Golubev, Kirill, Aleksandr Zagarskikh, and Andrey Karsakov described a brand-new framework for agent-based traffic modeling that combines various traffic model classes into a single vehicle agent and lets the user choose a particular model for each supported class in [13]. The framework was created with the help of the Unreal Engine 4 gaming engine, which enables users to simulate realistic vehicle interaction and create realistic visualizations for visual analysis and computational steering.

A. Limitations of Related Works

- The constraints of a vehicular network scenario that new communication, data, and resource approaches must address to increase overall network performance, such as low power, full storage, message's time-to-live, and bandwidth.
- SD VANET has insufficient performance evaluation, Uncertainty over the proposal's usefulness and correctness, as well as integration problems with fog, SDN, and VANET.
- No security analysis, no solution when connection loss with controller occurs. only weak security analysis.
- ANN and a fuzzy controller has hardware dependency, Sharing Difficulty, Overfitting Likely, ANN Solution Not Guaranteed.
- Fuzzy logic has two significant drawbacks: it cannot handle ambiguous data, and it cannot infer human thought.

III. PROPOSED SYSTEM

Our proposed system by dynamically calculating the green signal period based on the volume of traffic at the signal hopes to reduce such instances. By doing this, it will be ensured that the way with greater traffic receives a longer green signal duration than the route with a relatively lower volume of traffic. The suggested solution uses image processing and object detection to calculate real-time traffic density from images captured by CCTV cameras placed at traffic intersections. Fig. 1 illustrates how this image is transmitted to the vehicle detecting algorithm that uses YOLOv5. To determine the traffic density, the number of each type of vehicle is counted, including automobiles, cyclists, buses, and trucks. This density, along with a few other variables, is used by the signal-switching algorithm to set the

green signal timer for each lane. Accordingly, the red signal times are modified. To prevent a particular lane from going without traffic, there is a highest and lowest value for the green signal time.

So, the proposed system will work this way.

- The proposed system will use Closed Circuit Television (CCTV) for collecting live videos and snapshots installed at traffic signals.
- Snapshots from the CCTVs will be passed to servers at intersections for combining computer vision and image processing to calculate traffic density.
- For detecting vehicles, the YOLOv5 model will be used as shown before.
- A time scheduling algorithm will use these values and update the green and red signal times for each signal.

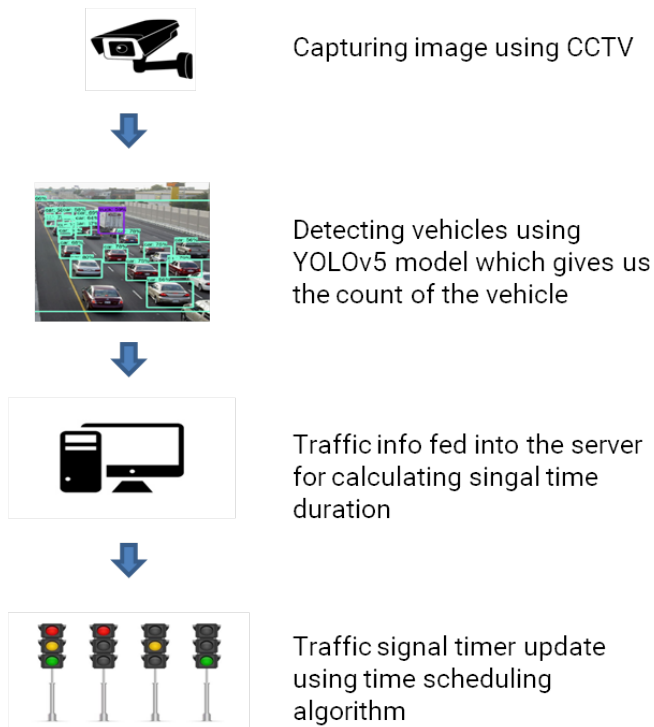

Fig. 1. Proposed system

Fig. 1 Shows the flow diagram of the proposed system.

A. Vehicle Detection System

The proposed system uses YOLOv5 (You Only Look Once) for automobile recognition. This is one of the most well-known object detection algorithms for its accuracy and speed. It can perceive vehicles of different modules and can provide the desired accuracy and processing time. A single neural network is applied to the entire image by the algorithm, which then divides it into regions and forecasts enclosing frames and possibilities for each region. The projected probabilities are used to weigh these bounding boxes. By downloading photos from Google and manually labeling them using the visual image annotation tool LabelIMG, the dataset for training

the replica was created. Then, the system was taught by pre-guided credence obtained from the YOLO site. By altering the 'classes' variable, the number of yield synapses in the ultimate coating was placed to be identical to the number of modules the system is intended to perceive. The replica was taught until the loss was much lower and didn't appear to be decreasing after making these configuration adjustments. The OpenCV library was then used to detect vehicles using these weights that were entered into the program. Following the model has been filled and a figure has been fed into it, it outputs the results in a JSON format, or as pairs of keys and values, where keys are labels and the values are the labels' confidence and coordinates.

Fig. 2 shows the test result of our vehicle detection system. Applying the YOLOv5 model, we can detect the different kinds of cars, in packages and with corresponding labels.

Fig. 2. Result of vehicle detection system

B. Signal Updating

The servers at junctions will receive images from the Closed-circuit- circuit television and process them to calculate the traffic volume. The traffic surveillance module's dynamic traffic data is used by the Signal Shifting Technique to set the green signal schedule and update other lights' red signal timers. The method uses previously observed vehicle data that is provided in JSON format. Following that, the cumulative number of automobiles in each class is determined using this data. The program then identifies the lane with the highest car density. The data is subsequently transferred to the server after being located in the more crowded lane. The computer then extends the signal's green light by a few seconds where a high vehicular density was observed.

The default timing is established for the primary signal of the very first loop when the program is initially executed. Two separate lines are activated here, one to handle vehicle detection for each lane, and another to lever the timer of the existing signal. While the green signal timer is running for the current signal, the system takes a snapshot of the next lane and the red-light time for the other lights, and the green-light time for the next signal, respectively. As the timer and the vehicle detection are handled by two different lines, the timer does not interfere. When, the green light time of the existing signal becomes zero, the timer for the next signal starts. The cycle of counting timers and detecting vehicles keep going in the same manner for each signal.

The green light duration for each signal can be measured by this:

Here, G_{dur} is the duration of green signal time The number of vehicles is the total number of cars of each type detected by the vehicle detection system Average time to cross intersection = $\text{Distance}/(\text{Average speed of the vehicle})$ The number of lanes is the total number of tracks available in the intersection

The typical speed of vehicles will be measured in advance and will be stored on the server. Depending on the class of vehicles, the speed will be different. Using the vehicle detection system, we will detect the type of vehicles as well, and according to that data, we will use the average speed values to measure the average time to cross the intersection. The signals do not shift in the direction with the highest density initially; instead, they do so in cycles. This is in line with the existing structure, which sees the signals convert to green sequentially in a predictable fashion without requiring inhabitants to adjust their behavior or create any perplexity. The yellow signs have also been taken into account, and the signal sequence is the same as it is in the existing system.

After the signal turns green, the picture is snapped after some time. This provides the structure a period to decode the figure, compute the number of automobiles in every class present in the figure, determine the time for the green light, and then set the timers for both the existing signal and the next signal's red signal based on that calculation. The best green light duration based on the number of cars of each type at a signal was determined using the bandwidth of automobiles at starting and their sprint times. From that, an estimated of the typical time each type of vehicle requires to cross a junction was found.

$$G_{dur} = \frac{\sum_{vehicletype} (\text{TotalVehicles} * \text{AverageCrossingTime})}{\text{TotalLanes} + 1} \quad (1)$$

Here,

G_{dur} is the duration of the green signal time

TotalVehicles is the total number of cars of each type detected by the vehicle detection system

$$\text{AverageCrossingTime} = \frac{\text{Distance}}{\text{AverageVehicleSpeed}}$$

TotalLanes is the total number of tracks available in the intersection

The typical speed of vehicles will be measured in advance and will be stored on the server. Depending on the class of vehicles, the speed will be different. Using the vehicle detection system, we will detect the type of vehicles as well, and according to that data, we will use the average speed values to measure the average time to cross the intersection. The signals do not shift in the direction with the highest density initially; instead, they do so in cycles. This is in line with the existing structure, which sees the signals convert to green sequentially in a predictable fashion without requiring inhabitants to adjust their behavior or create any perplexity. The yellow signs have also been taken into account, and the signal sequence is the same as it is in the existing system.

After the signal turns green, the picture is snapped after some time. This provides the structure a period to decode the figure, compute the number of automobiles in every class present in the figure, determine the time for the green light,

and then set the timers for both the existing signal and the next signal's red signal based on that calculation. The best green light duration based on the number of cars of each type at a signal was determined using the bandwidth of automobiles at starting and their sprint times. From that, an estimated of the typical time each type of vehicle requires to cross a junction was found.

C. Simulation

To show the process we have created two different simulations using Unreal Engine 4 from scratch. One of which shows the current traffic system and the other shows our proposed system. It helps with system visualization and comparison with the current static system. Unreal Engine (UE) is a free-to-use 3D computer graphics game engine developed by Epic Games. The next-gen real-time 3D content and experiences are made possible by Unreal Engine, which is used by game developers and producers across industries. Unreal Engine is a full set of development tools for games, broadcast and live event production, education and simulation, architectural visualization and automotive, television content and linear film generation, and other real-time functions.

A four-way intersection with four traffic lights is present there. A timer that shows how much time is left until a signal turns between green-yellow, yellow-red, and red-green is situated on top of each signal. The quantity of vehicles that have passed through the intersection is also shown next to each light. Different types of vehicles arrive from all directions. To make things even, we had to keep the environment and the traffic flow similar for each simulation. And for simplicity, we have set the speed of each class of vehicles to the average speed of their class.

Factors to consider (same for both simulations): 1. Number of lanes 2. Traffic flow 3. Speed of vehicle 4. Lag suffered by vehicles during startup 5. Similar road, intersection, and the same distance

1) *1st simulation (traditional system)*: In the traditional system, every phase of the traffic signals uses a fixed timer that does not update or vary in response to the actual congestion on the road. So, one particular direction with heavier traffic is given the same amount of green signal time as the other direction, which has lesser traffic than the other or in some cases, no traffic at all, which is inconvenient.

Fig. 3. Traditional traffic system (1)

Fig. 4. Traditional traffic system (2)

Fig. 6. Proposed traffic system (2)

Fig. 3 and Fig. 4 show the simulation of the traditional traffic system. In this simulation, we will see that, for every signal, the timer is fixed. Every signal is given the same amount of green signal time, in this case, 20 seconds each. But the flow of traffic in each direction is not the same, which doesn't allow proper traffic flow in the intersections as intended.

2) 2nd simulation (proposed system): By automatically calculating the green signal period based on the volume of traffic at the signal, the approach we've suggested tries to mitigate such issues. By doing so, it will be ensured that the route with greater traffic receives a longer green signal duration than the route with a relatively lower volume of traffic.

This simulation shows how our proposed system works. As the traffic flow of each lane is not the same, our proposed system updates the signal based on real-time traffic.

Fig. 5. Proposed traffic system (1)

Fig. 5 shows the lane with a lower traffic flow is assigned a less amount of green signal time, 10 seconds in this case.

Fig. 6 shows the lane with a higher traffic flow is assigned a large amount of green signal time, 40 seconds in this case. This value can vary from 10 seconds minimum to 70 seconds maximum in our simulation based on the real-time traffic.

IV. RESULT AND ANALYSIS

Using several sample photographs with various numbers of cars, our vehicle detection method was put to the test, and it was found that the detection performance ranged between 65 and 75 percent. Although sufficient, this is not ideal. The absence of a pertinent dataset is the primary cause of the lower accuracy. The system's accuracy can be improved by feeding the model data from actual traffic camera footage.

Two simulations were executed multiple times to assess the proposed method with the established system, and from those simulations, some data was acquired.

In both cases, we have took into account the factors to consider,

- Number of lanes
- Traffic flow
- Speed of vehicle
- Lag suffered by vehicles during startup
- Similar road, intersection, and the same distance

We ran both simulations for an hour and recorded the number of vehicles that passed through the junction over three minutes three-minute periods in each system.

TABLE I. TOTAL CARS PASSED IN THE TRADITIONAL SYSTEM

No	Time	Lane 1	Lane 2	Lane 3	Lane 4	Total
1	3	67	36	48	75	226
2	6	56	44	60	59	219
3	9	76	57	34	56	223
4	12	47	68	63	52	230
5	15	87	31	51	43	212
6	18	42	77	48	55	222
7	21	65	69	46	44	224
8	24	42	71	55	59	227
9	27	33	82	66	33	214
10	30	52	63	61	41	217
11	33	47	67	72	40	226
12	36	79	45	53	49	226
13	39	83	49	51	42	225
14	42	62	72	66	11	211
15	45	93	37	51	33	214
16	48	97	42	25	65	229
17	51	106	32	43	37	218
18	54	56	77	46	38	217
19	57	65	79	53	28	225
20	60	70	75	49	30	224

TABLE III. COMPARISON OF PASSING CARS IN 2 MODELS

No	Time	Total Car Passed(Current)	Total Car Passed(Proposed)	Difference
1	3	226	278	52
2	6	219	282	63
3	9	223	287	64
4	12	230	275	45
5	15	212	279	67
6	18	222	284	62
7	21	224	288	64
8	24	227	281	54
9	27	214	279	65
10	30	217	275	58
11	33	226	277	51
12	36	226	282	56
13	39	225	285	60
14	42	211	287	76
15	45	214	287	73
16	48	229	281	52
17	51	218	276	58
18	54	217	281	64
19	57	225	280	55
20	60	224	280	56
Total		4429	5624	1195

From Table I, we get the number of cars passing through the intersection every 3 minutes for 1 hour in the traditional system.

The result is shown in Fig. 7, where the number of vehicles passing through the intersection is between 210 and 230.

TABLE II. TOTAL CARS PASSED IN THE PROPOSED SYSTEM

No	Time	Lane 1	Lane 2	Lane 3	Lane 4	Total
1	3	87	56	72	63	278
2	6	73	68	66	75	282
3	9	95	55	68	69	287
4	12	61	78	72	64	275
5	15	74	76	60	69	279
6	18	88	63	81	52	284
7	21	97	67	66	58	288
8	24	81	77	52	71	281
9	27	102	64	62	51	279
10	30	107	59	51	58	275
11	33	85	82	58	52	277
12	36	97	58	66	61	282
13	39	77	71	81	56	285
14	42	73	75	71	68	287
15	45	91	70	59	67	287
16	48	80	84	71	46	281
17	51	66	92	72	46	276
18	54	78	75	76	52	281
19	57	107	55	61	57	280
20	60	82	69	60	69	280

Fig. 7. Number of cars passed in the traditional system

From Table II, we get the number of cars passing through the intersection every 3 minutes for 1 hour in our proposed system.

The result is shown in Fig. 8, where between 270 and 290 automobiles traveled past the crossing.

Fig. 8. Number of cars passed in the proposed system

From Table III, we can see the comparison of the result of the simulation we have run for both systems. The result, in this case, is quite satisfactory.

The result is shown in Fig. 9, where 40-80 more vehicles are being passed through the intersection in our proposed system compared to the traditional traffic system.

Fig. 9. Comparison of the number of cars passed in both systems

Here are 20 different results of 1 hour of simulation of both systems. Every 3 minutes, the traditional system lets 210-230 vehicles pass through the intersection whereas our proposed system is letting 270-290 vehicles pass through the intersection, which is a noticeable improvement.

TABLE IV. COMPARISON BETWEEN 2 MODELS

Parameters	Traditional system	Proposed system
Average cars passed per minute	74	94
Total cars passed in 1 hour	4429	5624

By comparing the simulations while maintaining the same set of conditions, the outcome of Table IV was obtained.

As we can see, keeping all the conditions alike, the current system was able to pass 4429 vehicles total in 1 hour, whereas our proposed system was able to pass 5624 vehicles in same

amount of time, which is 1195 more vehicles than current system.

Thus, our proposed system will increase the performance by 26.98126%

V. CONCLUSION

In conclusion, the suggested program guarantees that, by adaptively modifying the green signal timing according to the density at the light, the route with more vehicles is given a green light time for a longer period in comparison to the route with less traffic. Due to fewer unnecessary delays, less traffic, and shorter wait times, there will be less fuel use and pollution.

In regards to the number of vehicles passing the intersection, the system performs around 23 percent better than the current method, which is a substantial improvement. With more calibration and authentic surveillance data for the training set, this system has the potential to perform even more effectively. Additionally, the suggested method has some benefits over other intelligent traffic management systems that are already used, like Pressure Pads and Infrared Sensors. The system may be installed for a very low cost because it uses CCTV footage from traffic signal cameras and typically doesn't need any new hardware because these cameras are already present at intersections with considerable traffic.

There might only be a small amount of alignment required. Maintenance expenses are also decreased when compared to other traffic enforcement methods like "pressure mats", which frequently face stress for their installation on roadways where these are continuously imposed to tremendous stress. To allow improved traffic control, the proposed method can therefore be connected with Surveillance cameras in large cities

VI. FUTURE WORK

To improve traffic management and reduce congestion, the project could be extended further to include features like these:

1) *Detecting violations of traffic rules:* Vehicles that are breaking traffic rules can be identified easily by video streaming and capturing images of vehicles with number plates. It is feasible to recognize the automobiles that are skipping red lights in the picture or video stream by establishing a transgression barrier and recording the plate number of the image and whether that line has been crossed when the light is red. Similarly, lane changing of vehicles might also be detected. These can be accomplished through image processing methods or backdrop removal.

2) *Detecting violence or accidents on road:* Accidents can be detected easily and necessary steps can be taken quickly. Intersections commonly see catastrophic collisions as a result of the presence of numerous hazardous collapses, like crashes due to angular and turning left. To safeguard property and lives while simultaneously minimizing traffic and delays, it is crucial to accurately and quickly identify accidents at crossings. The list of automobiles that remain immobile for a lengthy amount of time in an inhospitable area, such as the center of the road, might be modified to exclude parked cars from this restriction.

Also if any occurrence happens by any vehicle, it can be detected and tracked. Also, the probability of the vehicle taking a specific route can be predicted in advance.

3) *Detecting emergency vehicles*: Vehicles like ambulances or fire service can be detected and the timer can be adapted accordingly to make a quick passage for the emergency vehicle. The model can be programmed to recognize emergency vehicles in addition to other types of cars, allowing it to adjust timers to give them precedence and enable them to cross the signal as soon as possible.

Emotion Detection from Text and Sentiment Analysis of Ukraine Russia War using Machine Learning Technique

Abdullah Al Maruf¹, Zakaria Masud Ziyad², Md. Mahmudul Haque³, Fahima Khanam⁴
Department of Computer Science and Engineering, Bangladesh University of Business and Technology
Mirpur, Dhaka, 1216, Bangladesh

Abstract—In the human body, emotion plays a critical function. Emotion is the most significant subject in human-machine interaction. In economic contexts, emotion detection is equally essential. Emotion detection is crucial in making any decision. Several approaches were explored to determine emotion in text. People increasingly use social media to share their views, and researchers strive to decipher emotions from this medium. There has been some work on emotion detection from the text and sentiment analysis. Although some work has been done in which emotion has been recognized, there are many things to improve. There is not much work to detect racism and analysis sentiment on Ukraine -Russia war. We suggested a unique technique in which emotion is identified, and the sentiment is analyzed. We utilized Twitter data to analyze the sentiment of the Ukraine-Russia war. Our system performs better than prior work. The study increases the accuracy of detecting emotion. To identify emotion and racism, we used classical machine learning and the ensemble method. An unsupervised approach and NLP modules were used to analyze sentiment. The goal of the study is to detect emotion and racism and also analyze the sentiment.

