results show that the running time for PMRWE algorithm outperforms the PRWE algorithm when w_{min}=4. For example, the running times for PRWE and PMRWE algorithms are 39 and 17.6 seconds, respectively, when n=1 MB and t=2; see Fig. 2(a). From the experimental results, the percentage of improvements for the PMRWE algorithm over the PRWE algorithm using threads two, four and eight are 79.3%, 77.2%, and 77.8%, respectively, on average; see Table II.

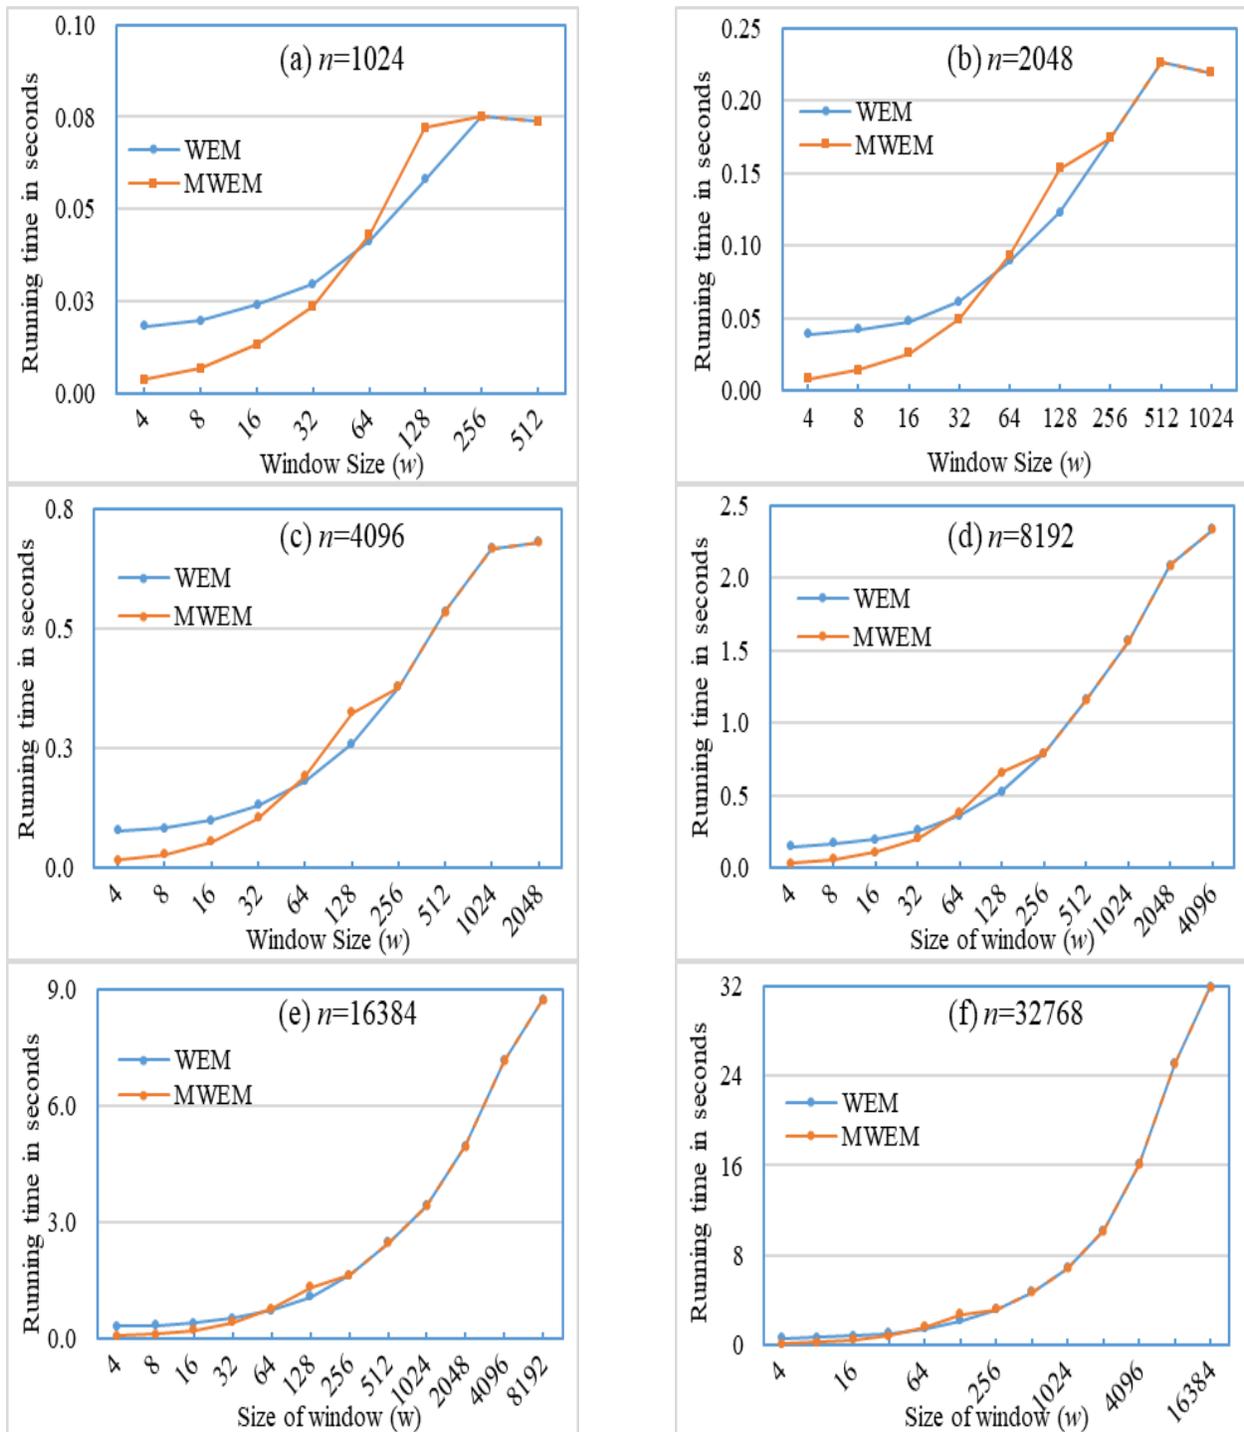
Also, we can compute the speed up of the PMRWE algorithm by computing the ratio between the running time of MRWE algorithm and PMRWE algorithm. The results of speed up of PMRWE algorithm is given in Fig. 3. The value of speed up when t=2 is linear and this value increase to be super-linear speed up when t=4 and 8. The increasing in the speed up came from the size of file is divided into small segment when t>2.


Fig. 1.   Running Time Comparison between RWE and MRWE Algorithms.

Fig. 3.   Speed up of PMRWE Algorithm.

VI. CONCLUSION

Malware analysis is important to study malicious software's functionality, purpose, origin, and potential impact. The running window entropy method is one of the methods used to find the entropy values of the malware sample. The main drawback of this method is the amount of time when the size of file is large. In this paper, two improved algorithms are given. The first improved algorithm is based on determining the best window size to minimize the running time of the window entropy method. The second improved algorithm is the parallelization of the improved sequential algorithm.

The experimental studies for different malware sizes and best window size show that the improved sequential and parallel methods outperform the original and the improved sequential methods, with 79% and 77% faster time, respectively.

There are many open questions related to improve the entropy method for malware analysis as follows: (1) How to use other high-performance systems, such as distributed system, GPU (graphic processing unit) and cloud, to speed up the execution time? (2) How to extend this work to other method for window entropy?

Abstract—**Flying Ad-hoc Network (FANET) is a type of Ad-hoc network on backbone of Unmanned Aerial Vehicle (UAV). These networks are used for providing communication services in case of natural disasters. Dynamic changes in link quality and mobility distort the Quality of Service (QoS) for routing in FANETs. This work proposed a Multi Criteria QoS Optimal Routing (MCQOR) guided by prediction of link quality and three-dimensional (3D) movement of FANET nodes. The network is clustered based on prediction of movement of nodes. Over the clustered topology, routing path is selected in reactive manner with joint optimization of packet delivery ratio, delay, and network overhead. In addition, cross layer feedback is used to reduce the packet generation rate and congestion in network. Through simulation analysis, the proposed routing protocol is found to have 3.8% higher packet delivery ratio, 26% lower delay and 14% lower network overhead compared to existing works.**

Keywords—Flying ad-hoc Network; multi-criteria QoS; unmanned aerial vehicles; joint optimization

I. INTRODUCTION

FANET is a kind of ad-hoc network formed by Unmanned Aerial Vehicles (UAV). These UAVs are small sized, light weight flying nodes with dynamic speed and altitude. The network is characterized by frequency disconnections of links and partitioning of network. High-speed three-dimensional mobility introduces frequent link distortions in the network [1]. Unreliable packet delivery and high end to end latency are very common in FANET networks. Most traditional routing protocols designed for Mobile Ad-hoc Networks (MANETs) and Vehicular Ad-hoc Networks (VANETs) does not address the challenges in FANET. Challenges like flying in three dimensions, high mobility, low node density, rapid topology changes, unstable links, network partitioning and limited resources makes it difficult to achieve higher QoS in FANET [2].

The major factors to be considered in designing routing protocols for FANET are high mobility, unstable links, and low energy capacity of nodes. UAV nodes have greater mobility ranging from 30 to 460km/hour [3]. The higher mobility creates low link quality. Frequent link disconnections and network partitions increase route discovery and maintenance overhead [4]. The paths must be planned based on predicted positions of UAV to ensure higher packet delivery ratio and lower latency. Also packet collisions and congestion must be effectively controlled to ensure higher QoS. UAV nodes have limited energy and the routing

protocols must not drain the energy faster. Depleting the energy faster can create network partitions and reduce the reliability of the network. Most existing routing protocols for FANET (detailed in Section II) does not address all these factors of high mobility, unstable links, and low energy capacity of nodes in designing multi criteria QoS optimal routing paths. The joint optimization of multiple QoS criteria like delivery ratio, delay and network overhead has not been considered in most of the existing FANET routing protocols. This work addresses these problems.

This work proposes a multi criteria QoS optimal routing protocol for FANET. The network is clustered to accommodate dynamic topology and unstable links. The clustering is done based on prediction of three-dimensional mobility of nodes. Over the clustered topology, geographic routing with next relay selection based on joint optimization of multi criteria is done. Cross layer feedback of network dynamics is used to dynamically adjust the source rate of packet generation. By this way congestion is reduced in the network.

A. Following are the Novel Contributions of this Work

1) A novel clustering topology for FANET based on prediction of three-dimensional mobility of UAV nodes. Many existing works have been proposed for clustering in FANET based on current mobility. Different from it, this work proposes a clustering topology with joint consideration of density and predicted mobility. Nodes with higher stability based predicted mobility is selected as cluster heads and network is clustered based on them.

2) A novel geographic routing with next hop relay selection based on joint optimization of multi criteria QoS factors. Compared to links state based routing protocols, the proposed geographic routing has lower overhead. Relay selection in proposed work is based on QoS considering both delay and link reliability compared to distance based relay selection is existing geographic routing protocols.

3) A novel source rate control based on probability function of delay distribution to vary the packet flow on the routing path adaptive to traffic and application characteristics. By this packet loss due to congestion is reduced and reliability of the routing path is increased.

The paper is organized as follows. Section II presents the survey of exiting routing protocols for FANET. Section III presents the proposed multi criteria QoS optimal routing

protocol for FANET. Section IV presents the results of proposed routing protocol and its comparison to existing routing protocols. Section V presents the conclusion and scope of future research.

II. RELATED WORK

Lin et al. [5] proposed a shortest path routing algorithm based on grid position for FANET. Instead of Euclidean Distance, logical grid distance is used in route computation which is less sensitive to high mobility of UAV nodes. Adjacency relationship is constructed automatically, and Dijkstra's shortest path algorithm is used to construct the routing paths. Routing paths are further optimized using a region reconstruction strategy. The route selection considered link stability as the only criteria to be maximized. Xie et al. [6] proposed a new form of optimized link state routing protocol to handle dynamic topology changes in FANET. Link expiration time was predicted based on current position. The next hops were selected with higher link expiration time and higher residual energy. The network overhead to maintain the OLSR routing table is higher in this approach. Hou et al. [7] constructed OLSR routing table with trajectory prediction information of UAV. The optimal route is selected from OLSR using Q-learning. The approach considered link stability as the only criteria in route selection. Yang et al. [8] proposed a routing protocol for FANET using Q-learning and fuzzy logic. Routing path selection is based on fuzzy logic decision on both link and path performances.

Link parameters considered were transmission rate, energy state and flight status between neighbor UAV's. Path parameters considered were hop count and packet delivery time. The routing was done with objective of maximizing the lifetime. Oubbati et al. [9] proposed a route discovery mechanism for FANET. The routing paths with balanced energy consumption, link breakage prediction and higher connectivity degree are found. Packet delay and reliability were not considered in route discovery process. Sharma et al. [10] proposed a Distributed Priority Tree-based Routing protocol (DPTR) for FANET. The routing protocol addresses the problem of network partitioning and organizes the nodes in form of distributed Red-black tree. The appropriate node and channel for relaying are selected depending on application requirement. The approach considered link stability as the only parameters in routing decision. Usman et al. [11] proposed a forwarding protocol for FANET with next hop selection based on lifetime improvement.

A forwarding zone is created to spot the front relative nodes through forwarding angle and effective approximate node is selected with higher energy state. Packet reliability and delay were not considered in forwarding decision. Zafar et al. [12] proposed a multi cluster FANET topology to reduce the communication cost and optimize the network performance. Within clusters, transmission slot scheduling is done to reduce the packet collision and improve energy utilization. Authors considered only scalable network as the criteria in clustering decision and did not focus on routing protocols. Mariyappan et al. [13] proposed an energy aware routing protocol for FANET with Residual Energy Minimum (REM), Total Residual Energy (TRE), and Hop count as a

routing cost metric. The next hop is selected based the routing metric, so that routing path is energy balanced. Packet reliability, congestion and delay were not considered in the routing decision. Khan et al. [14] explored various topology-based routing protocols for FANET. Protocols were analyzed in terms of throughput, end-to-end delay, and network load. Authors found that zonal routing protocol were found to have lower delay and better throughput compared to other protocols.

But study did not consider various mobility models. Zhang et al. [15] proposed a three-dimensional Q-learning routing protocol to improve QoS and guarantee packet delivery ratio. The proposed solution has two important functionalities: link state prediction and routing decision. Three-dimensional mobile pattern is predicted to calculate link lifetime. Routing path is constructed with higher link lifetime. Energy, congestion, and packet delay etc. were not considered in the routing decision. Usman et al. [16] proposed a reliable link adaptive position-based routing protocol for FANET. The routing is based on multiple criteria of node speed, signal strength, energy, and geographic distance towards destination. The geographic distance is calculated along the forwarding angle. The relay node is optimal in terms of energy, relative speed and connectivity duration is selected and packets are forwarded. The forwarding angle is decided at source and there is no deviation in next hop. This results in sub optimal routes. Choi et al. [17] proposed a multi hop geo location-based routing protocol for FANETs. The method uses the geo-location of neighbors and finds the next hop to destination based only neighbor information. Though the method has low overhead and robustness to dynamic network topology, it does not include other factors like stability, congestion, energy availability in the path. Li et al. [18] proposed a preemptive protocol based on link stability.

Authors introduced a stability metric based on link quality, safety degree and mobility predictor factor. Multiple robust link disjoint paths are computed, and route maintenance is triggered when link is broken. Routing is done by selecting the most reliable path. The overhead for route maintenance is high and the method is suitable only for limited mobility scenarios. Hong et al. [19] proposed a topology change aware routing protocol. The topology changes are monitored continuously, and route is constructed based on the mobility mode.

Among the multiple routing modes, the best one is selected based on the predicted topology changes. The thresholds used in topology change monitoring in this approach is not generic and applies only for certain mobility models. Pu et al. [20] proposed link state routing protocol adaptive to link quality and traffic load. Link quality is estimated using statistical information of received signal strength. Traffic load is estimated using MAC layer channel contention information. The path with higher reliability and light load is selected for routing. The maintenance overhead is high in this approach. Zhang et al. [21] proposed a deep-reinforcement-learning-based geographical routing protocol based on link stability and energy prediction. The next hop selection decision was done using reinforcement learning. The reward for reinforcement learning was on maximization of packet delivery ratio, without consideration for factors like delay, overhead

reduction etc. Souza et al. [22] used fuzzy logic to improve the route discovery process in FANET. The routing decision is based on received signal strength indicator and mobility level. The factors like load on routing path, delay etc. was not considered in next hop selection in this work. He et al. [23] proposed an opportunistic routing protocol with distributed decision making. Each node exchanges aeronautical data with other nodes. From this, each node calculates the transfer probabilities to different neighbors jointly considering the position of neighbors and the destination node. Each node selects the neighbors with higher transfer probabilities as the next hop relay nodes for routing. The overhead in exchange of aeronautical data is higher in this approach. Xinchen et al. [24] used Q-learning for routing decision in FANETs. Nodes

exchange routing metric information with neighbors. Based on this information, reward function which maximizes reliability is triggered to select the next hop node. Authors considered reliability as the only metric in the routing decision.

From the survey, most of the FANET routing protocols are OLSR based with high maintenance overhead. Very few opportunistic routing protocols are available but their relay selection policies are very limited and they don't consider multi criteria QoS factors in relay selection. Also after the route path selected, there is no continuous adaptation of packet rate based on application/network dynamics. Based on these observations, this work proposes a routing protocol for FANET.

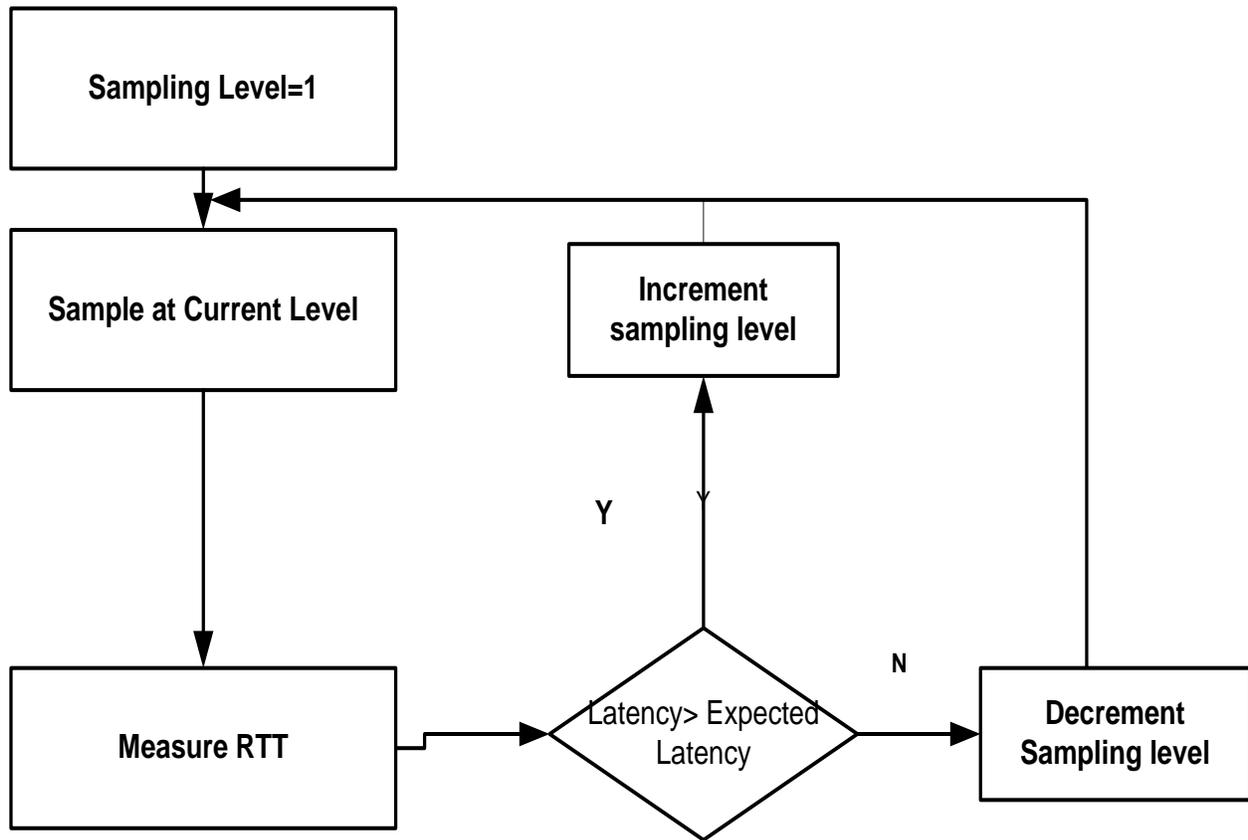

Fig. 2.   Source Rate Control.

III.   MULTI CRITERIA QOS OPTIMAL ROUTING

The proposed Multi Criteria QoS Optimal Routing (MCQOR) is constructed on clustering topology. The functionality of the proposed solution is given in Fig. 1. The proposed solution has three stages: clustering, routing, and source rate control.

The FANET network is first clustered using combined mobility and density-based clustering. The stable nodes in the clusters are selected and a routing backbone optimally connecting these stable nodes is constructed using Steiner Tree algorithm in 3D space. Geographic routing with next hop selection of nodes near the Steiner tree satisfying the multi criteria QoS factors is used for routing from source node to destination. Cross layer feedback from physical layer is collected at application layer to adopt the source data generation rate depending on traffic dynamics. Each of the stages of the proposed solution is detailed in below subsections.

A. Clustering

The FANET network is clustered by jointly considering mobility and density. For any two nodes i and , the mobility factor is calculated as:

$$M_{ij} = e^{1-\frac{V_r}{2V_{max}}}$$ (1)

Where V_r is the relative speed between nodes i and j, calculated over the period of time Δt as:

$$V_r = \frac{d_t - d_{t-\Delta t}}{\Delta t}$$ (2)

d_t and $d_{t-\Delta t}$ are the distance between the nodes observed in time between t and Δt. V_{max} is the maximum speed a node can move.

The distance between nodes is calculated in Euclidean 3D space as:

$$d_t = \sqrt{(x_i(t) - x_j(t))^2 + (y_i(t) - y(t))^2 + (z_i(t) - z(t))^2}$$ (3)

Higher the value of M_{ij}, the link between nodes i and j is highly stable.

M_{ij} is calculated between each pair of nodes in a communication radius of R and when the nodes having consistent M_{ij} are grouped as cluster. The R value is selected based on the density of nodes within the network area. It is calculated as:

$$R = T \times \frac{N_{CH}}{M}$$ (4)

Where T is total area, N_{CH} is the maximum number of clusters and M is the total number of UAV nodes. Once cluster are formed, the UAV nodes with consistent M_{ij} values to all other nodes are selected as stable nodes in the cluster.

Existing Link state-based routing protocols for FANETs have higher maintenance overhead but link state-based routing protocol provide reduced route discovery time compared to

ad-hoc search. This work adopts link state-based routing with a concept of routing backbone establishment with comparatively lower maintenance overhead. This work uses a graph theory concept called Steiner minimal tree to construct the routing backbone.

A Steiner Minimal Tree (SMT) is created with S points referred as Steiner points such that cost of N ∪ S is minimal. A weighted graph with vertex corresponding to each of N stable nodes and weight between the vertexes is set as the Received Signal Strength Index (RSSI) value between them is constructed and Steiner minimal is constructed for this graph.

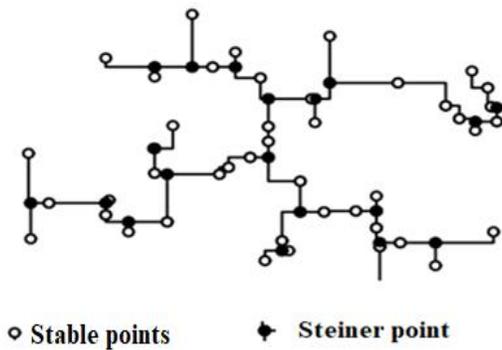
A sample SMT in 2D space is shown in Fig. 3. In this, the hollow points are the vertexes, and the dotted points are the corresponding Steiner Points. The line connecting the Steiner points is the Steiner minimal tree. The tree is almost near to each of vertexes.


Fig. 3. Steiner Point in a Graph.

Since the stable points are in 3D space, this work adopts improved smith algorithm [25]. With stable nodes given as input, Steiner minimal tree is constructed optimally connecting the stable nodes.

B. Routing

Geographic routing with next hop selection based on multi criteria QoS factor over the Steiner minimal tree is proposed for routing the packets.

The QoS (Q) is calculated as...

$$Q = \alpha \times DF + (1 - \alpha) \times RF \tag{5}$$

Where DF is the Delay Factor. It is calculated in terms number of packets in queue (np_i) and Transmission failure Probability (P_i) and Packet transmission Time (pt_i) over the link i as

$$DF = \sum_{i=1}^{n}\{(np_i + 1).\left(\frac{1}{1-P_i}\right).pt_i\} \tag{6}$$

In terms of throughput, pt_i is calculated as

$$pt_i = \frac{L}{(1-R_i)B_i} \tag{7}$$

Where B_i is the Channel Bandwidth for link i under the influence of interference and L is the packet size. The net bandwidth usage is expressed as $(1 - R_i)$.

Reliability Factor (RF) is calculated in terms of exponential moving average of past delivery ratio (ψ) and Recent Delivery Ratio (DR).

$$RF = \alpha * \psi + (1 - \alpha) * DR \tag{8}$$

α is the weight factor with value in range of 0 to1.

Any node which wants to forward the packet to next hop selects the nodes close to Steiner tree with highest value for Q and uses that node as the relay node for packet forwarding.

C. Source Rate Control

Though routing paths with better QoS are selected, the QoS can be affected due to congestion. This work adopts source rate control based on cross layer feedback to reduce congestion on the routing path.

On routing path, congestion is measured in terms of round trip delay. It is calculated in terms of probability mass function of delay distribution between nodes A and B as

$$RTT = \begin{cases} \sum_{i=0}^{\infty} f_i(a).f_i(b) , x = 0 \\ \sum_{i=0}^{\infty} f_i(a).f_{2x+i}(b) + \sum_{i=0}^{\infty} f_i(b).f_{2x+i}(a), x > 0 \end{cases} \tag{9}$$

$f_i(a)$ is the probability mass function of delay in direction of A to B and $f_i(b)$ is the probability mass function of delay indirection of B to A.

The data sampling level is set in discrete interval from lowest to highest. The flow of source rate control is given in Fig. 2. Initially the UAV node operates in the default sampling level. RTT is measured periodically, and it is compared against expected latency. If the latency is higher than expected latency, the sampling level is decreased; this reduces the number of packets transmitted from source thereby attempting to reduce congestion. If the latency is lower than expected latency, then sampling level is increased, thereby increasing the number of packets in the network. Thus, source control rate is adaptive to traffic dynamics of the network.

IV. RESULTS

NS2 platform was used for simulation of the proposed solution. Simulation was conducted for configuration parameters given in Table I.

TABLE I. SIMULATION CONFIGURATION

Parameters	Values
Number of UAV	50 to 250
Communication range	100m
Area of simulation	1000m*1000m
Node distribution	Random distribution
Simulation time	30 minutes
Interface Queue Length	50
MAC	802.11
Number of Data collection point	1
UAV Speed	20-50 m/sec

Comparison of proposed solution's performance is done against Q-learning based QoS routing proposed by Xinchen et al. [24], link stability-based routing proposed by Zhang et al. [21], trajectory aided OLSR routing proposed by Hou et al. [7].

The simulation was conducted to measure the QoS parameters and compare the solutions in terms of their QoS performance.

Performance is measured and compared in terms of (i) packet delivery ratio (ii) delay (iii) throughput and (iv) network overhead. The QoS parameters were measured in two conditions of varying the number of UAV and varying the speed. By varying the number of UAV, QoS performance in relation to density of UAV in the network was compared. By varying the speed, QoS performance in relation to mobility of UAV was compared.

The packet delivery ratio is measured by varying the number of UAV and the result is given in Table II.

As in Fig. 4, in the proposed solution, the average packet delivery is 6.8% higher compared to Hou et al., 3.8% higher compared to Zhang et al. and 4.2% higher compared to Xinchen et al. The packet delivery ratio has increased in proposed solution due to three factors of selection of stable routing backbone, selection of multi criteria QoS based next hop and source rate control. These three factors have reduction the effective packet loss.

Varying the number of UE, the average delay is measured and given in Table III.

TABLE II.   COMPARISON OF PACKET DELIVERY RATIO

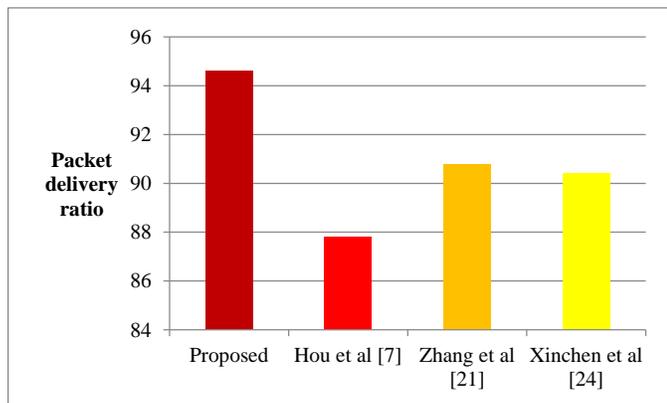
Number of UAV	Proposed	Hou et al [7]	Zhang et al [21]	Xinchen et al [24]
50	93	86	89	88
100	94	87	90	90
150	95	88	91	91
200	95	89	92	91
250	96	89	92	92
Average	94.6	87.8	90.8	90.4


Fig. 4.   Comparison of Packet Delivery Ratio.

TABLE III.   COMPARISON OF DELAY

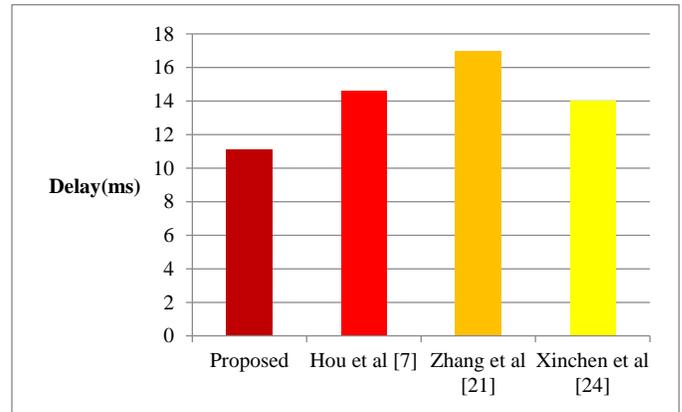
Number of UAV	Proposed	Hou et al [7]	Zhang et al [21]	Xinchen et al [24]
50	8	10	12	11
100	10	12	14	12
150	11	14	17	14
200	12.5	17	20	16
250	14	20	22	17
Average	11.1	14.6	17	14


Fig. 5.   Comparison of Delay.

As shown in Fig. 5, in the proposed solution, the average delay is 31% lower compared to Hou et al., 53% lower compared to Zhang et al. and 26% lower compared to Xinchen et al. The delay in proposed solution has reduced due to selection of Steiner minimal tree constructed based on delay minimization in the proposed solution.

Varying the number of UAV, throughput is measured and given in Table IV.

As shown in Fig. 6, the throughput is almost same across the solutions. Throughput has not increased much in proposed solution due to source rate control. Source rate control effectively controls the congestion in network but due is aggressive control also reduces the throughput marginally.

Network overhead apart from data payloads packets is measured varying the number of UAV and the result is given in Table V.

TABLE IV.   COMPARISON OF THROUGHPUT

Number of UAV	Proposed	Hou et al [7]	Zhang et al [21]	Xinchen et al [24]
50	197	185	182	188
100	206	193	191	195
150	211	201	194	204
200	220	209	196	210
250	226	211	197	215
Average	212	199.8	192	202.4

Fig. 6.   Comparison of Throughput.

TABLE V.   COMPARISON OF NETWORK OVERHEAD

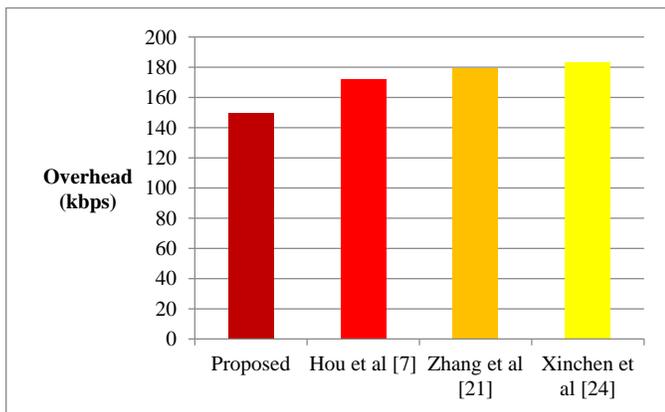
Number of UAV	Proposed	Hou et al [7]	Zhang et al [21]	Xinchen et al [24]
50	130	145	150	147
100	140	164	167	170
150	151	175	187	190
200	160	184	194	198
250	168	192	198	210
Average	149.8	172	179.2	183


Fig. 7.   Comparison of Overhead.

As shown in Fig. 7, the network overhead in proposed solution is 14% lower compared to Hou et al., 19.6% lower compared to Zhang et al., 22% lower compared to Xinchen et al. The network overhead has reduced due to construction of routing backbone using Steiner minimal tree which involves only stable nodes.

The packet delivery ratio is measured by varying the speed of UAV and the result is given in Fig. 8.

Fig. 8.   Packet Delivery Ratio vs. Speed.

As shown in Fig. 8, packet delivery ratio drops with increase in speed of UAV. But even in drop, the packet delivery ratio is higher in proposed solution compared to existing works.

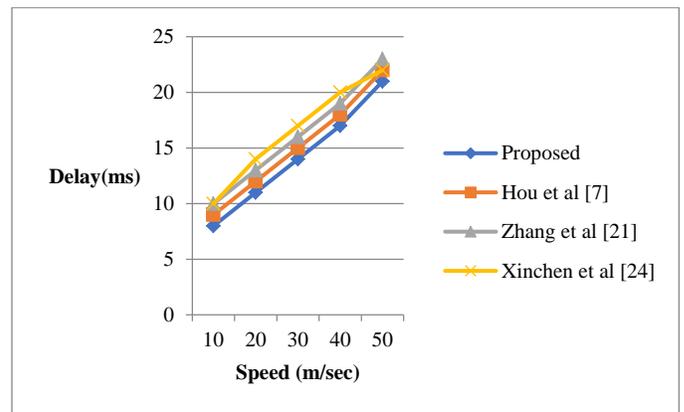
The delay is measured by varying the speed of UAV and the result is given in Fig. 9.


Fig. 9.   Comparison of Delay.

With increase in speed delay increases in all existing works. But in comparison to existing works, the delay increases at slower rate in proposed solution.

The delay is lower due to use of Steiner Minimal Tree-based routing in proposed solution.

Network overhead is measured by varying the speed and the result is given in Fig. 10.

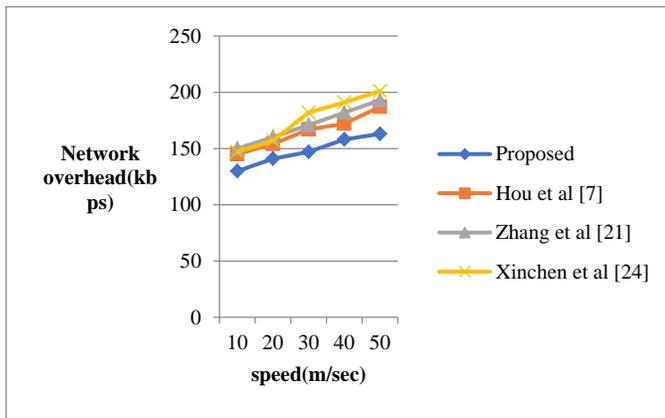
The network overhead increases with speed of UAV but the overhead is lower in proposed solution compared to existing works. Overhead has reduced in proposed solution, due to use of less maintenance overhead.


Fig. 10. Comparison of Network Overhead.

V. DISCUSSION AND RESULTS

The proposed solution performed better in all QoS metrics of packet delivery ratio, delay and throughput. Packet delivery has increased in proposed solution due to selection of more stable paths for routing and source rate control adaptable to network/application dynamics. Though Xinchen et al. used Q-learning to select the stable paths, it required high overhead to maintain the paths. Also the packet flow on the paths was not controlled based on application/network characteristics. Zhang et al. used OLSR based proactive routing protocol. Link stability was given more importance in route construction. But without packet rate control, congestion increases and affects the path reliability. Hou et al. solution was also based on OLSR. Similar to Zhang et al., the solution proposed by Hou et al. did not consider reliability after path establishment.

Delay has reduced in proposed solution due to use of geographic routing. Though Hou et al. and Zhang et al. used shorted OLSR path, due to node movement, the path has to be reconstructed. This created more packets in the network and as result, delay increased. The network overhead has increased in Hou et al. and Zhang et al. due to more route maintenance packets needed to keep OLSR link state fresh. Since the proposed solution used opportunistic routing, the overhead is lower in proposed solution.

The QoS performance was better in proposed solution compared to existing works even in higher speed. At higher speed, the link state maintenance overhead is higher in Hou et al. and Zhang et al. Due to this, number of packets increased in the network, creating congestion and reducing the reliability of the network. Proposed solution has source rate control mechanism to reduce the packet flow during congestion times, but this mechanism was lacking in the existing works.

VI. CONCLUSION

A Multi Criteria QoS Optimal Routing (MCQOR) for FANET is proposed in this work. The proposed solution has three stages of clustering, routing, and source rate control. The FANET network is clustered using combined mobility and density information. Over the clustered network, routing backbone is constructed using Steiner Minimal Tree (SMT) and Multi Criteria QoS based routing is done over the Steiner routing backbone. Due to stability consideration in clustering

and routing, the packet reliability has increased in the network. The proposed solution achieves 3.8% higher packet delivery ratio, 26% lower delay and 14% lower network overhead compared to existing works. Though QoS factors have been considered in this work, energy minimization and life time improvement has not been considered in this work. Life time maximization with joint consideration for QoS is in scope of future work.

Abstract—**Artificial neural networks are mathematical models of artificial intelligence that intend to reproduce the behavior of the human brain and whose main objective is the construction of systems that are capable of demonstrating certain intelligent behavior. The purpose of the investigation is to determine the influence of the use of Information and Communication Technologies (ICTs) in the digital culture in the learning process of university students in Peru and Bolivia in the context of the Coronavirus – COVID 19 sanitary emergency, through the application of artificial neural network models. The investigation has a quantitative focus, the applied type, with a correlational level and a non-experimental design. Data was recollected by means of a digital questionnaire, applied to students of two universities. The population is composed of 3980 students of the Universidad Privada Domingo Savio (UPDS, Tarija, Bolivia) and 1506 of the Universidad Nacional de Moquegua (UNAM, Moquegua, Peru). The sample consists of 496 students. The hypothetical-deductive and the artificial intelligence methods were used. It was determined that the ability to install software and data protection programs, the use of mobile devices for academic purposes and the command of specialized software are the most influential factors in the digital culture of the students at UNAM and UPDS.**

I. INTRODUCTION

In [1], the complexity of the human brain is amazing, consisting of hundreds of billions of neurons with billions of connections that make the neural function of the brain very complex. In [2], the artificial neural networks are systems that simulate the properties that are observed in the biological diversity through mathematical models that are recreated by artificial mechanisms. Artificial neural networks are information processing systems that are inspired by the behavior of biological neural networks [3], [4], [5]. The artificial neural networks are mathematical models that are inspired by the biological neural systems, like the human brain, and can be considered as a data processing technique that maps, or relates, a certain type of entry information flow with an exit processing flow. There are variations of artificial neural networks to perform classification tasks, pattern recognition and prediction [6]. Artificial neural networks stand out as an automatic learning technique, due to their ease of use and comprehension compared to statistical methods, and their good performance in different automatic learning tasks [7][8].

ICTs include any communication device, such as computers, telephones, television, radio, etc., as well as services and software that work with devices, such as e-mail, software used for management, learning, videoconferencing, and so on [9]. The use of ICTs enhances student protagonism [10], keeping them up to date with technological development to maintain their sustainability in time [11].

Digital culture is the influence of technology on the behavior of people [12]. In [13], digital culture can be identified as a component of the actual digital transformation and as an epistemological obstacle in the sociological analysis of the same phenomenon. Digital culture are the abilities, knowledge, creativity and attitudes necessary to use in digital media in order to learn and comprehend in a knowledge society [14].

This article demonstrates the application of a model of an artificial neural network to explain the use of ICTs in the digital culture of students at two universities in Peru and Bolivia. The artificial neural networks that were used have an input layer of 11 units, a hidden layer of 5 units and an output layer of 1 unit, as well as training and test or validation data of the neural models. The artificial neural networks demonstrate that the dimensions that have the greatest influence in the digital culture are the ability to install software and data protection software, the command of mobile devices for academic purposes and the command of specialized software, according to the models of UNAM and UPDS.

The content of the article is organized as follows: Section II gives a short review of the state of the art in ICT, digital culture and artificial neural networks; Section III describes the methodology used in the investigation; Section IV describes and analyses the results that were obtained; Section V discusses the results; Section VI describes the final conclusions of the investigation; finally, the description of the future work that could be implemented to improve the obtained results.

II. RELATED WORK

In [14] aspects of the digital culture of student in the Faculty of Humanities and Pedagogy are described; general characteristics like cyber culture, the level of use of software, the use of technological devices and their digital abilities. [15], revises and synthesizes the expectations of employers in terms of digital abilities of graduates, the steps and measures taken by institutions of higher education to prepare students and to take advantage of their motivation to be more competitive and satisfy the needs of employability in the Fourth Industrial Revolution, supplying information about the digital alphabetization abilities that are required of young graduates, their expectations, and how digital alphabetization can be developed in institutions.

For [16], the ICTs have become a part of everyday life of people in business, entertainment, education and many other areas of human activity. Students have just begun to learn and accept new ideas, show a mature creativity, develop critical thinking and the ability to make decisions. In education, the successful integration of ICTs in learning and teaching depends on the attitudes of the teachers and their capacity to use the technology of communication not only competently but also with ability and imagination. According to [17], the access of ICTs in the world has increased, but there is still a gap between the necessity of ICT infrastructure and its availability.

According to [18], the objective of the investigation was to connect the ICTs with the distribution processes and the use of knowledge in the institutions of higher education. There was evidence that the profiles of the universities to implement knowledge management are focused on two components: the distribution and the use of knowledge. Among the more relevant results, it can be highlighted those two main profiles were found that characterize the process of knowledge management using ICTs. The strength of the first group lies in the component of investigation, which means it manages the promotion and diffusion of investigation in academic spaces. On the other hand, the second group's major strength lies in ICTs for the use of knowledge, which indicates that the universities in the second group focus their efforts on the management of ICTs as a means of knowledge management.

In the last decades, [19] artificial neural networks have gained significant attention in a part of the scientific community, as a technique that creates and combines multiple models of automatic learning to produce an optimal model that obtains the best results.

The use of neural networks is an area of growing interest, especially due to the availability of large quantities of information from multiple sources [20]. The algorithms of Artificial Intelligence (AI) have been used frequently to model complex functions for which the traditional mathematical methods no longer suffice. The artificial neural networks are one of the artificial intelligence methods that have the capacity to perform highly accurate simulations with potent learning algorithms and training capacities [21]. For [22], the neural network is an automatic learning algorithm. Neural networks help to simulate the functioning of the human brain [5].

III. METHODOLOGY

The investigation has a quantitative focus, the applied type, with a correlational level and a non-experimental design. The data were recollected through a digital questionnaire, implemented by means of the Google Forms tool, sent to students of two universities, one in Peru and the other in Bolivia. The population consisted of 3980 students of the Universidad Privada Domingo Savio in Bolivia and 1506 students of the Universidad Nacional de Moquegua in Peru. The sample consisted of 496 students (306 of the UPDS and 190 of the UNAM), for which the Stratified Random Sampling method was used. For the variables use of ICT and digital culture, questionnaires were used as the technique and a digital questionnaire as the instrument. The hypothetical-deductive method and artificial intelligence were applied.

The variables used in the investigation are the following:

1) Access to ICTs.
   a) Computer and communication resources.
   b) Command of Microsoft Office applications.
   c) Command of specialized software.
   d) Use of mobile devices for academic purposes.
   e) Use of computer accessories.
   f) Ability to install software and data protection programs.

2) Digital culture.
   a) Study habits in a virtual environment.
   b) Use of computer and communication resources in the learning process.
   c) Use of digital resources in the learning process.
   d) Command of video conferencing software.
   e) Frequency of use of computers and devices for academic and investigation purposes.
   f) Frequency of consulting virtual libraries and internet search engines.
   g) Frequency of use of social networks for academic purposes.

IV. RESULTS

A. Modeling, using an Neural Network

These are the processing results of the artificial neural networks for the Universidad Nacional de Moquegua and Universidad Privada Domingo Savio students.

The results of Table I demonstrate that the artificial neural networks used 11 units in the input layer, 5 in the hidden layer and 1 unit in the output layer. The standardized method was used as the rescaling method for the scale dependents to improve the training of the neural network. The hyperbolic tangent was used as the activation function of the hidden layers. Identity was used as the activation function of the unit of the output layer.

Fig. 1 shows the model of the artificial neural network for UNAM. The blue lines are the negative synaptic weights, and the gray lines are synaptic weights with positive values.

Valid		190	100.0%
Excluded		0	
Total		190	

In Table III, the neural network model for UPDS considered 70.9% of the data for training and 29.1% for testing and validation of the model.

TABLE III.   CASE PROCESSING SUMMARY - UPDS

Case Processing Summary		N	Percent
Sample	Training	217	70.9%
	Testing	89	29.1%
Valid		306	100.0%
Excluded		0	
Total		306	

Table IV represents the results of the training and testing process of the artificial neural network of the Universidad Nacional de Moquegua in Peru.

TABLE IV.   MODEL SUMMARY - UNAM

Training	Sum of Squares Error	14.533
	Relative Error	0.233
Testing	Sum of Squares Error	7.720
	Relative Error	0.271

Dependent Variable: Digital Culture

a. Error computations are based on the testing sample.

Table V shows the results of the training and testing process of the artificial neural network of the Universidad Privada Domingo Savio in Bolivia.

TABLE V.   MODEL SUMMARY - UPDS

Training	Sum of Squares Error	18.476
	Relative Error	0.171
Testing	Sum of Squares Error	10.615
	Relative Error	0.234

Dependent Variable: Digital Culture

a. Error computations are based on the testing sample.

Table VI shows, the importance of the independent variates is observed. This measurement indicates the size of the variation of the value that is predicted by the network for different values of the independent variates. The variates are ordered by importance, from major to minor, with the variates of Ability to install software and data protection programs, use of mobile devices for academic purposes and command of specialized software as the most important ones for the network to predict the digital culture for the UNAM and UPDS models.

A comparative table (Table VII) is presented to know the realities about the use of information and communication technologies in higher level educational entities, referenced with results in other research works: Universidad Católica Andrés Bello - Venezuela, Universidad de Extremadura-España, Universidad Privada Domingo Savio - Bolivia, Universidad Nacional de Moquegua-Peru and Universidad Nacional de Cordova - Argentina [23].

TABLE VI.   IMPORTANCE OF INDEPENDENT VARIABLES IN DIGITAL CULTURE

Independent variates	UNAM		UPDS	
	Importance	Normalized Importance	Importance	Normalized Importance
E2: Gender	0.025	8.0%	0.023	6.9%
E6: Marital status	0.050	15.8%	0.041	12.6%
D1: Computer and communication resources	0.071	22.2%	0.086	26.5%
D2: Command of Microsoft Office applications	0.039	12.4%	0.055	16.8%
D3: Command of specialized software	0.169	53.3%	0.103	31.6%
D4: Use of mobile devices for academic purposes	0.259	81.7%	0.287	88.2%
D5: Use of computer accessories	0.069	21.7%	0.080	24.6%
D6: Ability to install software and data protection programs	0.317	100.0%	0.325	100.0%

TABLE VII.   COMPARATIVE ANALYSIS

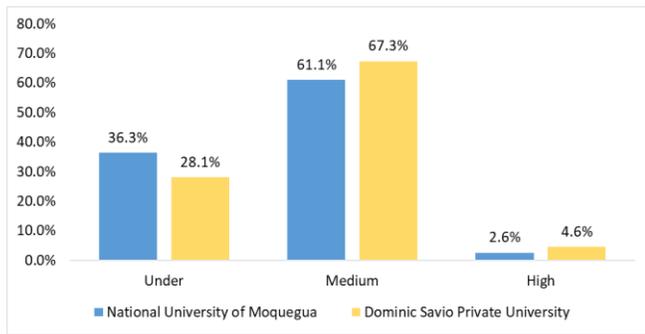
Comparison of results in the use of ICTs	Universidad Católica Andrés Bello - Venezuela	Universidad de Extremadura-España	Universidad Privada Domingo Savio- Bolivia	Universidad Nacional de Moquegua-Peru	Universidad Nacional de Cordova-Argentina
Computer resources - Technological infrastructure - They have a computer		100.0%	26.5%	22.2%	100.0%
Mastery of Microsoft office applications - digital content	57.4%	50.5%	16.8%	12.4%	
Mastery of specialized software	81.2%		31.6%	53.3%	
Mastery of mobile devices for academic purposes	85.9%	77.2%	88.2%	81.7%	89.2%
Ability to install software and data protection programs - users of information technology	43.5%		100.0%	100.0%	
Internet connection at home		69.3%			89.2%
Use of virtual platform	56.2%	68.3%			98.0%
Virtual platform	Moodle	Moodle con H5P	Moodle	Plataforma SIGEUN	Classroom y Moodle
Videoconferences	Modulo 7	Zoom -Teams	Plataforma Office 365	Zoom Office 365	Zoom o Google Meet


Fig. 3.   Access to ICT.

Fig. 3 shows that 36.3% of the Universidad Nacional de Moquegua students have a low level of access to ICTs, compared to 28.1% of the Universidad Privada Domingo Savio students. 67.3% of the Universidad Privada Domingo Savio students have medium access to ICTs, versus 61.1% of the Universidad Nacional de Moquegua students. 4.6% of the Universidad Privada Domingo Savio students have a high level of access to ICT, compared to 2.6% of the Universidad Nacional de Moquegua students.

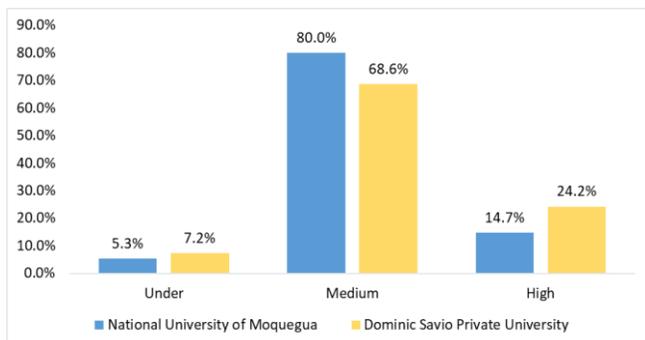
Fig. 4 shows that 5.3% of the Universidad Nacional de Moquegua students have a low level of digital culture, vs 7.2% of the Universidad Privada Domingo Savio students. 80% of the Universidad Nacional de Moquegua students show a medium level of digital culture vs 68.6% of the Universidad Privada Domingo Savio students. 24.2% of the Universidad Privada Domingo Savio students have a high level of digital culture vs 14.7% of the Universidad Nacional de Moquegua students.


Fig. 4.   Digital Culture.

V.   DISCUSSION

The main characteristic of the study was to perform a comparative analysis of the use of ICTs and its implication on the digital culture of the students in two countries with similar social and economic realities in order to analyze the behavioral pattern of the Universidad Privada Domingo Savio students in Bolivia and Universidad Nacional de Moquegua in Peru.

The advantage of the methodology that was applied is that an artificial neural network can obtain reliable results due to its tolerance to errors and because it is permissive to the intervention of all neurons; even when a part of the system is damaged, the total functioning is not affected as it learned

from the experience of the representative sample or from the training data. In this investigation, 11 units were identified at the entry level, 5 in the hidden layer and 1 in the output layer. They required previous training through the weight adjustment of the connections in order to find an effective solution to the problems of the weight values and elements of the input variates and output variates with numeric values.

The quality of the training data represented in Tables I, II, III, IV and V warrant the model of the adaptive learning pattern, considering that the test data suffice to generate meaningful results in the time applied to adjust the weights of the entry layers of all neurons and to validate the application of the neural networks.

The variates of ability to install software and data protection programs, use of mobile devices for academic purposes and command of specialized software predict the digital culture in each of the universities involved in the investigation, which are assumed to be a product of the digital disruption due to the use of digital platforms, advanced generations of mobile networks, the Internet of Things, cloud computing, artificial intelligence and even the digital economy, that have an effect on the teaching learning processes, which requires the construction of new models of ecosystems of education and ICTs, reason why the university authorities have to anticipate this context.

The low levels of access to ICTs in both universities, 36.3% at the Universidad Nacional de Moquegua and 28.1% at the Universidad Privada Domingo Savio are determined by the social and economic conditions of the students, on top of limited connectivity. The minimal level of intermediate access to ICT of 4.6% at the Universidad Privada Domingo Savio and 2.6% at the Universidad Nacional de Moquegua are a warning signal that an intervention of the state authorities is required to focus on the necessities and inequalities in order to diminish the vulnerability of the students and to educate and promote national development through educational policies that tend to achieve equality of opportunities.

Even if the medium level of digital culture of students at 80% and 68.6% for the Universidad Nacional de Moquegua and the Universidad Privada Domingo Savio respectively is favorable, a bigger investigation is needed to determine the positive of negative incidence in academic performance, as it can be observed that in the majority of cases, students access low quality information, or that social networks are used as a source of distraction or even tend to stimulate social isolation.

A consistency is found with [14] which describes aspects of the digital culture, cyber culture, the level of use of software, the use of technological devices and their digital abilities. In [15] the expectations of employers towards digital abilities of graduates are revised and synthesized, an aspect that is not addressed in this investigation, but which has implications when it is necessary to determine the levels of employability and to project the new competencies of graduates for labor insertion, which demands a change in the curricular structure, the study plans and the need to project tendency analysis, scenarios and prospects of university education, parallel to the digital transformation of companies and the automation processes.

In [16] the successful integration of ICTs in the learning and teaching process is assumed, which leads us to believe that if new teaching tools are introduced, the teacher must also find new methods of teaching, creating and editing new contents in order to achieve active participation, even more when working with interactive young digital natives with access to an abundance of information.

The investigation is also in agreement with [17] in terms of the existence of a vast breach between the necessity of ICT infrastructure and its availability, which depends on factors in the economic, social and technological environment.

Finally, there is consistency with [18] in terms of knowledge management in universities that are focused on the distribution and use of knowledge through the application of ICT by means of promoting and diffusing investigation or the adequate management of ICTs as a means to manage knowledge. In both cases the environment determines the acquisition of knowledge, abilities and digital attitudes of the teacher and how the student assumes a critical attitude towards the use of ICT, through the selective use of information that is assessed on its quality. Only this way it is possible to achieve an efficient interrelation between the ICTs and the digital culture in the university system.

VI. CONCLUSION

The artificial neural networks made it possible to discover in an automatic way the relation between the variates Use of ICT and Digital Culture in function of the empirical data that were applied to the students of the Universidad Nacional de Moquegua - Peru and the Universidad Privada Domingo Savio - Bolivia, which information will allow for problem solving and better academic decision taking in each of the universities that were subject to the investigation.

The dimensions that have the greatest influence on digital culture as predicted by the artificial neural networks are the following: the ability to install software and data protection programs, the command of mobile devices for academic use and the command of specialized software in accordance with the models of the Universidad Nacional de Moquegua and the Universidad Privada Domingo Savio.

VII. FUTURE WORK

Future work will be related to the application of artificial intelligence algorithms to solve public management problems.

A Study of Modelling IoT Security Systems with Unified Modelling Language (UML)

Hind Meziane*, Noura Ouerdi

LACSA Laboratory, Faculty of Sciences (FSO)
Mohammed First University (UMP), Oujda, Morocco

Abstract—**The Internet of Things (IoT) has emerged as a technology with the application in different areas. Hence, security is one of the major challenges that has the potential to stifle the growth of the IoT. In fact, IoT is vulnerable to several cyber attacks and needs challenging techniques to achieve its security. In this paper, the use of a UML (Unified Modelling Language) aims at modeling IoT systems in various views. The purpose of this study is to discuss the need for more modeling in terms of security. For this reason, this paper focuses on modeling security of IoT systems. The objective is to make a comparison in terms of layers by describing the IoT architecture and presenting its components. In other words, the research question is to look for the modeling of security in the IoT layers. There is no standard that takes into account the security of the IoT architecture, there are different proposals of IoT levels, which means that each author has his own vision and own proposition. Moreover, there is a lack of modelling languages for IoT security systems. The main interest of this study is to choose the layer on which we should be interested. The question then is as follows: "which is the layer whose modeling is relevant?" The obtained results were conclusive and provided the best insight into all the specifications of each layer of the IoT architecture studied.**

Keywords—Internet of things (IoT); IoT systems; IoT security; modelling; Unified Modelling Language (UML); UML extensions; IoT applications

I. INTRODUCTION

IoT or Internet of Things is a big area. The general idea of it is to make objects connected or linked together in order to communicate and exchange information via communication technologies like LoRa, LoRaWan, 4G, 3G, 2G, etc. IoT was coined by Kevin Ashton (pioneer of Radio Frequency Identification (RFID) technology (Automatic Identification Technology)) in 1999 [1]. IoT is a vast domain [1][2]. The IoT aims at enabling things to be connected at anyplace, anytime with anyone and anything using any network/path and any service. IoT is now used in multiple fields like Healthcare, Transportation, Factory, Building, City, Retail, Surveillance, Manufacturing, Agriculture, Logistics, Lifestyle, Industrial, etc.

Software engineering goals include gaining the greatest knowledge of the problem and modeling complicated systems utilizing tools such as UML (Unified Modelling Language) diagrams. The UML diagrams can be used for modelling the complex systems. In this sense, realistic IoT application scenario modeling on a wide scale with various operating conditions necessitates/requires a mix of edge devices, sensors, and actuators [3]. The goal of this paper is to review

published studies and look into the current state of IoT modelling security. The modelling of security systems for IoT is the main step, thus, security modelization is essential. In the literature, there are two types of tools: modeling languages (UML, SysML (System Modelling Language) and ThingML (Internet-of-Things Modeling Language)) and extensions to these languages (UML4IoT, IoTsec, UMLsec, SysMLsec, SysML4IoT). Various languages with their extensions have been provided to simulate and model IoT systems like IoTsec, ThingML, SysML, UML4IoT, SysML4IoT, etc.

In this context, networking and designing IoT and edge computing layers [3] is a very laborious process because of: (1) end-point networks like Bluetooth, Wi-Fi, and 4G are complex and heterogenous; (2) heterogeneity of edge and software stack and IoT hardware resources; (3) mobility of IoT devices; and (4) the complex interaction between IoT and edge layers [3]. Creating an edge computing and IoT testbed with high verisimilitude is not only difficult or complex, resource-intensive and expensive but also time-consuming. Furthermore, because of the high cost and broad domain expertise necessary to reason about their variety, usability, and scalability in actual IoT and edge computing settings, testing in reality edge computing and IoT environments is not practical [3]. Hence, in this article, we are interested in modelling IoT security systems and we also discuss the modelling challenges in the IoT environment context.

In UML 2.5, there are now fourteen diagrams that developers utilize to build systems. However, for some specific application domains, these diagrams are ambiguous. As a result, specific domain notations are covered by the UML extensions [4]. In UML, there are some extension artefacts that are well defined, these are: tags, values, stereotypes and constraints. These extensions mechanisms allow designers to develop specific models for certain areas/domains, such as modeling security concerns in systems, UML extension for Hypermedia Design [4], profiles to model Internet of Things (IoT) systems, …. [4]. However, security is one of the major issues. Three issues in designing IoT applications are addressed due to the lack of a strategy to develop/model IoT applications, the lack of a model to design security challenges in IoT, and the heterogeneity of different software and hardware devices.

The objective and originality of this paper are as follow: A lot of research work on modelling languages have been provided, but we could not find works on the following question "what is the relevant layer to model that really contributes to the security of IoT systems?" that is the strong

---

*Corresponding Author.

point of this research. In the literature, there is a lack and absence of works in the same section/point and this can be considered among the criticisms. The main idea of this work is to choose an IoT layer for which modelling is relevant. The problem to be discussed is as follows: which layer should be specified? The main objective is to look for the modeling of security in these layers, i.e., on which layer we should be interested? To do this, we compare the four layers by considering various parameters. However, there are no answers about the following question: What is/are the relevant layer(s) to model that really contributes to the security of IoT systems?

A. Contribution

The contributions of this survey are summarized as follows:

- This paper presents a state of the art of modelling IoT systems with UML, SysML and ThingML to perform a comprehensive study on modelling IoT security systems.

- This survey defines and describes the challenges that IoT systems are currently facing.

- The architecture of IoT systems is proposed as well as the role of each IoT layer is also described.

- This paper proposes a summary and taxonomy of security attacks and vulnerabilities at different layers. Then, the security issues, problems, vulnerabilities and challenges of each layer were also introduced. It also explores the security requirements for IoT layers.

- The strong point is to define the layer that needs more security in the IoT architecture. The added value is as follows: there is no survey that has been made to confirm "which is the layer whose modelling is relevant?"

B. Outline

This paper is organized as follows: The related works done in IoT security modelling are presented in Section II. Section III provides the IoT challenges. Section IV outlines the proposed methodology including architecture of IoT systems, challenges of each IoT layer, classification of attacks and vulnerabilities in IoT, IoT security requirements, OWASP IoT Project by analyzing security threats and vulnerabilities, followed by an example of modeling IoT security with UML. Results and discussion are covered in section V. Finally, Section VI concludes the paper.

II. RELATED WORKS

Currently, modeling the security of IoT systems has become highly important among researchers, each researcher uses a language (whatever its extension, e.g. IoTsec, UML4IoT, SysML-Sec...) to prove the quality of its work. In this section, we review and discuss the literature of some previous papers which are related to our theme in order to keep up with the languages and extensions used. It is extremely difficult to model a real IoT scenario due to several challenges that we will discuss later in the results and discussion section.

There are several simulation environments currently available such as IoTSim-Edge, IoTsuite, SimIoT... For instance, Jha et al., (2020) [3], aims to build a novel simulator, IoTSim-Edge, that allows users to evaluate the edge computing scenario in an easily configurable and customizable environment. Further, the authors give the general architecture of edge computing considered for modeling by IoTSim-Edge simulator. The architecture of the proposed simulator consists of multiple layers. IoTSim-Edge targets to model smart devices using low energy protocols. The authors also consider the simulation of battery power by using a predefined drainage rate. The presented architecture of IoT-Edge computing consists of two components: actuator nodes and sensing nodes. The sensing nodes collect the information of surroundings via sensors and send it for processing and storage. Whereas, the actuators will be activated according to the analysis of the information/data. The communication layer is responsible for transferring data to IoT devices, cloud, and edge devices. Different communication protocols are used for transferring data. Edge infrastructure is the next layer that consists of several types of edge devices (e.g., Raspberry Pi and Arduino). These devices can be transparently accessed through the help of various types of containerization and virtualization mechanisms. It provides an infrastructure to deploy the raw data produced by the sensing nodes. The services or application layer consists of various services which can be accessible directly to the users. These services (applications) will be accessed through a subscription model.

A. Modelling IoT Security System using UML Language

Robles-Ramirez et al., (2017) [4], mention a number of approaches that aim to model IoT systems and security considerations. They used IoTsec, which is a UML extension and another example that includes a notation for security modelling in IoT systems. Furthermore, to model IoT systems, they propose a UML/SysML extension, which attempts to encapsulate security knowledge. In particular, a new UML extension is proposed, which characterises security issues encapsulated within a nomenclature, and UML stereotypes, in order to model common actors and UML notation extensions. The objective is to move IoT development at a previous step from the implementation stage; the designing phase. This work targets security concerns in IoT development. Besides, the authors provide a simple model language to describe security actions and entities. The main aim is to facilitate the representation of security issues using a visual notation [4], even if the developers are unfamiliar to Internet security concepts. To represent an IoT system in terms of security issues/concerns, the authors, adopted the four layers architecture including sensing, network, service, and application layer.

Dhouib et al. (2016) [5], give a highlight to the current status of "Papyrus for IoT". It is a modeling environment that enable to deploy, specify and design complex IoT systems by using an IoT-A lightweight methodology. Furthermore, in order to illustrate the modelling environment, they use the example of a smart IoT-based home automation system, which consists of five steps:

- Step 1: Design the requirements and the purpose of the system by using SysML requirements diagrams and UML use case diagrams in Papyrus SysML Component.

- Step 2: Define the process specification. The IoT system's use cases are described, derived from and based on the requirements and purpose specification.

- Step 3: Define the system's functional architecture based on the IoT domain model.

- Step 4: Define the operational platform for the functional system's execution.

- Step 5: With Papyrus Designer Component, define deployment plans that include information about the allocation/assignment of functional blocks (step 3) to operational ones (step 4).

Moreover, they introduce MDE4IoT frameworks covering more than only a single MDE technique. Moreover, papyrus is an open-source Modeling Environment. In contrast to the other publications, the introduced approach already uses IoT-A in the Papyrus for IoT modelling environment.

Reggio (2018) [6] presents a method (IoTReq) for the elicitation and specification of requirements for IoT systems. The method uses UML for modelling the domain, requirements elicitation and specification of IoT requirements. This method also supports the specification of non-functional specifications. Reggio proposes a UML profile for the requirement gathering for IoT applications.

Ouchani (2018) [7] creates a formal framework for assessing the functional correctness of IoT systems. The suggested framework includes all of the major components of IoT systems, and the process is completely automated. Author describes the IoT architecture by showing its components with their interactions. The suggested IoT architecture enclosed five components which are demonstrated and analyzed subsequently in the next section. (1) Object devices, (2) User devices, (3) Computing services, (4) Social actors (are human agents) and (5) The environment. These components interact via communication protocols of various ranges (ZigBee, WiFi, Cellular, Human-machine, Bluetooth, SSH, IpSec, etc.). However, the proposed work suffers from PRISM's restrictions, and the security proprieties are not described.

(Thramboulidis and Christoulakis, 2016) [8], presented UML for IoT (UML4IoT) domain-specific modelling language to tackle the IAT (Industrial Automation Thing) domain. They presented the UML4IoT approach, a UML profile aimed at modeling cyber-physical components as their integration into IoT systems in manufacturing domain. UML4IoT is an UML profile for IoT, which have been already employed in the domain of real-time and embedded systems. However, UML4IoT extension does not support security modeling. Moreover, the authors didn't provide any reason about their choice.

B. Modelling IoT Security System using SysML Language

Ferraris et al. (2020) [9], present a model-driven approach extending UML and SysML diagrams. The aim of this work is to provide developers with a tool helping them to consider domains such as trust and security during the SDLC (System Development Life Cycle) of an IoT entity.

C. Modelling IoT Security System using ThingML Language

Harrand (2016) [10] introduced ThingML (Internet-of-Things Modeling Language), which is a modelling language that focuses on a distributed and heterogeneous systems, for generating code framework for diverse targets. ThingML is designed to support the development code generation. It can be considered as a DSML (domain specific modeling language). Generally, it has more been applied to IoT and CPS (Cyber-Physical Systems). Nonetheless, the authors do not take security into account.

However, for the existing papers in this field of modeling IoT security systems with UML, SysML, or ThingML, no survey has been made to confirm which is the layer whose modeling is relevant. In other words, there is no answer about the following questions: "Which layer whose modeling is relevant?" This means what is the relevant layer to model that really contributes to the security of IoT systems? Which calls the need for an in-depth comparison on the IoT layers including the upcoming and existing security issues. In general, as another limitation of similar works, modeling IoT security systems is still very superficial.

III. IoT CHALLENGES

The IoT infrastructures and security are still in infant phases. IoT systems have its own specific challenges. Hence, there are several obstacles to the development of the IoT. The following are some challenges and constraints in IoT systems:

A. Interconnectivity

Interconnectivity characterizes the ability of IoT systems and their constituents to communicate and use each other's services in a seamless manner [1], [2], [11]. The global information and communication infrastructure [12] allows for the interconnectivity of anything.

B. Heterogeneity

IoT devices are heterogeneous, since they are based on several networks and hardware platforms [12]. They can communicate with other service platforms or devices via various communication technologies and networks like LoRa, 2G, 4G, etc. Indeed, these IoT protocols are heterogeneous. Therefore, we need to make sure that there is a compatibility between them.

C. Interoperability

Interoperability is a basic value of the traditional Internet, the first criterion of internet connectivity is that "connected" systems/computers "speak the same language" of protocols and encodings. To support their applications, various industries nowadays use various standards. The adoption of common interfaces between these different entities becomes increasingly critical when there are various sources of data and heterogeneous devices. As a result, IoT systems must be able to deal with a high level of interoperability [1], [2],[12].

D. Scalability

In an IoT network, there are a large number of IoT devices [1] and nodes, Cisco estimated that in 2020, 26.3 billion devices were connected to the Internet [13]. Because of this large number (including the number of users and the number of participating IoT things), scalability is a crucial issue for creating effective defensive methods [13].

E. Big Data

Not only the number of smart objects [13] will be enormous, but the data generated by each object will be huge. Because each smart device is supposed to be supplied by too many sensors, each of which generates massive amounts of data over time, and also exchanges it on multiple IoT layers [1], [2], [13].

F. No Standardization

There is a lack of standardization in terms of IoT definition, vision, architecture, attacks, [1], [2]. For the IoT layers architectures, there are several proposals of IoT architecture with three, four, five, and seven layers (for the Cisco IoT model). Further, there is no robust solution that will solve most of IoT security issues.

G. Resource Constraint

Resource constraint (Limited Resources) in terms of energy, storage space and computing capacity. End devices in the IoT have limited resources like memory, storage, CPU, battery, and transmission range [13]. In other words, IoT devices are uniquely identifiable and are mostly characterized by limited processing, small memory, and low power. Furthermore, IoT devices [4] have many constraints like software based, network-based, and hardware based limitations, which depict new challenges for IoT developers. Moreover, implementing conventional security measures is impossible because it would be a very hard and complex process [14]. Since IoT devices have constrained resources, standard encryption algorithms cannot be applied directly for the IoT system. Lightweight cryptographic techniques were suggested by [14]. Therefore, a comparative study of existed lightweight cryptographic algorithms must be required. In addition, due to the rapid growth of IoT devices and the great developpement of new technologies and elements in the market, IoT systems have become vulnerable to several attacks.

H. The Lack of Encryption

The lack of encryption in the cloud which should also be considered [1]. An encryption procedure is important for IoT systems.

I. Security and Privacy

That means provide the necessary protection for data and maintain the privacy of users; this is the biggest challenge of the IoT. This is especially critical in healthcare devices. For applications in personalized medicine, such intelligent devices are becoming more popular. The information gathered is typically highly substantial and frequently includes meta-data like time, place, and context [15]. Besides, it describes the five security features, like confidentiality, availability, integrity, authentication and non-repudiation. Another serious problem is about how to get a secure and an efficient IoT platform to deliver what is required to be delivered.

J. Security Policies

We need to have policy. Policies are operational rules that must be maintained in order to keep data organized, secure, and consistent. Because security is also about how to use this flow of data. Security policies should be followed by users.

IV. METHODOLOGY

The objective of this paper is to conduct a comparative study of different layers of the IoT architecture taking into account the specifications of each layer. The layer is a factor among the factors that differentiates the modeling of IoT systems. Thus, to ensure the security of IoT systems, this contribution will compare these layers based on IoT architecture in order to outline the relevant layer to model.

The problem to be discussed is as follows: at which layer we are going to work? Do we combine two layers or we work on one layer? So, the main aim of this section is to choose which layer requires more security. To answer this research question, a systematic review on IoT architecture and security concerns could be done regarding several important axes/points. In other words, we need to do a comparison in terms of layers. By looking for layer modeling, we report the results and findings of this section. Thus, the proposed methodology is based on six steps. We gathered all specifications for each layer of IoT. For this purpose, the author is looking for a detailed description on IoT layers as well as an analysis of each layer was also done by covering the next points:

1) At first we will present the functionalities of IoT architecture to understand how IoT system basically works and underline the architecture we are working on.

2) After that, we will detail in the second step the security issues/problems of the IoT architecture which contains multiple layers, to give a detailed explanation and general understanding of different security challenges in different layers.

3) Then, we will provide a classification of security attacks and vulnerabilities in each layer of IoT systems, to conclude the most security attacks in each layer.

4) Followed by security requirements in IoT to analyze an in-depth the security services that must come with each layer.

5) In the fifth step, we will talk about the OWASP IoT Project as an example of security threats analysis.

6) And finally, we will end with, a comparison that were obtained previously to outline the extension that meet our needs regarding/in terms of security. That is why we took a UML extension as an example for modeling IoT security.

To be clearer, we followed these steps in the methodology section in order to compare the different layers by keeping the results of the six steps.

There are many papers, and researchers have presented different architectures. Some researchers present architecture composed of five layers [1], [2], some architecture composed

of three layers and in our research, we are interesting and we choose the architecture of four layers: physical layer, then, network, middleware and application layer. In this paper, the author adopts four layers architecture to present or choose the relevant layer to model that really contributes to the security of IoT systems and also to reflect the IoT architecture concerns. The proposed model of the IoT system is innovative, that take into consideration all characteristics, concerns, issues and threats of the four layers of the IoT architecture. Therefore, the best IoT architecture is that of four layers. Because, it is very general and presents in a great way the concept of the IoT. Besides, security at the middleware layer (storage/cloud/data) is not the same as security at the application layer (authentication/identification); as more than we separate the problems, we find solutions. In other words, security concepts in the cloud/middleware layer may not be integrated in the application layer. Moreover, we need cloud because we have so much data generated by many connected objects. Therefore, the middleware layer is also provided as a necessary and an integral part of the IoT model. Fig. 1 shows proposed and detailed architecture of IoT systems. It shows various devices and technologies at these layers. In this paper, author is using and describing the functionality of the following layers:

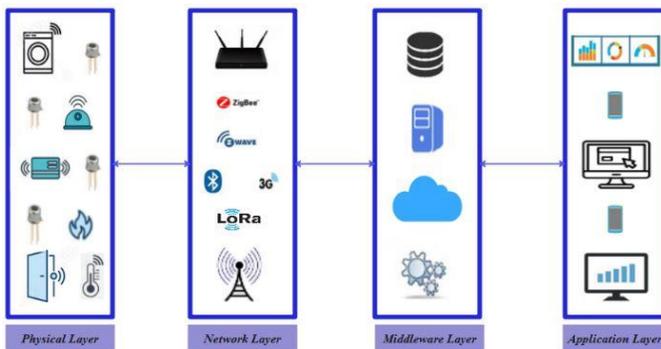
- Physical Layer
- Network Layer
- Middleware Layer
- Application Layer


Fig. 1. IoT Architecture based on Four Layers.

A. IoT Architecture

There is not a standard for the IoT architecture, there are different proposals of IoT levels. It consists of different layers. To achieve this goal, and for simplicity, this paper focuses on four IoT layers.

1) Physical/Perception layer: Physical layer, which is also called the Perception layer. In [1] and [2], the first or base layer has been generalized by physical layer, that is not limited to actuators and sensors, it is composed of sensors, controllers, RFID tags and reader, actuators, and devices. IoT devices include mobile devices, single-board computers, and micro controller units [2]. IoT involves objects or things such as sensors, actuators, RFID tags and readers, to permit

interaction between the physical and virtual worlds. The capacity of a connected thing to optimize the probability of satisfying/achieving the user's goals may be used to determine its intelligence. Connected things intelligence spans from non-existent to perfectly rational [11]. The sensors may monitor or measure values like temperature, pressure, humidity, air quality, movement, speed, flow, and electricity…. Sensors collect information about their surroundings. This layer's main purpose is to collect useful data from the environment (like humidity, WSN, temperature, and heterogeneous devices, etc), then process, and digitize these information/data [1]. Body sensors, vehicle telematics sensors, environmental sensors, home appliance sensors, are classified according to their specific purpose. The actuator can be used for performing particular action.

The functionalities of this layer include actuating, sensing, actuating and sensing, storage, and processing [11]. Gathering and generating information by devices are the main operations of the physical layer. The collected data with the networks will be sent to the cloud. There are three types of things [11] smart things (or physical objects), sensors or/and actuators, and gateways. Finally, the first layer is "physical layer" also known as recognition, perception. The main function is to identify, generate and collect data from the physical world to perceive their environment by detecting changes using sensors.