Keywords—Emotion detection; racism; sentiment analysis; social media; machine learning; ensemble; Ukraine-Russia

I. INTRODUCTION

Emotion is a strong feeling caused by one's circumstances and conditions, moods, interpersonal connections, or pleasure and dissatisfaction. The emotional experience includes perceptions of the world, cognitive capacities, behavioral reactions, metabolic anomalies, and instrumental activity. Emotions are difficult to define because they are a fleeting state of mind. Images, speech, facial expressions, textual information, emoticons, and other kinds of expression may all be used to determine emotion. Textual data is essential for research [1]. Massive amounts of text-based data have been generated regularly in recent years via social media and conversations such as messenger, Whatsapp, Twitter, and other means [2]. The progression of digital communications and its popularity, particularly virtual networking, keeps individuals interested in how they connect and communicate amongst themselves. People have become accustomed to expressing feelings lightly and intuitively through social media communication and the simplicity of responses. People use social media to keep up with what's happening in the world and to share their opinion and feedback via likes, comments, and shares, among other things [3]. Today's most popular social media platforms are Facebook, Twitter, and Instagram. People visit Facebook to keep in touch with friends, family, and loved ones, learn about what's happening worldwide, and express what's important

to them, according to Facebook's vision and mission. People incline to be more verbose on Facebook, yet posts go through more simple "likes" than lengthy comments. Since February 2017, Facebook has included additional capabilities that allow users to express their specific feelings in reaction to a post, such as the ability to mention "love" or "sadness" instead of liking a post [4]. People use Twitter to express their thoughts, feelings, and views through short messages or tweets at any time. Individuals' emotional states of mind, such as joy, worry, and hopelessness, are captured overtly or indirectly within those short messages along with bigger communities, such as the viewpoints of people in a particular country [5][6]. There are five ways to emotion identification from text, including keyword-based, lexical/corpus-based, learning-based, hybrid-based, and deep learning-based approaches, but each has its limitations[7]. Specifically, identifying object words from tweets is named object-oriented feature to perform sentiment—Bi-gram, uni-gram model with object-oriented feature effective better [8]. Emotion was discovered and recognized using machine learning and deep learning methods. There are also several classifications for identifying emotions; some of them are the k-nearest neighbor(KNN) algorithm, Support vector machine(SVM), decision tree(DT), random forest(RF), linear discriminant analysis(LDA), etc. DT is a decision support tool that uses a tree-like graph or model of decisions and their possible consequences, KNN is a method for classifying objects based on closest training examples in the feature space, LDA is a method used in statistics, pattern recognition, and machine learning to find a linear combination of features which characterizes or separates two or more classes of objects or events and SVM analyze data with recognizing patterns used for classification and regression analysis. Based on the lexical approach, Real-time emotional analysis was carried out, and the data was obtained from online social media[9]. Sentiment analysis may be performed using a deep learning model that has been pre-trained, as well as unsupervised algorithms such as Valence Aware Dictionary and sEntiment Reasoner(VADER), textblob, and k-means clustering. It's also possible to gauge sentiment using lexicons. The sentiment was analyzed using large-scale data from Twitter and a machine learning-based technique. Sentiwordnet and sentiment are sentic computing-based public lexicons [10]. Emotion is identified from audio sources following machine learning techniques and categorized into six basic emotions. Auto weka performed the best outrun compared to SVM, KNN, and multi-layer perceptron (MLP) [11]. Finding out mental instability RF shows (87%) accurate

results from the manually surveyed datasets [12]. The basic facts are that domain adaptability and accuracy are the main constraints for emotion recognition from text. The advantages of the suggested approach are an improvement in emotion detection accuracy. The dataset was compiled from a number of sources. The dataset will aid researchers in overcoming this industry's problem of domain adaptation. The research project also analyzes the war between Russia and Ukraine's tweets for mood. The topic has fewer datasets that are readily available. Therefore, gathering a dataset is the main contribution to this field. The desired model to address accuracy issues is ensemble model learning. The main goal of the research was to increase accuracy, thus we utilized a variety of ensemble techniques. We proposed a unique technique where ensemble and classical machine learning are applied. We also used an unsupervised approach to analyze the sentiment. In our work, we will show an approach that detects emotion, analyzes sentiment, and detects racism. We used various methods and techniques to identify emotion, racism, and sentiment analysis. To increase the speed and quality of the learning process, we applied machine learning and ensemble method using parameters. The following is the structure of this paper: Some recent studies in this field are addressed in Section 2. Section 3 details our study technique. Section 4 contains the results, and We'll talk about our strengths and weaknesses and provide suggestions for the future. Then, we eventually finished the paper.

II. RELATED WORK

According to a case study [12], a 3-turn dialogue detects and distinguishes emotions. In three turns, it contains a collection of human emotions on Twitter. They also talk about the Amiens system, which detects emotions in text messages. The algorithm applied the Long short-term memory (LSTM) model to recognize human emotions based on the in-depth reading. The system's primary input is a mix of word2vec and doc2vec embedding. Then, for that issue, utilize the most current Bi-Long Memory Short Term category, which used word embedding as input and predicted human emotion. When the Amiens score is 0.7185, the output results reveal considerable variations in f points above the model's base. As a potential future project, they plan to expand hybrid approaches through emotion handling and emotion lexicons management. A case study showed the interaction of emotion by applying hybrid and machine learning methods for six basic emotion categories. A comparison study of speaker-independent and dependent recognition was represented [13]. As different formats of emotion detection systems exist, the text identification system is one of them. A machine learning-based automated system was implemented to understand a textual form of data to analyze its class. SVM was performed with a 63.5% accuracy rate in the following system of automatic text identification [14]. Linguistic-related emotion identification has some complexity, and little research has been done on it. For every individual language, the data preprocessing step becomes the most challenging part. Preprocessing steps followed tokenization, segmentation, and other extraction methods to filter raw data for better applicability. A system was implemented to perform a hybrid approach to classify six basic emotions for Punjabi words [15]. Urdu language-based work focused on commercial-related emotion detection [16]. The algorithm support vector classifier(SVC), KNN, RF,

and Naive Bayes(NB) was applied to datasets (Smartphone and Sports), and SVC performed best among them with accuracy above 80%. NB achieved the goal of detecting Bangla text-related emotion. As a complex linguistic analysis, three emotions category presented in this process [17]. Facial expression means a lot of things about the mentality of a person. The machine learning-based method SVM algorithm was used to detect the actual emotion of a person from an image. Framework and UI environment constructed in their system [18]. In the present world, the most used handheld electronic device is a smartphone. A self-automated system named "iself" is represented in their work where it can detect the user's emotions from their smartphone data. The system's structure describes how emotion detection happened by analyzing smartphone users' data [19]. Social media is a great source for mass data collection. Five preprocessing techniques were used for Arabic language emotion detection contextual research. The minimal sequential optimization(SMO) classifier performed better than NB and SF in classifying six basic emotions distinguished from the text [20]. Emoticons can be an expression of emotion. The study reviewed the Arabic tweets and labeled them into the four emotion categories. Testing was performed using SVM and MNB algorithms for developing the system[21].Deep learning techniques were used for detecting emotion from the Persian text document. Preprocessing technique word2vec was used for normalizing the dataset. NB, DT, and SVM algorithms were executed to classify emotion, and 10-fold cross-validation was performed to evaluate the performance. The SVM algorithm scored the highest accuracy in their system [22]. A system overviewed in the research is SEDAT, which can detect emotion from Arabic social media tweets in real-time. Convolutional Neural Network(CNN)-LSTM neural network technique was applied to construct the system. Their work shows that the system is better accurate than the TeamUNCC system [23]. Arabic language-based sentiment analysis work combined three Arabic Steemers (ISRI, Light Steemer, snowball). The research outcome exhibits a comparison between deep learning and machine learning where CNN, SVM, NB, and MLP are exerted in implementation [24]. Emotion classification and social media are almost connected in parallel cause it is a rich data sources. In this case, comparative model analysis on different datasets is highlighted. TME model acquires maximum accuracy than other models, and WME remains close to TME [25]. From youtube users' text comments, emotion identification was conducted in this research. Unsupervised machine learning technique executed to determine emotion category from YouTube comment data corpus. The system achieved an average of 92.75% precision, close to another existing system that applied the SVM algorithm[26]. The microblog-based emotion classification task is represented by using deep learning techniques. CNN model was selected for this purpose, though the experiment was held in four phases. Sina Weibo was the data source for the experiment. This study exposed CNN as the maximum accurate (97.60%) for detecting emotion from microblogs [27]. Another research is a deep learning-based emotion recognition system. It also demonstrates how excellent deep learning is at detecting text emotion. Data preparation includes sentence segmentation and word embedding. SVM and LSTM are employed to categorize seven different emotion groups. Among these, LSTM has a higher efficiency (94.7%) than SVM [28]. Most of the existing

sentiment analysis and emotion detection research is performed on deep learning or machine learning-based unique techniques. This study presents a system that converts multi-label classification problems into a single binary classification and then solves the problem by applying the deep learning method. The proposed system model Binary Neural Network (BNET) shows the best accuracy in evaluation measured in (multi-label accuracy) Jaccard [29]. Although several textual-based emotion recognition systems exist, the researcher concentrated on discovering emotional states from poetry text in this study. The suggested method is capable of detecting 13 different emotion classes. The system recognizes the context and value of tokens. Comparative investigation demonstrates that the suggested model outperforms the CNN-BiLSTM model in this system[30]. Emotion-based research is becoming more popular since computer machines can predict likely outcomes. Several research and records used a variety of procedures and strategies to identify particular human emotions. Previous work had various drawbacks; thus, the suggested system employed the layered LSTM approach to identify emotion. The suggested system outperformed the LSTM and SVM approaches, reaching a 99.2% accuracy rate [31]. Another research represents EmoDet2, a system that innovates deep learning architecture for identifying emotion from the text. The suggested system used two different algorithms: BERT and BiLSTM. EmoDet2 has been created by applying the ensemble method. The system F1 score (0.75) outperforms the baseline model, which was encouraging. SEMEVAL-2019 dataset had the best accuracy in recognizing emotion from the text, allowing the EmoDet2 system to outperform the baseline model[32]. A suggested method was given in another study that used a machine-learning approach to identify emotions. The dataset is divided into two types, one binary, and the other multi-class. The system was programmed with seven machine-learning models for the experiment. The sentiment is divided into two categories: joyful and unpleasant. The LR-SGD and the tf-idf classifier produced ideal results in a comparison study. The voting classifier beat all others, obtaining 84 percent accuracy using both TF and tf-idf[33]. According to a study by [34], social media is getting a lot of attention in today's world. Public and private opinions on various topics are constantly expressed and distributed via social media platforms. One of the most prominent social media platforms is Twitter. Twitter is a social media platform that allows buddies, relatives, and colleagues to interact and keep in touch by exchanging short, frequent messages. Twitter is the main microblogging website that allows users to post status updates (known as "tweets"). These tweets occasionally reflect thoughts on a variety of issues [35]. Twitter is a real-time microblogging platform that allows individuals or groups to express their opinions on a topic and have them appear on a timeline. Web search apps and real-world applications such as current global trends and world events, and extracting the most up-to-date information regarding occurrences use microblog data for analysis and conclusion-making. Sentiment Analysis and Opinion Mining are two types of text mining that involve the analysis of sentiments, opinions, and emotions and the assessment of the text's content. When evaluating people's thoughts, feelings, assessments, attitudes, and responses to services, goods, organizations, personalities, events, themes, and issues, and their qualities, sentiment analysis is another name for opinion mining. Sentiment and subjectivity are strongly influenced by the context and domain in which they occur.

It is not only due to language changes but also to the dual meaning of feelings of the same term in various domains. The processes of extracting nontrivial patterns and intriguing information from unstructured script texts are called opinion mining and sentiment analysis, respectively [36]. Before the internet, it took a long time for information about a company's stock price, direction, and general attitudes to spread among individuals. Web technology has ushered in a new era of rapid information transmission and retrieval. Applying positive or negative information about a company, product, person, or other entity may be as simple as clicking a mouse or utilizing microblogging services like Twitter [37]. Social media platforms have grown in importance as a forum for political debate worldwide. Users may use Twitter to send tweets, which are short communications of up to 140 characters. The number of people using Twitter is steadily increasing. Over 100 million active users throughout the world send over 250 million tweets every day, according to the business. In several fields, including the financial market, politics, and social movements, sentiment in Twitter data has been utilized for prediction or assessment. Emerging events or news are frequently followed by a surge in Twitter activity, offering a unique chance to assess the relationship between stated public mood and political outcomes. Furthermore, sentiment analysis may be used to investigate how these occurrences impact public perception. It provides a fresh and contemporary perspective on the dynamics of the election process and public opinion to the general public, the media, lawmakers, and academics. They present a method for real-time analysis of popular sentiment toward presidential candidates, as stated on Twitter during the 2012 U.S. election [38]. Many readers value social media platforms such as Twitter and Facebook because they enable users to easily discuss and express their thoughts on various issues and send messages worldwide. Every day, millions of quick messages (tweets) are shipped on Twitter, making it one of the most prominent microblogging and social networking services. The challenge of assessing users' tweets in terms of emotions, ideas, and viewpoints in a wide range of activities and domains is addressed by Twitter sentiment analysis [39]. Twitter sentiment analysis is a tricky issue, even though sentiment analysis has recently garnered significant popularity in various fields. Businesses use sentiment analysis to look at customer reviews of their services, while the government and other organizations use it to observe public health and forecast political trends, among other things. Manual procedures were frequently used for this before the advent of social networks. Manual techniques were frequently used for this before the beginning of social networks [40]. Customers who want to buy a quality product based on user reviews at reliable online retailers can take advantage of the service offered by the Twitter Sentiment Analysis for Business Project. Additionally, it benefits commercial enterprises that wish to accelerate their firm's growth by revamping goods or services following customer demands and preferences [41]. One of the most crucial tasks in text mining is automatic sentiment analysis of texts, which aims to establish if a given document has a positive, negative, or neutral attitude. Nowadays, It has gotten a lot of attention because opinion mining on microblogging sites is widespread. Both public and commercial companies increasingly rely on the ability to determine whether a written document has a favorable or unfavorable impression [42]. SVM, LR, NB,

and KNN are the techniques employed for sentiment analysis of how people feel about moving the nation's capital. As measured by the performance evaluation algorithm's accuracy, precision, recall, and F-measure findings, the support vector machine fared better than the other three algorithms. The administration will receive an overview of public opinion from the perspective of data from social media through sentiment analysis of the dialogue surrounding the relocation of the nation's capital [43]. With the development of Web 2.0 and the rising popularity of social media platforms like Face book, Twitter, and Google+, users can now exchange information and, as a result, have a say in the material published on these platforms[44]. Many analysts, businesspeople, and politicians use blogs, microblogs, social networks, and other types of websites as a massive source of information to grow their businesses by taking advantage of the copious amounts of text produced by users who provide ongoing feedback on the prominence of a particular subject through emotions, viewpoints, and feedback. The last ten years have seen a growth in sentiment analysis methods, mainly when applied to tweets, in both the academic and industrial areas [45]. Twitter sentiment analysis is a useful tool for various activities using Twitter-based analysis. Twitter sentiment analysis using attentional-graph neural networks is done by the Attentional-graph Neural Network-based Twitter Sentiment Analyzer (AGN-TSA). A three-layered neural network used by AGN-TSA combines information from the tweet's text and its user connections [46]. Recurrent neural networks (RNNs) are also used to examine sentiment in tweets. The technique can categorize tweets with an accuracy rate of 80.74% while considering a binary task, following testing 20 various design strategies [47]. Furthermore, A brand-new unsupervised learning framework built on Concept-based and Hierarchical Clustering is suggested for Twitter Sentiment Analysis. Serial ensembles combine common hierarchical clustering techniques, including single linkage, complete linkage, and average linkage algorithms. Additionally, TF-IDF performs better than the Boolean method compared to other feature representation techniques also examined [48]. One of the most intriguing study areas is sentiment analysis from Twitter [49]offered a comparative emotive analysis from a different linguistic standpoint. Several models, such as PLMs, RoBERTa, and BERT, were used to evaluate each language separately. For fine-tuning, four Nigerian languages were pooled in the training dataset. Among the models tested in the proposed system, the AfriBERTa model fared the best. At present, politics and virality in social media is a common phenomenon. This study [50] overviewed sentimental analysis from Twitter in Greece, Spain, and the United Kingdom. The dataset originated from tweets of parliament members and politicians. The experimental models are distinguished into two types multilingual and Monolingual. A comparative analysis was conducted between these regions. Another study [51] used NB Classifier to determine the tweet's word semantic analysis. The proposed system collects data from live-fetched twitter according to user input. After analyzing the stored user data, the visual heat is represented through Google Maps. There is a variety of methods that may be used to analyze sentiment. Both automatic and hybrid approaches were used for the experiment. Using Deep learning [52] performed, the analysis of sentiment on stemmed Turkish Twitter user data. Twitter API was used to create the dataset. The data was preprocessed by eliminating tokens, id numbers, and punctuation marks, among other

things. The training dataset was followed by three distinct techniques: shift, shuffle, and hybrid. As DL algorithms, CNN, RNN, and Han architecture were used. Compared to previous systems, the suggested system can acquire a modest advantage. The research [53]presented a one-of-a-kind effort on sentiment inspection based on online meal delivery. Food reviews are well-known for their commercial worth. It isn't just about Twitter users; it's also about evaluating business competitors. A comparative analysis was done on Twitter user data connected to food delivery to categorize users' attitudes and customer reviews regarding the organization. Lexicon-based categorization was used to differentiate sentiment polarity.

The literature focuses on the research's shortcomings, gaps, and advancements. A lot of studies have been done on the broad topic of emotion detection from text. But something needs to be improved. Accuracy is one among them. Therefore, the suggested model is created to increase accuracy. There isn't much work left over from the Russia-Ukraine war. This study looks into how people feel about going to war. The research also examined racist behavior. Since we lacked a labeled dataset, we used the Python library to evaluate the data and used unsupervised learning to determine sentiment. Racism originating from the war is detected via semi-supervised learning. The literature demonstrates that sentiment varies according to the domain.

III. METHODOLOGY

Social media sites like Facebook detect emotion. Another dataset was obtained from Kaggle and was used to identify racism. Finally, we collected a dataset from Twitter. The Twitter dataset is about the conflict between Russia and Ukraine. This dataset was used to identify racism and assess public opinion on the Russia-Ukraine conflict. The datasets' source and application are given in Table I. Overview of the entire system is shown in Fig. 1. As previously stated, dataset 1 was acquired via social media and manually classified. After that the dataset is divided into two parts. During the training phase, 18000 data were trained, whereas 3000 data were tested. Fig. 2 depicts the number of classes in dataset 1. Fig. 3 illustrates dataset 2, where 0 denotes a non-racist speech, and one represents a racist utterance. Despite the recent and rising interest in utilizing Twitter to study human behavior and attitudes, the capacity to use Twitter data for social science research and scientific research still has a long way to go[54]. Twitter provides an API, and by using the API, data can be collected for research [55]. We used Twitter API to collect tweets about the Ukraine-Russia crisis. Our dataset 3 had a total of 16,208 records. We used some keywords to find the exact data we needed. Fig. 4 depicts the stages involved in gathering data from Twitter. The ensemble approach is used to address the challenges with emotion detection accuracy. The ensemble technique combines a variety of models. The accuracy rises when the ensemble approach is used. First, we used the suggested model to analyze our dataset, and the accuracy was higher than with the old approach. Later, we applied the model to additional datasets used by academics. The accuracy of the model greatly increases whenever we apply it to new datasets.

Fig. 1. Overview of the entire system

TABLE I. DATASET SUMMARY

Dataset	Application	Source
Dataset 1	Detect Emotion	Social media(self made)
Dataset 2	Racism Detection	Kaggle
Dataset 3	Sentiment Analysis Racism Analysis	Twitter(Self made)

A. Text Representation

1) *Text preprocessing*: Text preprocessing prepares text data for machines to use for analysis and prediction. Data preprocessing is an essential aspect of machine learning. The algorithms and models need to forecast the result accurately. Besides lowering the extracted feature space, preprocessing can increase classification accuracy [56]. The neat text and some NLP packages are used to text preprocess. The text preprocessing technique applied in our work:

Removing Numeric, punctuation, and special character: We deleted any superfluous punctuation, digits, or symbols to enhance the dataset and replaced them with space. Also, to make the dataset more algorithmically implementable.

Removing Twitter Handles (@user): A was created to eliminate the undesirable pattern of text from the tweets. It takes two arguments, the original and refined strings, which remove the text patterns. The method will give the desired string after removing unwanted text patterns in the output. To withdraw the design from our data, we used the function.

Removing short words: Short and useless words are deleted in this stage. Words with a length of three or fewer were eliminated from this list. As like hmm, oh, and so forth.

Removal of emoji,URL and hashtag: We must remove emojis from text to gain accurate output in our work. Therefore, we also eliminated URLs and hashtags from our text.

Segmentation: Text segmentation is the technique of splitting written material into valuable components, including words, sentences, or themes. We applied the segmentation technique. First, any kinds of commas, dots, and hyphens were deleted.

Tokenization: The tokenizer breaks up the input text into little chunks known as tokens. For example, if elements of a word are more prevalent than the word itself, there can be more tokens than words.

Fig. 2. Number of each class in the dataset emotions

Fig. 3. Number of class in the dataset of racism detection

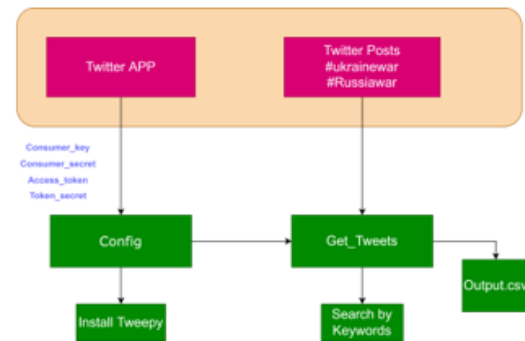

Fig. 4. Process of data collection from Twitter

Streaming: Data streaming is sending a continuous stream of data to extract useful information. A data stream is a collection of pieces arranged in time. Stemming is the process of removing suffixes (“,” “ly”, “es”, “s”, and so on) from a word using a set of rules. For Example, play, playing, and player, are the different variations of the word – “play”.

Lemmatization: It seems the term yet ensures that it retains its meaning. Lemmatization has a pre-defined vocabulary that records the context of words and checks the word in the dictionary while decreasing the term’s length. Twitter users occasionally utilize lengthy words, such as “loooovveee, greeeeat”, when they purposely type or add more letters that

TABLE II. EXAMPLE OF BAG-OF-WORDS FEATURE

She	He	Good	Girl	Will	Guy	
1	1	2	1	0	0	B1
0	0	1	0	1	1	B2

repeat more frequently. We replace the long and needless character

2) *Feature extraction*: The most crucial phase in detecting emotion is feature selection, which influences the task’s overall outcome. Therefore, it is critical to choose features carefully to improve classification because better feature selection leads to accurate prediction. We used various features to analyze our procedure data after completing the pre-processing step. We applied several feature extraction techniques to find the suitable one for our proposed system. Combining several strategies to achieve the best potential result is beneficial [17]. Feature extraction techniques applied:

Bag-of-Words Features: An approach for extracting characteristics from text documents is a Bag of Words. Machine learning algorithms may be trained using these features. It develops a vocabulary of all the unique terms in the training sets. Take a corpus, for example, shown in Table II (a textual compilation) named A comprising B documents b1, b2, bB, with X unique tokens retrieved from the corpus A. The list of X tokens (words) will be formed, and B X X will determine the size of the bag-of-words matrix Y. In document B(i), the frequency of the token is represented in each row of the matrix Y. For instance, suppose we have two documents-

B1: She is a good girl. He is also good.

B2: Will is a good guy.

It starts by building a vocabulary from the documents’ unique terms. [“She”, “He”, “good”, “girl”, “Will”, “guy”] Here, B=2, X=6. The 2 X 6 matrix Y will be expressed as follows:

The scenario above shows the training characteristics, which include the frequency of each word on each page. This’s strategy known as the bag-of-words approach since it’s based on the number of occurrences rather than the sequence or order of words.

Word n-grams: Several component evaluation approaches are available for AI-based, more aesthetic implementation, such as n-gram, tf-idf, count vectorizer, and word integration[57]. The n-grams feature combines n consecutive words or characters that are considered beneficial for categorizing texts. Here, we looked at the performance of uni-gram and bi-gram to acquire the optimum model. To achieve the entire situation, we integrated the bi-gram and tri-gram features, providing a substantially superior outcome in our study. We also observed scikit-learn to explore features [58]. A series of N words or characters is referred to as an n-gram. Consider the following sentence: **“Emotion detection from text”**.

Unigram model(n=1)

[“Emotion”, “detection”, “from”, “text”]

Bigram model(n=2)

[“Emotion detection”, “detection from”, “from text”]

In natural language processing, n-grams are an essential but fundamental notion. N-grams play a large part in our system since so many applications need to extract insights from text. The n-gram parameter’s range affects the outcome.

Tf-idf Vectorizer: The term frequency multiplied by the inverse document frequency is known as tf-idf. The tf-idf vectorizer [59], which evaluates the presence of a word in a document rather than using only raw numbers, is an excellent example of a suitable input representation [60]. The term frequency refers to the number of times a specific word occurs in a conferred document. On the other hand, Inverse document frequency considers all that include that term. **Term Frequency (TF)**: First, let’s define the term “frequent” (TF). It is a metric for the number of times a phrase, t, appears in a document, d:

$$tf_{t,d} = \frac{n_{t,d}}{\text{Number of terms in the documents}} \quad (1)$$

Here, The number of times the phrase “t” appears in the document “d” is represented by n in the numerator. As a result, each paper and word would be assigned a unique TF value. We used the same vocabulary as in the Bag-of-Words model to demonstrate how to compute the TF for B2. B2: Will is a good guy.

Here,

- Vocabulary: ‘She’, ‘He’, ‘good’, ‘girl’, ‘Will’, ‘guy’
- Number of words in B2 = 5
- TF for the word ‘Will’ by equation (1)= 1/5 Similarly,
- TF(‘She’,B2) = 0/5
- TF(‘He’,B2) = 0/5
- TF(‘good’,B2) = 1/8
- TF(‘girl’,B2) = 0/8
- TF(‘guy’,B2) = 1/8

Inverse Document Frequency (IDF): The IDF is a metric that determines how essential a phrase is. Therefore, the IDF value is required since simply computing the TF is insufficient to comprehend the significance of words.

$$idf_t = \log \frac{\text{number of documents}}{\text{number of documents with term "t"}} \quad (2)$$

he IDF values for all the words in B2 are calculated by equation 2:

$$IDF(‘Will’) = \log(2/1)$$

TF-IDF: The TF-IDF score for each word in the corpus is now computed. Higher-scoring words are more important, whereas lower-scoring words are less significant. Calculate the tf-idf score:

$$(tf_i df)_i df)_i df)_{t,d} = tf_{t,d} idf_t \quad (3)$$

Countvectorizer: The scikit-learn module in Python provides a fantastic feature called count vectorizer. The count vectorizer employs a bag-of-words method that avoids textual structures. Instead, only word counts are used to extract information. So, First and foremost, each document will be converted to a vector format. Then, the vector's input measures how many times each word appears in the content [61]. Finally, we combined n-grams with Countvectorizer techniques [62].

B. Proposed Work

We proposed a model for detecting emotion in text. Our model will also see racism. We'll look for and examine racism in the context of the Ukraine-Russia conflict. The public's viewpoint toward the competition is also investigated.

1) *Detect emotion from text:* The dataset description and data preparation techniques, such as text preprocessing and feature extraction, have previously been covered. The dataset is divided into two steps for identifying emotion. During the training phase, 18000 data points were learned, whereas 3000 data points were tested. We used classical machine learning as well as an ensemble model. In training the model to recognize emotion, many classifiers were utilized. Six primary emotions are detected by the system (anger, fear, surprise, joy, love, and sadness). We'll go through the classifier that we used in our system later. Fig. 5 presents the architecture for emotion recognition.

2) *Racism detection:* Racism was detected using data from Kaggle (dataset 2) and Twitter (dataset 3). The Kaggle dataset has labels, whereas the Twitter dataset does not. We combined the two datasets and utilized text preparation and feature extraction techniques. The boosting approach, as well as a machine learning classifier, were used. One-third of the data is tested, and the rest is trained. The best prediction model was determined after using all approaches and algorithms. The model investigated racism in dataset 3, which concerned the Ukraine-Russia war. In the suggested process for detecting racism, the following algorithm was utilized to categorize tweets as racist or non-racist.

Algorithm 1 Racism Detection Thresholds

```

if prediction ≥ 0.3 then
    label ← 1
else
    label ← 0
end if
    
```

Where 1 implies racism and 0 denotes non racism. The framework for detecting racism is depicted in Fig. 6.

3) *Sentiment analysis:* The present research's ultimate job is sentiment analysis. Dataset 3 was used to investigate the sentiment. We want to look at how people feel about the Ukraine-Russia conflict. Dataset 3 is obtained from Twitter and is on the conflict between Ukraine and Russia. On Twitter, a tweet is a microblog message. It's only allowed to be 140 characters long. Most tweets include text, embedded URLs, photos, and usernames. There are also misspellings in them. As a result, several preprocessing processes were performed on the tweets to eliminate unnecessary data. The reasoning is that

Fig. 5. Emotion detection architecture

cleaner data is more suitable for mining and feature extraction, resulting in more accurate results. We didn't need to use all of the preprocessing approaches outlined above since VADER can understand the sentiment of a text that incorporates emoticons, slang, conjunctions, capital phrases, punctuation, and other idioms. We avoided misspellings, short words, and unusually lengthy letters.

Algorithm 2 Sentiment Score Range

```

if compoundscore ≥ 0.05 then
    sentiment ← positive
else if compound_score ≤ -0.05 then
    sentiment ← Negative
else if then
    sentiment ← Neutral
end if
    
```

We compute a compound score to analyze sentiment. After assessing the sentiment, we determined the positive, negative, and neutral phrases used in the war. The result and discussion section will provide the top terms used negatively

Fig. 6. Racism detection architecture

in the conflict. In addition, positive and neutral words will be highlighted.

C. Proposed Model

1) *Supervised machine learning classifiers:* The learning process is divided into training and testing phases. First, training data samples were used as input, and then the learning algorithm was applied to learn the feature and build the learning model [63]. Finally, for prediction for the data or test, the learning model executes in the testing phase. The approach of supervised learning aims to train the machine. For each of the algorithm, we used parameters based on need. Fig. 7 depicts the model in detail. The dataset is first split into two phases: training and testing. The data were prepared using a feature engineering technique. In order to forecast the label, the baseline method was used. The test data was finally employed to predict the value and contrast it with its actual value. Finally, a number of evaluation criteria are used to gauge performance. Some of the used supervised algorithms in this system:

Decision Trees: A DT [64] is a classifier defined as a recursive split of the instance space. The DT consists of nodes that form a rooted tree, a dispersed tree with no incoming

Fig. 7. Supervised learning model architecture

edges, and a root node. Each node has one incoming advantage. An internal node has outgoing edges, whereas leaves are the other nodes. Based on the input values, each internal node in a decision tree separates into multiple sub-spaces. In the simplest case, each test evaluates a single attribute, and the occurrence space is partitioned according to the attribute's value. Every node has a label representing the property being tested, and its branches have starting values. `Mini_samples_split`, `max_depth` and `class_weight` were used as parameter.

Linear Regression: The purpose of LR, a portion of the regression algorithm family, is to discover the interrelationships and dominance of variables. Regression analysis is used to forecast a target variable; predicting an attribute from a limited set is one topic of classification. LR [65] pertains to the supervised learning algorithms area as well.

Naive Bayes: Another supervised learning approach and statistical classification method is Bayesian classification [66]. The Bayesian classification's primary goal is to tackle problems with prediction and solve prediction difficulties. This classification may mix observable data and delivers effective learning techniques. Learning techniques and algorithms have been simplified to understand and analyze using Bayesian classification.

Logistic Regression: LR is the most powerful statistical and data mining technique [67]. LR has several key benefits, including the ability to generate probabilities naturally and the ability to handle multinomial classification issues. A further advantage is that far too many LR model analysis techniques rely on the same fundamentals as linear regression. We determine the likelihood that the output variable's perception corresponds to the proper category using LR [68]. The LR model is used to categorize emotions from inside the input text [69]. With training and testing sets, LR classifies text into several emotion categories [70]. Logistic regression is a broader version of linear regression. Consider the linear regression equation below:

$$x = x_0 + x_1z_1 + x_2z_2 + \dots + x_nz_n \quad (4)$$

Here x is the response variable, and the predictor variables are $Z_1, Z_2, Z_3,$ and Z_n . So if we apply a sigmoid function to equation 1, we will get a logistic function.

$$l = \frac{1}{1 + e^{-(x_0 + x_1z_1 + x_2z_2 + \dots + x_nz_n)}} \quad (5)$$

Random Forest: RF is among the technique in Machine Learning used to process the data in vast quantities and widely used algorithm based on the results of a DT formed throughout training [71] [72]. The RF algorithm combines numerous trees with training data to generate greater accuracy. The concentrated output from every DT seems to be the forest’s output. Each tree has a different set of features and uses typical tree-building methods, and these properties generate the nodes and leaves [73].

Support Vector Machine: SVM is a pattern identification and categorization technique that is pretty simple to use [74]. SVM is among the most extensively utilized cutting-edge machine learning technology (SVM). The SVM approach is related to supervised learning, which requires feature extraction and produces desired results. SVM has the benefit of being very easy to execute and scaling vast amounts of data more efficiently than neural networks [75]. The kernel approach allows SVMs to effectively conduct nonlinear classification by implicitly translating their inputs within high-dimensional feature regions [76]. SVM finds the biggest and best margin hyperplane to categorize the text into numerous emotion classifications. Choosing an appropriate kernel function to get better results is critical because it determines the transformed feature space in which the training set instances will be categorized. Some well-known kernels were used:

$$Linear : K(A_i, A_j) = A_i^T X_j \quad (6)$$

$$Polynomial : K(A_i, A_j) = (\gamma A_i^T X_j + r)^d, \gamma > 0 \quad (7)$$

The kernel parameters are

$$\gamma, r, d$$

$$A_i$$

is a training vector that the function maps into a high-dimensional space. The linear kernel used sigmoid in the research and the n_samples were 100.

2) *Ensemble method:* Ensemble learning is a procedure that involves integrating many models or classifiers to address a specific issue. Both machine learning and deep learning techniques can benefit from the ensemble approach. It is followed to attain the intended aim and improve system performance. We applied bagging and boosting in our suggested method to discover the outcome. Though many existing systems use the ensemble approach, we attempted to construct this system using a machine learning-based ensemble model. AdaBoost, Gradient boost, and XGBoost have been used to develop and evaluate overall system performance. AdaBoost uses a recursive technique to help poor classifiers better by learning from their mistakes. Although XGBoost is identical to AdaBoost, it outperforms AdaBoost in highly condensed and sophisticated data and system optimization. Ensemble learning is commonly implemented using decision trees, which aid in the solution of quantitative issues. Ensemble learning computes the final classification based on the ensembled findings given by decision trees rather than relying on a single decision tree’s predictive analysis and outcome. In our ensemble learning, we used a variety of machine learning classifiers, including LR, SVM, RF, and others, in addition to the decision tree, to train and analyze the model and find the best output. We used

TABLE III. HYPERPARAMETERS OF THE XGBCLASSIFIER

Types	Values
learning_rate	0.2
max_depth	10
n_estimators	200
subsample	0.8

Fig. 8. Proposed ensemble model

several n estimators (10,50,100) to improve performance because the ensemble approaches heavily depend on parameters. Fig. 8 depicts the architecture and base estimator used in our ensemble model. Soft voting and Hard voting classifiers are two types of voting classifiers used to create the results [77]. The test preprocesses ing approach and feature extraction are completed initially. When we deployed the XGB classifier of the boosting ensemble, we employed the grid search parameter tuning strategy to choose the optimum hyperparameters. Table III displays the XGB classifier’s hyperparameters.

3) *VADER:* VADER is an analytical program that uses both analyses of lexical and rules-based to analyze sentiment. It generally employs a combination of strategies that classify lexical characteristics according to their semantic orientation, which might be positive or negative. This approach not only detects the polarity of positive or negative attitudes but also determines how the sentiment is [78]. This tool is consistent and has a higher accuracy ratio for performing sentiment analysis from social media. There are several advantages of VADER. It works well with social media content while quickly summarizing various topics. No need for training data though it includes defined vocabulary for analyzing sentiment. Because of its speed and precision, it may be utilized for asynchronous data. The VADER packages display a positive, neutral, or negative value from individual tweets [79]. We used VADER to analyze the sentiment. First, a compound score is calculated based on these values. Next, a compound score is calculated based on these values. The compound score thresholds were used to categorize the sentiment into negative, positive, and neutral, as indicated in Algorithm 2. However, VADER performs better for social media data which is unsupervised learning.

IV. RESULT AND DISCUSSION

The accuracy of all the models is calculated. After finding the best model, we compute each class’s precision, recall, and f-score. Combining word-n-gram with a count vectorizer is the most outstanding result to detect emotion. We employ bigrams and trigrams in our implementation. The accuracy could be determined as described in the equation since accuracy was chosen as the assessment criteria, where TP = True Positive,

TABLE IV. CLASSIFIER PERFORMANCE OF SUPERVISED MODEL

Classifier	Training Result	Testing Result
Logistic Regression	0.99	0.88
Decision Tree	0.99	0.86
Naive Bayes	0.96	0.76
SVC	0.98	0.86

TABLE VI. OVERALL PERFORMANCE OF APPLIED METHOD

Model	Testing Result	Training Result
Supervised	0.88	0.99
Bagging	0.89	0.99
Boosting	0.90	0.97

TABLE V. BOOSTING METHOD PERFORMANCE (EMOTION DETECTION)

Algorithm	Training Result	Testing Result
ADABOOST	0.99	0.89
GradientBoost	0.96	0.78
XGBoost	0.97	0.90

Fig. 9. Racism found in dataset 3

Fig. 10. Sentiment result

TN =True Negative, FP = False Positive, and FN = False Negative.

The performance of the base model was shown in Table IV. The best testing outcome came from LR. The testing results are the same for DT and SVC. However, NB has the worst results, and overfitting problems are a big deal here. From Table V, XGBoost achieves the desired outcome. Gradient boosting performs the poorest out of all methods, with Adaboosting marginally outperforming the baseline method. The performance of the supervised classifiers for identifying emotion is displayed in Table IV. Since we utilized the supervised model and ensemble model bagging and boosting, Table V shows boosting model performance, while Table VII shows all classes' precision, recall, and f-score. Table VI shows the overall performance of our applied mode to detect emotion. Our technology outperforms the prior method when it comes to seeing emotion. Finally, we compared our model to some of the most recent works in emotion recognition. Table VIII compares our model with others. The accuracy of the proposed ensemble model is higher than that of earlier systems, as demonstrated in Table VIII. Accuracy for gloves, SVM, and LR is under 80%. C-BiLSTM, however, achieved 88% accuracy. The suggested technique, meanwhile, achieves 90% accuracy.

We only use the F-score to detect racism. We used F-score instead of accuracy since we can see how unbalanced our dataset 2 is in Fig. 3. Compared to the values with labels:1, we can observe that the deals with label:0 have a far higher number of differences. As a result, if we use accuracy as our assessment criterion, we may meet a significant proportion

TABLE VII. PRECISION, RECALL, F-SCORE OF ALL CLASSES

Emotion	Precision	Recall	F-score
anger	0.90%	0.90%	0.90 %
fear	0.90%	0.83%	0.86 %
joy	0.90%	0.93%	0.91 %
love	0.80%	0.71%	0.75 %
sadness	0.93%	0.94%	0.94 %
surprise	0.67%	0.74%	0.72 %

TABLE VIII. COMPARISON OF RESULT WITH OTHER PAPERS

Ref.	Method/Algorithm	Result
[2]	Glove	F1-69.3 %
[14]	SVM	Accuracy-63.5 %
[30]	C-BiLSTM	F.score-88 %
[33]	LR-SGD	Accuracy-79 %
Proposed system	Ensemble (Boosting)	Accuracy-90.45%

of false positives. The percentage of our relevant findings is referred to as precision. The rate of relevant total results accurately categorized by our algorithm is called recall. We are constantly faced with a trade-off between accuracy and recall, with high precision resulting in low memory and vice versa. F-core is calculated using equation 5. Both bag-of-words and tf-idf perform best when it comes to detecting racism. Table IX shows the results of the racism detection.

$$F\text{-score} = 2 * \frac{Precision + Recall}{Precision * Recall} \quad (8)$$

Fig. 11. Most common positive words

TABLE IX. RACISM DETECTION ACCURACY

Algorithm / Model	Feature Extraction	F-score
Logistic Regression	Bag-of-Words	0.552
Logistic Regression	Tf-Idf	0.560
XGBoost	Bag-of-Word	0.563
XGBoost	Tf-Idf	0.547

We chose our best model for identifying racism and used it to examine racism in tweets on the Ukraine-Russia conflict. According to our research, people are less racist regarding this war.

The outcome is shown in Fig. 9. The figure shows that to examine the racism in dataset 3, people are less racist about the war—15459 sentences that are non-racist and 749 sentences that are racist. Finally, when it comes to sentiment analysis, the results show that negative sentiment was identified in 7002, the positive feeling was found in 4639 tweets, and neutral attitude in 4567. Fig. 10 depicts the sentiment discovered in dataset 3.

A. Discussion

We integrate the best model of our used procedures into our website after obtaining it. When a user registers on the website, a unique user name is assigned to them. Then, our system can discern their emotion using that person’s textual data. The person’s emotional state is kept in the database after the emotion is detected. The system can only store an individual’s feelings and restore their output over time. As a result, anyone can examine their feelings throughout time. The system can display a person’s emotions at any time. However, in the future, we will expand the system to automatically analyze a person’s

feelings and warn the user of any emotional changes. A future study could look into the dynamic alterations.

We have had some issues with the application of detecting racism.

The accuracy of racism detection was low, as seen in the results section. We discovered that an unbalanced dataset caused the problem after further investigation. We detected more nonracist text in our dataset than racist text. When a dataset is unstable, it refers to the data dominance space vs. the dispersed data. Unbalanced learning challenges can be divided into two categories. There are two types of relationships:

- 1) between classes and
 - 2) inside classes.
- Between the classes: This refers to the unequal distribution of data samples between two classes.
 - Inside the class: when the classes of data differ between more than one idea, the unbalanced problem is considered inside the class.

As a result, our dataset issue was sandwiched between the problem of class imbalance. Oversampling and undersampling approaches are two techniques for sorting this problem [80]. Future studies can handle these issues. If we have a sizeable balanced dataset, we can use deep learning in the future. In addition, we may address the issue of data imbalance to achieve better results. The globe is in the grip of the Ukraine-Russia conflict. We attempted to overserve the sentiment of the general public. Geographical sentiment analysis can help decision-makers understand a particular country’s sentiment. It will aid in taking any measures necessary to end the problem. Positive, negative, and neutral words are illustrated in Fig.

Fig. 12. Most common negative words

Fig. 13. Most common neutral words

11, 12, and 13. The most frequently used words are Ukraine, Russia, and Ukrainian, which can be used in positive, negative, or neutral contexts. Every term has a mixed connotation, meaning that some people will interpret it positively while others will interpret it negatively. Therefore, more research is required, and each word can be given as a bigram or trigram.

The most common words in the study are visually depicted. Therefore, a thorough analysis is advised.

V. CONCLUSION

This study was designed to accomplish several goals. This study first tries to assess an individual's emotional trajectory through time and to recognize emotion from textual format using machine learning techniques. The ensemble technique works best for detecting emotion. However, there were various difficulties in determining the best accuracy from our dataset. We decided on the ensemble model's optimal accuracy by integrating several data preparation methods. XGBclassifier demonstrated 90% accuracy in identifying the mood in the text.

There are several applications for emotion detection, including marketing, customer reviews, the detection of psychological instability, and others. XGBclassifier and Logistic Regression perform best in identifying racism. However, the ability to recognize racism has to be improved. In our study, we looked at how individuals felt about the conflict between Ukraine and Russia. Nearly half of the Twitter users had unfavorable feelings (43%). The study of this conflict had not received much attention from artificial intelligence researchers. The professional can remedy the problem if we further investigate this. No system is flawless, after all, and we are fully conscious of the constraints of our system. We are looking to implement this system using multiple or large datasets, and deep learning techniques will be applied in the future. Our system comparatively works better than the previous systems to detect emotion. The novelty and future development have already been explored. We hope that this study will contribute to further research and influence the field of emotion recognition, racism detection, and sentiment analysis.