The first layer components are: Tag, sensors/actuators, coordinator and network (LAN, PAN). In other words, LAN or PAN can be considered as a form of connectivity between sensors and sensor gateways. While WAN can be considered as a form of connectivity between sensors and servers.

Enabling technologies for the IoT can be grouped into three categories [12]:

- Technologies that enable "things" to acquire contextual information.
- Technologies that enable "thing" to process contextual information.
- Technologies to improve Security and privacy.

2) Network layer: The network layer is the connectivity layer which connects the perception layer to the cloud trough, a gateway using different technologies such as Lora, satellites, 3G, and others technologies. It is responsible for the transfer of this sensitive and massive volumes of data between different layers via network. It contains Router, Internet, Switches, Gateway [1], This layer is used for the connectivity, it defines the different protocols and communication networks or technologies such as Sigfox, 3G, 4G, 5G, WIFI, Zigbee, Bluetooth, LoRaWAN, LoRa, which represent the edge where the collected data can be processed. This layer is responsible for the connectivity of the IoT infrastructure. It also collects data from the physical layer and transmits it to the upper layer. The transmission medium can be wired or wireless.

These technologies include, but not limited to ZigBee, RFID, NFC, WSN, MANET, Wi-Fi. Furthermore, these technologies have their own security issues. Multiple networks with various technologies and access protocols are needed to work with each other in a heterogeneous configuration.

IoT communication technologies are based on two different categories [1]: Short-range and Long-range technologies. The first one include Z-Wave, Zigbee, RFID, NFC, 6LoWPan, etc. The second includes LPWAN technologies, among them LoRa/LoRaWAN, Cellular communication (2G/3G/4G/5G), NB-IoT, Sigfox, etc.

3) Middleware layer: The middleware layer contains (data analysis, data visualization, Cloud, API, Datacenter,) [1]. It stores, processes and analyses huge amounts of data, big data processing modules, employs databases, cloud computing, classification and polymerization [1]. In this layer there are different methods, tools and techniques that can be used to analyze the data collected by sensors and network layer in order to visualize it in the next layer (application layer). The stored data will be exploited by users. The main function of this layer is the complete analysis via very robust systems that contain Artificial Intelligence, other models/algorithms to do the analysis of the data. Due to its unlimited processing and storage capacity, cloud computing is crucial for the IoT [14]. It also provides a distributed architecture/infrastructure for processing and analyzing IoT data before pushing it to the application layer.

4) Application layer: The application layer visualizes the data produced by IoT computing. It is responsible for delivering personalized services to all industries and to the user [1]. It is the interface for users to communicate to their IoT things and access data. It supports protocols that can be deployed for IoT like MQTT (Message Queue Telemetry Transport)[1], XMPP (Extensible Messaging and Presence Protocol) [1], CoAP (Constrained Application Protocol) [1], SMQTT (Secure MQTT), AMQP (Advanced Messaging Queuing Protocol), etc. HTTP (Hyper Text Transfer Protocol) is used by [16]. This protocol cannot be employed in the application layer, it is not suitable/appropriate for resource-constrained since it is heavy in weight and therefore requires a large parsing overhead [17]. This layer provides personalized services based on the demands of the user. The IoT application covers "intelligent" environments/spaces in areas such as wearable devices, agriculture, transport, factory, building, health, city, lifestyle, home, commerce, vehicles, emergency, supply chain, environment and energy.

5) Summary: This subsection adopted and introduced four level model. To sum up, the IoT objects and things of the physical layer communicate with each other in order to deliver intelligent applications and services for users or human. These IoT devices collected information/data that need to be secured. Billions of devices (medical devices), sensors, actuators and IoT things are connected to the Network. The number of these connected devices is expected to grow increasingly over the coming years. Sensors, RFID and actuators are the major

components of physical layer that can be easily accessed by attackers. These devices need to be managed and secured appropriately, to avoid their significant security risks.

Moreover, IoT involves various communication technologies, which could be affected by different threats. Consequently, for each communication technology, a taxonomy of all possible attacks with their degree of severity/impact/danger must be required. In other words, the communication between these layers need to be secured. Therefore, a secure architecture is needed with some recommended technologies. The first result in this subsection illustrates that the physical and network layer contain the most components that are targeted by attackers. Moreover, because of generating and gathering information by IoT things and devices are the main operations of the physical layer. Therefore, the risk of data theft can be decreased or minimized with physical layer security. Indeed, these data can be stored and processed in local network, so communication technologies and protocols should also be secured. The next subsection will offer insights into the security issues and problems of the IoT architecture. Here, we will give some common issues and challenges of each layer of IoT architecture.

B. The Security Challenges of the IoT Architecture

In this subsection, we analyze security challenges in each layer of the proposed model. Because each IoT layer has its own challenges and security issues.

1) Security challenges and problems of physical layer: At this first layer, the main challenge is the limited resources on IoT devices: storage, memory, CPU, and energy. For instance, sensor is a small equipment with limited resource. Devices of the physical layer are often limited in terms of process and data storage resources, and the applied technologies (such as RFID, NFC, Bluetooth, ZigBee) are being limited in data transmission range and rate. For many IoT devices that are mobile and rely on embedded batteries, energy is one of the most important resources [11]. In terms of energy, the IoT devices need a significant amount of electricity because of their powerful processing capability.

The malicious attack on the identification technology and the sensor is the main challenge for the physical layer [1], which interferes with the collection of data. Things include physical objects (micro-controllers, sensor/sensor nodes, actuators, RFID tags and readers), this physical hardware are targeted by several attacks in the both layers (physical and edge computing layers).

Every IoT devices and Things is linked to the internet in order to talk and communicate to each other. So, there is the possibility of hindering the privacy. Indeed, due to a variety of security vulnerabilities, RFID, and sensors are in threat. Moreover, hardware components and IoT objects are vulnerable to several physical attacks like Object replication attacks, RF Interference on RFID, Hardware Trojan, Object jamming, Physical damage, Camouflage, Malicious node injection, Object tampering, social engineering, Side-channel attack, Malicious code injection, Tag cloning, Outage attacks

[16], False Data Injection Attack, booting vulnerabilities [17], Node Tampering, Node Jamming in WSNs [18] . For instance, the malicious node injection attack targets the physical layer since the node is physically inserted/injected into the network [18]. Besides, side channel attack is conducted at the physical layer because attacker uses side channel information to find the encryption key [18]. At sensors, an attacker can manipulate data, can also do boot attacks, and can capture a node [19].

IoT software are targeted by many attacks. Indeed, hardware components of IoT, like types of RFID tags, sensors, RFID readers, are also vulnerable [16]. The major attacks are targeting the IoT hardware components. Attackers must be located near to hardware or devices in order to launch physical attacks. The attackers may want to physically destroying the devices/hardware, endanger the communication mechanism, tampering the energy source, limiting its lifetime, etc. Also, the attacker can directly access the related attributes of the device through physical attacks, and then start further attack.

The weaknesses of the various devices are exploited in security attacks against IoT systems. IoT devices are subject to well-known vulnerabilities such as the use of unauthenticated requests to conduct/perform actions, broken authentication, sensitive data exposure, infection flaws, XSS (cross-site-scripting), CSRF (Cross Site Request Forgery), missing function-level access control [20].

2) Security challenges and problems of network layer: At the second layer, one of the main/most challenges that face this layer is the heterogeneity of data; for instance, in the network part, there is a huge heterogeneity of data in term of IoT communication technologies (Lora, WI-fi, ZigBee, 4G). This may cause compatibility problems. Compatibility is another major problem. There are some attacks specific to some IoT technologies communication. These technologies of communication include, but not limited to ZigBee, WSN, LoRa, MANET, Bluetooth, RFID, 3G, NFC, Wi-Fi, etc. Moreover, these technologies of communication have their own security concerns and issues. The following are the major security attacks that are faced at the network layer: Phishing Site Attack, Access Attack, DDoS/DoS Attack, Data Transit Attacks, Routing Attacks, unlawful attacks, common attacks [17], Traffic Analysis Attacks, RFID Spoofing, RFID Cloning, RFID Unauthorized Access, Man in the Middle Attacks, Routing Information Attacks [18], Selective Forwarding, Routing Information Attacks, RFID Unauthorized Access, RFID Spoofing, Replay Attack, Traffic Analysis Attack [21].

Additionally, the network attacks consist of manipulating the IoT network system to cause damage. Attack can be started without being close to it (network) [21]. Attacks on networks can have significant consequences, sometimes causing a total shutdown [21]. The software attacks happen when the IoT applications present some security vulnerabilities that allow the attacker to seize the opportunity and harm the system. The main attacks in the Network layer,

targeting the network protocols. An example of network and software attacks in reality is described in [1].

3) Security challenges and problems of middleware layer: Today, the most significant data attacks that are happening in the IoT world: Data Inconsistency, Data Breach and Unauthorized Access [21]. An example of data attacks was launched in reality in March 2018 [21], Cambridge Analytica had obtained access to the private data of more than 50 million Facebook users. Other major security issues at the middleware layer include cloud and data security as well as database security [17].

In the middleware layer, various possible attacks are discussed in [17] such as: Man-in-the-Middle, SQL Injection Attack, Signature Wrapping Attack, Cloud Malware Injection, Flooding Attack in Cloud.

4) Security challenges and problems of application layer: The application layer has specific security problems and issues such as privacy issues and data theft [17]. In the application layer, major attacks are discussed in [17] like Data thefts, Access Control attacks, Service Interruption attacks, Malicious Code Injection attacks, Sniffing attacks, Reprogram attacks.

5) Summary: In this subsection, we have given of the security challenges and problems being faced in each layer of IoT. In my view, the main challenges of IoT systems mainly relate to the first and second layers which are explained and analyzed previously. Since the influence stemming on IoT as IoT devices limitation (resource constraint) and heterogeneity or compatibility problem is very strong. For instance, limited resources challenge for the physical layer and the second challenge is about the heterogeneity of data for the network layer. So, we have to focus on both layers (Perception/physical, and network layer) due to their big/huge challenges and also for other reasons that will be discussed later.

C. Classification of Attacks and Vulnerabilities in Each Layer of IoT Systems

Based on [1], IoT attacks can be classified into fifteen categories: attacks based on vulnerability, on layers, on behavior, on technology of communication, on impact, on security concepts, on target, on software, on source, on devices, on encryption, etc. It is absolutely important to identify vulnerabilities and attacks against each IoT layer. The identification of IoT security attacks is crucial due to the ever-growing number of threats and vulnerabilities in the IoT domains. It is firstly necessary to identify the IoT attacks and vulnerabilities and then classify them.

1) Vulnerabilities in each layer of IoT systems: In terms of vulnerabilities of physical layer, the work [21] have highlighted the vulnerabilities against physical devices like IP cameras, Amazon Echo. For example, attacks such as device spoofing, device scanning, and brute force may control of the cameras. Attackers can get the password for a camera of any length or combination via a device spoofing attack.

Additionally, the attacker can perform a device scanning attack to discover all online cameras by enumerating all MAC addresses that could exist [21]. The vulnerability issue for the "Things" is caused by careless program design, which opens opportunities for the installation of malware or backdoors [22]. The attacker can attack an IoT system by physically weakening or tampering a node [18].

In terms of vulnerabilities of network layer, the attacker can target an IoT system from their own network by exploiting faults in the routing protocol and other network-related protocols or by employing malicious software. The network layer is highly vulnerable/susceptible to phishing site attacks [17].

In terms of vulnerabilities of middleware layer, XML signatures are utilized in the middleware's web services. By exploiting SOAP (Simple Object Access Protocol) vulnerabilities, the attacker can execute operations or alter eavesdropped messages in a signature wrapping attack, which breaks the signature algorithm [17].

At the application layer, insecure cloud interface is a vulnerability in an IoT system that can be an attack vector. Buffer overflow consists in exploiting a vulnerability of an application resulting in abnormal behavior sometimes leading to access to the system with the rights of the application. Software vulnerabilities that allow resource buffer overflows or pushing an IoT device to exhaustion state by an attacker [23]. For instance, a low battery level may cause the laptop to shut down unexpectedly. Due to the majority of the system being in "sleeping" mode, other "things" could not be interoperable [23].

2) Classification of attacks and vulnerabilities based on Layers: In this section, author proposes to summarize the attacks and vulnerabilities based only on the IoT layers, the list is endless. Moreover, each attack has a degree of severity [1], [2]. According to [1], [2], [16]–[18], [21], the security attacks and vulnerabilities at each layer in IoT system are collected and shown in Table I.

3) Summary: After establishing the taxonomy of security attacks and vulnerabilities in each layer of IoT systems. All of these attacks cause significant harm since they alter data, steal sensitive data, drop packets and encryption key, etc.[18]. According to Table I, we showed that the two first layers have been threatening by many IoT attacks and vulnerabilities compared to middleware and application layers. Most attacks on the IoT often occur in IoT objects and IoT network. In other words, most IoT attacks and vulnerabilities have resided in physical layer and network layer because of the poor security design of these connected objects as well as vulnerabilities in IoT protocols and communication technologies. In the next subsection, we will examine and summarize the security requirements for IoT.

TABLE I. CLASSIFICATION OF ATTACKS AND VULNERABILITIES BASED ON LAYERS IN IoT SYSTEMS

Layer	Attacks and vulnerabilities in IoT	Attacks description
Physical Layer	Social Engineering, Node Capture, DoS (Denial of Service) Attack, Distributed DoS Attack, spoofing attack, Fake Node, Replay Attack, Mass Node Authentication, Tag cloning, Unauthorized Access to the Tags, Denial of Sleep Attack, RF Interference on RFID, Eavesdropping, Man In the Middle, RF Jamming, Routing Threats, Object replication, Hardware Trojan, Object jamming, Camouflage, Object tampering, Sleep Deprivation Attack, Outage attacks, Wormhole and Timing attack. Malicious Node Injection, Malicious code Injection, False Data Injection Attack, booting vulnerabilities, Physical damage, Side Channel Attack, Node Tampering, Node Jamming in WSNs, Data Manipulation, Boot Attack.	Both software and hardware components of IoT are targeted by several attacks. Additionally, attackers must be located near to hardware or devices with different intent to launch physical attacks, which can also directly access the related attributes of the device through physical attacks.
Network Layer	Spoofing, MITM attack, Routing Information attack, Sinkhole attacks, Sybil attacks, DoS, Denial of Sleep Attack, Selective forwarding, Eavesdropping/sniffing, Routing attacks (Worm Hole, Hello Flood, Black Hole, Gray Hole, Sybil attack), Phishing Site Attack, Access Attack, DDoS Attack, Data Transit Attacks, Routing Attacks, Malicious code injection, RFIDs interference, unlawful attacks, common attacks, Traffic Analysis Attacks, RFID Spoofing, RFID Cloning, RFID Unauthorized Access, Man in the Middle Attacks, Replay Attack, Routing Information Attacks.	The network attacks consist of manipulating the IoT network system to cause damage. The software attacks happen when the IoT applications present some security vulnerabilities that allow the attacker to seize the opportunity and harm the system.
Middleware Layer	Flooding Attack in Cloud, Malicious Insider, Cloud Malware Injection, Unauthorized Access, Signature Wrapping Attack,Data Inconsistency, Cryptanalysis Attacks, Web Browser Attack, DoS, SQL Injection Attack, MITM, Data Breach, Data Security.	The main challenges are Cloud/data security, and database security.
Application Layer	Buffer Overflow, Botnet, Code Injection, DoS, Sleep Deprivation, Phishing Attack, Sniffing Attack, Authentication and Authorization, DDoS Malicious Scripts, Data Access and Authentication, Trojan Horse, Social engineering, Cryptanalysis Attacks, Brute Force and Cross Site Scripting, Access Control attacks, Service Interruption attacks.	Data theft; Attackers exploit the vulnerabilities of application and programs.

D. IoT Security Requirements

This subsection provides the details about the IoT security requirements. According to [1], [2], [24], the basic security services include authentication, authorization, availability, integrity, confidentiality, and non-repudiation. Therefore, the authors of [24] illustrated only three IoT layers namely Perception, Networking, and Application. Nevertheless, IoT security must also come in the Middleware layer as well as with some other security services including Privacy, Authenticity and Compatibility.

- Privacy needs to be adapted to information as well as devices, this key property must be concerned to the Network and Application layer.

- Compatibility must be concerned to the Network layer.

- The middleware layer must be integrated with confidentiality, integrity and authenticity services [25]. The middleware layer provides these three services to the data exchanged [19].

1) Security services requirements for IoT layers: Generally, security solutions consist of five main objectives as shown in Fig. 2. While, IoT security requirement must be represented by the key properties that are listed below. The IoT security requirements including integrity, availability, confidentiality, authentication, authorization, non-repudiation, privacy, compatibility and authenticity are represented at different layer of IoT as shown in Table II.

a) Confidentiality: It is the property which ensures that only authorized users, under predefined conditions, have access to the information. The IoT system cannot directly apply standard encryption algorithms due to the limited resource of IoT devices. Lightweight cryptographic algorithms are used to guarantee data protection and confidentiality [14].

b) Integrity: It is the property which ensures that information is only modified under predefined conditions. To provide data integrity, a number of cryptographic hash algorithms are utilized, such as MD5 and SH1. However, the majority of these approaches, cannot be used since IoT devices are resource constrained. Many lightweight hash functions were suggested to address this issue [14].

c) Availability: Terminology of the security environment to characterize the proper functioning of the computer system at a given time. IoT device availability is highly necessary. IoT network availability should be handled in both hardware and software. The IoT application's hardware availability refers to every device being present at all times, whereas software availability refers to the capacity to offer services anytime and anywhere[14].

d) Authentication: It is the property that ensures that only authorized entities and users have access to the system or the IoT devices. Authentication protects against identity theft. It is the procedure of validating an identity [14]. Before exchanging data, to connect a device to the network, it needs authenticate itself. Lightweight cryptographic techniques, biometric identification or physical primitives can be used to verify the authentication [14].

e) Authorization: It makes sure that entities have the necessary control permissions to carry out the operation they've requested [13].

f) Non-repudiation: It is the property which ensures that the author of an act cannot then deny having carried it out. The second idea contained in the usual notion of signature is that the signatory undertakes to honour his signature: contractual, legal commitment, he can no longer go back. It is an important element of network security [14]. It is the capacity to assure that an IoT node cannot reject/deny having

sent a message and that the recipient cannot deny having received it. Public Key Cryptography can be used to achieve it.

g) Privacy: Attacks on privacy are linked to the unauthorized collection of sensitive information about individuals. When collecting, transmitting, and storing data, data privacy must be considered. The issue of data privacy has received many practical solutions. Stream ciphers, Block ciphers, pseudo-random number generators, and anonymization are some of these methods [14].

h) Compatibility: Of the emerging and the existing IoT protocols in the network layer, the big challenge concerning this layer is the huge heterogeneity of data in term of IoT communication technologies (LoRa, Wi-fi, ZigBee, 4G, etc.).

i) Authenticity: [25] Illegal users are not permitted to access the system or obtain sensitive data.

2) Summary: According to Table II, we showed that generally, the two first layers are missing various security shields. For instance, confidentiality, integrity, authentication, availability, and authorization are the major problems/needs in the physical layer. The network layer requires integrity, availability, authentication, authorization, non-repudiation, privacy and compatibility. If these security requirements have identified in the two first layers, so the risk of unauthorized access can be minimized, this means that if IoT devices and things are secured then, the access control in the middleware and application layers can be achieved.

Fig. 2. Taxonomy of IoT Attacks based on Security Concept.

TABLE II. THE BASIC SECURITY REQUIREMENTS FOR IOT SYSTEMS

IoT Layers	Security Services/concepts								
	Confidentiality	Integrity	Availability	Authentication	Authorization	Non-repudiation	Privacy	Compatibility	Authenticity
Physical Layer	✓	✓	✓	✓	✓				
Network Layer		✓	✓	✓	✓	✓	✓	✓	
Middleware Layer	✓	✓							✓
Application Layer		✓		✓	✓		✓		

E. Security Threats and Vulnerabilities Analysis

1) Overview of OWASP Internet of Things Project: Based on an open community and a collection analysis provided by security industry professionals, the Open Web Application Security Project's or OWASP IoT Project released its Top 10 2018 [26], which publish a report that represents the top 10 security problems and issues to avoid when using, managing, creating, deploying an IoT system. This project has listed the main concerns and vulnerabilities of IoT systems based on different IoT architecture levels. The OWASP IoT Project [15] shown that a large number of IoT vulnerabilities are caused by a lack of adoption of existing/common security mechanisms including access control, authentication, role-based access control and encryption. Therefore, because of the complicated characteristics of IoT, establishing and implementing security techniques, measures, practices, and tools is not easy. The Table III represents each security concerns by a number ranged from 1 to 10.

2) Summary: After analyzing this project, author observed that the most of issues and vulnerabilities are surrounding physical layer and most of them target the IoT devices. For instance, "Lack of Physical Hardening" has been identified by this project. This means the lack of physical security measures enables potential attackers to access sensitive data that may be used in a future distant attack or to obtain local control of the device. So, "Lack of Physical Hardening" is the most important concern that tackles the physical layer. In addition, we need to ensure that only the authorized people can access the sensitive data produced by devices or physical objects. Besides, if the security will be implemented in the physical layer including IoT things, as well as in the network layer including IoT protocols and communication technologies, then, data theft will be minimized. Consequently, significant enhancements are required to make the IoT framework secure and safe. In the next subsection, we will examine an example of security modeling in IoT systems with a UML extension called IoTsec.

F. Example of IoT Security Systems Modeling with UML

Any artificial language that may be used to convey information, knowledge, or systems in a framework determined by a set of rules is referred to as a modeling language. The UML aims to standardize the various ways for describing object-oriented systems that already exist. IoT interconnects smart entities anyhow and anywhere. Since, IoT rises new issues as well as modeling IoT security systems is a field that lacks the modelling languages for representing IoT systems in several views. The main objective of this subsection is to find the most effective extension instead of a language for IoT security modeling. Based on the characteristic of each tool, we choose two important criteria: (1) specific for IoT systems and (2) System security modeling. The choice of these points depends on our goal which is modeling IoT security. According to the extensions comparison mentioned in [4], we note that UML4IoT and SysML4IoT extensions can model IoT systems, but they lack of security matters. Other extensions like UMLsec, and

SysMLsec can be specified for security modeling, but they are not specific for modeling IoT systems. In IoT systems, IoTsec aims at modeling security issues, it is a subset of SysML and UML. It combines UML, SysML, and UMLsec. All these reasons make the IoTsec an ideal example of UML extensions, because it is the only one designed to enable security modeling for IoT systems. In this section, we give an interesting example which used a new UML extension called IoTsec that involves security issues of IoT systems (see Fig. 3). Another example done by [4] shows a layer diagram with IoTsec. Fig. 3 shows a class diagram for an IoT device with IoTsec [4], where an IoTdevice called RapberryPi3. RapberryPi3 uses a relational class N to authenticate a temperature sensor, N means authentication, in this example the attributes N have not been established yet, but they might be any authentication protocol. According to this analysis, we justified the choice of IoTsec as the best UML/SysML extension compared to the existing ones.

TABLE III.   OWASP IOT TOP 10 SECURITY CONCERNS –2018 VERSION

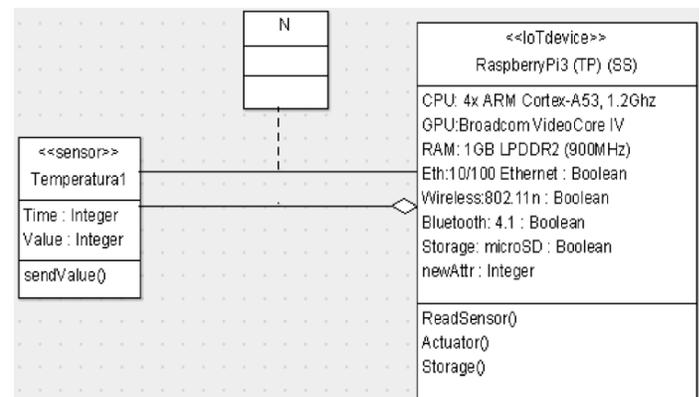
N°	The main concerns in IoT systems	Description
1	Weak, Guessable, or Hardcoded Passwords [26]	Use of easily brute forced, publicly available, or unchangeable credentials
2	Insecure Network Services [26]	Unneeded or insecure network services running on the device itself
3	Insecure Ecosystem Interfaces [26]	Lack of authentication/authorization, lacking or weak encryption
4	Lack of Secure Update Mechanism	Lack of ability to securely update the device
5	Use of Insecure or Outdated Components [26]	Insecure software components/libraries that could allow the device to be compromised
6	Insufficient Privacy Protection [26]	All aspects of the IoT architecture that potentially expose sensitive unencrypted data must be taken into account[27].
7	Insecure Data Transfer and Storage [26]	Lack of encryption or access control of sensitive data anywhere within the ecosystem
8	Lack of Device Management [26]	Lack of security support on devices deployed in production
9	Insecure Default Settings [26]	Devices or systems shipped with insecure default settings
10	Weak, Guessable, or Hardcoded Passwords [26]	Use of easily brute forced, publicly available, or unchangeable credentials


Fig. 3.   Example of a Class Diagram for an IoT Device with IoT Sec [4].

For instance, Fig. 4 shows the Ouchani's modeling. For this example, the author suggested IoT architecture enclosed five components:

- Object devices: physical objects embedded with software and sensors.

- User devices: physical objects that collect data from objects and communicate with servers.

- Computing services provided by external, internal, and cloud servers.

- Social actors: human agents that can manipulate and hold devices.

- The environment: the infrastructures which envelops the IoT entities.

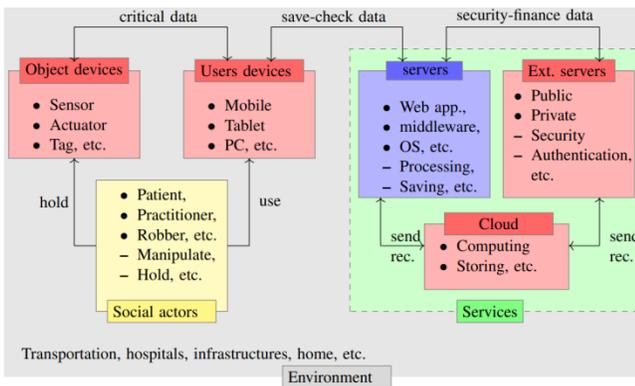
These components interact via communication protocols of various ranges (ZigBee, WiFi, Cellular, Human-machine, Bluetooth, SSH, IpSec, etc.). Table IV shows results achieved and describes clearly what has been done before on the problem.


Fig. 4. IoT-SEC Components Architecture [7].

TABLE IV. COMPARATIVE STUDY RELATED TO MODELLING IOT SECURITY

Survey	Modelling IoT security
Jha et al., 2020 [3]	Authors represent the architecture of IoT-Edge computing. Authors modeled an edge infrastructure. So, they implemented and designed numerous new classes.
Robles-Ramirez et al., 2017[4]	Regarding security concerns, authors aim to represent an IoT system. They adopted the four layers architecture including sensing, network, service, and application layer. Moreover, the nomenclature in classes is also shown. Further, this may be reached by the Block Diagram of SysML.
Samir Ouchani, 2018 [7]	The author describes the IoT architecture by presenting the IoT components with their interactions. The suggested IoT architecture enclosed five components including object devices, social actors, user devices, computing services, and the environment.
Proposed	Through this paper, the four-layer IoT architecture (Physical/perception, Network, Middleware, and Application) are proposed. Further, Physical and Network layers are chosen for IoT security modelling, which really contributes to the security of IoT systems

V. RESULTS AND DISCUSSION

In this work, the main idea is to choose the layer whose modelling is relevant. Ensuring security in IoT systems is more difficult due to several challenges. There are four layers generally, so far there is no standardization. So, according to my analysis, we should specify which layer we will work on, otherwise, we model the different layers. Several IoT architectural models have been proposed in the literature. To understand better IoT systems, we choose to work with a four-layer IoT architecture, which is composed with: perception layer, network, middleware, and application layer. Based on all observations and the Tables II and III, author found that there are two layers that must be modelled in IoT security systems, these two layers are called the physical and network layers which contain great challenges, issues, concerns, major attacks and vulnerabilities.

As we discussed in methodology section that security issues and concerns were only designed for both physical and network layers and not for middleware and application layer. In other words, taking the conclusions and results into consideration from each subsection of the previous section, it is fitting that we should only center on physical and network layers, while middleware and application layers are left out. This means that both physical and network layers have specific security concerns, issues, problems, attacks, vulnerabilities, and challenges which are not present in both middleware and application layers. The main focus is on the physical layer and the network layer due to the limitations and constrains brought by the IoT devices as well as the compatibility issue.

In addition, for each layer a detailed analysis has been done in terms of four-layer architecture. The goal is to model IoT security system at the design stage, even if developers are not fully familiar with cyber security concepts. IoT system design is difficult, and UML modeling is proving to be a useful tool for overcoming it. In general, UML, SysML, and ThingML are the three modeling languages. While, IoTsec [4], UMLsec [7], SysMLsec [7], SysML4IoT [7], UML4IoT [8] are some extensions of UML and SysML. Based on extensions comparison which have done in [4], we noticed that, neither UML nor SysML languages can be used for security modeling of IoT systems. Whereas ThingML is the most used language for modeling IoT systems. However, this language only specific for IoT systems and does not model the systems security. The only UML/SysML extension to model IoT security is the "IoTsec".

There are some challenges for modelling/designing IoT applications:

- Heterogeneity: due to its different virtual and physical components with several characteristics that are embedded, forming a complex system; as well as the compatibility problem (communication technologies).

- Interoperability: in terms of infrastructure. Indeed, resources are restricted and limited in the physical layer.

- Distribution: over a large number of processing nodes.

- The absence of a model for addressing security concerns in IoT systems.

- A lack of a design paradigm for IoT applications.

- The lack of standardization in IoT architecture is another restriction.

Thus, the challenge of evolving and deploying software for the IoT is frequently underestimated [28]. IoT applications have two primary characteristics from the standpoint of software engineering. The first factor is the distribution over a large number/range of processing nodes. While, the second one is the high/significant heterogeneity of processing nodes as well as the protocols that connect them [28]. With UML resources, it is possible to represent a small IoT system. UML diagrams and extensions can be used to represent the various views of an IoT environment (security, static, behavioral, etc. [29]). Tables V and VI present the added values and the weakness of each paper to deduce what have been done before on the problem, and what is new.

Therefore, modelling IoT systems is challenging due to their heterogeneity, which is caused by the integration of physical and virtual components, resulting a complex system [29]. Indeed, the IoT is often viewed as a single-issue domain [30]. The UML is a language [29] of general usage for documenting, specifying, visualizing, and constructing artifacts of the software system [29]. Simulating a realistic scenario in IoT is very challenging [31]. The challenge of modeling such complex systems lies in the heterogeneity of these systems, due to their different virtual and physical components that are embedded. Indeed, UML resources are used to represent the various views of an IoT environment or application using its extensions and diagrams [29]. Since security is considered as one of the most crucial quality attributes in networking [32] and also in the field of IoT and software engineering, it is necessary to provide holistic protections for IoT architecture [33].

To answer the research question, author mainly based on the proposed methodology including the results of all subsections and challenges related to the security of IoT systems (IoT layers). As we discussed in the above section, the physical layer can be easily accessed by attackers as well as the main operations of this layer. The IoT communication technologies and protocols of the network layer are susceptible to security vulnerabilities. Both layers impacted differently by the security issues, problems, attacks, threats and vulnerabilities compared to two last layers. Compatibility, heterogeneity and resource constraint of the two first layers made the IoT security worse. All these reasons make security of IoT systems complex and more difficult. Consequently, we need to model the two first layers (physical and network layers).

Finally, the relevant layers to model that really contribute to the security of IoT systems are two layers namely, the physical layer and the network layer. The choice of these two layers poses at least two major and huge problems which may

slow down the whole IoT systems development. For that, we should have interested in these two layers more. To sum up, security needs to be modeled in both physical and network layers. According to Table V and Table VI we can notice that a method to design IoT systems with their security issues is required.

TABLE V. COMPARISON OF RELATED SURVEYS

	Objectives	Results
[3]	Authors aim to model realistic IoT and edge environments. To model an edge infrastructure, they implemented and designed numerous new classes. IoT & Edge computing	The findings demonstrate that IoTSim-Edge has different capabilities in terms of mobility modeling, heterogeneous protocols modeling, battery-oriented modeling, application composition and resource provisioning for IoT applications.
[4]	For IoT systems the use of the UML was proposed by the authors of [4], with also the suggestion of extensions. Besides, IoTsec was also presented by authors; The aim is to facilitate the representation of security concerns with a visual notation, even if the developers are not totally or completely familiar to Internet cybersecurity concepts.	For modeling common actors, IoTsec uses UML extensions for security encapsulated in UML nomenclature and stereotypes. They aim at detailing the activities developed in three stages.
[5]	Authors aims at modeling environment that enable to deploy, design, and specify complex IoT systems;	The approach introduced by authors uses already IoT-A in the Papyrus for IoT modelling environment.
[6]	Authors suggested extensions and used UML for IoT systems; IoTReq was the proposed method;	The IoT system present peculiar characteristics that necessitate the use of specific approaches to represent their requirements, implementing hardware, software intersection.
[7]	Authors describes the IoT architecture by showing its components with their interactions.	The suggested IoT architecture enclosed five components as shown in Fig. 4.
[8]	Authors aims at using the UML, or UML profiles, for supporting the IoT systems development.	Authors used UML4IoT an UML approach based on the use of UML profile. UML4IoT is an UML profile for IoT

TABLE VI. ANALYSIS OF THE EXISTING SURVEYS

Survey	Weakness
[3]	The authors didn't mention some different factors such as storage technology, …
[5]	This paper has not a detailed and comprehensive look;
[7]	The authors don't consider privacy, security and trust domains.
[8]	The mentioned extension does not support Security;
[10]	This paper lacks more experiments. Moreover, the proposed framework suffers from the limitations;

VI. CONCLUSION

Existing visions have resulted in a lack of knowledge of the architecture of IoT systems. Hence, there is no standardization about the IoT architecture. Moreover, in the previous works, there is no answer about the following questions: Which is the layer whose modeling is relevant? What is/are the relevant layer(s) to model that really contribute to the security of IoT systems? Through this work, several axes have been presented and detailed. Hence, a proposed IoT architecture has also been investigated. Moreover, security concerns at various layers of IoT architecture were described in this study. Then, the challenges of IoT architecture were demonstrated. The chosen or proposed IoT architecture consists of four layers (see Fig. 1), known as the perception, network, middleware and application layer.

This paper covers the modelling of IoT systems. The objective of this article is to model complex systems. Modelling of IoT application in the real environment is difficult, complex, time-consuming and not effective in terms of cost [3]. To facilitate modelling of IoT systems, several languages and extensions have been developed. As a result, this study recommends the use of IoTsec for modeling IoT security because it is the only one that enable us to model IoT systems and security that are our needs/goal. In this paper, we have studied the comparison in terms of IoT layers. Further, a comparison between previous works in terms of modelling IoT security systems have been also made in order to deduce the relevant layer to model that really contributes to the security of IoT systems.

We have studied in detail the architecture of the IoT systems in order to be able to deduce that physical and network layers have many challenges, issues, vulnerabilities, attacks and need more security. In this paper, the physical layer and the network layer are the two layers chosen for modelling. Therefore, the security of IoT systems must be taken and considered in an earlier stage during the design phase.

Our future study will focus on making a comparison between UML and SysML modeling languages to prove the efficiency of SysML with a concrete case of IoT systems which is forest fires.

DevOps Enabled Agile: Combining Agile and DevOps Methodologies for Software Development

Shah Murtaza Rashid Al Masud, Md. Masnun, Mst. Afia Sultana
Anamika Sultana, Fahad Ahmed, Nasima Begum
Department of Computer Science and Engineering
University of Asia Pacific, Dhaka, Bangladesh

Abstract—The Agile and DevOps software development methodologies have made revolutionary advancements in software engineering. These methodologies vastly improve software quality and also speed up the process of developing software products. However, several limitations have been discovered in the practical implementation of Agile and DevOps, including the lack of collaboration between the development, testing and delivery sectors of different software projects and high skill requirements. This paper presents a solution to bridge the existing gaps between Agile and DevOps methodologies by integrating DevOps principles into Agile to devise a hybrid DevOps Enabled Agile for software development. This study includes the development of a small-scale, experimental pilot project to demonstrate how software development teams can combine the advantages of Agile and DevOps methodologies to fulfill the gaps and provide further improvements to the speed and quality of software development process while maintaining feasible skill requirements.

Keywords—Agile; DevOps; gaps; collaboration; skill; DevOps Enabled Agile; software development

I. INTRODUCTION

The field of software development is evolving continuously with new methodologies and techniques constantly being devised to bridge the gaps of previous ones. Our motivation is to propose and verify the DevOps Enabled Agile methodology, a methodology that will combine Agile with DevOps to fulfill the gaps of both methodologies in order to further advance the field of software development.

This study includes an in-depth analysis of Agile and DevOps methodologies, describing and comparing the different practices, requirements, challenges etc. and concluding that both methodologies have disadvantages and drawbacks that can reduce the effectiveness of individually implementing them for software development projects. On the basis of this analysis, the implementation of DevOps Enabled Agile has been justified as the solution to this problem.

For practical application of implementing DevOps Enabled Agile methodology, we propose combining standard Agile methods with the cross-functionality and collaboration principles of DevOps. We have developed an experimental pilot project using this procedure and conducted an in-depth comparison of the results gained by observing the performance of both Agile and DevOps Enabled Agile methodologies in order to demonstrate the benefits of DevOps Enabled Agile methodology.

The remaining parts of this paper are organized in the following ways; Section II presents an in-depth comparative analysis of Agile and DevOps methodologies and provides justification for combining these methodologies into DevOps Enabled Agile methodology. Section III contains the background and related works of our study in the form of a systematic literature review. Section IV describes the proposed methodology used in this study to test and verify the effectiveness of DevOps Enabled Agile for an experimental pilot project. This is followed by Section V which contains the results from the experimental pilot project and a discussion of the findings that justify the implementation of DevOps Enabled Agile. Lastly, in Section VI, the study is concluded with a brief analysis of the scope for future research.

II. ANALYSIS OF AGILE AND DEVOPS

Agile methodology is a highly efficient and effective software development methodology which is focused on four core principles [1]. These principles emphasize the importance of individuals and interactions over processes and tools, working software over comprehensive documentation, customer collaboration over contract negotiation, and responding to change over following a plan.

There are many methods and techniques to implement Agile methodology depending on project scope, knowledge domain and other factors including DAD, SAFe, XP, Scrum etc. [2] Scrum in particular is an agile framework designed for small teams which is relatively simple to use and highly adaptable to changes [3].

Agile methodology provides many different benefits over traditional software development methodologies [4]. The main benefits include lower documentation requirements, strong collaboration with customers, rapid delivery and continuous alignment with business needs and goals.

However, we have discovered that Agile methodology has a number of major gaps including the separation of the development, testing and delivery sectors and lack of cross-functionality [5]. Agile methodology does not support continuous integration of feedback during development, thus limiting the speed and efficiency of software development. Additionally, the lack of cross-functionality within developer teams may result in disconnected and uncoordinated development, testing and delivery sectors which may lead to project completion and progression not aligning with planned estimates.

However, DevOps (Development-Operations) is an extension of Agile methodology which can harmonize the development and operation processes/sectors and provide cross-functionality within teams. Thus, DevOps can mitigate some of the drawbacks of Agile methodology.

DevOps is a software development methodology focused on the collaboration of developers and operators, but it lacks concrete definition and is referred to as a skillset, a set of practices and even as a job description [6]. DevOps focuses on cross-functionality between different sectors of development, operations and quality assurance which would result in highly coordinated development, testing and delivery which would lead towards smoother project progression [7].

But, pure DevOps certainly cannot focus on fulfilling continuously changing user requirements by receiving and incorporating feedback in incremental cycles. Additionally, pure DevOps has high skill requirements that cannot be fulfilled by software engineers who lack extensive training and experience on DevOps culture and practices. Thus fully incorporating DevOps into public sectors such as mid and low level software development projects would result in difficulties and drawbacks that would be unacceptable for efficient and effective software development process [8] [9] [10].

Hence, to mitigate the existing problems, we propose combining Agile and DevOps methodologies into the hybrid DevOps Enabled Agile methodology for software development. Our research and analysis have revealed that DevOps and Agile methodologies can be combined together to produce the best results and mitigate the existing problems of both methodologies. Our method will follow the examples set by related works that have suggested combining Agile with DevOps to utilize the benefits of both methodologies [11] [12] [13] [14].

Our proposed methodology, DevOps Enabled Agile has been designed to combine the collaborative and cross-functional aspects of DevOps with the simplicity and low skill requirements of Agile to bridge the gaps of both methodologies, thus ensuring rapid progression and maximum effectiveness of the development, testing and delivery sectors of software development projects. Therefore, this analysis justifies the implementation of DevOps Enabled Agile for software development.

III. RELATED WORK

Our study includes a systematic literature review of different related works. We have screened ten existing papers in particular as the basis of our research and analyzed the problem statement, research method and limitations of these papers as presented below in order to conduct the literature review.

Marius Andersen Bjørni and Simen Haugen have conducted interviews and observations to discover the major challenges of Agile methodology which consist of high sprint workloads, lack of testing in sprints before release, poor PBI descriptions, lack of business agility, lack of documentation, inadequate PBI grooming, lack of team improvement, inefficient release process and not holding sprint reviews.

However, this study has not considered work estimation during research, leaving this factor as a research gap [5].

Koi-Akrofi et al. have also conducted a study on Agile methodology based on literature review. They have pointed out the notable advantages of Agile over traditional methodologies, which include adaptability towards changing customer requirements, simple method of updating, priority assessment, feedback integration, continuous testing and motivation for developers. They have also pointed out the notable challenges of Agile methodology which are the unpredictability of development, requirement of high dedication, time and effort, greater customer demands, lack of documentation and projects going off-track. However, this study is purely a literature review and does not use any additional method of research, thus showing that fully transitioning to DevOps also has major difficulties and drawbacks [15].

Farid et al. have conducted a study on combining DevOps with Lean Software Development. This study has presented Lean Software Development as a software development methodology focusing on waste reduction and continuous improvement while presenting DevOps as a set of practices targeted towards improvement of the overall development life cycle by integrating development and operations together in cross-functional teams. The research method involves implementing DevOps practices to bridge discovered gaps in Lean Software Development. This method was able to utilize DevOps practices to overcome issues of Lean Software Development in a number of different areas including Delays, Defects, Extra Features, Task Switching etc. The limitation of this work is that the application of DevOps principles to overcome existing issues has only been tested with Lean Software Development and the exploration of similar cases of applying DevOps principles for Scrum, XP and other methods have been left as prospects for future research [16].

Banica et al. presented DevOps as a Project Management methodology for software development projects. It utilizes a pilot project as the method of research, incorporating DevOps facilities into the development process of a website using VersionOne tool which is highly suitable for project management systems supporting DevOps methodology. The results of this project show that DevOps speeds up and improves the development process. However, due to the inexperienced teams used, some problems were faced during development, including delays and missing certain development goals, which classifies as the limitation of this research [17].

Wiedemann et al. provides an in-depth analysis on the application of DevOps methodology for IT projects. A qualitative multiple case study was conducted in eight different industries that utilize DevOps to achieve intra-IT alignment, justifying the use of DevOps in IT project management in order to orchestrate development and operations within IT functions. However, this study only proposes using DevOps methodology for this purpose, neglecting the potential of combining it with Agile methodology to gain further advantages and overcome existing disadvantages, thus leaving a gap in the research [18].

Kuusinen et al. observed and analyzed the progression of two groups of students working on software projects transitioning from Agile to DevOps methodology. This research discovered several challenges and problems in the transition process, including legacy systems, issue of rights and slow testing. Applying continuous testing and the collaboration of cross-functional teams have been suggested as solutions to solve these problems. However, a more complete solution involving the utilization of Agile methodology in coordination with DevOps methodology instead of fully transitioning to DevOps methodology has been left unexplored, which is a limitation to be addressed by future research [19].

Sikender Mohsienuddin Mohammad briefly compares Agile and DevOps Methodologies by analyzing their similarities and differences. The similarities of Agile and DevOps are that both are focused on quick and efficient iterative feedback-based development of software. They can be used together in a coordinated way to speed up and improve the software development process. On the other hand, there are also some major differences between the two methodologies. These differences include Agile only taking feedback from customers while DevOps additionally takes feedback from internal team and Agile minimizing the gap between developers and customers while DevOps minimizes the gap between developers, testers and operators. However, this paper neglects to mention the challenges of DevOps methodology, leaving it as a gap in the research [20].

Hemon et al. have proposed a maturity model for transitioning from Agile to DevOps, utilizing three stages of progression; Agile, Continuous Integration and Continuous Delivery. This model focuses on the alignment of development and operations while aiming to achieve greater smartness in IS function. However, the scope of this research does not extend towards the field of software development despite Agile and DevOps having a high degree of application in this field. Thus, it can be considered as a research gap [8].

Hemon et al. conducted an additional study on the subject of Agile to DevOps transition, focusing on individual roles, collaboration and skills. The research method applied data collected from a case study in an organization with years of experience in DevOps to form the basis of the research. The results of the research conclude that DevOps allows for balanced collaboration between individuals but also requires skilled developers and operators to be used efficiently. However, the extent of more diverse collaboration has not been fully demonstrated in this study, which could be explored in future research [10].

IV. PROPOSED METHODOLOGY

Our study has utilized the development of a small scale, experimental pilot project using Agile and DevOps Enabled Agile methodologies followed by a systematic comparison of the results in order to justify and validate our proposed methodology for software development.

The development process consists of a three-phase method followed by the developer teams:

1) The first phase consists of the identification of customer requirements before converting them into a sprint backlog.

2) The second phase consists of developing the components of the project and testing them to resolve any issues.

3) The third phase consists of delivering each component to the customer and gaining feedback to keep the project on track and ensure fulfillment of requirements.

We have selected a simple web application for the students of a university to perform course selection and manage payments as our pilot project. In the initialization process, we have formed a team consisting of three members, the developer, the tester and the customer representative.

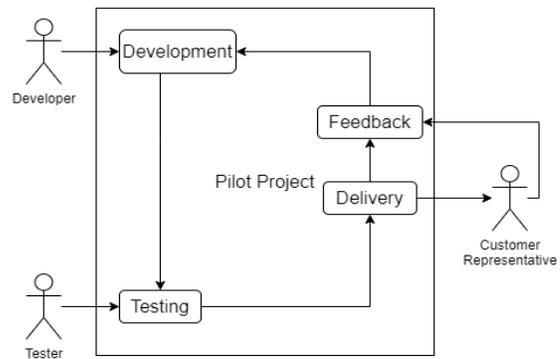
A use case diagram illustrating the team members, their contributions to the pilot project and the information flow between them is given in Fig. 1:


Fig. 1. Use Case Diagram of the Pilot Project.

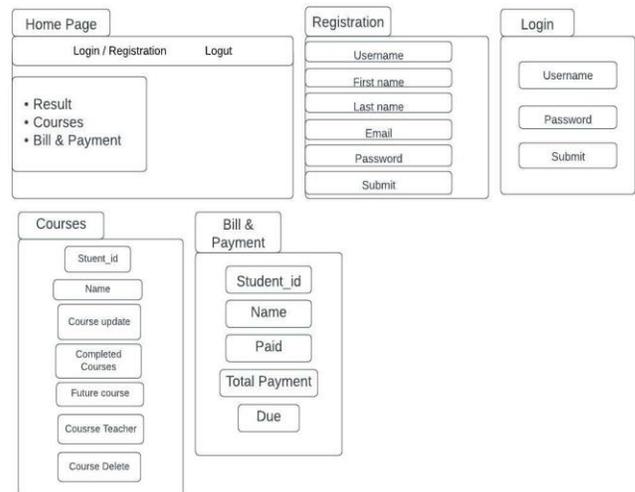
The customer representative provided a list of requirements for the project, illustrated in Fig. 2:


Fig. 2. Requirements Diagram of the Pilot Project.

We have analyzed these requirements describing the structure of the project and converted the results into a sprint backlog consisting of four sprints for each module of the web

application with two to three story points denoting module features adding up to a total of 10 story points, as shown in Table I.

Sprint No.	Sprint Description	Story Point No.	Story Point Description
1	Front End	1	Structure of front end system
		2	Design of front end system
		3	Navigation through front end system
2	Authentication	4	Registration feature
		5	Login feature
		6	Log out feature
3	Course Selection	7	Course Selection feature
		8	Course Viewing feature
4	Payment	9	Payment Status feature
		10	Make Payment feature

In the first iteration, we used Agile methodology by assigning the team members to work separately on the development, testing and delivery sectors over a five-day period. We have catalogued the observed data on performance and progression in the form of a series of Burndown Charts plotting actual remaining story points and estimated remaining story points against the number of days passed. The Burndown Charts of this iteration have tracked the performance of the development, testing and delivery sectors using Agile methodology.

For the next iteration we switched to DevOps Enabled Agile methodology with cross-functional team members working together over a five-day period. This led to continuous collaboration and cooperation among the team members, allowing for the development, testing and delivery sectors to become coordinated without having to fulfill the high skill requirements of fully transitioning to DevOps. We have observed the performance of this methodology by generating another series of Burndown Charts tracking the performance of the development, testing and delivery sectors using DevOps Enabled Agile methodology.

Thus, the implementation of our pilot project has been completed using both Agile methodology and DevOps Enabled Agile methodology with the Burndown Charts generated for both iterations allowing for in-depth comparisons of their performances to determine that DevOps Enabled Agile is the superior methodology in terms of project progression. The findings and discussion of our methodology have been presented and further discussed in the next section of our study.

V. FINDINGS AND DISCUSSION

The results of our pilot project have been observed and catalogued in the form of two separate series of Burndown Charts that denote the performance of Agile methodology and DevOps Enabled Agile methodology for the development and

delivery of a simple pilot project by a small team of inexperienced developers.

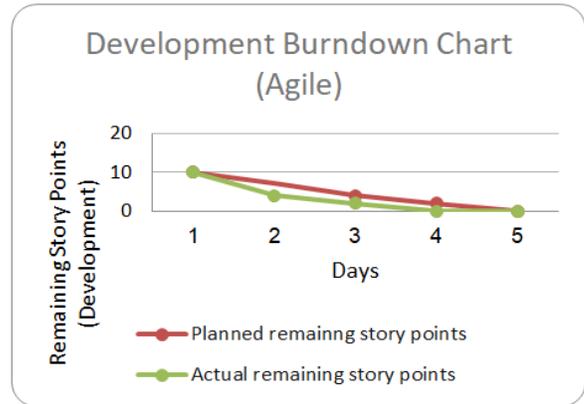
The Burndown Charts for the first iteration (Agile) are given below:


Fig. 3.   Development Burndown Chart (Agile).
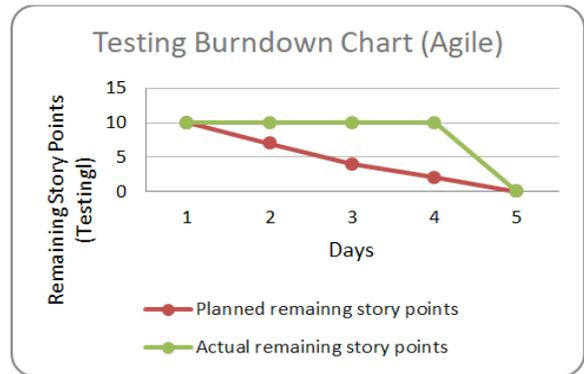

Fig. 4.   Testing Burndown Chart (Agile).
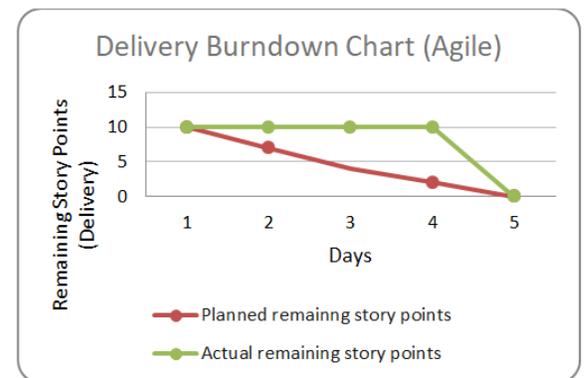

Fig. 5.   Delivery Burndown Chart (Agile).

In the first chart of this iteration shown in Fig. 3, we can see that the number of actual remaining story points consistently stayed below the number of estimated remaining story points throughout the project and development reached completion before the estimated deadline on day five, meaning that the development sector performed better than estimated, progressing faster and finishing earlier than planned.

In the second and third charts of this iteration shown in Fig. 4 and Fig. 5 respectively, we can see that the actual remaining story points for testing and delivery have not decreased at all until the last day. This means that testing and delivery sectors were unable to make any progress before the completion of the development sector on day four, which shows that the observed performance is not up to estimated standards.

Therefore, Agile methodology has not performed as well as estimated due to the lack of consistent progression in the testing and delivery sectors. Our proposed reasoning behind this is that the lack of cross-functionality or collaboration between team members lead to the testing and delivery sectors heavily depending on the completion of the development sector, resulting in overall project progression lagging behind planned estimates until the end of the project timeline.

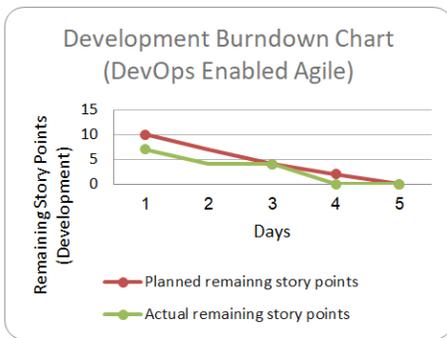
The Burndown Charts for the next iteration of the project using DevOps Enabled Agile are illustrated below:


Fig. 6.   Development Burndown Chart (DevOps Enabled Agile).
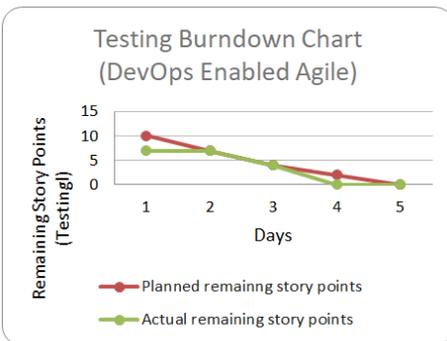

Fig. 7.   Testing Burndown Chart (DevOps Enabled Agile).
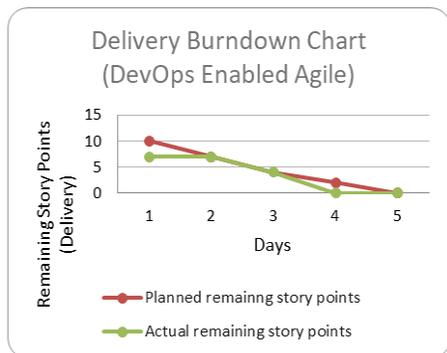

Fig. 8.   Delivery Burndown Chart (DevOps Enabled Agile).

In the first chart of this iteration shown in Fig. 6, we can see that the development sector performed better than estimated similar to the previous iteration, showing faster progression throughout the project and reaching completion before the estimated deadline.

In the second and third charts of this iteration which are shown in Fig. 7 and Fig. 8 respectively, we can see that the actual remaining story points for testing and delivery have mostly remained below the estimated remaining story points and reached completion earlier than planned. This means that the testing and delivery sectors have performed better than planned estimates, leading to consistent and efficient progression of project goals and the completion of the testing and delivery sectors before the estimated deadline.

By comparing this data with the data gained from testing Agile methodology in the previous iteration, we can conclude that our proposed methodology, DevOps Enabled Agile methodology has performed far better in terms of consistent project progression and completion of project goals. DevOps Enabled Agile methodology utilized the cross-functionality aspect of DevOps to ensure that all three sectors would progress in a coordinated way leading to all three sectors gaining significant progress throughout the project timeline as opposed to Agile where testing and delivery could not progress until development reached completion. Therefore, DevOps Enabled Agile has been validated as a superior software development methodology when compared to Agile.

VI.   CONCLUSION AND FUTURE WORK

Our research has been focused on discovering the different gaps of the existing DevOps and Agile Methodologies and combining them to devise a new hybrid methodology, DevOps Enabled Agile, designed to bridge these gaps. From our findings, we have verified the effectiveness and integrity of DevOps Enabled Agile methodology in fulfilling the gaps of Agile methodology while also avoiding the drawbacks of fully transitioning to DevOps methodology and thus we have validated the accomplishment of our research objectives.

The limitation of our research is that we have only tested our proposed DevOps Enabled Agile methodology on a small scale, experimental project. Thus, its effectiveness has not been verified for large scale industrial software development projects. Additionally, our methodology is more focused on the cross-functionality and collaboration principles of DevOps methodology without utilizing any advanced DevOps tools. Application of DevOps Enabled Agile using DevOps tools has been left unexplored as a prospect for future research.

In the near future, we are planning on further optimizing and enhancing DevOps Enabled Agile methodology to make it suitable to be used universally for software development in both small and large scale projects. Additionally, we plan to test the application of DevOps Enabled Agile using different tools and techniques that have not been used in our experiment in order to verify whether this methodology is able to effectively adapt to them. This concludes our current study with a brief description of our future plans for further research.

Issues in Requirements Specification in Malaysia's Public Sector: An Evidence from a Semi-Structured Survey and a Static Analysis

Mohd Firdaus Zahrin[1], Mohd Hafeez Osman[2]*, Alfian Abdul Halin[3], Sa'adah Hassan[4], Azlena Haron[5]
Faculty of Computer Science and Information Technology, Universiti Putra Malaysia, 43400 Serdang, Malaysia[1, 2, 3, 4]
National Administrative Institute, Public Service Department of Malaysia[5]

Abstract—**Requirement specifications (RS) are essential and fundamental artefacts in system development. RS is the primary reference in software development and is commonly written in natural language. Bad requirement quality, such as requirement smells, may lead to project delay, cost overrun, and failure. Focusing on requirement quality in the Malaysian government, this paper investigates the methods for preparing Malay RS and personnel competencies to identify the root cause of this issue. We conducted semi-structured interviews that involved 17 respondents from eight critical Malaysian public sector agencies. This study found that ambiguity, incompleteness, and inconsistency are the top three requirement smells that cause project delays and failures. Furthermore, based on our static analysis, we collected the initial Malay RS documents from various Malaysian public sector agencies; we found that 30% of the RS were ambiguous. Our analysis also found that respondents with more than 10 years of experience could manually identify the smells in RS. Most respondents chose the Public Sector Application Systems Engineering (KRISA) handbook as a guideline for preparing Malay RS documents. Respondents acknowledged a correlation between the quality of RS and project delays and failures.**

Keywords—Ambiguity; requirements engineering; requirement smell; requirement specification; semi-structured interview

I. INTRODUCTION

Software Requirement Specification (SRS) is a document that details the behaviour of a system. It describes the functionality and non-functionality of the software to meet the requirements of all relevant stakeholders (business, users, and software). RS impacts entire software development project stages [1] as it may specify the Business Requirements Specification (BRS), User Requirements Specification (URS), and Software Requirements Specification (SRS) that define the expectation of the stakeholder of a system to be developed. RS is commonly expressed in Natural language [2], which is exposed to requirement smell [3] such as ambiguity, inconsistency, incompleteness, etc. [4]. The requirement smells impact the requirements' quality which may lead to low product quality.

In Malaysia, the public sector has funded a massive amount of money to digitise its systems. A lot of systems have been developed to realise the e-government initiative. However, from our initial observation, some system development projects faced problems such as project delays

and low-quality product quality. We may assume that RS can be one of the causes of this problem. Based on a survey, 50% of requirement engineers were unaware of ambiguous Malay RS [5]. Zahid et al. [6] have highlighted those smells in RS cause roughly 70% of the project to fail. A lack of precise RS is one of the causes of project failure [7]. Unintentional ambiguity in natural language requirements leads to diverse implementations later in software development [8]. Based on Sommerville [9], "Clients of systems often struggle to translate their desires into requirements," resulting in smells and general terms in the requirements [4]. According to Iqbal et al. [10], "Ambiguous and generalised RS add significantly to project time and cost." Quality RS is determined by comprehending and managing requirements correctly [11]. Furthermore, Rios et al. [12] mentioned that based on survey results, 53% of respondents (software developers) reported that document debt is associated with requirement issues. These previous studies show that requirement smells can cause project delays or failures.

These issues motivate us to investigate the requirement smells and other problems in Malay RS. We focus on Malaysian government projects since most of the RS in the Malaysian government usually use the Malay language.

This paper aims to investigate the preparation of Malay RS and identify the issues that can result in project delays and project failures (incomplete or unfinished). This paper focus on four (4) perspectives (in four (4) research questions (RQ)): The Human factor (RQ1), the Communication factor (RQ2), the Process and Procedure (RQ3), and the Issues in RS (RQ4). We formulate the RQ (as shown in Table I) based on the Ab Aziz [13] guidelines.

This study contributes to the following:

1) We discover factors influencing the requirement smells in Malay RS.

2) We reveal the relation between requirement smells detection and software developer experience.

The remaining sections of this work are organised as follows. The Related Works section describes the relevant studies. The Methodology section reports the approach used to conduct the research. The Findings section explains the result. We discuss the findings in the Discussion section, and the Conclusion section summarises the paper.

TABLE I.   RESEARCH QUESTIONS AND RESEARCH OBJECTIVES

Problem Statement	Research Question (RQ)	Research Objective (RO)
The requirement smells in Malay RS contribute to project delays and project failures.	RQ1: How competent are Malaysian public sector requirement engineers and software developers?	RO1: To investigate the competency level of requirement engineers and software developers in the Malaysian public sector.
	RQ2: What is the most used language in RS?	RO2: To identify the most language used in RS.
	RQ3: How is RS prepared and verified?	RO3: To identify the methods used to prepare and verify the RS.
	RQ4: What are the issues in RS?	RO4: To explore and identify the RS smells.

II. RELATED WORKS

We explored credible sources and found articles that are close to our study are the following:

A. Survey on Agile Requirements Engineering (RE) Practices

Barata et al. [14] studied the agile requirements in practice that focused on how professionals view the significance of requirements in an Agile methodologies-based software development project. A survey of 46 Brazilian software development experts asked about methods for collecting and expressing Agile requirements and their features, benefits, and challenges. The authors studied respondents' experience, viewpoints on collection methods, and Agile requirements specifications. On the contrary, we focused on some factors, i.e., investigating the issues in RS, methods for preparing the RS, RS verification and validation approaches, and requirement engineers' competencies.

B. Survey on Requirement Smells Among IT Practitioners

Lenarduzzi et al. [15] surveyed requirement engineers to understand the theoretical and practical perceptions of the harmfulness of requirement smells and to compare these perceptions with one another. A precise and validated approach for reducing issues during requirement elicitation is proposed to avoid introducing requirement smells. The authors focused the survey among requirement engineers on requirement elicitation processes to prevent the requirement smells. In contrast, our survey involved requirement engineers and software developers regarding the smells commonly found in requirements documents that could delay and fail software development projects.

Rios et al. [12] surveyed to obtain feedback from a software engineer on the factors leading to documentation debt, the effects of this problem, and potential solutions. The term document debt (DD) describes issues with software project documentation, namely the search for missing, inconsistent, out-of-date, or inadequate documentation [16]. These surveys (questionnaires and an interview-based case study) involved 39 practitioners from replications in Brazil, Chile, Colombia, and the United States. The fourth research question, "Which phase of the software development life cycle is most affected by the presence of DD?" reveals a substantial correlation between DD and requirements problems. In their

examples of DD, around 53% of participants highlighted requirements issues. Examples include: "Lack of clarity and precision in the formulation of requirements" and "Needing to construct unspecified code because the requirement was not addressed in the documentation." The researchers focused on identifying the factors that led to DD based on the software development life cycle. In the way of comparison, we focused on the requirements phase. We surveyed the strategies in preparing Malay RS to determine the cause of requirement smells based on IEEE [4] quality attributes.

Within the software development life cycle context, Ahmad et al. [17] published the results of a survey that aimed to ascertain the relative importance of software requirements defects. Using questionnaires, the authors surveyed Malaysian IT professionals from diverse businesses (public, private, and software houses) and job titles (business analyst, system analyst, software engineer, etc.). According to the result, the requirement has defects, such as missing, incorrect, inconsistent, ambiguous, etc. Ahmad et al. [17] concentrated on the survey employing instruments such as questionnaires. In contrast, we conducted a semi-structured interview to investigate the smells in Malay RS documents in Malaysia's public sector agencies. Ahmad et al. [17] did not mention the language of the requirements. We assumed the authors selected the English requirements for their study. In this paper, we highlighted the most significant requirement smells.

C. Survey on Formalising System Requirements and Validation

Mokos and Katsaros [18] surveyed advancement in formalising and early validating system requirements. Several industrial research projects have provided valuable experience in pattern languages and formal property derivation. RS can use domain ontologies to identify missing information, inconsistencies, and under-specification. Our study differs because the author did not specify the survey method, whereas we used the semi-structured interview method. Mokos and Katsaros [18] also reviewed design paradigms not covered by our research.

D. Survey on Industrial IT Professionals' Awareness of Malay SRS

Haron and Abdul Ghani [5] surveyed IT professionals about their perception of ambiguity in the Malay SRS. The survey shows that IT professionals, especially in SRS, tend to overlook ambiguity. More than 50% of the respondents were unaware of the occurrence. The need for a tool to help solve the problem is undeniable. The difference with our study is; that the author sent a set of Malay SRS to IT professionals to assess their understanding of the functional specification. Meanwhile, we used Likert-scale and open-ended questions to gather software developers' understanding (semi-structured interview).

E. Survey on RE in Practice

Aguilar et al. [19] investigated the impact of RE practice in 16 small-sized software firms through a survey in Sinaloa, Mexico. The degree of relationship between each variable was determined using Pearson correlation analysis. The identified variables, i.e., company location, the scope of coverage,

number of workers, etc. The survey found no strong correlation between the seven variables analysed. The significant issues to address; are i) Ineffective client-software development team communication can harm the RS; ii) Ad-hoc RE practices that are hard to track and possibly lost (untraceable) because respondents think RE is not essential for small firms. Our study differs; Aguilar et al. [19] concentrated on issues related to RE practice in the organisation through questionnaires, while our research focused on smells and issues in RS obtained from semi-structured interviews.

Ilyas et al. [20] surveyed Pakistani software companies' current requirement process practices for identifying issues. 10% of companies are unaware of the value of standards in product development. The most critical activity in software development is gathering system requirements. This step is crucial to understanding the user's needs. Our study differs because the author used questionnaire methods, and Ilyas et al. [20] focused on organisational issues. Çamoğlu and Kandemir [21] investigated the software RE processes in Turkish firms (energy, finance, and telecommunication sector). This study identified common issues and problems in business analysis. Insufficiently defined requirements and demands are the leading cause of process failure in all sectors. There is no standardisation of RS documentation. The most commonly used RS documentation tools are Microsoft Word and Excel. The authors focused on high-level RE issues while we concentrated on RS issues. Çamoğlu and Kandemir [21] collected data from many participants via questionnaires, but we interviewed a few for more in-depth feedback.

F. Survey on Techniques Suggested by Industrial Standards

Jarzębowicz and Połocka [22] surveyed requirements documentation techniques in various software project contexts in Poland IT firms. The survey asked 42 Polish IT professionals to choose strategies for multiple projects. After the survey, two interviews with business analysts were conducted to interpret the results. Our study differs because Jarzębowicz and Połocka [22] focused on RS and documentation techniques while we concentrated on problems and requirement smells in RS. The authors used questionnaires and interviews, but we used semi-structured interviews.

G. Quality Assurance in RE

Noorin and Sirshar [23] organised a survey on quality assurance in RE. The authors focused on analysing quality parameters that ensure the requirements are met. The authors discovered that models like LaQuSo Software Product Certification Model, Neural Network, Case-Based Reasoning, and others are used to check other quality parameters like correctness and completeness. In addition, analysing quality characteristics improve requirement quality. Our study focused on RS issues gathered through semi-structured interviews, while the authors surveyed models and quality attributes to strengthen requirements.

H. Factors of Projects Failure in Terms of RE Processes

Hussain and Mkpojiogu [24] investigated the success or failure factors of software development projects related to RE processes using secondary data analysis. As can be seen, poor requirements processes lead to software project challenges and failures. However, a reasonable requirements collection and process contributes to software project success. The authors advise software project planners, engineers, and managers to include adequate RE processes in all software development projects to avoid failures and challenges. It differs from our study; the authors concentrated on causes related to RE processes that influence the software development project failure or success. In contrast, we focused on requirement smells contributing to project delays and loss.

III. METHODOLOGY

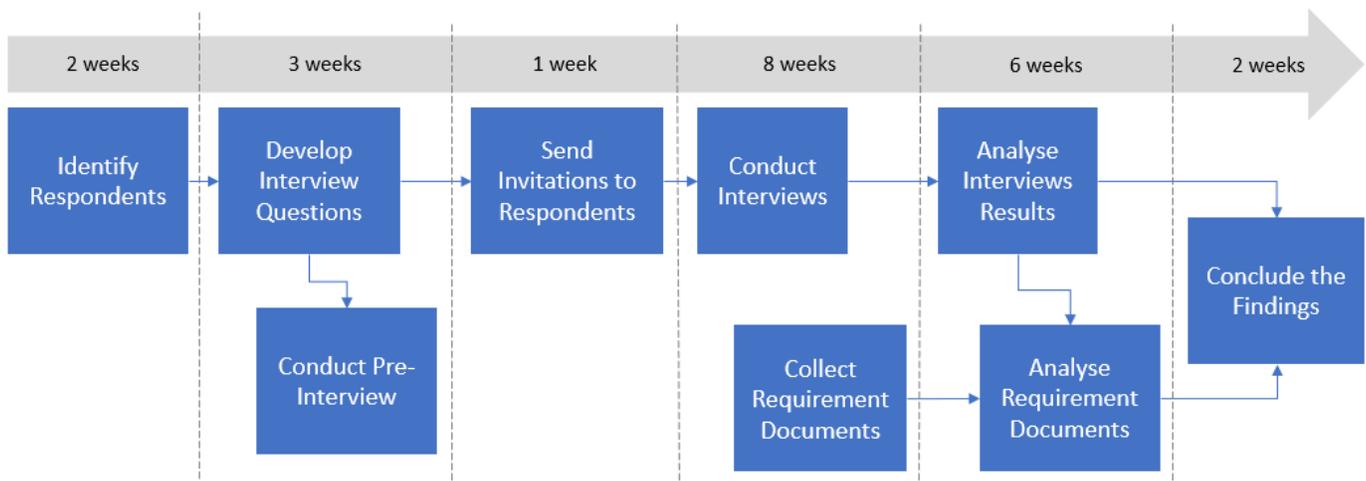
This study is conducted to understand and observe RS preparation in the Malaysian public sector. We followed Ab Aziz's [13] guidelines to perform the study through the semi-structured interview. Overall, there are nine (9) steps to conduct the study, i.e., identify respondents, develop interview questions, conduct pre-interview, send invitations to respondents, interview, collect requirement documents, analyse interview results, analyse requirement documents, and conclude the findings. Fig. 1 illustrates the research methodology.


Fig. 1. Methodology of the Study.

A. Identify Respondents

First, we emailed selected agencies to nominate 15 respondents based on the criteria specified in Table II. Fortunately, we received feedback from various critical public sector agencies involving 17 respondents.

TABLE II.   RESPONDENTS' CRITERIA SELECTION

Roles:	Requirement Engineer	Software Developer
The critical domain of Government agencies	Yes	
Expertise	Attended any RS course	N/A
Experience	At least two (2) years	
Involve in RS	Preparing the RS	Developing the software based on the RS

B. Develop Interview Questions

Indeed, questions are listed as a guide to ensure the smooth running of the interview. The developed semi-structured interview questions are based on RQs in the Introduction section. There are 16 main questions; seven open-ended questions, two Likert-scale, and six follow-up questions. An expert has validated these questions. The details of the interview questions are in Table III.

TABLE III.   INTERVIEW QUESTIONS

	Question
RQ1 - Identify the competencies	
1)	How many years of service?
2)	How many years of service as a requirement engineer/ software developer?
3)	Have you attended any course related to preparing the requirements specification? Have you ever attended a professional course such as CPRE/ academic at the University (Requirement Engineering subject)?
RQ1 - Level of understanding of the requirements specification (software developer perspective)	
4)	Do you understand each of the requirement specifications? If not, why?
5)	Overall, state your understanding of the requirements specification used as a reference in developing the system. (1 - Do not understand to 5 - Understand) – Likert scales
RQ2 - The most used language in requirements specification	
6)	What are the languages used in preparing the requirements specification?
7)	How much percentage of requirements specifications are prepared in specified languages?
8)	Is there any policy for using a specific language for the requirements document?
9)	What is your preferred language for requirements specifications? And why?
RQ3 - The methods used to prepare and verify the requirements specification	
10)	What are the templates used in preparing the requirements specification? What are these templates used for?
11)	Is there any verification for the requirements specification? If not, why? If yes, how is the verification conducted? What are the verifications quality attributes?

12)	What are the tools used for requirements verification?
13)	Do you need a tool to check the quality of the requirements specification? (e.g., Checking the ambiguity, inconsistency, and incompleteness in the requirements specification) If yes, what are the specific features that you require? (e.g., syntax-based checking, template-based checking)
RQ4 - Identify the issues in requirements specification (software developer perspective)	
14)	What are the issues that frequently occur in understanding the requirements specification? How do you solve the problems?
15)	How much do you agree that the problem in the requirements causes project delays? (1 - Strongly disagree to 5 - Strongly agree) – Likert scales
16)	Choose the top three (3) smells commonly found in the RS that may contribute to project delays/ failures. ***Quality Attributes** / **Description** **Unambiguity** - The requirement is expressed so that it can be interpreted only one way. The requirement is defined and easy to understand. **Appropriate** - The specific purpose and detail of the requirement are suitable to the degree of the body to which it refers (level of abstraction appropriate to the entity's class). **Complete** - The requirement adequately briefs the necessary capability, characteristic, constraint or quality factor in meeting the entity's need without needing other information to understand the requirement. **Verifiable** - The requirement is structured and worded so that its realisation can be proven (verified) to the customer's satisfaction at the requirements level. Verifiability is enhanced when the requirement is measurable. **Necessary** - The requirement defines an essential capability, characteristic, constraint or quality factor. **Correct** - The requirement accurately represents the entity's need from which it was transformed. **Singular** - The requirement states a single capability, characteristic, constraint or quality factor. **Feasible** - The requirement can be realised within system constraints (e.g., cost, schedule, technical) with acceptable risk. * IEEE [4] quality attributes

C. Conduct Pre-Interview

Before conducting semi-structured interviews, pre-interviews were performed to validate the questions developed. Two experienced system analysts from the Malaysian public sector agency (selected based on the criteria in Table II) participated in the preliminary interviews.

D. Send Invitations to Respondents

Afterwards, invitations to respondents are made via email and attached to an invitation letter. When the respondents agree to participate, the date and time are set based on the respondents' availability.

E. Conduct Interviews

Semi-structured interviews are conducted via online video communication for one hour each. This interview involves eight critical agencies. Due to confidentiality, we could not name the agencies. Table IV lists the study's respondents.

TABLE IV.   LIST OF RESPONDENTS

Respondent (R)	Position	Grade	Working Experience	Experience with RS
R1	REng	44	11 years	9 years
R2	REng	48	18 years	3 years
R3	REng	44	14 years	10 years
R4	REng	41	9 years	6 years
R5	REng	44	14 years	6 years
R6	REng	44	20 years	10 years
R7	REng	48	17 years	12 years
R8	REng	44	11 years	6 years
R9	REng	44	13 years	10 years
R10	SD	29	8 years	8 years
R11	SD	29	12 years	10 years
R12	SD	32	13 years	13 years
R13	SD	32	15 years	13 years
R14	SD	29	11 years	10 years
R15	SD	29	6 years	2 years
R16	SD	32	18 years	18 years
R17	SD	32	13 years	2 years

Requirement Engineer (REng), Software Developer (SD)

F. Analyse Interview Results

This paper employed data visualisation and descriptive-analytic techniques by Regnell et al. [25] to analyse and synthesise the data collected following the RQs presented in the Introduction section.