Abstract—Induction motors are commonly used in most electricity generation due to their low investment cost. However, the performance of the induction motors for different applications highly depends on rotor design and machine geometry. For example, changing rotor bar height and width varies the rotor resistance and reactance, thereby leading to variation of the motor efficiency. A parametric study on rotor slot geometry parameters such as opening height, rotor slot depth, and rotor slot width, is carried out to investigate the effect of the parameters on the efficiency of a squirrel cage induction motor. The study is based on analytical model that considers a general-purpose squirrel cage induction motor with the specification of 5.5 kW, 60 Hz, and 460 V. The analytical model is developed and simulated within the MATLAB software environment. The effects of each parameter variation toward efficiency of the induction motor are investigated individually as well as all together using a 4D scatter plot. Results show that the efficiency can be improved up to 0.1% after designing a suitable setting of rotor slot parameters from the initial settings.

Keywords—Analytical model; efficiency; induction motor; rotor slot parameters

I. INTRODUCTION

Electrical machine is widely used for electromechanical energy conversion either to operate as generator or motor [1]. The electrical machines can be categorized as motors and generators depending on their energy conversion mechanism. They are considered electrical motors when they convert electrical energy into mechanical energy. Among various types of electrical motors, DC motors, synchronous motors, and induction motors are more popular for applications in residential and industrial [2], [3]. On one hand, DC motors require commutation mechanisms in their operation, leading to high maintenance cost. On the other hand, the synchronous motors are very expensive due to the use of high-cost permanent magnets; furthermore, they require starting mechanisms. Therefore, the induction motor is a promising option for electromechanical energy conversion applications [4] because this type of electrical machines is a low cost, low maintenance, and self-starting mechanism. Although the induction motors are favorable for many applications; they suffer from some disadvantages particularly low efficiency [5]. Efficiency is an important indicator to show the performance of an electrical motor. It can be improved by modeling the electrical motor using optimal parameter settings [6]. Among the design parameters of the electrical motor, rotor slot geometry parameters provide more effect to its performance. This condition is mainly due to the rotor slot design, which determines the resistance and leakage reactance of the electrical motor.

Several works have been carried out in the past few years to improve the performance of induction motors by redesigning the rotor slot. In [2], various shapes of rotor bar were considered to determine the best shape that provides the highest efficiency with minimum overall cost. The effect of using different materials specifically aluminium and copper for the rotor bar were studied in [7]. Flux2D software was used in [8] to carry out a parametric study of rotor slot design using a finite element method (FEM) technique to showcase their effect on the behavior of induction motors, such as flux distribution and power losses. The FEM technique was also used in [9] to study the impact of changing rotor slot parameters toward the induction motor performance, total harmonic distortion and starting characteristics of the motor. In [10], the FEM technique was used to analyze the electromagnetic characteristics of induction motors using various shapes of rotor bars to obtain the best design. Apart from studying normal rotor bar shapes, the effect of broken rotor bar and different stator slot opening settings were tested using FEM technique to evaluate the induction motor performance [6], [11]. Investigation on the rotor bar shapes was also carried out in [12], but they focused on generator rather than motor applications.

In the previous works, the investigation of changing the rotor slot geometry parameters was mainly based on 2D analysis instead of 3D analysis, which provides less accurate results. The FEM technique, which is based on a commercial software, is not flexible because of computational burden particularly for the parametric study at the initial design process. Furthermore, the important performance parameters, such as efficiency, could not be appropriately addressed. Therefore, this work is carried out to investigate the effect of changing rotor slot parameters toward efficiency of the induction motor using an analytical model. In the following section, the basic principles of induction motor is discussed to provide better understanding before the analytical model to calculate efficiency can be constructed. Then, a development of the analytical model is explained in Section III. In Section IV, results on varying rotor slot parameters are showcased and discussed. Finally, a conclusion of the research work is drawn in Section V.

II. EFFICIENCY OF INDUCTION MOTOR

Induction motors are used in most applications to fulfill either industrial and domestic needs known as workhorse of modern industry [13]. The induction motor can be divided into two types: 1) wound rotor induction motor and 2) squirrel cage induction motors. The squirrel cage type is widely used in the

industrial applications because of its idiosyncratic characteristics, such as simplicity, robustness, easy maintenance, and low cost [14]. Therefore, a squirrel cage induction motor model is used in this work.

Operational principles of squirrel cage induction motor are very much similar to transformers. Two magnetic circuits in transformers, referred to as primary and secondary windings, are isolated by a small air-gap. The circuits can be represented as two relatively movable windings which are called stator and rotor in the induction motor [14], [15]. The stator winding of the three-phase squirrel cage induction motor is connected to the three-phase AC source either in a star or delta configuration. Current is supplied to the rotor circuit by the process of electromagnetic induction [16] from the magnetic field of stator circuit. The induction motor is called a singly excited machine because the rotor has no external source. The induction motors are considered self-starting motors because they do not require any external means during the starting condition [17]. Induction motor normally operates at a speed that slightly lower than its synchronous speed; therefore, it is known as asynchronous motor. The difference between operating speed and synchronous speed is known as slip speed of the motor.

Understanding the power losses of the induction motor is important before its efficiency can be calculated. Power flow diagram, as shown in Fig. 1, is used to illustrate the power losses of induction motor. Power transfer from stator to rotor is referred as the airgap power loss, P_{ag} . P_{ag} is calculated by taking into account stator copper losses, P_{sc} and iron losses, P_{iron} as expressed in (1). On the other hand, the conversion power loss, P_{conv} is the total electrical output power from the rotor after subtraction of all types of electrical losses. P_{conv} is calculated by subtracting the rotor copper losses from the airgap power loss. Rotor copper losses, P_{rc} are copper losses generated inside the rotor due to the rotor internal resistance. The output power of the motor is obtained by considering all the losses due to the rotational motion of the rotor shaft. The losses related with rotation motion of the shaft consist of mechanical and ventilation power losses, P_{mv} and stray power losses, P_{stray} .

$$P_{ag} = P_{input} - P_{sc} - P_{iron} \quad (1)$$

$$P_{conv} = P_{ag} - P_{rc} \quad (2)$$

Fig. 1. Power flow diagram of induction motor [15], [16], [17]

Total power loss of induction motor can be calculated as follows:

$$P_{loss} = P_{sc} + P_{rc} + P_{iron} + P_{stray} + P_{mv} \quad (3)$$

The value of P_{mv} can be obtained depending on the number of poles, as shown in Table I. In this work, a four-pole induction motor is considered; therefore, the mechanical and ventilation losses are 1.2% of the output power.

TABLE I. MECHANICAL AND VENTILATION LOSSES, P_{mv} [18]

No. of poles	P_{mv}
2	$0.03 \times P_{out}$
4	$0.012 \times P_{out}$
6,8	$0.08 \times P_{out}$

The stator copper losses, P_{sc} due to resistance in the stator winding can be calculated using stator current, I_s and stator resistance, R_1 as expressed in (4). On the contrary, the rotor copper losses, P_{rc} due to resistance in the rotor winding can be obtained from the rotor current, I_r and rotor resistance, R_2 using expression in (5). The values of R_1 and R_2 can be derived from stator and rotor slot modeling subsections that will be discussed in detail subsequently in the induction motor modeling section.

$$P_{sc} = 3(I_s)^2 R_1 \quad (4)$$

$$P_{rc} = 3(I_r)^2 R_2 \quad (5)$$

The iron losses, P_{iron} are the summation of stator tooth iron losses, P_{st} , stator yoke iron losses, P_{sy} , and tooth flux pulsation core losses, P_{tp} , as follows:

$$P_{iron} = P_{st} + P_{sy} + P_{tp} \quad (6)$$

The stator tooth iron losses, P_{st} can be calculated as follows:

$$P_{st} = K_T P' (f/50)^{1.3} B_{TS}^{1.7} W_T \quad (7)$$

where f refers to frequency, K_T represents the core loss augmentation due to mechanical machining, and P' is the specific weight losses in W/kg at 1.0 T and 50 Hz. The value of P' is normally between 2 and 3 W/kg as used by the manufacturer [11]. B_{TS} is the stator tooth flux density, and W_T is the weight of the stator tooth. In this model, B_{TS} and W_T are set to 1.55 T and 4 kg, respectively.

The stator yoke iron losses, P_{sy} can be determined using the following formula:

$$P_{sy} = K_Y P' (f/50)^{1.3} B_C^{1.7} W_Y \quad (8)$$

where K_Y stands for the mechanical machining factor of the stator yoke that normally takes the value in the range between 1.6 and 1.9. B_C and W_Y represent yoke flux density of stator and weight of the stator, respectively.

The tooth pulsation core losses, P_{tp} are neglected because the value is remarkably smaller than the iron losses related with stator tooth and stator yoke.

The stray losses, P_{stray} include the core losses associated with rotor surface and space harmonic cage losses. In most

applications, the stray losses are considered by the manufacturers as 1% of the expected output power of the motor [19] and can be expressed as follows:

$$P_{stray} = 0.01 \times P_{out} \quad (9)$$

The efficiency of induction motor, η can be obtained from the total power losses, P_{loss} and output power, P_{out} using the following expression:

$$\eta = \frac{P_{out}}{(P_{out} + P_{loss})} \quad (10)$$

III. MODELING OF INDUCTION MOTOR

Fig. 2 shows an equivalent circuit of the induction motor as referred to the stator side using the concept of transformer modeling. The stator winding resistance, R_1 represents copper losses in the stator, and the stator winding reactance, X_1 represents leakage flux of the stator. The magnetization reactance, X_m represents magnetization effect of the induction motor. R_2 and X_2 are rotor resistance and rotor leakage reactance, respectively.

Fig. 2. Equivalent circuit of induction motor

An induction motor can be modelled using equations derived from the per phase equivalent circuit in Fig. 2. In this work, a 5.5 kW, 460 V, and 60 Hz squirrel cage induction motor is considered; its specifications are tabulated in Table II. Single-cage type slots are used for rotor and stator slots.

TABLE II. MOTOR SPECIFICATIONS

Parameters	Values
Output power(kW)	5.5
Frequency(Hz)	60
Rated voltage (V)	460
Power factor	0.83
No. phase	3
No. poles	4

Fig. 3 shows a quarter section of an induction motor model where all the parameters should be obtained to fulfill the design requirement. Parameter settings of the induction motor are presented in Table III. The parameter stack length refers to the total length of lamination stack, which provides rigidity to the stator. Stack length excludes the end ring length.

A. Stator Slot Design

Fig. 4 illustrates a shape of stator slot and its geometry parameters that can be used to calculate the stator resistance (R_1) and stator leakage reactance (X_1). This work provides focus on the rotor slot parameters; thus, all stator slot dimensions

Fig. 3. Quarter section of an induction motor

TABLE III. INDUCTION MOTOR PARAMETER SETTINGS

Parameters	Dimension
Stator outer radius (R_{os})	90 mm
Stator inner radius (R_{is})	56 mm
Rotor outer radius (R_{ro})	55.65 mm
Rotor shaft radius (R_{shaft})	17.5 mm
Airgap length (g)	0.35 mm
Stack length	132 mm
No. stator slots (N_s)	36
No. rotor slots (N_r)	28

are fixed as shown in Table IV. R_1 and X_1 can be calculated using the following expressions:

$$R_1 = \frac{L_c W}{A_{co} a_1} \times R_{co} \quad (11)$$

$$X_1 = \frac{2\mu_o \omega L_c W^2}{pq(\lambda_s + \lambda_{ds} + \lambda_{es})} \quad (12)$$

where L_c is the stator coil length, W is the number of turns in stator windings, A_{co} is the area of a conductor, a_1 is the number of parallel current paths, R_{co} is the resistivity of the copper, p is the number of poles, and q is the number of stator slot per pole per phase; λ_s , λ_{ds} and λ_{es} are the stator slot, differential and end ring coefficients, respectively.

The stator slot coefficient (λ_s) can be calculated as follow:

$$\lambda_s = \left[\frac{2H_s}{3(B_{s1} + B_{s2})} + \frac{2H_w}{(B_{os} + B_{s1})} + \frac{H_{os}}{B_{os}} \right] \times \left(\frac{1 + 3\beta}{4} \right) \quad (13)$$

β is known as chording factor, which takes the values in range as follows:

$$\frac{2}{3} \leq \beta \leq 1 \quad (14)$$

The stator differential coefficient (λ_{ds}) is calculated using

the following expression:

$$\lambda_{ds} = \frac{0.9\tau_s q^2 K_w^2 (0.18 \sin \phi + 1.24)}{1.21g(1 + K_{st})} \times \left[1 - 0.033 \frac{B_{os}^2}{g\tau_s} \right] \quad (15)$$

$$\phi = \pi(6\beta - 5.5) \quad (16)$$

where τ_s is the slot pitch of the stator, K_w accounts for winding factor, and K_{st} is the saturation factor. The stator end ring coefficient (λ_{es}) can be obtained from the following:

$$\lambda_{es} = 0.34 \frac{q}{L} (L_{es} - 0.64 \beta \tau) \quad (17)$$

where L is the stack length, L_{es} is the stator end ring length, and τ is the pole pitch. R_1 and X_1 are calculated using the values given in the Table IV, and they take the values 0.94 and 2.16 Ω , respectively.

Fig. 4. Design of stator slot

TABLE IV. STATOR SLOT PARAMETER SETTINGS

Parameters	Length(mm)
B_{os}	2.5
B_{s1}	5.4
B_{s2}	9.2
H_{os}	2
H_w	1.5
H_s	20.4

B. Rotor Slot Design

The geometry parameters for rotor bar design are shown in Fig. 5. Resistance and reactance of the rotor can be derived from the rotor bar design parameters. The rotor bar design parameters are rotor slot opening height (Hor), rotor slot height (Hr), rotor slot tooth width (Btr), rotor slot opening width (Bor), rotor slot lower width (B_{r1}), and rotor slot upper width (B_{r2}). In this study, Bor is fixed to a constant value at 1.5 mm because the number of rotor slot remains the same

throughout the work, causing constant magnetization effect [11]. In addition, B_{r1} and B_{r2} depend on the Hor , Hr and Btr as expressed in (18) and (19).

Fig. 5. Design of rotor slot

$$B_{r1} = \frac{\pi(Bor - 2Hor) - N_r Btr}{\pi + N_r} \quad (18)$$

$$B_{r2} = B_{r1} + 2Hr \tan\left(\frac{\pi}{N_r}\right) \quad (19)$$

Then, rotor resistance (R_2) and rotor leakage reactance (X_2) can be calculated using the following expressions:

$$R_2 = \frac{4m(WK_w)^2 R_{co}}{N_r} \left[\frac{LK_R}{A_b} + \frac{L_{er}}{2A_{er} \sin\left(\frac{\pi p}{N_r}\right)^2} \right] \quad (20)$$

$$X_2 = \frac{4m(WK_w)^2 \omega \mu_o L}{N_r (\lambda_r K_x + \lambda_{dr} + \lambda_{er})} \quad (21)$$

where m is the number of phases, K_w is the winding factor, K_R is skin effect coefficient for resistance, A_b is the area of rotor slot, L_{er} is the rotor end ring length, A_{er} is the area of rotor end ring, and K_x is the skin effect coefficient for rotor reactance. λ_r , λ_{dr} and λ_{er} are the permeance values of the rotor slot, differential and end ring coefficients, respectively.

The end ring and skin effects on the resistance and reactance of the rotor are also considered in the rotor resistance and reactance calculation. Equation (20) represents total resistance of the rotor including end ring part resistance and resistance due to the rotor slot [20].

IV. RESULTS AND DISCUSSION

This work focuses on the design of rotor slot, where Bor is fixed. Table V shows the dimension constraints of rotor slot to ensure that it does not violate the considered size of the induction motor as given in Table III. As a reference, the initial values of Hor , Btr and Hr are set to 0.5 mm, 4.25 mm and 14 mm, respectively the same as that in [11]. Fig. 6 depicts the variation of efficiency over increasing motor speed. It clearly shows that the motor synchronous speed is 1800 rpm at 60 Hz frequency. On the contrary, the efficiency at the rated speed (1757 rpm) is observed at 89.7%. The effect of changing the rotor slot parameters (Hor , Hr and Btr) on motor efficiency will be discussed in detail in the following subsections:

Fig. 6. Performance of the induction motor at initial settings

Fig. 7. Individual variation of efficiency when changing H_r

TABLE V. ROTOR SLOT GEOMETRY PARAMETER SETTINGS

Parameters	Length(mm)	
	Min	Max
H_{or}	0.5	5
B_{tr}	2	5.5
H_r	1	22

A. Effect of Changing Rotor Slot Height

In this case study, the rotor slot height, H_r is varying within the limits as given in Table V, whereas the other parameters are maintained in the initial condition. Fig. 7 shows the variations of efficiency when changing H_r between 1 and 22 mm. Evidently, the efficiency increases with increasing H_r value from the initial point at 14 mm. A significant improvement in the effective area of the rotor slot can be obtained at higher value of H_r which reduces the rotor resistance. Copper losses related to the rotor slot also decreased due to the lower resistance, resulting in higher efficiency. When reducing H_r below 14 mm, the efficiency decreases up to 89.63% at $H_r = 5$ mm, and then rebounds. In this case, the effect of increasing the rotor resistance continues when decreasing H_r . However, the lower value of H_r causes the depth of the rotor slot to reduce, leading to the flux lines coupled with the stator lines. As a result, the leakage reactance of the rotor is reduced; therefore, the efficiency is improved. At a certain point, the leakage reactance becomes more dominant than the effect of increment on the rotor resistance (might be due to less effect on the effective area of the rotor slot). As can be seen from the figure, the highest value of efficiency (89.79%) can be obtained when H_r is at the upper bound, at 22 mm. At this setting, the efficiency can be improved by 0.09% as compared with the initial condition.

B. Effect of Changing Rotor Slot Opening Height

Fig. 8 shows the variations of efficiency when the rotor slot opening height, H_{or} varies between 0.5 and 5 mm. In this case study, H_r and B_{tr} are maintained at the initial

condition at 14 and 4.25 mm, respectively. As shown in the figure, efficiency slightly decreases until $H_{or} = 2.5$ mm, and then, it steeply increases to the highest value at 89.715% when $H_{or} = 5$ mm. The efficiency can be improved up to 0.015% compared with the initial condition for individual H_{or} settings. It is important to notice that H_{or} provides less impact on the efficiency than H_r . This finding is mainly because the H_{or} is located very close to the stator surface area in which the flux lines through the H_{or} are almost coupled with the stator flux lines. Therefore, significant improvement in efficiency is difficult to obtain when changing H_{or} .

Fig. 8. Individual variation of efficiency when changing H_{or}

C. Effect of Changing Rotor Slot Tooth Width

Fig. 9 depicts the variation of efficiency when varying the rotor slot tooth width, B_{tr} . In this case study, B_{tr} is varied between 2 and 5.5 mm, whereas H_r and H_{or} are maintained

at the initial condition at 14 and 0.5 mm, respectively. The range of Btr is based on the number of rotor slot in Table III. The figure shows that variations of efficiency have completely different pattern from the previous results, where the efficiency drastically drops in the middle because reactance and resistance become dominant at this value. The highest efficiency at 89.78% can be achieved when Btr is set to 3.75 mm. The efficiency can be improved by 0.08% as compared with the initial condition.

Fig. 9. Individual variation of efficiency when changing Btr

D. Effect of Changing All Selected Parameters

In previous subsections, the effect of individual parameters on efficiency have been discussed, but they could not explain the overall effect of changing Hr , Hor , and Btr simultaneously. Therefore, a 4D plot is used in this subsection to explain the effect of changing all selected rotor slot parameters. Fig. 10 shows a 4D scatter plot of efficiency when changing all the three parameters. The figure shows that the efficiency reaches maximum value at 89.8% when Hr , Hor and Btr at the maximum settings or more specifically at 22, 5, and 5-5.5 mm, respectively as highlighted by red circle. When all parameters are at maximum settings, the overall area covered by the rotor slot is increased and leads to a significant reduction in rotor resistance. Therefore, copper losses can be reduced, and the efficiency is improved. Among the three parameters, Hr provides the highest influence to the efficiency improvement, followed by Btr as shown by arrows in the figure.

V. CONCLUSION

This paper presents an analytical approach to investigate the influence of rotor slot geometry parameters on motor efficiency. An analytical model of three-phase squirrel cage induction motor was developed within a MATLAB environment for the investigation purposes. Several case studies were carried out and they can be categorized into individual and amalgamated changing of rotor slot parameters. In the individual case studies, the effects of changing each individual rotor slot geometry parameters namely, rotor slot height (Hr), rotor

Fig. 10. 4D Scatter Plot of Efficiency when Changing All Parameters

slot opening height (Hor) and rotor slot tooth width (Btr) were analyzed. The results show that the maximum efficiency can be obtained up to 89.79%, 89.715%, and 89.78% (0.09%, 0.015%, and 0.08% improvement from the initial condition) when changing the individual parameter of Hr , Hor and Btr , respectively. However, the results cannot sufficiently explain how much the improvement can be achieved when considering all parameters. Therefore, the three parameters were changed and analyzed together in the amalgamated case study. In this case, the efficiency can be increased up to 0.1% compared with the initial condition or achieve the maximum value at 89.8%. It clearly shows that the performance of a squirrel cage induction motor can be improved substantially when the selected rotor slot geometry parameters are set appropriately. However, this approach is limited to only three parameters as presented in this paper. Thus, an optimization approach can be used in the future to solve the problem when considering more parameters.

ACKNOWLEDGMENT

Abstract—Software vulnerability detection is one of the key tasks in the field of software security. Detecting vulnerability in the source code in advance can effectively prevent malicious attacks. Traditional vulnerability detection methods are often ineffective and inefficient when dealing with large amounts of source code. In this paper, we present the BBVD approach, which treats high-level programming languages as another natural language and uses BERT-based models in the natural language processing domain to automate vulnerability detection. Our experimental results on both SARD and Big-Vul datasets demonstrate the good performance of the proposed BBVD in detecting software vulnerability.

Keywords—Vulnerability detection; BERT; software security

I. INTRODUCTION

Software vulnerability is security flaw that exists in software [1]. When developers develop software, security issues such as logic error, buffer overflow, array out-of-bound access and other errors can easily occur in the source code. Vulnerability can be exploited for privilege escalation, leakage of secret data, denial of service and many other types of attacks [2], which put the integrity and availability of the software and the computer system at risk. The size and complexity of modern software are increasing dramatically, which also diversifies the types and causes of vulnerability. Thus, the traditional vulnerability detection methods are facing new challenges.

Traditional source code vulnerability detection depends on manual code auditing [3], relying on the expertise of the security personnel to review the software source code. However, in the face of the massive amount of code in complex software, the workload of manual audit vulnerability is large and the effectiveness of detection relies strongly on the amount of a priori knowledge of security personnel. It is unrealistic to rely entirely on manual audits to discover existing types and possible variants of vulnerability types. Now, automated vulnerability detection is becoming an important supplement to manual audits.

There are many similarities between high-level programming languages and natural language [4], [5]. High-level programming languages such as C/C++ that inherit the syntax of natural language have a defined syntax and semantics. Long sentences in natural language consist of words and phrases. A programming language also consists of a series of instructions. If these instructions are treated as words in a natural language, different combinations of instructions produce more complex

operations, which correspond to long sentences in natural language. The choice of different words, the difference in word placement and the contextual connection all affect the semantics of sentences in natural language. In the case of programming language, the placement and combination of instructions also affect the logic of the programming language. Therefore, considering these similarities, we can use language models in NLP for software vulnerability detection.

The BERT-based model allows for parallelized computation in the model. Also, multiple experimental results show that BERT-based models [6]–[9] have outperformed existing models in natural language processing, including recurrent neural network (RNN) architectures. Therefore, BERT-based language models are more effective than RNNs and we choose to use BERT-based models to detect software vulnerability. Our contributions in this paper are as follows:

- We propose a method called BBVD for detecting vulnerability in C/C++ source code by using BERT-based models.
- We verify that the BERT-based language models used in the BBVD approach can be migrated to areas outside of the natural processing domain such as vulnerability detection.
- Our experimental results on both SARD [10] and Big-Vul [11] datasets show that BBVD outperforms the state-of-the-art method such as SySeVR [12].

The rest of the paper is organized as follows: Section I presents the related works on BERT-based models and software vulnerability detection methods. Section III describes the proposed BBVD method and the flow for the software vulnerability detection. Section IV describes the experimental setup of datasets and BERT-based models used in our work. Section V reports the experimental results and performance of the BERT-based models. Section VI concludes our paper.

II. BACKGROUND AND RELATED WORK

A. BERT beyond NLP

In recent years, some classical methods have yielded good performance using model optimization strategies to process data containing noise and outliers, such as graph-based [13], [14] and information- and cue-based [15], [16] strategies. Furthermore, neural networks can be more efficient by fusing attention mechanisms when processing large amounts of input information. These networks using attentional mechanisms have been used in a wide range of tasks such as image text matching [17], visual sentiment analysis [18], video question

*Corresponding authors.

answering [19], generative adversarial task [20], multi-task travel route planning [21], etc.

Attention mechanisms are also used in BERT to focus each element in the input sequence on other elements. The paper [6] demonstrates that BERT pre-training facilitates almost all types of NLP tasks (except generative models). The question-and-answer (QA) domain is an important area of NLP. BERT in the field of QA is more effective than the previous methods, and the experimental results of some papers [22]–[25] in question retrieval and answer determination show that a significant improvement can be achieved by using BERT or attention mechanisms. The application of BERT to the reading comprehension task also had a huge impact on the various original techniques [26]. The effectiveness of works [27] using BERT in document retrieval tasks similarly demonstrates the usefulness of BERT in the field of information retrieval. In addition to these domains, BERT has also shown significant enhancements in areas such as text summarization [28], text classification [29], [30] etc.

The BERT can also be migrated to domains other than natural language processing. Inspired by pre-training models in the BERT model, Kanade et al. [31] proposed the CuBERT (CodeUnderstandingBERT) model designed with two pre-training tasks of predicting masked tokens and whether two logical lines of code are related to each other in a contextual sentence. The CodeBERT model proposed by Feng et al. [4] used bimodal data of natural and programming languages. They pre-trained CodeBERT in six programming languages and showed optimal performance on the NL-PL downstream task. The above two code pre-training models only consider codes as token sequences, ignoring the structural information in the codes. Guo et al. [32] proposed the GraphCode-BERT model using the data flow information of codes in the pre-training process, which significantly improved the performance of four downstream tasks, including code search, code clone detection, code translation and code summarization.

There have been studies using the BERT model to detect software vulnerability. Ziems et al. [33] fine-tuned the 100,000 C/C++ source code files on a pre-trained model known as BERT base and tested the fine-tuned model with over 100 types of vulnerability. Their work shows the feasibility of BERT for vulnerability detection. Although our approach is also based on BERT related model, there are several differences compared to their approach: (i) Their input is source code files without comments. Ours is the code slice that can better represent the syntax and semantic information of the program; (ii) They use pre-trained model which based on an English Wikipedia dataset containing 2.5 billion words, we use the C/C++ code slice to pre-train and then generate a pre-trained model; (iii) They consider only BERT, we have experimented on other BERT-based models; (iv) They only experimented on the synthetic dataset SARD, we do experiments on both the synthetic dataset SARD and the real dataset Big-Vul.

B. Vulnerability Detection Methods

Source code vulnerability detection methods can be divided into two categories: static and dynamic methods. Static methods do not require the execution of source code and can detect vulnerability by combining information from source code files,

control flow graph [37], program dependency graph [42], LLVM IR [38], etc. Dynamic methods obtain the execution path and data flow of program crashes by executing the code file to obtain the heap, stack, registers and other information of the actual running program. Typical dynamic methods are fuzz testing and taint analysis, these methods applied to large project source code files have problems such as low path coverage and path explosion, which require a lot of computational resources. Therefore, we focus on static methods.

Static detection methods can be divided into two categories: traditional methods and machine learning based methods. Traditional detection methods are mainly based on code similarity and pattern match. Code similarity-based detection is suitable for vulnerability caused by code clone. It has a high false negative when the cloned code itself is not vulnerable but other code fragments are flawed. There are four types of code similarity-based detection methods: text-based, lexicon-based [34]–[36], syntax-based [39]–[41] and semantic-based [42]–[45]. Text-based and lexicon-based methods are simple to implement and can detect the source code of almost all programming languages. However, recognizing only textual information or lexical information will lose the syntactic and semantic information of the source code, which leads to a low accuracy rate. Syntax-based and semantic-based methods can identify syntactic and semantic information of programs with high detection accuracy. But as program size increases, the subtree matching algorithm for detecting abstract syntax tree similarity and the subgraph matching algorithm for detecting program dependency graph similarity grow dramatically in time and space complexity.

In contrast, pattern-based approaches require a large number of experts to define rules for matching vulnerability manually. The subjectivity of experts may lead to high false positives and high false negatives. For a specific vulnerability, the corresponding vulnerability patterns can be extracted. The pattern matching method describes these vulnerability patterns in a specific syntax. Then the source code is compared and detected after a series of processing. Methods that use pattern matching to detect vulnerability include PMD, Coverity Prevent [46], etc.

Researchers have started applying machine learning to detect software vulnerability due to increased computer computing power. Yamamoto et al. [47] applied machine learning algorithms such as naive bayes model to the vulnerability descriptions of the National Vulnerability Database (NVD) [48] for vulnerability detection. Their proposed method shows good prediction performance on a dataset containing more than 6000 vulnerable source codes. Toloudis et al. [49] combine techniques related to text analysis and principal component analysis to process the vulnerability descriptions of the NVD and perform experiments on a large dataset containing 70,678 vulnerable source code. Spanos et al. [50] use classical machine learning methods on the same dataset to predict software vulnerability, the experimental results achieved an accuracy of about 80%.

As the number of public vulnerabilities grow, it becomes possible to use deep learning models to extract abstract feature representations from vulnerability samples. Not all information in the source code file is helpful for software vulnerability detection. Too much irrelevant information may interfere with

Fig. 1. Framework of BBVD

prediction. Program slicing techniques are widely used in vulnerability detection tasks which can obtain code fragments related to vulnerability. Li et al. [5] proposed the concept of code gadgets to serve as an intermediate representation of source code for obtaining semantic information related to vulnerability. They predicted the existence of vulnerability related to API and library function calls in programs based on code gadgets and BiLSTM. Li et al. [12] proposed code slices based on code gadgets combined with program dependency graphs. The code slices can represent the vulnerability syntax and semantic features of the program and fed into the BiGRU model to obtain vulnerability detection results.

In addition to using models in NLP to detect software vulnerability, some studies use graph neural networks to detect vulnerability. The Devign model proposed by Zhou et al. [51] uses an abstract syntax tree as a skeleton. The model incorporates the control flow and data flow information to generate a joint graph representation. A gated graph neural network and a convolutional neural network model are used for graph classification to detect vulnerable code. Chakraborty et al. [52] proposed ReVeal using a combination of gated graph neural networks and multilayer perceptrons. Their experiments showed that adding multilayer perceptron modules to gated graph neural networks helps in vulnerability detection.

III. DESIGN OF BBVD

In this section, we present a brief overview of the BBVD method. Fig. 1 illustrates the detection pipeline which trains from scratch. We divide the whole process into four phases: training the tokenizer, pre-training phase, fine-tuning phase and inference phase. In the first stage, we extract code slices from the source code files and then train the tokenizer based on the tokens in the code slices. The second stage converts the code slices into ids using the tokenizer and pretrains on the ids using a BERT-based model. The ids are token indices, numerical representations of tokens building the sequences that will be used as input by BERT-based models. The third stage labels the code slices and defines the downstream task as the classification for fine-tuning. The fourth stage uses datasets not identified by the model for inference.

A. Train Tokenzier Phase

In the stage of training tokenizer, we need to extract code slices from the source code files. Specifically, code slices are

syntax-based vulnerability candidates (SyVCs) and semantics-based vulnerability candidates (SeVCs) which proposed by Li et al. [12]. In order to get the code slices, we need to use the open-source code analysis tool joern to parse the source code files and obtain the corresponding control flow graph and program dependency graph. Then, parsing out the call graph of function based on the CFG and PDG to extract array-related, pointer-related, api-related and arithmetic-related code slices. Furthermore, keeping the original name of keywords in the programming language and mapping the user-defined variable and function names one-to-one to symbolic names (e.g. “variable_0”, “variable_1”, “func_0”, “func_1”) to reduce the interference of user-defined function names and variable names. Fig. 2 shows different types of code slices extracted from the same source file. Finally, a tokenizer is generated based on these code slices.

B. Pretrain Phase

During the pre-training phase, the code slices of the pre-training dataset are transformed into ids using the tokenizer generated in the first phase. Fig. 3 shows an example of converting code slices and ids to each other. The ids are filled or truncated according to the max position embeddings in the model network parameter config. That is, when the length of ids is less than the max position embeddings, special token ids (e.g. “*pad*”) correspond id is 1) are used to fill in the right side of ids. When the length of ids exceeds the max position embeddings, the redundant part to the right of the ids is truncated. The BERT-based model trained with unsupervised learning to learn the context of code slices and their syntax and semantics. We use language masking model approach to train the BERT-based model. The language masking model masks some of the input locations based on probabilities (the original token is replaced with “*mask*”) and trains the model to predict the masked parts using the remaining parts. Meanwhile, the model is optimized based on the original masked tokens and the predicted ones.

C. Finetune and Inference Phase

After pre-training is completed, we need to perform the downstream task on the pre-trained model. Since vulnerability detection can be regarded as a binary classification, we define the downstream task as a classification task. Similarly, the code slices extracted from the fine-tuned dataset are transformed

Fig. 2. Code slices

Fig. 3. Interconversion between the ids and code slices

into ids using the trained tokenizer. In order to make the classification task work properly, we need to add the appropriate labels to the ids at this phase. Label 0 means the code slice is a normal sample and label 1 means a vulnerable sample. Then, the fine-tuning dataset is split into a training set and an evaluation set. The pre-trained model is fine-tuned on the training set and evaluated on the evaluation set. Finally, generating the fine-tuned model. Using the fine-tuned model can inference whether the source code file is vulnerable or not. Repeat the steps of extracting code slices and transforming them into ids. Input the ids into the fine-tuned model can get the detection results.

IV. EXPERIMENT SETUP

We designed follow three Research Questions (RQs).

- RQ1: Do the BERT-based models work better than the RNN-based models for vulnerability detection?
- RQ2: Do the use of irrelevant datasets in the pre-training and fine-tuning phases interfere with the detection performance of the model?
- RQ3: Do the different value of max embedding lengths (e.g., the max lengths of ids) have an influence on the detection effect of BERT-based models?

We implement BERT-based models by using the huggingface [53] with PyTorch 1.8.0. The computer running the experiment has an NVIDIA GeForce GTX 2080TI GPU and 16 Intel(R) Xeon(R) Gold 5117 CPUs running at 2.00 GHz.

A. Datasets

We experiment on two vulnerability datasets: SARD and Big-Vul. SARD is a synthetic dataset in which most of the testcases are written for academic and research purposes to reproduce specific vulnerability. SARD contains a batch of testcases composed of code in C/C++. These testcases are classified into different CWEs (Common Weakness Enumeration) according to the associated vulnerability types. They are classified into good, bad, and mixed types according to whether the code file is a vulnerability, among which mixed means that the code file contains both the vulnerability and the fix code. For the testcases of bad and mixed types containing vulnerability, the additional information about the line number where the vulnerability is located is also given. The entire sard dataset consists of 10,682 cpp source code and 24,633 c source code files.

Big-Vul dataset is a real dataset which collects testcases from the commit records related to CVEs(Common vulnerability and Exposures) that have appeared in the git repositories of 310 well-known C/C++ open source projects between 2002 and 2019 including Linux, Chrome, etc. All the data is provided in the form of CSV and each testcase containing information, such as the project name, associated CVE number, description, code content, and function differences before and after the commit. All vulnerability are categorized into ten types such as denial of service attacks, memory corruption, and privilege escalation. Each testcase labeled as vulnerable is one of the combinations of these types. To facilitate extracting

code slices, the samples in Big-Vul need to be filtered. The function differences in commit contain the corresponding code lines which change after the patch. We select the data where the number of code lines change by less than 100. The total number of filtered data is 16,608, of which 16,436 are c source code files and 172 are cpp source code files. Due to the complexity of the vulnerability types in the Big-Vul dataset, we called the memory corruption-related vulnerability data from filtered Big-Vul dataset as Big-Vul-MemCorr and the entire filtered Big-Vul dataset as Big-Vul-All.

B. Models

We conducted experiments on five models. Specifically, this experiment contains two RNN-based models (BiGRU and BiLSTM) and three BERT-based models (RoBERTa, DistilBERT and MobileBERT). Table I shows some important network structure-related parameters of BERT-based models used in this paper.

TABLE I. NETWORK STRUCTURE RELATED PARAMETERS

Model	Hidden Size	Hidden Layers	Attention Heads	Intermediate Size	Max Position Embeddings
RoBERTa	768	12	12	3072	514
DistilBERT	768	6	12	3072	512
MobileBERT	512	24	4	512	512

RoBERTa. This model mainly based on BERT with several adjustments: longer training time with larger batch size and more training data; longer training sequence; dynamic adjustment of masking mechanism.

DistilBERT. It's proposed for the most popular BERT pre-training model with a 40% reduction in model size and 60% faster inference operations while retaining 97% of the performance.

MobileBERT. It compresses the BERT model which reduces the model size by a factor of three to four and increases the speed by a factor of four to five with little loss of effect, allowing a variety of NLP applications to be easily deployed on mobile.

C. Evaluation Metrics

The effectiveness of vulnerability detection can be evaluated using the following metrics: accuracy (A), precision (P), recall (R), F1-score ($F1$) and Mathews Correlation Coefficient (MCC). True positive (TP) indicates the number of samples with vulnerability detected. False Positive (FP) indicates the number of samples without vulnerability but detected as such. True Negative (TN) indicates the number of samples without vulnerability detected. False Negative (FN) denotes the number of samples with vulnerability but detected as not having vulnerability. The metric $A = \frac{TP+TN}{TP+FP+TN+FN}$ is the number of correctly predicted samples out of all the samples. The metric $P = \frac{TP}{TP+FP}$ represents all the samples that are declared to be vulnerable but what percentage of them are actually vulnerable. The metric $R = \frac{TP}{TP+FN}$ represents all the samples that are actually vulnerable but what percentage declared vulnerable. The metric $F1 = 2 * \frac{P * R}{P + R}$ is used to measure test accuracy,

which is a weighted average of the precision and recall. The $F1$ score is 1 when it's best and on 0 when it's worst. The $MCC = \frac{TP \times TN - FP \times FN}{\sqrt{(TP+FP)(TP+FN)(TN+FP)(TN+FN)}}$ returns a value between negative one and positive one. A coefficient of positive one represents a perfect prediction, zero means no better than random prediction and negative one indicates total disagreement between prediction and actual label.

V. EXPERIMENTS AND RESULTS

In this section, we conduct experiments on SARD, Big-Vul-All, Big-Vul-MemCorr datasets based on the design of BBVD described in section III. Comparative experiments are conducted using the models and evaluation metrics described in section IV.

A. Preprocess

1) *Code slices*:: For the SARD, Big-Vul-All and Big-Vul-MemCorr datasets, we extracted four types of code slices, corresponding to the API function call, array usage, pointer usage and arithmetic expression, respectively.

- The API function call related code slices: We extract 135,145 from SARD, 68,686 from Big-Vul-All and 6,381 from Big-Vul-MemCorr.
- Array usage related code slices: We extract 56,346 from SARD, 11,566 from Big-Vul-All and 4,953 from Big-Vul-MemCorr.
- Pointer usage related code slices: We extract 318,912 from SARD, 161,596 from Big-Vul-All and 4,525 from Big-Vul-MemCorr.
- The arithmetic expression related code slices: We extract 7,810 from SARD, 16,842 from Big-Vul-All and 5,192 from Big-Vul-MemCorr.

Since there are still duplicates in the above extracted code slices, we need to de-duplicate these data. For the SARD dataset, the API function call related code slices are reduced from 135,145 to 69,432; the array usage related code slices are reduced from 56,346 to 24,680; the pointer related code slices are reduced from 318,912 to 128,492; the arithmetic related code slices are reduced from 7,810 to 6,956. The total number of non-duplicate data in the SARD dataset is 229,560, of which 44,447 are vulnerable and 185,113 are non-vulnerable. For the Big-Vul-All dataset, the API function call related code slices are reduced from 68,686 to 29,865; the array usage related code slices are reduced from 11,566 to 6,151; the pointer related code slices are reduced from 161,596 to 101,804; the arithmetic related code slices are reduced from 16,842 to 15,476. The total number of non-duplicate data in the Big-Vul-All dataset is 153,287, of which 19,908 are vulnerable and 133,379 are non-vulnerable. Table II describes the number of extracted code slices for the SARD, Big-Vul-All and Big-Vul-MemCorr datasets.

2) *Tokenizer*:: Tokenization is an important step in natural language processing which breaks long texts such as sentences, paragraphs, and articles down into word-based data structures for subsequent processing and analysis work. In order to translate code slices into vectors that can be recognized by the BERT-based models, we need a tokenizer to translate them into vectors which can be recognized by BERT-based models.

TABLE II. NUMBER OF CODE SLICES EXTRACTED FROM DATASETS

Datasets	Slices Type	Total Slices	De-duplicated Slices	Vul Slices	Non-Vul Slices
SARD	API Related	135145	69432	12786	56646
SARD	Array Related	56346	24680	7195	17485
SARD	Pointer Related	318912	128492	11680	116812
SARD	Arithmetic Related	7810	6956	12786	56646
Big-Vul-All	API Related	68686	29865	4919	24946
Big-Vul-All	Array Related	11566	6151	325	5826
Big-Vul-All	Pointer Related	161596	101804	13406	88398
Big-Vul-All	Arithmetic Related	16842	15476	1258	14191
Big-Vul-MemCorr	API Related	6381	2064	538	1526
Big-Vul-MemCorr	Array Related	4953	1067	204	863
Big-Vul-MemCorr	Pointer Related	4525	3154	657	2587
Big-Vul-MemCorr	Arithmetic Related	5192	2911	440	2471

Specifically, we used two tokenizers in experiments, one based on byte-pair encoding and the other based on wordpiece. DistilBERT and MobileBERT model use tokenizer based wordpiece. RoBERTa use tokenizer based byte-pair encoding.

- Tokenizer based byte-pair encoding (BPE). BPE is an algorithm for encoding based on byte pairs. The algorithm is described as a cascading iterative process in which the most frequent pair of characters in a string is replaced by a character that does not appear in the string.
- Tokenizer based wordpiece. The wordpiece method is very similar to BPE in general, except that when selecting characters for merging, BPE uses the highest frequency, while wordpiece uses the highest probability.

B. Experiments for RQ1

To answer RQ1, we use SySeVR to perform the vulnerability detection on the SARD and Big-Vul datasets, respectively. We use the detection results as a benchmark. The BERT-based models are then used to perform the detection on the same datasets and the detection results are compared with the benchmark. In detail, the BERT-based models used in RQ1 is the same as that described in section IV. All BERT-based models used in this paper are pretrained for 10 epochs with $learning_rate=1e-04$ and fine-tuned for 10 epochs with $warmup_steps=1000$, $learning_rate=1e-05$, $weight_decay=0.1$. The loss functions used for both pre-training and fine-tuning phase are cross-entropy loss.