G. Collect Requirement Documents

We gathered the Malay RS documents to confirm the existence of the issues raised by respondents. We officially request the Malay RS documents from 10 critical public sector agencies (11 domains). Due to confidentiality and requested by respective agencies, we could not reveal the agencies. After receiving the agencies' approval, we collected 18 documents, including the 12 BRS/URS and six SRS. These RS documents were sent to us via email in Microsoft Word and Adobe PDF format. Other than that, we received some RS documents in hard copies. Table V lists the domain of the collected Malay RS documents.

H. Analyse Requirement Documents

We identify and eliminate the non-RS. We chose and extracted the textual RS into SQL format (repository). Next, we cleaned the textual-based RS using the Rapid Miner [26]. The data cleaning process comprises identifying, addressing missing values, and manually validating Malay spelling. We manually labelled the class based on the most significant

requirement smell. Two Malay requirement specialists confirmed the class label. This paper employed the statistical descriptive-analysis method by Christopher [27] to analyse the percentage of the most significant requirement smell mentioned by respondents.

TABLE V.   DOMAIN OF COLLECTED MALAY RS

Domain	No. of RS
Business	65
Career	6
Customer Services	137
Funds/ Finance	892
Human Resources	76
General Administration	78
Miscellaneous	21
Survey	107
Trade	89
Training	49
Welfare	15
Total RS:	1535

I. Conclude the Findings

We conclude the results in the Findings section and discuss the insights in the Discussion section.

IV. FINDINGS

This section presents the key findings that answered the RQs in the Introduction section through the semi-structured interviews. Section A corresponds to the competency level of respondents (RQ1). Section B reports the languages employed by RS (RQ2). Section C corresponds to methods used to prepare and verify the RS (RQ3). Section D presents the issues in RS (RQ4).

A. Human Factor (RQ1)

1) Requirement engineers: This study investigates the competency level of requirement engineers in Malaysia's public sector. We found the respondent's minimum and maximum years of service were nine and 20. The minimum and maximum years of involvement in requirement engineering were between three and 12 years. Fig. 2 illustrates the years served as a requirement engineer. 78% of requirement engineers have attended various courses related to RS. The courses, i.e., Certified Professional Requirement Engineer (CPRE) [28], took a subject at university, boot camp, and internal courses organised by respective agencies. Hence, most of the requirement engineers in Malaysia's public sector are competent and well-equipped with training. This study also shows that we have selected trained and experienced requirement engineers.

2) Software developers: We studied the competency level of software developers in Malaysia's public sector. As a result, the respondent's minimum and maximum years of

service were six and 18 years of experience. Fig. 3 shows the years served as a software developer.

3) Level of Understanding of the RS: This study determined the understanding of the SRS provided by the software engineer from the software developer's standpoint. Therefore, we require experienced software developers with a good understanding of SRS for software development. Fig. 4 illustrates that 86% of the respondents understood the RS given to them by the requirement engineer during the software development. However, 14% of respondents sometimes did not understand RS provided by their requirement engineer. Several respondents mentioned using flowcharts and mock interfaces, not RS, as a reference for system development. Fig. 5 shows that 57% of respondents understood the overall RS used as a reference in developing the system, while 43% of the respondents sometimes did not understand. The top three typical issues found in RS were ambiguity, incomplete and incorrect. Other than that, RS was constantly changing specifically for in-house development. This condition makes it difficult for software developers to expand the system and contributes to project delays. Most of the resolution of these issues is meeting with the project team and discussing the impact analysis and feasibility of the project with requirement engineers and clients.

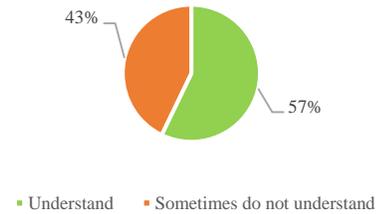
Fig. 4. Level Understanding Each RS.


Fig. 5. Level Understanding Overall RS.

B. Communication Factor (RQ2)

This paper only focused on the language used in preparing RS Malaysia's public sector for the communication factor. We would investigate the most used prominent language. Fig. 6 shows 84% Malay and 16% English used to prepare the RS. Fig. 7 shows the policy to use a specific language for the RS. 78% did not have any policy, 11% used the internal memo, and 11% used the Service Circular No.1 / 2020 Empowerment of the National Language in the Public Service [29]. The Service Circular was to encourage writing in Malay for formal documents, including RS. Most respondents used Malay to prepare the RS, specifically for in-house projects. Most Malay RS were prepared for in-house projects because of communication among clients and requirement engineers, understanding of the RS, validation, and verification, and working culture. 44% of respondents used the English RS for outsourcing projects. Some of the outsourcing projects were prepared in English RS because the requirement engineers and developers are foreigners.

11%

11%

78%

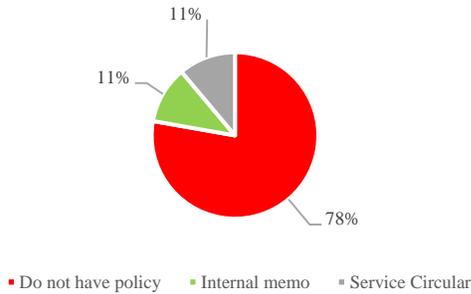
- Do not have policy - Internal memo - Service Circular


Fig. 7. Policy to use a Language for RS.

C. Process and Procedure (RQ3)

This study identified the methods and approaches used to prepare and verify the RS. Fig. 8 illustrates that 56% of the respondents used KRISA [30] to prepare the RS, and 44% did not have any template. Requirement engineers used only 48% of KRISA content as guidance. There were no formal instructions from the internal agencies or enforcement from the central agency to use KRISA documents. Most respondents took the initiative to implement KRISA as a handbook without any supervisor's orders. The KRISA document was used as a guide to preparing URS, BRS, SRS, and other documents. Fig. 9 shows that 89% of the respondents had verification methods for the RS. The respondents' verification methods, e.g., reviewing and confirming the RS through the committee meeting chaired by the Project Manager and Project Director. Most respondents mentioned that clients or subject matter experts verified the BRS and URS.

44%

56%

- KRISA - No template

78%

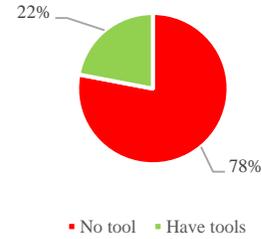
- No tool - Have tools


Fig. 10. Tools for RS Verification.

11%

89%

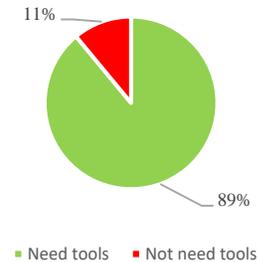
- Need tools - Not need tools


Fig. 11. Need Tools for Verifying the RS.

Meanwhile, the SRS was verified by requirement engineers. 25% of respondents found the requirement smells during verification. Fig. 10 illustrates that 78% of the respondents said no tool was used for RS verification. Verify the RS manually using Microsoft Word and Microsoft Visio tools (22%). Other tools were a mock-up interface, workflow, and flowchart. Fig. 11 depicts that 89% need tools to check RS quality, i.e., ambiguity, incomplete etc. In addition, most respondents suggested the tool could check the syntax and KRISA template-based conformance.

D. Issues in RS (RQ4)

This paper focused on exploring and identifying the smells in RS. Fig. 12 illustrates that 88% of the respondents (software developers) agreed that issues in RS could cause project delays or failures. Ambiguity, incomplete and incorrect were the top three familiar smells found in RS. Since ambiguity was the most significant requirement smell, we analysed the collected documents that may contain ambiguous RS. We found that 30% of the initial gathered Malay requirements were ambiguous.

13%

13%

75%

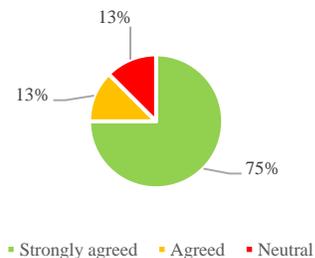
- Strongly agreed - Agreed - Neutral


Fig. 12. Issues in RS Could Cause Project Delays or Failures.

V. DISCUSSION

In this section, the findings are further discussed. Also, this section discusses the threats to validity.

A. Software Developers' Experience Versus Requirement Smells

From the perspective of software developers' experience, Fig. 13 shows that 38% of respondents with more than 10 years of experience found the ambiguity as requirement smells commonly found in RS. Fig. 13 suggests that respondents with more than 10 years of experience can identify the requirement smells in RS.

B. Software Developers' Experience Versus Understanding the RS

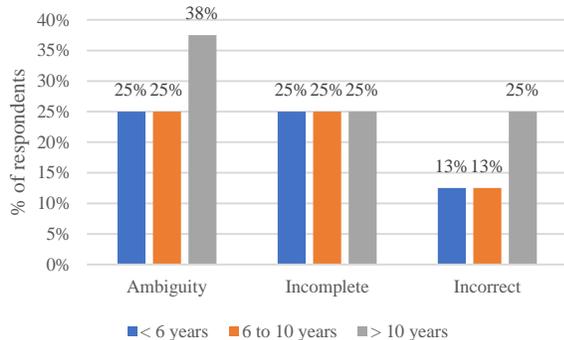
From the software developers' experience perspective, Fig. 14 illustrates that 29% of respondents with six to 10 years of experience are neutral in understanding the RS. The term neutral means sometimes understanding and sometimes not understanding the RS. The factor of neutral understanding happened caused of the inexperienced requirement engineers in developing the RS. Software developers with more than six years of experience could identify the requirement smells. Therefore, experienced software developers need further clarification from requirement engineers to understand the RS. Meanwhile, 29% of software developers with less than six years of experience understand the overall RS. Software developers with less than six years of experience typically follow the RS without screening the RS's quality.


Fig. 13. Software Developers' Experience Vs Requirement Smells Commonly Found in RS.
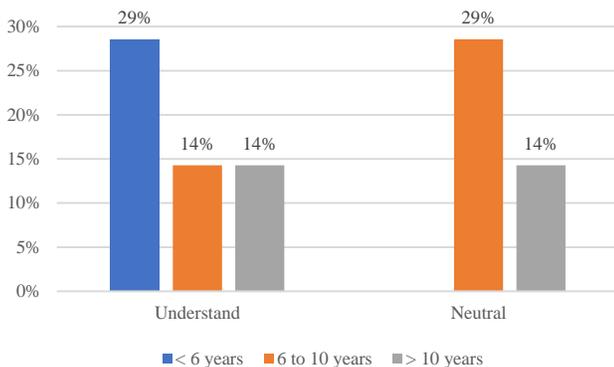

Fig. 14. Software Developers' Experience Vs Understanding the RS.

C. KRISA Handbook

No one instructed the requirement engineer to use any guide to prepare the RS. It is up to the requirement engineer to decide the template for creating the RS until completion. Most requirement engineers used the KRISA as a handbook to prepare the RS because it is written in Malay and easy to understand in their mother tongue. However, the KRISA handbook contains no clear or complete template for constructing the Malay RS.

D. Threats to Validity

During this research, there is a possibility that a few risks developed by accident due to a few circumstances brought on by various kinds of validity, such as internal, external, construct validity, and so on [31].

1) External validity: The respondents were aware of the open-ended nature of the interview questions, but they provided succinct responses nonetheless. Aside from that, respondents did not give the anticipated feedback in their responses. It may impact the low reliability of the data acquired. As a result, we questioned respondents and asked them to elaborate on their short answers.

2) Construct validity: The interview questions were vetted and tested for understandability through a preliminary interview session with some qualifying candidates before the actual interview session (illustrated in Table II).

VI. CONCLUSIONS AND FUTURE WORKS

A. Conclusions

We conducted semi-structured interviews based on RQs in the Introduction section, i.e., RQ1) Human factor, RQ2) Communication factor, RQ3) Process and Procedure, and RQ4) Issues in RS. We found that requirement smells in RS may cause a delay in the RE processes and lead to project failure. Ambiguity is the top smell in Malay RS. Based on a static analysis, 30% of the initial collected Malay RS are ambiguous. These issues can only be identified by experienced software developers, i.e., those with more than 10 years of experience. The participants mentioned that KRISA is the primary reference for preparing RS in the Malaysian public sector in terms of a template. Nevertheless, KRISA does not contain a complete requirement specification structure template compared to ISO IEEE/ISO/IEC 29148-2018, EARS, and RUPPs.

B. Future Works

The government needs automatic tools to detect and improve ambiguous RS based on the respondents' feedback. The respondents who wish to have tools could check the RS's quality based on the KRISA handbook. The automated tools would cover the functional and non-functional RS. Therefore, we would create the aforementioned automated tools. In addition, we are ambitious to design and prepare a Malay RS template.

A Guideline for Designing Mobile Applications for Children with Autism within Religious Boundaries

Ajrun Azhim Zamry, Muhammad Haziq Lim Abdullah, Mohd Hafiz Zakaria
Faculty of Information and Communication Technology, Universiti Teknikal Malaysia, Melaka

Abstract—Autism spectrum disorder is a condition related to brain development that impacts how a person perceives and socialises with others, causing problems in social interaction and communication. The disorder also includes limited and repetitive patterns of behavior. Children with autism spectrum disorder (ASD) develop at a different rate and don't necessarily develop skills in the same order as typically developing children. Nowadays, children with autism spectrum disorder (ASD) are having difficulties in gaining religious skills. This is due to the lack of schools that provide special religious education for disabled children. Many technologies have been developed to help children with autism for education. Mobile applications have extensively been used to enhance their daily learning. Researchers are extremely trailing their applications but not many applications are able to meet the requirements and needs of children with autism, especially in the religious context. The lack of religious mobile application guidelines is crucial as a reference for researchers. This paper aims to propose a guideline to design a mobile application for children with autism in religious context. A systematic review of previous literature on mobile application guidelines for autism and religious mobile application guidelines was conducted. This study resulted in two key findings: (1) elements of multimedia consist of text, images and sounds (2) features of application consist of interface, navigation, customisation and interaction. The proposed guidelines are potentially to be used by researchers who are interested in designing religious mobile applications for children with autism.

Keywords—Autism Spectrum Disorder (ASD); guidelines; mobile applications; religion; assistive technology; communication

I. INTRODUCTION

In recent years, the study of children with autism has been on the rise as many have become aware of the importance of helping this group. Mobile application has become the main platform for researchers to develop technologies that can assist them [18]. However, not all applications can work well and can be used by children with autism in improving their daily learning activities. This is due to the lack of guidelines for mobile applications, especially in religious studies. Therefore, this paper will propose a guideline for the development of mobile applications for children with autism in religious context.

Assistive technology (AT) refers to any product, equipment, software program or system that enhances learning, working, and daily living for persons with disabilities. AT has been used in the field of education to overcome barriers to learning [1]. Children with autism appear to learn differently from other individuals and frequently have difficulty with spoken and written communication. For children with autism, computer-assisted training has proven to be more effective than personal instruction [19]. Children with autism were discovered to be more interested in computers than toys, and to prefer computer education to personal instruction [4]. However, the application development for children with autism must follow the guidelines that have been established.

It is crucial to avoid building applications without proper guidance. This is because developers need to ensure children with autism feel comfortable to use applications that will assist their daily routine. The study [3] reported that there is still a lack of providing guidelines for the design of spiritual mobile applications and the need to have the certification and authentication of these digital apps must be considered especially for digital Quran. This paper focuses on two categories of guidelines which are mobile apps guidelines for autism and religious apps guidelines. The proposed guidelines have the potential to be used as a guide for researchers who want to develop mobile applications for autistic children, especially in the field of religion.

Mobile apps were frequently used as assistive technology to assist special groups such as children with autism. Mobile apps are promising to help these children in their daily learning including in religious studies which makes religious activities highly relying on mobile apps these days [6]. Religious mobile apps are becoming widely popular and changing the faith-based landscape across the world [20]. The aim of religious mobile apps is to ensure that religious practices would no longer be limited to a specific time or place. With the help of a mobile app, these religious places can build a faith in community and transfer religious teachings to a younger generation.

The next section presents the literature review, followed by the methodology of this research, findings, discussion and the last section concludes the paper with potential benefits of the proposed guidelines and the next step of this research which to evaluate the proposed guidelines.

II. LITERATURE REVIEW

A. Multimedia Elements (Apps for Autism)

It is necessary for an effective mobile application to have better features for easy to use. The main factor for effective application is multimedia elements. Multimedia elements that are often emphasised in application development are text, images, and audio. The first important element in multimedia applications is text. The study [8] mentioned that the text used

for mobile apps must be clear, simple, and short. Correspondingly, [22] stated that the font used must be clear and large and only used a maximum of two typefaces. Furthermore, [24] suggested that sans serif fonts with 14 font size are suitable for children with autism. On the other hand, [3] mentioned that developers need to avoid writing long paragraphs by using lists and heading titles in paragraphs. In addition, [3] stated that apps for children with autism spectrum disorder should avoid jargon, misspellings, metaphors, abbreviations, and acronyms, and instead utilise terminology, idioms, names, and symbols that are known to the users. This study also demonstrated that those factors are important to prevent users from feeling disturbed and losing focus while using the apps.

Images are also among the multimedia elements that need to be considered in creating apps for autistic children. Each autistic child has different preferences in using apps based on their personal interests included in the selection of images that are suitable for them [30]. It is important to have a suitable size of pictures and images in developing apps for children with autism. The authors [3] suggest allowing images magnification for better visualisation and ensure that the children with autism are able to understand when enlarged. Similarly, this statement was mentioned by [26] in her study that the mobile application must be able to allow users to adjust image size based on their preferences. Meanwhile, [13] stated that the use of photographs for concrete places and people while icons, pictograms and symbols for abstract terms is appropriate. Sharing the same opinion is [8] who said that the picture can be drawings, photographs and symbolic images. He added that the images should be easy to understand, should not fade into the background and should be in a sharp focus. The author in [21] also thinks that images must be identical to real life. For example, use a picture of real food instead of illustrated food. The research in [13] similarly reported that an application should use real images to represent people and places.

Audio also plays an important role in the creation of a successful application. The use of appropriate audio can also attract users [33]. However, audio selection for children with autism must adhere to guidelines so that it does not become a distraction for them. In [24], it was reported that mobile applications for autism should use clear, comprehensible short audio expressions. The app developer must select audio content in a way to motivate and not to distract users. In a similar vein, [3] mentioned that the application must be able to provide audio instructions and subtitles for texts but ensure that it is not the only alternate content representation. The author [5] added that the apps need to avoid the use of disturbing and explosive sounds like sirens and fireworks. In addition, [21] stated that the audio should correspond to the images and must be user-friendly. Each step can also have audio added to it, especially with the voice of someone the children is familiar with. For example, the instructor voice for the apps might be the voice of the teachers or parents.

This concludes that these multimedia elements are essential for developers to emphasise before they develop apps for autism. It should be noted that the use of multimedia elements for children with autism is not similar to normal users. The selection of text, images and even audio should be appropriate and not cause discomfort to them. These guidelines should be followed and adapted by all developers to avoid the development of less effective apps to users.

B. Features of Application (Apps for Autism)

In addition to the element of multimedia, application features for children with autism also play an important role. This is to ensure that children with autism can take full advantage of the applications developed for them. Among the following features are interface, navigation, customization and interaction. As for the interface, most researchers agree that the interface for apps for children with autism must be simple. The study [8] stated that design and structure should be simple, clear and predictable. The research [22] mentioned that an application must be designed for simplicity and few elements on screen. A simple interface only presents the features and content needed for the current task to be performed by the user [3]. In addition, [26] suggested to design an interface that is easy on the eye of users. For example, use simple icons that can be easily understood by the users. Moreover, [22] stated that a mobile application for children with autism should avoid cluttered interfaces. The arrangement of the app interface must be well-organised and easy to use. Similarly, [13] mentioned that an application for children with autism must provide an uncluttered layout with white space between the text in one column. White space helps the user to read faster and will focus on the specific paragraph [29].

The second important feature of the apps for children with autism is navigation. A simple navigation is needed to ensure children with autism can easily understand how to use the application properly. The author [21] mentioned that the application should have simple navigation and easy to use. in [22], author also stated that a mobile app for children with autism should strive for simple and clear navigation. A simplified navigation should be provided on every page [3]. Furthermore, navigation in an application should be consistent and similar in every section [8]. The position and icon used must be similar without making any changes to avoid confusion for children with autism. For example, the icon of a home was used to indicate back to the homepage and the location of the icon was located at the center bottom of each page. The study [21] describes consistent navigation as similar actions and similar buttons located in similar positions. The research in [22] suggested using standard navigation icons that are familiar to children with autism. Similarly, [3] reported that an application must present a global navigation button such as exit, back to home page and help button.

Every child with autism has different preferences and interests. It helps in making them feel comfortable when using the apps. Therefore, customization is needed in each application to assist the children with autism to choose what is best for them. Similarly, [8] and [22] mentioned that every application should allow customization for children with autism. For example, the customization of font type, font size, themes and colours. The developers must provide options to customise information visualisation with images, sound and text according to users' individual preferences [3]. For instance, the user can choose whether to use a small or large

font, loud or slow audio and small or large images. The existence of customisation in this application enables children with autism to feel more confident to use it and attract their interest in using this application.

Furthermore, the feature of application that needs to be taken into account is interaction. An interactive app is more user friendly when you allow users to interact with the app as it creates a connection between them. An interactive app provides users with the freedom to navigate from one window to another comfortably. The author [13] suggested avoiding simultaneous tasks and only one task is allowed in every section. Also, [13] stated to avoid distraction in the apps such as captchas and pop up advertisements. Moreover, [8] mentioned that the application has to make adaptive interaction with users by considering their interaction history, preferences, request, and needs. Further, [3] suggested that an application should have high sensitivity and responsiveness. Touch screen interactions should have the appropriate sensibility and prevent errors in selections and accidental touch in interface elements [25]. Lack of sensitivity will cause children with autism to feel depressed and give up using the apps again. In addition, [24] reported that it is important to provide feedback after learning activities and navigation actions. For instance, the correct text should appear for the correct answer and "try again" for incorrect answers. Prioritising in-app interaction will definitely make children with autism more focused and complete the tasks given in apps [31].

C. Multimedia Elements (Religious Apps)

Guidelines are also needed to build applications related to religion. Although there are some similarities between mobile apps guidelines and religious apps guidelines, there are still some details that need to be carefully scrutinised to distinguish between the two guidelines. In the context of elements of multimedia, emphasis is always given to elements such as text, images and even sounds. The study [1] suggested using suitable font size in developing an application for children with autism. The font size should not be too large or too small where the use of font size should be between 12 and 14 points. In a similar vein, [3] stated that an application must use a large size font type and try to make it adjustable. Medium or boldface type is encouraged. Further, [3] also added to make sure the use of text coincides with the original source. For instance, the Arabic text in the application was written based on the same number of pages in the Holy Quran. This means that if the verse in the Quran contains 10 verses, then the verse in the application must have the same number of verses which is 10 verses.

Next, the elements that need to be emphasised in multimedia are images. The author in [16] mentioned that the dress code of man and woman should be appropriate. The applications are encouraged to use formal attire that are modest to religious sentiments for any character, figure or real person. For example, the compliant driven ('awrah or clothing boundary). In addition, [3] suggested choosing appropriate images for the apps. The images used in apps should be relevant to the content and not display images that are not related to Islamic elements. The study [2] added that the application's selection buttons, icons, menus, and information

should be of excellent quality and resolution to make it easier for viewers to understand and receive clear Islamic material. Furthermore, the final multimedia element that needs to be considered in developing apps for children with autism is sounds. Also [16] suggests that the page be accompanied by an Islamic background sound. The many sorts of Islamic audio sound may help to enhance the site's Islamic spiritual sense. Moreover, [16] also suggested to use audio commonly used in Islam. For example, the sounds of Al-Quran recitation and the sounds of azan. The author [3] suggested providing good recitation audio. Pronunciation and melodious voice are important elements to attract users in learning Islam. For instance, a voice of Qari reciting Al-Quran can help the user to listen to the recitation clearly and can improve their pronunciation correctly. Finally, [3] also mentioned that an application should allow the user to adjust the volume. These customizations are required for the user in determining their preferred volume.

D. Features of Application (Religious Apps)

Apart from the elements of multimedia, features of apps also play an important role in building successful religious apps. Interface, navigation, customization and interaction are the categories that are often mentioned and discussed by previous studies. For interface, the most important thing to consider when developing a religious application is to ensure that the application shows the identity of a specific religion [23]. For example, [16] stated that the application should be based on the elements that best symbolize Islam which are widely recognized by the Islamic community. Similarly, [3] reported that an application should use features that present the Islamic identity like using the mosque icon as a homepage button for the user. Meanwhile, [2] mentioned that in terms of information and distribution, an application layout is characterised by Islamic concepts. For instance, the application needs to display an ustaz icon for male voice selection and ustazah icon for female voice.

Navigation is the second category that is important for religious application development. The research [1] suggested to ensure the user interface navigation structure is simple and straightforward. The buttons should be familiar to the user and predictable. For example, the home icon is used as a homepage button that will navigate the user to the home screen as the safe point to return. Similarly, [2] stated that the user should be able to navigate between screens in the built application at a reasonable cost and with ease. A consistent navigation button is required as it has to be arranged in the same position with the same size and same icon.

Customisation is also involved in ensuring that an application successfully meets the needs of users. The study [2] suggested that for the Islamic features, the application should provide for relevant modification based on the user's preferences. For example, the volume of the audio, the colour of text and the magnification of the screen. Furthermore, [3] stated that the application has to provide fonts, buttons and icons that can be easily resized. The users are able to choose the font size, font type and the colour of the buttons according to their preferences.

The last category to consider in developing a religious mobile application is interaction. Fast response is often mentioned by previous researchers when it comes to interaction. Further, [16] reported that the speed of the application interaction must be consistent without any delay occurring. Similarly, [2] said that the application must provide accurate and fast response to users. Interruption should be avoided while the application is running as it will distract children with autism when they are using the apps. The author [2] added that all functions in the application must work well and be reachable by the user. It is important to facilitate users in obtaining religious knowledge in the application. By using the mobile application, students can obtain information on religious studies more quickly and easily [32]. Moreover, [1] mentioned that the application should avoid using interaction timeouts to memorise Al-Quran using fast-moving objects and animation. Interaction timeout can be a distraction in memorising Al-Quran. It is encouraged to allow customization for moving objects and animation speed as the users are able to control the speed based on their preferences.

In summary, both these mobile apps guidelines are crucial as guides and references for future developers in focusing on children with autism. Each guideline has important features that the developer must adhere to. From the combination of these two categories of guidelines, a new guideline focusing on religious mobile apps for children with autism will be produced at the final stage of this study. This is in line with the goal of the study to fill in the gap where there is a lack of guidelines that focus on religion and children with autism at the same time.

III. Methodology

Systematic Literature Review (SLR) method was used in this study to identify, evaluate and summarize the related guidelines from previous literature. This study follows five steps for systematic literature review as suggested by [34]. The steps are framing questions for a review, identifying relevant work, assessing the quality of studies, summarizing the evidence and interpreting the findings. Meta analysis was conducted to take findings from several studies on the same subject and analyze this using standardized statistical procedures. In meta-analysis patterns and relationship are detected and conclusions are drawn. Meta-analysis is associated with the deductive research approach.

In order to obtain previous studies related to mobile apps guidelines for children with autism, several searching techniques were performed. The search for related information was divided into two categories which were mobile apps guidelines for children with autism and religious mobile apps guidelines. For the first category, the keywords used in the search were "mobile apps", "guidelines" and "autism spectrum disorder". As many as 12,900 publications were successfully obtained using the keyword. After filtering for published articles from the last five years (2015-2020), the number of articles decreased to 8,600 publications. Of these, only 35 articles were relevant to be analysed based on the guidelines criteria related to the study. The relevance of a paper was assessed based on its relation to searches on mobile applications guidelines for children with autism. Any paper

that writes about the guidelines used to develop mobile applications for children with autism will be selected and shortlisted for further analysis. Based on the relevant papers, only 20% of the papers were further analysed related to the study domain. As a result, this paper proposed a guideline for the development of mobile apps for children with autism.

The second searching category used the same terms of "mobile apps" and "guidelines" with additional words such as "religious" and "Islamic". A total of 32,200 publications was found based on the keywords. Last five years publications were inserted in the filters and the number of publications reduced to 16, 800 publications. Of these, only 26 publications were analysed for analysis in the first cycle. This publication was selected based on its relevance to religious mobile application guidelines for children with autism. After an extensive analysis of related guidelines criteria, only 19% publications were further analysed related to the study domain. Therefore, mobile apps guidelines for religion will be elaborated in the next section.

IV. Findings

This study found that the lack of religious mobile apps guidelines was clearly proven based on analysis that was conducted in the literature review section. Most researchers only focused on general mobile apps guidelines for children with autism and for religious guidelines researchers, most of the researchers do not focus on children with autism. From these two guidelines, a guideline focusing on religious mobile apps guidelines for children with autism was identified. This guideline will be based on the criteria that had been extracted from the literature review analysis. 19 % papers were used during the literature review analysis which combined mobile apps guidelines for children with autism and religious mobile apps guidelines. Two main categories were identified which are multimedia elements and application features.

Text, images and audio are often mentioned by previous researchers when discussing mobile application guidelines for children with autism. Table I shows the guidelines which have been classified according to the elements.

Text is a crucial component of any user interface (UI). Text was utilised to deliver immediate context-based assistance information to interactive elements, often known as hints [33]. One of the challenges that children with autism have is reading comprehension. Usability will be affected by a complex user interface with numerous text fragments [34]. It is important to organise the textual UI elements in such a way, that they do not impose reading difficulties. Real-life images aid recognition and help children learn more quickly and effectively [7]. The use of inappropriate images will cause children with autism to be confused. This will cause them to lose focus during the learning session. Appropriate sound selection helps motivate and not to distract the user [35]. The audio should be clear but not too loud as it will be disturbing for the children with autism. The audio should correspond to the images and must be user-friendly [15]. Children with ASD can benefit from visual assistance such as text, graphics, and sound to help them learn and communicate with their family, friends, and teachers [21].

The second category is the features of application. Interface, navigation, customisation and interaction are features that are required to develop applications for children with children with autism. Table II shows the guidelines which have been classified according to the features.

Making a simple interface helps children with autism to navigate easily. Complex interface with many text fragments will reduce usability [22]. The use of intuitive navigation principles will help users to navigate quickly by discovering and without additional support. Customisation is a key element for the successful user experience for children with autism because they have very different personal preferences and needs [9]. Customisation enables users to adapt documents (font typeface, font size, line spacing, colours) to their preferences [17]. It also helps children with autism to match their own reading and comprehension abilities. Providing interaction in multiple dimensions and providing them in a balance is important [36]. Considering characteristics and differences of children with autism, these interaction types should be chosen carefully and only if necessary. The study [24] reported that interactive learning software with gesture-based user interaction designed on the basis of universal design principles are highly effective learning materials.

TABLE I. MULTIMEDIA ELEMENTS GUIDELINES

Elements	Autism Apps	Religious Apps	Sources
Text	1. It should be clear, simple, and short. 2. Use a simple visual and textual language. 3. Avoid writing long paragraphs. 4. Textual style features according to individual differences and learning backgrounds of the users. 5. Amount of words must be reduced. 6. Avoid too many texts in a column 7. The typeface must be consistent and do not exceed more than two types.	1. Use suitable font size 2. Information should be well-organised. 3. Use a large size font type and try to make it adjustable. 4. Make sure the use of text coincides with the original source	[8], [22], [24], [26], [3]
Images	1. Pictures can be drawings, photographs, and symbolic images. 2. Allow images magnification for better visualisation and ensure they continue to be understandable when enlarged. 3. Able to have a suitable size of pictures, images. 4. Use photographs for concrete places and people; icons, pictograms and symbols for abstract terms. 5. Images must be identical to real life. 6. Do not overlap transparent images and text	1. The dress code of men and women should adhere to Islamic dress code. 2. All graphics should be of excellent quality and resolution to make it easier for viewers to understand and receive clear Islamic material. 3. Choose appropriate images.	[8], [2], [13] [16], [22], [24], [26], [3]
Sound	1. Provide audio instructions and subtitles for texts but ensure that this is not the only alternate content representation. 2. Avoid the use of disturbing and explosive sounds. 3. Using distinctive audio and visual effects. 4. Using non-destructive, plain and melodic effects. 5. Using clear, comprehensible short audio expressions. 6. The audio should correspond to the images and must be user-friendly.	1. The Islamic background sound accompanying the page and the types of Islamic audio sound may further stimulate Islamic spiritual sense of the site. 2. Use male voice. 3. The user can easily adjust the volume. 4. Provide good recitation audio.	[8], [3], [21] [26]

TABLE II.   FEATURES OF APPLICATION

Elements	Autism Apps	Religious Apps	Sources
Interface	1. Design and structure should be simple, clear and predictable. 2. Simple interface. 3. Using simple, objective oriented, presentative layout design. 4. Interfaces must be easy on the eye of users. 5. Provide an uncluttered layout white space between text in one column. 6. Should be user friendly. 7. Design for simplicity and few elements on screen.	1. The Islamic identity is characterised by identity identifiers. 2. Application layout is characterised by Islamic concepts in terms of information and delivery. 3. Use features that present the Islamic identity.	[8], [2], [13] [16], [22], [21] [24], [26], [3]
Navigation	1. Navigation should be consistent and similar in every page/section. 2. Provide a simplified and consistent navigation between pages on every page. 3. Employing intuitive navigation principles in which users can navigate easily by discovering and without additional support. 4. Limit the number of options in menus to reduce cognitive load. 5. Ensure the user can identify menus and navigation functions. 6. Strive for simple, clear navigation. 7. Do not use complex menus.	1. Ensure navigation structure is simple and straightforward. 2. Navigation between screens to other screens in the developed application should be affordable and easy to control by the user.	[8], [3], [13] [21] [26]
Customisation	1. Provide options to customise information visualisation with images, sound and text according to individual user's preferences. 2. Allow personalisation of apps for users. 3. Allow customization in the application.	1. On the program's Islamic features, the application should provide for relevant modification based on the user's preferences. 2. Users can easily resize the font, buttons or icons.	[8], [22], [24], [26], [3]
Interaction	1. Adapt the interaction with users. 2. Touch screen interactions should have the appropriate sensibility and prevent errors in selection and accidental touch in interface elements. 3. Providing interaction through hardware and sensors of application device. 4. Avoid captchas and simultaneous tasks.	1. Usability traits may ignite a sense of professionalism in Islam. 2. Must have good interaction with users. 3. Avoid using interaction timeouts to memorise Al-Quran. 4. Avoid using fast-moving objects and animation. 5. Users receive accurate and timely responses from the application. 6. All functions in the application work well and are fast and accurate when reached by the user. 7. Users should be able to obtain religious information through the application's interactions, which should perform smoothly and consistently	[8], [2], [13] [16], [22], [21] [24], [26], [3]

V. DISCUSSION

Based on the findings, this paper resulted in two key findings in relation to mobile application guidelines on religious context for autism. Firstly, findings revealed that elements of multimedia consist of text, images and sounds is important to encourage children with autism to engage in active learning by mentally representing the material in words and in pictures and by mentally making connections between the pictorial and verbal representations. Secondly, the features of application consist of interface, navigation, customisation and interaction makes user interfaces perceivable, operable, and understandable by people with a wide range of abilities, and people in a wide range of circumstances, environments, and conditions.

Thus, the findings extended a previous guideline to inform design framework for design with children with autism still has validity. However, this paper builds on it and adapts two new perspectives which consist of 24 guidelines under two categories as outlined in (1) and (2).

1) New perspective on multimedia elements guideline for designing apps with children with autism.

Proposed Religious Mobile Apps Guidelines for children with autism (Multimedia Elements) are as follows:

a) The text used must be clear, simple and short. (Font size of 14).

b) Use only a maximum of two typefaces.

c) Use of text coincides with the original source. (Arabic text in the application was written based on the same number of pages in the Holy Quran).

d) Provide suitable size of images.

e) Use images that are identical to real life.

f) Use formal attire that are modest to religious sentiments clothes for any character, figure or real person. For example, the compliant driven ('awrah or clothing boundary).

g) The images used in apps should be relevant to the content and not display images that are not related to Islamic elements.

h) Use clear, comprehensible short audio expressions.

i) Avoid using disturbing and explosive sounds.

j) Use familiar sounds and voices. (Voice of parents and teachers).

k) Use audio commonly used in Islam. (For example, the sounds of Al-Quran recitation and the sounds of azan).

2) New perspective on application features guideline for designing religious mobile apps with children with autism

Proposed Religious Mobile Apps Guidelines for children with autism (Features of Application) are as follows:

a) Design and structure should be simple, clear and predictable.

b) Avoid cluttered interfaces.

c) Application should be based on the elements that best symbolizes Islam which are widely recognized by the Islamic community.

d) Application should use features that present the Islamic identity.

e) Applications should have simple navigation and easy to use.

f) Navigation in an application should be consistent.

g) Use standard navigation icons that are familiar to children with autism.

h) Allow customization (Font type, font size, themes and colours)

i) On the program's Islamic features, the application should provide for relevant modification based on the user's preferences. Avoid simultaneous tasks at one time.

j) Avoid distraction and interruption in the apps.

k) Speed of the application interaction must be consistent without any delay occurring.

l) Avoid using interaction timeouts to memorise Al-Quran using fast-moving objects and animation.

This research presents 24 guidelines under two categories. The first theme was the elements of multimedia used in developing mobile applications for children with autism. The findings section highlighted three important multimedia elements which are text, images and audio.

1) Text: This element refers to the selection of appropriate and accurate text in the application. This includes font size, font type and colours. It is necessary to use clear and simple text for children with autism [28]. It is well known that people with children with autism literally interpret the text content, and have problems understanding complex sentences [10]. Some researchers suggested allowing text customization for children with autism to choose what is best according to their individual preferences. It is important to choose and organise the textual elements in such a way to ensure children with autism do not experience reading difficulties.

2) Images: This element refers to the use of proper and suitable images in the application. In a religious context, the images should be appropriate which do not expose children with autism to forbidden views such as awrah in Islam. In addition, parents, teachers and children with autism requirements, interests, and preferences should be able to be reflected in the app through personal images of genuine scenarios and activities [11].

3) Audio: This element refers to the appropriate audio selection and arrangement in the application. Familiar voices are recommended to be used in the application to ensure that the children with autism feel comfortable when using the application. Some children feel scared and less confident when hearing voices that are unfamiliar to them. For religious mobile apps, the sounds that are commonly used need to be included in the apps such as Quran recitation, sounds of Azan and Doa recitation. This will help them to better know and approach their religious studies that are in line with the practice of daily life.

The second theme is the features of applications that are required in developing apps for children with autism. The features are interface, navigation, customization and interaction.

1) Interface: This element refers to the simplicity in designing interface for the mobile application. A cluttered interface must be avoided. Cluttered applications will be frustrating to be used by children with autism. When there are too many elements on a single page, the user might miss important information. Besides, the application should use features that present Islamic identities. These requirements are less mentioned by the previous researcher but have been extended in this paper.

2) Navigation: This element refers to the use of standard and consistent navigation. The icons, buttons and symbols must be familiar to the children with autism. This will help them to easily understand the use of the button and prevent confusion [27]. The arrangement of the navigation button must also be consistent to avoid any errors while using the application. This will help children with autism to use the application with their own capability without the need for special monitoring from teachers and parents.

3) Customisation: This element refers to the enabling customization in the application. Because children with autism have highly varied personal preferences and demands, customization is a critical component of a good user experience [14]. It notes that children with autism can benefit from this as it enables them to directly ensure that the interface is personalised to their individual needs. Font size, images magnification and colours are among the customization that is needed to be inserted into the application.

4) Interaction: This element refers to the responsiveness of the application. Delay, interruption and distraction must be avoided. The application should improve the speed and accuracy to complete a task. It is also referred to give responses toward the action performed by the children with autism. The application must be able to reduce the time in performing the task. According to [12], attention deficit and concentration times are very short among children with autism with at least 10-15 minutes per session. Therefore, it is important for mobile apps to interact with children with autism to prevent them from losing focus while using the application.

There are some significant differences when comparing the previous guidelines with the proposed guidelines. Previous guidelines focus more on guidelines in general for mobile applications while the proposed guideline focuses more on

guidelines improvement in a religious context. For example, the use of text in previous guidelines focused more on font, typeface and also the readability of text in the application. For the proposed guidelines, emphasis is placed on the use of text that needs to coincide with the original source (Al-Quran). In addition, previous guidelines highlight more on the use of images, size, and quality. While the proposed guidelines have improved the existing guidelines by emphasizing the importance of using images that are compatible with religious sentiments such as clothing boundaries. Most other elements also have improvements especially in the context of religion. This clearly shows that there is a significant difference between the previous guidelines and the proposed guidelines.

The limitation of this study is that the literature review that examines mobile applications for autistic children in the context of religion is very limited. Most of the articles found are related to mobile apps for autism context. As for the context of religion, limited study do not use mobile applications as the main platform for their research. This causes difficulties in finding accurate information in line with the objectives of this study.

VI. Conclusion

In conclusion, this research found that there are guidelines that can be used for the development of religious mobile applications for children with autism. The guidelines were based on the reviewed guidelines provided in the literature. It is hoped that these findings can be used as a reference for other researchers who are interested in developing applications that focus on religious context. However, these guidelines need to be verified by experts who are experienced in developing religious mobile applications for children with autism. It is important in order to ensure that the application is effective to be used by children with autism. Next, a prototype of a mobile application that applied the proposed guidelines will be developed and given a trial. An evaluation of the application is needed to determine how children with autism react and interact with the application. Feedback from the teachers, parents, and the children with autism will be gathered as it will be useful to improve the existing guidelines.

Fuzzy Support Vector Machine based Fall Detection Method for Traumatic Brain Injuries

A New Systematic Approach of Combining Fuzzy Logic with Support Vector Machine to Achieve Higher Accuracy in Fall Detection System

Abstract—**Falling is a major health issue that can lead to both physical and mental injuries. Detecting falls accurately can reduce the severe effects and improve the quality of life for disabled people. Therefore, it is critical to develop a smart fall detection system. Many approaches have been proposed in wearable-based systems. In these approaches, machine learning techniques have been conducted to provide automatic classification and to improve accuracy. One of the most commonly used algorithms is Support Vector Machine (SVM). However, classical SVM can neither use prior knowledge to process accurate classifications nor solve problems characterized by ambiguity. More specifically, some values of falls are inaccurate and similar to the features of normal activities, which can also greatly impact the performance of the learning ability of SVMs. Hence, it became necessary to look for an effective fall detection method based on a combination of Fuzzy Logic (FL) and SVM algorithms so as to reduce false positive alarms and improve accuracy. In this paper, various training data are assigned to the corresponding membership degrees. Some data points with a high chance of falling are assigned a high degree of membership, yielding a high contribution for SVM decision-making. This does not only achieve accurate fall detection, but also reduces the hesitation in labeling the outcomes and improves the heuristic transparency of the SVM. The experimental results achieved 100% specificity and precision, with an overall accuracy of 99.96%. Consequently, the experiment proved to be effective and yielded better results than the conventional approaches.**

Keywords—*Fall detection; fuzzy logic; SVM; traumatic brain injuries; wearable sensor*

I. INTRODUCTION

The main goal of this paper is to introduce and propose a new fall detection method for traumatically brain-injured people. The goal is to suggest a highly accurate method that uses the advantages of both Fuzzy Logic and SVM. The main reasons behind the idea of integrating these two latter methods are their well-known limitations as standalone techniques, with SVM considered a "black box" and Fuzzy logic being especially limited for nonlinear problem solving. Falling is one of the major life-threatening problems faced by people with physical disabilities. According to World Health Organization research, falls are the second most common cause of injury-related death worldwide. Nationally, there was

a 53% increase in the number of total deaths due to falls from 2000 to 2019 [1]. Health systems are significantly impacted by falls. The quality of life of elderly persons can also be significantly impacted out of the fear of falling.

An Ambient Intelligent (AI) environment can improve the lifestyle of the disabled by using different sensor technologies. With such technologies, environments might become sensitive, adaptive, and responsive to people's presence for the sake of supporting them to live independently in the environment they prefer. One important aim of assistive technology is to allow disabled people to stay in their homes as long as possible without changing their lifestyles. Smart fall detection can offer support to people with special needs, enabling them to live actively and independently both at home and in their communities. This improves the quality of their lives on the one hand, and reduces costs for their families and the entire society on the other hand.

Currently, available techniques that are used to design fall detection systems are classified into two main categories based on their sensor type: one is an ambient-based fall detection system whereas the other relies on a wearable-based fall detection system [2]. Ambient-based approaches use ambiance sensors, including acoustic sensors, vibration sensors, pressure sensors, and infrared sensors for detecting a fall event [3,4,5]. They also use single or multiple cameras in an indoor environment to track a person's movements and body shape while falling [6,7,8]. One main drawback of ambient sensors is that they limit falls to only those detected in a pre-set area, and this does not seem suitable for people's mobility.

Wearable sensor-based fall detection methods track the user's body motion using embedded sensors such as accelerometers. These methods can detect a fall when the person is wearing the sensor anywhere and at any time. Wearable sensors have several advantages, including low cost, low power consumption, and ease of use. As a result, they are commonly used to detect human falls. However, those with a single accelerometer are insufficient to offer a robust system and are susceptible to false positive fall detection; which reduces system accuracy [9].

*Corresponding Author.

Recently, a fusion system in which the process of combining multiple data sources can produce more robust measurement and accurate detection was developed. In this context, fall detection based on Inertial Measurement Units (IMUs) sensors, which are composed of an accelerometer, gyroscope, and magnetometer can be attached to the body. This fall detection technique is of special interest due to the fact that it is undetectable, widely available, inexpensive, and has a low power consumption [10,11]. Additionally, this technique can offer complementary information about the activity performed [12]. The IMU has been widely used for data collection and for differentiating a fall event from Activities of Daily Living (ADLs) based on two main approaches which are threshold-based or machine learning classification algorithms.

In a threshold-based approach, the system notifies that a fall happens if the real-time sensor data surpasses the given threshold values after comparing them. In particular, a low threshold value brings out false alarms whereas a high threshold value causes large fall missing issues. The authors in [13] show that machine learning algorithms can effectively enhance the system's performance in comparison to the threshold-based method. In machine learning approach, impressive results can be obtained using various classifiers [12]. An SVM is one of the most popular algorithms used in supervised machine learning for activities of recognition and classification [5]. However, labels for the dataset are needed for the employment of SVM algorithms for fall detection. In more detail, some training points of falls that are uneven and similar to being mixed with the features of ADLs can significantly impact the performance of the learning ability of SVMs. Here, it is worth mentioning that classical SVMs can never solve inaccurate and ambiguous problems. FL has the ability to mimic the human way of thinking to productively use reasoning methods that are uneven and not precise, and it has been verified to be effective in reducing the false fall detection rate [9].

SVM as a standalone algorithm, just like FL, has its own advantages and disadvantages. Merging both methods by making use of the best traits of each algorithm will certainly yield outstanding results in some applications, as in the case of fall detection. The specific contributions of this study could be summarized as follows:

- Identifying the types of disabilities that require smart fall detection as this can help in developing the desired device.

- Proposing a new fall detection method that takes advantage of both FL and classical SVM. Our proposed method uses the logical reasoning of FL by Fuzzification of all input values of the training data into fuzzy membership functions to obtain the intermediate output. Different memberships reflect various contributions to the learning of decision-making. A high degree of membership of data points, which have a significantly high chance of falling, provides a significant contribution to SVM decision-making. As a result of the functions of the fuzzy membership, an SVM output is properly produced for

modeling data and driving training. This network combination reduces false positive alarms to obtain more accurate fall detection and it achieves better generalization ability that was motivated to perform much better than conventional SVM methods on smart fall detection.

The rest of this paper is structured as follows: Section II provides a review of existing papers related to fall detection systems. Section III presents a brief review of classical SVM and Fuzzy SVM basic theory. Section IV identifies the types of disabilities that require smart fall detection. Section V describes the hardware design to collect data and highlights the proposed fall detection method with a classification process. Section VI details the experimental settings, the performance evaluation, the experimental results, and the analysis for the various scenarios. Section VII summarizes the conclusion with a comment on future work.

II. RELATED WORK

Generally, the framework of automatic fall detection systems using wearable sensors consists of the collection of sensor data, a fall detection algorithm, and an emergency alarm. Data collected by the accelerometer and gyroscope are transmitted to a microcontroller to be processed to differentiate a fall from an ADL. Recently, there has been a growing interest in identifying and detecting fall events using IMU sensors [14]. The fusion of inertial sensor-based wearable systems can be effectively used to recognize fall events by examining the impact of the body on the ground as well as the body orientation before, during, and following the fall. Nevertheless, the location of the sensor can influence the performance of the system. Thus, numerous studies related to the topic of optimal sensor placement were conducted. The waist, wrist, trunk, thigh, back, ankle, foot, neck, and head represent the most common wearing positions. The authors in [15] studied fall detection by placing accelerometers on the subject's head, waist, and wrist. They reported that the most efficient positions are the waist and the head in contrast to the wrist which is not. The authors in [16] placed sensors on the trunk and thigh and reported the trunk as a better position. The authors in [17] identified that the waist location utilizing a single sensor was a suitable placement after evaluating single IMU sensors deployed at several places in the body. In conclusion, sensor location is an important factor in developing wearable sensor-based fall detection systems. Furthermore, the waist could be the best option for a wearable sensor-based fall detection system.

The classification algorithm is applied to classify ADL and several fall events. A wearable-based fall detection algorithm can be categorized into two approaches, namely: threshold-based and machine learning. Threshold-based approaches use single or multiple threshold values that can be adjusted automatically depending on motion history to classify events [15,16,18]. Due to the low computational complexity, current fall detection studies have widely used the threshold-based method. However, a high threshold must be set in order to obtain a highly accurate system. Hence, with a high threshold, there will be some lags in the system and, subsequently, some missed falls. In contrast, with an excessively low threshold,

there will be some misjudgments and frequent false alarms. This is why a suitable threshold should be set to avoid any problems.

Machine learning is a field of Artificial Intelligence. It explores how to use computers to imitate human learning activities [19]. It uses learning algorithms to extract features from raw data in order to gain new abilities, recognize current knowledge, and constantly improve performance and achievement [20]. Data processing includes pre-processing, smoothing data, and data reduction methods where the data are acquired from the sensor and then processed. This is followed by the classification stage, which either provides a prediction or a decision at the end of the process. Learning methods can be categorized into two main groups: supervised and unsupervised learning. The algorithm in supervised learning is trained using a labeled input dataset. In the case of unsupervised algorithms, there are no explicit labels associated with the training dataset, which saves time during processing [21]. Examples of algorithms used in fall detection experiments include Hidden Markov Model (HMM), K-Nearest Neighbors (K-NN), Random Forest (RF), SVM, Decision Tree, Linear Regression, Naïve Bayes, Fuzzy Inference System (FIS), and Artificial Neural Network (ANN), which have achieved significant success in detecting falls and classifying fall events from ADLs [22].

Based on the preceding, [23] successfully differentiate falls from ADLs using six machine learning classifiers, which are the K-NN classifier, Least Squares Method (LSM), SVM, Bayesian decision making (BDM), Dynamic Time Warping (DTW), and ANNs. They achieved the greatest results with the K-NN classifier and LSM; with sensitivity, specificity, and accuracy all above 99%. The authors in [24] attained the best accuracy in fall detection using the K-NNs classifier and the highest accuracy in distinguishing various falling activities using the RF classifier. However, [25] compared the applicability of RF and SVM in the development of wearable intelligent devices. The obtained results show that SVM is more suitable for the development of wearable intelligent devices. The authors in [26] used the K-NN and SVM algorithms for classifying the fused accelerometer and gyroscope data collected from smartphone sensors. They reported a classification performance of 98.32% for SVM and 97.42% for K-NN. ANNs have been greatly improved in recent times [27]. This method regularly outperforms classic machine learning algorithms in terms of learning ability. However, the model of the Neural Network is highly dependent on the quality and quantity of the training datasets and can be affected by too much disorienting information.

Study [13] evaluated the accuracy of these two approaches, which are threshold values and five machine learning algorithms. In fact, they concluded that five machine learning algorithms' gross production was greater than the overall performance of five algorithms based on the threshold. In addition, SVM-based classification has outperformed the five machine learning in terms of sensitivity and specificity. Since they are highly accurate in comparison with threshold-based fall detection methods, machine learning based fall detection algorithms are nowadays being widely used. The authors in [28] achieved the best accuracy performance of

99%, indicating that the system's performance in comparison to the threshold-based method can be effectively enhanced. Decision-making based on machine learning algorithms, on the other hand ensures high rates of true positives.

A. SVM-Based Fall Detection

SVM is a powerful tool in machine learning for classifying data with good generalization ability that is less computationally intensive than other algorithms like artificial neural networks, decision trees, and Bayesian networks due to their high accuracy, elegance, mathematical practicability, and simple geometric interpretation. In addition, they do not require a lot of training data to prevent overfitting [29,30].

In SVM-based fall detection, distinguishing between falling activities and non-falling ADLs is possible. For instance, [31] used a hyperplane of SVM as the separating plane to replace the traditional threshold method for the detection of falling ADLs. They used the Gaussian radial basis function to construct the kernel function with the cost parameter tuned where the constant (C) is the regularization parameter in the SVM. When adjusted, a balance between margin maximization and classification is realized [32]. The results showed that the SVM method is better than the threshold-based algorithm when the parameters of falling and non-falling ADLs are very close. The authors in [33] extracted features from data collected by the Kinect sensor followed by fall recognition by using an SVM algorithm. In [3], the authors proposed a Multi-Feature Semi-Supervised SVM framework for human fall detection to specifically handle the human fall classification problem where the Radial Basis Function (RBF) classifier is selected in SVM training on extracted features from the training samples. The authors in [34] proposed a system that detects human falls by using the audio signal from a microphone. Their system was designed in a way that models each fall or noise segment by means of a Gaussian Mixture Model (GMM). Then, the SVM classifier would be employed to classify audio segments into falls and different types of noise. Study [35] collected the body's acceleration and rotational angle data in the wearable terminal to execute the SVM algorithm. As such, the hyperplane, which separates fall events from ADL events, was introduced. RBF kernel function which allows nonlinear mapping in this model was selected with a penalty parameter factor (C) that was adjustable to obtain the largest gap distance. The authors in [36] employ multiple kernels of learning to distinguish difficult fall-like events. The classification performance kept improving until it became constant at a certain point when the tuned parameter (C) was increased. Nonetheless, the number of selected kernels also expanded with (C), which raised the computational cost. Another model proposed by [10] showed that an SVM classifier provides the best performance metrics when trained on a fall dataset containing simulated falls and when cross-validated with real-world falls. The classifier appears to be appropriate for further evaluation concerning real-world applications due to robust results and high accuracy, sensitivity, and specificity. The authors in [25] found that SVM is more suitable for fall detection algorithm based on multi-sensor data fusion.

The SVM can accomplish great performance in the classification and calculation processes. This can be achieved through the use of a relatively low amount of the provided learning data. However, they cannot give a comprehensible representation of where a produced output has been attained. They are similar to black-box models due to their complex structure, numerous parameters, and excessive abstraction [37]. With classical SVMs, the experimenters can never depend on their prior knowledge to process accurate classifications or solve inaccurate and ambiguous problems, which can also greatly impact the performance of the learning ability of SVMs.

B. Fuzzy Logic-based Fall Detection

Fuzzy systems are systems in which the variables have domain fuzzy sets. Such systems allow the encoding of structured, empirical, heuristic, or linguistic knowledge in a numerical framework. As opposed to conventional logic, FL is based on the mathematical theory of fuzzy sets, which mimics human thought and tries to reflect reality while taking into account all outcomes between 0 and 1 [38], where 1 means absolute truth and 0 means absolute falsehood. The FL consists of three main parts. The first part is Fuzzification which allows the conversion of crisp values into fuzzy membership functions. The second part is the fuzzy inference aggregation which contains all the rules and if-then conditions to control the decision-making system. In this phase, the Mamdani method, which requires finding the centroid of a two-dimensional shape by integrating it across a continuously varying function, is the most commonly used technique. The third part is the defuzzification process that converts the fuzzy sets into crisp values. Despite the availability of several defuzzification methods, the centroid technique remains the most popular among all of them [39,40].

In Fuzzy Logic-based fall detection, [41] confirmed that Fuzzy is capable of detecting a fall from real-time data as it requires minimum hardware and software specifications. Reusing the existing data, balancing the load amongst FLS devices, and cost-efficiency are some of the advantages offered by the FLS architecture to introduce flexible and smooth decisions. In their proposed method, they "fuzzify" each input value as a function of fuzzy membership, where each input contains three linguistic values: low, medium, and high. Every membership is classified as a turning point with different values. To perform their experiment, the researchers created nine rules to identify whether a fall occurred or not. Finally, they transformed a fuzzy output set into a crisp value in the defuzzification phase. The authors in [42] used FL to identify the range and type of fall, which can include the position before fall, fall direction, fall velocity, and post-fall inactivity. The authors in [43] looked beyond the traditional threshold-based approaches and implemented a fuzzy inference technique for precise decision making. They fused the data from multiple sensors and generated a value between 0 and 1, which implies the chance of a fall; thus reducing the number of false alarms. The authors in [44] initiated a new FL algorithm, which is worn on wrists to detect falls and reduce the number of false alarms. The fall detection system has three major phases which are data sampling, data processing, and fuzzy classification. In the three stages, a typical FL procedure

is followed by fuzzily setting all input values into fuzzy membership functions, executing all relevant rules to calculate the fuzzy output functions, and "defuzzifying" the fuzzy output functions to get output values. They used Mamdani's minimum operation and the AND-output rule in their fall detection algorithm and a weighted average formula in defuzzification. Furthermore, since the Mamdani approach is generally accepted for the development of expert knowledge, this helps one to explain the ability in a more perceptive, human-like manner. However, this technique is not computationally effective and can be expensive due to calculating a two-dimensional form by adding it up or combining it more accurately through a function that change continuously.

III. SVM AND FUZZY SVM BASIC THEORY

In this section, we briefly review the basics of the theory of SVM in classification problems and fuzzy support vector machines, which are discussed by [45,46,47.48].

A. SVMs Theory

SVM is a robust classification method that was developed by Vladimir Vapnik and aims to construct a decision function that separates the data in the input space into different classes. The basis of this method is minimizing the structural risk method in order to reduce the error [32]. An optimal hyperplane must be found through maximizing the margin between classes in input space. Nonetheless, the samples close to the hyperplane are called support vectors [49].

In the input space, it is assumed that the patterns are drawn by the training points $\{x_1, .., x_n\}$. If this input data are linearly separable, the hyperplane that produces the separation could be described as: $w^T x + b = 0$ where x is an input vector, $w = (w_1, w_2, .., w_d)$ is a weight vector, d is the number of the input variables, and b is a bias that will determine the distance between the hyperplane and the origin. It can classify the points using the following equation:

$$\begin{cases} w^T x_i + b \geq 0 \ for \ y = +1 \\ w^T x_i + b \leq 0 \ for \ y = -1 \end{cases} \tag{1}$$

where $y_i \in \{-1, +1\}$ is the binary class label for a new point x_i, this output enables x_i to be classified as belonging to one of the two classes.

The goal of the support vector machine is to build the optimal hyperplane that maximizes the distance between the closest points of each class and the separation [50]. This is presented by solving the linear problem:

$$\begin{cases} min \ \frac{1}{2} \|w\|^2 \\ y(w^T x_i + b) \geq 1, i = 1, 2, .., N \end{cases} \tag{2}$$

To deal with data that are not separable cases, slack variables ε_i are introduced. This represents the misclassified sample of the corresponding margin hyperplane, where $i \in \{1, 2, 3, .., N\}$ is an upper bound of the number of error [48]. Thus, the optimal hyperplane in a nonlinear space can be determined by:

$$minimize\ 0.5\|w\|^2 + c \sum_{i=1}^{N} \varepsilon_i$$

subject to:

$$\begin{cases} y_i(w^T x_i + b) \geq 1 - \varepsilon_i, i = 1, 2, .., N \\ \varepsilon_i \geq 0, i = 1, 2, .., N \end{cases} \quad (3)$$

In this sense, the adjustable parameter (C) plays a major role in maximizing the margin and carefully tuning the number of misclassifications. If (C) is bigger, it makes the training of SVM fewer misclassifications and it narrows the margin. In contrast, if (C) decreases, it makes SVM disregard more training points and it widens the margin.

However, the search for a suitable hyperplane in an input space is too restrictive to be of practical use when the samples are linearly non-separable. Thus, SVM techniques utilize a group of mathematical functions known as the kernel that satisfies Mercer's theorem [51]. This can be applied to map data relevant to the feature of higher dimensions, hence seeking an optimal separating hyperplane in the feature space [29].

The main approach is to find the function that performs the mapping from the input to the feature space. By introducing the vector of Lagrange multipliers [31], the nonlinear separating hyperplane can be found as the solution of:

$$\max \sum_{i=1}^{N} \alpha_i - \frac{1}{2} \sum_{i,j=1}^{N} \alpha_i \alpha_j y_i y_j K(x_i . x_j)$$

subject to:

$$\begin{cases} \sum_{i=1}^{N} \alpha_i y_i = 0, \forall\ i \\ 0 \leq \alpha_i \leq c \end{cases} \quad (4)$$

where $k(x, x_i) = \langle \emptyset(x), \emptyset(x_i) \rangle$ is the dot products of the corresponding feature vectors into high dimensional space [51].

Four common types in kernel at the SVM algorithm are linear, polynomial, Gaussian RBF, and sigmoid kernel where each kernel function has a particular parameter that must be optimized to obtain the best result performance [49]. Three kernel types will be used in the experiments to compare their results to those of our proposed method. These kernel types are:

- Linear kernel: $k(x, x_i) = \langle x, x_i \rangle$.

- Polynomial kernel: $k(x, x_i) = (\langle x, x_i \rangle + 1)^d$ with degree d.

- RBF kernel: $k(x, x_i) = e^{\frac{-(\|\vec{x} - \vec{x_i}\|)^2}{2\sigma^2}}$ with adjustable width parameter σ.

B. Fuzzy SVMs Theory

SVM is a powerful tool for classifying data points that are assumed to belong to the one and only class [52]. However, as discussed previously, the effects of the training points are different. Especially for fall detection, classical SVM can neither use prior knowledge to process accurate classifications nor solve problems characterized by inaccuracy and ambiguity. In more specific terms, some values of falls are inaccurate and similar to the features of normal activities, which can also greatly impact the performance of the learning ability of SVMs. Furthermore, some training points no longer exactly belong to one of the two classes. For example, 80% belong to the class of falls and 20% to the class of ADLs. These points are critical and may cause false positive alarms which reduce the accuracy of the system.

To do that, the points that have a low potential for falling or normal activity will be assigned to lower membership functions. Otherwise, a high chance of falls will be assigned with a high degree of membership function. In this sense, each training point is fuzzified into a membership function. This fuzzy membership $\mu_i \in \{0, 1\}$ is considered to be the attitude of the corresponding training point toward one class in the classification problem whereas the value $(1 - \mu_i)$ is considered to be the attitude of meaninglessness. So, the idea of SVM will be expanded and combined with a fuzzy membership function to make it a Fuzzy SVM.

The term μ_i is introduced as a membership vector for each training point x_i. Thus, the optimal hyperplane problem is then regarded as the solution to:

$$min\ 0.5\|w\|^2 + c \sum_{i=1}^{N} \mu_i\ \varepsilon_i$$

subject to:

$$\begin{cases} y_i(w^T x_i + b) \geq 1 - \varepsilon_i, i = 1, 2, .., N \\ \varepsilon_i \geq 0, i = 1, 2, .., N \end{cases} \quad (5)$$

where the term $\mu_i \varepsilon_i$ is a measure of error with different weighting. Hence, it can be noticed that the effect of misclassified parameter ε_i will be reduced when the membership functions μ_i are smaller. In this case, the training point x_i is treated as less important in the training. By applying Lagrange multipliers, the above problem is reformulated as:

$$\max Q(x) = \sum_{i=1}^{N} \alpha_i - \frac{1}{2} \sum_{i,j=1}^{N} \alpha_i \alpha_j y_i y_j K(x_i . x_j)$$

subject to:

$$\begin{cases} \sum_{i=1}^{N} \alpha_i y_i = 0, \forall\ i \\ 0 \leq \alpha_i \leq s_i c \end{cases} \quad (6)$$

Solving problem (6), dual of (5), is the same for classical SVM with a slight difference. As a consequence, this is the basic theory of Fuzzy SVM.

IV. CLINICAL STUDY

A clinical study was conducted to identify the disabled group that needs fall detection. Patients and specialists in healthcare centers were interviewed to collect data on health and welfare. The interviewer was a physiotherapy officer in Lebanon, and the interviewees were people with special needs living in the sample households. A survey was distributed to a

group of physically disabled people who suffered traumatic brain injuries. Each case had a different kind of disability, such as Cerebral Vascular Accident (CVA), Cerebral Palsy (CP), Meningitis, or Guillain-Barre. This survey included information on the installation of sensors based on the preference of disabled people. As a result, patients with brain injuries were asked to fill out a survey with a special focus on the duration of their disability, the reason for disability, and the number of falls in the last 6–12 months.

In Fig. 1, it is illustrated that 65% of the studied cases were patients with CVA, 25% were patients with CP, 6% were patients with Meningitis, and 4% were patients with Guillain-Barre. In Fig. 2, which studies the number of falls in each case, it is revealed that CVA cases aged above 55 ran into 83 falls, which is 37%, while CVA cases aged under 55 ran into 60 falls, ranking a lower percentage, which is 27%. In general, CVAs ranked 64%, indicating the highest percentage of falls. In addition, CP cases marked 59 falls, indicating the second-highest percentage of falls, which is 26%, whereas other cases marked 24 falls, showing the lowest percentage of falls, which is 10%. Thus, it was noticed that people with disabilities related to traumatic brain injuries such as CVA, CP, Guillain-Barre, and Meningitis have a high frequency of falls. Each respondent gave a different answer regarding the position of the fall detection sensor.

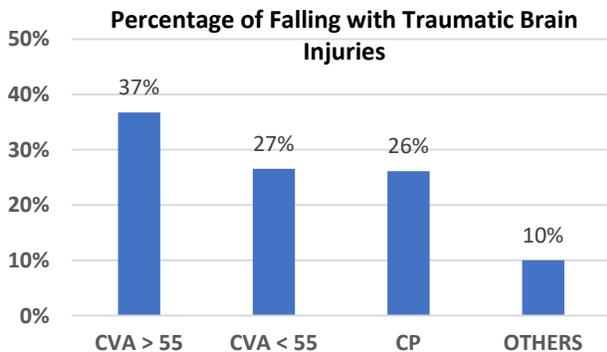
Fig. 1. Percentage of Participants with Traumatic Brain Injuries.


Fig. 2. Percentage of Falling for Participants with Traumatic Brain Injuries.
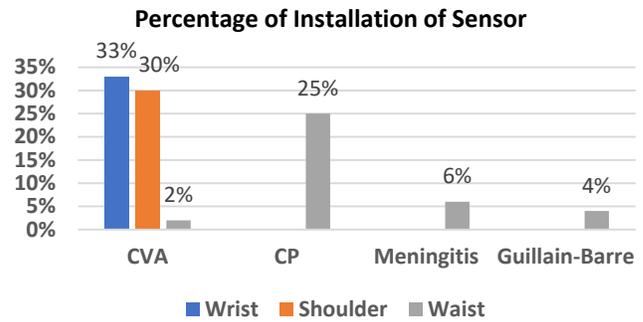

Fig. 3. Preferred Position of the Sensor.

Fig. 3 shows that 37% of the CP, Meningitis, and Guillain-Barre cases suggested placing the sensor on the waist in a way that allows it to be balanced right between the upper part of the body and its lower part. On the other hand, CVA cases had different answers, each according to their age. Those aged 55 and above (33% of the CVA cases) wanted to install the sensor on the wrist to quickly detect a fall, while people under the age of 55 (30%) wanted to install it on the shoulder.

In this paper, we are going to install a sensor for brain injury cases on the waist since it is the most fixed point of the body and is needed to maintain joint stability. Thus, it can track any movement easily.

V. PROPOSED METHOD

A prototype of the wearable device is designed using hardware in the form of a small-sized IMU sensor. The digital output of a 9-axis motion tracker by the IMU module is accessible by the I2C communication protocol (Inter-Integrated Circuit). This module is based on the MPU-9250, which assists in detecting activity changes, determining the slope of the object on which the sensor is mounted, generating acceleration, and expressing the angle and rotation about each axis in 3D space. It also achieves targets with low power consumption and robustness during the short duration of dynamic accelerations. Data gathered by the sensor are defined by an Arduino Uno microcontroller that operates at a voltage of 3.3/5 volts and is used to read the accelerometer, the gyroscope, and the magnetometer, as well as the internal temperature and the Tait Bryan angle-like pitch roll and yaw. The Baud rate is set to 9600 bits per second for serial communication between the Arduino board and the MPU-9250. The acquired data are transferred via a low-energy Bluetooth interface to the classification part. The Bluetooth module HC-05 is used for wireless communication between the Arduino Uno and MPU-9250. Bluetooth technology is a suitable choice for a lot of applications in daily life as it provides a reliable connection and low power consumption [53].

This paper suggests a new method to detect falls through the effective combination of FL and SVM (Fuzzy SVM). The input matrix consists of a 9-axis accelerometer, gyroscope, and magnetometer to collect multiple human body data points at the same time, including human body acceleration, rotational velocity, and displacement along the three

directions. The next step involves smoothing the data collected and computing the standard deviation of each of the nine axes from the IMU sensor in 3D space. After that, the magnitude of standard deviation features is extracted to indicate abnormal activity in the preprocessing phase. The building of the FL model is formed by using a trapezoidal membership function along with the input dataset to obtain the intermediate output. SVM, with selected kernels, will use the high degree of membership function of the three inputs to determine whether a fall has occurred or not and to obtain a confidential decision. Additionally, and to summarize, hyperparameters, including sensitivity, specificity, accuracy, and precision, were monitored during the methods' evaluations. As for the 9-axis sensor, all nine parameters (projections of acceleration, gyroscope, and magnetometer into three-dimensional space) were included in the model's inputs with different correlation indices.

A. Data Smoothing

A simple moving average filtering method is used for smoothing noisy raw data in order to obtain clearer data and state estimation of signals from human activities [25]. This can be obtained in (7) from the mathematical definition of a vector x:

$$y(n) = \frac{1}{windowSize} (x(n) + x(n-1) + \cdots + x(n-(windowSize-1))) \tag{7}$$

where, $y(n)$ is the current output, $x(n)$ is the current input, $x(n-1)$ is the previous input, etc.; noting that n is the length of the window size.

In Fig. 4, the signal in the original data is a pulse buried in random noise. In Fig. 5, this signal is filtered with $n = 5$ point moving average filters. The noise level becomes lower when the number of points in the filter increases. The optimal solution for this problem is the moving average filter, which gives the lowest noise possible for a given edge sharpness. The smoothing action of the moving average filter reduces the amplitude of the random noise when $N = 5$. Averaging the raw data leads to smoothing out the incidental peaks.

B. Feature Extraction

The acceleration value of human movement for specifying the changing rate of human motion can be calculated by using standard deviation. This function is sensitive to fall detection and can detect sudden tilt changes [54]. Standard deviation is useful for distinguishing static from dynamic activity and for identifying dynamic activity. Assumingly, a human fall is of high acceleration whereas walking is regarded as a low-acceleration activity [55,56].

The standard deviation is an index of how near the individual data points cluster around the mean. If we called each data point x_i, an index of dispersion, it would be represented in (8):

$$\sigma = \sqrt{\frac{1}{N-1} \sum_{i=1}^{i=N} (x_i - \bar{x})^2} \tag{8}$$

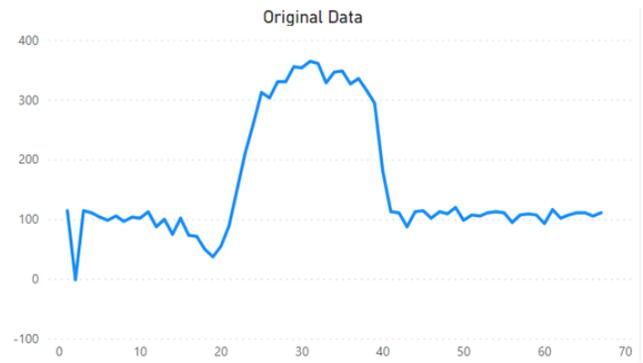
where $i = 1, .., N$ is an index of data sample, N is the number of data sample, and $\bar{x}$ represents the sample mean.


Fig. 4. Original Data by Moving Average Filter.
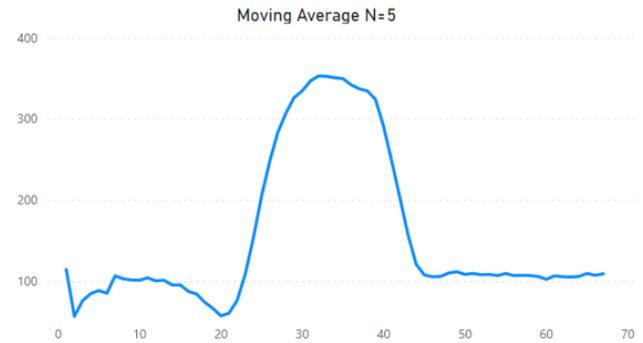

Fig. 5. Smoothing Raw Data by Moving Average Filter.

We computed the standard deviation of each of the nine axes depending on whether they were an accelerometer, a gyroscope, or a magnetometer raw data. After that, three features were extracted from the IMU sensor, which are:

The norm of a standard deviation of the acceleration $|\sigma_A|$ is calculated in (9):

$$|\sigma_A| = \sqrt{\sigma_{Ax}^2 + \sigma_{Ay}^2 + \sigma_{Az}^2} \tag{9}$$

where σ_{Ax}, σ_{Ay}, and σ_{Az} are the standard deviation along the directions of $x, y,$ and z axes of the acceleration raw data that are represented by A_x, A_y, and A_z respectively.

The norm of a standard deviation of the rotation $|\sigma_G|$ is calculated in (10):

$$|\sigma_G| = \sqrt{\sigma_{Gx}^2 + \sigma_{Gy}^2 + \sigma_{Gz}^2} \tag{10}$$

where σ_{Gx}, σ_{Gy}, and σ_{Gz} are the standard deviation along the directions of $x, y,$ and z axes of the rotation raw data that are represented by G_x, G_y, and G_z respectively.

The norm of a standard deviation of the magnetometer $|\sigma_M|$ is calculated in (11):

$$|\sigma_M| = \sqrt{\sigma_{Mx}^2 + \sigma_{My}^2 + \sigma_{Mz}^2} \tag{11}$$

where σ_{Mx}, σ_{My}, and σ_{Mz} are the standard deviation along the directions of $x, y,$ and z axes of the magnetometer raw data that are represented by M_x, M_y, and M_z respectively.

Thus, when a standard deviation method is applied, it can differentiate between an actual fall and other activities.

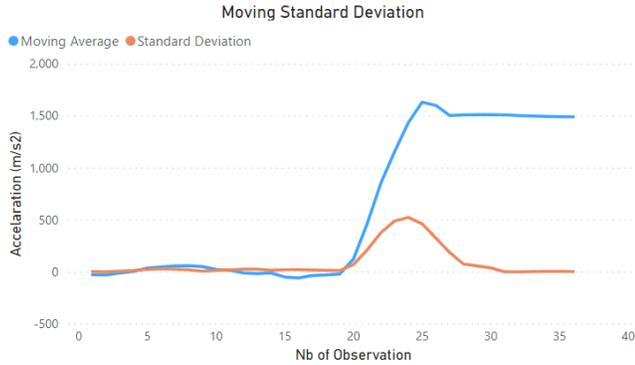
This method can compute a sudden change in acceleration in zero gravity. If this standard deviation value has a high changing trend, it indicates unusual activity. In Fig. 6, a fall might be shown to arise if this value has a high changing rate. As a result, the human motion after this is re-examined to check if the human body has no movement. In this way, it can be ensured that it is the actual fall.


Fig. 6. Example of Standard Deviation for Accelerating Raw Data.

C. Generate Fuzzy Membership Function

A membership function is a function that is responsible for defining how each point in the input space is mapped to a membership value (or degree of membership). A fuzzy set F in X will be explained as a group of ordered pairs, as expressed below:

$$F = \{x, \mu_F(x) | x \in X\} \qquad (12)$$

In particular:

- $\mu_F(x)$ is the degree of membership of x in F.

- The boundaries of a fuzzy set F is the set of all $x \in X$ such that $0 < \mu_F(x) < 1$.

- X is the input space and its elements are denoted by x.

In this paper, an MPU–9250 sensor device in an IoT-enabled environment is used to effectively recognize fall events by examining the impact of the body on the ground in addition to the body orientation prior to, during, and following the fall. Next, the proposed method fuzzily analyses these inputs and produces an output as a crisp value between 0 and 1, which signifies the possibility of a fall. FL is used to solve such classification and decision problems without a clear threshold boundary. When a specific value does not completely belong to a certain category, the membership function is used to measure it. The process of converting the logical input value into the membership of each set (normal, medium, high) is called fuzzification.

Three input features, $|\sigma_A|$, $|\sigma_G|$, and $|\sigma_M|$, are introduced to build the suggested approach in order to get the intermediate output. These three linguistic variables for every three inputs are represented in (13):

$$f_{|\sigma_A|} = f_{|\sigma_G|} = f_{|\sigma_M|} = \{NORMAL, MEDIUM, HIGH\} \qquad (13)$$

In this paper, trapezoidal Membership Function (MF) was considered as this type is most frequently used, very flexible, and a small amount of data is needed to define it. The trapezoidal function guarantees the existence of a certainty interval in the fuzzification [40].

Each membership is configured with specific values as specification points based on our experimental test to balance sensitivity and specificity. An FL model will be built based on selectable membership functions of the input datasets to get the intermediate output.

The general form of high trapezoidal MF for the fuzzy set $|\sigma_A|$, in terms of the degree of membership, could be defined in (14):

$$\mu_{high_{|\sigma_A|}} = \begin{cases} 0, \text{for x} < 145 \\ \frac{x-145}{160-145}, \text{for } 145 \le x \le 160 \\ 1, \text{for x} \ge 160 \end{cases} \qquad (14)$$

The general form of high trapezoidal MF for the fuzzy set $|\sigma_G|$, in terms of the degree of membership, could be defined in (15):

$$\mu_{high_{|\sigma_G|}} = \begin{cases} 0, \text{for x} < 12 \\ \frac{x-12}{15-12}, \text{for } 12 \le x \le 15 \\ 1, \text{for x} \ge 15 \end{cases} \qquad (15)$$

The general form of high trapezoidal MF for the fuzzy set $|\sigma_M|$, in terms of the degree of membership, could be defined in (16):

$$\mu_{high_{|\sigma_M|}} = \begin{cases} 0, \text{for x} < 30 \\ \frac{x-30}{35-30}, \text{for } 30 \le x \le 35 \\ 1, \text{for x} \ge 35 \end{cases} \qquad (16)$$

Fig. 7 illustrates the membership of the magnitude of a standard deviation of the acceleration in a plan. The normal magnitude is assigned to 80, the medium magnitude is distributed between 95 and 145, and the maximum is defined as 160. Therefore, we put a minimum value that a fall can happen at 145 and consider it as the medium acceleration value.

Fig. 8 depicts memberships of the magnitude of a standard deviation of the rotation in a plan. The normal magnitude is assigned to 6, the medium magnitude is distributed between 9 and 12, and the maximum is defined as 15. Therefore, we put the minimum value that a fall can happen at 12 and consider it the medium angle value.

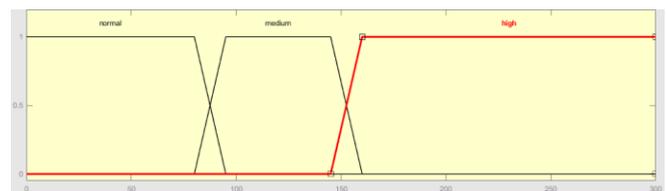
Fig. 9 represents memberships of the magnitude of a standard deviation of the displacement in a plan. The normal magnitude is assigned to 20, the medium magnitude is distributed between 25 and 30, and the maximum is defined as 35. Therefore, we put a minimum value that a fall can happen at 30 and consider it the medium magnetometer value.


Fig. 7. Membership Function for the Input 1: $|\sigma_A|$.
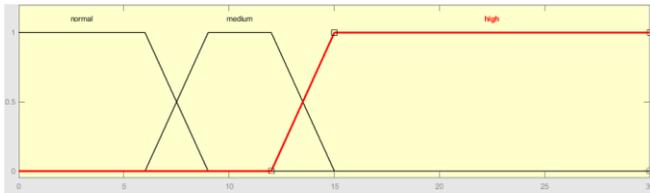

Fig. 8. Membership Function for the Input 2: $|\sigma_G|$.
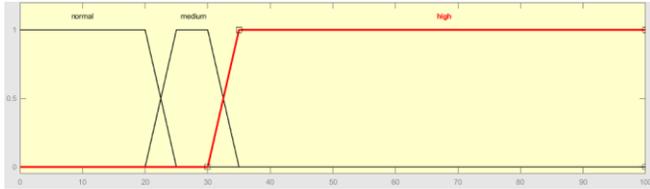

Fig. 9. Membership Function for the Input 3: $|\sigma_M|$.

The output of such FL analysis is a block formed from a high degree of membership based on these three inputs. This means that the event will be considered to have a high degree of membership if the magnitude of the standard deviation of the acceleration is greater than 145, if the magnitude of the standard deviation of the rotation is greater than 12, and if the magnitude of the standard deviation of the magnetometer is greater than 30. The intermediate output will be used as an SVM input with selectable kernels to reach the decision. This will help provide an initial decision bias on whether an event of falling likelihood is high. SVM will use the high degree of membership function of the three inputs to determine whether a fall has occurred or not. However, data points that have a potential normal or medium chance of falling are assigned lower membership degrees.

VI. Experimental Scenario

The prototype was attached at the waist to collect real-time motion data since this is the most fixed position of the body and is needed to provide joint stability and efficiently track any movement. Unlike wired systems, wireless data collection allows users to perform movements more fluently. Four volunteers were chosen to participate in a simulated falling event where they implemented the fall activities on 30 cm thick mats to prevent injuries. These volunteers have a healthy body, are aged between 25 and 35 years, weigh between 70 and 100 kg, and are 1.68 to 1.94 m tall. In this paper, different subcategories and characteristics of falls in five directions (forward, backward, left, right, and vertical falls) and normal activities including (walking, sitting, and stumbling while walking) were examined in the experiments to achieve our goal. The average duration of each trial was about 40 seconds. Each fall type was repeated more than ten times in a total of 100 trials.

The dataset was read from the CSV file and was implemented with the assistance of the LIBSVM library for MATLAB (version R2018a). Three predictors were introduced where they showed the value of each nine-axis of the trapezoidal membership function of the magnetometer, accelerometer, and gyroscope. Two classes of responses, -1 and 1, were designated to sort the non-falling and falling events, respectively. To make model predictions and estimate how accurate a predictive model will be when implemented, a

cross-validation model was used. The default option is 5-fold cross-validation to partition the data set into 5 folds. This helps protect against overfitting and examines the predictive accuracy of the fitted models. We trained an SVM classifier in the supervised machine learning model. This was done by providing a known input data set (2250 observations) in addition to known replies to the data that comprise two classes: -1 indicating data points of the non-falling type, and +1 indicating data points of the falling type. We used linear, cubic, quadratic, and RBF SVM kernel functions and standardized the features.

In this paper, the kernel function will be specified as a Medium Gaussian or RBF kernel, a Quadratic kernel, and a Cubic kernel. In order to tune the SVM classifier, the kernel scale was picked by different scales. Next, we adjusted the box constraint level with diverse values for every kernel scale to reach the self-confidential decision. The adjustable parameter (C) usually plays a vital role between cautiously tuning the number of mistakes and maximizing the margin. Therefore, the increase in the box constraint level might decrease the number of support vectors, but it can also increase the time of training, make the training of SVM have fewer misclassifications, and narrow the margin. On the other hand, it allows the SVM to discount more training points and it widens the margin. The evaluation of the Fuzzy SVM network included dividing the datasets from model training (75%) and real-time data for testing new data (25%).

A. Experimental Results Metrics

In the final phase, to show the effectiveness of the proposed method, the confusion matrix plot was calculated between the model predictions and the ground truth labels in order to check each class's performance and to know how the current classifier performed in every class [57]. Classification algorithm performance has traditionally been evaluated using a range of performance criteria, which are presented in Table I.

TABLE I. DESCRIPTIONS OF PARAMETRIC EVALUATION

	Detected Fall	Undetected Fall
Fall Occurrence	True Positive (TP)	False Negative (FN)
Fall Unoccurence	False Positive (FP)	True Negative (TN)

In this paper, we compute the following common machine learning classification metrics to assess the classifier's effectiveness in our evaluation. Sensitivity and specificity are calculated by (17) and (18), respectively. Accuracy could be defined by (19), which is the ratio of all samples that the classifier correctly classified [58]. The precision metric could be described by (20), which evaluates the number of correct positive predictions made. Hence, low precision might be an indication of a large number of FP.

$$\text{Sensitivity} = \frac{TP}{TP + FN} \tag{17}$$

$$\text{Specificity} = \frac{TN}{TN + FP} \tag{18}$$

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{19}$$

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}} \qquad\qquad (20)$$

B. Experimental Results of Proposed Method without Fuzzy MFs

This section reports the preliminary results of the fall detection system. We used the Gaussian RBF kernel for training and adjusted the optimal regularization parameter with diverse values for every kernel scale. The box constraint level, denoted as the soft margin penalty (C), was varied with different values for each kernel scale in this experiment to provide increased flexibility.

Table II shows the experimental results of the proposed method without employing Fuzzy MFs with RBF kernel function. The percentage of accuracy ranges between 97.78 and 97.96, the percentage of sensitivity ranges between 93.39 and 95.21, whereas the percentage of specificity ranges between 98.91 and 99.45; with precision between 96.96 and 98.43. The boldfaced numbers reveal the best-obtained results in the current classifier that were used later to compare with employed Fuzzy MFs to show the improvement of the proposed method.

In Table III, the experimental results indicate that the best model was selected in the Quadratic kernel, where the percentages of accuracy and sensitivity are 97.78 and 94.71, respectively. As for specificity and precision, the best results were obtained in the cubic kernel, which reached 99.03 and 97.26, respectively.

TABLE III. EXPERIMENTAL RESULTS WITHOUT FUZZY MFS FOR LINEAR, CUBIC, AND QUADRATIC KERNEL FUNCTIONS

Kernel function	Accuracy %	Sensitivity %	Specificity %	Precision %
Linear SVM	97.47	93.88	98.78	96.6
Cubic SVM	97.64	93.88	**99.03**	**97.26**
Quadratic SVM	**97.78**	94.71	98.91	96.95

C. Experimental Results of Proposed Method with Fuzzy MFs

Table IV shows the experimental results of the proposed method by employing Fuzzy MFs with RBF kernel function. The percentage of accuracy ranges between 99.82 and 99.96, the percentage of sensitivity ranges between 99.63 and 99.81, whereas the percentage of specificity ranges between 99.88 and 100; with precision between 99.63 and 100. The boldfaced numbers reveal the best-obtained results in the current classifier by employing Fuzzy MFs to show the improvement of the proposed method.

In Table V, the experimental results of Fuzzy SVM with Cubic and Quadratic Kernel Function indicate that the percentage of accuracy is 99.96, the percentage of sensitivity is 99.81, whereas the percentage of precision and specificity is 100 for both types of the kernel function. An overall score of 100% for specificity and precision and 99.81% for sensitivity was obtained by using the new method.

TABLE V.   EXPERIMENTAL RESULTS OF THE PROPOSED METHOD WITH FUZZY MFS FOR LINEAR, CUBIC, AND QUADRATIC KERNEL FUNCTIONS

Kernel function	Accuracy %	Sensitivity %	Specificity %	Precision %
Linear SVM	99.56	99.44	99.59	89.70
Cubic SVM	99.96	99.81	100	100
Quadratic SVM	99.96	99.81	100	100

In Table VI, we compared the effectiveness of our proposed fall detection method when we employed the Fuzzy MFs. The overall performance in terms of accuracy, sensitivity, specificity, and precision was increased by 2%, 4.6%, 0.55%, and 1.57%, respectively.

A fall detection system should avoid acquiring FP and FN results to obtain more reliable results. The experimental results demonstrate that the proposed method with fuzzy membership reduced false alarms and achieved accurate fall detection with better performance than traditional SVM.

TABLE VI.   EXPERIMENTAL RESULTS OF THE PROPOSED FUZZY SVM VS. CONVENTIONAL METHOD

Proposed method	SVM WITH FUZZY MFs			
Kernel function	Accuracy %	Sensitivity %	Specificity %	Precision %
Linear SVM	99.56	99.44	99.59	89.70

VII. CONCLUSION

In this paper, we introduced a new hybrid method integrating FL and SVM as a powerful technique for fall detection. The obtained results based on the defined environment showed a significant improvement in the accuracy of detection as compared to standalone, independent methods. Moreover, this paper examined the ways of identifying, expressing, and inspecting the relationship between disabled people suffering from traumatic brain injuries and falling events. Detecting falls accurately in time can reduce the severe consequences, especially since it can improve the quality of life of people with disabilities by promoting their independence. Besides, the prototype we examined was based on the Arduino platform, with the MPU-9250 sensor forming the part that was fixed on the patient's body and that wirelessly connects over the IoT platform via a low-energy Bluetooth interface. Thus, a 9-axis of

accelerometer, gyroscope, and magnetometer data formed the input matrix. The data were then smoothed using the moving average method to obtain clearer data and reduce the amplitude of the random noise. The standard deviation of each of the nine axes from the IMU sensor, depending on whether it was an accelerometer, gyroscope, or magnetometer, raw data in the x, y, and z planes in 3D space, was then computed. After that, the magnitude of standard deviation features was extracted in a way that makes it possible to differentiate between an actual fall and other activities, and thus to indicate abnormal activity in the pre-processing phase. Our proposed fall detection method is based on the effective combination of FL and SVM algorithms. In Fuzzy SVM, a fuzzy membership is given to each data point and set by expert experience. Different memberships reflect various contributions made to the decision-making learning process. SVM uses a high degree of membership functions extracted from selected features to automatically generate a model of the data and drive training, which enhances generalization ability and makes the heuristic obviousness of the traditional SVM efficient. The overall performance of the proposed fall detection system in terms of sensitivity and accuracy were 99.81% and 99.96%, respectively. This experiment achieved the maximum specificity and precision of 100% and, accordingly, proved to be effective and yielded better results than the conventionally used approaches. In other words, there was clear evidence that combining FL and SVM detects falls more accurately and performs better in reducing the effects of false positive alarms. This type of work is common abroad, yet it is still novel in Lebanon. So this study is considered a pioneering experience in fall detection systems for disabled patients. Furthermore, knowing that fall event datasets for this type of patients are not currently available in the literature, further trials must be conducted to simulate and refine the fall detection system and evaluate it outside the workplace. The application can be tested in real-world scenarios involving various types of disability. Our continuing research includes integrating fall detection algorithms into a smartphone that would be worn around the waist. This will be very useful to improve the robustness of our proposed method.

Mansoura University
Cairo, Egypt

Abstract—**In the last few years, data streams have drawn lots of researchers' attention due to their various applications, such as healthcare monitoring systems, fraud and intrusion detection, the internet of things (IoT), and financial market applications. A data stream is an unbounded sequence of data continually generated over time and is prone to evolution. Outliers in streaming data are the elements that significantly deviate from the majority of elements and then have to be detected as they may be error values or events of interest. Detection of outliers is a challenging issue in streaming data and is one of the most crucial tasks in data stream mining. Existing outlier detection methods for static data are unsuitable for use in data stream settings due to the unique characteristics of streaming data such as unpredictability, uncertainty, high-dimensionality, and changes in data distribution. Thus, in this paper, a novel ensemble learning framework called** <u>E</u>**nsemble-based** <u>S</u>**treaming** <u>O</u>**utlier** <u>D</u>**etection (ESOD) is presented to perfectly detect outliers over streaming data using a sliding window technique that is updated in response to the incoming events from the data streaming environment to overcome the concept evolution nature of streaming data. The proposed framework has three phases, namely the training phase, testing/offline phase, and outlier detection/online phase. A detection weighted vote technique is used to determine the final decisions for potential outliers. In the extensive experimental study, which was conducted on 11 real-world benchmark datasets, the proposed framework was assessed using many accuracy metrics. The experiment results showed that the proposed framework beats many other state-of-the-art methods.**

Keywords—Outlier detection; data streams; data stream mining; ensemble learning; concept evolution

I. INTRODUCTION

Due to the recent advances in both software and hardware, many applications are generating streaming data, such as sensor networks, financial markets, real-time video monitoring, internet traffic, and medical data. The term "data stream" refers to a collection of temporally ordered, massive, usually arriving at a high rate, and potentially infinite data objects. A data stream can be formalized as $DS_t = \{x_{1,t}, x_{2,t}, x_{3,t}, ..., x_{N,t}\}$, where $x_{i,t}$ is the element number i at time t, and it has a set of high-dimensionality attributes or features. Through its large volume, it is therefore difficult to fully store data streams in memory and scan them several times [1]. Data streams differ from static data where they have some unique characteristics such as *concept-evolution*, *concept-drift*, and *feature-evolution*. In particular, concept-evolution happens

when new classes emerge in streams, concept-drift occurs when the distribution of data points shifts over time, and feature-evolution occurs when the feature set of data streams changes over time [2]. Data Stream Mining (DSM) is a new approach for extracting important information from data streams [3]. Hence, the traditional data mining techniques are not applicable to processing data streams because of the special characteristics of streaming data as shown in Table I.

Data streams, like traditional data, may have outliers, or data points that are considerably different from the bulk of data points [4]. They can be noise data points or interesting instances and have to be detected in many cases to achieve better performance and accuracy. Outlier detection is one of the most important data mining tasks for detecting unusual and anomalous data points or sequences hidden in a dataset [5]. However, outlier detection over data stream datasets completely differs from traditional data ones because it must be performed under only one pass, the available memory is limited, real-time response, and the concept-evolution nature of streaming data. In real life, outlier detection has a variety of essential applications, such as detecting credit card fraud; intrusion detection in computer networks or cybersecurity; system fault diagnosis in industry; early disease detection in the health care sector, etc. [6]. Outlier detection techniques may be based on one of the following learning methods: unsupervised, semi-supervised, supervised, or ensemble learning. The unsupervised learning technique does not need training data to build the model, while the semi-supervised learning technique combines a small collection of labelled data with a large dataset of unlabeled training data. In the supervised learning approach, it requires labelled training data availability [4]. On the other hand, the ensemble learning approach requires a group of multiple trained classifiers learning algorithms to detect outliers in order to improve the detection accuracy. In particular, a number of different base learners are used in an ensemble model, which is normally much stronger than all standalone base learners because it has the ability to improve the performance of weak learners [5]. For this purpose, this paper presents an effective outlier detection approach based on the ensemble learning technique where the iForestASD, decision tree, and Adaptive Random Forest (ARF) classifiers are used as the base learners to build an ensemble-based model over streaming data using the sliding window fashion with the objective of improving detection performance while decreasing detection time consumption. In the data streams environment, the sliding

window is a time-based streaming model which is generally used to effectively process the flow of streaming data through dividing these streams into several windows, as shown in Fig. 1, where each window has an equal pre-defined size *(w)* in time *(t)*. The size of a window may be specified in terms of time points or the number of recent objects. Hence, each window maintains only recent objects, while older ones are discarded, and all objects within the active sliding window have the same importance.

TABLE I. COMPARISON BETWEEN STREAMING DATA AND STATIC DATA

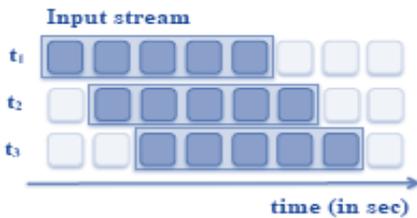
Characteristic	Streaming Data	Static Data
Volume	Infinite	Finite
Type of Data	Heterogeneous	Homogeneous
Scanning Time	Single pass	Multiple passes
Data Processing	Real-time processing	Offline processing
Data Storage	Aggregated and summarized data only	Raw data
Concept	Evolving	Static
Type of Result	Approximate result	Accurate result
Temporal and Spatial Contexts	Important aspects	May be considered for certain applications
Space and Time Complexity	Strict	Not strict


Fig. 1.   The Sliding Window Time-based Model.

To detect outlier values, a combination of different base detectors; iForestASD, decision tree, and adaptive random forest algorithms; were chosen to develop an ensemble-based learning framework, which has never been explored before in the literature. The iForestASD model can be retrained more quickly than models trained with higher complexity like SVM. IForestASD allows you to retrain the model with a sliding window so that detection performance does not degrade even with concept evolution. While the decision tree technique does not need data normalization or scaling, and it has a shorter training period. Furthermore, random forest has high learning performance with good data visualization for high dimensional data and does not require hyper-parameter tuning or tree pruning. Moreover, it enables rapid detection model training even with limited computational resources. This is the main motivation for choosing this combination of base learners to construct our ensemble-based learning model for streaming outlier detection. In streaming data, the proposed framework (ESOD) attempts to detect both outliers and new class concepts. ESOD provides a more effective solution to this problem by integrating active learning in a supervised approach to detect any novel concepts and outliers in the

streaming environment. The main research contributions and novelty are summarized in the following points:

- Proposing an effective Ensemble-based Streaming Outlier Detection (ESOD) framework for accurately detecting outliers in the context of streaming data adapting to the concept drift nature of streaming data.

- Building an ensemble-based model for the proposed framework using some heterogeneous machine learning algorithms as base learners, such as iForestASD, decision tree, and adaptive random forest, and then selecting the best combination.

- Using the sliding window time-based technique in the ESOD framework to process the flow of streaming data.

- Reducing computation time by allowing parameter tuning and comparing the outcomes of multiple algorithms in a single trial.

- Providing a detection weighted vote technique to report the potential outliers that outperforms the standalone base learners and state-of-the-art techniques in terms of accuracy, precision and other evaluation metrics.

The remainder of this paper is structured in the following way: related work on outlier detection techniques in streaming data is introduced section II. Section III explains the preliminaries of the used base learners. Section IV introduces the proposed framework. Section V discusses the experimental evaluations and the model development details. Finally, Section VI summarizes the proposed study and the next directions are given.

II.   RELATED WORK

Many attempts in the literature have been devoted to the outlier detection problem over streaming data. Nevertheless, many of these detection approaches work in batch mode, in which all data points are stored and many passes can be made over the data [7-9]. Several batch outlier detection algorithms have been adapted for data stream outlier detection, according to a review in [10]. These methods, while applicable to streaming data, are inefficient because they do not take into consideration the special features and characteristics of data streams. The outlier detection approaches in the streaming data context may be divided into three main categories, which are statistical-based, clustering-based, and classification-based methods [11, 12]. The first attempts at outlier detection were statistical-based approaches based on defining a model to represent the normal behavior of the data [13]. If an incoming data point does not fit the model or has an extremely low probability of fitting the model, it is termed an outlier. In [14], The authors proposed an algorithm called UKOF for top-n local outlier detection based on the kernel density estimation (KDE) model over large-scale high-volume data streams, in which they defined a KDE-based outlier factor (KOF) to measure the local outlierness score, as well as upper bounds of the KOF and an upper-bound-based pruning strategy to reduce the search space. Although this method had a low computational cost, it assumed a stable distribution of data, which is inappropriate in a data stream setting. In recent

research [15], a maximal weighted frequent-pattern-based outlier detection approach (MWFP-Outlier) was proposed to detect potential outliers from uncertain data streams. This approach had two phases, namely pattern mining phase and an outlier detection phase. The MWFP-Mine approach was proposed in the pattern mining phase to mine maximal weighted frequent patterns using the list structure, tree structure, and pruning strategies by fully considering the existential probabilities and weights for each pattern. During the outlier detection phase, four deviation indices were created to measure the degree of deviation, and then the top k ranked transactions were reported as potential outliers. It is unclear, however, how it dealt with outliers and fast processing.

The clustering-based methods are one of the common unsupervised methods used in outlier detection problems, which creates data clusters that represent the underlying data distribution [16]. Clustering-based methods divide the data into some clusters according to the similarity between the data points. Outliers are observations that are remote from clusters or clusters with significantly fewer data points. The clustering methods are categorized into distance-based and density-based. In 2019 [17], Tran et al. proposed three distance-based algorithms using the micro-clusters concept, and they claimed that the proposed algorithms had a reasonable processing time and a low space cost. Regarding the density-based methods, there are some state-of-the-art methods developed to detect outliers in data streams, such as [18–20]. Another notable attempt was presented in [21], a method called LiCS was introduced to detect outlier that classifies the samples using K-nearest neighbors of each node. Most recently, [22] proposed an incremental local density and cluster-based outlier factor method for detecting outliers in streaming data called iLDCBOF. The proposed method combined density-based spatial clustering of applications with noise (DBSCAN) and incremental versions of the local outlier factor (LOF), but it suffered from excessive computations. On the other hand, classification-based methods may either be incremental single model or ensemble classifier techniques, where the classification output is a function of the predictions from different classifiers. In addition, streaming ensemble-based methods have been developed to deal with the high dimensionality of data streams, and these techniques have great success in the outlier detection and prediction domains because of their accurate results and higher efficiency in both performance and resource consumption. Ensemble-based techniques integrate the results of many base models to create a more robust model that can detect outliers more effectively. Masud et al. [23] proposed a hyper outlier detection model for streaming data. They utilized the k-NN classifier first, followed by the SVM polynomial kernel classifier, and a data point is reported as an outlier if it is identified as an outlier by at least one of the classifiers. Then, to distinguish between novel and outlier data points, a neighborhood silhouette coefficient is applied. This approach addresses the novelty detection in multi-class underlying concepts, yet it requires all data chunks to be labelled to define the new concept. Wang et al. [24] proposed a model for detecting anomalies based on a matrix of uncompressed data against a matrix of compressed data, and this model utilized the original uncompressed data while considerably reducing computing costs. In [25], a new

ensemble approach called RED-PSO was presented, which is suited to the drift notion of a data stream in the classification of non-stationary data streams. In [26], the authors proposed a sliding window-based ensemble approach for streaming outlier detection where a combination of clustering algorithms were utilized to construct clusters, which were later used in a one-class classification to identify outlier data. Togbe et al. [12] afforded iForestASD, i.e., an alternative isolation forest for streaming data implementation. They built the iForestASD on the scikit-multiflow framework; it is a machine learning framework for streaming data that is free and open source. In 2021 [27], they modified their implementation of iForestASD to address the idea of data stream drift, proposing three algorithms for drift detection: ADWIN, KSWIN, and finally extending KSWIN to deal with n-dimensional data streams. Another recent study was presented in [28], where the authors proposed an ensemble-based outlier detection framework for high-dimensional data named Average Selection and Ensemble of Candidates for Outlier Detection (ASEC-OD). The proposed framework selected the most effective base outlier detectors, which have the highest performance. To summarize, none of these approaches can detect outliers accurately and efficiently in streaming data environments while maintaining high performance rates. Our approach differs from the aforementioned outlier methods in two ways. First, the proposed framework integrates outlier detection and the concept evolution phenomenon of streaming data by considering concept evolution for new outlier or inlier concepts that appear in incoming streams. It can sequentially update the outlier detection model in the case of concept evolution, resulting in a more robust outlier detection system that is matched with a streaming scenario. Second, it takes advantage of each heterogeneous base classifier in building an ensemble model to achieve the highest rates of performance metrics.

III. BASE LEARNERS

The outlier ensemble learning method will be very effective when heterogeneous base classifiers of diverse types are used. Thus, the distinct features of data can be identified or learned due to the variation between classifiers [29]. To boost efficiency, the proposed ensemble model constructs a set of models from three heterogeneous base learners. The chosen base learners (isolation forest, its variant iForestASD, decision tree, random forest, and its variant adaptive random forest) of the proposed framework are briefly introduced in this section.

A. Isolation Forest (iForest) and IForestASD

Isolation Forest (iForest) is a famous tree-based approach to outlier detection to isolate outlier instances [30]. The random selection of an attribute iteratively creates an isolation tree *(itree)* until each data point is isolated. Isolation forest is based on the notion that it is simple to isolate an outlier but more complex to characterize an inlier data point. Accordingly, the isolation forest consists of all the isolation trees constructed from its training set subsampling. The outlier score $s(x, n)$, equation (1), is calculated by calculating the path length $h(x)$ from the root to an instance x in an isolation tree constructed from n data instances [31].

$$s(x,n) = 2^{-\frac{E(h(x))}{c(n)}} \tag{1}$$

where $E(h(x))$; which is defined by equation (2); is the average path length $h(x)$ of x over an isolation trees collection, i.e., *itrees*.

$$E(h(x)) = \frac{\sum_{i=1}^{t} h_i(x)}{t} \tag{2}$$

where $c(n)$ represents the average path length of the binary search tree's unsuccessful search process. Finally, equation (3) calculates $c(n)$, which is used to normalize an outlier score.

$$(n) = 2H(n-1) - (2(n-1)/n) \tag{3}$$

where $H(i)$ is formulated by equation (4).

$$H(i) = \ln(i) + \gamma \text{ , } \gamma \text{ is the Euler's constant} \tag{4}$$

Therefore, x is considered as outlier data if the outlier score is close to 1, but it is considered as normal data if the score is less than 0.5.

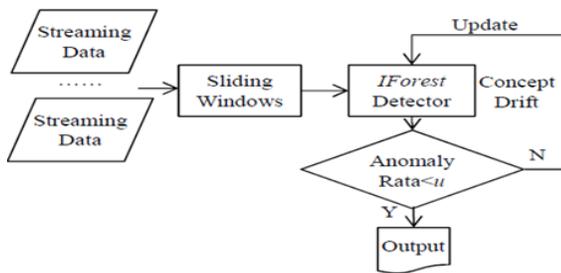
On the other hand, the iForestASD [32] is an alternative version of the iForest method and is suitable for outlier detection over streaming data. The phrase "iForestASD" is an abbreviation for Isolation Forest Algorithm for Stream Data, where it uses the sliding window mechanism to process streaming data. In addition, iForestASD implemented the standard isolation forest technique to build the random forest. The IForestASD technique was developed to deal with the concept drift of the data stream by keeping a pre-defined anomaly rate threshold *(u)*. Fig. 2 displays the workflow of the iForestASD approach to updating the model. If the anomaly rate in the active window is higher than u, then concept drift has occurred. The iForestASD then deletes the current detector and constructs another detector using all the data in the active window. Otherwise, there was no concept drift. The trained anomaly detector was then would not change.


Fig. 2. The iForestASD Workflow. The Image is Reproduced from [32].

B. Decision Tree (DT)

Decision trees are popular tree-based classification methods where each non-leaf node represents an attribute, whereas the edge links between its child nodes represent the attribute values and the leaf node represents a class label. In general, a decision tree is built in three main steps:

- Select the best features of the training dataset to build the root node.
- Split the training dataset into nodes using the Gini index.

- Loop until no further splitting can be done.

Information gain, gain ratio, and Gini index are used to partition the training dataset [33]. In this research, the Gini index is used as the DT splitting criterion, which is calculated by equation (5).

$$G(X) = 1 - \sum_{i=1}^{n} p_i^2 \tag{5}$$

where p_i is the proportion of the ith class samples of the feature X.

C. Random Forest and Adaptive Random Forest

Firstly, the classical random forest (RF) [34] method is a tree-based approach that can be used for both classification and prediction tasks. The prediction of a new data point is determined by aggregating the predictions of n trees in classification tasks. Random predictors are chosen to split a node in random forests; therefore, every tree is grown based on a different random data sample. After multiple models have been generated, the overall trees of the model contribute to a weighted decision or vote to produce an overall determination. Regarding randomness splitting of the data, RF has two main sources of randomness which are bootstrap aggregating or bagging and boosting. In bootstrap aggregating, each classifier is trained on random sampling with replacement from the original dataset. On the other hand, in boosting approach, instead of evaluating all features at each tree split, only a random set of samples is used to make the eventual decision. RFs can model high dimensional data and they can handle missing values.

Adaptive Random Forest (ARF) is one variant technique that adapts the standard random forest algorithm [35]. It produces decision trees by training them on resampled varieties of the original data and by randomly picking up a small number of features that can be inspected at each node for splitting. ARF offers data visualization of high dimensional data and it has a high accuracy and resistance to overfitting.

IV. PROPOSED ENSEMBLE-BASED FRAMEWORK

In this section, a novel ensemble-based outlier detection framework for data streams called Ensemble-based Streaming Outlier Detection (ESOD) is introduced. The proposed framework utilizes three heterogeneous machine learning algorithms, which are iForestASD, decision tree (DT), and adaptive random forest (ARF) as the base learners to build the ensemble model for detecting outliers in streaming data based on a weighted voting technique. To enhance efficiency, the proposed framework employs various base learners to build an ensemble-based model. Ensemble-based Streaming Outlier Detection (ESOD) has three main phases, as shown in Fig. 3, namely the training phase, testing/offline phase, and outlier detection/online phase. These phases are detailed in depth in the subsections that follow.

A. The Training Phase

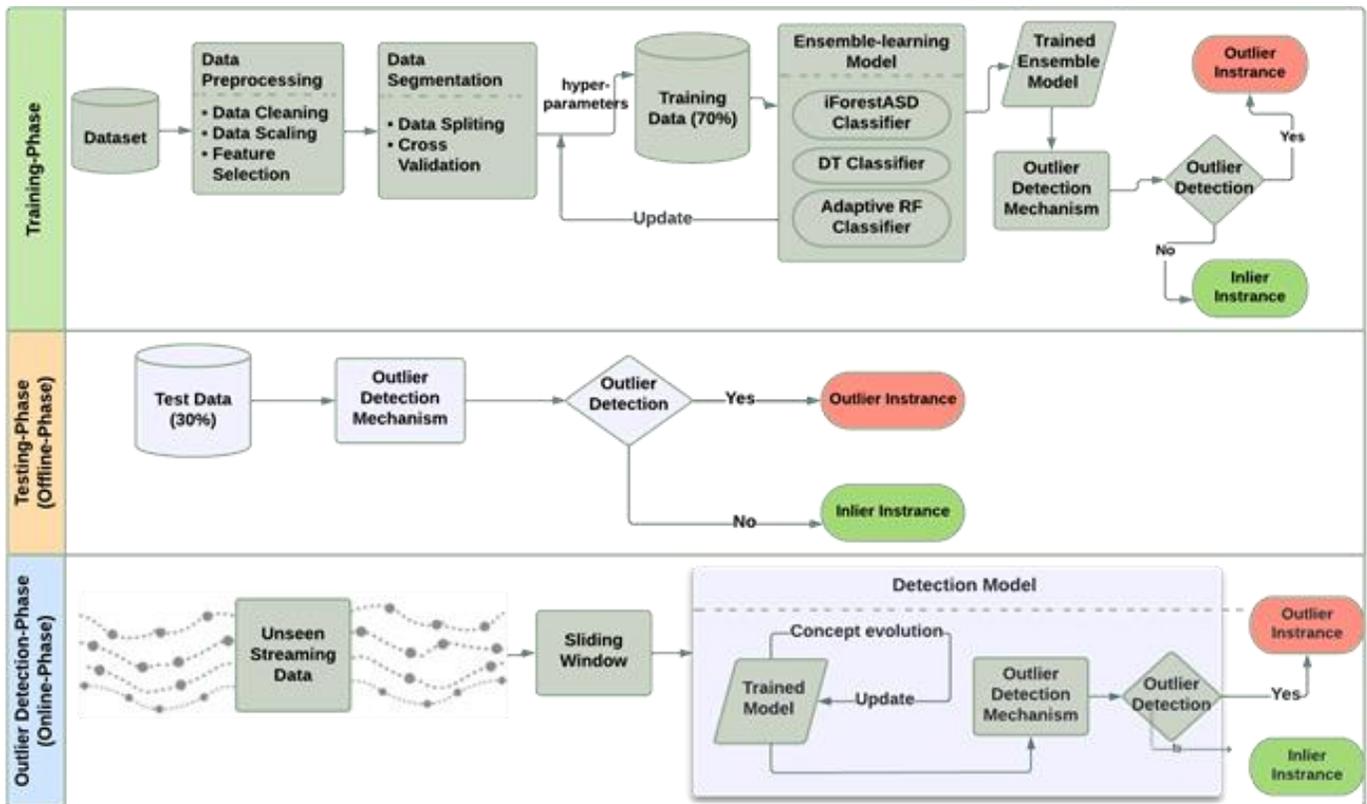
The ESOD training phase is used to prepare data and tune the hyper-parameters of each classifier for the finest outcome. It consists of a series of steps that must be completed in the following order:


Fig. 3.   The Ensemble-based Streaming Outlier Detection (ESOD) Block Diagram.

1) Data preprocessing step: Certain data preprocessing techniques are done in order to turn raw data streams into meaningful patterns. The preprocessing stage is a critical step for the proper representation of streaming data. Hence, many different preprocessing techniques are employed, such as the removal of missing values, min-max scalar and one-hot encoding, for a more efficient classification process. There are three further phases in the ESOD's preprocessing stage, which are the *data cleaning*, *data scaling*, and *feature selection* phases. In the *data cleaning* phase, missing data is first examined and eliminated if it exists. The *data scaling* phase then employs the one-hot encoding approach on nominal or non-binary categorical data, and the min-max scaler is employed to scale values into the range of 0-1. Finally, the *feature selection* phase, where the main goal is to extract the set of relevant and non-redundant features, makes the learning model more meaningful and quicker because not all features are important for the model's learning process. In this study, the Least Absolute Shrinkage and Selection Operator (LASSO) technique is used to choose the most important and correlated features from the feature space that have a strict reflection on the target.

2) Data segmentation step: In the data segmentation step, the preprocessed data D of n selected features is divided into two groups: training set X_{train} with m data points of ratio 70% where $X_{train} \in D^{m \times n}$ and testing set X_{test} with r data points of ration 30% where $X_{test} \in D^{r \times n}$. The testing set, in contrast to the training set, should be unlabeled. Then, the K-fold cross

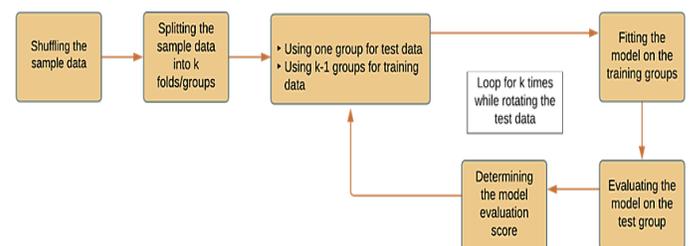
validation (CV) method is used, in which the training set is divided into k equal non-overlapping subsets, determined by random sampling or the bootstrap mechanism, and the model is tested on different subsets of the dataset. Fig. 4 depicts the K-fold cross validation process. If $k = 10$, for example, nine groups of the sample data are used to train the model and only one group is used to test the model at each fold, where the model parameters with the lowest mean squared error from the k training models are chosen for the final model. For each fold, the outlier detection models are trained with only data from the inlier class, so the model is trained k times. The k-fold cross validation approach is used in this study to choose the model hyper-parameters for setting each model as well as the configured models.


Fig. 4.   The K-Fold Cross Validation Process.

3) Ensemble-learning model step: The heterogeneous base classifiers $B = \{\beta_1, \beta_2, ..., \beta_i\}$; iForestASD, decision tree, and ARF classifiers are built in this step, employing many hyper-parameter settings that are continually updated to

acquire the optimal parameters of each classifier. All three classifiers were trained using K random data samples (s_1, s_2,… s_K) and were then used to classify outliers of the test set X_{test} in the testing phase. Specifically, the outlier detection approach ESOD uses similar insights as in the random forest approach, where all these base learners are considered as trees for the ensemble model. In more detail, the outlier detection final decision is made by the weighted voting of these trees where it is the class label that has the highest weighted vote of classifiers predicted. After constructing the base learning models, the ensemble learning model $\psi_{\beta1, \beta2,…, \beta i}$ tries to combine their outlier results to declare the final decision by estimating the weights of individual base learning models β_1, β_2, … , β_i. to aggregate their results with a weighted combination. The ESOD weighted voting approach involves assigning various weights to each classifier depending on its performance accuracy [36], calculated by equation (6), and voting on the classifiers based on this weight. After calculating the weight for each classifier, the most votes of classification results are selected as the ensemble's final detection result.

$$\omega_{\beta i} = \frac{A_{\beta i}}{\sum_i^3 A_i} \tag{6}$$

where $\omega_{\beta i}$ is the weight of classifier β_i, $A_{\beta i}$ is the classifier β_i accuracy, and A_i is the accuracy summation of the three base classifiers used in the ensemble model. The trained ensemble model has been constructed at this point and can classify a data point as an inlier or outlier.

B. The Testing/Offline Phase

The test set was made up of the remaining 30% of the whole dataset. This test data is used as a final evaluation of an unseen dataset in the offline phase to ensure that the trained model was appropriately trained and predicts correctly. Hence, any unseen test sample x is classified into inlier or outlier instances using these trained base classifiers based on the above detection voting technique.

C. The Outlier/Online Detection Phase

During the outlier detection phase, i.e., the online phase, a flow of fresh unseen data streams is generated and processed using the sliding-time window technique. As a result of the ever-changing nature of stream data, detection mechanism updates are frequently based on time intervals in the form of sliding windows, where current items are given higher priority during the detection phase than older ones. The trained model can classify the known classes on which it was trained, identify any novel classes, and finally update the model with the most recent data to include any detected outliers. The model, in particular, tries to classify incoming samples of streaming data into known classes, which are outliers or inliers, or novel patterns. Hence, it predicts class labels for instances that belong to known classes, and the novel patterns are identified as "*concept evolution*". Once the new class is detected, it is integrated into the model for detecting repeated patterns. Thus, the trained model is automatically updated to handle the concept evolution by comparing the mean difference of two adjacent sub-windows [37].

V. EXPERIMENTAL EVALUATION

This section presents the datasets, experimental setup, and parameter fine-tunning process followed by the assessment metrics and a brief discussion of the results.

A. Dataset Description

This research uses 11 publicly available outlier benchmark datasets (http, Credit-card-fraud, smtp, Annthyroid, Thyroid, Cardio, Pima Diabetes, Breast-cancer, Arrhythmia, Heart Disease, Hepatitis) from the UC Irvine Machine Learning Repository [38] for the evaluation of the base learner classifiers, state-of-the-art methods, and proposed framework. Description of these datasets is summarized in Table II by name, number of points, dimensions, outlier samples, percent of outliers, outlier class, and application domain of the datasets.

TABLE II. DESCRIPTION OF THE BENCHMARK DATASETS USED IN THE PERFORMANCE EVALUATION

Dataset	Samples (m)	Features (n)	Outliers (%)	Outlier Class	Application Domain
http	567,479	22	2,211 (0.39%)	Attack	Intrusion detection
Credit-card-fraud	284,807	30	492 (0.17%)	Fraudulent	Fraud detection
smtp	95,156	22	29 (0.03%)	Attack	Intrusion detection
Annthyroid	7,200	6	534 (7.42%)	Hyperfunction and Subnormal functioning	Disease detection
Thyroid	3,772	6	93 (2.47%)	Hyperfunction and Subnormal functioning	Disease detection
Cardio	1,831	21	176 (9.61%)	Pathologic	Disease detection
Pima Diabetes	768	9	193 (3.98%)	Diabetes	Disease detection
Breast-cancer	683	30	239 (34.99%)	Malignant	Disease detection
Arrhythmia	452	279	66 (14.60%)	The smallest classes (3, 4, 5, 7, 8, 9, 14, 15)	Disease detection
Heart Disease	297	13	137 (46%)	Class 0	Disease detection
Hepatitis	155	19	32 (20.65%)	Die	Disease detection

B. Experimental Setup

All the developed models are implemented in the open-source Python programming language using the Anaconda distribution API. The main libraries and packages used include pandas, NumPy, SciPy, matplotlib, and seaborn. Furthermore, the scikit-learn library [39] is the most widely used open-source Python machine learning package. Scikit-learn structures various machine learning tasks such as regression, classification, and clustering algorithms and contains random forest, decision tree, K-NN classifiers, and more. Finally, to develop algorithms and conduct experiments, we used the Scikit-Multiflow framework [40], a Python-based open-source machine learning framework for evolving data streaming.

C. Hyper-parameter Tuning

The model hyper-parameters were tuned through a series of loops that iterated through changes in each relevant parameter of the given model based on the Grid Search strategy, and the model performance was assessed using stratified 10-fold cross-validation setting. Table III displays the optimal hyper-parameter values for each classifier used in the evaluation process after executing the hyper-parameter

fine-tuning method. In addition, the model performance is assessed using several ranges of sliding window size settings because of the relevance of this parameter in terms of computation time and memory use. For small datasets (Pima Diabetes, Breast-cancer, Arrhythmia, Heart Disease, Hepatitis), we used the sliding window of sizes w = 100, 120, 140, 160, 180, and 200. Whereas w = 100, 200, 300, 400, 500, 600, and 700 are the window sizes chosen for huge datasets (http, Credit-card-fraud, smtp, Annthyroid, Thyroid, Cardio).

D. Performance Metrics

To assess the effectiveness of the proposed framework, the average scores of ten separate trials were used to construct the most popular performance metrics in the outlier detection area, which are accuracy, precision, sensitivity or recall, and F1-score measures. All these metrics are calculated by the following equations, equation (7) – (10). For the binary classification, there are only four possible outcomes, which are True Negative (TN), False Negative (FN), False Positive (FP) and True Positive (TP).

$$\text{Accuracy} = (TP+TN)/(TP+TN+FP+FN) * 100 \qquad (7)$$

$$Recall = TP/(TP + FN) * 100 \qquad (8)$$

$$Precision = TP / (TP + FP) * 100 \qquad (9)$$

$$F1 = 2*(\text{Precision} * \text{Recall}) / (\text{Precision} + \text{Recall}) \qquad (10)$$

E. Results and Discussion

The proposed framework is evaluated by comparing results with its standalone base learners and other some predictive machine learning techniques such as Logistic Regression (LR), SVM, GaussianNB, K-NN, Artificial Neural Network (ANN), Gradient Boosting, and Local Outlier Factor (LOF). In addition, ESOD is compared with many state-of-the-art methods found in [14], [15], [21], [22], [26], [27], and [28]. We individually show the performance of the comparisons on the aforementioned 11 datasets using the accuracy, precision, recall, and F1-score metrics. The performance results are the average of 30 trials of independent experiments.

In the first experiments set, the efficiency of the proposed framework is evaluated using the accuracy, precision, and recall metrics with all baselines on the datasets. Table IV compares performance results of all base learners with the proposed model. From the results, it is clear that the linear regression, K-NN, SVM, and LOF perform worse than other algorithms in most cases. Although the base learners, i.e., iForestASD, decision tree, and adaptive random forest classifiers, of the proposed model independently perform very well, but the proposed framework performs better than these three standalone base learners. On the other hand, the experimental results reveal that the ESOD performs very well on the large-scale datasets such as http, credit and smtp datasets, beside its superior performance over other small datasets. For instance, ESOD achieves 98.65% and 99.64% of

precision score on http and heart disease datasets, respectively. Another notable issue is that ESOD gives the highest recall or outlier detection rate, where it gets 99.78%, 99.05%, 99.66%, and 99.54% rates on http, credit, smtp, and hepatitis datasets, respectively.

Fig. 5 plots the performance comparison between different machine learning algorithms, and ESOD method in terms of F1-score. It should be noted that the K-NN, SVM, and LOF methods exhibited very low performance rates compared to ESOD and the others. On the http dataset, which is the biggest dataset, the K-NN, SVM and LOF models exhibit poor recall rates of 77.90%, 70.78%, and 61.58%, respectively, demonstrating their inability to learn enough samples to accurately classify outlier data, while ESOD achieves 99.21% on the same dataset. Furthermore, all the K-NN, SVM and LOF models get the lowest F1 rates on the Breast-cancer dataset, which has the largest outlier ratio, with 77.34%, 75.25%, and 69.59%, respectively, while ESOD can achieve the highest F1-score of 89.18%. In general, the proposed model has the best F1-score rates on all datasets.

The next set of experiments is performed to compare the proposed framework with some state-of-the-art methods for streaming outlier detection presented in [14], [15], [21], [22], [26], [27] and [28] and the results are shown in Fig 6. In more detail, from Fig. 6(a)-(k), the performance of the proposed model (ESOD) is better than its competitive methods on all benchmark datasets, where it achieves higher rates than others. For instance, ESOD has attained 97.37% accuracy, 98.65% precision, a recall of 99.78% and finally F1-score of 99.21% on the http dataset, Fig. 6(a). In contrast, other methods have achieved lower rates, which are 71.87%, 70.63%, 73.22%, 88.03%, 90.16%, 93.81%, and 84.32% of the recall measure for the methods UKOF [14], MWFP-Outlier [15], LiCS [21], iLDCBOF [22], Method in [26], Method in [27], and ASEC-OD [28], respectively. One thing is notable here is that the MWFP-Outlier and LiCS methods have the lowest performance rates on all datasets in most cases. However, the model in [27] has a slightly high rates like our proposed model, where it gains 93.81%, 91.75%, 91.83%, 91.75%, 92.43%, 91.31%, 81.82%, 87.33%, 90.27%, 93.50%, 90.70% of recall on http, credit, smtp, Annthyroid, thyroid, cardio, Pima, breast-cancer, arrhythmia, heart, and hepatitis datasets, respectively. Overall, the precisions of the seven state-of-the-art methods are also lower than the ESOD precision (61.86% - 93.52%). One can observe that the performance rates of our proposed framework is more consistent with increasing number of features on the dataset as compare to the other seven state-of-the-art methods on all datasets. On Arrhythmia dataset, which has 279 features, LiCS performs slightly better than iLDCBOF, Method in [26] and ASEC-OD. Meanwhile, UKOF obtains the lowest rates on breast-cancer dataset, which has the highest outlier ratio, but method in [26] approximately performs as good as ASEC-OD [28].

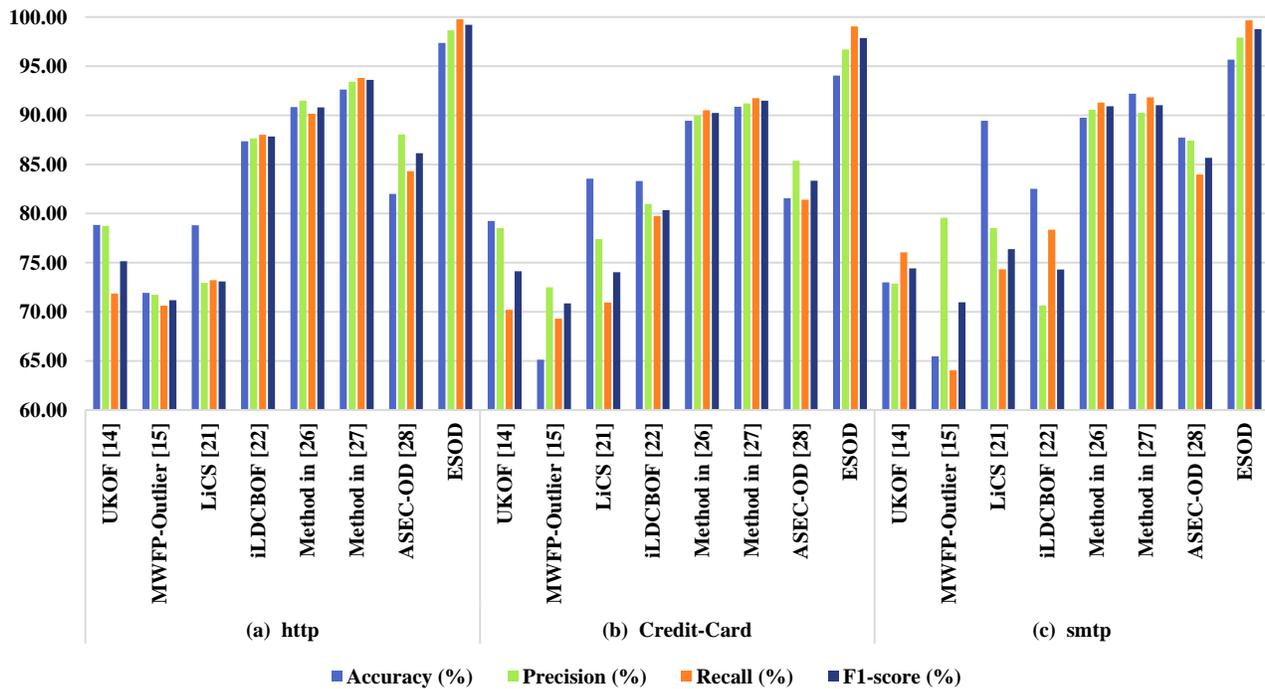

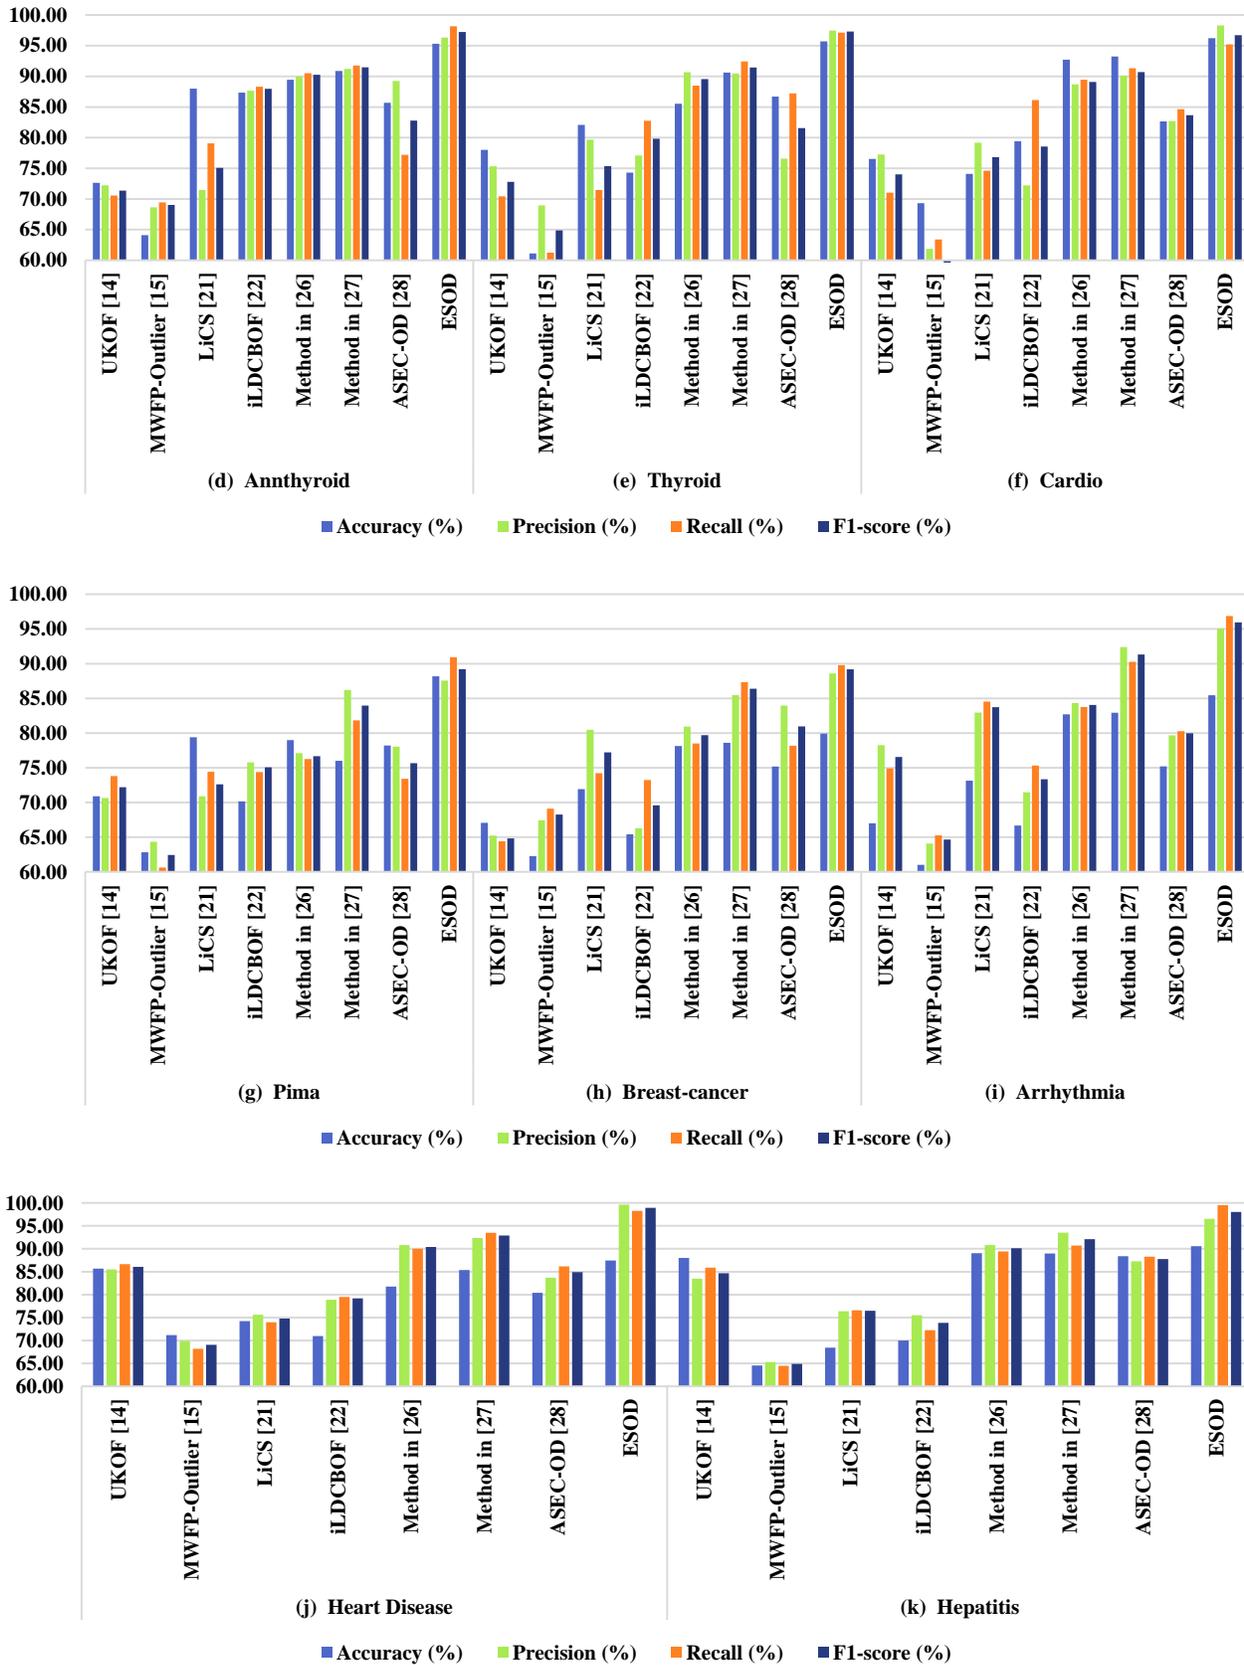

Fig. 6. Performance Comparison between State-of-the-Art Methods and the Proposed ESOD Model.

Another experiment was conducted to assess the impact of changing the window size of streaming data on the proposed framework. Table V compares the performance evaluation metrics when the window sizes were varied *(w)*. When the window size is increased to *w* = 500 for the http, credit, smtp, Annthyroid, thyroid, and cardio datasets, while *w* = 180 for the Pima, breast-cancer, arrhythmia, heart, and hepatitis datasets, the rates have improved as the F1-score grows for all datasets. However, when the window size is greater than 500 for large datasets and greater than 180 for small datasets, the F1-score falls dramatically. Furthermore, the model's performance varies significantly depending on the dataset, with ESOD earning a F1-score over 99% for the http dataset, which is the largest dataset. As a result, we expect ESOD to perform better on datasets with a high scale data.

The final experiments set is performed to evaluate the average execution time of ESOD against the other methods.

Fig. 7 shows that on the http dataset, for instance, ESOD performs with an execution time of 27.46 milliseconds compared to the LiCS, which takes about 41.56 milliseconds while the iLDCBOF method takes 37.89 milliseconds. Furthermore, LiCS takes the longest time among all the investigated methods, and the proposed method executes the http dataset at almost half the execution time of LiCS. On the other hand, comparison of execution time within the Hepatitis dataset, for instance, displays that ESOD has the shortest execution time of 11.40 milliseconds as compared to the others. In addition, within the Pima dataset, the result indicates that ESOD has an execution time of 19.64 milliseconds as against UKOF which has resulted in 26.47 milliseconds of execution time. In general, the results demonstrate that the proposed method is significantly faster than all other methods in every tested case on all datasets.

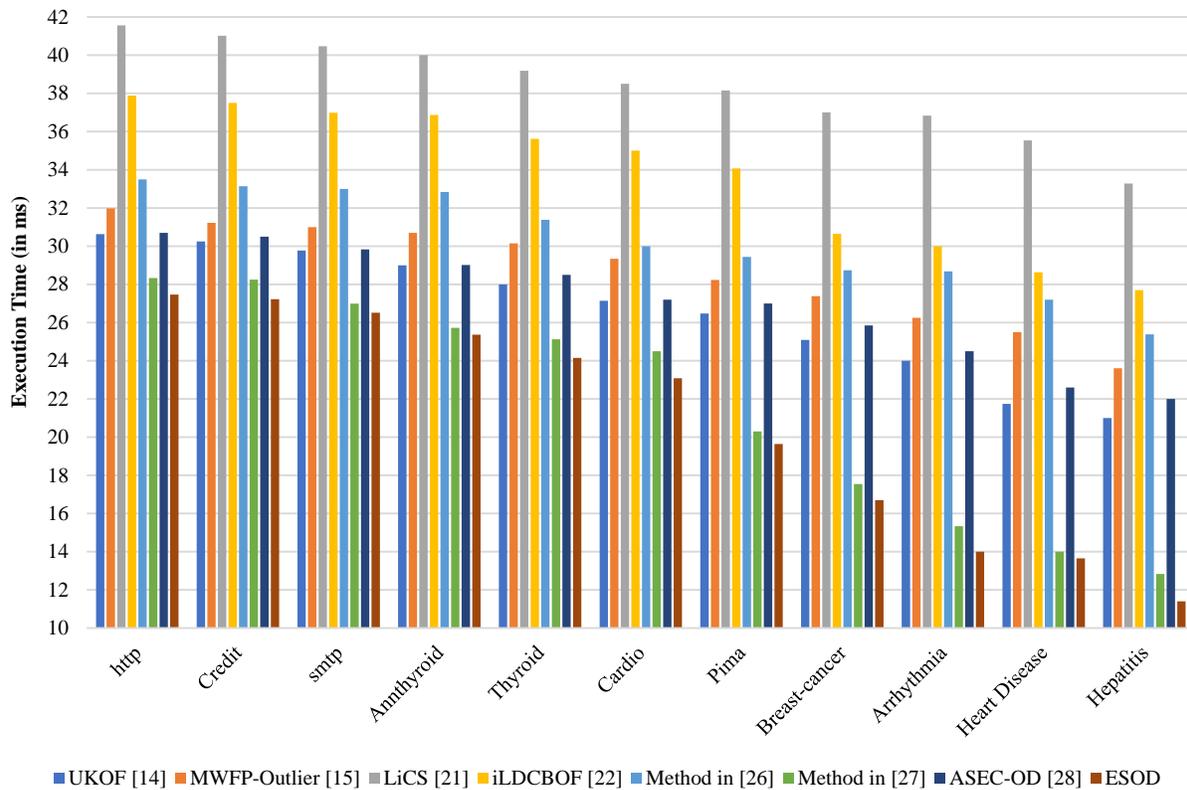

Fig. 7. Execution Time Evaluation for ESOD Compared with different Methods on different Datasets.

VI. CONCLUSION AND FUTURE WORK

In this study, we propose a novel sliding window ensemble-based framework for detecting outliers in data streams called an Ensemble-base Streaming Outlier Detection (ESOD). To improve outlier detection decisions, the proposed framework was built with three machine learning algorithms as base learners: iForestASD, decision tree, and adaptive random forest (ARF) based on a weighted voting detection technique. Furthermore, ESOD considered the concept evolution nature of streaming data. Extensive empirical evaluations on various real datasets demonstrate the performance of our framework in comparison to that of existing algorithms in the literature. The results showed that the proposed framework beat existing algorithms in terms of outlier detection rate, as well as overall performance. In the future, we will look into how to adapt the framework to the feature-evolution nature of data streams. Another option is to use more optimization techniques and different feature selection methods. Aside from improving execution performance, we are also interested in implementing various time-based techniques that may lead to improved detection and accuracy rates.

Abstract—**Structure from Motion is a pipeline for 3D reconstruction in which the true geometry of an object or a scene is inferred from a sequence of 2D images. As feature extraction is usually the first phase in the pipeline, the reconstruction quality depends on the accuracy of the feature extraction algorithm. Fairly evaluating the robustness of feature extraction algorithms in the absence of reconstruction ground truth is challenging due to the considerable number of parameters that affect the algorithms' sensitivity and the tradeoff between reconstruction size and error. The evaluation methodology proposed in this paper is based on two elements. The first is using constrained 3D reconstruction, in which only fixed numbers of extracted and matched features are passed to subsequent phases. The second is comparing the 3D reconstructions using size-error curves (introduced in this paper) rather than the value of reconstruction size, error, or both. The experimental results show that the proposed methodology is more transparent.**

Keywords—Feature extraction; feature matching; structure from motion; 3D reconstruction

I. INTRODUCTION

Structure from Motion (SfM) is a processing pipeline intended for reconstructing 3D models of objects from a sequence of 2D views (images). It involves several different phases in which various algorithms can be used, such as feature detection, feature description, feature matching (correspondence), triangulation, and finally 3D reconstruction. In addition, pruning or masking-out outliers may be performed between different phases. As it commonly starts with detecting features and computing descriptors, its accuracy depends mainly on the robustness of the used feature extraction algorithm. This raises a critical question; which of the available feature detectors-descriptors is best for SfM [1], [2]?

Feature detection and description is a low-level process that can be considered the cornerstone and is usually used as the starting point of many applications in computer vision. A feature (keypoint) is an interesting or important piece of information, such as points, blobs, corners, edges, junctions, etc., that is relevant to the solution of the computational task (correspondence) behind a specific application (3D reconstruction). Accordingly, a feature detector is an algorithm that can detect these interesting keypoints in a given image. On the other hand, a feature descriptor describes each detected feature in an image by assigning it a distinctive identity formed by the pixels within a certain neighborhood. This identity enables effective recognition of the

corresponding features during matching [3], [4]. After feature detection, detected features can be pruned using either a threshold for the detector response or by selecting the features with the highest response.

The simplest strategy for matching two sets of feature descriptors and finding the corresponding features is brute-force matching. In this strategy, each feature descriptor in the first set is compared with each feature descriptor in the second set. This allows for finding all possible pairs of corresponding features. However, it requires extensive computational resources. A better and faster strategy for feature matching, especially in large datasets, is to adopt a hash table or a multi-dimensional search tree as an indexing data structure for rapidly retrieving neighbors (features) from the second set that are nearest to a given feature from the first set [5].

The list of corresponding features can be pruned by comparing the similarity (distance) of each pair with a predefined threshold representing the maximum allowed distance. Only pairs that satisfy the predefined threshold are kept, while other pairs are discarded. The downside of this method is the difficulty of deciding the appropriate threshold. In addition, applying the same threshold to all pairs can be inaccurate in some circumstances, as the distance of a correct match can be greater than that of an incorrect match. A better pruning strategy in such cases is to select only the best pair (the one with the smallest distance) for every feature or adopt the Nearest Neighbor Distance Ratio (NNDR) [6]. Matching results can be further pruned by selecting the pairs with the smallest distance.

The remaining incorrect matches (outliers) can be removed or filtered out during the triangulation using many robust probabilistic methods [4], [7]. Random sampling consensus or RANSAC is one of the most widely used methods. It works by randomly picking a small subset of the seed matches, using that subset to estimate the transformation function, and then using a larger subset to check the transformation function correctness [8].

In SfM, detected features in a sequence of images are required to be accurately matched despite the image transformation (rotation and/or scaling) and illumination changes. The matched features across the sequence of images allow for predicting the camera motion by estimating the calibration matrix as well as the fundamental matrix. Accordingly, the accuracy of these estimations and consequently the 3D reconstruction is directly affected by the

robustness of the feature extraction algorithms and the accuracy of the feature matching algorithms [3]. Once feature correspondences between multiple views (images) are established, corresponding features are grouped into feature tracks. Corresponding features in each track are triangulated into a single 3D point. A sparse 3D point cloud is the result of triangulating corresponding features in all tracks [9].

More images can be incorporated into the current model using image registration. During image registration, new images are registered to the current model. This can be done by solving the Perspective-n-Point (PnP) problem. Given a set of correspondences between 3D points of an object (the current model) and their respective projections on the camera plane (of the new image), PnP problem can be solved to estimate the relative pose between the object and the camera by minimizing the reprojection error from 3D-2D point correspondences. To improve this incremental SfM pipeline, the reconstructed 3D point cloud is refined using Bundle Adjustment optimization technique resulting in a jointly optimal 3D point cloud [10].

The remaining part of this paper is organized as follows: Section II briefly covers the related work. Section III is a brief review of different feature extraction algorithms implemented for the experiment. Section IV describes the evaluation methodology proposed. Section V discusses the experimental results obtained. Section VI conclusion and future work reported.

II. RELATED WORK

Up to the best of the author's knowledge and as shown in Table. I, published research evaluates feature extraction algorithms (particularly in SfM) in terms of feature extraction time, number of extracted features, descriptor size (storage), number of matched features, point cloud size (density), and reprojection error.

As shown in Table II, each algorithm has one or more parameters that affect its sensitivity in most cases. Using the default values for these parameters results in a quite different average number of extracted features, as shown in Table IV. Therefore, it may be unfair to use the number of extracted features as an evaluation factor of feature extraction algorithms without trying to tune the parameters of each algorithm. In addition, the extraction time depends on the number of extracted features and the descriptor type and size. Therefore, it may be unfair to evaluate feature extraction algorithms in terms of the extraction time without taking the number of extracted features (i.e., by averaging), descriptor type, and descriptor size into consideration. Moreover, there is a trade-off between the point-cloud size and the reprojection error. Therefore, it may be unfair to evaluate feature extraction algorithms in SfM based on the value of point-cloud size only or reprojection error only.

The scope of this paper is fairly evaluating the robustness of the feature extraction algorithms in SfM in terms of point cloud size and reprojection error regardless of the space and time efficiency.

III. FEATURE DETECTORS AND DESCRIPTORS

Table II lists the fourteen feature extraction algorithms that were evaluated in this paper. A feature extraction algorithm can be designed for feature detection only, feature description only, or both feature detection and description. In the last case, feature detectors are combined with their own feature descriptors. In the first two cases, different types of feature descriptors can be paired with different kinds of feature detectors.

Algorithms identified by * in Table II do not have a default feature detector. For such algorithms, FAST (Features from Accelerated Segment Test) feature detection algorithm is combined with them in the experimental work in Section V. FAST algorithm was proposed by Rosten et al. in 2006 for fast feature detection [27], [28]. Therefore, it is considered a viable choice for complementing those algorithms.

Feature descriptors can be categorized into two main categories: namely parameterized descriptors and binary descriptors. Each element in parameterized descriptors is a floating-point number (or any non-binary discretization of a floating-point number). On the other hand, each element in binary descriptors is a binary number (0 or 1). Typically, binary descriptors are derived using pixel-level comparisons that require minimal computational resources and result in a compact representation. Consequently, they became an attractive option for numerous contemporary applications [10]. Out of the fourteen feature extraction algorithms that were evaluated in this paper, only DAISY, KAZE, SIFT, SURF, and VGG are parameterized while the others are binary.

IV. PROPOSED EVALUATION METHODOLOGY

In this section, the proposed methodology for fairly evaluating the robustness of feature extraction algorithms in SfM is presented. The proposed methodology is expressed using Python-like pseudo-code in Fig. 1 and Fig. 2. It is also illustrated by a block diagram in Fig. 3.

```
Algorithm Constrained 3D Reconstruction (I, feat_alg)
Input : sequence of images I
         feature extraction algorithm feat_alg
Output: point cloud pc
F = {}
for i in I:
    f = feat_alg.extract(i)
    F[i] = sorted(f,
       key = lambda item:-item.response
    )[:MAX_FEAT]

M = {}
for i in I:
    for j in I:
        if I == j:
            continue
        m = feat_alg.match(F[i],F[j])
        M[i,j] = sorted(m,
           key = lambda item:item.distance
        )[:MAX_MATCH]
return colmap. mapper(I,M)
```

Fig. 1.   Proposed Algorithm for Constrained 3D Reconstruction.

Constrained 3D Reconstruction algorithm shown in Fig. 1 takes a sequence of images as well as a feature extraction algorithm and returns a point cloud. Constrained 3D reconstruction is required since the quality of the 3D reconstruction depends on not only the robustness of the detected features but also the number of detected features. In order to ensure fairness and due to the difficulty of optimizing the parameters of each algorithm to produce the same number of features, only a fixed number of features detected by each algorithm is passed to the subsequent phase, as illustrated by Constrained Feature Extraction block in Fig. 3. Selection of the detected features can be performed by sorting them in non-increasing order of their respective responses and selecting the features with the highest response. In addition, only a fixed number of corresponding features matched using each algorithm is passed to the subsequent phase, as illustrated by Constrained Feature Matching block in Fig. 3. Selection of the corresponding features can be performed by storing them in

non-decreasing order of matching distance and selecting the correspondences with the smallest matching distance.

Instead of the *ratio test* proposed by Lowe in [23] in the matching phase, brute-force matcher with cross-checking was used to return only consistent pairs of features. A pair of features (i, j) is considered consistent if j is the nearest feature to i and i is the nearest to j in the feature space. The consistent pairs of matching features are then passed to the next phase, where sparse point clouds are reconstructed.

Size-Error Curves Generation algorithm shown in Fig. 2 takes a list of point clouds generated using different feature extraction algorithms for a specific dataset and reconstructs size-error curves. Such curves visualize the average reprojection error of different 3D reconstructions as a function of the point cloud size. Moreover, the use of size-error curves allows employing methods like the elbow method [29] and finding a suitable operating point on ROC curve [30] for carefully selecting and/or pruning a reconstructed point cloud. Size-error curves are generated by first creating a list of sample sizes. The points in each point cloud are sorted in non-decreasing order of their respective reprojection error and then sampled using every sample size. The size-error curve can be visualized by plotting the average reprojection error of the points in each sample against the sample size.

```
Algorithm Size-Error Curves Generation (PC)

Input : list of point clouds PC,
         each point cloud is composed of a list of
         3D points (x, y, z, e)
Output: list of dictionaries D,
         each dictionary is a map from point cloud
         size to average reprojection error
K = []
for pc in PC:
    K.append(len(pc))
K = sorted(K)

D = []
for pc in PC:
    d = {}
    e = sorted(pc.e)
    for k in K:
        if k > len(pc):
            break
        d[k] = sum(e[:k])/k
    D.append(d)

return D
```

V. EXPERIMENTAL RESULTS

A. Datasets

To evaluate the robustness of feature extraction algorithms, a well-known and publicly available collection of datasets was used as a benchmark. The collection contains six different datasets of outdoor scenes of different architectural objects. All images were captured at 3072×2028 resolution and have been corrected for radial distortion. Each dataset name, number of images, and sample image are shown in Table III. More information about the dataset can be found in [31], [32].

TABLE III.   THE SIX DATASETS USED IN THIS RESEARCH

Sample						
Size	19	30	10	11	8	25

B. Setup

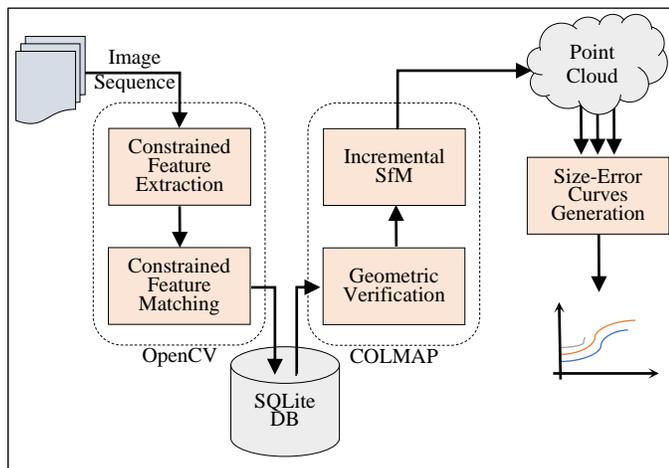
An experiment was performed on a virtual machine with a 2 x Core Intel(R) Xeon(R) CPU @ 2.20 GHz and 13.00 GB of RAM provided by Google Collaborate Pro to evaluate the robustness of different feature extraction algorithms. OpenCV 4.6.0 was built with OPENCV_ENABLE_NONFREE as well as OPENCV_EXTRA_MODULES_PATH, while COLMAP 3.8 was built with the default configuration.