TABLE III. DETECTION RESULTS OF SARD (THE METRICS UNIT: %)

Model	Dataset	A	P	R	F1	MCC
BGRU(SySeVR)	SARD	95.16	89.63	86.36	87.97	84.96
BLSTM(SySeVR)	SARD	95.06	88.65	86.99	87.81	84.72
RoBERTa	SARD	95.42	85.25	93.90	89.37	86.63
DistilBERT	SARD	95.39	88.01	89.73	88.86	85.97
MobileBERT	SARD	95.02	84.56	92.56	88.38	85.36

Table III shows the detection results of 2 RNN-based models and 3 BERT-based models on the SARD dataset. The entire SARD dataset is divided into a training set and a test set after randomly sorted, with four-fifths of the training set and one-fifth of the test set. The RNN-based model is trained with the training set and tested with the test set. The BERT-based model is pre-trained with the entire SARD dataset, fine-tuned with the training set, inferred with the test set, and the inference results are compared with the benchmark.

In terms of F1, and the MCC metric, all the three BERT-based models outperform RNN-based models. Among the BERT-based models, RoBERTa has the best result. The corresponding F1 and the MCC metric is 93.90%, 89.37%, and 86.63%, respectively. All the BERT-based models outperform RNN-based models in accuracy metrics except MobileBERT. As for the precision metric, although the RNN-based model exceeds the BERT-based models, the recall rate of BERT-based models outperform RNN-based models. That is, the BERT-based model has a lower miss detection rate. Also, considering the metrics F1 and MCC, the overall detection effect of the BERT-based model is better than that of the RNN-based model.

TABLE IV. DETECTION RESULTS OF BIG-VUL-ALL (THE METRICS UNIT: %)

Model	Dataset	A	P	R	F1	MCC
BGRU(SySeVR)	Big-Vul-All	70.69	13.09	14.30	13.67	-3.94
BLSTM(SySeVR)	Big-Vul-All	72.41	12.90	12.18	12.53	-3.82
RoBERTa	Big-Vul-All	83.96	9.97	9.32	9.63	0.85
DistilBERT	Big-Vul-All	84.23	11.16	10.32	10.72	2.09
MobileBERT	Big-Vul-All	83.97	9.24	8.46	8.83	0.07

Table IV shows the detection results on the Big-Vul-All dataset. Compared to the detection results on the synthetic dataset SARD, the detection results show a huge drop. This means that real vulnerabilities have complex syntax and semantic informations and it is impractical to experiment on Big-Vul-All, which covers multiple vulnerabilities. Therefore, we focus on one vulnerability type called memory corruption and perform experiments on the Big-Vul-MemCorr dataset.

TABLE V. DETECTION RESULTS OF BIG-VUL-MEMCORR (METRICS UNIT: %)

Model	Dataset	A	P	R	F1	MCC
BGRU(SySeVR)	Big-Vul-MemCorr	69.90	42.55	26.08	32.34	15.11
BLSTM(SySeVR)	Big-Vul-MemCorr	70.50	44.73	29.56	35.60	18.12
RoBERTa	Big-Vul-MemCorr	71.94	48.87	37.82	42.64	24.82
DistilBERT	Big-Vul-MemCorr	66.78	39.46	38.26	38.85	16.06
MobileBERT	Big-Vul-MemCorr	72.18	49.13	24.78	32.94	19.39

Table V shows the results of several models on Big-Vul-MemCorr. Because the vulnerability types in Big-Vul-MemCorr dataset all fall into one category, the detection results are much better than those for Big-Vul-All. Of these five models, the one works best is the RoBERTa model. Its accuracy reaches 71.94%, precision reaches 48.87%, recall reaches 37.82%, F1 reaches 42.64% and MCC reaches 24.82%. Such results also illustrate that, despite the complexity of the real vulnerability types, it is feasible to use the BERT-based model for detection if only one vulnerability type is targeted.

C. Experiments for RQ2

To answer RQ2, we use different combinations of three datasets (SARD, Big-Vul-All and Big-Vul-MemCorr) described in section IV in the pre-training phase and fine-tuning phase. Similarly, the BERT-based model is also shown in section IV. The combination of datasets has the following five combinations (COMBs).

- COMB1: Pre-training phase and fine-tuning phase using SARD dataset.

- COMB2: Pre-training phase using Big-Vul-MemCorr dataset and fine-tuning phase using Big-Vul-MemCorr dataset.
- COMB3: Pre-training phase using Big-Vul-All dataset and fine-tuning phase using Big-Vul-MemCorr dataset.
- COMB4: Pre-training phase using SARD dataset and fine-tuning phase using Big-Vul-MemCorr dataset.
- COMB5: Pre-training phase using Big-Vul-All dataset and fine-tuning phase using SARD dataset.

TABLE VI. DETECTION RESULTS OF COMBs (THE METRICS UNIT: %)

Max Length	COMBs	Metrics	RoBERTa	DistilBERT	MobileBERT
512	COMB1	A	95.42	95.39	95.02
		P	85.25	88.01	84.56
		R	93.90	89.73	82.56
		F1	89.37	88.86	88.38
		MCC	86.63	85.97	85.36
		A	71.94	66.78	72.18
512	COMB2	P	48.87	39.46	49.13
		R	37.82	38.26	24.78
		F1	42.64	38.85	32.94
		MCC	24.82	16.06	19.39
		A	69.42	67.38	69.18
		P	43.16	39.60	42.19
512	COMB3	R	34.34	34.78	31.73
		F1	38.25	37.03	36.22
		MCC	18.49	15.21	16.73
		A	70.02	64.14	62.82
		P	42.64	35.44	32.75
		R	25.21	36.52	33.04
512	COMB4	F1	31.69	35.97	32.90
		MCC	14.88	11.08	7.19
		A	95.34	95.09	95.16
		P	94.11	92.62	90.54
		R	82.41	82.59	85.29
		F1	87.87	87.32	87.84
512	COMB5	MCC	85.29	84.50	84.88

Table VI shows the results of using different combinations of datasets in the pre-training and fine-tuning phases. For the comparison of COMB1 and COMB5 or the comparison of COMB2 and COMB4, we can see that using the same dataset for the pre-training and fine-tuning phases is helpful for the vulnerability detection. All three BERT-based models have slightly higher F1 on COMB1 than on COMB5 and on COMB2 than on COMB4. In the comparison between COMB2 and COMB3, the two COMBs use different datasets in the pre-training phase. The COMB2 uses Big-Bul-MemCorr, while COMB3 uses Big-Vul-All. Both the RoBERTa and DistilBERT models have better F1 and MCC metrics on COMB2 than COMB3. This illustrates that the dataset used in the pre-training phase can affect the detection results. Big-Vul-All covers multiple vulnerability types, while Big-Vul-MemCorr covers only one vulnerability type. If the model learns too many vulnerability features in the pre-training phase it may affect the detection results of a single vulnerability.

D. Experiments for RQ3

To answer RQ3, we set the maximum sequence length for the BERT-based model to two lengths: 512 and 1024.

Table VII shows the results of the model for vulnerability detection using different maximum sequence lengths. For SARD, the total number of tokens in code slices less than or equal to 512 is 142,303 and less than or equal to 1024 is

TABLE VII. DETECTION RESULTS WITH DIFFERENT MAX LENGTHS OF IDS (THE METRICS UNIT: %)

Max Length	COMBs	Metrics	RoBERTa	DistilBERT	MobileBERT
512	COMB1	A	95.42	95.39	95.02
		P	85.25	88.01	84.56
		R	93.90	89.73	82.56
		F1	89.37	88.86	88.38
		MCC	86.63	85.97	85.36
		A	95.40	95.57	95.25
1024	COMB1	P	93.33	95.34	93.72
		R	83.52	82.41	82.35
		F1	88.16	88.40	87.67
		MCC	85.52	86.04	85.02
		A	71.94	66.78	72.18
		P	48.87	39.46	49.13
512	COMB2	R	37.82	38.26	24.78
		F1	42.64	38.85	32.94
		MCC	24.82	16.06	19.39
		A	69.30	68.22	64.62
		P	43.36	40.93	39.05
		R	36.95	34.34	50.43
1024	COMB2	F1	39.90	37.35	44.02
		MCC	19.58	16.39	19.10

144,526. For Big-Vul-MemCorr, the total number of tokens in code slices less than or equal to 512 is 2,430 and less than or equal to 1024 is 3,135. If the maximum sequence length is set to 512, the code slice will be truncated when the number of tokens in the code slice is greater than 512. As a result, these code slices lose some of their syntactic and semantic information. However, the results on COMB2 show that it is not the case that the larger the maximum sequence length, the better the detection. The model does not detect as well at a maximum sequence length of 1024 as it does at a maximum sequence length of 512. At a maximum sequence length of 1024, the F1 of the RoBERTa model on COMB2 is about 5 percent lower than at a maximum sequence length of 512.

VI. CONCLUSION

In this paper, we propose BBVD by studying BERT-based models for software vulnerability detection. Specifically, the proposed BBVD uses C/C++ code for pre-training, fine-tuning, and inferencing to detect vulnerability. Our results show that these BERT-based models outperform existing RNN-based models such as BiGRU and BiLSTM for vulnerability detection. There are still issues that can be investigated, such as detection results on real datasets are not as good as on synthetic datasets. Future work should use more real vulnerability datasets to improve the effectiveness of the BERT-based models in detecting vulnerability.

Abstract—Deep Learning algorithms have become more popular in computer vision, especially in the image classification field. This last has many applications such as moving object detection, cancer detection, and the classification of satellite images, also called images of land use-land cover (LULC), which are the scope of this paper. It represents the most commonly used method for decision making in the sustainable management of natural resources at various geographical levels. However, methods of satellite images analysis are expensive in the computational time and did not show good performance. Therefore, this paper, on the one hand, proposes a new CNN architecture called Modified MobileNet_V1 (MMN) based on the fusion of MobileNet_V1 and ResNet50. On the other hand, it presents a comparative study of the proposed model and the most used models based on transfer learning, i.e. MobileNet_V1, VGG16, DenseNet201, and ResNet50. The experiments were conducted on the dataset Eurosat, and they show that ResNet50 results emulate the other models.

Keywords—Deep Learning; image classification; land use-land cover; MobileNet; ResNet; satellite images

I. INTRODUCTION

Nowadays, the artificial intelligence domain is knowing an important development, especially in image classification. It is one of the most common challenges in computer vision [1]. Indeed, it refers to the categorization of images into one of many predetermined classes. A single image can be classified into a number of different categories. However, manually inspecting and classifying images can be time-consuming, especially when the images have a large size. Thus, automating the process would be extremely beneficial [2].

Image classification is used in several domains [3], [4] e.g. medicine, videos surveillance, economy, and agriculture especially for the classification and categorization of Land Use-Land Cover (LULC) images. Moreover, at the local, regional, and national levels, the LULC classification plays an important role in program planning, management, and monitoring [5]. On the one hand, The LULC information helps in understanding the land occupation issues, and on the other hand, it is crucial in the constitution of policies and programs that are necessary for development planning. Furthermore, it is important to track the LULC pattern's evolution throughout time in order

to ensure long-term development. To accomplish sustainable urban growth and to control the random expansion of cities, urban development authorities need such planning models that allow every available piece of land to be used in the most reasonable and optimal way possible. It requires knowledge of the area's current and previous LULC. In addition, the LULC maps can be used to track changes in our ecosystem and environment [6], [7], [8].

Currently, image processing of LULC using deep learning algorithms is gaining more attention [9], [10], [11]. Since, they outperformed the classical approaches, even if the interpretation of LULC images requires good agricultural experience.

The main objective of this work is to study the efficiency of deep convolutional neural network (CNN) architectures for LULC image classification. Thus, our work aims to solve the following research questions: (1) Is there any deep learning technique that consistently outperforms the other ones? (2) Is it possible to use deep learning to correctly categorize LULC images and surpass previous methods? (3). What is the highest level of accuracy that DL can attain with LULC images ?

The contributions of our paper are the following: we design a comparison between different fine-tuned DL architectures (VGG16, DenseNet201, ResNet50 and MobileNet_V1) and a Modified MobileNet_V1 (MMN) architecture that combines MobileNet_V1 and ResNet50 on several levels namely: performance, and amount of parameters etc. Since there is a lack of LULC image datasets, the different models were evaluated on the Eurosat dataset [4] of LULC images and on the same dataset using data augmentation techniques. The rest of this paper is organized as follows: The second section presents the literature review, the section three provides the used methods and materials. Section four exposes the experimental results. Section five provides the discussion, and the paper is concluded in the last section.

II. LITERATURE REVIEW

A. LULC Classification Datasets

There are several LULC classes, such as developed or urban areas, farmland, and wooded areas, and so on. LULC

maps have many applications such as conservation of natural resources, entry of GIS data, delineation of tax and property boundaries, etc. Unfortunately, the existing and published datasets are rarely labeled, which makes the classification process very challenging. Thus, some datasets have been proposed, but each of them has a disadvantage. For example, the UC Merced dataset [12], [13], [14], [15], [16], which has been suggested by [16], contains 21 land use land cover classes with 100 images per class and is extracted from USGS National Map Urban Area Imagery. However, this dataset is a bad choice for a comparison based on deep learning models because it has a very small number of images.

Although PatternNet [17] and NWPU-RESISC [18] have high resolutions, they share the same issue of having 100 images per class. Additionally, SAT-6, which was developed by [19], has six classes: barren land, trees, grassland, roads, buildings, and water, and has a resolution of 1 m/pixel and a size of 28×28 and the images were produced using imagery from the National Agriculture Imagery Program (NAIP). Moreover, the AID Dataset, which was first presented by [15], includes 30 classes with 200-400 images each with a size of 600×600 .

B. LULC Classification Methods

Several methods have been proposed in the field of LULC classification. There are the traditional methods based on color analysis, shape and texture, or a combination of all this information [20], [21], but their effectiveness in the real world is still constrained. To solve the limitations of the old methods, numerous modeling tools, including dynamic, statistical methodologies, have been employed to create accurate simulations that consider economic, spatiotemporal and social factors [22]. Remote sensing imaging classification, anomaly detection, and prediction issues can be resolved using machine learning modeling. Maximum likelihood classifiers, Markov chain models, support vector machines, Markov chain models and other machine learning algorithms have been historically used to classify images [23], [7], [8], [11], [24]. But, in recent years, with the advancement in the performance of computing units, several approaches in the context of deep learning have been used. In order to provide superior performance for the treatment and classification of images (categorical image mapping and classification using convolutional neural networks (CNN)), deep learning models outperform traditional models in extracting spatial characteristics at various levels of remote sensing images [25]. A method in [10] presents an architecture called Joint Deep Learning (JDL), which integrates a multi-layer perceptron (MLP) and a convolutional neural network (CNN) and is implemented via a Markov process.

In [6], Scale Sequence Joint Deep Learning (SS-JDL) is introduced as a new DL method for LULC classification. The effectiveness of this SS-JDL method has been tested on the digital aerial photography of three complex and heterogeneous landscapes. Thus, In [26] a simple discriminative CNN (D-CNN) method is proposed to improve the performance of remote sensing image scene classification. Furthermore, the spectral and spatial information content of remote sensing images is captured and utilized in [27] and employing a multi-attention method using a bidirectional long-term memory network. To address the imbalance in LULC classes, a recent work in [28] recommended the use of oversampling, while in

[29], the authors suggest using consensus-based collaborative multi-label learning to balance labels. To explain the model predictions in [30], the authors tested various interpretable artificial intelligence methodologies while using the DenseNet model [31]. The framework for learning deep representations of spectral bands for the same purpose is finally proposed in [32].

The deep CNNs utilized in this paper were improved using a pre-trained network in the context of deep learning. The ILSVRC-2012 image classification challenge dataset served as the main source of pre-training data for the networks. Even though these pre-trained networks were developed on images from a completely unrelated field, the features generalized effectively [33], [34]. As a result, it was discovered that the pre-trained networks were appropriate for classifying remote sensing images. Consequently, we use for comparison some deep CNN models like VGG16 [35], ResNet50 [36], MobileNet_V1 [37] and DenseNet201 [31] which represent the state of the art for the classification of the introduced LULC classes.

III. MATERIALS AND METHODS

Recent studies have proved that DL algorithms are very efficient in image processing and computer vision [38]. They have been applied in various remote sensing imaging modalities with high performance [39] in segmentation, detection and classification. Although these technologies have shown promising results in remote sensing, they require a lot of data. Motivated by the success of DL and remote sensing image processing, our work will present a comparative study between a new CNN architecture that combines the MobileNet_V1 architecture with the concept that characterizes the ResNet50 architecture and different DL architectures (VGG16, ResNet50, MobileNet_V1 and DenseNet201) (application in the LULC domain).

Fig. 1. Process of LULC Classification

Fig. 1 illustrates the used processes to compare the various models. The first step is image acquisition. Then, the preprocessing and splitting of data. Finally, training, and classification.

A. LULC classification

LULC data indicates the extent of an area covered by forests, wetlands, impervious surfaces, agriculture, and other

land and water types [40]. It refers to the categorizing or classification of human activities and natural landscape elements over a period of time using scientific methodologies.

With this information, it is possible to better understand the effects of natural phenomena and human use of the landscape [40]. Maps can be also used to assess urban growth, model water quality issues, predict flood and storm surge impacts, track wetland loss and potential sea level rise impacts, prioritize conservation efforts, and compare land-cover changes with environmental effects or linkages in socioeconomic changes like population growth [23].

In the literature, there exist several approaches of features extraction from remote sensing images. In this context, CNNs are a sort of neural network [16], that is considered as the state of the art of image classification approaches [4] due to its good results.

B. Data Preprocessing

Even if some DL architectures can handle 13 bands of images as an input, they can not use the TIFF files. Therefore, all the images should be converted to RGB format. In order to avoid over-fitting, data augmentation was applied after the preprocessing and only to the training data. Additionally, some geometrical transformations were included i.e. rescaling, rotations, shifts, shears, zooms, and flips. We also used multiple augmentation approaches to build a new image from each input image.

C. Training and Classification

1) *Convolutional neural network*: CNN is not merely a deep neural network with many hidden layers. It is a deep network that analyses and recognizes images based on the brain's visual cortex. This is how CNN differs from previous neural networks in terms of idea and function [41]. It also gets its name from an operation called convolution, a linear mathematical action involving matrices. CNN has several layers, including a convolutional layer, a non-linearity layer, a pooling layer, and a fully-connected layer [1].

The pooling and non-linearity layers do not contain any parameters, while the convolutional and fully-connected layers do. In terms of machine learning issues, CNN performs exceptionally well. Specifically, in applications dealing with high resolution images [42]. CNN collects features from images automatically by constructing many convolution layers [43] resulting in a feature hierarchy. The shallower front convolution layer employs a smaller perceptual domain, allowing it to learn some features of the local image, whereas the deeper back convolution layer employs a broader perceptual domain, allowing it to learn more features [1].

2) Deep learning architectures:

a) *VGG16*: Simonyan and Zisserman proposed the Visual Geometry Group (VGG) CNN architecture in 2014, and it won the ILSVR competition. VGG16 enhances the decision function by replacing the huge filters with numerous 3×3 filters one after the other and 2×2 for max pooling, resulting in a more discriminative decision function (decrease in the number of parameters). VGG16 is easy to understand and utilize because it only has two layers: convolution and pooling

[35], [44]. There are a total of 16 weighted layers, as indicated by the number 16.

b) *ResNet50*: ResNet50 is a deep residual network created by K. He, X. Zhang, S. Ren, and J. Sun in 2015, and it won the ILSVRC 2015. It's a model that tackles the problem of disappearing gradients (gradient tends to zero quickly) by using a novel notion called skip connection (stacking convolution layers and adding the original input to the convolution block's output). ResNet50 is made up of five stages, each with a convolution and identity block and three convolution layers. ResNet50 uses images with a resolution of 224×224 pixels and has 50 residual networks [45], [36].

c) *MobileNet_V1*: MobileNet_V1 is a 28-layer architecture that accepts input images that are $224 \times 224 \times 3$ pixels in size. It introduced the notion of Depthwise Separable Convolution, in which two 1D convolutions with two kernels are used instead of a single 2D convolution to minimize the model's size (fewer parameters) and complexity (fewer multiplications and additions). MobileNet_V1 also adds two new global hyperparameters (width multiplier and resolution multiplier) that allow model developers to trade latency or accuracy for speed and compact size based on their needs [37], [46].

d) *DenseNet201*: The dense convolutional network (DenseNet201) is a CNN with 201 depth layers that takes a 224×224 input image. DenseNet201 is a ResNet improvement that incorporates dense layer connections. Each layer receives more inputs from the all preceding layers and delivers its own feature maps to the layers below it. Concatenation is used by each layer to obtain "collective knowledge" from all previous layers. DenseNet outperforms ordinary networks by reducing processing requirements, reducing the number of parameters, encouraging feature reuse, and improving feature propagation [31], [47].

D. Proposed Architecture Modified MobileNet_V1 (MMN)

The input layer, convolutional layers, pooling layers, fully connected layers, and the output layer are the five layers that make up a CNN model. Furthermore, a CNN model can be trained from end to end to enable feature selection, extraction and prediction or classification. It's difficult to figure out how a network understands and analyzes an image. However, features extracted by layers of a network have been demonstrated to outperform human-built features [48].

Our model is a combination of the MobileNet_V1 and ResNet50 architectures. We took the same architecture of the MobileNet_V1 which uses the notion of depthwise separable convolution, and we optimized it by adding the notion of skip connection, which characterizes the ResNet50 model. It means that we add the output of a layer to the next one. This is to try to improve the results of MobileNet_V1 by providing an alternate gradient path, and it has been experimentally proven that these additional paths are frequently beneficial for model convergence.