Fig. 3.   Proposed Methodology for Fair Evaluation.

Feature detection and extraction subroutines contained within OpenCV library framework [33] were used with their default parameters provided by the library for Python. When a required parameter does not have a default value, the value recommended by the algorithm author(s) is used. Each detector is only combined with its own descriptor in this experiment, and detectors with no descriptor are combined with FAST due to its speed and availability in a real-time environment. OpenCV BFMatcher was used along with crossCheck flag and the default norm of each feature extraction algorithm for feature correspondence. COLMAP SfM pipeline [34], [35] was used on the CPU for spare 3D reconstruction. The complete pipeline is illustrated by Fig. 3.

Only the best 2000 detected features are passed to the next phase. In addition, only the best 500 corresponding matches are passed to the next phase. The two numbers were chosen empirically to suit almost all the feature extraction algorithms.

In order to connect OpenCV to COLMAP, an SQLite database is used for storing the following:

- Camera parameters.
- Images filenames.
- Coordinates of each extracted feature for each image.
- Indexes of each pair of corresponding features.

In order to reconstruct the corresponding sparse point clouds, a total of 14 x 6 SQLite databases were created and passed to COLAMP as command-line parameters.

C. Results and Discussion

During this experiment, 84 different point clouds were created. As shown in Section II, the projection error is the most common and obvious way to measure how good a point cloud is. V and the radar chart in Fig. 4 illustrate the reprojection error of each point cloud. By comparing the reprojection error resulting from different feature extraction algorithms on each dataset, the feature extraction algorithm with the smallest reprojection error can be considered the winner. Based on the result of this experiment, it is clear that FREAK resulted in the smallest reprojection error on most datasets (four out of six) and on average. Therefore, it can be considered the winner. However, the quality of the resulting point cloud is defined not only by the reprojection error but also by the point cloud size (density).

According to the results shown in VI and illustrated by the radar chart in Fig. 5, it is clear that the density of the point clouds generated using FREAK feature extraction algorithm is disappointing. It is almost the smallest for most of the datasets. This means that FREAK's low reprojection error comes at a cost (the sparsity of the point cloud).

Obviously, neither Fig. 4 nor Fig. 5 (alone or side-by-side) provide an accurate measure or visualization of the relative performance of different feature extraction algorithms in SfM. This raises the need for a measure or visualization that takes care of the quantity-quality trade-off.

On the other hand, using the size-error curves shown in Fig. 6, a true winner can be easily identified by observing the area under the curve (AUC). The feature extraction algorithm corresponding to the smallest AUC and adequate density can be considered a winner regardless of point cloud size and the average reprojection error. For instance, it is clear from Fig. 6 that SIFT is the winner in Herz-Jesus-P8 dataset even though it did not generate the point cloud with the largest size or the smallest average reprojection error.

VI. CONCLUSION AND FUTURE WORK

In this research, fourteen different OpenCV feature extraction algorithms were evaluated in COLMAP SfM pipeline on six public datasets. Based on the experimental results reported in Section V, it can be concluded that the best feature extraction algorithm does not necessarily generate a point cloud with the minimum reprojection error nor the maximum number of points in SfM. So, the size-error curves proposed in this paper should be used for comparing different 3D reconstructions of a given dataset, as they are more transparent than using the value of point cloud size, reprojection error, or both.

The size-error curves demonstrate that SIFT feature extraction algorithm outperforms other algorithms in almost all six datasets. Our future work is to consider combining feature detectors other than FAST with descriptors that do not have a default detector and those that do. By applying the fair evaluation method proposed in this paper to the different combinations, a better combination of feature detector and feature descriptor for SfM may be found.

Abstract—**Indian poultry industry has evolved from a simple backyard occupation to a large commercial agri-based enterprise. Chicken dominates poultry production in India, accounting for almost 95% of total egg production. Several factors affect the egg production such as feeding material, drinking water, environmental factors etc. Analyzing the water quality is one of the important tasks. Cauvery River is considered as the study area because of its importance in several states of South India which have significant contribution in poultry farming. The aim of the proposed study is to develop an automated approach of water quality analysis and present a novel machine learning approach which considers an improved feature ranking method and ensemble tree classifier with majority voting. The experimental result shows that proposed approach performs better with an accuracy of 95.12%.**

Keywords—Water quality; poultry; machine learning; Cauvery river; feature ranking; ensemble tree classifier; accuracy

I. INTRODUCTION

Agriculture and farming has become the most important source of income and it plays an important role in Indian economy. The livestock with poultry farming is one of the major parts of Indian agricultural population and considered as backbone of the Indian Farmers. According to a study presented by *Statista*, the demand of chicken meat and eggs has increased drastically worldwide [1].

Animal husbandry plays a major role in Indian economy under which taming birds such as chicken ducks, turkeys for production of various goods such as egg, meat, feathers, is called poultry farming. It has evolved from a backyard hobby to a full-fledged technological-commercial industry [2]. Chicken farming is prevalent in places like as Andhra Pradesh, Tamil Nadu, West Bengal, Maharashtra, Orissa, Bihar, Kerala, and Karnataka, among others [3].

The recent 20th Livestock Census has reported that total numbers of 851.8 million poultry birds are present in India and 30% (250 million) of this population is covered by backyard, small or marginal farmers [4].

Below given Table I present the data of 20th Livestock census which shows the livestock population and egg production in South India [4].

There is a significant variation in poultry industry in different regions of India. The South Indian states like – Karnataka, Tamil Nadu, Kerala and Andhra Pradesh produce for about 45 percent of the country's egg production, with a per capita consumption of 57 eggs and 0.5 kg of broiler meat [5].

Based on the above facts and data, we can say that the poultry is considered as the expediting segment of the agricultural sector. Moreover, current technological advancements, up gradations have paved the way for multi-fold growth in the poultry and its allied sectors. This growth has led to high yielding layers, broilers, with the help of appropriate nutrition, and management, the egg and meat production also have grown during last decades.

On the other hand, poultry industry suffers from various challenges which degrade the production of eggs. Some of the challenges are feeding material, raw materials, disease outbreak, water quality, and temperature etc. Water plays an important role in this context of poultry rearing and management. For chickens, water is one of the most vital nutrients for the following reasons:

- To maintain maximum egg production and egg shell quality, and to achieve good body weight and growth, good quality of water is needed.

- To properly manage bodily functions water is essential.

Some of the water related factors which affect the performance of poultry are as follows:

- Water source: The water source is an important parameter to be considered because the acidity or alkalinity of water depends on the depth of well from where water is extracted. Water found at 30-meter depth is generally acidic in nature whereas water level of more than 100 meters is more alkaline nature [6].

TABLE I. LIVESTOCK POPULATION EGG PRODUCTION IN INDIA [4]

State	Livestock population (million)	Year (2019-2020)
Karnataka	59m	66511 lakh
Tamil Nadu	120m	200216 lakh
Kerala	29m	21845 lakh

Consumption of acidic water is prone to parasitic infestation whereas consumption of alkaline water leads to deficiency of required minerals such as calcium, phosphorus, magnesium and potassium.

- Watering system: The water consumption through the trough based system is greater when compared with the nipple system. Layers which are using the nipple drinker system have reflected in feed conversion, less mortality when compared with channel based watering systems. Table II shows the comparison of nipple and trough watering system. Moreover, the nipple based drinker system are enclosed and more sanitary can be ensured by disinfecting and cleaning the system which prevents the disease problems [7].

TABLE II.   COMPARATIVE PERFORMANCE OF BROILER REARED ON NIPPLE OR TROUGH WATERING SYSTEM [7]

	Trough	Nipple
Water consumption	166	245
Food conversion	1.91	1.92
Bodyweight (kg)	1.95	1.96
Mortality in first 14 days (%)	1.20	1.30
Condemnations (%)	1.17	1.40

- Water temperature: For four weeks, researchers tested the effects of cold water (8°C) and regular water (29.5°C) on the production characteristics of chickens. The effects of heat stress were eased by using cold water, and the birds were able to acquire more weight and had improved feed efficiency as a result. When given cold water, birds were more sensitive to vitamin C supplementation (500mg/liter of water), resulting in enhanced survival and carcass quality, with a focus on breast meat output [8].

When exposed to different environmental temperatures the consumption of water and feed intake varies as shown in the following Table III.

TABLE III.   CONSUMPTION OF WATER AND FEED INTAKE AT DIFFERENT TEMPERATURES [9]

Characteristics	Temperature		
	18°C	29°C	35°C
Age (days)	245	200	180
Feed (lbs/hen/day) (g)	0.23	0.19	0.14
Water(gal/100hens/day)	5.5	5.8	7.9
Water to Feed Ratio	2.03	2.60	4.67

For the adequate performance of laying hens and other poultry, good quality of water is essential. The foreign substances present in water may affect its' drinkability and well-being of the hens. Drinking water composition will differ in various regions across the country. Water may get polluted from the practices that occur naturally or from run-off sources. Water quality standards include many factors that affect the quality of water used in the poultry. These factors include items like pH, bacterial load, color, hardness, total solids, and dissolved oxygen, biochemical oxygen on demand, conductivity, water temperature and mineral content [9].

Water quality plays important role in the poultry farming. The source of water should be good in poultry farms otherwise it may lead to water borne diseases which affect the egg quality and egg production. To characterize water quality several parameters are used. Below given Table IV illustrates the standard water parameters for poultry farming.

The manual inspection of water sample is not feasible solution due to continuous variations in several quality parameters. Our paper aims to analyze and predict quality of water based on water quality index computation and machine learning algorithms. However, the performance of machine learning techniques depends on the nature of attribute, dimensionality of attribute and classifier model. Thus, the main objectives of the proposed work are as follows:

- To use the weighted arithmetic model for dataset generation.

- To present the feature ranking and selection model.

- To present the tree based ensemble classifier to improve the prediction accuracy.

Rest of the paper is organized as follows: Section II presents the brief literature review about the recent existing techniques of water quality prediction, Section III provides the proposed solution for WQI prediction by using machine learning, Section IV presents results and the comparative analysis of proposed approach and finally, Section V describes the concluding remarks of the proposed approach.

II.   LITERATURE SURVEY

This section presents the brief literature review about existing schemes of water quality prediction based on chemical parameters. The previous section has described the advantages, growth of poultry farming in India. However, the review study briefs about various challenges faced in poultry farming such as manoeuvrability in broiler prices, availability of trained workers, shortage of raw material and many more. However, water quality has a significant impact on the egg and meat production.

Pujar et al. [10] presented a study for Krishna river water quality analysis by using an IoT system. The IoT system was utilized to gather data for several water quality indicators such as pH, turbidity, DO, BOD, NO3, temperature, and conductivity from selected stations, resulting in a data collection that was used to monitor water quality. Using one-way ANOVA, the acquired data was effectively used to analyze the quality of water of Krishna River. One-way ANOVA is used to analyze a specific parameter and predicts the quality of water based on the value obtained.

The study of two parameters as a separate entity as well as a combination of two parameters was done using two-way ANOVA [10].

Nayak et al. [11] developed a fuzzy logic based model by using triangular and trapezoidal membership function. This model used centroid, bisector and mean of maxima (MOM) methods for defuzzification.

TABLE IV. WATER QUALITY STANDARDS FOR PROPOSED STUDY

Parameter	Average level	Maximum Acceptable Level	Remarks
pH	6.8-7.5	8	pH of less than 6.0 is not desirable. Levels below 6.3 may degrade performance
Total Coliforms(TC)	0CFU/ml	0CFU/ml	Presences of Coliforms affect growth of poults.
Dissolved Oxygen(DO)	4.0-6.0mg/L	6mg/l	Affects growth and performance of chickens.
Biochemical Oxygen Demand(BOD)	1.0-5.0mg/L	5.0mg/L	Affects growth and performance of chickens.
Temperature(Temp)	25°C	-	Affects feed conversion ratio and growth
Conductivity(CND)	300μS	-	Performance of chickens get reduced

Khullar et al. [12] focused on anticipating the water quality of the Yamuna River in India by using a deep learning based Bi-LSTM model. Generally, the existing schemes do not focus on missing value an imputation which degrades the reliability of the system. To overcome these issues, author demonstrated novel scheme that includes missing value imputation in the first phase, feature maps generated from the given input data in the second phase, Bi-LSTM architecture in the third phase to improve the learning process, and finally, an optimised loss function to reduce the training error in the fourth phase.

Kim et al. [13] developed a water forecasting method to improve the water quality analysis. The first phase is developed by using ensemble of empirical mode decomposition with Bidirectional LSTM model. Once the predictions are obtained, a novel error correction module is incorporated which uses variation mode decomposition and BLSTM neural network. Thus, this combination helps to achieve the less accuracy during forecasting.

Prasad et al. [14] reported that handling the complexity of existing schemes is cumbersome process. Thus, authors developed artificial intelligence based machine learning approach.

Choi et al. [15] adopted three standalone and a hybrid deep learning scheme for water quality analysis based on time series analysis. These methods include univariate dataset with single dependent variable, multivariate dataset with single and multiple dependent variables and identifying the other parameters which has impact on the performance.

Dimri et al. [16] presented water quality analysis for Ganga River by using multivariate statistical techniques such as Pearson correlation, principal component analysis and cluster analysis.

Several works have considered underground water for water quality analysis and presented machine learning based techniques such as Panneerselvam et al. [17] identified that the rock-water interaction and ion exchange are also considered as important factors which affect the water quality. To identify their impact authors developed a Hierarchical Cluster Analysis (HCA) and K-mean cluster analysis based approach.

Vijay et al. [18] presented artificial neural network based approach for water quality prediction. The preliminary steps include pre-processing, and feature extraction. The ANN classifier uses three different activation functions such as Tanh, rectifier, and Maxout to process these features.

Wang et al. [19] used an AI-based LSTM (long short-term memory network) to identify water pollutant features as well as identifying the industrial pollution source. In line to this, a correlation based map is used to extract the relation among attributes. The correlation map is used to trace the fluctuations and identify the location and causing agents.

In our previous work [20], experimental study was conducted to test the water quality of different sources used in poultry farms using sensors and laboratory methods.

III. PROPOSED MODEL

According to literature survey, several water quality parameters are analysed to characterise the water quality. In this work also, we consider various parameters as in Table to predict the water quality whether it is drinkable or not and to provide the recommendation for poultry farm. In order to perform this task, we have collected the samples of Cauvery River.

A. Study Area: Cauvery River

In proposed study, we considered the Cauvery River which is a great river of India flowing in Southern region is considered as Dakshin Ganga. The origin point of this river is Talakaveri which is in the Coorg district of Karnataka. The catchment area of this river includes Karnataka, Tamil Nadu, Pondicherry, and Kerala before merging in Bay of Bengal. These southern states have agriculture as its main occupation. These states have significant livestock population where poultry farming is also considered as an important segment and share 50% of total production value. In this regard, it is important to consider the quality of Cauvery River water flowing in these regions as it is primary source of water. The water quality can have impact on the egg yield and meat production thus analyzing water quality is most important task.

The Fig.1 shows the Cauvery River basin and its tributaries flowing from Karnataka to Tamil Nadu.

We have obtained the data from various locations [21] and these samples are processed through the water quality analyser where indicator parameters are extracted.

B. Architecture Diagram for the Proposed Model

The proposed model architecture is shown in Fig. 2 and each component is explained:

1) Feature ranking method: In this work, we adopt the Relief algorithm based feature selection method to identify the relevance of features. This approach computes the proxy statistics known as feature weights $W[A]$ for each feature to identify its relevance which is ranging from -1 to +1 i.e. worst to best. Generally, the feature relevance is assigned based on the difference of probabilities. The pseudo code of complete process of this method is presented Algorithm 1. This approach estimates the nearest instance of the target where one is with same class is known as nearest hit H and the opposite class is nearest miss M. In algorithm 1 Step 9 updates the weights of feature.

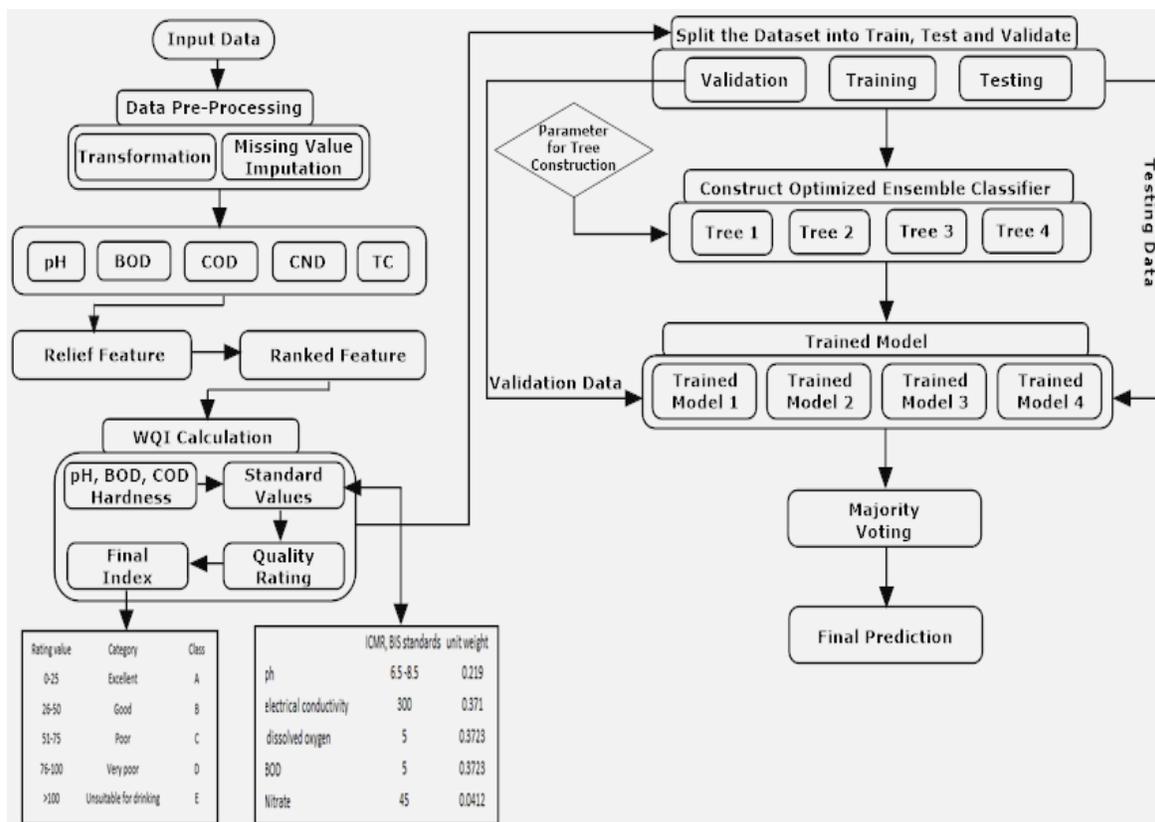
Fig. 1. Cauvery River Basin.


Fig. 2. Architecture of the Proposed Model.

Algorithm 1:Relief Algorithm

Step 1: Input: each training instance with feature values and corresponding class values.

Step 2: $n \leftarrow$ number of training instances

Step 3: $a \leftarrow$ number of attributes

Step 4: Output: m $\leftarrow$ pick random training from n and update the weights W

Step 5: for $i \coloneqq 1$ to m do

Step 6 : initialize the selection of random 'target' from R_i

Step 7: identify the nearest hit and miss as H and M

Step 8: For $A \coloneqq 1$ to a do

Step9: $W[A] = W[A] - diff\ (A, R_iH)/m + diff\ (A, R_iM)/m$

Step 10: End for

Step 11: End for

Step 12: Return updated weights to identify the quality of attributes

To perform weight updates, calculate the difference in value for feature A between two instances I_1 and I_2, where $I_1 = R_i$ and I_2 is either H or M, the diff function in Algorithm 2 is computed as:

$$diff(A, I_1, I_2) = \begin{cases} 0, if\ value\ (A, I_1) = value\ (A, I_2) \\ 1\ if\ otherwise \end{cases} \quad (1)$$

In order to further, improve the weight update process, we define a Bayes rule based on the conditional probability of prediction differences and probability of different class. The Bayes rule can be expressed as:

$$W[F] = \frac{P_{diffC|diffF}P_{diffF}}{P_{diffC}} - \frac{(1 - P_{diffC|diffF})P_{diffF}}{1 - P_{diffC}} \quad (2)$$

In order to calculate the difference between feature spaces, we used a weighted Euclidean distance measure which is calculated as:

$$diff(S_i, S_j) = \sqrt{\sum_k w(c_k)(L_{i,k} - L_{j,k})^2} \quad (3)$$

Where S_i and S_j represents the target description for random instance R_i and target instance I_j, respectively. $L_{i,j}$ and $L_{j,k}$ denotes their corresponding binary representation. The updated algorithm of k feature ranking and selection is given in Algorithm 2. Initialize random instance R_i and find the k nearest instances I_j. Using these instances, approximate the relevance $W[F]$ from Equation 2 for each feature by calculating $N_{diff\ C}$, $N_{diff\ F}[F]$ and $N_{diffC\ \&\ diffF}[F]$ described in lines 6, 8 and 9 of Algorithm 2. The values of these estimations are based on the calculation of distance in the feature space, $diff(F, R_i, I_j)$ as specified in lines 8 and 9 of Algorithm 2.

Algorithm 2: Pseudo code for Feature ranking and selection

Input: training instances and corresponding class values
Output: weight vector W to estimate relevance of features.

Step 1: initialize $N_{diff\ C}$, $N_{diff\ F}$, $W[F]$ to 0

Step 2: for $i = 1\ to\ m$ do

Step 3: initialize with randomly selected instances R_i

Step 4: select k instances from I_j as nearest instances to R_i

Step 5: for j=1 to m do

Step 6: $N_{diffc} = N_{diffc} + diff(S_i, S_j).d(i,j)$

Step 7: for $F = 1\ to\ f$ do

Step 8: $d_{diffF}[F] = N_{diffF}[F] + diff\ (S_i, S_j).d(i,j)$

Step9: $N_{diffC\ \&\ diffF}[F] = N_{diffC\ \&\ diffF}[F] + diff(S_i, S_j).diff(F, R_i, I_j).d(i,j)$

Step 10: end for

Step 11: end for

Step 12: end for

Step 13: for $F = 1$ to f do

Step14: $W[F] = N_{diffc}|diffF\ [F]/N_{diffc} - (N_{diffF}[F] - N_{diffc|diffF}[F])/(m - N_{diffc})$

Step 15: end for

2) Water quality index calculation: In this section, we consider the water quality parameters such as conductivity, hardness, nitrates, BOD, pH, and dissolved oxygen and presented a method to obtain the water quality index which can be used to classify the potability of water. In this work, we have used weighted arithmetic method to compute WQI which is expressed as:

$$WQI = \frac{\sum Q_n W_n}{\sum W_n}$$

□□□

Where, Q_n is the quality rating and W_n is the weight for each quality parameter. The quality rating can be calculated based on the observed value and ideal values. It can be computed as follows:

$$Q_n = 100 \left[\frac{V_n - V_0}{S_n - V_0}\right] \quad (5)$$

Where V_n is the observed value, V_0 is the ideal value (V_0 value is 7 for pH and 14.6 for DO and 0 for others). Similarly, W_n is the unit weight vector which is computed as:

$$W_n = \frac{1}{S_n} \quad (6)$$

Where S_n is the recommended value such as WHO temperature standard value is 28, then $W_n = \frac{1}{28} = 0.036$, DO recommended value is 6 then $W_n = \frac{1}{6} = 0.166$.

By substituting the values of (5) and (6) in (4), we obtain the WQI parameter and based on this value the water grading can be presented. Below given Table V shows the quality index parameters.

TABLE V. WQI WATER QUALITY GRADING

WQI Value	Comment	Grading	Labels
0-25	Excellent	A	1
26-50	Good	B	2
51-75	Poor	C	3
76-100	Very Poor	D	4
Above 100	Unsuitable	E	5

A sample dataset used for training the network is obtained as presented in Table VI which considers pH, DO(Dissolved oxygen), TC(total colifroms), BOD(biochemical oxygen demand), CND(conductivity) and temperature to measure the WQI value.

TABLE VI. WATER QUALITY PARAMETERS

pH	DO	TC	BOD	CND	Temp	WQI
7.4	10.2	6800	1	445	24.5	1
8.2	8.4	110000	2	514	25	2
8.3	9.1	1300	1	449	26	1
7.8	13.1	1100	6	374	27.5	2
8.3	7.7	7800	4	730	27.5	2
8.3	7.7	7800	4	730	28	2
7.3	6.1	9200	2	236	27	1
7.3	6.1	9200	2	236	26	1
7.8	6.4	17000	1	300	27	2
7.7	7.4	3300	1	401	26.5	1
8.5	9.5	1700	2	460	27	1
7.7	11.5	3300	4	710	27.5	1

3) Classifier model: In this work, we present an ensemble classifier where multiple instances of random forest model are constructed which produces the preliminary classification results. Later, these predicted outcomes are processed through the majority voting where final prediction is computed. Fig. 3 depicts the ensemble of tree classifier.

The Random Forest is a promising technique which is a collective learning method used for classification, regression, and other machine learning tasks. It imitates with cluster formation of decision trees and generates a class as mean of individual tree. This approach follows specific these steps which are mentioned below:

- First stage: Random Forest Tree construction.

In order to construct the tree, this approach performs four operations as:

- Selection of k random features from the m set of features.
- Determining d as the best point for split

- These nodes are further distributed as daughter nodes
- This process is repeated until l numbers of nodes are obtained via tree construction.
- Second stage: Classification

In next stage, the constructed trees are considered as inputs and classification is performed by following the steps mentioned below:

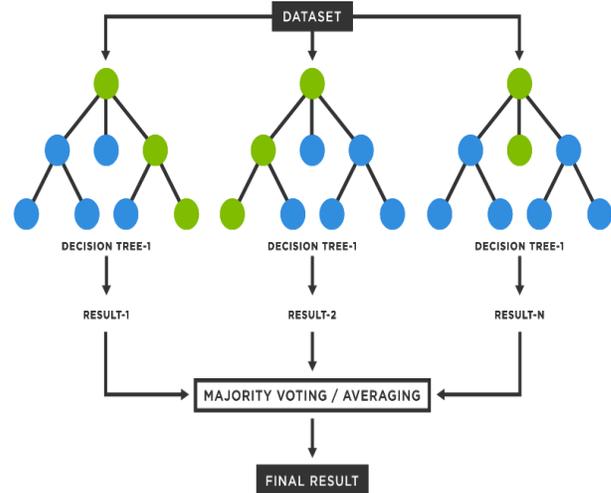
- Rules are assigned for each tree and a decision tree is formulated based on test features.
- Votes are calculated according to the target value
- The target which obtains the highest votes is considered as final result.


Fig. 3. Random Forest Tree Ensemble Classifier.

IV. RESULTS AND DISCUSSION

This section presents the complete outcome of proposed approach. The proposed approach uses WQI dataset generation as the first step and later classifiers are trained to obtain the predication performance. In this work, we have considered pH, electrical conductivity, dissolved oxygen, BOD, and nitrate. For these parameters, ICMR has given some standard values for identifying the water quality. These standard values are presented in Table VII.

Based on these standards, we compute the water quality parameters. Samples of generated and their calculation example for WQI data is presented in below given Table VIII.

TABLE VII. STANDARDS OF ICMR FOR WATER QUALITY ANALYSIS

	ICMR, BIS standards	unit weight
pH	6.5 -8.5	0.219
electrical conductivity	300	0.371
dissolved oxygen	5	0.3723
BOD	5	0.3723
Nitrate	45	0.0412

TABLE VIII.   WQI DATASET GENERATION

Parameter Name	Standard value	Observed value	Unit Weight	Quality rating	$W_i Q_i$
pH	6.5-8.5	7.7	0.2190	46.67	10.22
Conductivity	250 $\mu S/cm$	$96.3 \mu S/cm$	0.3710	38.52	14.29
Dissolved oxygen	$500 mg/L$	$3.2 mg/L$	0.3723	118.75	44.21
BOD	$5 mg/L$	$1.1 mg/L$	0.3723	22	8.19
Nitrate	$1.70 mg/L$	$1.7 mg/L$	0.0412	3.40	0.14
Temperature	28	27.04	0.036	96.57	3.476
			1.4118		80.52

Based on these values, we compute the WQI parameter as:

$$WQI = \frac{80.52}{1.4118} = 57.033$$

Similarly, complete dataset is generated and trained.

1) Performance measurement: The classification performance is measured using performance metrics such as accuracy, specificity, sensitivity, precision, recall and F-score. These values can be computed with the help of confusion matrix which is given in Fig. 4.

Accuracy is defined as a rate of correct classification and it is denoted by Accuracy. It is calculated by taking the ratio of correct prediction and total number of prediction [22]. It can be expressed as:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \qquad (7)$$

Sensitivity is another parameter used to do the sensitivity analysis of the model. It is used to measure true positive rate. This can be expressed as:

$$Sensitivity = \frac{TP}{TP+FN} \qquad (8)$$

Fig. 4.   Confusion Matrix.

Then, the proposed approach precision can be computed by taking the ratio of True Positive and (True and False) False positives.

$$P = \frac{TP}{TP+FP} \qquad (9)$$

Similarly, recall is computed based on TP, and FN, as given below:

$$Recall = \frac{TP}{TP+FN} \qquad (10)$$

Finally, F-measure is calculated using the mean of precision and sensitivity performance. It is expressed as:

$$F = \frac{2*P*Sensitivity}{P+Sensitivity} \qquad (11)$$

2) Comparative analysis: This section presents the comparative analysis by considering different classifiers such as K-Nearest Neighbour (KNN), Naïve Bayes, Decision Tree and proposed ensemble approach. First of all, we present an experiment, where feature selection algorithm is not combined with the classification module. The classification performance in terms of percentage is presented in below given Table IX.

TABLE IX.   COMPARATIVE PERFORMANCE WITHOUT FEATURE SELECTION

	KNN	Naïve Bayes	Decision Tree	Ensemble Tree Classifier
Accuracy	92.11	93.51	94.5	95.12
Sensitivity	87.5	91.2	93.56	94.8
Specificity	91.2	93.5	95.2	96.1
Precision	92.2	93.8	95.6	96.5
F-score	93.5	94.25	95.05	97.5

Below given Fig. 5 shows the graphical representation of different classifiers where feature selection approach is not incorporated.

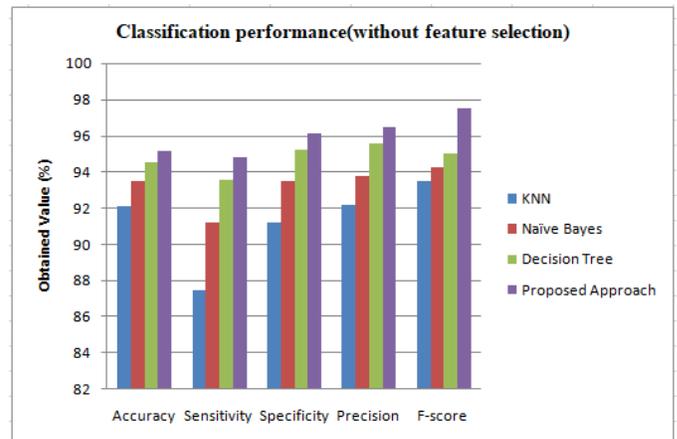
Further, we extend this experiment and incorporated feature selection approach with different classifiers. The obtained performance in terms of percentage is presented in below given Table X.


Fig. 5.   Classifier Performance without Feature Selection.

TABLE X.   COMPARATIVE PERFORMANCE WITH FEATURE SELECTION

	KNN	Naïve Bayes	Decision Tree	Ensemble Tree Classifier
Accuracy	93.52	94.63	95.86	96.55
Sensitivity	88.12	93.1	94.52	94.8
Specificity	92.5	94.5	96.12	97.22
Precision	93.42	94.68	97.1	97.3
F-score	94.6	95.2	96.3	98.21

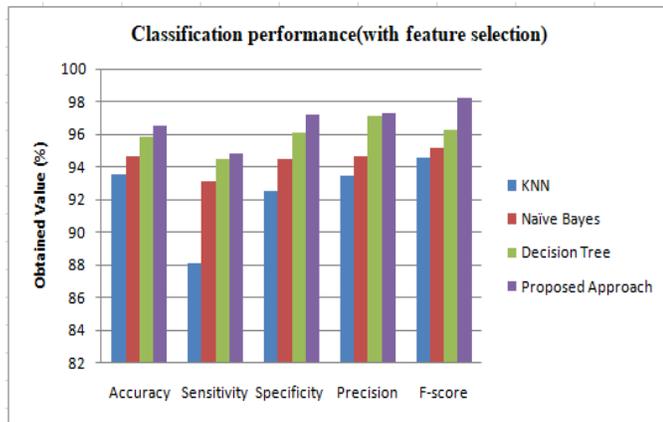
Similarly, the overall performance with feature selection strategy is depicted in Fig. 6.


Fig. 6.   Classifier Performance with Feature Selection.

These analysis results shows that the proposed feature selection and classification approach improve the classification accuracy when compared with the conventional methods.

This model can be used by the poultry farmers to analyze the quality of water used in the farms in order to reduce the effect of water borne diseases which lead to decrease in egg quality and egg production in layer poultry farms.

V. CONCLUSION

In our work, the suitability of Cauvery River water for layer poultry farm is carried out. Several methods are present for predicting the water quality analysis but accuracy and reliability become a challenging task.

The proposed machine learning model introduces a feature ranking model along with the ensemble tree based classifier for water quality analysis and prediction. The comparative analysis shows the significant improvement in prediction performance when compared with the conventional machine learning algorithms. This automated approach can be used by the poultry farmers to analyze and predict the potability of water used in the farms.

Detection of Abnormal Human Behavior in Video Images based on a Hybrid Approach

BAI Ya-meng*, WANG Yang, WU Shen-shen

School of Information Engineering, Jiaozuo University, Jiaozuo 412000, China

Abstract—The analysis of human movement has attracted the attention of many scholars of various disciplines today. The purpose of such systems is to perceive human behavior from a sequence of video images. They monitor the population to find common properties among pedestrians on the scene. In video surveillance, the main purpose of detecting specific or malicious events is to help security personnel. Different methods have been used to detect human behavior from images. This paper has used an efficient computational algorithm for detecting anomalies in video images based on the combined approach of the differential evolution algorithm and cellular neural network. In this method, the input image's gray-level image is first generated. Because it may be possible to identify several large areas in the image after the threshold, the largest white area is selected as the target area. The images are then used to remove noise, smooth the image, and fade the morphology. The results showed that the proposed method has higher speed and accuracy than other methods. The advantage of the algorithm is that it has a runtime of three seconds on a home computer, and the average sensitivity criterion is 98.6% (97.2%).

Keywords—*Cellular neural network; detection of abnormalities; differential evolution algorithm; video images*

I. INTRODUCTION

The analysis and investigation of human movements have attracted the attention of many researchers in different fields. Such systems aim to understand human behavior from a sequence of video images [1, 2]. Security cameras are installed in many organizations that are important for security and can monitor and record the situation of a place at all times. Human behavior detection systems are also one of the most important needs of surveillance systems in the sequence of video images captured by surveillance cameras [3, 4, 5]. Usually, all automatic detection or monitoring systems limit the detection mechanisms of the desired objects in the field of view to the tracking and activities of objects in the same image areas. Crowd monitoring is used to identify general characteristics among passers-by in a scene [6, 7, 8, 9]. These properties include population size, density, growth rate, traffic patterns, and the detection of abnormal events. In video surveillance, the main goal is to detect specific or abnormal events to help security personnel. Surveillance systems in use today rely on the performance of a human operator. They are expected to view many screens recorded by different cameras, often simultaneously. Generally, classification is one of the most important and difficult steps in image processing [10, 11]. Various methods have been used to recognize human behavior from images, but some of these methods do not show optimal performance in some situations, and in some cases,

the methods used are either not able to detect people under certain conditions or do not have high accuracy [12, 13, 14, 15, 16]. Another problem with several methods is that they require a powerful processing unit to achieve the desired detection speed. Among the significant problems, when there is a need to model busy and complex scenes due to occlusion, the use of background reduction to classify motion areas and the trajectory method for feature extraction fail [17, 18, 19]. Some of these problems can be seen in Fig. 1. As seen in Fig. 1, people have much variety in the shape and color of their clothes. Also, different lighting conditions can be seen in the images. There is also a partial or total overlap of the person's image with other objects and people [20, 21, 22, 23]. The superiority of cellular neural networks in low-level image processing over common digital image processing systems is due to two features of this network. These features include parallel processing of the analog image signal and cross-sectional or local connections among network cells, making it easy to build cellular neural networks. In this research, abnormalities will be detected from video images. For this, the cellular neural network method will be used. Since this network needs optimized parameters, the differential evolution algorithm will be used to optimize the features for training. This algorithm is similar to the genetic algorithm, except that changes have been made in the operations of mutation and combination. The differential evolution algorithm will use the training data set to calculate the fitness function for the produced chromosome. Based on this, the template generated by the differential evolution algorithm is coded. Then, one of the two main images from the database is randomly selected. After producing a suitable template for the cellular neural network, all the images in the database will be given to the network for segmentation. Recognizing moving objects and people in the dark or in environments with insufficient light is one of the limitations of this research.

A. Motivation and Contributions

Detecting and tracking moving people (such as the abnormality of a person in several consecutive images of a scene) has many challenges, including the great variety of people in terms of shape, color, and clothing. It is also possible that, according to the angle of placement of people in front of the camera, the person's appearance may change, or a person may overlap with another person or other objects in the scene. For this reason, it isn't easy to detect and recognize people in crowded environments. Therefore, local motion information should be extracted at the pixel level using spatial and temporal detectors and the optical flow characteristics of shape, color, and clothing to extract features in such scenes. It

is also possible that, according to the angle of placement of people in front of the camera, the person's appearance may change, or a person may overlap with another person or other objects in the scene.

For this reason, it isn't easy to detect and recognize people in crowded environments. Therefore, local motion information should be extracted at the pixel level using spatial and temporal detectors and optical flow characteristics to extract features in such scenes. It will be possible to view the video image. The contributions of the authors in the article are as follows:

- Using a cellular neural network and a differential evolution algorithm to improve the accuracy of finding things that aren't normal.

- Increasing classification sensitivity in abnormality detection based on video images.

The continuation of the paper is configured as follows: The second section discusses previous work in detecting abnormal human behavior in video images. In the third part, the proposed method is given in detail. In the fourth part, the results of the proposed method are compared with similar methods. Finally, general conclusions and suggestions for future work are stated in the fifth part.

Fig. 1.   Complications in Identifying People [1].

II.   RELATED WORKS

This section introduces some methods to detect human behavior abnormalities in video images. It is presented a method for detecting local and series anomalies in crowded scenes using k=24 bucket representation with sparse (MHOF). In this method, the multi-comparison histogram of the optical flow on three scales is used to accurately store the movement direction information and the movement energy information to express the characteristics [24]. Another support vector regression machine (SVR) method has been used for pedestrian detection. In this paper, to extract the feature, the features of the Harr wavelet and directional histogram have been used, and in the classification section, in addition to using SVR, the classifier K-nearest neighbor (KNN) has also been used. The results of the experiments have shown the high accuracy of the algorithm presented in this paper [25]. Researchers used fuzzy logic to detect anomalies in human behavior. In this paper, to determine which rules are suitable, the effectiveness of each rule was evaluated based on the speed and environmental conditions of the pedestrian. This method is very time-consuming due to the type of search that requires the search window to be moved pixel-by-pixel in both horizontal and vertical directions and is not suitable for real-time or live applications [26]. Also, researchers have used graph formulation to diagnose human behavioral abnormalities. In this method, a model of the appearance and dynamics of the scene is created, and the features of the pixel level are used. Each designated location defines the center of the video cell, from which the edges and vertices of the graph are extracted. A tree is trained during the training phase. The probability of each of the obtained spatio-temporal volumes and the representation of its salient points are generated. An anomaly is where the probability is less than a threshold. The results showed that using graphs provided complete coverage of the problem space. However, it takes a long time to process

and calculate [27]. In this research, optical flow and gradient have been used to detect anomalies. As a result, among these methods, a bag of words is a suitable method for distinguishing abnormal combinations from normal events, especially in complex scenes that include different classes of objects and events. Like anomalies in traffic scenes, a method for rapid anomaly detection for surveillance systems, with real-time capability and reliable detection and localization, is proposed. Each event includes a set of spatio-temporal volumes. This method creates a model of normative behavior by initializing the algorithm with a small number of video sequences, then seeks to detect anomalies and gradually updates the model [28]. Researchers tried to speed up pedestrian detection by using a neural network. In this method, they were recognized based on the rescaling method in deep learning and by sharing features across the model. The results of this method have been better than the normal neural network in terms of processing speed [29]. In order to build an advanced driver assistance system (ADAS), researchers introduced a method based on fuzzy clustering and convolutional neural networks. In this paper, the candidate areas are revealed first. Then a quick method is used to extract the features. In order to extract the candidate areas, the fuzzy clustering method is used. After the features are extracted, to check whether there are pedestrians in those candidate areas or not, neural networks have been used. This type of neural network is made by imposing restrictions on weights and how to connect the neurons of a standard neural network and creates a network suitable for processing data with temporal or spatial distribution [30]. In another study, pedestrians were recognized based on gradient and texture features. This method used principal component analysis (PCA) to reduce the dimensions of textural and rotational features. Experiments on two different data sets showed the better efficiency of this approach compared to similar methods [31]. A robust method for human detection in underground image sequences that

works based on learning systems was presented. An SVM support vector machine classifier is used for detection, so that after the preprocessing process, the patterns of the image in which human presence is likely are extracted and fed into the SVM. The OSU pedestrian database has been used to learn and test the proposed algorithm. The results of the implementation of the presented algorithm on this database show the efficiency and appropriateness of the algorithm [32]. They presented another method to remove the background in the images of the outside environment that does not have a fixed background. There are things like the movement of leaves and moving flags in them. Their main idea is that the pixels of the neighboring blocks, which are assumed to be the background, have similar changes over time and that the same patterns can be extracted from them. Although this argument is correct for the blocks extracted from an object in the background, it does not seem correct for the blocks that fall on the boundary of the objects separately due to different changes on both sides of the boundary. They are used to support pedestrian detection based on underground images. This method was performed on a dataset with 18 images, and the detection accuracy of this method was 98.11% [33]. The study's [34] objective is to train the detector to identify a human action even when only a partial action example is present. To achieve this, a hybrid approach based on the fuzzy Bandler subproduct and the Kohut triangle is proposed in this work that combines the benefits of computer vision and fuzzy set theory. Building a frame-by-frame membership function for each potential motion type is novel. When a predetermined threshold is appropriately reached, detection is started. The benefits and efficacy of the suggested method are demonstrated by experimental results on a dataset that is publicly accessible. Source [35] offers a novel method for identifying and detecting human behavior. This work's major goal is to show how to identify abnormal behavior in a constrained domain. The suggested method automatically detects people in regular films, or video surveillance feeds. When a person is considered in a frame, the action is recognized, and the human position is approximated. After that, the behavior is categorized as normal or abnormal. The models included in the proposed work include SSD MOBILE NET for human action identification and the FAST R-CNN model for human detection in a video frame or image. Everyone needs to feel safe and secure at all times in our century. Many nations have purchased and implemented surveillance systems to secure their environment using high-definition CCTV cameras. As a result, automated CCTV surveillance systems can operate as security providers by spotting suspicious human behavior or intruder activity using CCTV footage. This is a difficult task. Models of suspicious behavior that only partially employ machine learning techniques can be used to do this. It has been discovered that several of the prior methods used techniques from deep learning, machine learning, IoT, and fuzzy logic. The proposed suspicious behavior detection model (SHBDM) efficiently extracts picture features using a CNN model pre-trained on the ImageNet dataset known as Inception V3 (VGG-16). Python was used to create this system using an open-source framework. Compared to VGG-16 + LSTM and a straightforward CNN model, the precision accuracy of the

system using Inception V3 + LSTM was enhanced by 88.8% [36]. Table I is an overview of the detection of abnormal human behavior in video images, whose problems and solutions have been studied in previous works.

TABLE I. OVERVIEW OF DETECTION OF ABNORMAL HUMAN BEHAVIOR IN VIDEO IMAGES

Work	Method	Solution
[37]	large numbers of people who never stop moving. The vertical arms and legs reaching out from the person distort the blobs' alignment.	Extrinsic appearance (geometry) and intrinsic appearance are used to parameterize the current mark
[38]	High volume video data, for example, has intrinsic non-linearity, spatial localization of patterns, and noise, all of which must be dealt with by the complex interplay between Multiobject and the uncontrolled scene.	Demonstrate a subspace detector that learns non-linearly
[39]	Use of Deep Metric Learning to Take Advantage of Label Correlation in a Transferred-Mediface Sample	The current bottom-up method focuses on a person's short-term behavior and trajectory.
[40]	It's challenging to make direct comparisons between motion and appearance representations, which are usually adapted to a certain scene domain.	Show a unified (temporal and spatial) model of form and movement (Mixture of dynamic texture)
[41]	Detection in a crowd scene may be impacted by factors like occlusion and fluctuating lighting.	The foreground was extracted using a double filtering technique, and the noise was diminished using a media filter.
[42]	Crowds make it hard to identify and follow individual people. When faced with unexpected situations, learning, adaptive, and incremental approaches are not effective.	Exhibit a tiered strategy encompassing low, medium, and high
[43]	Due to the intricate temporal dynamics and interactions among the behavior of numerous objects, anomalies tend to be subtle.	Implementing a Staggering Arrangement of Evolving Bayesian Networks
[44]	Analysis of crowd behavior is challenging. Complex behaviors such as line formation, laminar and turbulent flow, arching and clogging at exists, jamming around barriers, and panic have been seen in the movements of crowds.	A grid of particles was placed on top of the image, and the particles were advected using the average space-time optical flow.
[45]	Normal behavior in a video scenario is difficult to predict, necessitating intensive labeling and training. Due to the high number of objects in a crowd scene, it is challenging to precisely monitor individual objects.	Using a patch-based local motion representation, introduce the novel idea of contextual anomaly into crowd analysis.
[46]	In occlusions, the mobility of the people and things in the scene is exceedingly erratic. In a film with that many people, dissecting the behavior of each individual is an arduous process.	Exhibit a 3D Gaussian gradient in space and time that is rich, non-uniform, and localized.

III. SUGGESTED APPROACH

The aim of this research is to increase the accuracy of abnormality detection using a cellular neural network based on video images. Observations show that, when there is a need to model busy and complex scenes, due to the presence of occlusion, the use of background subtraction for zoning motion regions and the trajectory method for feature extraction fail. So, to get features out of these kinds of scenes, local motion information should be extracted at the pixel level with the help of spatial and temporal detectors and optical flow features. The proposed detection system provides an improved method for feature selection using the differential evolution algorithm in the image using a cellular neural network. Fig. 2 shows the block diagram of the proposed approach.

B. Reading the Image

The first step in the proposed approach is to pre-process the video image to obtain the anomaly region. Since the changes in the intensity of the gray levels in the images prevent the accurate detection of the area related to the abnormality, therefore, in the proposed approach, the lighting improvement technique is used to linearly map the intensity values in the image to new values that are normally distributed in the range of 0 to 255. are used. Also, to reduce existing noise and improve the image, a common median filter has been used.

C. Noise Reduction

The histogram is balanced by increasing the intensity values with the highest frequency. This method is useful in images where both background and foreground are dark, or both are light. In particular, this method can lead to better details in images produced under or overexposed to X-rays. In this paper, a median filter is used to reduce its noise. This filter is a non-linear digital image filtering method that considers each pixel and examines its nearest neighbors to determine a median value. Then the value of the pixels is replaced with the determined median value.

D. Increase Contrast

The first step in pre-processing is to use Gaussian function to increase the contrast in the original image. It is used before identifying the edges. Gaussian function in two-dimensional space is shown as Eq. (1) [4].

$$G_\sigma = \frac{1}{\sqrt{2\pi\sigma^2}} e^{\left(-\frac{i^2+j^2}{2\pi\sigma^2}\right)} \quad \text{،} i = 1\text{،}2\text{،}...\text{،}n\text{،} \; j = 1\text{،}2\text{،}...\text{،}m \qquad (1)$$

Gaussian filter plays an important role in many feature extraction methods in such a way that the implementation of its function is equivalent to filtering the image using the Gaussian kernel and non-uniform sampling of the image.

E. Feature Extraction

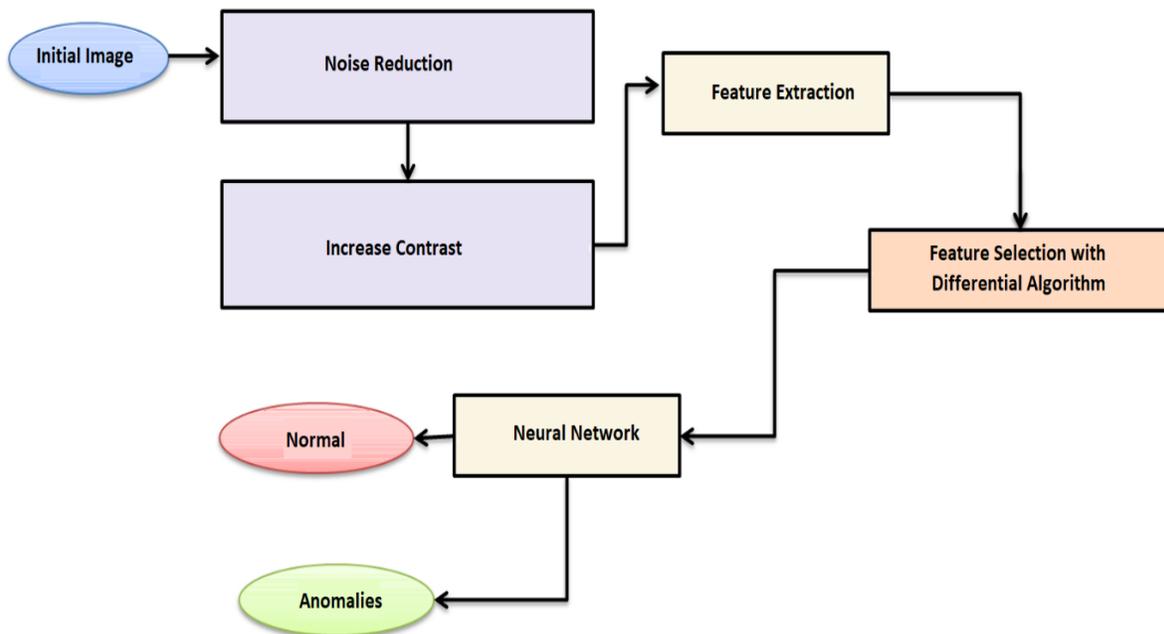
The shape of objects is one of the important features in detecting anomalies in video images. Usually, anomalies with similar shapes belong to several classes. Therefore, in this research, most of the extracted features are related to the shape of the abnormality.


Fig. 2. Steps of the Proposed Method.
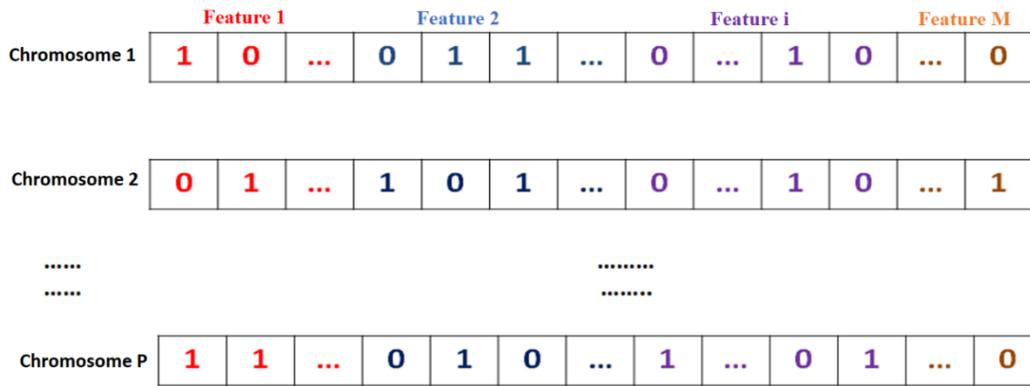

Fig. 3. Structure of Chromosomes in the Proposed Approach.

F. Feature Selection

Feature extraction is a process in which its salient and defining features are determined by performing an operation on the data. Feature extraction aims to make the raw data more usable for further statistical processing, classification, and clustering. Due to high convergence, the differential evolution algorithm was used at this stage to select basic features from among the extracted features. The dimensions of the images are 480 x 640. Due to the high and variable number of features in the images, this step on the image is necessary thing in order to be able to recognize the abnormality from the extracted features. In the differential evolution algorithm, a measure called mutual information according to Eq. (2) is used to evaluate (fitness calculation) of each chromosome produced in the algorithm:

$$MI(x; y) = \sum_{x \in X} \sum_{y \in Y} p(x, y) \log(\frac{p(x,y)}{p(x)p(y)}) \qquad (2)$$

where, generally, p(t) is the probability of variable t.

In order to further investigate and evaluate the performance of the differential evolution algorithm in the feature selection stage, in addition to using the mutual information merit function, the Merit criterion according to Eq. (3) was also used as the merit function in the proposed method (main fitness function).

$$Merit = \frac{k\overline{R_{cf}}}{\sqrt{k+k(k-1)R_{ff}}} \qquad (3)$$

The differential evolution algorithm uses the generated training set to calculate the fitness function for the generated chromosome. Therefore, the evaluation of the chromosome to be in the fitness function includes the following three steps:

- A differential evolution algorithm codes the generated template.

- The selection of one of the two main images was randomly selected from the database and used by the differential evolution algorithm. In the next step, the evaluation begins.

- The output image produced by CNN to evaluate the chromosome fit value.

After generating a suitable template for CNN, all the images in two different databases were given to the CNN algorithm for classification. Also, the structure of chromosomes in the M-dimensional space of features is shown in Fig. 3. The features are coded as chromosomes in Fig. 3 to search in the space of the differential evolution algorithm. A unique code is considered for each feature in all P chromosomes.

G. Neural Network

In this research, the classification and diagnosis of the type of abnormality are based on the cellular neural network. For image processing purposes, the most common architecture is a two-dimensional network in which each processing unit interacts only with the M × N pixel cells that are its neighbors in the cell's permeation domain. Having a cellular network is a set of cells that has the property expressed in relation (4) C_{ij} for the cell $r \geq 0$ with radius $S_{ij}(r)$ neighbors:

$$S_{ij}(r) = \{C_{kl}: max(|k-i|, |l-j|) \leq r ، 1 \leq k \leq M ، 1 \leq l \leq N\} \qquad (4)$$

That the stimulus $u_{ij}(t)$ which is generally not visible, the input $x_{ij}(t)$ using the mode c_{ij} of each cell that shows a measurable and observable value, and the input $y_{ij}(t)$ is external that enters the cell, the output is M × N using the coupled M × N differential equation called bias. The neural network dynamics describe the evolution of each cell's state and its interaction with its neighbors. For image processing purposes, the most common architecture is a two-dimensional network in which each processing unit interacts only with the M × N pixel cells that are its neighbors in the cell's permeation domain. Having a cellular network is a set of cells that has the property expressed in relation (5) C_{ij} for the cell r≥0 with radius $S_{ij}(r)$ neighbors:

$$S_{ij}(r) = \{C_{kl}: max(|k-i|, |l-j|) \leq r , 1 \leq k \leq M , 1 \leq l \leq N\} \qquad (5)$$

The infiltration area with radius r = 1 corresponds to the neighborhood of 3x3, r = 2 to the neighborhood of 5x5 (Fig. 4).

That the stimulus $u_{ij}(t)$ which is generally not observable, the input $x_{ij}(t)$ using 4-time variables of the state c_{ij} of each cell that shows a measurable and observable value, and the

input $y_{ij}(t)$ is external to the cell is input, the output is M × N using the coupled M × N differential equation called bias. The neural network dynamics $z_{ij}(t)$ is described as M × N redundancy, which describes the evolution of the state of each cell and its interaction with its neighbors. It is used to process an image with pixels. In order to classify humans automatically in M × N pixel images, the intensity value of each pixel is given to humans from a cellular neural network containing the suspicious area as the input of the corresponding cell in the cellular neural network. The neural network used in this method is a network with two neural layers and three neural layers, which has the function of activating linear hidden layers and sigmoid output. Table II shows the parameters used for the neural network algorithm.

The neural network used in this research is considered in Fig. 5. For this model, relation (6) holds true:

$$\hat{y}_j(t+1) = \sum_{i=1}^{l} G_i w_{ij} = \sum_{i=1}^{l} w_{ij} \exp\left(-\frac{\|x - m_i\|^2}{2\sigma_i^2}\right) \quad (6)$$

In this regard, $x(t) = [x_1(t) \dots x_m(t)]^T$ indicates the input vector, $\hat{y}_j(t+1)$, indicates the jth output, w_{ij}, indicates the synaptic weight between neurons i-th hidden and j-th output neuron, G_i, the Gaussian function in the i-th neuron of the hidden layer, m_i and σ_i^2 respectively represent the center and width of the Gaussian function and l, the number of the Gaussian function, or in other words, equal to the number of hidden layer nodes.

Fig. 4. Neighborhood of Cell c(i,j) r = 1, r = 2 Respectively.

TABLE II. PARAMETERS USED FOR NEURAL NETWORK ALGORITHM

arrangement	Variable name

IV. EVALUATION AND EFFICIENCY

In this section, the numerical results of the proposed methods are presented in comparison with similar algorithms. This comparison has been made for samples in different conditions and challenges. All the experiments of this research have been done with MATLAB version 2017b software in Windows 10 operating system and on a Dell laptop with a 2-core 2 GHz central processor and 2 GB internal memory.

A. Numerical Results Obtained

This research will analyze and select images from the UCSD Anomaly Detection Dataset database. Also, the presented method will be implemented using MATLAB software, and the results presented in this thesis will be compared with those presented in previous papers. In some cases, where there are both color and abnormal size lesions, thresholding can play an important role because it has a uniform illumination intensity. In contrast, the anomaly does not have uniform illumination dimensions. As a result, thresholding determines the approximate location of the abnormality better. It should be noted that small objects and objects that exist after thresholding can be removed by calculating their area. Fig. 6 shows the implementation of the proposed method on different images from the video.

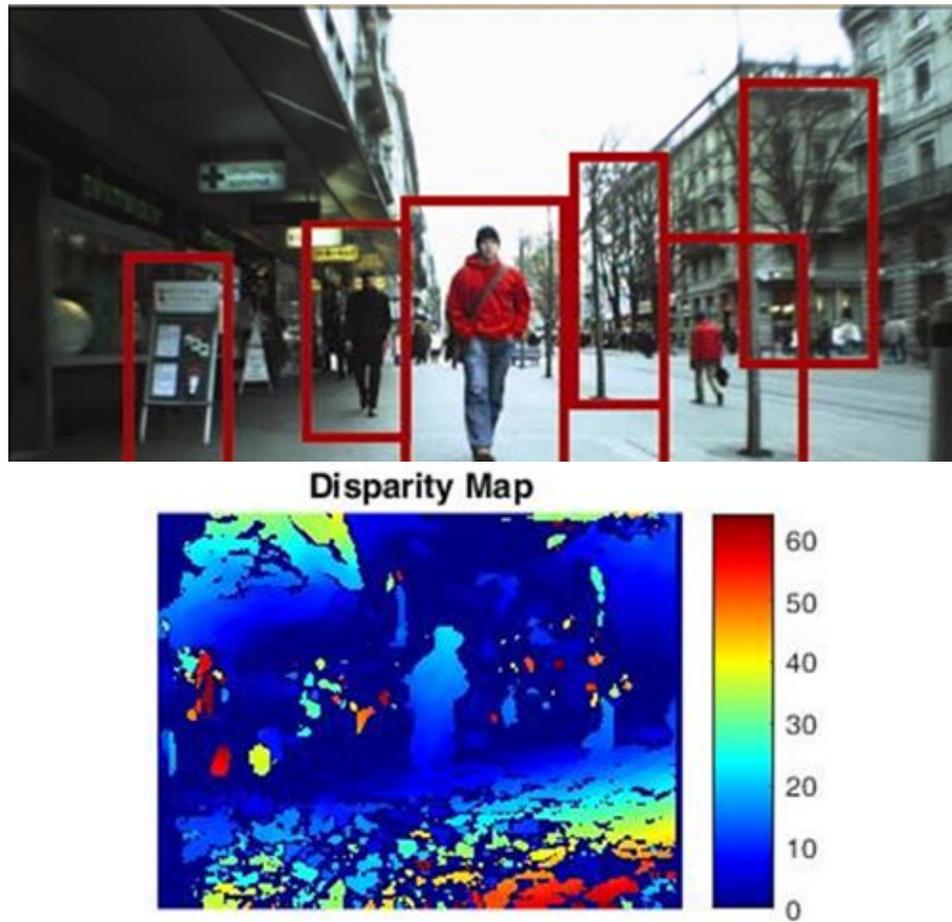
The comparison of anomaly detection in training data as seen in Fig. 7 is shown for the accuracy of detection at different levels. And as the accuracy of diagnosis has increased, the amount of training data has taken a downward trend. The more training data there are, the better the model created using the suggested algorithm covers the images, resulting in a similar system with the arrival of new test data and the ability to detect anomalies. This is the reason for improving the accuracy of detection by increasing the number of training data.


Fig. 6. Anomaly Detection using the Method in different Images from the Video.
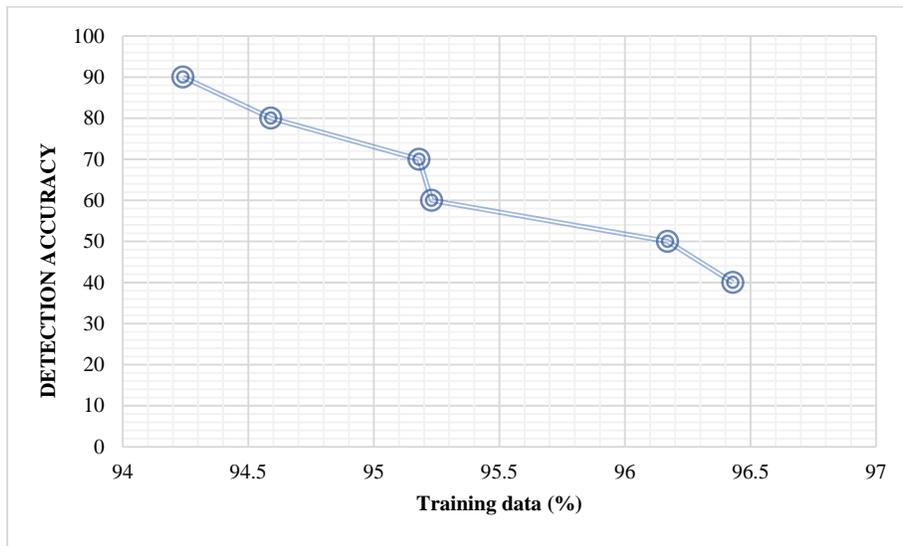

Fig. 7.   Comparison of Anomaly Detection on Training Data.

TABLE III.   ALGORITHM PARAMETERS

parameter	value
Initial population size	50
number of iterations (generations)	400
The number of features of each variable	20
Cutting rate	0/9
Composition rate	0/7
beta	0/08

Table III shows the parameters of the proposed difference evolution algorithm and their values. It should be noted that the values of the operators were selected by trial and error.

To ensure the correctness of the abnormality diagnosis, the final results and images must be reviewed and approved by an expert. However, to evaluate and check the efficiency of the proposed algorithm, the following criteria such as sensitivity, accuracy, and precision can be checked to estimate the correctness percentage of the proposed methods.

B. Comparison of Anomaly Estimates

Table IV shows the results of the proposed method. In our experiments, 40% to 90% of the training data were used, and we evaluated the anomaly detection results of the training data.

TABLE IV.   ANOMALY ESTIMATION RESULTS WITH DIFFERENT NUMBER OF TRAINING DATA

Educational data (%)	Our Method
40	96.43
50	96.17
60	95.23
70	95.18
80	94.59
90	94.24

The decrease in detection accuracy with the increase in training data is because the more training data is, the more the model built with the proposed algorithm will have a higher computational load and perform anomaly detection with less accuracy. However, as it can be seen, the presented method is also effective in a small amount of training data. It is concluded from this figure that with fewer input data, we will have better training and better results will be obtained, and the prediction error will be minimized. It can be seen that even though all the parameters of this network are the same and only their initial weights and biases are different, the number of periods required to reach the desired error limit is very different. The interesting point is that, although after training, all the networks have reached the desired error limit and stopped at that limit, they will give different answers compared to the test samples.

C. ROC Curve

It has been used to evaluate and compare the tests presented in order to detect abnormalities with other methods in the same conditions. One of the ways to detect the strength of a classifier is to use the ROC chart and the area under that chart in such a way that if the area under the curve is low, it means a weak classification, and the more it is, it means a strong classification.

The difference between the ANN method and PROPOSED is in the combination of evolutionary algorithm and ANN, which parameters were optimized with differential evolution algorithm before neural network training. In Fig. 8, three classifications are compared based on the ROC curve. As can be seen, the sub-level of the proposed method is higher compared to the other two methods, and this means that the learning method has a better performance in classifying and diagnosing people's abnormalities.

D. Comparison of the Results of Several Methods for Abnormality Diagnosis

Accuracy and time criteria have been used to evaluate the presented algorithms to classify anomalies with other methods

in the same conditions. Fig. 9 and 10, as well as Table V, compare the evaluation results of several methods for abnormality detection.

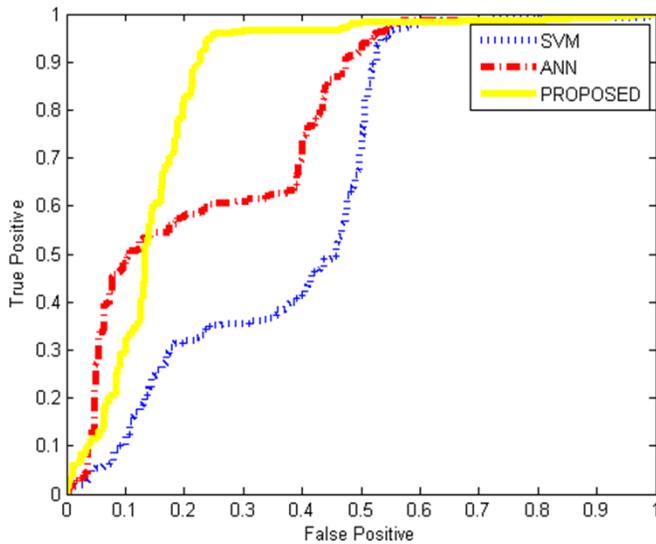
As seen in Fig. 9 and 10, the proposed solution was able to perform the anomaly detection operation in much less time and with relatively higher accuracy, which shows that the solution is optimal. This level of efficiency and optimality has been made possible with the help of a combined approach and the use of the differential evolution algorithm and the cellular neural network, which has found the solution to detect abnormalities in much less time and with proper accuracy. In the following, in the forms of 11 to 13 percent, the sensitivity, accuracy, and amount of correct prediction of the solutions are compared. The reason for checking these parameters is to evaluate the solution in the correct diagnosis with relatively high sensitivity. In diagnosing abnormal human behavior using video images, the sensitivity and correctness of the predictions must be high because the lower this level, the more reliable it is. It will also come down to the solution.


Fig. 8. Comparison of Methods.
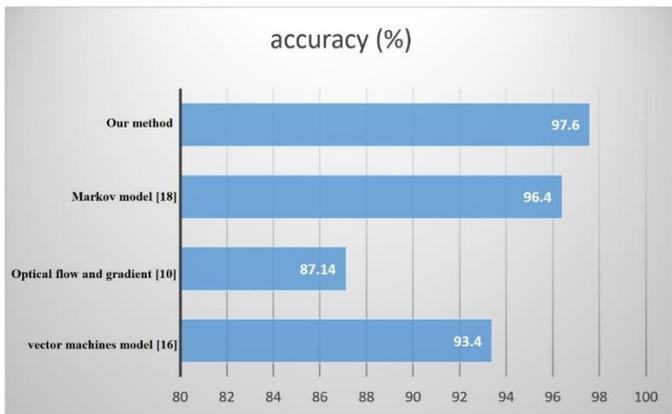

Fig. 9. Accuracy of Anomaly Detection in the Evaluated Solutions.
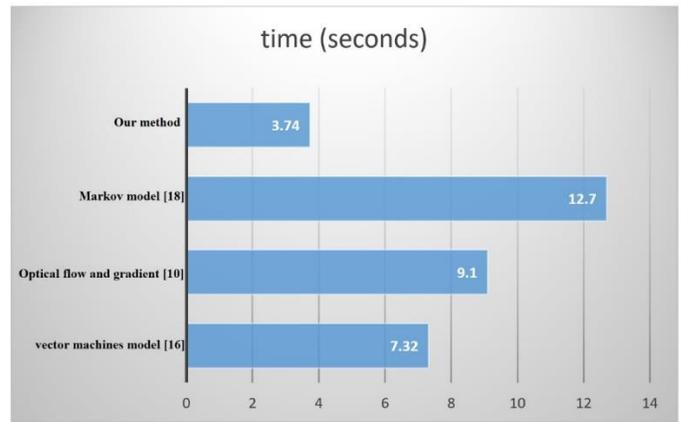

Fig. 10. Abnormality Detection Time in the Evaluated Solutions.

TABLE V. COMPARISON OF THE RESULTS OF SEVERAL METHODS FOR ABNORMALITY DIAGNOSIS

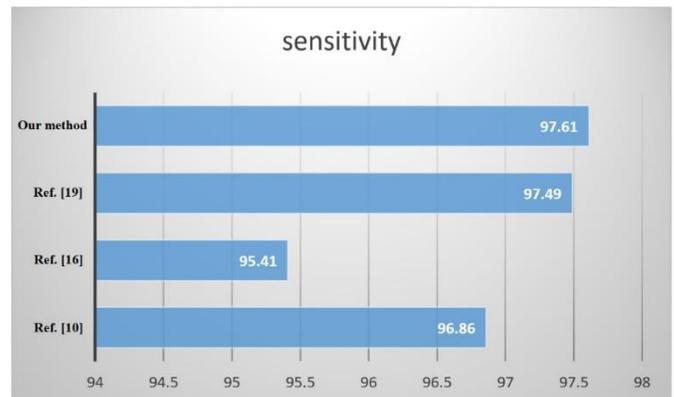
Method	accuracy (%)	time (s)
Vector machine model [16]	93.4	7.32
Optical flow and gradient [10]	87.14	9.1
Markov model [18]	96.4	12.7
Our method	**97.6**	3.74


Fig. 11. The Level of Sensitivity in the Evaluated Solutions.

As seen in Fig. 11, the proposed solution has been able to perform better than all three solutions in terms of sensitivity. This level of optimization is possible due to the combined solution presented in the previous chapter.

In Fig. 12, the proposed solution has performed better than the two solutions presented in [19] and [10], but with a slight difference, it has performed weaker than the solution presented in [16], but considering that the method presented in this research In terms of other important parameters such as percentage of correct prediction or sensitivity, it has performed much better, this small weakness can be ignored.

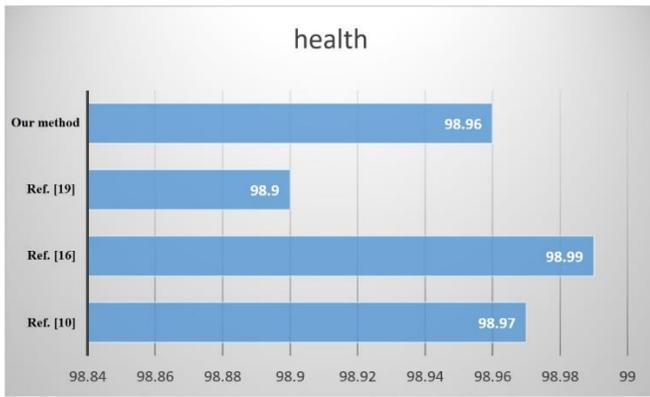
Fig. 13 shows the percentage of correct predictions. As can be seen, the proposed solution was higher than the other evaluated solutions by a large margin. This level of optimality can compensate for the relative weakness of the solution in terms of accuracy. Table VI shows the numerical values of the proposed method in abnormality detection.


Fig. 12. The Degree of Accuracy in the Evaluated Solutions.

V. CONCLUSION

In this research, a computationally efficient algorithm for anomaly detection on video images with high resolution is presented. The proposed method has higher speed and accuracy compared to other methods. The advantage of the algorithm is that it has an execution time of three seconds on a home computer. The proposed method has higher accuracy and precision in comparison with other methods. The advantage of the algorithm is that it has an accuracy of 96.5% on a home computer, and the average sensitivity criterion is 98.6%/97.2%.

VI. SUGGESTIONS

It is suggested that in the future, the following things should be investigated to improve the methods presented in

this paper. The proposed method has a good potential for classifying video objects such as cars in color images. Improving the proposed methods to reduce the time of abnormality detection, which can be used to improve the abnormality detection using the combined methods of the neural network, which requires a supercomputer.

Transformer-based Neural Network for Electrocardiogram Classification

Mohammed A. Atiea, Mark Adel

Computer Science Department, Faculty of Computers and Information
Suez University, Suez, Egypt

Abstract—**A transformer neural network is a powerful method that is used for sequence modeling and classification. In this paper, the transformer neural network was combined with a convolutional neural network (CNN) that is used for feature embedding to provide the transformer inputs. The proposed model accepts the raw electrocardiogram (ECG) signals side by side with extracted morphological ECG features to boost the classification performance. The raw ECG signal and the morphological features of the ECG signal experience two independent paths with the same model architecture where the output of each transformer decoder is concatenated to go through the final linear classifier to give the predicted class. The experiments and results on the PTB-XL dataset with 7-fold cross-validation have shown that the proposed model achieves high accuracy and F-score, with an average of 99.86% and 99.85% respectively, which shows and proves the robustness of the model and its feasibility to be applied in industrial applications.**

Keywords—Electrocardiogram classification; transformer neural network; convolutional neural network

I. Introduction

Cardiovascular diseases (CVDs) happen due to malfunctions in the heart as well as blood vessels. CVDs are one of the main causes of global deaths as issued by the World Health Organization (WHO) [1], CVDs share 32% of the global death causes in 2019. ECG is an essential tool for CVDs diagnoses and treatment, also it is required for continuous heart monitoring. As WHO reported, 85% of deaths by CVDs located in developing countries where there is a shortage of professional doctors who are required to interpret the ECG for going through the proper medication and treatment [2]. CVDs unleash the potential for the need to automate the ECG interpretation process to overcome the aforementioned challenges.

An extensive amount of research was done to introduce an efficient and sophisticated method for ECG classification. Cognitive algorithms are more suitable to process the ECG signals since the ECG parameters are not standard for all people, also it requires special types of models that are capable to handle sequential data efficiently due to the nature of the ECG signals [3]. Using classical signal processing techniques, machine-learning-based classification methods are introduced to operate on manually extracted ECG features. Especially, deep neural networks present an outstanding performance due to the introduction of various new, well-structured datasets.

This paper introduces a novel method for ECG beat classification based on transformer networks and convolution operation for feature embedding to prepare model inputs. Two instances of the proposed model were trained independently by the raw ECG signals as well as the morphological feature R-R Interval (RRI), as illustrated in Fig. 1, where the output of both models is concatenated with the other to give the final prediction. The experiments in this paper were held based on the PTB-XL dataset [4] where the resampling methods were done to overcome the imbalanced data distribution of the used dataset.

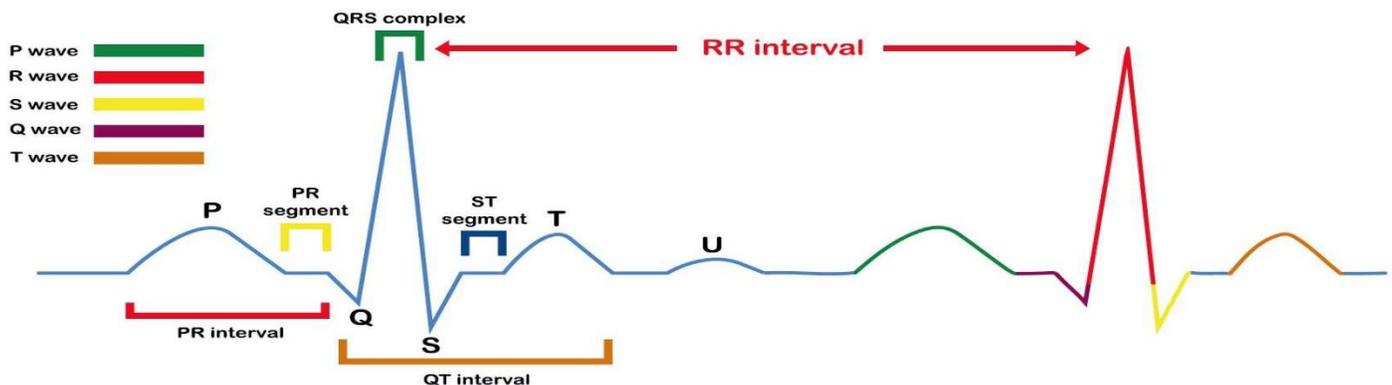
The remaining sections of this paper are organized as follows: Section II involves the state-of-art previous related work, Section III introduces a detailed description of the proposed model, Section IV gives the experiments setup and the results, and Section V gives the conclusion about the paper main points and the future vision.