Fig. 2. Architecture of proposed CNN MMN

The proposed CNN MMN has the following architecture (Fig. 2):

- Input layer: the inputs are images with dimension (244×244) .
- Convolutional layers: a convolution is a linear process that involves the input and a set of weights. It's made for two-dimensional inputs, with multiplication taking place between a two-dimensional array of weights (filters) and an array of input data. We have three sorts of layers in the proposed architecture MMN : one with a 3×3 size filter and the same padding, one with a 1×1 size filter and the same padding, and one with a 1×1 filter and valid padding.
- Depthwise separable convolution : This layer was employed in our architecture with the same padding and a 3×3 filter.
- Pooling layers: a technique for subsampling feature maps by aggregating the presence of features across feature map patches. Average pooling and maximal pooling are two different types of pooling algorithms. To calculate the average value in each patch for each feature map in the proposed design, we used avg-pooling.
- BatchNormalization: This method involves refocusing and rescaling layer inputs to normalize them and makes artificial neural networks faster and more stable.
- After each BatchNormalization, we employed Rectified Linear Unit Layers (ReLU).
- Fully connected layers: they treat input data as a single vector and produce a single vector as output.

IV. RESULTS

A. The Used Dataset

Fig. 3. Dataset classes [4]

TABLE I. EUROSAT DATA DISTRIBUTION

Class name	Number of images
Annual Crop	3000
Forest	3000
Herbaceous Vegetation	3000
Highway	2500
Industrial	2500
Pasture	2000
Permanent Crop	2500
Residential Buildings	3000
River	2500
Sea and Lake	3000

In this study, We used the EuroSAT database of Sentinel-2 images of different European cities. It contains 27000 of 64×64 images. It covers several classes [4] i.e., Industrial Buildings, Residential Buildings, Sea and Lake, Herbaceous Vegetation, Annual Crop, Permanent Crop, River, Highway, Pasture, Forest (Fig. 3, Table I).

TABLE II. SENTINEL-2 BANDS, WAVELENGTH, AND RESOLUTION [4]

Sentinel-2 Bands	Central Wavelength (μm)	Resolution (m)
Band 1 – Coastal aerosol	0.443	60
Band 2 – Blue	0.490	10
Band 3 – Green	0.560	10
Band 4 – Red	0.665	10
Band 5 – Vegetation Red Edge	0.705	20
Band 6 – Vegetation Red Edge	0.740	20
Band 7 – Vegetation Red Edge	0.783	20
Band 8 – NIR	0.842	10
Band 8A – Vegetation Red Edge	0.865	20
Band 9 – Water vapour	0.945	60
Band 10 – SWIR – Cirrus	1.375	60
Band 11 – SWIR	1.610	20
Band 12 – SWIR	2.190	20

Sentinel-2 data is multispectral, with 13 bands covering the visible, near-infrared, and shortwave infrared spectrum (Table II). Since these bands are available in various spatial resolutions ranging from 10 m to 60 m, the images can be classified as high-medium resolution. Although data from other satellites with higher resolution (1 m to 0.5 cm) is available. Sentinel-2 data is free and has a long revisit duration (5 days), making it a good choice for LULC monitoring.

B. Evaluation Metrics

After training the various architectures, the final step is to evaluate the performance of the used architectures. Among the various classification performance properties, our research uses the following benchmark metrics: Accuracy (ACC), Precision (PRE), Recall, F1-score (F1) [49].

– Accuracy :

Accuracy is the proportion of true results among the total number of cases examined.

$$ACC = \frac{(TP + TN)}{(TP + FP + FN + TN)} \quad (1)$$

– Precision:

Precision is the proportion of predicted positives that are actually positive.

$$PRE = \frac{(TP)}{(TP + FP)} \quad (2)$$

– Recall:

Recall is the proportion of actual positives that are correctly classified.

$$PRE = \frac{(TP)}{(TP + FN)} \quad (3)$$

– F1-score:

The F1-score is a number between 0 and 1 and is the harmonic mean of precision and recall.

$$PRE = 2 \times \frac{(precision \times recall)}{(precision + recall)} \quad (4)$$

Where: TP stands for: True Positive. FP: False Positive. TN: True Negative, and FN: False Negative.

C. Results without Data Augmentation

Our research was conducted on a publicly available image dataset of LULC images (Eurosat Dataset [4]) and on the same dataset using data augmentation. During the experimental study, 80% of images were used for training and 20% for testing and validation, and this operation was repeated 20 times randomly, the average of the results was retained. This using the following experimental parameters for classification: All images in the dataset were 64×64 pixels, with the exception of the proposed model image, which was scaled to 224×224 pixels. Thus for the data augmentation techniques, we trained the different models with an image size of 224×224 . We used a batch size of 32 and a total of 20 epochs to train the models. For optimization, Adam is used with $\beta_1 = 0.9$, $\beta_2 = 0.999$, and the learning rate is set to 0.0001. As a result, a ReduceLROnPlateau with a min_lr of 1e-20 and val_accuracy as the monitor is employed. We utilized the ReLU to train a fully connected layer, and we changed the last dense layer in all models to yield 10 classes corresponding to the distinct classes in the Eurosat database [4], rather than the 1000 classes used by ImageNet. The results of the Eurosat image classification with the following architectures (Proposed Architecture, Fine-tuning the top layers of VGG16, ResNet50, DenseNet201, and MobileNet_V1) are shown in this section. Several experiments were carried out to evaluate the performance and resilience of each given model, based on the cited metrics in Section IV-B and the confusion matrix.

TABLE III. DIFFERENT METRICS OF THE PROPOSED ARCHITECTURE MMN

Metrics	Training	Testing
Accuracy	99.09%	94.01%
F1-Score	99.08%	94.02%
Recall	98.96%	93.9%
Precision	99.2%	94.8%
Loss	0.03	0.18

1) *Proposed Architecture Modified MobileNet_V1 (MMN)*: According to Table III, we observe that the accuracy of the training data is remarkably high compared to testing, with values of 99.09% and 94.01% respectively, and this is the case for all the other metrics (F1-score, Recall, Precision). However, the loss metric has been significantly increased from training to testing with values of 0.03 and 0.18, respectively.

Fig. 4. Confusion matrix of proposed architecture MMN

From the confusion matrix (Fig. 4), we note that the most recognized class is “Residential” with 607 images. Therefore, for “Pasture” the model was able to identify just 373 images.

TABLE IV. DIFFERENT METRICS OF VGG16

Metrics	Training	Testing
Accuracy	100%	96.9%
F1-Score	100%	96.87%
Recall	100%	96.84%
Precision	100%	96.89%
Loss	2.8e-05	0.18

2) *VGG16*: Table IV shows the Accuracy, F1-score, Recall, Precision, and loss of VGG16. Indeed, the accuracy decreased from training to testing with a difference of -3.1%. The same was noticed in the other metrics except for the loss which increased from the value of 2.8e-05 for training to 0.18 for testing.

Fig. 5. Confusion matrix of VGG16

Fig. 6. Confusion matrix of ResNet50

As shown in Fig. 6, the most identifiable class is “Residential”, whereas the model was capable to predict only 377 images as “Pasture”.

TABLE VI. DIFFERENT METRICS OF MOBILENET_V1

Metrics	Training	Testing
Accuracy	99.91%	76.31%
F1-Score	99.89%	76.37%
Recall	99.87%	74.96%
Precision	99.91%	77.88%
Loss	0.01	0.9

Fig. 5 shows the confusion matrix of the VGG16 model, which illustrates that 609 images were correctly labeled as the “Residential” class, but only 378 images for “Forest” were classified by the model.

TABLE V. DIFFERENT METRICS OF RESNET50

Metrics	Training	Testing
Accuracy	100%	96.31%
F1-Score	100%	96.34%
Recall	100%	96.28%
Precision	100%	96.4%
Loss	1.55e-05	0.17

3) ResNet50: Table V presents the obtained results with the Resnet50 classifier. We observe an increase in the accuracy of the training compared to the testing where its values are equal to 100%, 96.31% respectively, and it is the same for the other metrics. The value of F1-score for the training is equal to 100%, while for the testing it is 96.34%. We also observe that the recall and the precision have increased from the training (100%, 100%, respectively) in comparison with the testing (96.28%, 96.4%, respectively). For the loss function, its value is equal to 1.55 e-05 for training and 0.17 for testing.

4) MobileNet_V1: Table VI illustrates the obtained results of MobileNet_V1. The table shows a remarkable difference between the results of the different metrics for the training data compared to the testing data with values of 99.91%, 99.89%, 99.87%, 99.91% and 0.01 (Accuracy, F1-score, Recall, Precision, and Loss, respectively) for the training and for the testing (76.31%, 76.37%, 74.96%, 77.88% and 0.9). According to these results we can distinguish that the model overfit.

Fig. 7. Confusion matrix of MobileNet_V1

Fig. 8. Confusion matrix of DenseNet201

Fig. 9. Confusion matrix of proposed CNN MMN

TABLE VIII. THE RESULTS OF THE PROPOSED CNN ARCHITECTURE MMN WITH DATA AUGMENTATION

Metrics	Training	Testing
Accuracy	91.89%	90.79%
F1-Score	91.89%	90.79%
Recall	90.52%	89.75%
Precision	93.34%	91.91%
Loss	0.23	0.27

The confusion matrix (Fig. 7) indicates that the model can correctly predict 550 images of the “SeaLake” class and just 255 images of the “Pasture” class.

TABLE VII. DIFFERENT METRICS OF DENSENET201

Metrics	Training	Testing
Accuracy	100%	94.07%
F1-Score	100%	94.11%
Recall	100%	93.98%
Precision	100%	94.24%
Loss	8.72e-05	0.25

5) *DenseNet201*: As shown in Table VII, we can observe that accuracy, F1-score, recall and precision have remarkably high values for training (100%, 100%, 100%, 100%) compared to testing (94.07%, 94.11%, 93.98%, 94.24%), as well as for loss which has decreased from testing (0.25) to training (8.72e-05).

Concerning the confusion matrix (Fig. 8), the model was able to correctly identify 609 images of the class “Residential”, however only 364 images were correctly labeled as “Pasture”.

D. Results with Data Augmentation

In this section, we present the different results of the trained models, but this time using data augmentation techniques on the same dataset.

1) *Proposed Architecture Modified MobileNet_V1 (MMN)*: According to Table VIII, we can see that the different metrics do not vary remarkably from training to testing. There is a

TABLE IX. DIFFERENT METRICS OF VGG16

Metrics	Training	Testing
Accuracy	96.87%	96.01%
F1-Score	96.87%	96.09%
Recall	96.49%	95.71%
Precision	97.26%	96.5%
Loss	0.09	0.12

TABLE X. DIFFERENT METRICS OF RESNET50

Metrics	Training	Testing
Accuracy	99.97%	97.59%
F1-Score	99.97%	97.61%
Recall	99.97%	97.59%
Precision	99.97%	97.63%
Loss	0.001	0.17

small decrease in the accuracy, the F1-score, the recall, and the precision. However, the loss function was increased from 0.23 in training to 0.27 in testing.

From the confusion matrix (Fig. 9), we note that the model correctly recognizes 595 images of the class “River”, the model was also able to identify only 366 images of “Forest” and “Pasture”.

2) *VGG16*: Table IX shows the accuracy, f1-score, recall, precision and loss of the VGG16 model on the training data and on the testing data. We notice that for all the metrics, there is an insignificant difference between training and testing.

Concerning the confusion matrix (Fig. 10), the model was able to classify 600 images of “Residential” as well as 367 images of the “Forest” class.

3) *ResNet50*: As shown in Table X, the different evaluation metrics decreased from training to testing, with values of more than 97% for testing and more than 99% for training. The loss function showed a remarkable increase between the two cases with 0.001 for training data and 0.17 for testing data.

For the confusion matrix (Fig. 11), the most recognized class by ResNet50 is the “SeaLake” class with 599 images,

Fig. 10. Confusion matrix of VGG16

Fig. 12. Confusion matrix of Mobilenet_V1

Fig. 11. Confusion matrix of ResNet50

TABLE XI. DIFFERENT METRICS OF MOBILENET_V1

Metrics	Training	Testing
Accuracy	97.18%	96.59%
F1-Score	97.17%	96.64%
Recall	97.03%	96.56%
Precision	97.32%	96.73%
Loss	0.08	0.12

TABLE XII. DIFFERENT METRICS OF DENSENET201

Metrics	Training	Testing
Accuracy	98.77%	97.24%
F1-Score	98.74%	97.27%
Recall	98.62%	97.18%
Precision	98.87%	97.36%
Loss	0.03	0.09

Fig. 13. Confusion matrix of DenseNet201

therefore the least classified class is the “Forest” with just 392 images.

4) *MobileNet_V1*: Table XI represents the evaluation result of MobileNet_V1 architecture. It shows that there is a small difference between training and testing i.e. accuracy, f1-score, recall, precision and loss.

As shown in Fig. 12, the model was able to recognize correctly 596 images of the class “River” and only 375 for the class “Forest”.

5) *DenseNet201*: All metrics have a minimal variation between training and testing, as shown in Table XII, with the exception of loss, which has a small increase between training and testing.

Fig. 13 shows that 593 images were correctly marked as “SeaLake” and “River”, but the model was able to identify just 389 images of “Forest”.

E. Results on Real Images

The satellite image was acquired in the surroundings of Berrechid, Morocco, in May 2022, we took two patches from it to test several classifiers.

Fig. 14. The results of the different models

The Fig. 14 shows the results of the different models on two real images. We notice that for the proposed architecture MMN, the model gave as classification for the first image “Herbaceous Vegetation” and for the second image “Residential”. For VGG16 and ResNet50, we got “Highway” for the first image which is clearly wrong classification, and “Industrial” for the second, while MobileNet_V1 has classified the first and second image as “AnnualCrop”, which can not be possible for the second one. Finally, for DenseNet201, the model gave an erroneous classification for the first image (SeaLake) and classified the second as “Industrial”.

Fig. 15. The results of the different models with data augmentation

The obtained results with data augmentation are shown in the Fig. 15. We can observe that the proposed method identified the first image as “Herbaceous Vegetation” and the second as “Industrial”, while VGG16 classified the 2 images as “Industrial” which can’t be true for the first image. For ResNet50 and MobileNet_V1, they recognized the first image as “Permanent Crop” and the second as “Industrial”. DenseNet201 identified the first and second image as “Residential”, it gave wrong classification for the first image.

V. DISCUSSION

In this study, we addressed the multiclass classification of the LULC domain, based on the Eurosat dataset [4]. The training was applied using transfer learning, in order to identify the best architecture. The experimental study proved that the neural networks architectures are very useful for LULC image classification since they have shown high performance.

TABLE XIII. EVALUATIONS METRICS OF DIFFERENT ARCHITECTURES

Models	Accuracy	F1-Score	Recall	Precision	Loss	parameters number
MMN	94.01%	94.02%	93.9%	94.8%	0.18	6402506
VGG16	96.9%	96.87%	96.84%	96.89%	0.18	15768906
ResNet50	96.31%	96.34%	96.28%	96.4%	0.17	27787658
MobileNet_V1	76.31%	76.37%	74.96%	77.88%	0.9	3239114
DenseNet-201	94.07%	94.11%	93.98%	94.24%	0.25	22259786

Table XIII compares the performance of each architecture based on the mentioned metrics in Section IV-B, and the number of parameters. From the results, it can be seen that accuracy, F1-score, recall and precision when using the

MobileNet_V1 model are remarkably lower than the other models, with values of 76.31%, 76.37%, 74.96% and 77.88%, respectively, and this is due to the minimum number of parameters (3.2 M). Furthermore, the DenseNet201 and the proposed model showed the same performance except for the loss function, which has a value of 0.18 for the proposed architecture and 0.25 for DenseNet201. This with a too small number of parameters (6.4 M) in comparison with DenseNet201 (18.35 M), It is due to the fact that the extracted features from the previous layer have been added to the next layer. The main advantage of our architecture is that it needs a small number of parameters.

Both the VGG16 and ResNet50 architectures perform well, with 96% accuracy, F1-score, recall, and precision, which is expected considering ResNet50's depth and VGG16's usage of small filters. It can be seen that the MMN architecture is almost as accurate compared to the other architectures while being smaller in terms of parameters.

TABLE XIV. EVALUATIONS METRICS OF DIFFERENT ARCHITECTURES WITH DATA AUGMENTATION

Models	Accuracy	F1-Score	Recall	Precision	Loss	parameters number
MMN	90.79%	90.79%	89.75%	91.91%	0.27	6402506
VGG16	96.01%	96.09%	95.71%	96.5%	0.12	15768906
ResNet50	97.59%	97.61%	97.59%	97.63%	0.17	27787658
MobileNet_V1	96.59%	96.64%	96.56%	96.73%	0.12	3239114
DenseNet-201	97.24%	97.27%	97.18%	97.36%	0.09	22259786

Table XIV shows the obtained results of the different architectures with the use of data augmentation. Based on the presented results, ResNet50 and DenseNet201 showed good performance with an accuracy of more than 97%. Thus, we notice that data augmentation has improved the results for both architectures. Then we have the MobileNet_V1 and VGG16 with an accuracy of more than 96%. We also have for the loss function, 0.09 for the DenseNet201 model, 0.12 for VGG16 and MobileNet_V1, and an increase for ResNet50 with 0.17. Therefore, we can see that MobileNet_V1 with a lower number of parameters was able to achieve such remarkable results compared to the other models. Generally, this is expected since data augmentation is one of the best techniques for reducing overfitting. Table XIV shows that the MMN architecture was able to achieve an accuracy of 90.79% which is a reduced value compared to other architectures. This is most likely due to the model's limited capacity, which prevents it from learning all of the patterns in the data, or because some architectures are very sensitive to data augmentation.

VI. CONCLUSION AND PERSPECTIVES

In this work, we evaluated the performance of the automated methods used to classify LULC images into 10 classes on the Eurosat dataset using four DL architectures (VGG16, ResNet50, MobileNet_V1 and DenseNet201) and a proposed CNN architecture MMN based on a combination of the two methods MobileNet_V1 and ResNet50. Comparing the results, we found that our architecture proved good performance but

performs poorly using data augmentation compared to the other architectures. Therefore, our model needs to be adjusted to get better performance on the dataset with data augmentation. We also found that the performance of the DenseNet201 model and the proposed architecture is equivalent but the proposed model involves fewer parameters, which means it requires less memory consumption. In the experiment, we found that with and without the use of data augmentation, the VGG16 and ResNet50 models perform well (accuracy greater than 96%) compared to the other architectures. Moreover, we noticed that MobileNet_V1 can efficiently classify LULC images in the case of data augmentation, but with the original dataset its results were poor.

The proposed model will be improved by applying parameter tuning and studying the loss function. In addition, the used dataset in the training phase has a high impact on the efficiency of the model, thus it is very important to test the model with another dataset. Since each model has its own method to extract features, which highly influences the classification accuracy, we aim to study deeply the layers of feature extraction in order to improve the proposed model efficiency.

Viettel High Technology Industries Corporation
Ho Chi Minh City, Vietnam

Abstract—With the emergence of digital newspapers and social media, one can easily suffer from information overload. The enormous amount of data they provide has created several new challenges for computational and data mining, especially in the natural language processing field. Many pieces of research focusing on the information extraction process, such as named entity recognition, entity linking, and text analysis methodologies, are available. However, there is a lack of development for a system to unify all these advanced techniques. The current state-of-the-art systems are either semi-automatic or can only handle short-text documents. Most of them are not real-time or have a long lag. Some of them are domain restricted. Many of them only focus on a single source: Twitter. In this work, we proposed a system that can automatically collect, extract, and analyze information from public source text documents, like news and tweets. The system can be used in different domains, such as scientific research, marketing, and security-related domains.

Keywords—named entity recognition; entity linking; text analysis system; data mining; natural language processing

I. INTRODUCTION

We live in an age of information overload. The explosive growth of digital newspapers and online social networks creates enormous amounts of text data daily. This situation creates new challenges for computational and natural language processing (NLP) [1], [2], [3], [4], [5], [6]. While many pieces of research in the information extraction process and text analysis methodologies are available, there is a lack of development for a system to unify all these. This work proposed a system that can automatically collect, extract, analyze, and monitor information from text documents, such as named entities. The system takes in unstructured text from open public sources, like digital newspapers and Twitter, employs some information extraction processes, and records the information analysis results. It is fully automatic and has a real-time monitoring feature.

The system is not limited to any data domain. It can be applied in the news report system to automatically support reporters in detecting popular keywords. The proposed system can detect trending topics from scientific papers for research purposes. Trends are also crucial for analysts, marketing professionals, and retailers who want to monitor their and competitors' online products. Also, some government-run organizations can benefit from the proposed system by having security information about hot events related to entities from digital news or social media.

Many existing systems have applications comparable to ours, but they still have a few limitations. Some do the text analysis task on a single Twitter data stream [7], [8], [9],

[10], while others only serve on their specific domains [11], [12], [13]. Also, many systems are not real-time as Trend Miner, [10], or not fully automatic as LRA Crisis Tracker, [12]. In addition, several studies analyze documents using various entity recognition methods to extract entities [9], [14], [15]. Still, they do not mention how to address the issue of many different entities co-referring to the same real-world object. To overcome these drawbacks, we propose a system with the below contributions:

- It can automatically collect data from Twitter and digital newspapers.
- It can process both long and short text.
- It employs an extra Entity Linking after the Named Entity Recognition module to map the extracted entities to their unique identities.
- It is capable of real-time processing.