Fig. 1. An ECG Signal Sinus Rhythm.

II. RELATED WORK

ECG beats classification is considered frequently in recent scientific literature. There are two main approaches to solving an ECG signal classification problem, one of them is to use classical machine learning approaches such as random forests [5], support vector machine (SVM) [6], ensemble SVM [7], etc.

Usually, classical machine learning algorithms are preceded by many phases to achieve an acceptable performance. These phases include the ECG noise elimination process which is mainly encountered by digital signal processing techniques such as low- and high-pass filters.

Also, one of the most essential phases, that has a considerable effect on classifier performance, is feature extraction which can be based on signal domain transformations like different variants of Fourier transform [8] and Wavelet transform such as tunable Q-wavelet transform [9], the maximal overlap wavelet packet transform (MOWPT) [10], and continuous wavelet transform (CWT) [11]; features extraction can also be done based on some statistical measurements as skewness and kurtosis [9]. Another way to do feature extraction is to depend on the morphological characteristics of the ECG signal; such methods acquire features mainly from the QRS complex component of the ECG.

On the other side of classical machine learning algorithms, the deep-natural-networks-based models provide exceptional performance over other machine learning algorithms, especially when a large amount of data is fed to the models.

Convolutional neural networks (CNN) were used in two ways of manner: 1-D CNN that accepts 1-D ECG signal as its input also 2-D CNN can be adapted after applying higher signal domain transformation to generate a representative visual representation of ECG signal as a spectrogram and then feed these spectrograms to the 2-D CNN which requires a considerable amount of computational effort.

Recurrent neural networks (RNN) also can be accommodated because of the sequential nature of the ECG data [12]. Also, RNN variants such as gated recurrent units (GRU) [13] and long-short-term memory [14] are introduced to solve the ECG classification problem [15]; since these architectures solve gradient exploding and vanishing problems in the backpropagation algorithm in the network training process [14]. The main disadvantages of the RNN and its variants are that RNN cannot handle long dependencies in the sequential data also because of its sequential behavior RNN does not benefit from parallel hardware accelerators [16] such as graphical processing unit (GPU) and field-programmable gate array (FPGA). A hybrid architecture can be combined of CNN and RNN or its variants can also present a sophisticated accuracy in ECG classification [17].

III. METHOD

A. ECG Morphological Features Extraction

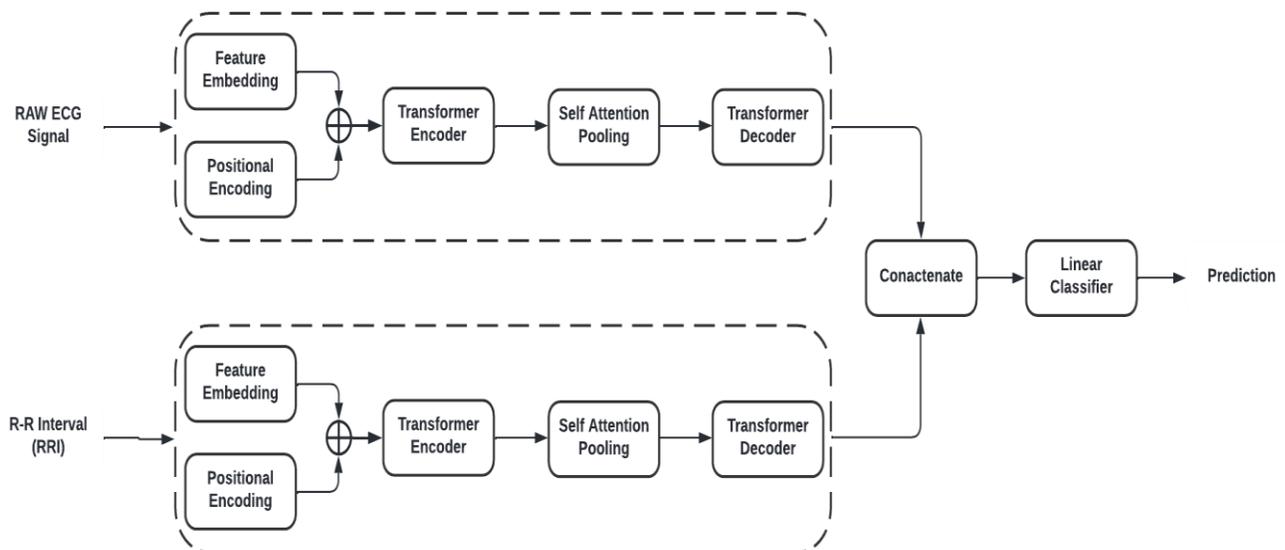
Morphological features of the ECG signals introduced an outstanding performance with different classifiers [18] since these features present critical information that is required to recognize different types of ECG signals. R-R interval (RRI) was chosen to be fed to the proposed model besides the raw ECG signals to optimize the model performance. The RRI was extracted by Pan–Tompkins algorithm [19] as it represents sophisticated performance measurements. The RRI and raw ECG examine two different independent paths of the same model architecture where the output of each model in concatenated before entering the classification head. The proposed model takes advantage of both the CNN and the transformer neural network [20]. The proposed classification model consists of 2 paths each with 4 main stages as illustrated in Fig. 2. Each main stage is explained in detail in the following subsections and the internal structure of each main stage is illustrated in Fig. 3.


Fig. 2. Abstract Model Architecture.
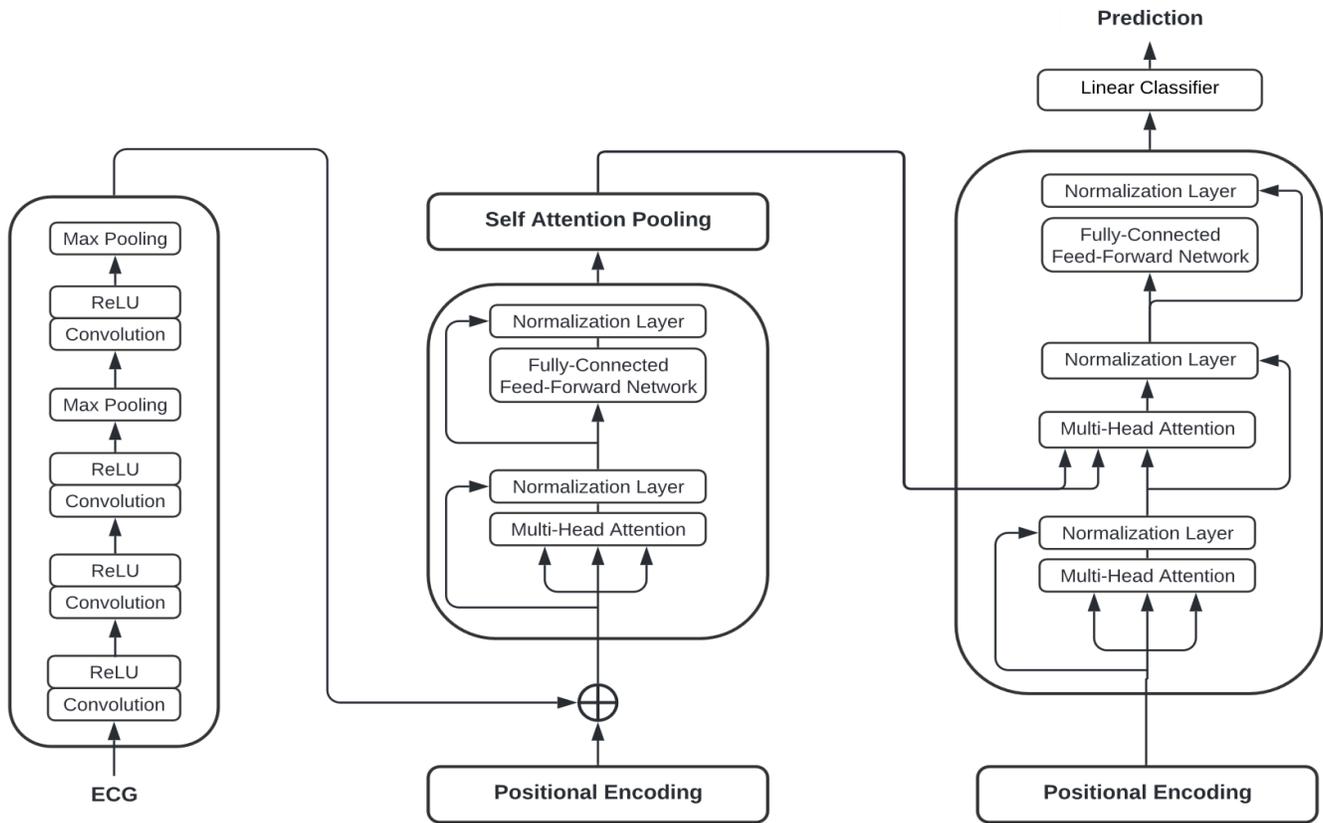

Fig. 3. Detailed Structure of the Embedding Module and Transformer Neural Network.

B. Feature Embedding

The feature embedding module consists of four convolutional layers as illustrated in Table I to generate a compact and concrete ECG features map, each of the two convolutional layers is followed by the Rectified Linear Unit (ReLU) activation function to provide the non-linearity in the ECG signals, while each of the last two layers is followed by maximum pooling layers which output a feature map with the highlighted features of the current ECG signal. Hence the fed data is a sequence of one-dimensional ECG signals, the output of the discrete convolution operation is given as

$$S(t) = (x * w)(t) = \sum_n x(n)w(t-n) \qquad (1)$$

Where x is the input signal, and w is the sliding kernel window. Also, the applied ReLU function can be computed with the following

$$y(x) = max(0, x) \qquad (2)$$

The size of the output of the feature embedding layer will be the same in the original transformer literature [20], which equals 512 (d_{model}). The size of the feature embedding output has to be the same as the output of the positional encoding, which is illustrated in the next subsection to provide the summation of both to the transformer encoder.

C. Positional Encoding

Hence the proposed model has no recurrence relation, it is a necessity to provide information about the absolute and relative positions of different timestamps in the ECG signals.

In order to introduce this information, the output of a positional encoding layer is summed to the output of the feature embedding module to be provided as an input to the transformer encoder and decoder [20].

Any periodic function is sufficient to implement the positional encoder, but in this work, the positional encoder is implemented by different frequencies of the sine and cosine functions because of their linear properties, which are feasible to be learned by the model [20]. Positional encoding can be modeled by the following

$$PE_{(pos,2i)} = \sin(pos / 10000^{2i/d_{model}})$$

$$PE_{(pos,2i+1)} = Cos(pos / 10000^{2i/d_{model}}) \qquad (3)$$

where *pos* represents the position of the sequence token, and *i* represents the spatial location of the ECG feature.

TABLE I. FEATURE EMBEDDING MODULE LAYERS

Layers	Layer Name	Kernel Size
1	Convolution	3 X 1
2	Convolution	3 X 1
3	Convolution	3 X 1
4	MaxPooling	3 X 1
5	Convolution	3 X 1
6	MaxPooling	3 X 1

D. Transformer Encoder

The proposed model consists of four identical layers where each layer is subdivided into two sublayers which are a multi-head self-attention sublayer and a position-wise fully connected feed-forward neural network. Residual connections exist around each sublayer to handle gradient flow in the network during the training time. To accommodate the residual connections each sublayer and the embedding dimension have a dimension of 512. The output of the multi-head self-attention sublayer and its input via the residual connection is normalized to provide a sustainable training process to the network. Then, the data will flow through a fully-connected feed-forward network to provide a more convenient representation of the attention output.

A self-attention pooling [21] block was added to accept the output of the encoder block to reformulate the attention score tensor, from the dimension of [length of sequence, batch size, embedding dimension] to [batch size, embedding dimension], to be accepted by the multi-head attention sublayer in the decoder module where the attention function [20] can be written as

$$Attention(Q, K, V) = softmax \left(\frac{Q\,k^t}{\sqrt{d_k}} \right) V \qquad (4)$$

where Q is the query, K is the key, V is the value, and $d_k = d_{model}/h$ [20].

E. Transformer Decoder

The transformer decoder contains the same structure as the transformer encoder with the same sublayers proceeded with normalization as well as residual connection.

In addition to a multi-head self-attention sublayer and a position-wise fully connected feed-forward neural network, the decoder provides a multi-head attention sublayer to attend over the output of the transformer encoder module. Also, the multi-head attention sublayer is modified to attend only to the previous sequence tokens from the encoder output which is performed by masking the attention tensor [20].

F. Linear Classifier

At this stage, the outputs of each path of the raw ECG and RRI are concatenated into one tensor which is passed through this linear classifier to give the final prediction. The linear classifier consists of a flatten layer and two fully-connected feed-forward networks that are separated by a dropout layer for regularization [22].

IV. EXPERIMENTS RESULTS

All the experiments were carried out by Google Colaboratory where the dataset handling and the model implementation were held in Python 3.9.

A. Dataset Description

In the training process, we used the PTB-XL dataset [4]. PTB-XL is the to-date largest freely accessible clinical 12-lead ECG-waveform dataset. The dataset covers a broad range of diagnostic classes including a large fraction of healthy records. A total of 2183721837 clinical 12-lead ECG records of 10 seconds length from 18885 patients are included in the dataset. The data is gender-balanced (52 percent male, 48 percent female) and includes the ages of 0 to 95 years old (median 62 and interquartile range of 22).

The ECG statements used for annotation are conformed to the SCP-ECG standard [23] and were assigned to three non-mutually exclusive categories diag (short for diagnostic statements such as "anterior myocardial infarction"), form (related to considerable changes of particular parts within the ECG such as "abnormal QRS complex") and rhythm (related to specific changes of the rhythm such as "atrial fibrillation"). There are 71 different statements in all, which are broken down into 44 diagnoses, 12 rhythms, and 19 form statements, four of which are also utilized as diagnostic ECG statements. A hierarchical classification into five coarse superclasses and 24 subclasses is also provided for diagnostic statements. As shown in Table II, We mainly classified by the 5 main classes (NORM, HYP, MI, STTC, CD) and by 14 classes which are (LVH, IVCD, ISC_, LAO/LAE, IMI, CRBBB, NST_, CLBBB, RAO/RAE, ILBBB, LMI, AMI, NORM, WPW).

Apart from its large nominal size, PTB-XL is notable for its diversity, both in terms of signal quality (with 77.01 percent of the highest signal quality) and in terms of a broad range of pathologies, many different co-occurring diseases, and a high proportion of healthy control samples, which is uncommon in clinical datasets. This variability is what makes PTB-XL such a valuable resource for training and evaluating algorithms in a real-world scenario, where machine learning (ML) algorithms must function reliably independent of recording settings or potentially low-quality data.

As you can see, the dataset still doesn't have a normal distribution, hence data augmentation was necessary to improve accuracy. By using data augmentation, we were able to improve the diversity of training data without having to acquire additional data.

B. Classification Model Metrics

Two models were created, one of them operates on ECG superclasses while the other operates on the ECG subclasses as shown in Table II.

Several statistical metrics were established to evaluate the classification performance of the proposed model where these metrics are precision, sensitivity, F1-score, and accuracy. All the mentioned metrics were computed due to the equations in Table III, where TP is a true positive, TN is a true negative, FP is a false positive, and FN is a false negative. The aVR lead was fed to the two models due to the amount of information it contains about the cardiac state of the individual as well as it is proven to present a good performance for classification and detection tasks [24].

Table IV shows all the classification performance metrics for the superclasses model while Table V presents the classification performance metrics for the subclasses model.

TABLE II. PTB-XL DATASET SUPERCLASSES AND SUBCLASSES

Superclass	Subclass	Records	Description
HYP	LVH	2137	left ventricular hypertrophy
	LAO/LAE	427	left atrial overload/enlargement
	RAO/RAE	99	right atrial overload/enlargement
CD	IVCD	789	non-specific intraventricular conduction disturbance (block)
	CRBBB	542	complete right bundle branch block
	CLBBB	536	complete left bundle branch block
	ILBBB	77	incomplete left bundle branch block
	WPW	80	Wolff-Parkinson-White syndrome
STTC	NST_	770	non-specific ST changes
	ISC_	1275	non-specific ischemic
MI	LMI	201	lateral myocardial infarction
	AMI	354	anterior myocardial infarction
	IMI	2685	inferior myocardial infarction
NORM	NORM	9528	normal ECG

TABLE III. STATISTICAL METRICS EQUATIONS

Metric	Equation
Accuracy	$\dfrac{TP + TN}{TP + FP + FN + TN}$
Precision	$\dfrac{TP}{TP + FP}$
Recall	$\dfrac{TP}{TP + FN}$
F1 Score	$2\,x\,\dfrac{Rec\ x\ Pre}{Rec + Pre}$

TABLE IV. CLASSIFICATION PERFORMANCE METRICS FOR SUPERCLASSES MODEL

Class	Precision	Recall	F1 Score	Average Acc.
HYP	99.73%	99.83%	99.78%	
CD	99.69%	99.72%	99.70%	
STTC	100%	99.86%	99.93%	
MI	99.86%	99.86%	99.86%	99.86%
NORM	100%	100%	100%	
Average	99.86%	99.85%	99.85%	

The proposed model was trained through 32 epochs for the superclasses model and 35 epochs for the subclasses model, Table VI introduces the average time required per epoch for each model. Also, the cross-entropy loss function is used to establish the loss during training and validation processes concerning the number of epochs which is illustrated in Fig. 4. Also, the accuracy of the training and validation processes is shown in Fig. 5 concerning the number of epochs. As illustrated in Table VII and Table VIII, the experimental results demonstrate that the proposed model introduced a considerable improvement over the current state-of-arts models for ECG classification.

TABLE V. CLASSIFICATION PERFORMANCE METRICS FOR SUBCLASSES MODEL

Class	Precision	Recall	F1 Score	Average Acc.
LVH	99.86%	100%	99.93%	
LAO/LAE	99.96%	100%	99.98%	
RAO/RAE	99.73%	100%	99.86%	
IVCD	99.83%	100%	99.91%	
CRBBB	99.02%	97.22%	98.11%	
CLBBB	100%	100%	100%	
ILBBB	99.96%	99.96%	99.96%	
WPW	99.93%	100%	99.96%	99.6%

V. CONCLUSION

This paper introduces a novel classification model for 12-lead ECG signals based on PTB-XL. The proposed model depends on the transformer neural networks for ECG sequence modeling and CNN for feature embedding. The model can be fed by the raw ECG signals as well as the RRI feature of the ECG to achieve robust classification performance. The proposed model achieved accuracy and F-score, with an average of 99.86% and 99.86% respectively where these metrics can compete with the many recent state-of-art models. Due to the model performance and since the transformers were introduced to solve the sequential models' complexity challenges, the proposed model is capable to be deployed in practical applications. In future work, this model can be integrated with wearable device technology to assist in critical cases with continuous monitoring to save more lives.

BCT-CS: Blockchain Technology Applications for Cyber Defense and Cybersecurity: A Survey and Solutions

Naresh Kshetri[1]*, Chandra Sekhar Bhushal[2], Purnendu Shekhar Pandey[3], Vasudha[4]

Assistant Professor (Cybersecurity), Dept. of Math, CS & IT, Lindenwood University, St. Charles, MO, USA[1]
School of Eng, IT & Physical Sciences, Federation University, Victoria, Australia[2]
Department of CSE, KIET Group of Institutions, Ghaziabad, UP, India[3]
Department of CSE, United Institute of Management, Prayagraj, UP, India[4]

Abstract—Blockchain technology has now emerged as a ground-breaking technology with possible solutions to applications from securing smart cities to e-voting systems. Although it started as a digital currency or cryptocurrency, bitcoin, there is no doubt that blockchain is influencing and will influence business and society more in the near future. We present a comprehensive survey of how blockchain technology is applied to provide security over the web and to counter ongoing threats as well as increasing cybercrimes and cyber-attacks. During the review, we also investigate how blockchain can affect cyber data and information over the web. Our contributions included the following: (i) summarizing the Blockchain architecture and models for cybersecurity (ii) classifying and discussing recent and relevant works for cyber countermeasures using blockchain (iii) analyzing the main challenges and obstacles of blockchain technology in response to cyber defense and cybersecurity and (iv) recommendations for improvement and future research on the integration of blockchain with cyber defense.

Keywords—*Applications; blockchain technology; blockchain solutions; countermeasures; cyber-attacks; cyber defense; cybersecurity; survey*

I. INTRODUCTION

Cyber defense is a defensive mechanism or coordinated act of resistance designed for the safety of information, system, and networks against offensive cyber operations by implementing various security procedures. Some of the major cyber defense activities include set up and maintenance of the hardware and software for security infrastructure, examination of the network's system for vulnerabilities, implementation of real-time countermeasures to stop zero-day attacks, and recovery from attacks that were either completely or partially successful [1]. It ensures the survival of any state from cyber-attacks [2]. The main focus of cyber defense is the prevention, detection, and regulation of timely response to cyber-attacks or threats to make sure that infrastructure or information are not harmed. Cyber defense aims to reduce possible attacks and understand the critical location and sensitive information by carrying out various technical analyses to find out the possible paths and areas that could be targeted by the online attackers [3].

To achieve regulatory compliance, protect assets, and compromise the assets of adversaries, information safeguards, security procedures, and IT security tools and techniques are governed, developed, managed, and applied in cybersecurity [3]. It is the actions and policies implemented to protect cyberspace by the military, public and private business sector. Cyber security has been identified as one of the crucial strategic fields of national security [4]. It is related to protecting information/data, infrastructure, and service to reduce the possibility of loss, damage, and compromise of misuse by unauthorized users. Mainly cyber security focuses on sensitive information stored electronically on computers, computer networks, mobile devices, and the internet [5].

Blockchain is a distributed database technology based on cryptography that maintains a constantly expanding list of data entries that are verified by every network node. Data records are stored in blocks, which are linked together to form the chain. Each participating node keeps a replica of the data records and transmits it to every other node in the network, improving trust and transparency, as opposed to information being routed through a central node [6]. Blockchain technology minimizes the probability of unsecured transactions because applications function decentralized and do not require intermediary authority to monitor the transactions between participants [7].

Blockchain underlying characteristics of decentralization, consensus mechanism, immutability, traceability, and privacy provide a strong foundation for cyber defense and security of data and information in cyberspace. Blockchain decentralized property with use of distributed ledger eliminates the intermediaries that are potential risk for security of the network. Also, there is no single point of failure in decentralization so there is a very low chance that an IP-based DDoS attack will disrupt the daily operations. By establishing a decentralized network using client-side encryption where data owners have complete transparency of their data, blockchain increases the security of data sharing and storing [8] [9]. Next blockchain's Consensus mechanisms govern how participants agree on a single common version of the facts when storing and verifying blocks (a shared truth). The Consensus enables nodes to trustworthily verify brand-new

---

*Corresponding Author.

blocks in the network. The Consensus enables nodes to trustworthily verify brand-new blocks in the network [9].

The immutability property of blockchain ledger provides the solid base for data integrity. Each transaction in a block is cryptographically signed by its sender, and every block in the blockchain is signed by its miner. To alter a single transaction in the blockchain, an attacker ought to modify each next block in the same manner, resolving the consensus problem for that block and all succeeding blocks, and convincing more than 50% of users on the network to adopt the updated chain. Modifying blocks in the network is nearly impossible due to the hashing features and the amount of computing and electrical effort required to achieve this goal [8] [9]. Traceability characteristics of blockchain technology makes the network more secure. Every transaction uploaded to the blockchain is digitally signed and timestamped, allowing organizations to go back to a precise time period for each transaction and identify the corresponding participant (by their public address) on the blockchain [8]. Privacy is one of the core properties of blockchain technology. The identity of those involved in a transaction is protected by cryptographic functions that ensure the anonymization of the entities participating in the blockchain, which help to gain a high degree of privacy [9].

The rest of the article is organized as related work in Section II which discusses several recent works of blockchain-based security and models. We then presented Section III of our paper as BCT for cyber defense and cybersecurity. Section IV of our study is about Countermeasures and defense initiatives with the help of blockchain technology. The advantages of blockchain technology with respect to cyber defense and cybersecurity are summarized in Section V of our findings. We have pointed out several solutions and challenges while incorporating those blockchain-based solutions in Section VI (blockchain-based solutions and challenges). In Section VII, we presented the conclusion and future scope of the study as recommendations for improvement and future research on the integration of blockchain with cyber defense.

II. RELATED WORKS

In [10], A. Razaque et al. (2021), introduced a web-based Blockchain-enabled cybersecurity awareness program (WBCA) to reduce the risk of cybercrimes. The proposed WBCA enhances user understanding of cybersecurity hygiene, best practices, current cybersecurity vulnerabilities, and trends while training users to better their security capabilities and comprehend the typical actions of cybercriminals. Blockchain technology is used by WBCA to safeguard the software against threats, and it is evaluated and tested using real-world cybersecurity issues with actual users and cybersecurity professionals. The suggested WBCA was also tested on a CentOS-based virtual private server to determine its efficacy, and the authors anticipated that the proposed program might be expanded to other areas, such national or corporate courses, to raise users' cybersecurity awareness levels. At the end, the authors also contrasted WBCA with other cutting-edge web-based cybersecurity awareness program.

In [11], A. Razaque et al. (2021), proposed a blockchain-enabled transaction scanning (BTS) approach for the discovery of anonymous actions that outlines the guidelines for outlier detection and quick currency transfers, which limits aberrant transactional behavior. The BTS method is designed to limit money laundering since using bank cards or money transfers gives terrorist groups and anyone who engage in money laundering new opportunities. The BTS method's prescribed rules determine the distinct patterns of fraudulent activity in transactions, scan the transaction history, and offer a list of entities that receive money in a suspicious manner. The performance of the proposed BTS technique was also verified using a Spring Boot application built by the authors using Java programming. Based on the outcomes of the experiments, the proposed method automates the investigation of transactions and limits the occurrences of money laundering.

In [12], H. H. Alhelou et al. (2021), proposed model using Hilbert-Huang transform and Blockchain-based ledger technology to identify fake data injection attacks (FDIA) in a micro grid (MG) system. By analyzing the voltage and current signals in smart sensors and controllers and extracting the signal features, the model is utilized to improve security in the smart DC-MGs. These networks are susceptible to numerous cyberattacks because of the concurrent growth of DC-micro grids and the employment of sophisticated control, monitoring, and operation technologies, as well as their structure. The authors also considered the outcomes of simulations on various instances in order to confirm the effectiveness of the suggested model. The findings offer that the recommended model can increase the security of data exchange in a smart DC-MG and give a more accurate and reliable detection mechanism against FDIA.

In [13], M. Sadigov et al. (2021), proposed a system-dynamic model of the business's cybersecurity system developed with blockchain technology, giving the capacity to create a computer model of a complicated cybersecurity system for more efficient design. Since 34% of cases are accounted for by system vulnerability due to user behaviors, the authors have placed a strong emphasis on reducing the threat associated with human factors. The goal of the research is to use contemporary BCT to address the problem of rising levels of cybersecurity in big businesses. A causal relationship diagram analysis, differential equations for some of the model's components, and experimental modeling for various values of some parameters at the initial level of others are the foundations of the system-dynamic model, which aims to pinpoint the system sensitivity.

In [14], S. Lee and S. Kim (2021), conducted a survey of official records, interviews, relevant news, technical reports, and research papers from 2016 to 2021, which, by methodically conducting research and analysis, helps to close the gap in blockchain for cyber security. The authors discovered that government-led program and research are both aggressively supporting blockchain, proving that it will play a significant role in cyber protection. Due to its relationship to national security, the cyber defense industry needs advanced security technology. In contrast to conventional systems, blockchain offers strong security features without a

centralized control entity, and its use in the cyber defense industry is receiving attention. With a conclusion of recommendations for future research in elements of the blockchain technology, evaluation, and survey, this work offered prospects that blockchain presents for cyber defense, research, national initiatives, restrictions, and other areas.

III. BCT FOR CYBER DEFENSE AND CYBERSECURITY

There is a rapid increase in the number of digital populations' worldwide and online businesses every year. Presently, cybercrime has pop up as the enormous security loophole and threat to the global computer information technology industry [15]. The increasing number of online connected devices and online users will ultimately give rise to online crimes, which in turn cost billions of losses to the tech field and companies globally. The digitalization of data and information offers numerous merits but also creates several loopholes and security warnings. The mode of cybercrime is slowly shifting its operating ground from home computers/laptops to mobile phones, tablets, wearable sensors, digital watches, etc. In order to explore the remedies of such threats and provide counter methods to detect or slow down those threats, we have gone through several background studies in the section above.

TABLE I. SUMMARY OF BLOCKCHAIN-BASED SECURITY AND PROPOSED MODELS FOR CYBER DEFENSE AND CYBERSECURITY AS INTRODUCED IN BACKGROUND STUDY AND LITERATURE

As we have already mentioned, cyber awareness and threat identification play a vital role in combating or fighting against the bad guys or cyber criminals, who are trying to steal/damage online data and secure personal information via various social engineering techniques. We have summarized the blockchain architecture and models (from the Literature Review section of the study) for cyber defense and cyber security in the Table I. The summary includes the proposed model or system with author details and a paper published in the respective conference or journal.

IV. COUNTERMEASURES WITH BLOCKCHAIN TECHNOLOGY

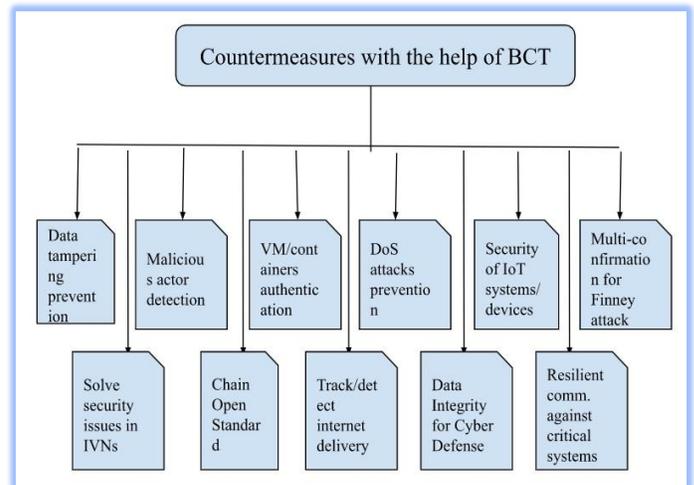
Based on increasing cybercrimes and cyberattacks reported in Post Covid era, various countermeasures, and security strategies are pointed out as Legal countermeasures, Phase-wise ethics, Minimum use of Autonomous Weapons Systems (AWS), Robot Weaponry (RW) & Autonomous Vehicles (AV), Detecting insider threats from social & online data, Increase cyber capabilities & awareness, and Online gaming prevention and authentication [16] (see Fig. 1). Besides developing legal countermeasures and an increase in military cyber knowledge/power, implementation of phase-wise ethics and minimal use of AWS, RW, and AV will certainly help to counter cybercrimes and cyberattacks. The proposed model by authors (EAMV model as Ethics Authentication Monitoring Verification for online data) is also solely focused on the prevention of cybercrime in post-COVID scenarios. EAMV are described as four firewalls or security processes that hackers have to go through one by one in order to access user data or information.


Fig. 1. Various Countermeasures and Cyber Defense Techniques with the Support of Blockchain Technology (BCT) and the Types of Blockchain used for such Countermeasures [16] - [21] [25].

One of the greatest discussed methods for safeguarding data storage, and transfer from decentralized, trustless, peer-to-peer systems is the blockchain. The preliminary keyword explorations by authors highlight blockchain as a standalone technology that carries with it an exorbitant array of possible answers for finance, logistics, healthcare, and cybersecurity [17]. Blockchain uses for cyber security have progressed and bolstered the standing efforts to deter mischievous actors and to boost security. There is an ever-increasing prerequisite to securely cope the cryptography and certification orders as the

WWW transports towards bulk adoption of HTTPS encryption and end handlers are expending it. Ethereum permits for very customizable programming of smart contracts and blockchain uses in the dialectal Solidity. Several major studies alarmed with IoT have offered their own clarifications such as the Proof-of-Possession in the IoTChain proposal.

Not only countering the attacks over the web and malicious actor detection, but a decentralized database of Blockchain on cryptographic practices is also gaining consideration to comfort the security of IoT systems [18]. The blockchain outline within an IoT system is a fascinating auxiliary for old-style database models, which has apprehensions about fulfilling the request for smart home safety. Devices such as door ringlets, light bulbs, control switches, sensor garage doors, etc. are increasing in the marketplace which has limited storage and processing power. Sensors are everywhere surrounded by the home devices via wireless connectivity for remote admission by owners to operate the devices. Design and implementation of a secure home framework model for household IoT devices on Consortium Blockchain (a refined version of blockchain) are experimented with and proposed.

The blockchain perform duties as an immutable log that allows dealings in a decentralized approach. Security threats and existing vulnerabilities to the blockchain systems because of transactions collected into bricks for processing and customary network protocol guarantees each node receives each transaction in close range real-time [19]. Some of the possible and major threats to blockchain systems or blockchain networks are Double-spending security threats, Race attacks, Finney attacks, Brute force attacks, Vector 76 attacks (One confirmation attack), Alternative history attacks, 51% (or > 50%) attack (Majority hash rate attack), Block discarding attack (Selfish mining attack), Block-withholding (BWH) attack, and Fork-after-withholding (FAW) attack. Possible countermeasures for the mentioned attacks include (i) installing observers in the web, communicating binary spending cautions among groups; (ii) waiting for multi-confirm actions for transactions; (iii) informing the merchant about an ongoing binary consume in the network; (iv) disincentive huge mining reserves, twinsCoin, PieceWork; (v) ZeroBlock technique, a timestamp-form technique such as bloomness preferred, DECOR+ protocol; (vi) involve only familiar and committed miners in the pool, cease and terminate a pool when revenue sinks from calculated or sudden change occurs; and (vii) use of cryptographic commitment schemes.

The connection amid the vehicular network and the exterior world has several security pigpens that hackers can be custom to abuse a vehicular network. Some popular protocols for in-vehicle networks (IVN) are Controller Area Network (CAN), FlexRay, and automotive Ethernet, which are not designed with security in concentration. A blockchain is a noble approach to solving standing security issues in IVNs and using hybrid blockchain, there exist several ways to improve IVN security [20]. Protocols used for IVNs have numerous vulnerabilities, such as a shortage of message authentication, a shortage of message encryption, and an ID-based arbitration appliance for conflict determination. Sophisticated attacks by hackers can be launched that may clue to the loss of property and lives using these vulnerabilities. Although several algorithms were proposed in the past for IVN intrusion detection, there are several limitations to the proposed algorithms.

Blockchain technology has cracked two major problems of the digital economy - (i) once assets are digitized, movement can be over the chain, and (ii) zero-trust cost under anonymous societies for innovative chances for the internet economy. BCT is a double-edged weapon for old-fashioned economic and financial progress that places a high demand on data handling and risk-response capabilities [21]. The ultimate goal of BC is to analyze and process information through the active integration of financial funds. BCT can benefit the financial industry to automatically and accurately detect customer credit conditions to restructure the financial shop credit system and progress the efficiency of cross-border payment. To advance the blockchain financial and economic provision quality, smart contracts can be measured in order to track criminal activities. Supervision of financial firms appealing in financial derivatives ought to be strengthened; management authorities must stipulate the bottom capital of financial firms.

V. ADVANTAGES OF BLOCKCHAIN TECHNOLOGY W.R.T. CYBER-DEFENCE AND CYBER-SECURITY

Blockchain technology is one of the popularly noted and known terms nowadays in the field of secure transmission of credential data over the internet. Each block contains user data with high secure hash code as well as the previous block hash code and forms a secured chain. Any unauthorized accessibility can be easily detected in blockchain technology. With its strong security policy, this technology uses in many areas like Markets (Billing, Marketing, etc.), Government Sector (Document digitization / Contracts, Voting, Registries etc.), IOT (Self-driving cars, personalized robots) [27] , HealthCare systems, Finance, and Accounting and many more.

As we know that in the current scenario where the number of internet users increased day by day, the number of cyber-attacks also increased comparatively [28]. The actual data of a user is threatened by the attacker and used in an unauthorized manner. So, blockchain technology with its security mechanism helps to increase the security in cyber-attacks. The use of this technology has many advantages over cyber defense [29] and cyber security [30] which are categorized in the Table II and Table III.

TABLE II.   ADVANTAGES OF BLOCKCHAIN TECHNOLOGY W.R.T. CYBER DEFENSE THAT HELPS TO INCREASE SECURITY IN CYBER-ATTACKS [27] - [31]

S.N.	Security aspects of BC	Advantages over Cyber Defense
1	Decentralized data	It reduces possible attacks. The attackers did not know where the actual data was stored.
2	Traceability	It increases the cyber defense approach by easily tracing which block gets infected and prevents it.
3	Strong Encryption	A strong encryption mechanism using hash code increases cyber defense.
4	Transparency	Transactional data can be digitally authorized and accessible by all the members of the network.
5	No Setup and maintenance of h/w, s/w	No additional security infrastructure is placed for cyber-attacks.

TABLE III.   ADVANTAGES OF BLOCKCHAIN TECHNOLOGY W.R.T. CYBER SECURITY THAT HELPS TO INCREASE SECURITY IN CYBER-ATTACKS [27] - [31]

S.N.	Security aspects of BC	Advantages over Cyber Security
1	Secured Data	User credential data is secured in blocks with high-security hash codes. It reduces cyber-attacks and increases security.
2	Unchangeable transactions	The insertion of new blocks in a chain cannot be removed or modified. Not an easy task for attackers to change the block data or address.
3	Prevention of Fraud	The consensus approach prevents it from external access and cyber-attacks.
4	No middleware security breach	Data transfer from sender to receiver without the need of mediating third parties. So, in the middle attacks get reduced.
5	No Single point failure	Any type of network or cyber-attacks will not generate any type of data loss because of multiple copies of data at different sites.

VI. BLOCKCHAIN-BASED SOLUTIONS AND CHALLENGES

Keeping transparency and trust as vital drivers, blockchain technology might be a hopeful technology. Findings illustrates that BCT has the ability to aid transparency and build citizens' trust in community deal delivery while continuing a sufficient level of privacy [32]. Transparency of evidence and procedures shows a vivacious role in gaining the citizens' trust. Blockchain has a disrupting role in handling transparency, trust, citizen satisfaction, and reducing corruption in order to develop the efficiency of civic service delivery.

Although there are several solutions proposed and used by Blockchain for Cybersecurity and Cyber Defense, there are also huge challenges while embedding blockchain solutions on the other end. To come up with exact blockchain solutions and ongoing challenges and issues, we have summarized the blockchain challenges and blockchain solutions in the Table IV with respect to cybersecurity, cyber defense, and countermeasures.

TABLE IV.   BLOCKCHAIN-BASED SOLUTIONS AND BLOCKCHAIN-BASED CHALLENGES FOR CYBER DEFENSE AND CYBERSECURITY WHILE INCORPORATING THE SOLUTIONS [17] - [26]

SN	Ref. (Year)	Solution domain(s)	BC Type	BC solutions for cybersecurity & cyber defense	BC challenges while incorporating those solutions
1.	[17] (2019)	Sidechain Security, IoT Security	Public & Private	Deployed to decipher problems related to the safety of devices, networks, and users. Cryptocurrency is preserved through a Proof-of-Work (PoW) tool.	A decentralized, trustless system cannot by this one crack all glitches in cybersecurity. Need to strongly succeed the adjoining cryptography and certification patterns.
2.	[18] (2020)	Smart Home Security	Consortium	Blockchain framework (for a secure smart home within an IoT system), a decentralized database, as a substitute to traditional centralized database models.	The complexity to instrument smart contract results possibly can rise the system fee. Public blockchain design is not suitable for smart homes owing to scalability.
3.	[19] (2018)	Privacy and Transaction Security	Public, Private & Consortium	Contains a certifiable record of each and every transaction ever finished in the system. BC is a distributed sleeve system where contestants keep replicas of files and approve on the alterations by consensus.	Despite the giant opportunities BC compromises, it undergoes from challenges and limitations such as scalability, privacy, compliance, and government disputes that have not been discovered and addressed.
4.	[20] (2021)	In-Vehicle Network (IVN) Security	Hybrid	BC is a good approach to solving existing security issues in in-vehicle networks (IVNs). A suggested way to develop IVN security is constructed on a hybrid blockchain.	Hybrid BC framework for securing in-vehicle webs uses private BC to shelter message flows between sensors and components inside the vehicle and open BC for connecting which is insecure.
5.	[21] (2018)	Finance & Economics (Cross-Border Payment Security)	Public & Private	The goal of BC in the internet era is to analyze and route data through the current integration of financial services. BC can exactly identify consumer credit situations to rearrange the market credit system &advance cross-border payment efficiency.	The weak foundation of related research, difficulties encountered, and finance applications of BC are in their infancy in countries. Governments and countries should build a general-purpose application facility platform for enterprises via BC.
6.	[22] (2020)	Electronic Health Record (EHR) Security	Private	The properties for protected EHR systems (like Data accuracy & integrity, Data privacy, Efficient data sharing, Control return of EHRs back to	Has numerous restrictions and aggressive extensions will need fundamental protocol redesign. Personal healthcare figures collected are tall in volume and at

				patients) can be accomplished using blockchain as Decentralization, Security, Pseudonymity, Immutability, and Autonomy.	reckless rate. It could lead to high network invisibility due to physical space& traffic congestion. Also, mining process may cost great, limit blockchain use.
7.	[23] (2018)	Cloud-Based Data Security	Public & Private	BC is secure by policy that provides the aptitude to achieve decentralized consensus and consistency, and resilience to planned / unplanned attacks with crucial benefits (settlement without mediator, patient's control).	Strong data integrity outcomes in immutability (data cannot be reformed or deleted). One of the ethics of privacy standard, based on data safety laws, provides the right-to-erasure to folks. Healthcare data can be huge and requires examining.
8.	[24] (2017)	Automotive Security and Privacy	Private	BC based architecture to shelter the user's privacy and to upturn vehicular ecosystem security with evolving services like dynamic vehicle insurance charges and wireless remote software modernizes.	Some of forthcoming research challenges include the Key management (each vehicle owns several communication key with users which may alter) and Data caching (vehicle must take data from cloud, that suffers overhead and interval).
9.	[25] (2016)	National Defense (Cyber-enabled defense systems)	Private	BC work independent of security and trust by conserving truths in dual ways – (i) ensure digital dealings on BC network, (ii) via consensus, events are safe in database, without modification.	Narrow awareness/knowledge of blockchain technology and need to create a line of research to confirm scalable, adaptable, and securable to back missions in air, space, and cyber domains.
10.	[26] (2018)	Electric Vehicles, Cloud and Edge Computing Security	Public & Private	Built on distributed consensus, BC-inspired data coins and energy coins are suggested where data contribution occurrence and energy contribution volume are applied to triumph the proof of work with security results for vehicular exchanges.	Proof grit via data contribution occurrence and energy contribution amounts can stance challenge and reply due to secret data transmission via sensors. EV and sensors will be charged by wired and wireless skill and trading coins can be risky.

VII. CONCLUSION AND FUTURE SCOPE

We have presented a comprehensive survey of how blockchain technology can be useful to provide security over the web/internet and can be used to counter ongoing cyber threats as well as increasing cybercrimes and cyber-attacks. We have summarized the recent blockchain models and architectures used for cyber defense and cybersecurity. Various countermeasures and cyber defense techniques from "prevention of data tampering" to "detecting internet delivery" have been analyzed and discussed. We conclude that blockchain technology can have several advantages over cybersecurity and cyber defense with various security aspects like traceability, encryption, transparency, data security, unchangeable transactions, fraud prevention, no single point failure, and no setup/maintenance of hardware/software etc. We also pointed out several challenges and solutions (blockchain-based), with particular blockchain types like public, private, hybrid, and consortium Blockchain that can act as recommendations for improvement on integrating blockchain with cyber defense and cybersecurity.

There is no doubt that Blockchain technology has already been used in many fields, especially finance, supply chain, digital advertising, IoT Security, and many more. Due to its unique properties, the scope of blockchain technology in the zone of cybersecurity and cyber defense can be revolutionary. Despite its open and public nature, data can be verified and encrypted using the most secure cryptographic technology which makes the authorization access of data or information impossible. The key strength of blockchain technology is decentralization property that highly increases the capabilities of the system in making security decisions of its own. The technology is most likely to be used in IoT and Networking Security, Secure Data Transmission, Securing DNS, Securing Data Storage, Verification of Cyber-Physical Infrastructure, and many more.

AUTHORS' PROFILE

Dr. Naresh Kshetri (Member, IEEE) is currently an Assistant Professor of Cyber Security at Lindenwood University, USA. He completed his Master of Computer Applications (MCA) from University of Allahabad, MS (Cybersecurity) from Webster University, and PhD (CS) from the University of Missouri–St. Louis (UMSL), Missouri, USA. He also worked as a graduate teaching assistant/graduate research assistant for the computer science department, UMSL besides working as an Adjunct Instructor (CS) at Lindenwood University. With nine+ years of experience in teaching and research, he has a total of eight publications *(all as first author)* in reputed journals, conferences/book chapters. His current research interests include blockchain technology and cybersecurity. For more about Dr. Kshetri, please visit: https://sites.google.com/view/nareshkshetri.

Chandra Sekhar Bhushal is a Master graduate from Federation University, Australia majoring in Software Engineering in the year 2020. He has also completed a Master of Computer Application (MCA) from Visvesvaraya Technological University (VTU), India (2015). He has 1.5 years of experience in teaching. He has a total of three publications in the International Journal. His current research interests include information security, social engineering, cybersecurity and blockchain technology.

Dr. Purnendu Shekhar Pandey has done his Ph.D. from IIIT-A (Indian Institut e of Information Technology, Allahabad) in Information Technology. He worked in various Government and private institutions. Presently he is working as an Associate Professor in the Department of Computer Science & Engineering, KIET, Group of Institutions, Ghaziabad, U.P. His areas of research are mainly in the field of IoT, Machine Learning, Cyber-Security, Sensor Networks, Network Coding, D2D assisted Networks, etc. He has published various papers in SCI and ESCI Journals, top-notch conferences like ANTS, FRUCT, NOPE, and CCNC (h-index> 25), and reviewer in various peer-reviewed SCI journals. He has given various talks on IoT and discrete process modeling, machine learning in industrial IoT, etc. in various national and international conferences and has hosted various session chairs at various international conferences.

Vasudha is currently working as an Assistant Professor in the Computer Science Department at United Institute of Management Naini, Prayagraj, Uttar Pradesh (India). She has done MTech (Computer Science and Engineering) from Dr. A.P.J. Abdul Kalam Technical University Lucknow, Uttar Pradesh in the year 2018. S he has also completed Masters in Computer Science (MCA) and Bachelor in Computer Science (BCA) from Integral University, Lucknow (U.P.) in the year 2014 and 2011 respectively. She has published two Conference Proceedings papers conducted by IEEE. Her research area is image processing, database security, cybersecurity and blockchain technology.

Low-rate DDoS attack Detection using Deep Learning for SDN-enabled IoT Networks

Abstract—**Software Defined Networks (SDN) can logically route traffic and utilize underutilized network resources, which has enabled the deployment of SDN-enabled Internet of Things (IoT) architecture in many industrial systems. SDN also removes bottlenecks and helps process IoT data efficiently without overloading the network. An SDN-based IoT in an evolving environment is vulnerable to various types of distributed denial of service (DDoS) attacks. Many research papers focus on high-rate DDoS attacks, while few address low-rate DDoS attacks in SDN-based IoT networks. There's a need to enhance the accuracy of LDDoS attack detection in SDN-based IoT networks and OpenFlow communication channel. In this paper, we propose LDDoS attack detection approach based on deep learning (DL) model that consists of an activation function of the Long-Short Term Memory (LSTM) to detect different types of LDDoS attacks in IoT networks by analyzing the characteristic values of different types of LDDoS attacks and natural traffic, improve the accuracy of LDDoS attack detection, and reduce the malicious traffic flow. The experiment result shows that the model achieved an accuracy of 98.88%. In addition, the model has been tested and validated using benchmark Edge IIoTset dataset which consist of cyber security attacks.**

Keywords—SDN; LDDoS attack; OpenFlow; Deep Learning; Long-Short Term Memory

I. INTRODUCTION

Communication networks have significantly evolved, allowing users to connect with each other anytime, anywhere. The proliferation of various intelligent devices and applications is increasing demand and generating unprecedented traffic [1]. The increasing number of Internet-connected objects has made the IoT an increasingly important topic in recent years, and with the introduction of fifth-generation (5G) mobile networks, data traffic in communication networks is expected to increase by 20% in the next three years. The number of IoT devices will reach five billion by 2025 [2]. The exponential rise of the Internet of Things is driving the development of new advanced services with stricter criteria, including flexible administration and low latency. Emerging technologies such as SDN and Network Function Virtualization (NFV) are fundamental to the subsequent 5G mobile networks [3]. These technologies make the network more versatile in terms of hardware management and control, as more complex algorithms can be employed to administer the network and new features can be introduced with simple software updates. Traditional networks frequently require the deployment of vendor-specific hardware and proprietary software, and closed development, which hinder

the introduction of new protocols and technologies in communication networks [4].

To achieve the integrated success that ensures the availability and high performance of advanced communications networks, advanced mechanisms must be developed to provide an adequate level of security to detect sophisticated cyberattacks. This is a significant challenge because IoT devices can handle sensitive data. Many low-cost commercial devices typically do not support robust security mechanisms, making them targets for various attacks. Although SDN can provide extensive functionality for IoT networks, network utilization efficiency has been improved. However, at the same time, SDN still faces many security challenges, such as DoS/DDoS attacks [5, 6], link failure [7, 8], switch data leakage [9], and other common attacks in traditional networks [10]. Distributed Denial of Services (DDoS) attacks is a security threat that has plagued the Internet for more than 20 years. It is becoming even more violent as the Internet evolves, such as with the development of IoT and 5G mobile networks. DDoS is a tremendously devastating attack that hackers frequently use to make numerous requests to a target and thwart the system's standard service. The DDoS attacks have developed from essential to high-rate traffic and sensible low-rate flows. As a result, a new evolution of DDoS attack called Low-rate DDoS (LDDoS) has recently emerged [11]. LDDoS attacks are described by low rapidity, persistence, and concealment, making them difficult to detect. The first problem with the current solutions is that the feature selection is not based on IoT networks, as it only relies on sampling the OpenFlow switches as features using the flow table. In this work, the traffic characteristics of IoT devices are targeted, and the features are sampled from the entire network traffic flows by the SDN controller. This improves the detection accuracy and achieves a precise detection effect. The second problem is that the current solutions have low detection accuracy if the type of network traffic varies. In this work, the LSTM activation function proposed to detect different types of LDDoS attacks by analyzing the characteristic values of different types of LDDoS attacks and natural traffic in IoT networks, so the characteristics are used to update the parameters. The sample is richer, which increases the detection rate, improves the accuracy of LDDoS attack detection, and reduces the flow of malicious traffic.

Therefore, this study proposes a DL-based method to detect LDDoS attacks for IoT network-based SDN. The method is based on the knowledge of the traffic of LDDoS

attacks from the IoT networks at the data layer of SDN architecture, including the network devices and the control plane belonging to the SDN controller. This paper makes the following contributions:

- Propose a Deep Learning-based LDDoS attack detection method for IoT networks based on SDN.

- Design and implement an LDDoS attack in an experimental SDN-based IoT environment that includes various IoT devices and OpenFlow messages managed by the SDN controller.

- Apply RNN as a supervised learning technique for the classification task and evaluate the performance of our method using various performance metrics.

The rest of this paper is organized as follows: Section II Related work. Section III presents Background on SDN, IoT, LDDoS, and Deep Learning. Section IV presents the LDDoS attack challenge. Section V describes our proposed model, analyzes and presents the results. Finally, the last section concludes this paper.

II. RELATED WORK

LDDoS attack detection is critical to communications network infrastructure, especially for advanced technologies such as SDN, IoT, and 5G mobile networks [12]. Presently, researchers in academia and industry are developing detecting algorithms to defend against LDDoS attacks. At the current, attack detection approaches are divided into two types: There are both threshold and machine learning-based detection approaches. Threshold detection methods identify one or more traffic indicators, including traffic rate, packet delay, and maximum entropy. When real-time traffic measurements surpass a predetermined threshold, an attack can occur. The burst time is commonly employed as a detection threshold for LDDoS attacks. In the machine learning-based detection methods, a classifier is used to differentiate between abnormalities and regular traffic. In general, these approaches employ machine learning algorithms to construct a classification model containing the features of the attack behavior to detect the attack. For example, W. Zhijun et al. [13], described a protective strategy based on the dynamic deletion of traffic flow rules. They used the LDDoS attack technique on the SDN data layer to improve identification accuracy and provide numerous functionalities based on the Factorization Machine (FM). In [14], L. Yang and H. Zhao, created an SDN framework based on machine learning to identify and prevent LDDoS threats. For the system, they employed two aspects (traffic detection and flow table delivery). To detect the attack traffic, they employed the SVM algorithm and traffic attributes extracted from the flow table's statistical data.

In [15], K. M. Sudar and P. Deepalakshmi propose that their detection system uses four network flow parameters, including the length of the flow, the number of packets, the relative distribution of the packet interval, and the relative distribution of matched bytes. When the module detects an LDDoS attack, it adds information about the attack flow to the blocklist table and alerts the controller to remove a particular

flow from the flow table by entering mitigation rules. However, the characteristics of the behavior of IoT networks based on SDN are different from the characteristics of the usual network based on SDN. For instance, IoT services have a stable temporal foundation and relatively consistent packet data volume, whereas SDNs separate information control and data forwarding. Therefore, attackers can leverage these new characteristics to launch LDDoS assaults that conceal themselves within normal data flows and are difficult to detect with conventional detection methods. For instance, attackers utilize compromised cameras to launch attacks, and the attack flow conceals itself among outgoing video flows. In this work, we solve the limitations of the current solutions, our method is based on sampling the traffic characteristics of IoT devices, and the characteristics are sampled from the entire network traffic flow by the SDN controller to improve the detection accuracy. In addition, we use the LSTM activation function to detect different types of LDDoS attacks by analyzing the characteristic values of different types of LDDoS attacks and natural traffic in IoT networks, so that the characteristics are used to update the parameters. The sample is richer, which increases the detection rate and improves the accuracy of LDDoS attack detection. Our proposed approach to detect LDDoS attacks using a DL-based model classifies traffic in several steps, which are explained in the Proposed Methodology Section.

III. BACKGROUND ON SDN, IOT, LDDOS, AND DEEP LEARNING

This section provides an overview of SDN model, IoT technology, LDDoS attack, and DL techniques; it also illustrates how LDDoS attacks in IoT network-based SDN cause bottlenecks.

A. Software-Defined Network

SDN is a proposed network model that avoids the limitations of existing network infrastructures, separating control data (control plane) from forwarding data (data plane) and breaking the vertical integration of network management using an SDN controller to control a network through a comprehensive view of all network devices, allowing easy control and flexibility in installing network devices from different vendors. Unlike traditional networks that are managed by multiple components, including specialized vendor software and switches that depend on vendor installation mechanisms, which complicates the management of IP networks and results in vendor solutions that often lack flexibility and scalability [16]. The SDN architecture, as shown in Fig. 1 contains three layers: The infrastructure layer, which contains the network devices, the control layer, which maintains the network, and the application layer, which executes the software on the network, are the three layers that make up the OSI model. At the infrastructure layer, network devices such as OpenFlow switches, IoT devices, gateways, etc. In the control plane, the network is logically managed centrally by the SDN controller, using the SDN data plane to make decisions that are made by the control plane in all network devices. The application layer includes network software and SDN applications that perform functions assigned to a network domain, IoT applications, and other

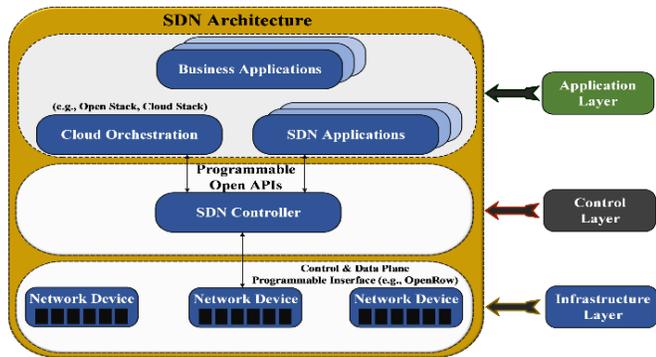
requirements such as cloud storage and client-server connectivity requirements [17].


Fig. 1.   Software Defined Networking Architecture.

B. *Internet of Things (IoT)*

The IoT is a computer term that conveys the idea of numerous physical items connected to the Internet and each device's capacity to recognize other devices. It's worth mentioning that the term "thing" on the Internet of Things refers to more than just inanimate items and tiny gadgets. A person wearing a heart rate monitor, a youngster carrying a tracker, a car outfitted with sensors, lighting systems in homes and retail centers, and so on are examples of "things.". In short, the term covers everything that could come to mind, and there are billions of connected objects in the Internet of Things network, which makes controlling and managing these devices a complex task [18]. Moreover, improving security in the IoT context has become a must [19]. The future IoT architecture must be secure enough to prevent the illegal activation of devices. Moreover, since most devices have limited resources, security techniques must be lightweight. In addition, verifying that data is up to date is critical. The lack of adequate security support in IoT can shake the confidence of IoT users and lead to the failure of the technology [20].

C. *Low-Rate Distributed Denial of Service Attack*

The LDDoS attack is a variant of a DDoS attack. Unlike a traditional flooding DDoS attack which requires a huge amount of resources to launch a successful attack by sending large data flows from infected hosts to the target element in the network [21]. LDDoS attack sends a small amount of malicious traffic, representing 20% or less of network traffic. Therefore, it does not show an apparent statistical anomaly to network monitors during the attack. LDDoS attack is hidden in the normal traffic flow and can perform a covert attack through slow traffic, so there is no obvious anomaly for network monitoring. Furthermore, [22], offers a thorough analysis of LDDoS attack detection techniques in software-defined networks. Currently, the most advanced detection methods for LDDoS attacks are mainly divided into three categories: Feature detection, frequency-domain detection, and time-domain detection. In feature detection, a feature dataset must be created. The feature record contains the features of the known LDDoS attack, and once the features of

the LDDoS attack are detected, the LDDoS attack flow is evaluated. In frequency domain detection, the multifractal features of the data flow in the frequency domain are used, and the change conditions in the frequency domain are examined by methods such as spectral analysis, wavelet transform, etc., to detect the LDDoS attack. In time-domain detection, algorithms such as autocorrelation, etc., are used to determine whether the attack flow is present or not by comparing the calculated value with a static threshold [23].

D. *Deep Learning*

Deep Learning (DL) is a subfield of machine learning concerned with discovering ideas and algorithms that enable a computer to learn autonomously by stimulating human neurons. Deep Learning is a science that focuses on the development of methods to obtain a high level of abstraction by studying a huge data set including linear and nonlinear variables. Numerous disciplines, such as speech recognition, face recognition, computer vision, and natural language processing have made substantial, rapid, and applicable strides due to this field's discoveries. The system learns from massive amounts of data using multiple deep learning network architectures, including Recurrent Networks (RNNs) commonly used with text and continuous data, Convolutional Neural Networks (CNNs) guided by biological processes in the visual center, and others capable of extracting raw data features without human intervention. It can meet the high-performance rate by automatically finding the correlation of the raw data by training the model and displaying the results [24]. Moreover [25], provide a comprehensive review based on deep learning capability, approaches for IoT security. To address the current security and privacy issues such as intrusion detection systems (IDS) within IoT environment. Deep learning approaches generally contain a deep structure of hidden layers as shown in Fig. 2. It relies on abstractions and on automatic learning of features that provide facilities for modularization and transfer of learning.

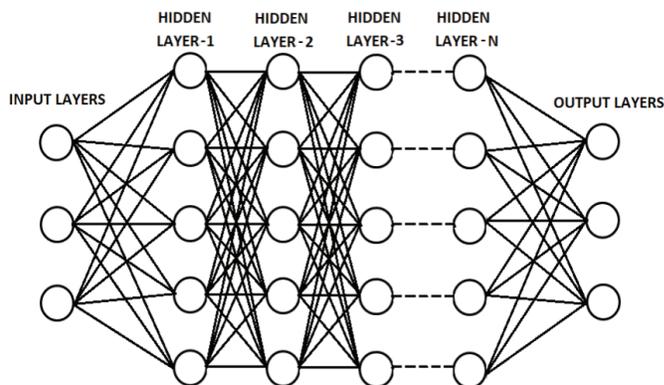
The RNN method is utilized to choose the essential features and then provides the best data classification. As a result, we have used RNN as a supervised learning technique for network traffic classification to distinguish LDDoS traffic from regular traffic.


Fig. 2.   Overview of Deep Learning Architecture.

IV. PROPOSED METHODOLOGY

A. SDN-based LDDoS Attack in IoT Networks

In SDN architecture, the infrastructure layer and its communication channel to the controller are most vulnerable to LDDoS threats in an SDN-based IoT network. The infrastructure layer consists of SDN forwarding devices, such as "OpenFlow switches, IoT gateways, and access points; the SDN device can be (re)configured for multiple reasons, including traffic separation, data path modification, and device virtualization". Forwarding rules are recorded in the flow table of a switch and govern the data forwarding path. The controller is accountable for receiving data forwarding requests and giving switch flow rules. SDN apps are responsible for starting data layer configuration instructions by calling controller-integrated functionalities. IoT gateways connect IoT devices using various protocols (WiFi, Bluetooth, ZigBee, etc.) and transmit the collected data to other network devices like switches and routers. Some IoT devices, such as WiFi-based cameras and sensors, can transfer data directly to other network devices by connecting to a WiFi access point without an IoT gateway [26].

In the SDN switches, the idle timeout for the input is the maximum amount of time the flow input can be mismatched. If there is no matching packet in the flow rule within this time, it is automatically discarded. Thus, an LDDoS attack can occur if the transmission rate remains constant and the inverse of the idle time is assured, as is the presence of the input flow and OpenFlow switch. The LDDoS attack target SDN switch, and control channel are seen in Fig. 3; when the capacity of the switch's flow table is complete, it can no longer install new flow rules and will not forward new packets. The number of low-rate attack flows grows in a linear fashion. If the attacker transmits 5 malicious packets during the first idle timeout interval, 10 flow rules are formed in the flow table at the same time. The attack packet is transmitted at regular intervals in the second idle timeout interval to ensure that the flow rules in the flow table do not disappear, but 5 attack packets are added concurrently. The flow table currently contains 20 flow bases. The flow rules will gradually increase as the attack continues until the flow table is saturated.

The data generated by IoT devices can be divided into two types: small data packets generated by sensors in vehicles, houses, etc., and large data packets generated by video display devices from surveillance cameras, among others. The infrastructure layer of the SDN presents these kinds of data packets as ordinary data flows. These two types of devices allow attackers to configure diverse LDDoS attack packets. Such as, they can utilize webcams to send high-volume malicious packets to overwhelm the target and, use IoT sensors to launch malicious volume packets to overwhelm the target or use a combination of both to launch a hybrid attack. For instant, attackers can utilize webcams to send large amounts of malicious traffic or IoT sensors to generate small amounts of malicious traffic, often using a combination of the two to launch a hybrid attack that floods the target. During this work, the model was developed to handle traffic from IoT devices that generate traffic and use traffic features to train

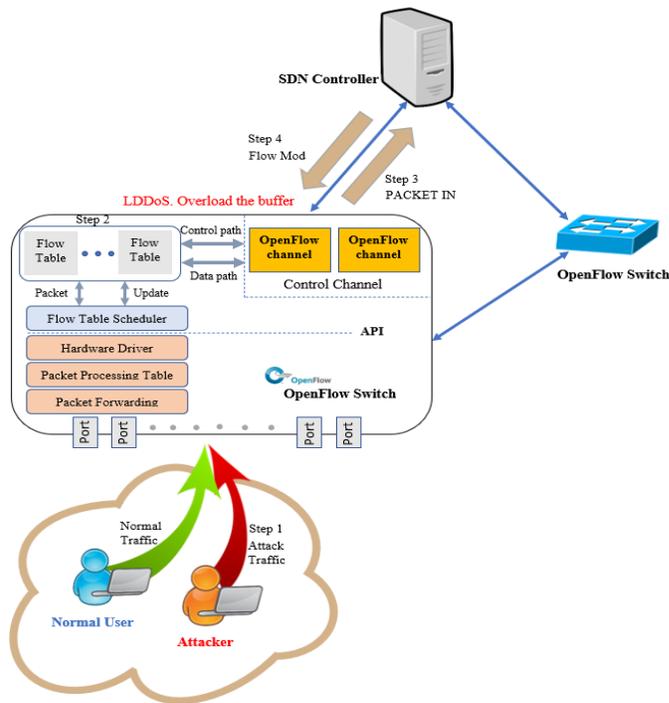
and test the models to present the results presented in the next section.


Fig. 3. LDDoS Attack Scenario Targeting SDN Switch and Control Channel.

B. LDDOS Attack Detection Method

The embodiment of the LDDoS attack detection method is based on RNN Deep Learning, which is used to effectively detect various types of LDDoS attacks for SDN-enabled IoT networks. The proposed method was tested using a comprehensive, realistic cybersecurity dataset for IoT and IIoT applications called Edge-IIoTset, which machine learning-based systems can use to detect intrusions. The Edge-IIoTset dataset is divided into several layers, including the IoT perception layer, the IIoT layer, the software-defined network layer and the network function virtualization layer. These layers leverage new emerging technologies that address the key requirements of IoT and IIoT applications, such as the ONOS SDN controller, Things Board IoT platform, and OPNFV platform. IoT data is generated from more than 10 different IoT devices, such as low-cost ultrasonic sensors, water level detection sensors, Ph sensors, soil moisture sensors, heart rate sensors, flame sensors, and digital temperature sensors for temperature and humidity, etc. In the Edge-IIoTset dataset, various attacks including DDoS attacks were identified and analyzed and extracted their features from various sources including alerts, system resources, logs and network traffic [27].

The sampling data were divided into training (70%) and testing (30%). Learning algorithms learn from current datasets and make informed decisions. The proposed detection method contains six main steps: data collection, data pre-processing, training, and testing data, model evaluation, model Prediction, and decision making. As illustrated in Fig. 4, multiple independent processes make up the proposed detection

method overall. The proposed method is based on Recurrent Neural Networks (RNN), where the model consists of an activation function of the LSTM layer to take time-series data as input and learn how to value time, each step of the method is explained as follows.

- Data collection: The datasets have been collected from Edge-IIoT and consist of cybersecurity attacks, which include DoS/DDoS. In these attack categories, the attackers tend to deny the services of legitimate users, either solely or in a distributed fashion. We look at the four most common methods: the TCP SYN Flood, the UDP Flood, the HTTP Flood, and the ICMP Flood. Also, the quality and variety of legitimate entries in a dataset are important for building a profile of how a system normally works. Additionally, malicious entries are essential for security solutions to recognize not only the precise attack patterns but also to identify new ones.

- Data pre-processing: Any machine learning approach requires exploratory data analysis and data observations, so we first create a data collection that can be fed to any classifier. The procedures involve dealing with the missing data, Colum, which was missing value from Edge-IIoT datasets. Our data reprocessing procedures include converting row data into a clean dataset and removing the missing data (column) that was missing from the Edge-IIoT datasets. Second, the phase will unify the engineering steps required to determine the data feature type among the datasets. The data set included categorical datasets as well as numerical data. It was normalized using min-max data normalization as shown in Eq. 1.

$$\mathbf{x}'_i = \frac{\mathbf{x}_i - min\,\mathbf{x}_i}{max\,\mathbf{x}_i - min\,\mathbf{x}_i} \qquad (1)$$

- LSTM model training: The datasets have been split into training 70% and testing 30%. The proposed LSTM model which has been calculated for 30 epochs using training and validation of Edge-IIoT datasets. The model parameter and calculation in percentage is an interpretable way to determine the model performance. The LSTM model has been optimized using Adam optimizer with a learning rate 0.03. The dropout method with a probability of 0.5 has been used to prevent the model from over fitting. Therefore, the proposed LSTM model attempts to sequence-dependent behaviour such as LDDoS attacks detection in network traffic known as IDS. This is performed by feeding back the output of a neural network layer at time T to the input of some layer at time T + 1. Moreover, we used deep learning solution based on LSTM for LDDoS attack detection in SDN enabled IoT networks due to its high efficiency of network data flow.

- Evaluation Metrics: accuracy (ACC) has been used for evaluation measure in this research. The classification models can be evaluated on a variety of parameters, including their accuracy. It depicts its single-class accuracy measurement. Accuracy will also be given by

the total number of predictions made by the primary performance metric used in the behaviour recognition domain that measures different values predicted by a trained model and observed values from the environment. Furthermore, the authors used accuracy for practical decisions and accuracy for model result outcomes in decision-making after training. The accuracy of the proposed LSTM model was determined using Eq. 2.

$$\text{Accuracy} = \frac{(tp + tn)}{(tp + fp + tn + fn)} \qquad (2)$$

where *tp* means true positive, *tn* is a true negative, *fp* denotes false positive, and *fn* is a false negative.

$$\text{Precision} = \frac{tp}{(tp + fp)}, \qquad (3)$$

$$\text{Recall} = \frac{tp}{(tp + fn)}, \qquad (4)$$

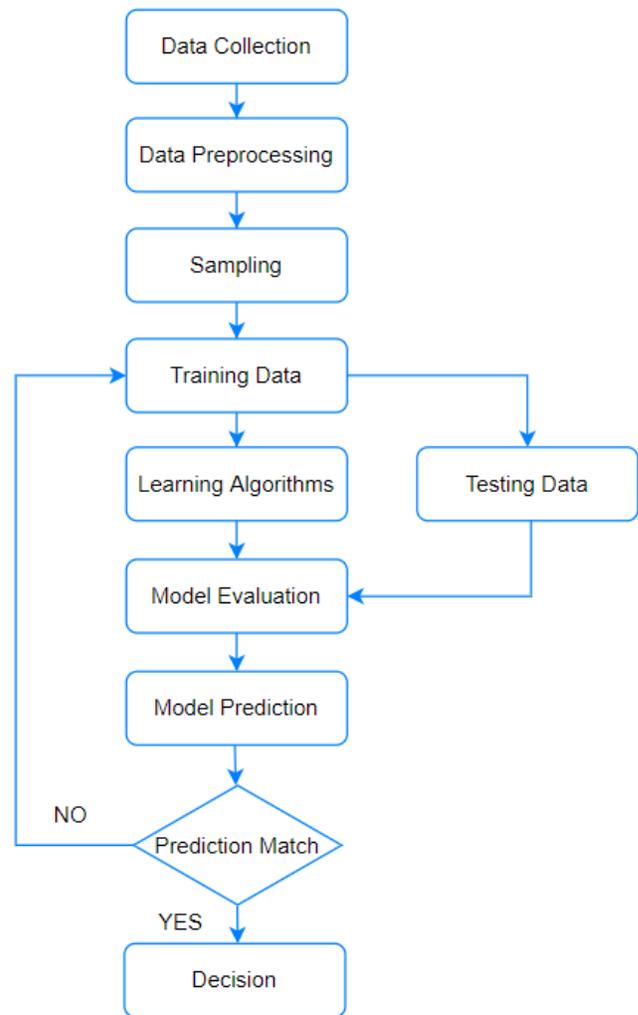
$$\text{F-measure} = \frac{2 \times precision \times recall}{recision + recall}, \qquad (5)$$


Fig. 4. Flowchart of Proposed Method.

V. RESULTS AND DISCUSSION

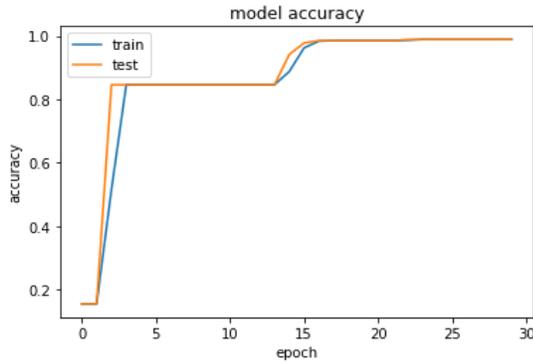
According to training and validation data from industrial Edge-IIoTset datasets in Fig. 5, the proposed RNN model's accuracy has been calculated over 30 iterations. The model parameter and percentage calculation are an easy-to-understand way to measure the model's effectiveness. As the result indicate training accuracy is 98.88%, this result can be used for LDDoS attacks prediction and decision, which determines that there is a significant increase after iterations with fluctuation.


Fig. 5. Training and Validation of Accuracy Performance for 30 Epochs.
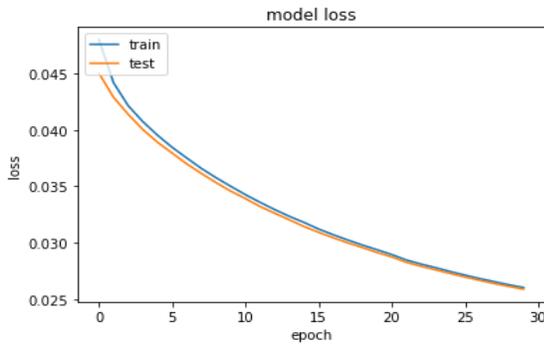

Fig. 6. Training and Validation of Loss Performance for 30 Epochs.

Fig. 6 shows the model's loss performance was also calculated for 30 epochs using training and validation datasets from the industrial Edge-IIoTset dataset. Adding to this, the authors' contribution results show better performance against LDDoS attacks with high accuracy, which was significantly improved after training and testing. Furthermore, the loss parameter calculates training and validation to interpret how the model performance of input datasets. The loss did not increase significantly after iterations but rather decreased. The final loss validation performance was 0.25.

A. Evaluation of Performance

Table I shows the model evaluation measures where the method obtains an accuracy of 98.88% and precision, recall, f1-score of 0.9746, 0.9657, 0.9691, respectively. The obtained performance of the method utilized in this research is presented in Fig. 7, where the model shows a good performance in term of the accuracy and the F1-score.

B. Evaluation Metrics

This section emphasizes o the proposed method performance comparing to the state-of-the-art methods. The proposed LSTM model performance in this work was benchmarked and compared with the related literature contributions with the available performance measures shown in Table II. Our proposed method shows an improvement in the network attack detection accuracy and surpassed other methods exist in the literature review. the proposed method performance outperformed the suggested methods by authors in [13], and authors in [14], as well as the introduced model in the work in [15]. Table II summarize the comparison with related work.

TABLE I. EVALUATION MEASURES OF THE MODEL

Accuracy	Loss rate	Precision	Recall	F1-score
98.88%	0.25	0.9746	0.9657	0.9691

VI. CONCLUSION

To conclude, despite the fact that SDN removes bottlenecks and helps handle IoT data efficiently without overloading the network. However, in an evolving environment, SDN-based IoT is vulnerable to various types of distributed denial of service (DDoS) attacks. Traditional DDoS attack detection methods only allow detection of high-rate DDoS attacks; there are problems with low detection accuracy and poor scalability in the case of low-rate DDoS attacks. Our proposed method based on RNN enables detection that targets various LDDoS attacks in the network and more finely divides the types of LDDoS attacks. Meanwhile, for each type of LDDoS attack, the feature types that are significantly different from the normal data flow are identified by the analysis, and the relevant features of the attack can be described using the feature set. Therefore, the proposed detection model can detect various types of LDDoS attacks with high accuracy, output classification results for detection, improve the extensibility of a detection system, and increase the rate of malicious data flow reduction. According to the analysis of the tests performed, our LSTM model has achieved better results in classifying LDDoS attacks because it achieves a fast training time and the results were measured based on accuracy. The accuracy is 98.8% after the training and validation of the model. Finally, one of the future research directions is to implement bio-inspired metaheuristic optimization techniques and investigates their significance performance in obtaining the optimal hyper-parameters and architecture of DNNs with massive-scale data. The other research direction will be exploring deep reinforcement learning in detecting low-rate DDoS attack in IoT networks.

Abstract—**Forecasting the correct stock price is intriguing and difficult for investors due to its irregular, inherent dynamics, and tricky nature. Convolutional neural networks (CNN) have impressive performance in forecasting stock prices. One of the most crucial tasks when training a CNN on a stock dataset is identifying the optimal hyperparameter that increases accuracy. In this research, we propose the use of the Firefly algorithm to optimize CNN hyperparameters. The hyperparameters for CNN were tuned with the help of Random Search (RS), Particle Swarm Optimization (PSO), and Firefly (FF) algorithms on different epochs, and CNN is trained on selected hyperparameters. Different evaluation metrics are calculated for training and testing datasets. The experimental finding demonstrates that the FF method finds the ideal parameter with a minimal number of fireflies and epochs. The objective function of the optimization technique is to reduce MSE. The PSO method delivers good results with increasing particle counts, while the FF method gives good results with fewer fireflies. In comparison with PSO, the MSE of the FF approach converges with increasing epoch.**

Keywords—Convolutional neural networks; swarm intelligence; random search; particle swarm optimization; firefly

I. INTRODUCTION

The non-linear characteristics of stock market data make it challenging to guess the next movement of stock value. Exact stock forecasting can boost consumer and seller confidence in the stock market, which will attract investors to buy shares and grow the nation's economy [1]. The accuracy of neural networks and their variations in predicting stock prices is rising day by day [2, 3]. Several studies using time-series data have demonstrated that CNN is useful for forecasting issues [4]. CNN can accurately and efficiently identify the changing trend in stock value, and it may be used in other financial transactions. Choosing the best CNN parameters is one of the difficulties we encounter while constructing CNN architectures. The result may vary if we apply different parameter values to CNN architectures while solving the same problem. An optimization process is defined as determining the ideal combination of inputs to reduce or enhance the cost of the objective function without impacting training performance. Optimization is a computational problem whose aim is to extract the best solution among all possible solutions. The hyperparameters that affect CNN's architecture include filters, kernel size, stride, padding, pool size, batch size, epoch, and others. In a reasonable amount of time, we would like to identify the ideal set of hyperparameter values for a particular dataset. To address this issue, several researchers have proposed various techniques based on evolutionary computation to automatically detect the best CNN structures and improve performance [5]. It can be difficult to determine the best parameter in a high-dimensional space.

The procedure used to set the hyper-parameter values is typically a random search, including running a number of tests or making manual adjustments. Random search is the process of selecting and analyzing inputs randomly for the objective function [6]. Swarm intelligence (SI) is inspired by social behavior found in nature, such as the movement of fish and birds. Based on a group's intelligence and behavior, the SI algorithms have a significant ability to determine the optimal solution [7]. The PSO algorithm is considered one of the meta-heuristic evolutionary algorithms. Each particle in PSO has its own position, velocity, and fitness and also keeps track of its best fitness value and best fitness position. The PSO maintains a record of the global best fitness position and the global best fitness value [8]. The FF algorithm is a metaheuristic algorithm based on the attraction of fireflies towards brighter fireflies. The FF algorithm is able to identify optimal parameters for CNN that minimize the error or fitness function with fewer iterations. Each firefly in the FF algorithm has a position in the search space that corresponds to a solution, and it progresses toward more brilliant solutions. For each iteration, the FF algorithm keeps track of the best position, which will reduce the objective function cost [9].

This study evaluates optimization techniques such as RS, PSO, and FF on CNN to forecast stock prices. The Tata Motors stock dataset was taken from Yahoo Finance between January 1, 2003, and September 30, 2022. The CNN is trained on hyperparameter return using RS, PSO, and FF algorithms, and the trained model is used to forecast stock prices for the next day as well as stock prices for the entire month of September. The results show that the FF method returns the best hyperparameters with fewer fireflies, reduces MSE, and requires the fewest training epochs. The remaining paper is structured as follows: In Section II, the stock price forecasting literature is discussed, and the dataset used, the CNN architecture, and different optimization techniques are explained in Section III. The evaluation metrics used and the accuracy of CNN trained on hyperparameter returns by different optimization techniques are discussed in Section IV. We conclude the work in Section V with a summary and recommendations for additional research.

II. Literature Survey

Traditional stock value analysis is based on economics and finance, and it primarily focuses on external factors influencing stock prices, such as international relations, exchange rates, interest rates, business policy, financial institutions, political factors, etc. It's challenging to convince people of the accuracy of the traditional fundamental analysis method. The technical analysis approach primarily concentrates on the movement of the stock price, psychological expectations of investors, trading volume, historical data, etc. [10]. In comparison to other deep learning models, CNN is more accurate and can detect both uptrend and downtrend stock movements [11]. Setting hyperparameters is necessary for CNN implementation, which influences accuracy, learning time, and CNN architecture. The effectiveness of machine learning will be significantly increased if an effective hyperparameter optimization algorithm can be designed to optimize any specific machine learning method. Bayesian optimization based on the Bayesian theorem can be used to solve the hyperparameter tuning problem, as it can be considered an optimization issue [12]. Manual search and RS are the most widely used strategies for hyper-parameter optimization. Randomly searching is more efficient for hyperparameter optimization, where random combinations of hyperparameters are chosen and used to train a model. The hyperparameter combinations with the best costs are selected [13]. Finding the ideal collection of hyperparameter values in a reasonable amount of time is difficult because the values of the hyperparameters change when the dataset changes. The weighted random search approach, which locates the global optimum more quickly than RS, combines RS with a probabilistic greedy heuristic method [14]. Reinforcement learning (RL)-based optimization algorithms give good performance and highly competitive results for CNN hyperparameter tuning with fewer iterations [15].

The hyperparameters include the number of layers, the size of the kernel in each layer, the loss function, the optimizer, and many others. Integers or real numbers may be used as hyperparameters, and there is an infinite range of possible values for each, so CNN hyperparameter tuning is a challenging problem. Swarm intelligence algorithms have been used for decades to solve challenging optimization issues and give promising results [16]. The fish swarm optimization method utilizes a fish's social behavior to carry out a variety of tasks, with each fish serving as a potential solution to the optimization problem. The aquarium is the design space where the fish are found, and the food density is related to an objective function to be optimized [17]. The bee algorithm emulates honey bee foraging activities to find the optimal solution to an optimization issue. The food source or flower is considered a candidate solution, and the population of n bees searches the solution space [18]. Two important parameters of a deep learning network are the number of hidden layers and the number of neurons in each layer. The PSO method has great potential for optimizing parameters and saving precious computational resources when deep learning models are being tuned. Each particle in a PSO has three properties: a position that corresponds to a solution's; a velocity that is a moving parameter; and a fitness value that is calculated by an objective function that takes the particle's position into consideration. The position of every particle in the swarm is updated such that it will migrate toward the one with the best position [19]. One of the most effective metaheuristic algorithms for solving optimization issues is the FF algorithm, which is based on the flashing characteristic of fireflies. The unisex nature of fireflies makes them attracted to brighter lights, and as distance increases, their attractiveness and brightness will decrease [20]. Metaheuristic algorithms, particularly evolutionary and SI algorithms, are strong methods for addressing a wide range of challenging engineering issues that arise in the real world. The echolocation abilities of microbats served as an inspiration for the bat algorithm. Each bat has some position, flying randomly with velocity, fixed frequency, varying wavelength, and loudness in order to search for prey [21]. While training CNN on a stock dataset, it is required to select optimal parameters that improve training performance and reduce error. It is essential to choose the best optimization technique to boost the CNN's performance and reduce errors.

III. Methodology

A. Data Description

From January 1, 2003, until September 30, 2022, historical stock information for Tata Motors was retrieved from Yahoo Finance [22]. Table I shows features and values for Tata Motors stock data. The dataset contains features such as date, open value, low value, close value, high value, volume, and adjacent close value.

It is typical to assess the calculation of profit or loss using the closing price of a stock on a given date; hence, we considered the closing price as the target variable. The plot of the target variable against time is shown in Fig. 1.

B. CNN

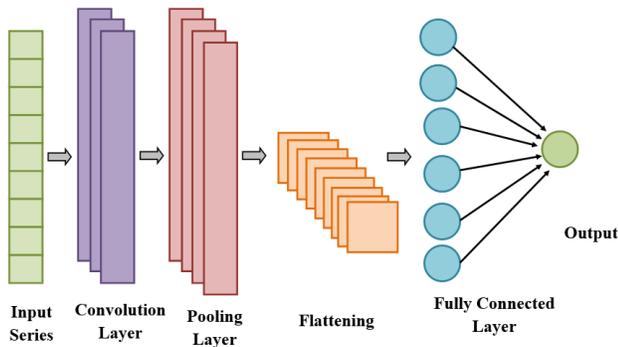
Deep learning is a subset of machine learning that contains algorithms that are designed to mimic how neural networks or the human brain function. CNN, or ConvNets, is one of the models that has significantly impacted image analysis and computer vision. Recently, there has been a rising interest among researchers in using CNNs for time-series forecasting challenges. We could use a CNN model effectively for the prediction issue if we could transform the 1D time-series sequence into an input image matrix structure. Fig. 2 shows the architecture for CNN.


Fig. 2.   CNN Architecture.

The convolution layer, the first layer of the CNN, extracts features from the input by sliding the filter over the input. In order to extract features, CNN uses filter matrices of various sizes that are multiplied by the input matrix. The stride and padding operations influence how the convolution process takes place, resulting in an increase or decrease in the output matrix's dimensions. The size of an output matrix is regulated by CNN using padding, which specifies the number of pixels that are added to an input matrix during the convolution process. The stride, or number of pixels shifted, regulates how the filter convolves across the input matrix. The following formula can be used to calculate the convolution process output matrix size:

$$d = \left(\left(\frac{I - F + 2P}{S} \right) + 1 \right) \tag{1}$$

Where I and F stand for the input and filter matrix dimensions, respectively, S stands for stride, and P stands for padding. The pooling layer's aim is to gradually reduce the spatial dimension of the representation in order to decrease the

number of parameters and calculations in the network by multiplying the resultant matrix from the convolution layer and pooling matrix. The input units are randomly set to zero at a random frequency at each step during training by the dropout layer, which helps in preventing overfitting. The dense layer is a combination of a fully connected layer and an output layer that implements the following operation:

$$O = activation \left((I \cdot K) + bias \right) \tag{2}$$

where 'I' is the input vector, 'K' is a weight matrix generated by the layer, and "bias" is a bias vector generated by the layer. The most frequently used activation functions are tanh, sigmoid, relu, etc.

$$sigmoid\ function\ g(z) = \frac{1}{(1+e^{-z})} \tag{3}$$

$$tanh\ function\ g(z) = \frac{e^{z} - e^{-z}}{e^{z} + e^{-z}} \tag{4}$$

$$relu\ function\ g(z) = max(0, z) \tag{5}$$

C. Random Search

Hyperparameter tuning refers to the building of the model architecture from the available space. Random search is a method for finding the optimal solution to build the model by selecting combinations of the hyperparameters at random or using probability.

$$x^{*} = \arg min_{x \in A} f(x) \tag{6}$$

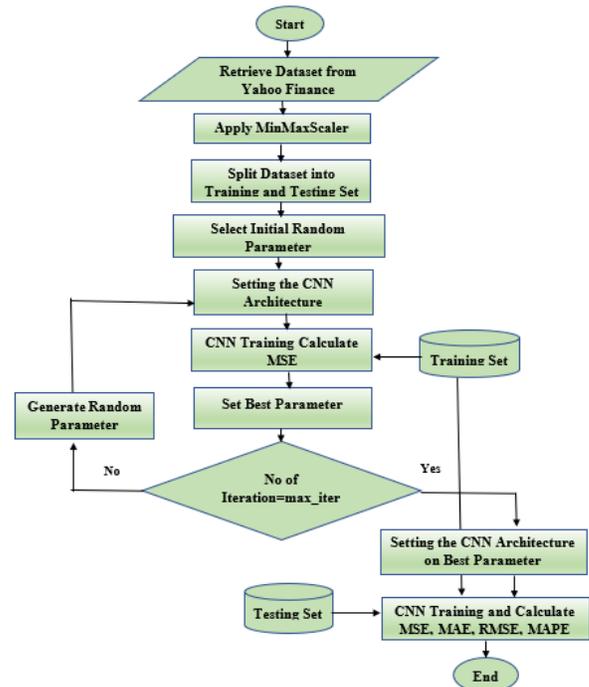
where 'f' is the objective function such as MSE to be minimized on the validation set. 'x*' is the set of hyperparameters for which the objective function returns the lowest value, and any value from the domain 'A' can be assigned to 'x' [23]. The flowchart for RS-CNN is shown in Fig. 3.


Fig. 3.   Flowchart of the RS-CNN Algorithm.

D. PSO Algorithm

The particle swarm optimization technique is inspired by the social behavior of bird swarms and was designed by Kennedy and Eberhart in 1995. PSO simulates swarm behaviors to optimize the way of finding food, and each bird in the swarms constantly changes the search pattern based on its own and other members' learning experiences [24]. The objective function in data science entails feeding a candidate solution into a model and evaluating it against the training dataset. The cost may be an error score, also known as the loss of the model, which is to be decreased, or an accuracy score, which is to be increased. The optimization process aims to increase or decrease the cost of an objective function. There may be multiple local maximums and minimums for objective functions, but only one global maximum or minimum. Each particle in a PSO has a position, which corresponds to the attributes of a solution; a velocity, which is a moving parameter; and a fitness value, which is determined by an objective function taking into account the position of the particle [25]. The particle's quality is measured by its fitness value. Each swarm particle's position is updated such that it will move closer to the one with the best position. Each particle maintains pbest, the best solution each particle independently found, and gbest, the best solution found by all particles, to update its position and velocity in each iteration [26]. The processing steps of the PSO algorithm are mentioned below [27].

Step 1: Generate random position p and velocity v in all dimensions by using the following equation:

$$x_i = l + r * (u - l) \tag{7}$$

$$v_i = l + r * (u - l) \tag{8}$$

x_i represents the position of particle i, r is a random number, l represents the lower bound, and u represents the upper bound. For velocity calculation, the lower bound is 0 and the upper bound is 1.

Step 2: Calculate objective function value $f(x_i)$ for each particle where i=1..n. The initial position of a particle is pbest for that particle, i.e., pbest=x_i.

Step 3: Find gbest i.e., best position from all particle.

Step 4:

For t=1 to max_iterations

    For i= 1 to no_of_particles

        Update particle velocity and position

        Calculate Objective function value and pbest

    End for i

    Find gbest position having less cost

End for t

Equation 9 describes how to calculate particle velocity, and Equation 10 describes how to calculate particle position.

$$V_i^{t+1} = WV_i^t + C_1 r_1^t (P_t^b - X_t) + C_2 r_2^t (P^q - X_t) \tag{9}$$

$$X_i^{t+1} = X_i^t + V_i^{t+1} \tag{10}$$

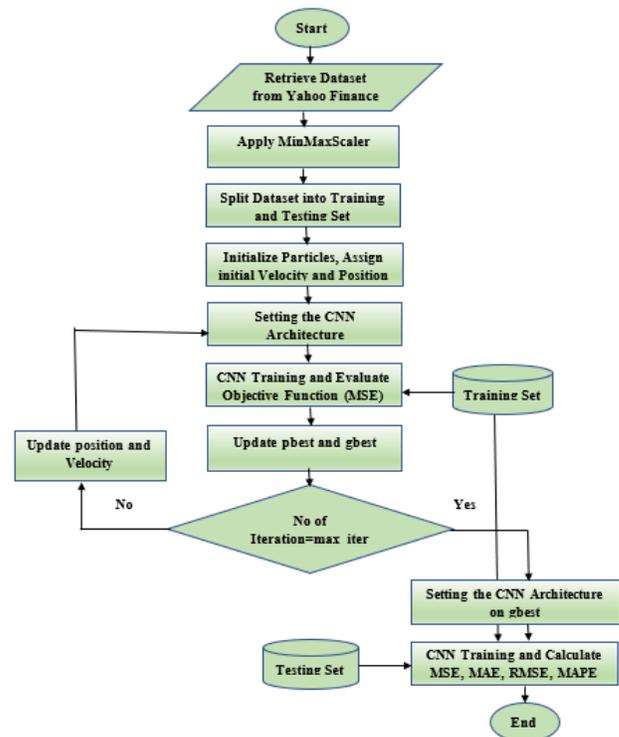
where V_i^{t+1} and X_i^{t+1} are the new calculated velocity and position, t represents the iteration number, V_i^t is the velocity of the ith particle at iteration t, X_i^t is the position of a particle. W is the inertia weight that regulates the motion of the particles. The particle may continue travelling in the same direction if W = 1, because the particle's motion is entirely determined by the preceding motion. if 0≤W<1, this influence is diminished, causing a particle to travel to different areas within the search domain. The C1, C2 are the correlation factors and if C1=C2 =0, all particles continue to move at their current speed until they collide with the search space border. The r_1 and r_2 are the random number in between 0 and 1. The P_t^b is the particle's best position for iteration t and P^q is the global best position. The updated position is used to evaluate the value for the objection function in each iteration. The particle best position (pbest) and global best position (gbest) are updated based on the objective function return value. The best parameters returned by PSO were used to train CNN, and performance was calculated using evaluation metrics. The flowchart for PSO-CNN is shown in Fig. 4.


Fig. 4. Flowchart of the PSO-CNN Algorithm.

E. Firefly Algorithm

An optimization issue is one where an objective function is maximized or minimized by selecting appropriate values from a set of possible values for the variables. This research takes into consideration a minimization problem in which the objective function calculates and returns the difference between the actual and forecasted stock price. The Xin-Shi Yang-developed Firefly Algorithm is a stochastic and metaheuristic optimization algorithm inspired by nature. It was designed to mimic the social behavior of fireflies based on their flashing and attraction properties [28].

Below are the guidelines for the FF optimization algorithm:

- An objective function is used to determine the brilliance of a firefly.

- Any firefly is attracted towards more brilliant fireflies, as all fireflies are unisex, and they will move randomly if there is no brilliant firefly.

- Attractiveness is directly proportional to brilliance, and as distance grows, both attractiveness and brilliance will decrease [29].

In an optimization problem, the objective function accepts input variables and returns costs based on their calculation. By taking into account the optimal parameters, an optimization algorithm aims to reduce or enhance the cost return by the objective function [30]. The processing steps of the firefly algorithm are as below.

Step 1: Generate a random position X in all dimension using Equation 11.

$$X_i = l + r * (u - l) \tag{11}$$

X_i is position of firefly i, r is random number, l is lower bound and u is upper bound.

Step 2: Calculate cost, determined by objective function $f(X_i)$, for each firefly where i=1..n.

Step 3:

For t=1 to max_iterations

    For i= 1 to n

        For j= 1 to n

            If $f(X_i) > f(X_j)$

                Move firefly i towards j in all d dimensions

                Evaluate new position and update cost

            Else

                Move firefly i randomly

            End if

        End for j

    End for i

Find best position having less cost

End for T

The following equation describes how a firefly i will migrate when it encounters a firefly j, which is more illuminated [31].

$$X_i^{t+1} = X_i^t + \beta_0 e^{-\gamma r_{ij}^2} * (X_j^t - X_i^t) + \alpha_t \epsilon_i^t \tag{12}$$

where t is the iteration count, X_i^{t+1} is the new position of the ith firefly, X_i^t is the current position of the ith firefly. The term β_0 and α_t in the equation are the attraction and randomization parameters respectively. The recommended values used in most of the implementation are $\beta_0=1$ and $\alpha \in$ [0, 1] respectively. The term ϵ_i is a random number obtained from a Gaussian or uniform distribution. Theoretically, the light absorption coefficient (γ) varies from 0 to ∞, but in most applications, it frequently ranges from 0.01 to 100. The distance r between fireflies i and j can be calculated using the Euclidean distance formula [32].

$$r_{i,j} = \sqrt{\sum_{k=1}^{d}(X_{i,k} - X_{j,k})^2} \tag{13}$$

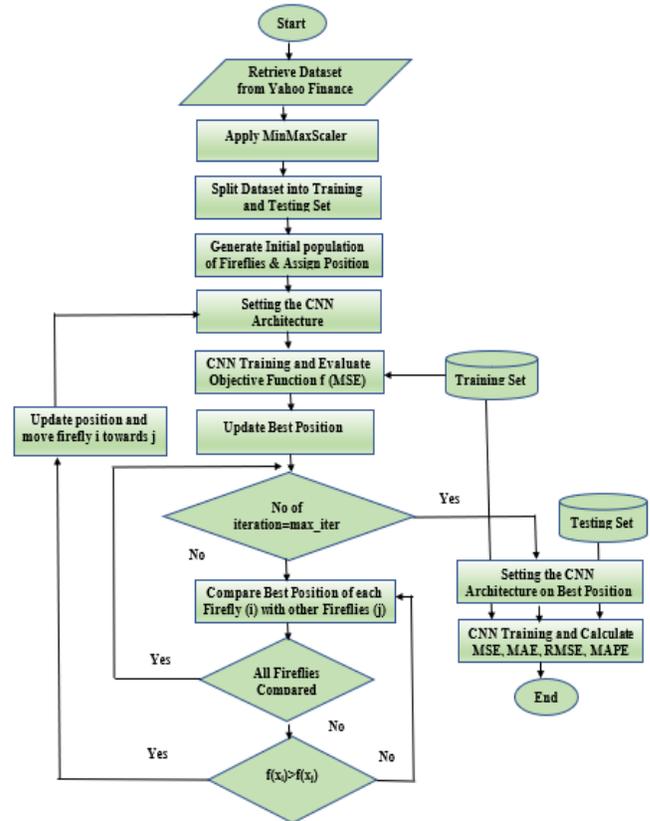
The flowchart for FF-CNN is shown in Fig. 5. Initially, the FF algorithm initializes a population, assigns a random position, and calculates the objective function cost. The initial position of the firefly is the best position. The cost of each firefly is compared with every other firefly in each iteration, and if the cost of firefly i is greater than the cost of firefly j, then firefly i will move towards firefly j. After n iterations, the best positions were used to train CNN, and accuracy on the training and testing datasets was calculated.


Fig. 5. Flowchart of the FF-CNN Algorithm.

IV. RESULTS

The dataset contains 4902 records split into two sets: the training set has 4882 records covering the period from 01/01/2003 to 31/08/2022; and the testing set has 22 records covering the period from 01/09/2022 to 30/09/2022. The CNN models are evaluated for their ability to predict the stock price for the following day and for the entire month of September. Based on the past 1000 samples, the stock price for the following day is computed, and the stock price for the entire month of September is predicted using the entire training set. The assessment metrics should show the difference between the actual and anticipated value in the stock forecasting problem, which is a regression problem. The performance of

the model is evaluated against MSE, MAE, RMSE, and MAPE [33]. The formula for evaluation metrics is as below.

$$Mean\ Square\ Error = \frac{1}{N}\sum_{i=1}^{N}\left(Y_i - \hat{Y}_i\right)^2 \qquad (14)$$

$$Mean\ Absolute\ Error = \frac{1}{N}\sum_{i=1}^{N}\left|Y_i - \hat{Y}_i\right| \qquad (15)$$

$$Root\ Mean\ Square\ Error = \sqrt{\frac{1}{N}\sum_{i=1}^{N}\left(Y_i - \hat{Y}_i\right)^2} \qquad (16)$$

$$\begin{matrix} Mean\ Absolute \\ Percentage\ Error \end{matrix} = \frac{1}{N}\sum_{i=1}^{N}\frac{\left|Y_i - \hat{Y}_i\right|}{Y_i} * 100\% \qquad (17)$$

where N is the total number of samples in the stock dataset, Y_i is the actual stock price, and $\hat{Y}_i$ is the predicted stock price by model. The evaluation metrics shows how forecasted value closer to actual and variation in between them.

The goal of an optimization problem is to identify the optimal solution from a collection of possible options. The parameters for CNN are convolution layer filters, kernel size, pool size in max pooling operation, batch size, etc. If we apply different parameter values to CNN architectures while solving the same problem, the result may vary. Selecting the right hyperparameter gives better accuracy with a minimum epoch. The hyperparameter values returned by the RS, PSO, and FF algorithms were used to train the CNN model. Table II displays the upper and lower bounds for the hyperparameters, and step size is used to increase or decrease their value. Table III provides a summary of the control parameters for the FF and PSO algorithms.

Tables IV and V compare the training and testing performances of CNN, RS-CNN, FF-CNN, and PSO-CNN. The manual hyperparameter was considered while training CNN on different epochs, and resultant metrics were calculated. The number of iterations in the RS-CNN is set to 10, and the current iteration's result is compared to the best one. The FF and PSO algorithms are executed using 5 and 10 particles for different epochs, and CNN is trained using the hyperparameter return from the FF and PSO algorithms. The evaluation metrics for the training set and the testing set are calculated. The objective function for FF and PSO is to reduce MSE. The results reveal that PSO delivers good results with increasing particle counts, while the firefly method gives good results with fewer fireflies. With a large number of particles, the PSO can find the ideal hyperparameter, and the MSE starts decreasing with increasing epoch. In comparison with PSO, the MSE of the FF approach converges with increasing epoch.

The FF-CNN method identifies the ideal parameter with fewer iterations and converges the result with subsequent iterations. This indicates that the FF-CNN strategy has the potential to be more beneficial than CNN, RS-CNN, or PSO-CNN in resolving the stock forecasting problem.

The manual hyperparameter selection method's cost decreases with increasing epoch, while the RS-CNN method's cost varies as parameters are randomly chosen. PSO-CNN requires more particles and epochs, while FF-CNN achieves

better outcomes with fewer fireflies and epochs. If we increase the firefly or epoch, the results converge in the early stages. The evaluation metrics value of a CNN trained on a hyperparameter return by various optimization approaches is shown in Fig. 6 and 7.

TABLE II.   UPPER AND LOWER BOUNDS FOR THE HYPERPARAMETERS

Parameter	Lower Bound	Upper Bound	Step Size
Convolution layer filters	16	128	16
kernel size	1	5	1
pool size	1	5	1
batch size	32	256	32

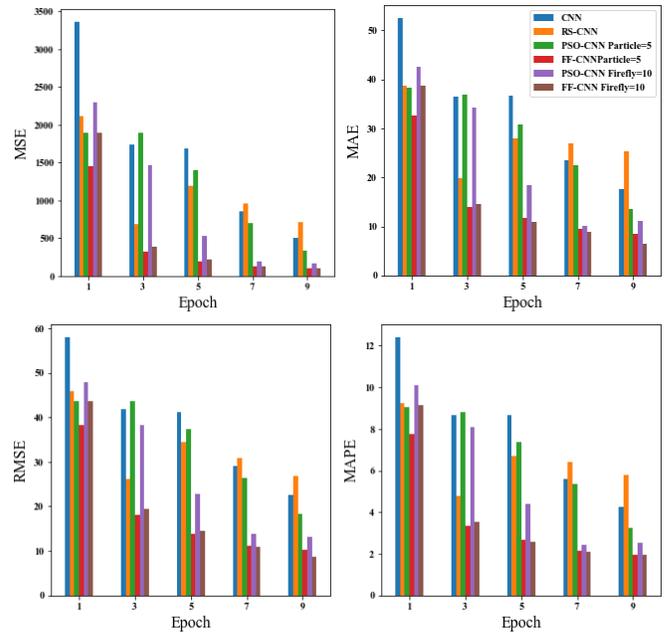
Fig. 6.   Evaluation Metrics for Training Dataset.


Fig. 7.   Evaluation Metrics for Testing Dataset.

The result shows that the FF-CNN technique returns the best hyperparameter for CNN that gives the best accuracy and a low value for evaluation metrics.

V. CONCLUSION

Multiple parameters, including convolution layer filters, kernel size, pool size of the max pooling operation, batch size, etc., must be determined while training a stock dataset using a CNN. The selection of hyperparameters in CNN has an impact on forecasting accuracy. When selecting a hyperparameter, it is essential to apply optimization techniques that reduce the objective function's cost. This research compares manual selection, random search, PSO, and FF optimization algorithms in order to choose the appropriate hyperparameter for training CNN on a stock dataset. The outcome demonstrates that PSO reduces costs as particle size and epoch increase, whereas FF has the ability to accomplish this with lower firefly counts and epoch. Less MSE is given for both the training and testing datasets by the CNN that has been trained on hyperparameter returns by the FF method. The experimental instance reveals that the FF-CNN framework outperformed other state-of-the-art methods in terms of both the quality of the best solutions and the efficient use of computational resources. Future improvements will focus on modifying the FF algorithm to identify the ideal parameter with fewer iterations, and multichannel CNN can boost the accuracy of the algorithm.

Abstract—**Human-robot interaction (HRI) and human-robot collaboration (HRC) has become more popular as the industries are taking initiative to idealize the era of automation and digitalization. Introduction of robots are often considered as a risk due to the fact that robots do not own the intelligent as human does. However, the literature that uses deep learning technologies as the base to improve HRI safety are limited, not to mention transfer learning approach. Hence, this study intended to empirically examine the efficacy of transfer learning approach in human detection task by fine-tuning the SSD models. A custom image dataset is developed by using the surveillance system in TT Vision Holdings Berhad and annotated accordingly. Thereafter, the dataset is partitioned into the train, validation, and test set by a ratio of 70:20:10. The learning behaviour of the models was monitored throughout the fine-tuning process via total loss graph. The result reveals that the SSD fine-tuned model with MobileNetV1 achieved 87.20% test AP, which is 6.1% higher than the SSD fine-tuned model with MobileNetV2. As a trade-off, the SSD fine-tuned model with MobileNetV1 attained 46.2 ms inference time on RTX 3070, which is 9.6 ms slower as compared to SSD fine-tuned model with MobileNetV2. Taking test AP as the key metric, SSD fine-tuned model with MobileNetV1 is considered as the best fine-tuned model in this study. In conclusion, it has shown that the transfer learning approach within the deep learning domain can help to protect human from the risk by detecting human at the first place.**

Keywords—*Human detection; deep learning; transfer learning; SSD; fine-tuning; human-robot interactions*

I. Introduction

Robotics and automation systems has become a key technology that can help in creating an idealistic future [1]. According to the worldwide trend, it is reported that although the deployment of concepts related to human-robot collaboration (HRC) and human-robot interaction (HRI) has increase progressively, yet it shows that the adoption of the market on these concepts is still in the early stage [2]. As much as the HRI concepts are concerned, the introduction of robots can be a stumbling block to the industries as it possesses potential risks to the human workers when it comes to sharing of working space between the robots and the human

workers [3]. Perhaps, both human workers and robots must ensure appropriate communication to promote safe collaboration [4].

Insufficient safety devices can be the most remarkable barrier in forming the trust of HRI concept [5]. It has been found out that the occupational safety has ranked as the most important factor in bringing successful HRI applications. Enormous amount of research has been carried out to improve the safety of HRI [6]–[8]. In light of this, the major safety mechanisms can be generally categorized into four senses, which are vision, tactile, audition and distance [9]. It is noted that even though vision-based sensor seems to be the trickiest and most computationally extensive, it is still considered to have the most unique sense owing to its irreplaceable richness of the features extracted from this sense. With that in mind, vision-based sensors were incorporated in the present study.

Recent advances in deep learning and transfer learning have garnered great success in various domains [10]–[12]. In particular to HRI applications, limited number of studies has exploited on the usage of deep learning in ensuring a safe interaction and collaboration, not to mention about using transfer learning approach. Within this context, this study intended to examine the applicability of deep learning-based object detection approach via transfer learning approach to detect human at the first place and evaluate on the performance of such approach.

II. Related Works

Mohammed et al. [13] presented a novel online collision avoidance approach that only relies on inputs from Microsoft Kinect sensors. The depth images were used with the background subtraction approach to obtain the virtual model of the human operators. Distance between human operators and the robot was then computed for the collision detection based on a threshold value. Instead of solely rely on the Microsoft Kinect sensors, Magrini et al. [14] established a layered control architecture to improve the safety of HRC applications by integrating multiple sensors and controllers. Microsoft Kinects sensors were utilized to compute the

*Corresponding Author.

distance between two parties while laser scanners were deployed to ensure in which area the human worker is located. Both studies used dual-camera settings as to obtain the depth information of the workers as well as to detect the presence of the human operators within the robot cell.

A study has claimed that it is the first time a deep neural network is utilized for developing a real-time collision detection system and solid results are yielded with a highly satisfied detection speed [15]. Joint signals were used as the input of the training of the deep neural networks. The authors highlighted that the study is limited to cyclic motion due to the fact that cycle-normalization technique is applied. Another study integrated both tactile and visual perception for safety purposes [16]. 1D-CNN was used for the physical contact detection while 3D-CNN was meant for the visual perception to perform human action recognition. Joint signals and images are used as the input for the networks, respectively.

As for the advance of deep learning, transfer learning seems to be a favourable approach in different research fields. The effectiveness of transfer learning approach are investigated to extract the wink-based EEG signals that is converted by means of continuous wavelet transform (CWT) method [17]. The findings were prominent which can potentially be used for controlling the rehabilitation devices. A deep learning-based pre-trained object detection model were adopted in the research with huge amount of data to diagnose the rice leaf disease in a real-time manner [12]. The results further justify the applicability of deep learning technologies, might as well for the transfer learning approach in yielding promising results across different domain.

III. METHODOLOGY

In this section, a general description of the overall research workflow is provided. First, the image acquisition process is explained and the dataset that is used in this work is reported, followed by the image annotation stage. Next, appropriate files are generated for training the models under specific deep learning framework. The training strategies and procedures are then clarified and visualized in a flowchart for better glance of the process. Lastly, the performance metrics that is used to evaluate the performance of the models are described.

A. Image Acquisition

The surveillance cameras that are mounted in TT Vision Holdings Berhad were used to acquire the image dataset. In particular, the recorded video footages were obtained from the surveillance database to extract relevant images. Since it is always beneficial to introduce variation to the deep learning models, the location of the surveillance cameras was carefully chosen. Among all the surveillance cameras, it was observed that the people working in the production area will have higher possibility of moving around compared to the office due to their work nature. Therefore, only the surveillance cameras that are in the production area were selected.

In total, 1463 images were acquired from the recorded video footages. Example of the obtained images was depicted in Fig. 1. In compliance to the standard data splitting procedure, the dataset was separated into three portions, which are training, validation, and testing. The ratio of the data

splitting used in this study was set to be 70:20:10. In addition, data augmentation methods such as horizontal flipping and cropping were utilized to further increase the size of the image dataset and allow more variation of the dataset.

Fig. 1. Examples of Training Images.

B. Image Annotation

All the human workers that shown up in the images were annotated manually with a tight bounding box and labelled with the "Person" class name. Not to confuse the model, it is noted that in this study the occluded part of the human workers was not annotated. With respect to the image annotation procedure, a popular image annotation tool known as LabelIMG [18] was used to perform the annotation. The output annotation files with the format of PASCAL VOC were generated after the bounding box annotation.

C. TensorFlow Records (TFRecords) Generation

Throughout the study, TensorFlow is used as the deep learning framework to develop the deep learning-based object detection models. Thus, TFRecords files were required to generate because this is the only format that can be translated by TensorFlow library for loading the datasets. For instance, TFRecord files can be understood as a simple format that stores the dataset as sequence of binary strings for efficiency purposes. A script was used to iterates through all the annotations in the XML files so that the annotations can be converted into TFRecord annotation files. Since TFRecords only stores binary strings, the label class are stored in binary value and a label map is required for the annotations to have a reference on the class name. For this reason, a one-class label map was developed for mapping the class integer presented in the TFRecords file and the class name.

D. Transfer Learning: Fine-tuning

An open-source deep learning framework that is developed on top of TensorFlow known as TensorFlow Object Detection API was leveraged since it can be considered as a ready to use toolkit in developing, training and inferencing object detection models. Particularly, the Single Shot Multibox Detector (SSD) within the TensorFlow 2 Detection Model Zoo was trained to perform human detection tasks [19]. The meta-architecture of the fine-tuned SSD models is shown in Fig. 2. In this study, both MobileNetV1 and MobileNet V2 that were pretrained on

COCO 2017 dataset were used as the backbone networks [20], [21]. The feature pyramid network was deployed as the neck to extract richer semantic features [22]. Whereas the single shot convolutional prediction head was used correspond to the class prediction and the bounding box regression.

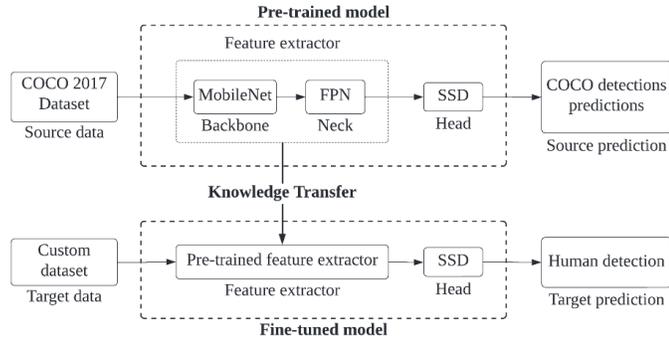
Instead of training the object detection models from scratch, transfer learning approach known as fine-tuning was applied as it is beneficial from the perspective of training time as well as the requirement of a large dataset. By mean of fine-tuning strategy, it is indicated that only the detection head was subject to the training of human detection task, while the backbone network and the neck was remained.


Fig. 2.   Meta-architecture of Fine-tuned SSD Models.

E. Learning Rate and Loss Inspection

Various hyperparameters can be adjusted in order to improve the learning performance of the models. Learning rate acts an important role due to the fact that it can affects the scale of how much the weights are updated within the networks. Instead of using a mere value for the learning rate, this hyperparameter was scheduled via the cosine annealing and warm restart techniques [23]. The motivation behind is to improve the learning behaviour and avoid the occurrence of exploding gradient and vanishing gradient. Both SSD models were configured to undergo a 2.5k warmup steps with learning rate of 0.001. In total, the models were fine-tuned for 100k training steps with learning rate of 0.01.

As for deep learning approaches as well as transfer learning, the learning behaviour has to be monitored throughout the training process. Despite that the scheduling techniques applied can help in improving the model learning, still it is possible for exploding gradient and vanishing gradient to take place. In this sense, loss graphs were utilized to further ensure the learning behaviour of the SSD models goes well throughout the fine-tuning process.

F. Performance Evaluation

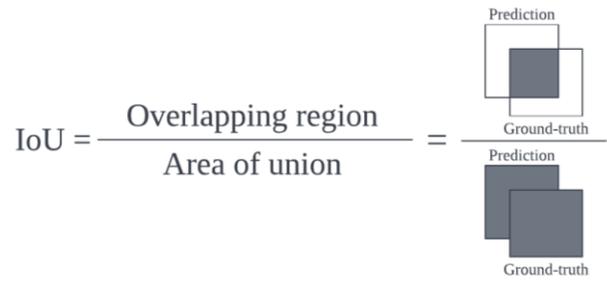
In the field object detection, Average Precision (AP) is commonly used as a standard evaluation metric to evaluate the robustness of an object detection model. With regards to the object detection task, precision is computed based on the Intersection over Union (IoU) threshold. IoU can be defined as the ratio of the overlap area between the predicted bounding box and the ground-truth box to the union area of these two boxes. The concept of IoU is visualized in Fig. 3.


Fig. 3.   Intersection over Union (IoU).

According to the predefined IoU threshold value, the predictions were then be classified as true or false. As such, the IoU threshold value is set to 0.5 in the present study. After the calculation of precision and recall, AP was then calculated by computing the area under the precision-recall curve with the expression as below:

$$AP= \sum_n (Recall_n Recall_{n-1})Precision_n \qquad (1)$$

IV. RESULT AND DISCUSSION

In this section, the results were reported throughout the fine-tuning process. The total loss of the models over the fine-tuning process was visualized and discussed, followed by the performance evaluation of the SSD models after the fine-tuning process. Then, the performance of the SSD models, particularly the AP was reported together with several considerable performance details.

A. Loss Inspection via Loss Graphs

To ensure the fine-tuning of the object detection models are neither underfitting nor overfitting, the learning behaviour of the models were monitored throughout the fine-tuning process via the training and validation loss graph [24], [25]. The training loss and validation loss graphs were plotted as in Fig. 4 and 5. As described in the graph legends, the orange line is the training loss while the grey line is the validation loss. Each of them corresponds to the training set and the validation set of the image dataset.

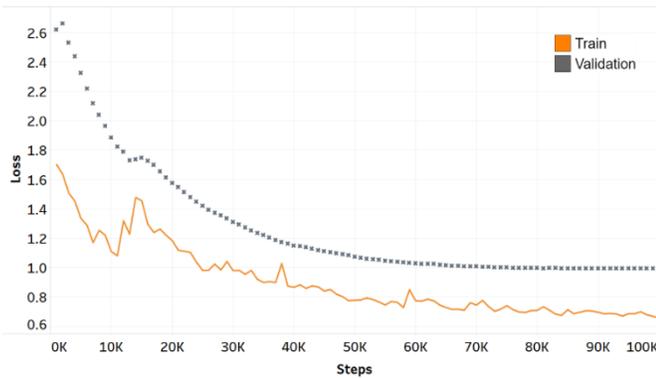
From both learning curves, it can be clearly seen that the training and the validation losses greatly decrease at the beginning and end up converge at the end of the fine-tuning process. It is reasonable for the losses to be high in the initial stage because the knowledge learned from the previous domain is not specifically cater for the human detection task. However, as the training steps increase, the models had learned the important features for the human detection tasks, hence the losses decrease over the iterations. Towards the end of the fine-tuning process, the losses have become more stable suggesting that the models have converge. In addition, it is shown that the validation loss curve stays above the training loss curve for both SSD models, in turn indicates that the fine-tuned models are neither underfitting nor overfitting.


Fig. 4.   Learning Curve of Fine-tuned SSD_MobileNetV1.
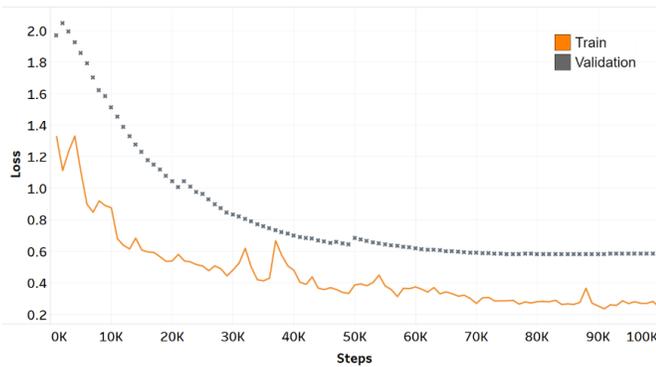

Fig. 5.   Learning Curve of Fine-tuned SSD_MobileNetV2.

B. Performance Evaluation

The AP of the fine-tuned models is depicted as in Fig. 6 and the performance details of the fine-tuned models are tabulated in Table I [26]. The SSD_MobileNetV1 is referring to the SSD model with MobileNetV1 as the base network while SSD_MobileNetV2 is referring to the SSD model with MobileNetV2 as the backbone network. In the performance evaluation stage, the SSD_MobileNetV1 achieves 94.10% train AP, 86.90% validation AP and 87.20% test AP with an inference speed of 46.2 ms. Whereas SSD_MobileNetV2 achieves 89.40% train AP, 82.40% validation AP and 81.10% test AP with an inference speed of 36.6ms. For instance, SSD_MobileNetV1 has a model size of 4.62MB and 10.89 million parameters, while SSD_MobileNetV2 has a model size of 6.46MB and 2.60 million of parameters.

Discussing with regards to the model size and number of parameters, noted that although the SSD_MobileNetV1 fine-tuned model has greater number of parameters than SSD_MobileNetV2, but it has a smaller model size than the SSD_MobileNetV2 fine-tuned model. This is because in the implementation of SSD_MobileNetV2, depthwise separable convolution technique is used for reduction of parameters. Still, the model size is not reduced given the fact the depth of SSD_MobileNetV2 is more than SSD_MobileNetV1.

Despite the comparison of model size and number of parameters, AP and inference speed are the key factors to evaluate the performance of the fine-tuned models. From Fig. 6 and Table I, it can be observed that the

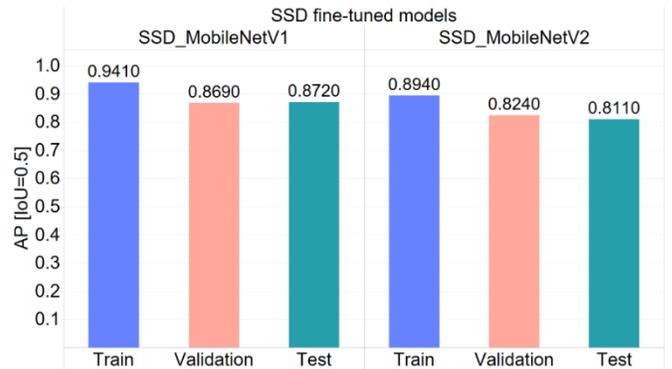
SSD_MobileNetV1 has higher AP for all three train, validation, and test AP with a slower inference speed on RTX 3070 GPU as compared to SSD_MobileNetV2. In fact, the only difference between these two fine-tuned models is the backbone network, hence the differences in AP and inference speed are most probably attributed to the architecture of the base network used in the fine-tuned models [27]–[30]. In a better context, SSD_MobileNetV2 is said to be the recommended fine-tuned model if inference speed comes into consideration before AP. Since this study has considered AP to be more important than inference speed as it is concerned with the HRI safety, SSD_MobileNetV1 is a better choice among these two SSD fine-tuned models. In summary, SSD_MobileNetV1 is proposed as the best fine-tuned model in this case with respect to the human detection task.


Fig. 6.   Average Precision of SSD Fine-tuned Models with Respect to Train, Validation and Test Dataset.

TABLE I.   PERFORMANCE DETAILS OF THE SSD FINE-TUNED MODELS

SSD Fine-Tuned Models	Performance Details		
	Model Size	No. of Parameters	Inference speed
SSD_MobileNetV1	4.62 MB	10.89M	46.2 ms
SSD_MobileNetV2	6.46 MB	2.60M	36.6 ms

V. CONCLUSION

In the present study, the surveillance system was used to acquire the image dataset for human detection task. The human workers presented in the images were annotated with relevant annotation tools. According to the deep learning framework that has been used in this study, the dataset was developed to specific format that suits the framework. The transfer learning strategy called fine-tuning was leveraged to decrease the training time. In particular, the pre-trained weights of the base network were restored, only the prediction head was subjected to the fine-tuning by using the custom dataset. The result has shown that the SSD_MobileNetV1 fine-tuned model has the highest AP with tolerable sacrifice of inference speed.

Data Warehouse Analysis and Design based on Research and Service Standards

Lasmedi Afuan, Nurul Hidayat, Dadang Iskandar, Arief Kelik Nugroho, Bangun Wijayanto, Ana Romadhona Yasifa

Informatics, Engeneering Faculty, Universitas Jenderal Soedirman, Purwokerto, Central Java, Indonesia

Abstract—Data are not easy to organize, especially if the data are big in quantity and stored manually and in a non-computerized way. Therefore, in the last few years, many organizations or companies used information systems to help their activities organize and manage the data. Universitas Jenderal Soedirman (UNSOED) is a state college that has existed for a long time and has many Study Programs and Faculties, including the Faculty of Engineering. Data organization in UNSOED is mainly performed through computerization. However, retrieving data needs to be improved because UNSOED has various information systems, and the data produced keeps increasing over time. The data have yet to be evaluated following the needs of Tri Dharma, with indicators of achievement as expressed in the Regulation of Minister of Education and Culture (PERMENDIKBUD) on the National Standard of Higher Education (SNDIKTI). Data warehouse technology can be applied to storing, collecting, and processing media within a specific time from various data sources. The data processing results in the data warehouse are later displayed using the tools Knowage which may help the executives of the Faculty of Engineering make a decision and monitor the businesses, mainly about research and service, by the society of academicians in the Faculty of Engineering regularly from time to time.

Keywords—Data warehouse; knowage; SNDIKTI; UNSOED

I. INTRODUCTION

In this digital era, any information can be easily acquired by anyone. In this era, data are essential and valuable, and any meaningful information can be retrieved for use from there, especially for organizations or companies that deal with data daily. Important information can be produced if the data in possession are processed appropriately. In addition, past data in possession can provide general and other important information that an organization or company may consider in performing their business.

The urgency of an organization or company's data storing keeps increasing, given that the longer an organization or company has been established or developing, the more data they produce. If the data produced are not well managed or stored, the organization or company will find it difficult to retrieve any critical information that it will take a long time to analyze the data, and applying a data management or storing system to the organization or company will take a long time since the data produced will be abundant and relations between data will be unclear. There will be possible duplicate data, requiring cross-checking for their validity.

UNSOED is one of the State Colleges in Indonesia established in 1963 and today has 12 Faculties, including the Faculty of Engineering consisting of five Study Programs: Electrical Engineering, Civil Engineering, Geological Engineering, Informatics, and Industrial Engineering [1]. The Faculty of Engineering took a long time to establish. This started in 2000 with only the Electrical Engineering and Civil Engineering study programs under the Undergraduate Program of Engineering, and finally, in 2014, the Faculty of Engineering was established [2].

In its implementation, Colleges, Faculties, and Study Programs must follow and comply with the existing standards and regulations issued by the Ministry of Education, Culture, Research, and Technology, including the Regulation of Minister of Education and Culture of the Republic of Indonesia Number 3 of 2020 on the National Standard of Higher Education (SNDIKTI), for Colleges to achieve the quality of learning, research and public service when they have exceeded the criteria defined in the National Standards of Higher Education [3].

Fulfilling the whole conditions or indicators in the SNDIKTI requires various data, especially related to Research and Public Service. In UNSOED, an institution manages the whole Research and Service activities performed by the society of academicians, the Research, and the Public Service Institution. In the data recording process, UNSOED has an information system, SINELITABMAS (Research and Public Service Information System) [4], in which the data are interconnected with other systems, including SIHURA (Human Resources Administration System) and SISTER (Integrated Resources Information System) that contain data of lecturers and educational workers.

The data collection, not only to satisfy SNDIKTI but also to satisfy other standardization such as accreditation or quality assurance, still needs to be done and takes a relatively long time for the UNSOED. The reason is that it has too many information systems. However, the data produced still needs to be evaluated following the needs of Tri Dharma Perguruan Tinggi (three pillars of higher education). Therefore, a working instrument is needed to process and store large-scale data from which a variety of important information can be displayed for the executives' use as an instrument and tool of evaluation in decision making.

By implementing a data warehouse and using Business Intelligent tools of Knowage, any data needed will be accessed more quickly, and they will be interconnected with each other. Besides, since the data warehouse is historical, it can be used in the long run. Previous data can be used for analysis and reporting to help executives in management decision-making.

II. RESEARCH METHOD

This research was conducted in phases by applying the Data Warehouse Life Cycle development method as follows [5]-[10]:

1) Literature study: The initial phase was conducted by learning some literatures such as textbooks and journals on data warehouse and, in addition, learning the content of Regulation of Minister of Education and Culture of the Republic of Indonesia Number 3 of 2020 on the National Standard of Higher Education for indicators to use.

2) Design: The initial process was interview with the executives of the Faculty of Engineering UNSOED to examine the kinds of data in possession and a business analysis on the process of and need for data was conducted, and from results of which, what data and where from the data were to be used were derived, were determined. Besides, database designing started from inter-table scheme, designing of dimension table and fact table along with attributes and sizes.

3) Prototype: This process was conducted using the results of designing and the need for data in the previous phase into data visualization or presentation dashboard designing. The prototype was made to adjust and describe user's needs. In case of shortcoming, developer can return to early phase and return to the prototype phase when added needs have been obtained. Second repetition in this phase can keep occurring until final prototype meets users all needs.

4) Deploy: Data presentation dashboard prototype agreed upon was then built into the environment or the tools of production used. In addition, integrated data processing was also conducted in this phase that completely processed data would be immediately stored into the data warehouse environment built.

5) Operate: In this phase, the data warehouse built was operated and tested. Test was conducted only on the developer part (Black Box Testing) and the operation in this phase could be observing suitability of information displayed, inspecting data processing performed, and other operation.

6) Enhance: In this final phase, some aspects lacking in the previous phases were modified and added covering physical components, operating process and data management, and logical scheme designing. One of the corrections included adding one dimension data with dummy data in order to produce information that was more suitable to the content of SNDIKTI.

III. RESULT AND DISCUSSION

A. Design

The design phase was conducted to examine the data needed for use. In this research, the needed data were collected through learning the document SNDIKTI No. 3 of 2020 and reconstructing the model or determining the format of data to be applied, and interview with the executives of the Faculty of Engineering UNSOED. The result of model reconstruction shown in Table I.

TABLE I. MODEL RECONSTRUCTION BASED ON SNDIKTI

Aspect in SNDIKTI	Description
Research Result	Research result is not confidential, does not disturb and/or does not harm public or national interest, must be disseminated through seminar, publication, patent, and/or other means that can be used to deliver the research results to the public.
Research Funding and Financing	College is obliged to provide fund for internal research and research management fund. Funding can also be derived from the government, cooperation with other domestic of foreign institutions, or fund from the public.

From the results of model reconstruction and interview, database was designed consisting of conceptual design, logical design, and physical design processes.

1) Conceptual design: In this phase, data were determined as needed, from process business identification and determining from which data were to acquire. The result of process business identification and some data mappings conducted can be seen on Table II.

TABLE II. RESULT OF PROCESS BUSINESS IDENTIFICATION

Process Business	Description	Function Involved
Research	Is business process related to research, from registration and submission of research proposal, selection, socialization, monitoring and evaluation, seminar of research results, and research publication.	LPPM
Public Service	Is business process related to service from registration and submission of service proposal, selection, socialization, monitoring and evaluation, seminar of public service results, and service publication.	LPPM

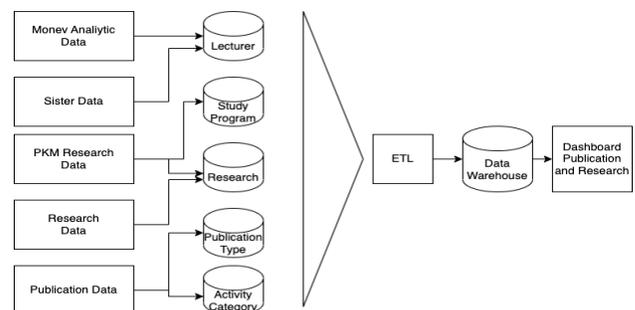
Research data could be acquired from some sources, such as data of lecturers from SISTER (Integrated Resources Information System) and data file analitik monev in which the data were contained in Excel file, data of study program could be generated from file of research data of PKM, research data could be acquired from file of research data of PKM and file of research data, data of types of publication and activity categories could be generated from file of publication data. The Mapping of Data Sources in Research Standards show in Fig. 1.


Fig. 1. Mapping of Data Sources in Research Standards.

After determining business process and data mapping, grains were determined to be fact table. Some grains that could later be taken as fact table shown in Table III.

TABLE III. GRAIN DETERMINATION

Grain	Description	Related Business Process
Research Transaction	Number of researches conducted along with publication and funding received	Research
Service Transaction	Number of public services conducted along with publication and funding received	Public service

The next phase was determining dimensions to be used pursuant to the predetermined grains. The description of dimension table to be made shown in Table IV.

TABLE IV. DIMENSION TABLE DETERMINATION

Dimension	Description	Grain
Lecturer	Data of lecturers were taken from data of SISTER in Excel file and from data of Excel file Analitik Monev	Research and Service Transactions
Researcher's Role	Information of researcher's role from Excel file	Research and Service Transactions
Time	Information of data of time including year, date, month, day, and semester generated from 2016 to present	Research and Service Transactions
Activity Category	Existing activity categories from data of research and service sources	Research and Service Transactions
Study Program	Data of study program	Research and Service Transactions
Type of SKIM	Data of the existing types of SKIM from data of research and service sources	Research and Service Transactions
Type of Publication	Data of the existing types of from data of research and service sources	Research and Service Transactions
Source of Dana	Information of source of fund of each research and service	Research and Service Transactions

After dimensions were determined, fact table was designed along with corresponding content of dimension. The fact table design produced can be seen on Table V.

2) Logical design: In this phase, dimensional modeling was made for dimension tables and facts made. The scheme used was star scheme which was a simple and easy-to-understand scheme. A dimensional modeling with star scheme designed to integrate data in data warehouse are shown in Fig. 2.

3) Physical design: In this phase, all dimension table and fact table designs were analyzed for metadata, covering information on the name of the table, detail of contents of the table such as a primary key or in data warehouse commonly known as a surrogate key, name of the field, type of field, size of the field, and source of data.

TABLE V. FACT TABLE DESIGNING

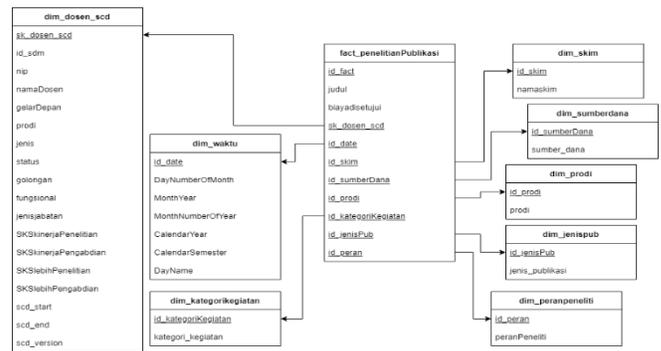
Fact	Description	Content
Fact_penelitianpublikasi	Facts of published research cover number of researches and funding obtained	Judul, biayadisetujui, dim_dosen_scd, dim_peranpeneliti, dim_waktu, dim_kategorikegiatan, dim_prodi, dim_skim, dim_jenispub, dim_sumberdana.
Fact_pengabdian	Facts of published service covers number of researches and amount of funding obtained	Judul, biayadisetujui, dim_dosen_scd, dim_peranpeneliti, dim_waktu, dim_kategorikegiatan, dim_prodi, dim_skim, dim_jenispub, dim_sumberdana.


Fig. 2. Star Schema 'Fact_penelitianPublikasi'.

B. Prototype

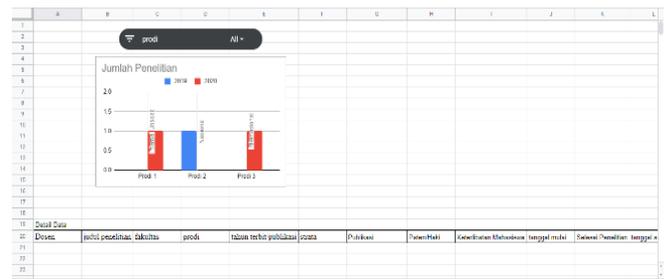
In the prototype phase, the dashboard was designed to depict how data or information was visualized with various graphical forms as needed. This was designed using Google Spreadsheets as the tools of visualization and using some dummy data for graphical display to be easily understood by both developer and executive. Some designs of the dashboard regarding the research are shown in Fig. 3.


Fig. 3. Research Dashboard Design Aspects of Research Results.

Based on the model reconstruction, in the research result aspect, information of publication along with the respective number by study program in certain years could be displayed.

C. Deploy

The next phase was building data warehouse along with data visualization or presentation in the development environment used. In this research, software Talend Open Studio was used as the instrument in building ETL process

and software Knowage as the instrument in building data visualization or presentation.

ETL process started with storing data in source data that would be used in staging area and in this early phase data transformation processing was still not performed [11]. If the whole source data to be used have been stored in staging area, dimension table or fact table could be formed out of the data. Below is ETL process in building dimension table of lecturer:

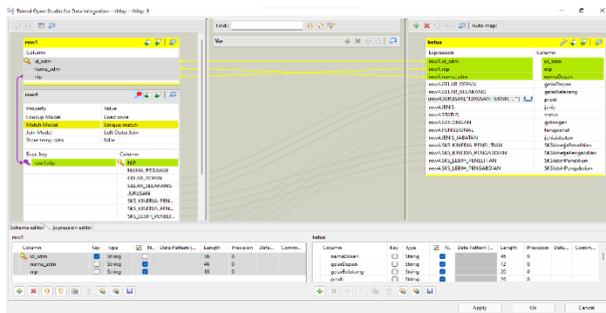
1) Extract: Lecturer data stored were retrieved from data of staging area 'stg_sdm' and 'stg_dosen' in which 'stg_dosen' served as lookup while data 'stg_sdm' served as main data. Out of the two data staging, left outer join was performed on attribute of data with the same value for the data to complete each other (see Fig. 4).


Fig. 4.   Fields or Data Attributes used in Compiling Tables 'dim_dosen_scd'.

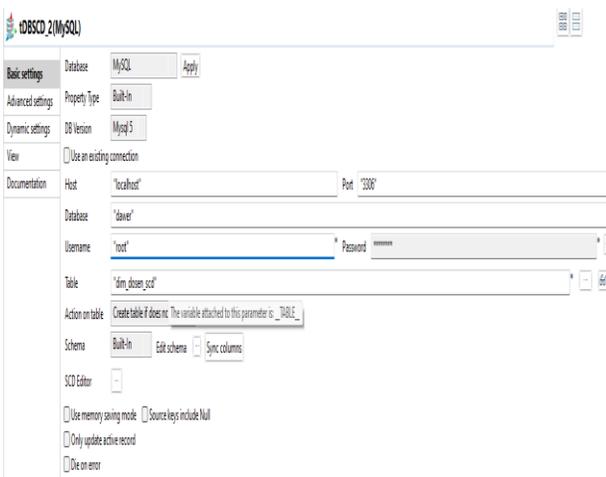
2) Transform: The attributes of data to be stored into lecturer dimension table were selected. The attribute 'JURUSAN' on 'stg_dosen' or on *row4* would be changed for more effective writing pursuant to agreed format. For example, regarding data change, data that were previously 'JURUSAN TEKNIK INFORMATIKA' would be changed and stored into 'INFORMATIKA'. *Loading.* The data were forwarded into target database or database 'dawer' such as the configuration shown in Fig. 5.


Fig. 5.   Output Database Configuration for Lecturer Dimension Table.

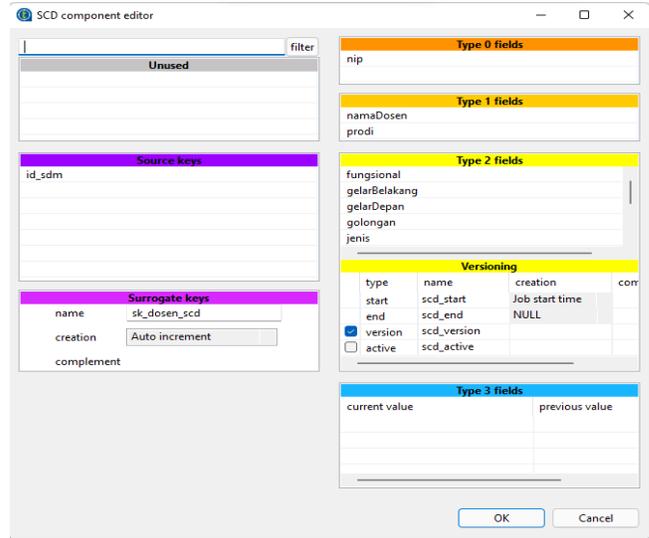
Since dimension table applied SCD concept, further setting was needed on each attribute pursuant to the type of SCD used.


Fig. 6.   SCD Component Settings.

Based on Fig. 6 above, 'id_sdm' was set to be the key attribute on the data source, attribute 'nip' was set to type 0 so that data could not change if the data were input, 'namaDosen' and 'prodi' were set to type 1 thus data change might occur by overwriting previous data. Other attributes were set to type 2 for changes to the other attributes to form a new record in the table. In addition, a key attribute or the surrogate key was needed for each record with setting to auto-increment, and this SCD concept would form additional attributes such as start and end dates record was a valid and higher version of the record equaled the latest, and that would be used in the subsequent data processing.

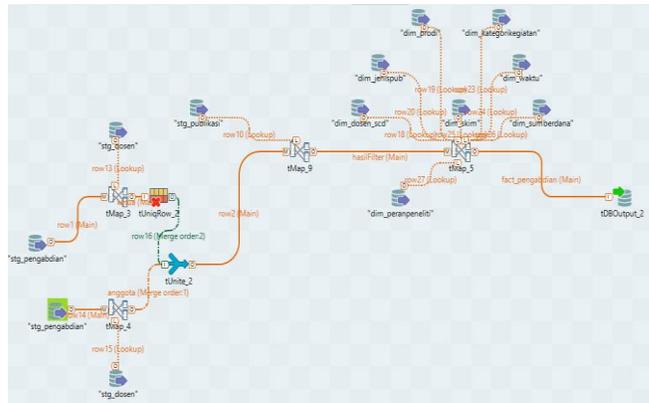
After dimension table was formed, ETL would be performed for fact table [12]-[13], one of which was service fact table are shown in Fig. 7.


Fig. 7.   ETL Process Forming Fact Table 'Fact_pengabdian'.

3) Extract: This phase started with retrieving and selecting data from the staging area of service data, the staging area of the lecturer, and the staging area of publication. Afterward, data from the staging area selected were connected with a dimension table designed in dimensional modeling as lookup for data in the staging area by applying Left Outer Join as a join model.

4) Tranform: 'Datajudul' and 'biayadisetujui' from the staging area and all data of the surrogate key in the dimension table were selected or retrieved for use in the fact table. In addition, in this phase surrogate key was made for the fact table, and the field biayadisetujui was conditioned in case of null data. They would be changed to 0.

5) Loading: Valid data would then be stored in the table 'fact_pengabdian' in dawer database.

The results of ETL processed stored in data warehouse were then connected with Knowage to present data that were processed into the form of dashboard, OLAP, and report. Below are some outputs of data presented made using research data. The result show in Fig. 8 - 11.

Fig. 8.   Presentation of Data in Dashboard Form for Research Data Publications 1.

Fig. 9.   Presentation of Data in Dashboard Form for Research Data Publications 2.

Fig. 10. Data Presentation in OLAP Form for Lecturer Research Financing Data.

Fig. 11. Presentation of Data in the Form of Reports for Lecturer Research and Publication.

All forms of data presented above can be used by the executives to monitor the lecturer's performance of research and publication as needed.

D. Operate

After Data Warehouse and data presentation had been made, a test was performed using Black Box Testing by developer [14]-[15]. The results of black box testing shown in Table VI.

TABLE VI.   RESULTS OF BLACK BOX TESTING

Test Scenario	Test Case	Output	Test Result
Data completeness	Input or load all data from data source into data warehouse	Number of data stored in data warehouse is equal to number of data in data source	Valid
Data transformation	Transform the data and compare data resulted from transformation with data in data source	Value of data resulted from transformation remains valid pursuant to data source	Valid
Data quality	Input false or invalid data into ETL processing	Data are not input into data warehouse and data value was changed to null, 0, or no remark if the data input were empty.	Valid
	Input the same data into ETL processing	Data do not increase and the value of data remains the same	Valid
	Specifically on dimension table of lecturer, data update was performed: 1. NIP update 2. Name update 3. Title update	Data are updated pursuant to the type of SCD applied 1. Data are not updated except data before update were null 2. Data are updated in the record or in the same key 3. Data are updated in the record or in the new key	Valid
Scalability and performance	Perform the whole ETL process	Not take too long time in processing	Valid
	Run dashboard, OLAP, and report	Aggregated data displayed in data presentation are valid	Invalid

Calculation was performed based on the test results in accordance with the number of valid scenarios. The calculation using Eq. (1).

$$evaluation\ result = \frac{Number\ of\ valid\ data}{Total\ test} x\ 100\% \qquad (1)$$

The results of black box testing above shows that data warehouse made shows valid results of 86%, that it was necessary to further correct the testing part with invalidity.

E. Enhance

In this phase, ETL processing and data presentation were corrected pursuant to the test results on previous phase or based on other suggestion. The corrections and additions include:

1) Correct Aggregation Data Displayed in Data Presentation.

2) Add data of Research and Service Technology Readiness Level (TKT).

3) Present TKT data on the dashboard of research publication and service.

4) Correct data presentation in the dashboard regarding number of researches and services by lecturer.

IV. CONCLUSION

Based on the research, data warehouse designing can be performed using the Data Warehouse Life Cycle and through interviews to examine the needed data. The data will be subject to the ETL process for data integration to be presented into the dashboard, OLAP, and report to facilitate the executives in monitoring the performance of research and service by the lecturer in the Faculty of Engineering UNSOED.

Abstract—With the emergence and the movement toward the Internet of Things (IoT), one of the most significant applications that have gained a great deal of concern is smart cities. In smart cities, IoT is leveraged to manage life and services within a minimal, or even no, human intervention. IoT paradigm has created opportunities for a wide variety of cyberattacks to threaten systems and users. Many challenges have been faced in order to encounter IoT cyberattacks, such as the diversity of attacks and the frequent appearance of new attacks. This raises the need for a general and uniform representation of cyberattacks. Ontology proposed in this paper can be used to develop a generalized framework, and to provide a comprehensive study of potential cyberattacks in a smart city system. Ontology can serve in building this intended general framework by developing a description and a knowledge base for cyberattacks as a set of concepts and relation between them. In this article we have proposed an ontology to describe cyberattacks, we have identified the benefits of such ontology, and discussed a case study to show how we can we utilize the proposed ontology to implement a simple intrusion detection system with the assistance of Machine Learning (ML). The ontology is implemented using protégé ontology editor and framework, WEKA is utilized as well to construct the inference rules of the proposed ontology. Results show that intrusion detection system developed using the ontology has shown a good performance in revealing the occurrence of different cyber-attacks, accuracy has reached 97% in detecting cyber-attacks in a smart city system.

Keywords—*Cyberattack; Internet of Things (IoT); ontology; machine learning; intrusion detection system*

I.   INTRODUCTION

The Internet of Things (IoT), defines the large number of devices that can be connected to the internet and perform different types of work. Different devices and sensors can provide our life with digital intelligence, which can serve peoples' needs with minimum or zero human intervention [1]. IoT devices are connected to each other as well as to the internet via a computer network. It is worth mentioning that wireless networks dominate the connectivity between IoT devices which may increases the opportunity for more potential attacks be launched [2].

Features of IoT facilitate the automation of a wide variety of applications and systems, such as health care, homes, traffic lights, and electricity grids to get a smart healthcare, smart home, smart traffic, and smart grids, respectively, as well as many other services and applications. Hence, the majority of recommended services of a city has been automated which creates the concept of a smart city [3]. The concept of a smart city has gained a large concern from governments and business agents as it plays a vital role in the progress and development of the new understanding of civilization in modern countries.

However, security is one of the most prominent challenges when we deal with smart life aspects such as smart cities. This is because developing intrusion detection or prevention systems to secure smart systems is not an easy task, especially with the continuous emergence of new attacks. This raises the need for a uniformed understanding of cyberattacks [4, 5]. The main goal of this uniformed understanding is to develop suitable protection tools for a certain category of attacks, which, at the same time, can protect the system against potential attacks which could appear in the future. Developing an ontology for cyberattacks can provide this formal and uniformed representation, which may provide a general base for a certain category of attacks based on predefined criteria.

Developing an ontology for cyberattacks can also help to understand needed characteristics of a certain system before selecting the protection method. Strictly speaking, different organizations may be interested in different security concepts based on the organizational type and function. A newspaper information system, for example, may consider integrity and authentication of the published news to be of great concern whereas, a healthcare system highly considers confidentiality and privacy of the exchanged patients' information to be essential [6]. By defining the security needs, potential cyberattacks and their impact on the system can be defined and characterized which could play a major role in developing and selecting the suitable protection system.

The contribution of this paper can be summarized with the following points:

1) Proposing an ontology for cyberattacks of smart cities in the context of IoT.

2) Defining the benefits of developing an ontology for cyberattacks from deferent perspectives.

3) Presenting a formal representation and implementation of the proposed ontology using Description Logic and protégé software to conduct reasoning.

4) Using ML as a tool to define the inference rules for the proposed ontology.

5) Using the proposed ontology to pick up the features needed to apply ML.

6) Integrating ML model with the implemented ontology to develop a simple knowledge base for certain attacks.

The rest of this paper is organized as follows. In Section II we present the most important related work. Section III illustrate the followed methodology in conducting this research. A case study is discussed in Section IV which is related to using machine learning to Secure Smart City which also include the conducted experiment and discussed results. We conclude the paper with Section V.

II. RELATED WORK

In cyber-security research area, developing ontologies is not new. A number of approaches have investigated ontology to develop or design a security framework [4]. In this section, we summarize some state-of-the-art research works focusing on the development of ontologies in the context of security and privacy.

Proposed ontologies of cyber-security can be categorized as follows: (1) ontologies that considered information security, (2) ontologies that considered security in IoT, and (3) ontologies that considered security in smart city. Fig. 1 presents the hierarchy of ontologies of cyber-security in state-of-the-art.

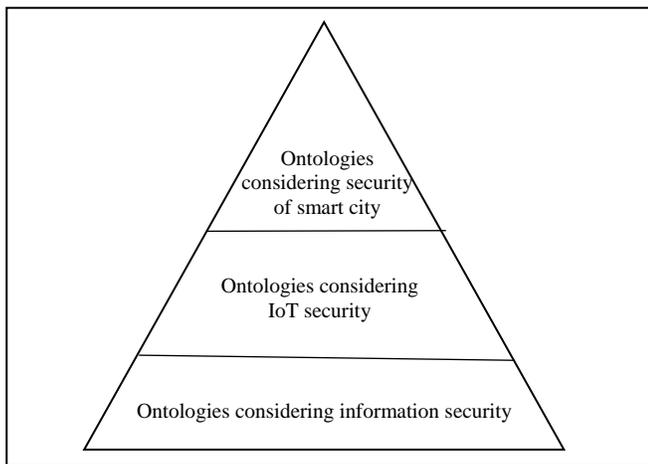
In category (3), authors of [7] and [8] have proposed ECA and OBPP ontologies, respectively. Both ontologies have considered only privacy issues with the use of cloud computing in smart cities. The other security requirements such as availability, integrity and confidentiality are not considered. In [9], authors have focused on setting guidelines to develop a secure and safe smart city system based on using ontologies. Nevertheless, no ontology is provided in the research paper. In [10] authors have proposed an ontology for cyberattacks in a smart city system. The ontology concentrated on securing smart city applications rather than cyber-attacks. Moreover, authors provided a number of use cases with mapping each use case with the proposed ontology with no inference rules to get a benefit from the proposed ontology.


Fig. 1. Hierarchy of Ontologies of Cyber-Security in State-of-the-Art.

In category (2), authors in [11] proposed an ontology to secure an IoT system, the ontology is designed based on analyzing IoT system's vulnerabilities. This work has focused on power-IoT cloud systems which are limited to power issues. Inference rules are set based on vulnerability analysis.

In [12], an ontological analysis has been proposed to enhance security services in IoT systems. The ontology has focused on the system vulnerabilities, potential threats and security needs, it does not elaborate cyber-attacks and their specifications and symptoms.

In [4], the ontology's objective is to create a unified representation for heterogeneous data generated by IoT devices, this work has focused on cyber-attacks and their properties, however, it considers only the general aspects of cyber-attacks. In our proposed ontology, we have concentrated on the cyber-attack properties and their detailed impact on the performance of the network.

In [13] an ontology is proposed to be utilized for higher security improvement in terms of the heterogeneity in the layered cloud platform, the ontological design has focused on the IoT environment and assets such as security devices rather than attack details.

Finally, in category (1), we present a number of these works to illustrate its main structure and focus. In [14] and [15], two cybersecurity ontologies are built by expanding existing ontologies. The main focus of the proposed ontology in [14] is the environment rather than the system itself, and proposed ontology is very general and the main goal is to improve cybersecurity awareness to make suitable decision by providing safe operations rather than detection malicious behavior. In [15], the cybersecurity ontology has concentrated on finding qualification metrics to assess how much a certain system is secure.

In [16] and [17], the main concern of the proposed ontologies is to create an organized schema for cyber information. The goal of using these ontologies is data analysis. While authors of [16] have focused on virus threats and IP and DNS problems, the main focus in [17] is system assets and how to protect these assets.

In [18], authors concentrated in the proposed ontology on data sources and users and potential threats based on these two elements. Rules of ontology are set based on cybersecurity standards and concepts.

Authors of [19] proposed Unified Cybersecurity Ontology (UCO), the main concern of UCO is to identify sources of attacks. Inference is related to derive possible sources of attacks. However, the proposed ontology cannot help to improve security when mapped to IoT. In [20], a cybersecurity ontology is proposed to find guidelines for security measures to protect critical infrastructure, the main focus in this ontology is system assets. Both ontologies in [19] and [20] are customized for specific platforms and to protect simple software. Moreover, most of such ontologies are not suitable on IoT environment according to its specifications and limitation.

Most existing research works are either environment-centric, assets centric, or threats-centric which is opposed to our ontology which is attack-centric scheme. This motivates us to develop Cyber Attack Ontology (CAO) for IoT-based smart city. Moreover, the process of setting inference rules in the previous research works depends on either the analysis of the systems' vulnerabilities and threats, or it depends on user-defined rules. In our approach, we have proposed the use of ML to set inference rules based on the superiority of artificial intelligence and ML in the security during the last years [21][22][23].

III. METHODOLOGY

In this section, we present and discuss the proposed ontology, we then show the steps of utilizing the ontology to identify cyber-attacks. In order to make accurate reasoning to identify cyber-attacks, precise rules must be defined. However, and because there is no scientific base to set the inference rules for our ontology, like those in other scientific fields, we will use ML to set up the rules, definitions of attacks and other concepts included in the proposed ontology, a detailed discussion is represented in the next sections.

A. Cyber-attack Ontology (CAO)

In this section we discuss the proposed ontology which is shown in Appendix A. The ontology graph in Appendix A was depicted using protégé OWL [24]. This plugin represents a visual notation for OWL ontologies and a graphical view for the ontology's classes and relations which are joined together to shape a directed graph layout for the ontology. The proposed ontology includes three main entities, which are adversary, system and cyberattack. The adversary is the person who designs and develops a malware or acts in a malicious behavior to launch a cyberattack. There are numerous types of attackers and there are multiple goals for an attacker to launch an attack. A system is described by a number of concepts such as its functionality, components, security needs, performance aspects and system's vulnerabilities. Fig. 2 shows the classes of the proposed ontology after we have implemented this ontology using protégé OWL. Adversary, Cyber-attack and IoT System present the main classes. They are subclasses of the general built-in class Thing initiated by protégé.

Fig. 2. Classes of Cyber-Attack Ontology in Protégé Owl.

A cyber-attack which is the major entity and the subject of this research connects an adversary with the target system of the attack from multiple perspectives. Examples are that the cyber-attack violates one or more of the security principles of the system, the cyber-attack may disrupt the system's functionality, the cyber-attack may degrade the system's performance (and may not) by exploiting the system's vulnerabilities. The cyber-attack also is characterized by the network type which is corrupted with it, the channel through which it is being launched, the protocol or protocols that have vulnerabilities through which the attack could be launched, the network layer for that attack, and the countermeasure adopted against the attack.

Concepts of CAO are shown in Appendix A along with other considered concepts and features. This ontology could be thought of as a base for a wider ontology, more concepts and relations could be added and investigated.

From the discussed ontology, we notice that we can get the following suggested benefits:

1) Ontology helps to develop a taxonomy for cyber-attacks, any entity in the discussed ontology can be picked up as a classification criterion, for example by the selection of channel entity, cyber-attacks could be classified as software-based attacks, hardware-based attacks and network attacks. If we select access level entity, cyber-attacks could be classified as either passive or active attacks, and so on.

2) Ontology provides a formal and unified description and understanding for cyber-attacks and security needs for IoT environment, especially with the heterogenous nature of IoT devices and IoT systems.

3) Ontology can be utilized to define security needs and the protection method for a certain system, for example, for a smart tourism system, we care about the integrity and availability rather than confidentiality, as tourism information tend to be public [25]. By defining our security needs, we can utilize the ontology by navigating ontology structure from one concept to another to define all related needs, costs and components in order to develop a suitable protection system.

4) From an ontology, we can extract features to apply ML which has got a considerable attention during the last decades for a wide variety of applications and especially in the security field.

5) Ontology enables automated reasoning about cyber-attacks, if we build a strong ontology, reasoning could be used to develop semantic graph database for cyber-attacks and all related characteristics such as effect, cost, and suitable countermeasures.

6) Ontology is easy to be extended or changed because we can add concepts and relationships. So, the proposed ontology can evolve with the emergence of new concepts or when discovering any wrong facts with no impact on the existing systems.

In this work, the intended use of the proposed ontology is to navigate its concepts starting from a pre-specified system. With the target is to construct a model to identify cyber-

attacks of that system using ML. We have conducted a case study to build the model, the case study details along with the model designed are discussed in the next sections.

B. CAO Implementation

In this section, we present the details of Cyber Attack Ontology (CAO) including main classes, sub-classes, properties and other elements of ontology. We have implemented the proposed CAO using protégé tool. Fig. 2 presents the main classes of CAO. We have implemented main classes and sub-classes. Then, we have defined properties of our ontology, which are divided into two types: object properties and data properties. Fig. 3 and Fig. 4 present object properties and data properties, respectively. Fig. 3 shows also a representation of the hierarchy of object property "exploits" which has the domain "cyber-attack" and range "vulnerability".

Data properties relates a class to an attribute data such as "integer"," float", "string", ...etc. Fig. 4 presents a number of data properties in CAO such as traffic_sent which indicates the total number of packets sent through the network during a period of time. Traffic_sent has the domain traffic and the range integer.

Rules of CAO are not defined at this phase as they will be derived at the last step where ML will be utilized to set CAO rules.

Finally, we have shown individuals of the ontology, these individuals represent fundamental components of the ontology and they include concrete instances of ontology. In CAO, for example, sinkhole attack is an instance of a cyber-attack class. Sinkhole attack can be described by multiple properties. In this work, a cyber-attack is described by the network performance resulted by the attack occurrence. The performance is presented by network traffic measurements. For example, sinkhole attack can be described with a certain PDR, delay, overhead, etc. Rules to organize and control these properties will be set using ML at section 4.5.

Fig. 5 presents data properties assertions of class traffic. Network traffic is extracted for a period of time and analyzed, performance metrics values such as packet delivery ratio, number of sent packets, and power consumption are calculated, and the resulted values of these metrics are added as assertions for data properties shown in Fig. 4.

In CAO we have defined each cyber-attacks with a certain traffic specification, or in other words, a traffic with particular values of the aforementioned performance metrics is considered as an attack.

C. Description Logic for CAO

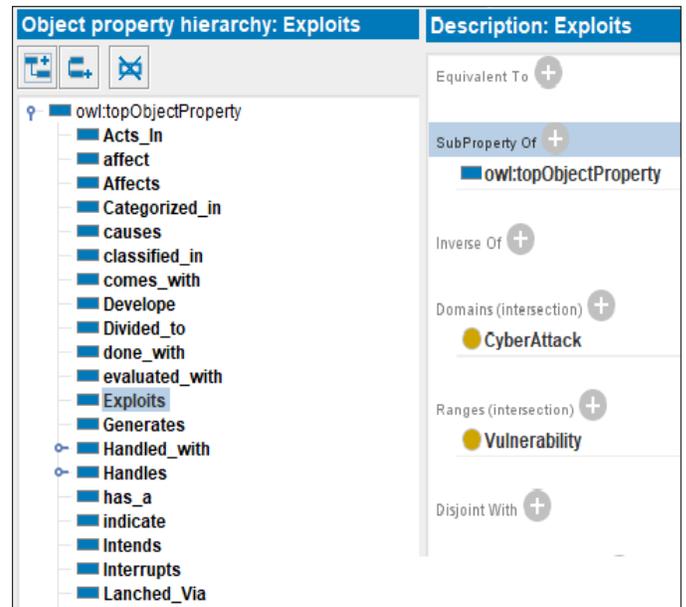
Description logic (DL) is one of the formal languages used for knowledge representation. DL is used in artificial intelligence applications to conduct reasoning from related concepts. In CAO, reasoning is needed to determine if there is an attack or not. In this section we present a number of concepts and relations of our proposed ontology, CAO, using DL. Fig. 6 presents DL for CAO.


Fig. 3. Object Properties of Cyber-Attack Ontology and Object Hierarchy "Exploits".
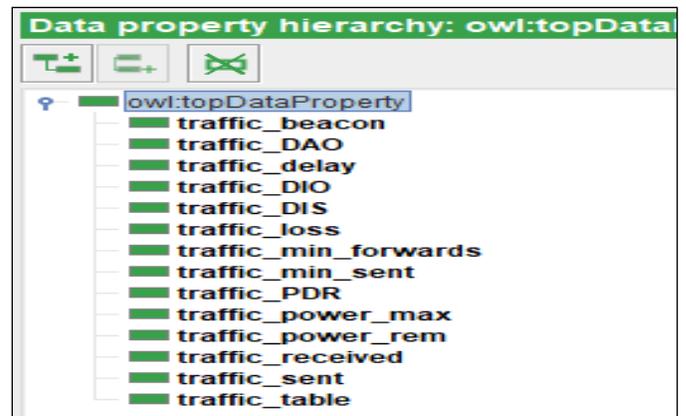

Fig. 4. Data Properties of Cyber-Attack Ontology.

Fig. 5. Data Property Assertions of a Traffic Instance (Traffic_1).

Fig. 6. Description Logic Representing CAO.

D. Ontology to Secure an IoT System

The main utility for cyber-attacks ontology in this work is to design and implement an intrusion detection system to secure a smart city. The first phase of designing any protection mechanism is to study the system to be secured and to highlight the main issues, risks and security needs. We will discuss how to go through these processes using the proposed CAO.

Before proceeding with designing and implementing a security mechanism for a certain system, we have to analyze that system and understand its needs precisely. As we mentioned before, security needs vary from one system to another depending on system's structures and goals. For instance, the most important security needs for a banking system are privacy, confidentiality and integrity, however, a newspaper or tourism systems consider integrity and availability as the most significant requirements to be maintained rather than privacy or confidentiality [25].

Thus, the first step is to determine the most important security needs for the targeted system. Then other elements can be defined in the same way, we can use and track the ontology for a specific system to determine the following proposed elements:

1) The most important security essentials needed to be maintained for the concerned system.

2) The potential domain of a cyber-attack which must be specified carefully. For instance, if computer networks are a potential domain. We have to specify network layer, network protocol and network type whether wired or wireless.

3) Vulnerabilities of the system.

4) The category of the most potential or damaging cyber-attacks that we need to handle.

5) System's components that are exposed to cyber-attacks must be specified, this component could be a computer network, file server, mail server, or any other component.

6) The functionality of each component specified in point number 5 which can be interrupted by a cyber-attack must be also determined.

7) If the performance of the system is of a considerable importance, the performance metrics should be identified.

8) If specifications of the adversary are of a significant importance, then attacker's type and benefit of a cyber-attack

are determined, the tactic of the adversary whether designing a malware or acting in a certain behavior are also specified.

9) Finally, and based on the previous points, we can decide what is the most appropriate countermeasure(s) to be designed to secure the concerned system. These may include intrusion detection system, intrusion prevention system or a mitigation method.

IV. CASE STUDY: ONTOLOGY TO SECURE SMART CITY USING MACHINE LEARNING

Wireless sensor networks (WSNs) play a significant role in smart city services. This is due to the fact that sensors comprise most of monitoring and automation systems which are the backbone of smart cities [26]. Actually, sensor networks are fundamental component in smart grids, home automation systems, traffic systems, health care applications, power system monitoring and many other smart city services. However, sensors are limited and constrained devices in terms of capabilities and resources such as power, processing and storage. This makes it harder to secure a sensor network using the common and traditional security means such as cryptography. More efficient and low-cost methods need to be investigated to secure sensor networks. ML is considered as one of the most suitable candidates in this context. ML can be employed to design an intrusion detection method by training the system to discriminate between normal traffic and traffic of a network under attack [27] [28].

To apply ML, we must have a suitable dataset, in the following subsections, we present the steps by which we use the proposed ontology to create a sample dataset with suitable features. We have opted to extract the dataset from the original network traffic, this traffic is generated from normal operations of the network. Thus, we do not add any additional packets or control message to get features of the dataset, which considers limited power of the sensors, so, we do not add any additional load onto the sensor nodes.

A. Ontology Navigation to Identify Main Entities

We have used CAO to make a decision about the features of the dataset, we have explored the ontology and specified the most significant entities. Phases of exploring the ontology that have been discussed in the previous section are applied to the selected case study. These phases are summarized in the following points:

1) The major security principle to be maintained is the availability of the sensor network.

2) Because network is the most potential domain to launch most cyber-attacks of WSNs. We have to specify network related elements including layer and network protocol through which an attack is launched. We have selected RPL routing protocol for our case study which belongs to network layer. Motives behind the selection of RPL protocol can be summarized in its convenience with the requirements of smart and its properties of self-configuration, self-restoration, and the ability to meet power consumption constraints.

3) The main vulnerabilities of WSNs in the light of sensors limitations and RPL protocol can be summarized as: lack of infrastructure, lightweight protocols which are not supported with security mechanisms, constraint devices where cryptography is not efficient, limited physical security, dynamic topologies, unreliable links, multi-hop transmission paradigm which acts as a helping factor to transmit and spread malicious messages, and finally, the distributed problem handling, which means that a malicious node can select the action of not solving a problem which can simply cause the entire network to be malfunctioning, such as local repair attack[29].

4) The most well-known attacks for sensor network regarding availability are specified. These attacks include sinkhole attack, wormhole attack, sybil attack, rank attack, flooding attack, copycat attack. These types of attacks are categorized within denial of service (DoS) attacks.

5) The system component to be secured is a sensor network which is considered as a vital part of smart city system.

6) The functionality of the sensor network which could be interrupted is the process of data transmission from all sensors to a central point. The role of each sensor is to monitor and record certain data in some location and send the sensed data to a central point (sink). We can explain the functionality as that the sensed data must be received by the sink within a certain period of time and entailed with the original sender.

7) The performance of sensor network is of a significant importance. For example, it is recommended that the transmitted packets are received within an acceptable period of time, which is referenced as delay. Moreover, all packets, or at least a satisfying portion, must be received by the intended receiver, which is commonly defined as packet delivery ratio. Both delay and packet delivery ratio can be considered as performance metrics for sensor networks. The next section describes how we have analyzed selected attacks to address the main performance metrics affected by each attack.

8) Characteristics of the adversary such as its type, benefit, or tactic are not customized in this work, the involved attacks include all these variations.

9) The countermeasure to be designed and implemented is an intrusion detection system that employs ML. The features of the dataset will be selected based on the performance of the sensor network, performance indicators or metrics will be extracted from the network traffic.

B. Impact of Studied Cyber-attacks on Performance

The targeted security principle of this work is availability, which means that the service provided by the WSN must be available when needed and with satisfying quality. Thus, we aim to detect attacks that cause the WSN to become unavailable or degrade its performance. Therefore, performance must be defined using suitable performance metrics. We have explored the ontology for the selected cyber-attacks to address performance metrics that could be affected for each attack. Performance metrics defined in this section will be considered as the features of the generated dataset:

Rank Attack: this attack interrupts the balance of routing paths distribution in a WSN uses RPL. The first result is the high congestion and interference within the attacker's zone, which causes packet loss, increases end to end delay, and decreases throughput and packet delivery ratio. Moreover, the un-optimal paths will be created and used which may increase power consumption. Furthermore, and as the rank attacker becomes the preferred router for many nodes, the length of routing table will be increased unusually in the attacker and its neighbor nodes. Therefore, the length of routing table could be considered as a feature in the generated dataset.

Sinkhole attack: this attack is similar to rank attack in its effect, however, the attacker can attract more nodes than rank attacker because it claims that it has the minimum rank. Nonetheless, it is easier to be detected. Therefore, the performance metrics affected are packet loss, end to end delay, throughput, packet delivery ratio, and power consumption.

Flooding attack: this attack is executed by broadcasting a large amount of control messages. Hence, we expect a noticeable increase in control packets. Furthermore, the generated traffic will affect end to end delay as a result of increasing interference. Nodes will spend more time in replying to the deceptive traffic which affects throughput and power consumption, Moreover, the resulted interference can increase packet loss which affects delivery ratio. Finally, the deceptive control packets may force nodes to set protocol related metrics, such as the frequency of sending hello packets, unusually.

Copycat attack: as a result of receiving old versions of control packets during this attack, nodes may adjust protocol metrics illogically, such as time interval between hello packets and routing information. Moreover, frequent and unnecessary control packet transmission can exhaust power resources.

Sybil attack: by receiving packets with fake sender's information, nodes build a faulty routing table, For example a node could be inserted in the routing table as a neighbor while it is actually far away or even it does not exist, or a node may be recorded as an optimal router while it presents a high-cost router. The result of such cases is a high packet loss and a higher cost routing paths which leads to a lower packet delivery ratio and higher power consumption and end to end delay.

Wormhole attack: the effect of wormhole attack varies based on the target of the adversary from the established tunnel. For example, if the target is to drop packets this will affect packet delivery ratio. In general, we expect longer and un-optimized paths to be created. So, the foreseeable impact will be relevant to power consumption, end to end delay and packet delivery ratio. Table I, lists the considered attacks as well as the performance metrics affected by each attack.

So far, we have specified targeted security principle that we want to preserve, which is availability, we have then defined attack category to be considered which is (DoS). Based on this category, we have specified six types of attacks from this category for our case study. Then, more navigation through the ontology has ultimately led us to the fact that these attacks affect the performance of the network, and the concerned performance metrics were defined. This has been illustrated in Table I. To set up the rules of the ontology, the most significant step is to determine what is the threshold for each metric that can be considered to decide if there is an attack or not. For instance, what is the value of PDR that

represents the lower limit of accepted PDR, and below it we decide that there is an attack? Since it is not easy to guess or evaluate these values, so we will utilize ML to set threshold values and to set rules of the ontology, and developing a model for attack detection in WSNs.

C. Dataset and Cyber Attacks

To set the rules of the proposed ontology, we have utilized ML. This is because there is no scientific rule or base for performance metrics by which we can detect cyber-attack occurrence based on performance. Thus, we applied supervised learning on labeled dataset that include the investigated attacks. The objective of using ML is not to construct the intrusion detection system (IDS), it comes as a complementary step to denote the importance of ontology in defining system needs and potential attacks, which facilitate the process of developing IDSs as well as other protection systems. To create the dataset, we have used Cooja emulator to establish a WSN, then, we have run multiple simulations with different configurations to generate both benign and malicious traffic.

TABLE I. PERFORMANCE METRICS AFFECTED BY EACH ATTACK

	Delay	Control Packets	Lost Packets	Received Packets	Sent Packets	Power Consumption	Packet Delivery Ratio	Routing Table Length	Protocol Settings
Rank attack	✓		✓	✓	✓	✓	✓	✓	
Sinkhole attack	✓		✓	✓	✓	✓	✓	✓	
Flooding attack	✓	✓	✓	✓	✓	✓	✓		✓
Copycat attack	✓	✓				✓			✓
Sybil attack	✓		✓	✓		✓	✓		✓
Wormhole attack	✓		✓	✓		✓	✓		

TABLE II. SELECTED PERFORMANCE METRICS AND DERIVED FEATURES

Performance Metric	Features derived and description
Delay	Average end to end delay (E2E)
Control Packets	Number of control packets transmitted through the network (Overhead). Presented as number of (DAO),(DIO) and (DIS) packets in RPL.
Lost Packets	The number of lost packets defined as (total sent packets – total received packets)(Lost)
Received Packets	The total number of packets received by the sink (Received), maximum number of packets received by a node (Max_received)
Sent Packets	The total number of packets sent by all nodes (Sent), minimum number of packets sent by each node (Min_sent), maximum number of packets sent by each node (Max_sent), minimum number of packets forwarded by each node (Min_forwarded), maximum number of packets forwarded by each node (Max_forwarded), total forwarding operations within the network (Forwarded).
Power Consumption	Total remaining power (Rem_power), maximum power consumption (Max_power), total power consumed by all nodes of the network (Total_power), average voltage of all sensors (Voltage)
Packet Delivery Ratio	The percentage of total received packets by the sink to the total packets sent by all nodes (PDR)
Routing Table	The maximum length of routing tables in all node (Max_length)
Protocol Settings	We have considered the beacon interval (Beacon), which is a varied period of time defines the frequency by which control packets are sent continuously by nodes in WSN.
Delay	Average end to end delay (E2E)

While benign traffic is generated by simulating a network with the original protocol, malicious traffic is generated by implementing a number of specified cyber-attacks. Then, the malicious copy of routing protocol is implemented and used to launch these attacks. The resulted traffic is collected and analyzed. Finally, features presented in Table I are extracted to form the final dataset. It is worth mentioning that the variations some features are considered instead of the mere features shown in Table I only. For instance, variations of sent packets are considered, such as minimum sent packets, and maximum sent packets for sent feature. Maximum power consumption, total power consumption and remaining power are considered instead of taking only average power consumption. Moreover, types of control packets are considered separately instead of counting the total control packets. We have included DIS, DIO, DAO control packets which are the main control packets in RPL protocol [30]. We have also considered forwarded packets as a special case of sent packets, which indicates packets received from neighbor nodes and sent again toward the intended destination. Table II presents selected performance metrics and features derived (between brackets).

D. Simulation Environment

Through this section, we present simulation that we have conducted and its related environment and tools. We have selected Cooja simulator to create and configure WSNs in a smart city. There are many reasons behind selecting Cooja simulator. Cooja simulator is designed specifically for WSNs, it implements Contiki operating system. Strictly speaking, a simulated sensor in Cooja presents an actual compiled Contiki system [31]. Moreover, Contiki, which is the operating system of sensors, is also the best candidate for IoT devices in a smart city. That is due to Contiki's design which is developed specifically for memory constrained devices with the consideration of low-power IoT. Existing employment of Contiki involves street lighting systems, radiation monitoring

systems, sound monitoring systems and alarm systems [31]. As a result, Cooja simulator with Contiki operating system is the best choice to simulate the heterogeneous WSNs in a smart city system. According to the aforementioned points, resulted traffic will be similar to a great extent with a real traffic generated from real WSN rather than being just a traffic generated from a simulation.

Table III shows simulation environment and configuration parameters selected to create the dataset. Each record of the generated dataset represents 110 seconds traffic of 50 nodes deployed within an area of 350 X 350 m^2. At each record, we have diversified network configuration, such as the distribution of nodes, nodes to sink allocation and network topology. Part of the generated dataset instances represents benign network behavior, while the remaining dataset instances represent a traffic with the discussed attacks launched. After the simulation has been conducted for the 180 instances, performance has been measured in terms of the aforementioned performance metrics which are considered as dataset features to be inputs to the classification algorithm. Table IV presents a part of the generated dataset.

TABLE III. SIMULATION ENVIRONMENT AND PARAMETERS

Simulation Parameter	Value
Network Size (Number of Sensor Nodes)	50
Routing Protocol	RPL
Transport Layer Protocol	UDP
MAC Protocol	CSMA
Sensor Type	Sky Mote
Terrain Area	350 X 350 m^2
Number of Attacking Nodes	2
Simulation Duration	110 Seconds

TABLE IV. GENERATED DATASET

Overhead	E2E	Sent	Received	PDR	Lost	Table	Max forwarded	Min forwarded	Max received	Min Sent	Max sent	Forwarded	Max power	Total power	Beacon	Rem power	Voltage	Class

E. Machine Learning

We have utilized ML as a tool to set up inference rules. We have used Weka 3.8.4 environment to apply ML on the dataset discussed in Section A [32]. Decision tree (J48) classifier has been used as it is easy to extract the model in the form of explicit rules by this classifier. Decision tree classifier is trained and tested based on 10-fold cross validation technique.

V. RESULTS AND DISCUSSIONS

By applying decision tree classifier on the discussed dataset, we have obtained 95% accuracy to classify a network traffic to either attack or normal traffic. We also have an accuracy of 81% to specify the name of the attack. The resulted rules then transferred to the ontology to carry out reasoning. Inference rules are shown in the table of Appendix B. Each rule in the table is represented in one row where the first column can be understood as a logical if statement and the second column represents the part of then statement.

A. Safety Factor

According to the previous accuracy values obtained, 95% for binary classification and 80% for attack type classification, 5% and 20% of cases are wrongly classified in both binary classification and attack type classification, respectively. However, these values cannot be considered as indicators for how much the system is secure. For instance, if the detection method wrongly classifies normal traffic as malicious, this can only add an additional cost, which is presented in taking a countermeasure reaction, but the system is still safe.

On the other hand, when the detection method classifies an attack traffic as normal, we can say that the system is not safe, because this means that we allow malicious behavior to proceed without being detected.

Fig. 7 presents confusion matrices for both binary and attack classifications. In binary classification, Fig. 7 shows that six cases out of 180 are malicious traffic that classified as normal, so, 174 cases are either correctly classified cases or they are normal traffic classified as attacks, which do not degrade the safety of a system. This means that the safety of the system in binary classification is 97%. In attack type classification, only four instances of attacks are classified as normal, which means that the safety of attack classification is 97.7%.

B. Use Cases

In this section, we introduce a simple use case to illustrate the validity of CAO. The ontology is implemented and rules obtained from ML model are added. Thus, we are ready to detect the occurrences of cyber-attacks using the proposed ontology. Different cyber-attacks are launched, traffic is analyzed to extract the defined performance metrics, then, calculated values are added and reasoning is conducted. Fig. 8 shows the description of copycat attack which has been defined as a network traffic using rules obtained from applying machine learning and in terms of performance metrics specified. Fig. 9 shows the definition of copycat attack in description logic.

We have simulated copycat attack, collected the resulted network traffic, analyzed the traffic to find out the values of performance metrics. We then defined the instance "traffic_1" of class traffic which have been assigned the obtained performance metrics as its data properties, and fed to the implemented ontology CAO. After reasoning is applied based on these inputs, an inference is done yielding that there is a copycat attack. The degree of accuracy of that inference is 95% in that there is an attack and 80% is that it is a copycat attack. The safety of using the proposed ontology along with the ML obtained rules is 97.7%.

```
      a    b    <-- classified as
     28    2  |   a = normal
      6  144  |   b = attack
```

Confusion Matrix of Binary Classification
Safety = 97%

```
      a    b    c    d    e    f    <-- classified as
     27    0    2    0    0    1  |   a = normal
      1   22    1    0    1    5  |   b = copycat
      3    0   24    0    1    2  |   c = Rank
      0    0    0   30    0    0  |   d = DISFlooding
      0    1    0    0   25    4  |   e = Sinkhole

C. Comparison with Existing Works

In this section, we provide a comparison between CAO and existing research works investigating ontology and machine learning to secure smart city. Since there is no research work that have adopted the integration between ontology and ML to set inference rules of the ontology. We will compare our proposed approach in developing CAO with existing ontology-based approaches.

From the literature review in Section II, we have noticed that proposed ontologies in the domain of security are either environment-centric, assets centric, or threats-centric. However, the ontology developed in this work is cyberattack-centric ontology. Moreover, security needs in literature are considered from general view, which is not enough in IoT environment where security needs are considerably varied based on the application. In CAO, security needs are defined specifically based on the studied IoT system.

Finally, the main difference between CAO and previously proposed ontologies is the process of setting inference rules. Previous works have used the analysis of systems' vulnerabilities and threats, or they depend on user-defined rules. In CAO, we have benefit from ML to set inference rules.

VI. CONCLUSION AND FUTURE WORK

In this article, we have proposed an ontology for cyber-attacks and we have shown how this ontology can be navigated to deduce the vulnerabilities, potential attacks, and the impact of the attack on the system in order to develop a model for an IDS for a smart city based IoT system. The proposed ontology is cyber-attack centric and includes other two main entities, adversary and system.

For future researches, CAO could be thought of as a base for more comprehensive ontologies, more concepts and relations could be added to develop cyber-attack oriented knowledge. Furthermore, CAO helps to develop a taxonomy for cyber-attacks. It also provides a formal and unified description and understanding for cyber-attacks and security needs for IoT environment.

We have investigated a case study for DoS attacks, six attacks have been considered and ML is used to set the rules for the proposed ontology. We have also proposed safety factor to evaluate the effectiveness of the IDS. The proposed ontology as well as the presented case study have shown that ontology can play a significant role to secure a smart city. The development of comprehensive ontology will establish a knowledge base for cyberattacks which creates the opportunity for robust protection for existing as well as coming security threats and attacks.

The proposed CAO needs to be supported by employing the proposed approach in a diversified set of computing environments, and investigating more types of cyber-attacks. Obtained accuracy values using CAO are less than detection accuracy in existing ML learning based security methods. The accuracy can be raised by studying several types of attacks or by the generating larger dataset which is the suggested future work.

A Novel Annotation Scheme to Generate Hate Speech Corpus through Crowdsourcing and Active Learning

Nadeera Meedin, Maneesha Caldera, Suresha Perera, Indika Perera

Dept. of Computer Science and Engineering, University of Moratuwa, Katubedda, Sri Lanka

Abstract—**The number of user-generated posts is growing exponentially with social media usage growth. Promoting violence against or having the primary purpose of inciting hatred against individuals or groups based on specific attributes via social media posts is daunting. As the posts are published in multiple languages with different forms of multimedia, social media finds it challenging to moderate before reaching the audience and assessing the posts as hate speech becomes sophisticated due to subjectivity. Social media platforms lack contextual and linguistic expertise and social and cultural insights to identify hate speech accurately. Research is being carried out to detect hate speech on social media content in English using machine learning algorithms, etc., using different crowdsourcing platforms. However, these platforms' workers are unavailable from countries such as Sri Lanka. The lack of a workforce with the necessary skill set and annotation schemes symbolizes further research essentiality in low-resource language annotation. This research proposes a suitable crowdsourcing approach to label and annotates social media content to generate corpora with words and phrases to identify hate speech using machine learning algorithms in Sri Lanka. This paper summarizes the annotated Facebook posts, comments, and replies to comments from public Sri Lankan Facebook user profiles, pages and groups of 52,646 instances, unlabeled tweets based on 996 Twitter search keywords of 45,000 instances of YouTube Videos of 45,000 instances using the proposed annotation scheme. 9%, 21% and 14% of Facebook, Twitter and YouTube posts were identified as containing hate content. In addition, the posts were categorized as offensive and non-offensive, and hate targets and corpus associated with hate targets focusing on an individual or group were identified and presented in this paper. The proposed annotation scheme could be extended to other low-resource languages to identify the hate speech corpora. With the use of a well-implemented crowdsourcing platform with the proposed novel annotation scheme, it will be possible to find more subtle patterns with human judgment and filtering and take preventive measures to create a better cyberspace.**

Keywords—Annotation; crowdsourcing; hate speech detection; social media data analytics

I. INTRODUCTION

Social media users keep updating and sharing posts and comments on social media platforms at an exponential rate. Users can express themselves freely across countries and cultures in dozens of languages. People use social media to share their experiences, connect with friends and family, and build communities. However, social media platforms try to maintain their community standards so that their users feel safe using their products. One such example is the Facebook

community standard [1]. In their standards, they have specified the content not to be posted by users to prevent possible harms related to content on Facebook under categories such as violence and incitement, dangerous individuals and organization, coordinating damage and publicizing crime etc. For example, Facebook does not allow users to post content, including hate speech on Facebook to avoid creating an environment of intimidation and exclusion and which would promote real-world violence. Similarly, Twitter and YouTube have their hateful policy conduct [2] [3].

However, policies and standards exist, and social media platforms take action to remove posts with inappropriate content; users tend to spread hate speech using social media. The information shared on social media can be offensive and could lead to creating social issues. Social media research includes analyzing social media data on various topics. Some of these topics would have a direct impact on creating social issues. Therefore, it is vital to have a mechanism to identify the contents that directly impact social issues.

It has been a challenge for social media platforms to moderate billions of daily posts in more than a hundred languages. It has been found that it is impossible to maintain a balance between what is considered "hate speech" and "free speech" since social media is global. Hate speech is a broad and contested term [4], and there is no common standard definition for hate speech [5]. Multiple definitions used by different authorities and platforms are explained in the Literature Survey section. United Nations strategy and plan of action on hate speech describe hate speech as "any kind of communication in speech, writing or behaviour, that attacks or uses pejorative or discriminatory language regarding a person or a group based on who they are, in other words, based on their religion, ethnicity, nationality, race, colour, descent, gender or other identity factors"[6]. Hence both "hate speech" and "free speech" are determined by region. When analyzing the speech, it is essential to consider context-specific details, social and cultural factors, etc. Determining hate speech based on user context is one of the challenges faced by social media platforms as they deal with more than a hundred languages [7] and nationalities.

By incorporating a crowdsourcing approach, it can reach a much larger audience and capture user opinions and behaviours. In social computing research, social media has provided a unique window into people's social experience; in particular, Twitter is used for assessing sensitive topics, such as discrimination[8]. Therefore, when capturing user opinions, it is required to ask the appropriate questions in the appropriate order to obtain responses effectively. Similarly,

the captured responses should be represented in such a way after ensuring their quality.

This research proposes a novel solution to address this problem: an adaptive questionnaire to identify hate speech, detect hate targets and keywords related to hate and label the social media posts written in Sinhala and Singlish. The main contributions of this paper are the following;

- A crowdsourcing framework for annotating hate speech.

- An annotating scheme to generate a hate speech corpus.

- Annotated dataset and hate speech corpus.

II. RELATED WORK

A. Use of Crowdsourcing in Annotating Hate Speech

Daniel Faggella [9] explains how crowdsourcing could be used in social media content moderation and states that moderation at a scale usually involves two elements; a trained machine learning algorithm informed by the user or outside data. In addition, several factors [10] affect the judgement of crowd moderators when deciding on the suitability of text content, such as participants often labelled unsure when they found it challenging to decide on marginal content. Considering these approaches, the factors considered in registering workers and how to direct workers to annotate, limiting the judgements are further explained in the Section III Crowdsourcing Platform.

Amazon Mechanical Turk(MTurk) is the most common crowdsourcing platform for performing labour-intensive tasks, data collection and annotation for hate speech identification [11], especially in NLP. MTurk facilitate quality management [11][12], ranking annotators[13], ensuring trustworthiness. There are no mechanisms in MTurk for detecting unfair evaluations and no metric called reputation. As a result, workers are highly susceptible to misbehaviour [14]. MTurk allows workers from only a limited number of countries to register. Hence the existing workers could not cater for the cultural, linguistic and contextual insights. Furthermore, MTurk is a general-purpose crowdsourcing platform which allows the annotation of many types of tasks and the annotation scheme adaptation for low-resource languages is crucial because of the linguistic challenges in MTurk.

B. Annotation in Hate Speech Detection

Both race and sexual orientation are among the top hate speech targets [15]. Our study examined the hate targets in the Sri Lankan context. It was different depending on the cultural, societal and religious differences. Amazon Mechanical Turk (AMT) was used in Relia et al. research for annotation after performing keyword filtering, and Support Vector Machine (SVM) and Neural Network (NN) was used for Twitter classification. As this task involved the exposure of humans to potentially sensitive content, the researchers have indicated the task was about racist Tweets as an individual Human Intelligence Task (HIT), giving workers a chance to discontinue at any point without losing payment if they felt uncomfortable. HaterNet [16] can identify and classify hate

speech in Twitter data. The Spanish national office is using it against hate crimes. HaterNet uses a combination of Long Short-Term Memory (LSTM) and Multi-layer Perceptron (MLP) neural networks.

Burnap [17] has annotated text using CrowdFlower, with a minimum of four humans, to assess whether it is likely to be offensive or antagonistic regarding race, ethnicity or religion. Scores are given based on a ternary set of classes, yes, no and undecided. Agrawal and Aweaker have used four DNN-based models for cyberbullying detection; CNN, LSTM, BLSTM, and BLSTM [18]. Here they have used a manually annotated dataset. Fernando and Asier [19] have introduced a new algorithm to detect hate speech messages. They used the Kappa coefficient to measure the degree of agreement when performing the subjective analysis. The researchers have categorized tweets into five categories: direct incitement or threat of violence, an attack on honour and human dignity, incitement to discrimination or hate and an offence to collective sensitivity.

The hate categories observed in [20] are race, behaviour, physical, sexual orientation, class, ethnicity, gender, disability, religion and others. A few of the top hate targets in the US, Canada, and the UK are black, fat, fake, stupid, gay, white, rude, ignorant, racist, old, selfish and religious, which is different in an Asian country Sri Lanka as it was found out in our study.

We followed the approach of Fernando and Asier [19] and used the five conditions given in Table IV to check if a post contains hate. In addition, the hate targets and the hate categories specified in each post were identified using the categories listed in [20]. These categories are listed in Table IV. Finally, we went one step further to identify the words, phrases and sentences which incite hatred in the post.

C. Benchmark Datasets for Hate Speech Detection

Table IX at the end of this paper summarizes existing benchmark annotated datasets used for hate speech detection in different languages. The system architecture, design and implementation of the crowdsourcing platform, information architecture of the system, the pre-selection criteria of contributors, and the proposed criterion to identify inappropriate content in social media are explained in the next section.

III. CROWDSOURCING PLATFORM

This paper presents a novel crowdsourcing platform that allows any interested participant to register by providing user profile details such as name, age, nationality, date of birth and location of contribution. The system architecture of the implemented crowdsourcing platform is given in Fig. 1.

The intrinsic rewarding process starts with the first digital badge, "Contributor", and after fulfilling the selection criteria specified in Table II, the contributors get the badge "Selected contributor" and the eligibility to earn financial rewards. The worker management process is illustrated in Fig. 2.

1) Pre-selection of contributors: Participants who were literate in Sinhala and Sri Lankan natives were selected as

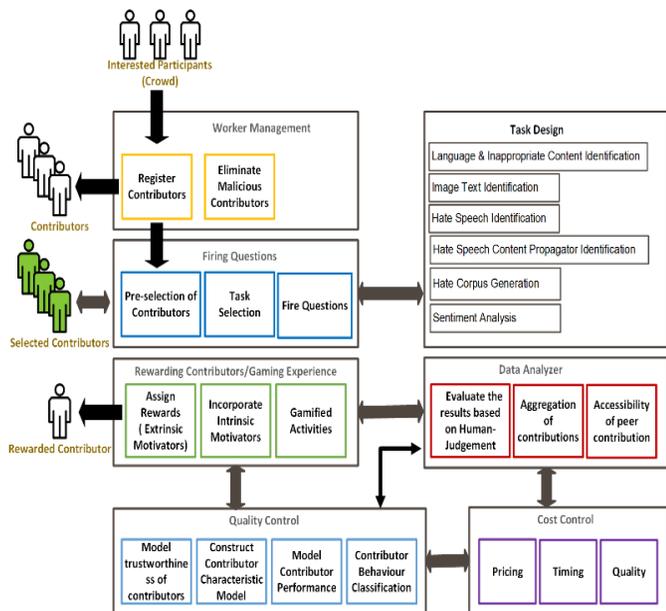
contributors to the evaluation process. Those who did not qualify in the pre-selection process, failed at quality control, and failed at the trustworthiness-ensuring process were eliminated. The list of symbol definitions for pre-selection contributors is given below in Table I.


Fig. 1.   The System Architecture of the Crowdsourcing Platform.
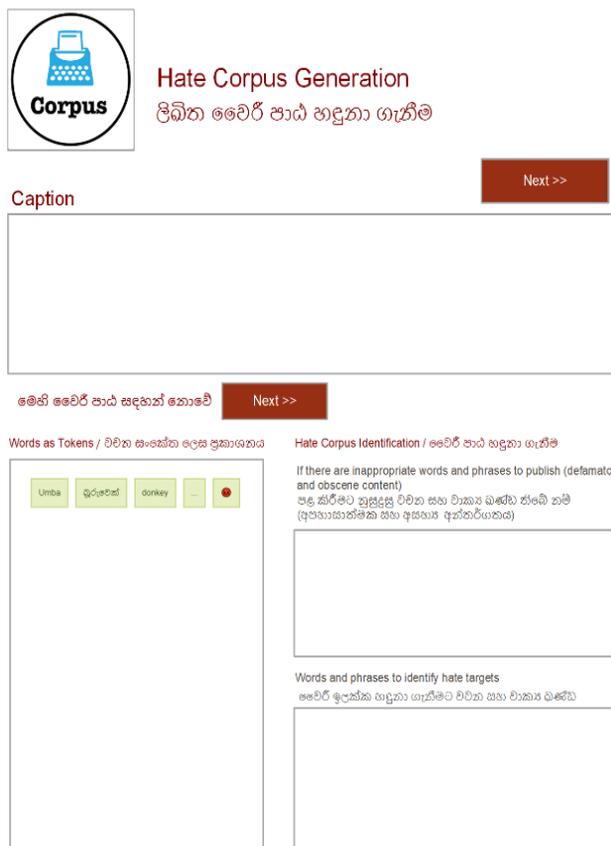

Fig. 2.   Worker Registration and Reward Process.

TABLE I.   LIST OF SYMBOL DEFINITIONS FOR PRE-SELECTION OF CONTRIBUTORS

Symbol	Definition
N	Nationality
A	Age
HS, HS_T	Knowledge level of hate speech, the Threshold value
LP, LP_T	Language proficiency(Sinhala), the Threshold value
CA, SCA_T	Comprehension & Analytical skill assessment(Sinhala), the Threshold value
L, L_T	Ability to read mixed codes(Sinhala words written in English letters), the Threshold value

TABLE II.   CRITERIA IN PRE-SELECTION OF CONTRIBUTORS

Pre-selection of contributors
if {(Nationality="Sri Lankan") and (A>=18) and (HS>=HS_T) and (LP>=LP_T) and (CA >= CA_T)and (L >=L_T)}
Badge="Selected Contributor"
else
Eliminate contributor
endif

The given threshold values were selected for the criteria in assessing prior knowledge in hate speech identification (HST=5), Sinhala language proficiency (LPT=8), ability to read Sinhala words written in English letters (LT=8), comprehension, and analytical skills (CAT=8) and the criteria in pre-selection of contributors is given in Table II.

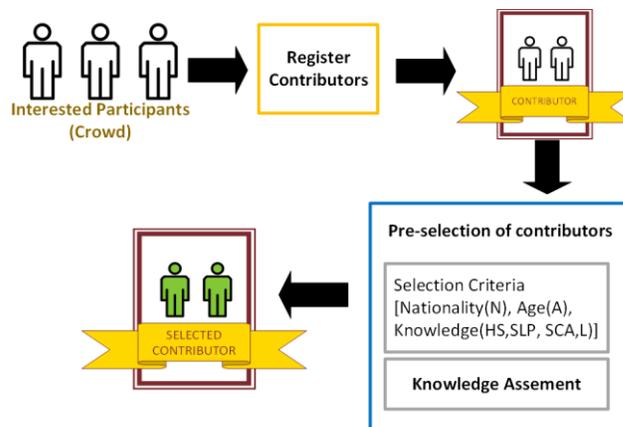
Task Selection: Selected contributors were asked questions randomly based on a question generation mechanism helping to generate a corpus with hate speech, annotate the posts to detect and classify the intention of the hate speech, identify Sinhala texts from images, identify inappropriate words in the social media content and to sort Sinhala, Singlish and English words in a given set of social media posts. Out of the six types of task designs allowed by the crowdsourcing framework, only the results of hate speech identification and hate corpus generation are explained in the evaluation section of this paper (See Fig. 3).


Fig. 3.   UI to Capture Inappropriate Contents and Words and Phrases Referring Hate Targets.

2) Fire questions: A rule base was used to assess the pre-selection criteria of contributors with forwarding chaining as the firing mechanism, and a dataset with JSON objects of Twitter, Facebook and Video posts was used during the task assignments.

3) Assign Rewards (Extrinsic and Intrinsic Motivators): Google crowdsource [21] is a global platform which uses the feedback of users to design products to provide a customized experience to its users. For example, they provide a gaming experience as an intrinsic reward to users instead of monetary rewards. After alterations, a similar approach has been taken in our research to motivate the Sri Lankan workers. The proposed reward system was designed after testing a few samples of workers by applying different rewarding methods.

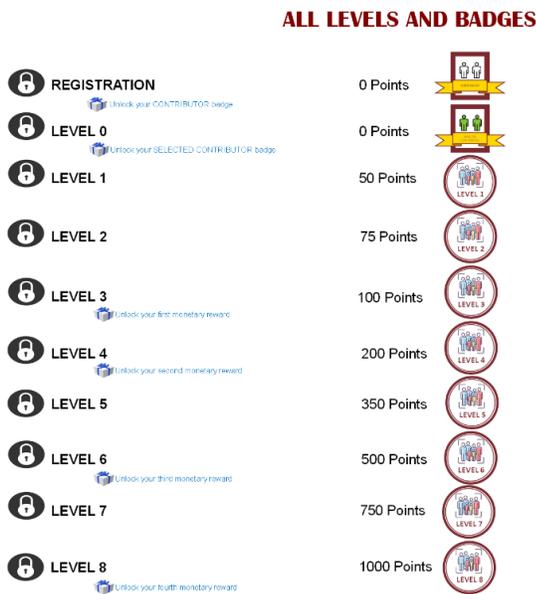
Workers were allowed to earn monetary awards considering the completion levels, accuracy, trustworthiness of the contributor, etc. To admire the effort of the contributors to make cyberspace better monetary rewards were assigned to those who showed higher trustworthiness scores, and based on the human intelligence tasks HITs) completed, digital badges were assigned. In addition, the platform would provide a gaming experience for contributors to retain in the cause. The intrinsic and extrinsic motivators were embedded in the gaming experience, as shown in (See Fig. 4).


Fig. 4.   Intrinsic and Extrinsic Rewards Assignment for Selected Contributors.

4) Model the trustworthiness of a contributor: An inbuilt mechanism was built to check the trustworthiness of a particular contributor's responses and assign a badge for trustworthiness. Ten golden rules were used as the primary method of measuring trustworthiness and were compared with the predicted trustworthiness score. In addition, a higher weightage of validity to the response from a trustworthiness badge-owned contributor was considered in assessing the quality of the response.

5) Aggregation of contributions: Evaluates the results based on human judgment for each post, store the results, ignored, hate speech or not, category of the hate nature, etc., to aggregate the contributions and generate advanced questions later. The agreement scores were calculated using Cohen's kappa coefficient, Fleiss' kappa coefficient and Krippendorff's alpha.

IV. EXPERIMENTATION

The research was carried out considering three cases, the first using Facebook posts, the second using Tweets and the third using YouTube posts, as specified below in the dataset section. The initial classification step involved classifying the posts in the language in which the post was written. Here we categorized the language into five categories Sinhala, English, Singlish, Both English and Sinha-la, and None of the above. Out of the five categories, the posts written in Sinhala, Singlish and both Sinhala and English were considered under the study. Posts written in English and other languages were not considered under the study. The second step involved the task design for hate post identification, and the third in hate speech corpus generation.

V. PILOT DATASET

There is no large publicly available data set of Facebook, YouTube and Twitter written in Sinhala, Singlish and mixed code. Therefore, in this research, we selected three subsets from the three social media platforms as our cases under study, with the most significant number of Sri Lankan users as of 2022[22]. Singlish is Sinhala words written using English. Therefore, our dataset tweets were collected using Twitter API based on 996 Twitter search keywords. Web crawling was used to collect Facebook posts from public Sri Lankan Facebook user profiles, pages and groups, and YouTube posts and comments were captured from popular Sinhala YouTube channels as shown in Table III. The dataset was annotated by 20 selected annotators who passed the pre-selection test and showed a higher trustworthiness score. UPF-08 encoding errors and inconsistencies were corrected in the labelled files.

TABLE III.   UNLABELLED DATA SETS FOR HATE SPEECH IDENTIFICATION

Case	Dataset	Instances
Case 1: Facebook	Unlabeled posts, comments, and replies to comments from public Sri Lankan Facebook user profiles, pages and groups(Post image, Comments, video thumbnail)	52,646
Case 2: Twitter	Unlabeled tweets based on 996 Twitter search keywords (Tweet text, replies for each tweet, 6317 video thumbnails and pictures). The average number of comments and replies per Twitter post is 4	45,000
Case 3: Youtube	Youtube Videos(Video title, thumbnail, Comments for each video). The average number of comments and replies per video is 6	45,000

VI. ANNOTATION SCHEME TO GENERATE A HATE SPEECH CORPUS

The annotation scheme specified below in Table IV was used to get the data annotated, and the annotated datasets were published in the GitHub repository.

TABLE IV.   LIST OF SYMBOL DEFINITIONS FOR LABELLING

Symbol	Definition
L_1	Content analysis
L_2	Hate speech identification
L_3	Who does a particular post target?
L_4	Hate categories
$C1, C2, C3, C4, C5$	Direct incitement or threat of violence, An attack on honour and human dignity, Incitement to discrimination or hate, An offence to the collective sensitivity or Other.
$L_4\{1$ to $16\}$	1. Race and Ethnicity 2. Religion 3. Nationality 4. Sexual Orientation5. Disability 6. Disease 7. Immigration 8. Victims of a major violent event and their kin 9. Veteran Status/Profession10. Caste11. Political12. Regional 13. Gender 14. Economic & Business 15. A particular individual 16. Other social groups

Definition to label L_1 to L_4

Starting set of labels L_1 is:

L_1={*Offensive content, No offensive content, Cannot tell*}

Starting set of labels L_2 is:

L_2={*C1, C2 , C3, C4, C5*}

Starting set of labels L_3 is:

L_3={*Individual, Group, Cannot tell*}

Starting set of labels L_4 is:

L_4={*1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16*}

VII. RESULTS AND DISCUSSION

A. Demographic Distribution of the Annotator Profiles

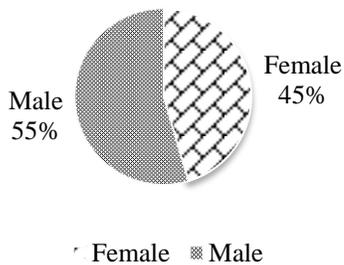
The demographic distribution of the selected contributors involved with the annotation process is given in Fig. 5 to 7.


Fig. 5.   Gender Distribution of Selected Contributors.
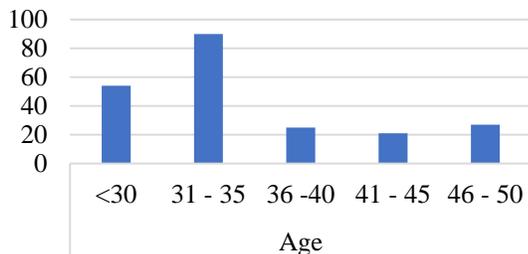

Fig. 6.   Age Distribution of Selected Contributors.
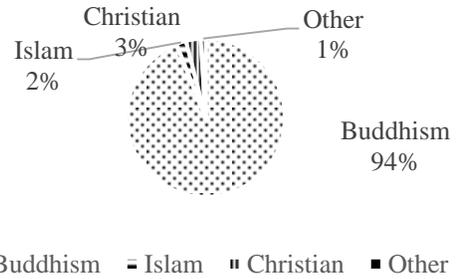

Fig. 7.   Religion-wise Distribution of Selected Contributors.

B. Inter Annotator Agreement

Table V shows the agreements obtained in terms of the average percent agreement (agr_i), average Cohen's kappa coefficient (avg k), Fleiss' kappa coefficient (Fleiss) and Krippendorff's alpha (α). The number of annotated posts/comments/tweets is also given for each batch.

If the set of items is $\{i | i \in I\}$, and is of cardinality i.

Observed agreement(A_0) over the values agr_i for all items $i \in I$.

$$A_o \frac{1}{i} \sum_{i \in I} agr_i \qquad (1)$$

$$agr_i = \begin{cases} 1, & \text{if the two coders assign i to the same category} \\ 0, & \text{if the two coders assign i to different categories} \end{cases}$$

Cohen Kappa coefficient(k) where expected agreement is A_e

$$K = \frac{A_0 - A_e}{1 - A_e} \qquad (2)$$

TABLE V.   INTER ANNOTATOR AGREEMENT ON CASE1, CASE 2 AND CASE 3 FOR L_1

Case	Instances	agr_i	k	Fleiss	α
Case 1:Facebook	52,646	90.4	0.623	0.615	0.800
Case 2:Twitter	45,000	89.4	0.624	0.613	0.740
Case 3: Youtube	45,000	88.7	0.598	0.600	0.757

C. Annotated Datasets

Hate posts/comments and tweets were identified after analyzing L_2 and L_3. If at least one choice was selected and the inter-rater agreement was more than 0.6, the posts were identified as hate posts.

If we compare Table VI and Table VII, it is evident that intuitive annotation of offensive and non-offensive content shows lesser percentages when compared with hate and non-hate classification.

TABLE VI.   DISTRIBUTION OF POSTS/COMMENTS/TWEETS ANNOTATIONS

	Facebook	Twitter	YouTube
Hate	9%	21%	14%
No Hate	88%	70%	83%
Skip	3%	9%	3%

D. Lexical Distribution

Table VIII lists the ten most frequently occurring words to refer to the hate targets with the most frequent occurrence for each class. Twitter search keywords, identified hate targets and the corpus associated with hate targets focusing on an individual or group are given in the GitHub repository. The annotated Facebook, Twitter, and YouTube datasets can be requested by emailing the authors of this paper.

TABLE VII.   DISTRIBUTION OF POSTS/COMMENTS/TWEETS OVER CATEGORIES IN THE CLEAN DATASET-FACEBOOK

	Offensive	No offensive content
Facebook		
Caption	1.68%	>98%
Video thumbnail	0.18%	>99%
Main image	0.015%	>99%
Comment text	0.023%	>99%
Comment image	0.002%	>99%
Reply text	0.78%	>99%
Group photo	0.04%	>99%

Video thumbnail	0.57%	>99%
Comment text	2.27%	>97%
Reply text	1.01	>98%

TABLE VIII.   DISTRIBUTION OF THE TEN MOST FREQUENTLY OCCURRING TERMS IN HATE SPEECH REFERRING HATE TARGETS

Word	Meaning of the word in English	Distribution
දෙමළා	Used as an insulting and contemptuous term for a person from a target community	0.65%
හම්බා	Used as an insulting and contemptuous term for a person from a target community	0.67%
තම්බියෙක්		0.65%
තම්බියා		1.9%
තම්බි	Used as an insulting and contemptuous term to refer target community	1.01%
තම්බියෝ		1.83%
තම්බිලා		0.38%
ගණයා	Used as an insulting and contemptuous term to refer to a priest from a target religion	0.25%
අන්තවදී	Used to refer to a person as an extremist	0.35%
සිංහලේ	Used to elevate an ethnicity and demean all the other ethnicities	0.65%

TABLE IX.   SUMMARY OF EXISTING BENCHMARK ANNOTATED DATASETS USED FOR HATE SPEECH DETECTION FOR DIFFERENT LANGUAGES

Dataset	Social Media Platform	Language	Criteria/Based on	Annotation question/s or Categories	Size	Intercoder-agreement score	Output
Davidson [23] Hatebase Twitter	Tweet	English	The words appearing in a given tweet and the context in which they were used.	Labelled categories: hate speech, offensive but not hate speech, or neither offensive nor hate speech	24,802 tweets	Majority Voting 92%	5% - hate speech 76% - Offensive 17% - Neither
Waseem[24]	Tweet	English	Criteria based on Critical Race Theory(CRT) : 1. uses a sexist or racial slur. 2. attacks a minority. 3. seeks to silence a minority. 4. criticizes a minority (without a well-founded argument). 5. promotes, but does not directly use, hate speech or violent crime. 6. criticizes a minority and uses a straw man argument. 7. blatantly misrepresents truth or seeks to distort views on a minority with unfounded claims. 8. shows support for problematic hashtags. E.g. "#BanIslam", "#whoriental", and "#whitegenocide" 9. negatively stereotype a minority. 10. defends xenophobia or sexism. 11. contains an offensive screen name, as per the previous criteria, the tweet is ambiguous (at best), and the tweet is on a topic that satisfies any of the above criteria	Labelled categories: Sexism, Racism, Neither	16,914 tweets	Cohen's kappa coefficient K=0.84	Racism – 12% Sexism – 20% Neither - 68
Gibert et al.[25]	Stormfront - Internet posts	English	a) deliberate attack, b) directed towards a specific group of people, c) motivated by aspects of the group's identity.	Hate, No hate, Skip	10,568 sentences	Average percent agreement 91.03 Cohen's kappa coefficient 0.614 Fleiss' kappa coefficient 0.607	Hate 1196 Skip 72 No hate 9674

Most of the phrases referring to the hate targets consisted of at least one term from the given list.

VIII. CONCLUSION

After performing this research, the following drawbacks were identified. (1) The workers found it challenging to identify if a particular comment is harmful or harmless by looking only at it. (2) based on the task, the number of annotator requirements should be identified and vary (3) eliminate the bias of the annotator response.

To make the decisions, they needed to see the original post, the replies against it, and the images associated with the comments, if any. Therefore, suggesting preventive measures would not work if we only remove a single comment. Instead, it would be required to remove a set of comments. Therefore when designing tasks for crowdsourcing platforms, it is required to redesign the tasks to include the relevant images and any context-specific data along with the post when asking questions from the crowd, as proposed in this research.

Though subjective responses were captured in labelling, it is mandatory to design the annotation scheme such that the annotator would consciously judge the comment based on the given criteria without intuitively completing the crowdsourcing tasks.

Two different techniques should be used to score the trustworthiness of users during the pre-selection of contributors to the crowdsourcing platform. Krippendorff's alpha coefficient could be used as the reliability estimation method, and the number of contributors for each type of task would be very, as shown in the results. Two contributors can be used to perform primary classifications, while in-depth analyses such as sentiment strength analysis and hate target identification should be increased by checking the reliability score.

It is essential to use equal percentages to represent each religion which is nearly impossible in this context as the majority of the Sri Lankan population is Buddhists, to avoid bias toward religion.

The beliefs of the contributor would affect their response. Therefore, it is required to randomize the worker selection to eliminate the bias and to fire different categories of posts for each worker type.

Despite the outcomes of this research, future research should aim to (1) identify multiple comments against the Facebook posts instead of a single comment or caption to remove as a preventive measure in spreading hate, (2) redesign crowdsourcing tasks to include the relevant images and any context-specific data along with the post when asking questions from the crowd (3) having a mechanism to ensure annotator would consciously judge the comment based on the given criteria without intuitively completing the crowdsourcing tasks (4) measure the biases and beliefs of workers to ensure the trustworthiness of crowd response (5) identifying clusters of worker types and fire different categories of questions to each type.

The outcomes of this research consist of a crowdsourcing framework for annotating hate speech for Sinhala, Sinhala written in English and English social media posts, an annotation scheme to generate a hate speech corpus and an annotated dataset. These outcomes can be used by NLP researchers in performing linguistic research and getting annotation done for local languages, and policymakers to take preventive measures in identifying inappropriate content, hate targets and hate categories.

The datasets, implemented project, hate targets, hate-related search key terms used with Twitter, and hate corpus could be found in the;

Abstract—Medical Images are most widely done by the various image processing approaches. Image processing is used to analyze the various abnormal tissues based on given input images. Deep learning (DL) is one of the fast-growing field in the computer science and specifically in medical imaging analysis. Tumor is a mass tissue that contains abnormal cells. Normal tumor tissues may not grow in other places but if it contains the cancerous (malignant) cells these tissues may grow rapidly. It is very important to know the cause of brain tumors in humans and these should be detected in the early stages. Magnetic Resonance Imaging (MRI) images are most widely used to detect the tumors in the brain and these are also used to detect the tumors all over the body. Tumors are of various types such as noncancerous (benign) and cancerous (malignant). Sometimes tumors may convert into cancer cells based on the stage of the tumor. In this paper, a hyper integral segmentation approach (HISA) is introduced to detect cancerous tumors and non-cancerous tumors. Detecting cancerous cells in the tumors may reduce the life threat to the affected persons. The agent based reinforcement classification (ABRC) is used to classify the Alzheimer's disease (AD) and cancerous and non-cancerous cells based on the abnormalities present in the MRI images. Two publically available datasets are selected such as MRI images and AD-affected MRI images. Performance is analyzed by showing the improved metrics such as accuracy, f1-score, sensitivity, dice similarity score, and specificity.

Keywords—Benign; malignant; magnetic resonance imaging; Alzheimer's disease

I. INTRODUCTION

The brain is one of the most important organs that play a major role in the human body. This organ controls the whole body by giving instructions to the rest of the body parts. In the world, the second cause of human death is caused by brain disease if the people are not identified in the early stages [1]. From the computer point of view, many applications are developed to analyze brain tumors and other brain disorders by using MRI, CT scans, and X-rays. Very fast and timely recognition and detection of brain tumors are required for curing the tumor. This depends on the experts and professionals to treat the patients. It is a very tedious task to predict the type of the tumors present in the brain for the proper treatment [2]. Segmentation of brain tumors is mainly based on a few important factors such as removing noise, missing borders, and contrast. MRI segmentation is one of the

better strategies for recognizing brain images. Based on the density functions the parametric approaches are used for selecting the tumors [3]. Some of the basic modalities used to detect and analyze brain tumors are positron emission tomography (PET), magnetic resonance imaging (MRI), and computed tomography (CT) [4].

Generally various types of tumors are present. Tumors may convert into cancer and non-cancerous cells. After the heart disease, most of the people causing deaths are cancer patients. Among all the types of cancers, brain cancers become more complex to detect and analyze in the early stages [5]. MRI is one of the popular approaches for detecting the cancerous tissues in brain tumors [6]. Traditional segmentation of analysis is a very tedious and time-consuming process for experts also [7] [8]. Thus an automated and dynamic detection and recognition of tumors belong to cancerous or not.

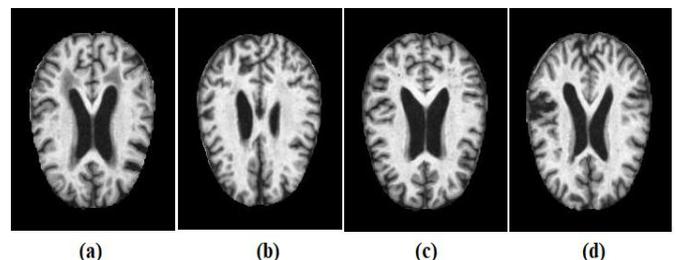
Reinforcement learning (RL) [9] is used to increase the performance of the existing approaches by using agent-based learning. The RL agent mainly controls the behavior of the policy mapping from given inputs to actions. RL mainly uses the labeled training with the expected output. This also uses the unique optimal action that receives the updated sample to indicate the accurately selected action. RL is used to solve the classification tasks in DCNN. Instead of the traditional classification process, the advanced RL classification works better on same brain datasets are straightly generated by using the classifier with estimated class labels. The agent plays the major role in RL to communicate with the input and takes the required action to process the MRI brain image classification (Fig. 1).


Fig. 1. Sample Images of AD (a) Mild Demented, (b) Moderate Demented, (c) Non Demented (d) Very Mild Demented.

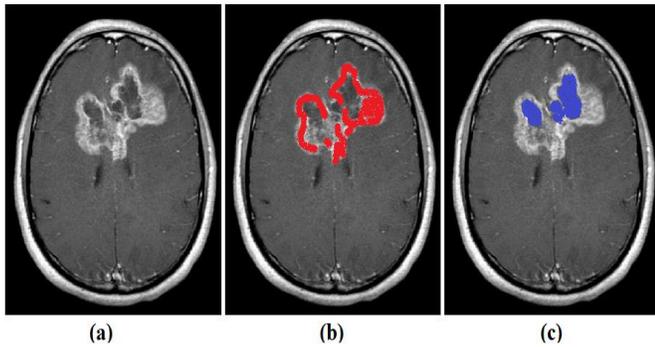
The proposed approach is also used to detect the AD and also types of AD based on the given brain samples. This approach finds the shape and curves of the cancer cells present in the brain. It consists of multi-layered approach that contains multiple layers to get accurate results. A powerful deep learning training model is used to train the types of tumor images. Fig. 2 shows the classification of tumor cells and cancer cells present in the input image. In Fig. 2(a) is the normal MRI brain image, Fig. 2(b) is the tumor image which is represented in red color and 2(c) represents in blue color with cancer cells region.


Fig. 2. (a) Tumor Image (b) Tumor Cells (c) Cancer Cells.

II. LITERATURE SURVEY

Z. Jia et al., [10] proposed the FAHS-SVM to segment the brain images. This approach is focused on detecting the cerebral venous system by using MRI images. This approach also contains one or more layers belonging to hidden nodes. M. S. Majib et al., [11] introduced the dynamic approach to classifying tumor-affected images without the interference of humans. The proposed approach VGG-SCNet's achieved a better performance for the detection of the tumor. M. N. Islam et al., [12] introduced a new approach to predicting the stage of childbirth accurately. S. Pereira et al., [13] developed the automated segmented approach by integrating CNN. Several steps are used to detect brain tumors by using the advanced segmentation approach. The normalization step is also utilized to remove the clamor from the image. Shakeel et al., [14] proposed the ML-based NN approach that analysis the tumor images by using infrared sensor imaging technology. Fractal dimension algorithm (FDA) is used for features extraction. This approach is mainly used to reduce the difficulties of tumor detection. Mallick, P. K et al., [15] proposed the improved compression approach that consists of a deep wavelet auto-encoder (DWA) for the feature reduction property. This approach also finds the size of the tumors. Li, G et al., [16] discussed various issues that are identified in the present pedestrian detection methods.

Zhang, D. et al., [17] proposed a novel approach to extract the features from the tumor images and these are called weights. This approach detects the tumor affected regions of the tumor images. Zhou, C et al., [18] proposed the lightweight model to solve several complex issues based on the detection of tumors. The post-processing method is also used to get the segmented outputs. Badrinarayanan, V., [19] presented a novel approach that deeply worked on a pixel-based segmented approach called as SegNet. The decoder network is also used to analyze the resolution of the brain images by using the feature maps. Hu, K. et al., [20] proposed a variety of segmentation approach that combines the two deep learning models such as MCCNN and CRFs. The proposed segmentation approach process the MRI images in two stages, in the first stage MCCNN is used to merge the components that take dependencies on multi-scale features segmentation. In the second stage, CRF is applied to get accurate segmentation by using spurious outputs. The proposed approach shows better results in detecting the tumors. Almahfud et al., [21] discussed several issues in detecting the brain tumors by using the optimal and nearest outliers based on the sensitive color variations. This approach is the combination of K-Means and Fuzzy C-Means. This is applied to MRI brain image datasets. This approach achieved better results compared with K-Means and FCM. K. Muhammad et al., [22] introduced the survey on various DL algorithms such as BTC models. These approaches discussed pre-processing, feature extraction, and classification. The existing approaches are applied to various benchmark datasets. M. Rizwan et al., [23] proposed the distinctive brain tumor approach that detects the tumors from the given quality MRI brain images. The proposed approach classifies the types of tumors such as pituitary, glioma, and meningioma. This approach is also focused on separating the tumor grades. A. Saleh et al., [24] aim to improve the tumor detection rate by using the DL algorithms. Various DL algorithms such as ANN, CNN, and D-CNN are applied to several approaches [35-37]. N. Noreen et al., [25] proposed the DL-based approach that contains the integrated approach to classify the tumors from MRI brain images. Several pre-trained models are used for training and feature extraction approaches are also used. All these features are combined and sent to the soft-max layer for the classification of tumors and non-tumors. The proposed approach achieved the accuracy of 99.35% with Inception-v3 and 99.56% with DensNet201. Zhou SK et al., [26] proposed the deep reinforcement learning (DRL) model that teaches the group of actions that increases the performance of the output. DRL utilizes the agent based approach that increases the accuracy of brain tumor detection. Chao Yu et al., [27] discuss several RL approaches that are applied on various medical and healthcare diagnosis. Al Walid Abdullah et al., [28] proposed the policy based redesigning the partial policies that ensures the robust and effective localization using the sub-agents by solving the several decision based approaches [29-34]. The proposed approach shows the optimal solution for the actual behavior learning framework.

III. FEATURE EXTRACTION METHODS TO REMOVE THE NOISE FROM THE MRI IMAGES

This step is mainly based on changing the pixel intensity values based on range. This approach will improve the contrast of the input image that helps image for better tumor detection. This is also called contrast stretching. This approach will transfer the n-dimensional MRI gray-scale image. The two types of MRI images such as cancer tumor image and AD based image are used to process. The following mathematical equation is used to analyze the pixels of the image.

$$\hat{X}[:,i] = \frac{X[:,i] - \min(X[:,i])}{\max(X[:,i]) - \min(X[:,i])} \quad (1)$$

For every brain image, the pixel numbers are positive and the range of normalized data is [0, 1] or [0, 255].

IV. IMAGE CLASSIFICATION USING DEEP-CONVOLUTIONAL NEURAL NETWORK (D-CNN)

Classification of brain MRI scan images is used to segment the various types of features. The MRI images have some features such as edges, intensity pixels, pixel value changes, and the size of the image. After the training and preprocessing the D-CNN is integrated with the feed-forward neural network (FFNN) and analyzes the normal and abnormal tissues based on the threshold values and processes the data in the grid-based topology. This is also called as ConvNet. Based on the types of tumors the classification is done by DCNN. Fig. 3 shows the processing of layers present in the DCNN. This is also shows the classification of AD images and normal images. Fig. 4 shows the execution flow for detecting AD and NON-AD images. This shows the functionality of every step and process the images for classification.

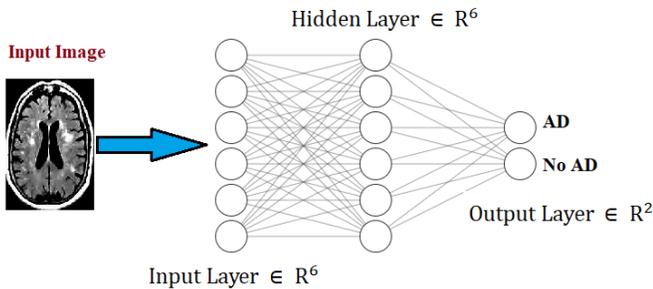
This consists of various hidden layers which are used to extract the data from the MRI scan images. This contains four layers such as:


Fig. 3. D-CNN to Find the AD or Not.

A. Convolution Layer

This is one of the significant layers and this consists of the first layer and this will extract the highly valuable features from the MRI images. These layers contain the filters that use the convolution operation. Every image initializes the matrix pixel value. The range of these pixel values is 0 or 1. 3x3 filter matrix is utilized. The dot product is calculated to get the accurate feature matrix.

$$Z^l = h^{l-1} * W^l \quad (2)$$

1) ReLU layer: ReLU (Rectified Linear Unit): This is used to extract the feature maps.

This operation performs the component wise operation and the negative pixels are represented as 0. This is also used the non-linearity network and generates the output as feature map. Graph represents the ReLU function:

The MRI scan image is analyzed with no of convolutions and ReLU layers are used to locate the features. Fig. 5 shows the range values among the ReLU layers.

$$R(z) = \max(0, z) \quad (3)$$

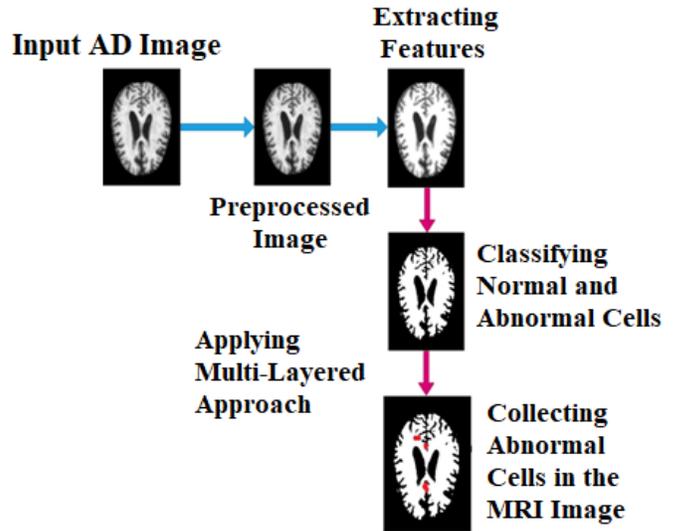
2) Pooling layer: This layer is utilized to reduce the dimensions of feature maps. This layer creates the pooled feature map.


Fig. 4. AD Detection Process using Proposed Approach.
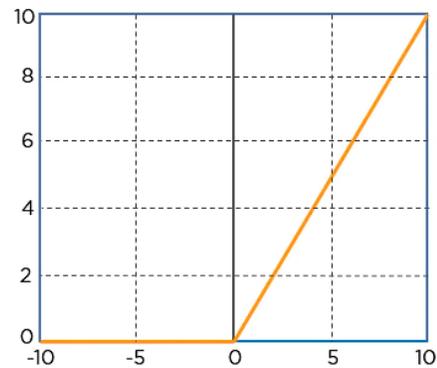

Fig. 5. Showing the Range Values 0-10.

This layer contains several filters that are used to find the significant regions such as normal and abnormal cells in the MRI scan images.

Every neuron is fully connected with all the neurons in the upper layer, the main aim of this layer is to transform the dimensions, and is also used to turn the high-dimensional features into low-dimensional every neuron in this system has activation function to get the final output.

$$h^l_{ab} = \max_{i=0,\dots,s, j=0,\dots,s} h^{l-1}_{(a+i)(b+j)} \quad (4)$$

$z^l \rightarrow$ pre $-$ activation output of layer l

$h^l \rightarrow$ activation of layer l

$* \rightarrow$ discrete convolution operator

$W, \gamma, \beta \rightarrow$ Learnable parameters

B. Steps for Agent Based Reinforcement Classification (ABRC)

The proposed classification is applied on two benchmark datasets.

Step 1: In the initial stage, the agent utilizes the Softmax exploration policy to find the strong values for original classes and low values for the wrong classes that are lies in the utilized exploration policy. The proposed approach is on-policy learning approach. Based on the changed actions the initial state is represented by.

$$P(x) = \frac{e^{\frac{P_i^x(s_t)}{\tau}}}{\sum_b e^{\frac{P_i^y(s_t)}{\tau}}} \tag{5}$$

Step 2: From the above equation the negative values shows the wrong classes and these are passed by TDlearning at the initial state. Here, 1 represents the errors (cancerous/AD affected) and 0 represents the 1 (non-cancerous/AD not effected). The testing approach calculates all the values $V_i(s0)$ for all the classes i and agents belongs to AC_i belongs to these classes. The predicted class y_p belongs to agent with high state value:

$$y_p = \text{argmax}_i V_i(s_0) \tag{6}$$

Output: The result shows that patient have affected with AD or Not and Cancerous tumors or not.

C. Segmentation

Edge-based segmentation is the technique that finds the accurate edges of the brain input images. This technique focused on detecting the edges based on the gray levels, image color, texture, etc. The gray level may change if the system moves from one region to another. If any abnormality is present then finding the edge is easy task. Different functions are used to get the image with edge segmentation and this output should not be confused with the final segmented image.

These edges are mainly connected with the "Magnitude" and "Direction". The edge detection used in this paper used both directions. This approach is represented with the following equations. To calculate the g the 7 or 8 or 9 formulas are used to calculate the g and theta. By using this strong edges are identified based on magnitude and direction.

$$g = (g_a^2 + g_b^2) \tag{7}$$

$$g = |g_a| + |g_b| \tag{8}$$

$$g = \max(|g_a| + |g_b|) \tag{9}$$

$$\theta = \arctan\frac{g_a}{g_b} \tag{10}$$

Where g_a = Magnitude of a

Where g_b = Magnitude of b

V. DATASET DESCRIPTION

For the experimental results, three datasets are used two datasets for brain tumor detection and one for AD detection. Two MRI brain tumor datasets are BraTS-2019 [12] [20] and the Kaggle dataset. Another AD dataset is collected from the Kaggle dataset and this contains 10000 MRI samples with four classes shown in Fig. 1. The training set contains 5000 images and testing contains 5000 images.

VI. PERFORMANCE METRICS

The performance is evaluated by calculating various metrics such as dice score, precision, sensitivity, specificity, accuracy. The segmentation of brain image result is analyzed by using dice score.

$$\text{Dice Score} = \frac{2TP}{FN + FP + 2TP}$$

Specificity: This parameter mainly detects the total number of TP and FP and this is used to calculate the model which is more ability to predict the background area.

$$\text{Specificity} = \frac{TN}{TN + FP}$$

Sensitivity This parameter mainly detects the total number of TP and FN and this is used to calculate the model which is more ability to predict the segmented area.

$$\text{Sensitivity or Recall} = \frac{TP}{TP + FN}$$

Accuracy is one metric that measures the reliability of the classification result. The formula is give below.

$$\text{Accuracy} = \frac{TP + TN}{TP + FN + FP + TN}$$

Precision: The overall percentage of the output results are defined as:

$$\text{Precision} = \frac{TP}{TP + FP}$$

Table I and Fig. 6 show the performance of training and testing in terms of time. Among all the existing models the proposed model achieved the low training and testing time (Sec).

VII. Conclusion

An integrated segmentation approach (ISA) is developed to detect the cancerous cells in MRI images and also work on AD detection. The proposed approach is integrated with various advanced steps to get accurate results. Generally detecting the AD from the MRI scan images is a very difficult task. But the proposed approach becomes very easy to detect the AD and also cancer cells in the MRI scan images. Advanced training and preprocessing approaches improve the performance. The proposed approach increases the performance for the detection of MRI scan images in terms of parameters such as Dice Score-99.12%, Specificity-99.12%, Sensitivity-99.56%, Accuracy-99.1%, Precision-99.67%. AD detection performance is Dice Score-89.34%, Specificity-97.87%, Sensitivity-98.56%, Accuracy-99.67%, Precision-99.45%.