The proposed system comprises six modules deployed as micro-services. First, the Data Stream collects raw documents from Twitter and multiple news sources. Next, named entities are extracted from the text by the Named Entity Recognition module. Once entities have been mapped with their identity by Entity Linking, they are fed into the Entity Tracking module to count the frequency within a time step. The Trend Detection module will take the calculated frequency and perform a trending test computation. Finally, The Entity Monitoring module will keep track of all the entities' occurrence frequencies and notify users if abnormal rising trends are detected.

A more detailed description of the system is included in Section III. Section II presents a brief overview of some current state-of-the-art event monitoring systems. Experiment results and evaluation are shown in Section IV. The summary and future works are discussed in Section V.

II. RELATED WORKS

There are a significant number of systems that analyze document streams. The majority of previous works focus on social media, such as Twitter. These include TwitterStand [16], TwitterMonitor [17], and Jasmine [18], which focus on detecting trending keywords that correspond to global or local events.

LRA Crisis Tracker¹ is a system that tracks armed group activities and conflict-related incidents in the remote border region encompassing the northeastern Democratic Republic

¹<https://crisistracker.org/>

of Congo and the eastern Central African Republic. It uses data from crowd-sourcing. Domain experts must re-examine the data before feeding it to the system. In contrast to the Crisis Tracker system, the proposed system is fully automatic.

Redites [7] is a system that monitors events based on Twitter's tweets. The system will decide if a new tweet contains a new event whenever it is streamed. The event is then classified. Only events in security categories are analyzed and monitored. Redites is fully automatic. However, it can only handle short text documents like tweets from Twitter. The proposed system can handle both long- and short-text documents.

Social Sensor² tracks and monitors predefined events on social media [19]. The proposed system automatically extracts the events from news and tweets. Moreover, Social Sensor can only handle short text documents like tweets.

Trend Miner³ is similar to our proposed system; however, it does not focus on real-time aspects and can only handle short-text documents [20].

Cheng et al. [10] proposed an early warning system to detect COVID-19 outbreaks based on Twitter's data. The system has a 6-27 days lag and is only applicable for short-text analysis.

Epitweetr [11] is a system that detects outbreaks and public health threats using Twitter's data. The system is fully automatic and provides additional support for public health experts in detecting and identifying the geo-location of an outbreak. However, compared to the proposal, the system is restricted by data domain and can only handle short-text documents.

Goh et al. [12] proposed an approach using structured data and unstructured clinical notes to predict and diagnose sepsis. This approach is, however, restricted by the data domain and is not a fully automatic system.

A real-time system [9] was built to ingest the stream of all tweets and identify clusters of event-related entities on a minute-by-minute basis. The system first extracts named entities, hashtags and internal knowledge graph entities from each tweet. It keeps only trending entities detected by its internal Trend Detection system known as Twitter Trends. Then, a weighted graph is naturally constructed with the entities as nodes and their cosine similarities as edge weights. Community detection algorithms have been used to detect the sub-graphs (clusters) based on their links to others. To solve the Event Evolution problem, they add a layer of Cluster Linking to form cluster chains. Finally, clusters are ranked based on the aggregate popularity of their entities and persisted in internal stores for future use.

EveSense [8] is an Event Detection application that detects real-life events and related trending topics from the Twitter stream and allows users to find interesting events that have recently occurred.

News Monitor [15] is a scalable real-time framework for analyzing and exploring news articles. The system collects

Fig. 1. System diagram

news from many RSS news sources and automatically extracts the main content and other metadata. News Monitor is analogous to our approach compared to many news services, such as Event Registry [21]. However, it cannot handle the entity ambiguity problem when data diversity increases.

Our system can handle both long texts like news and short texts like tweets. It is also capable of analyzing these data sources simultaneously. The design, thus, can explore the potential relationship between the information flows to produce more consistent, accurate, and valuable information. Moreover, the system has an Entity Linking module to assign a unique identity to entities mentioned in the text, which helps robust join and union operations that can integrate information about entities [22].

III. MAIN COMPONENTS

The system is engineered in modules and is extensible. Each module is a separate service that can be modified or removed without affecting the whole system. A new module can also be added easily. Fig. 1 presents an overview of the system.

A. Data Stream

The Data Stream module handles the task of streaming posts from social media (such as tweets from Twitter) and news from digital newspapers. The module uses Scrapy⁴ and Automation Browser⁵ for its streaming process. This module is updated accordingly to the newspapers and social media structures.

B. Named Entity Recognition

The Named Entity Recognition (NER) [23], [24] module handles the task of extracting and classifying named entities in

²<http://socialsensor.iti.gr/>

³<http://www.trendminer-project.eu/>

⁴<https://scrapy.org/>

⁵<https://axiom.ai/>

Fig. 2. Named entity recognition process

Fig. 4. Entity monitoring process

Fig. 3. Entity linking process

unstructured text into predefined categories. Two deep learning approaches, namely Bidirectional Encoder Representations from Transformers (BERT) [25], [26] and Bidirectional Long Short-Term Memory (BiLSTM) [27], [28], [29], were used in this module. Each sentence from an unstructured text document will be tokenized and vectorized using the BERT model. The result vectors are fed to the BiLSTM model for detecting and classifying the named entities and their categories, as shown in Fig. 2.

C. Entity Linking

The Entity Linking (EL)[30] module links the named entities extracted from the NER module to their corresponding predefined unique identity. For example, the entities “US”, “USA”, and “United States” have the same identity as “United States of America”. Whereas “New York” is the name for both a city and a state in the United States of America, they have two separate identities. Fig. 3 shows how the entity linking process works in this module. The core of this module is BERT deep learning approach [31], [32].

D. Entity Tracking

The Entity Tracking module handles the task of tracing and tracking the named entities from each unstructured document. The module computes and keeps a record of the occurrence frequency of each named entity in a defined time step. The entities are then ranked by their occurrence frequencies. Top-ranked entities are fed to a trend detection module to examine if there is an abnormal increasing trend. This work is a real-time process. Data is streamed and processed simultaneously.

E. Trend Detection

The Trend Detection module uses the Mann-Kendall approach [33], [34], [35], [36] to detect an abnormal increasing trend in the occurrence frequency of an entity. The Entity Monitoring module will notify the users if a rising trend is seen.

F. Entity Monitoring

The Entity Monitoring module controls both the Entity Tracking module and the Trend Detection module. It handles the task of monitoring the entities and notifying users if there is an anomaly, as shown in Fig. 4.

IV. EXPERIMENTS AND EVALUATION

We have implemented and tested our system. We manually labelled 927 text documents with 20000 sentences and 14 different entity categories to train and evaluate the NER module. After training, we used a set consisting of 1500 sentences for testing the trained module. The final f1-score of the module is 91.41%. The EL module is trained and tested on a dataset consisting of 4475 entities, 1244 of which were manually labelled. The recall rate of the EL module is 97.2%. The system is capable of monitoring up to 3000 entities simultaneously.

Currently, the system can automatically collect and process news from 63 newspapers and public tweets in English from Twitter. We tested the system on a dataset of news articles and tweets collected from mentioned sources from July 15, 2022 to October 20, 2022. We chose July 21, 2022 as a virtual “current date” and let the system simulate the process of extracting and analyzing data. The results of the analysis are visualized as graphs.

The systems will automatically monitor the top-ranked entities when nothing is specified, as mentioned in Section III-D. Fig. 5 and Fig. 6 show the example graphical presentations of the tracking and the monitoring processes over multi entities, respectively. As a default, the system will monitor the top 100 entities; however, we chose to showcase only five of them in the figures for readability. Each subgraph in Fig. 5 presents the time series of the occurrence frequency of an entity, i.e., the number of news articles and tweets mentioning the entity during some predefined time step. Each subgraph in Fig. 6 presents the monitoring process of an entity. The blue line presents the occurrence frequency of an entity, the yellow line shows the plot of the normalized Mann-Kendall values of that entity, and the vertical red lines indicate the time when abnormal rising trends are detected.

The system also allows users to choose the monitored entities and sources freely. Fig. 7 shows an example graphical presentation of the monitoring process of one specific entity. The upper graph presents the time series of the occurrence frequency of the entity. In the lower graph, the yellow line shows the plot of the computed normalized Mann-Kendall values of the entity, and the vertical red lines indicate the time when abnormal rising trends are detected. Each red line presents an anomaly. Fig. 8 shows a monitoring process of three entities of interest on Twitter, and Fig. 9 shows the same process on digital newspapers.

Moreover, the system can detect if two (or more) entities simultaneously have an abnormal rising trend. The upper graph of Fig. 10 shows the plots of two occurrence frequency time series of the two entities in comparison. The lower graph’s orange and blue lines present the computed normalized Mann-Kendall values of the two entities. At the same time, the vertical red lines indicate the time when both entities have

Fig. 5. Example of multi-entities tracking

Fig. 6. Example of multi-entities monitoring

Fig. 7. Example of an entity monitoring process

Fig. 8. Example of selected entities monitoring on twitter

Fig. 9. Example of selected entities monitoring on news

Fig. 10. Example of trend comparison between two entities

abnormal rising trends.

In all graphs, the y-axis presents values, and the x-axis is time.

V. CONCLUSIONS

We presented a system capable of automatically collecting, extracting, and analyzing information from open sources such as digital newspapers and Twitter. The system provides significant help for online exploratory analysis. Since the system is flexible, it can be used in different domains, such as scientific research, marketing, and security-related domains. As stated, the system is extensible. Possible future works may include but are not limited to (i) an event extraction module that detects and classifies possible events in which entities are involved, (ii) a sentiment analysis module that determines emotion about events, (iii) a language detection module that handles multi-lingual data, (iv) machine translator module that translates documents into a specific language, (v) a graphical user interface that is friendly for users in different domains, and (vi) a visualization improvement for the data and the outcome analysis.

Abstract—Cerebral palsy is a group of developmental disorders that affects a certain percentage of population motivating the development of several types of therapies ranging from conventional where physical therapies are included to some *alternative therapies* such as the dolphin-assisted therapies (DAT), in order to improve the quality of life of patients suffering these disorders. To find scientific evidence of the DAT effectiveness, in this work is developed a four-stage first-order cybernetic model: i) Signal Acquisition, ii) EEG Processing, iii) EEG Exploring and iv) Healthcare Informatics System (HIS-DAT), in order to explore the electroencephalographic signals behavior from a patient with Infantile Spastic Cerebral Palsy undergone DAT, as well as bioacoustic signals emitted by a female bottlenose dolphin via specialized transducers or passive sensors for aquatic environments, by using nonlinear mathematical tools. We found that the Power Spectrum of signals from EEG and Hydrophone yield similar densities along all DAT and the child's brain activity increases 3-fold higher-frequency when the therapist-dolphin pair interacts with the patient. These findings are supported by the Self-Affine Analysis outcomes, pointing out the emergence of negative correlations from the patient's brain activity during the whole session of DAT but the greatest changes occurred During DAT.

Keywords—Brain-computer interfaces; healthcare system; nonlinear dynamics; assisted therapies; infantile spastic cerebral palsy; analysis of EEG signals; power spectrum; self-affine analysis

I. INTRODUCTION

Artificial intelligence (AI) generally is entitled with the development of techniques and devices to perform tasks that involve human interpretation and decision-making. Recently has raised many advances in medical AI applications owing the substantially enhanced computing power of modern computers and the vast amount of digital data available for collection and utilization. AI technologies can ingest, analyze, and report large volumes of data across different modalities to detect disease and guide clinical decisions for health services management and patient care treatments [1]. For instance, in [2] processed electroencephalography (EEG) signals to detecting emotional states tested the effects of meditation music therapy to stabilize mental states in groups of three to anger, calmness, happiness and sadness. They collected 120 emotion signals by using an Emotive 14-channel EEG headset. Therefore, tools developed in AI can be applied to measure and evaluate the effectiveness of therapies carried out to improve the life-quality of patients suffering one or several developmental

disorders, based on EEG signals collected from the patients' brain activity undergone assisted therapies.

Cerebral palsy is a group of developmental disorders diagnosed by their disturbance of the subject's movement and posture, caused by early nonprogressive lesions of the central nervous system [3]. In 1862, William Little connected this disorder to a lack of oxygen during birth and described it as a disorder that appeared to strike children in the first year of life, affected developmental skill progression, and did not improve over time. In 1897, Sigmund Freud suggested that cerebral palsy might be rooted in the brain's development in the womb and related aberrant development to factors influencing the developing fetus. Birth asphyxia alone was thought to be the cause of cerebral palsy until the 1980s, when biomedical research found this etiology to be less likely and only one of many with potential to result in cerebral palsy [4].

Cerebral palsy can be defined according to the anatomical site of the brain lesion (cerebral cortex, pyramidal tract, extrapyramidal system, or cerebellum); clinical symptoms and signs (spasticity, dyskinesia [dystonic and choreo-athetotic forms], or ataxia); topographical involvement of extremities (diplegia, quadriplegia, or hemiplegia); timing of presumed insult (prepartum, intrapartum, or postneonatal); and classification of degree of muscle tone (isotonic, hypotonic, or hypertonic) [5], [6].

The main symptoms of cerebral palsy are disorders of movement and posture, but more recently other symptoms have been included in the definition: disturbances of sensation and perception, global or specific cognitive difficulties, communication disorders, behavioral disorders, and seizures [3], [7]. There is no cure for this lifetime condition, but therapy, education, and technology can maximize each child's potential by improving functional abilities and quality of life.

The diagnosis of cerebral palsy is made largely through clinical observations, whose major signs collectively can identify delayed motor milestones, abnormal neurologic examination, persistence of primitive reflexes, and abnormal postural reactions [4]. The Gross Motor Functional Classification System was developed by Rosenbaum and collaborators in 2002 to help professionals anticipate gross motor abilities and severity of cerebral palsy, according to five levels: Level I: able to walk without restrictions; Level II: able to walk without devices; Level III: able to walk with mobility devices; Level IV: self-

mobility with limitations; and Level V: self-mobility severely limited [4], [8].

More than 50% of children with cerebral palsy and mental retardation suffer from epilepsy, mostly revealed in the first 4–5 years of life. Epilepsy usually occurred in children with accompanying vision and hearing disorders, and the inability to walk [9]. Besides, children with cerebral palsy often have the following disorders: irregular sleep patterns, lower urinary tract dysfunction, gastrointestinal disorders, drooling, aspiration, swallowing, osteoporosis, malnutrition, inadequate growth, gastroesophageal reflux, impaired language skills or cognitive limitations, among others [10].

Spasticity refers some degree of loss of motor control, abnormal tone, and weakness, which commonly can lead to contractures, scoliosis, and hip subluxation or dislocation. The child with cerebral palsy needs frequent position changes and needs to be out of his or her bed and/or wheelchair frequently at home and at school. Scoliosis may not only progress more rapidly but may continue after skeletal maturity occurs. Progressive hip adduction and flexion is also common, leading to femoral anteversion, subluxation, deformities of the femoral head, and hip dislocation, which can progress to degeneration, sometimes with pain [10].

Treatment of spasticity involves systematic rehabilitation, if necessary, assisted by pharmacotherapy, physiotherapy or surgical interventions, offering benefit, at least in the short term. Most physical therapies are based on the principles of neuroplasticity, patterning, postural balance, muscle strengthening, or stretching [9].

The total degree of overflow brain damage from the initial insult, may not be realized until the preschool or school age period. One of the most limiting comorbidities of cerebral palsy is mental retardation. Children with cerebral palsy that suffer mental retardation can have self-abusive behavior such as biting, head banging, or scratching. These behaviors may stem from anxiety that results from being unable to communicate needs such as hunger or pain. However, children with cerebral palsy who have normal intelligence may have some degree of coexisting visual perceptual abnormalities and learning disabilities that can affect overall development and learning. The assessment of intellectual functioning is often challenging in children with motor impairment because the majority of tests used require verbal and motor responses [10].

Confirming the diagnosis allows the family to plan for long-term treatments and management options that may be needed by the child. Having a diagnosis of cerebral palsy may qualify the child for increased insurance benefits, admission into handicapped preschool or school programs, and assistance in the form of federal assistance. The prediction of the future deficits or abilities at the time of diagnosis often is a *wait and see* situation [4].

Moreover, we want to highlight the importance of trying to improve the functional abilities and quality of life of children with cerebral palsy in developing countries owing. For instead, in [5] it argued that people with *Cerebral palsy* has a high risk for discrimination, neglect, and abuse, particularly those in rural settings owing low school attendance and lack of access to professional assistive. Indeed, individuals with cerebral palsy

have a right not only to inclusion but also to full participation in society and pursuit of their hopes and aspirations.

There are several *alternative* therapies used by families to complement systematic rehabilitation (assisted by pharmacotherapy, physiotherapy or surgical interventions), in order to try to improve their children's quality of life. Although there is a little scientific evidence about the effectiveness of these therapies, for some parents it is essential to explore each and every possible intervention that may be available for their children. Regardless their effect, these alternative therapies may offer the parent a feeling of participation or control, but unfortunately they usually cost large sums of money. Some examples of these alternative therapies are the following: massage therapy, horse riding, hyperbaric oxygen, conductive education, patterning, transcutaneous electrical stimulation, chiropractic manipulation, or dolphin-assisted therapy [10].

Since 1971, the *alternative* therapies called dolphin-assisted therapies (DAT) have been proposed to try to improve the quality of life of patients suffering psychological and neurological disorders such as cerebral palsy [11], [12], including Infantile Spastic Cerebral Palsy. In these patients are manifested early nonprogressive lesions of their central nervous system produced during pregnancy, as well as a severe motor delay in the early stages of their development owing their brain undergoes changes in its structure and organization. Hence, these patients have difficulty making more precise movements such as taking a spoon or making a clamp with their fingers and they also lack muscle coordination in some movements.

DAT are based on interaction between live captive dolphins and patients who suffer from various conditions, and this kind of interaction is supervised for both the dolphin trainer and the child therapist. However, an important differentiator that highlights this sort of alternative therapies is the intelligence of these animals, described and being recognized since the development of the Minoan civilization in Greece (3000 BC and 200 BC), and being studied over the years by various researchers [13], [14]. Like in humans, the dolphins' brain is very big regarding their body, therefore communication between both species can be possible [15], [16], [17].

There is evidence [18], [19], [20] about the abilities of dolphins to learn simple tasks with greater efficiency than some primates, allowing to observe the dolphins' ability to transmit the acquired knowledge and complex behaviors learned to other members of their species even for generations [21], [22], [23]. Besides, dolphins have been able to modify their behavior to do the tasks in a more efficient way, showing their interest to be part of the assisted therapies [15], [24]. In part, these dolphin's capabilities make it a better candidate to be part of assisted therapies.

In summary, cerebral palsy affects a certain percentage of the population motivating the development of several types of therapies ranging from conventional wherein physical therapies are included to some *alternative therapies* assisted by animals such as DAT, in order to improve the quality of life of patients with these developmental disorders. To find scientific evidence of the effectiveness of DAT, in this work, based on information technologies, has been developed a Healthcare Informatics System (HIS-DAT), as the last stage of a four-stage first-

order cybernetic model, to explore biosignals or biomarkers for measuring mainly quality of patient's medical care. Our HIS-DAT explores the behavior of electroencephalographic (EEG) signals in addition with bioacoustic signals by using nonlinear mathematical tools.

To look for scientific evidence from exploring EEG signals in a patient with Spastic Cerebral Palsy undergone DAT by means of our HIS-DAT, we make use of several tools from both computer science, in particular with parallel computational systems, and non-parametric or non-linear mathematical algorithms for the EEG-signal processing, in order to find emerging patterns at different time scales in the brain activity of a child with spastic cerebral palsy.

Therefore, this article is organized as follows. Section II describes our method designed to collect and process EEG signals. Section III presents the main results obtained after processing both bioacoustic and EEG biosignals. Section IV discusses the results obtained from both the Power Spectral Density and Self-Affine analysis in terms of changes detected in patient's brain Before, During and After DAT. Finally, Section V provides the authors' main thoughts.

II. METHOD

A. Case Study

During Dolphin-Assisted Therapies (DAT), the fundamental participants are therapist, dolphin's trainer, patient with Infantile Spastic Cerebral Palsy (ISCP) and female bottlenose dolphin. In this work, the cerebral activity of the patient with ISCP and dolphin are measured and explored to determine with scientific evidence the cause-effect correlation between them during DAT. It is worth emphasizing that only one child with ISCP was used as a case study, which we will refer to hereinafter as *Patient*. Characteristics to be taken into account for this research are following:

- Patient with ISCP: Analysis of the cerebral electric fields resulting from interaction between neurons during process of DAT.
- Female bottlenose dolphin: Bioacoustic signal emitted for communication between frequencies of 200 Hz and 150 kHz. Added to these the *clicks* emitted for its echolocation ranging 20 kHz to 150 kHz.

B. Signal Acquisition Tools

Electroencephalography measures the spontaneous electrical activity of the cerebral *cortex*, i.e. the surface layer of the brain. This phenomenon is not due to the simple addition of the action potentials of the 1×10^{11} neurons that make up the brain. The rhythmic variations in the observed waves owed a large population of neurons oscillating coherently. In other words, they all generate a signal of the same frequency. The presence of these rhythms indicates brain activity at the level of millions of neurons acting together synchronously. The form of the EEG signals depends on the age and alertness of patient, changing markedly during childhood. In a healthy brain, this activity is very similar in the different regions of the brain, so there will be no appreciable differences between the different areas of the cortex, called *lobes*. The real-time recording of brain electrical activity lacks a reproducible pattern, which

resembles a *chaotic* signal of very small amplitude, around 10-100 μV so it is not difficult to confuse it with a random noise. For this reason, normally studies of the EEG signals focus on its power spectrum via an analysis in frequency bands, but we also introduce a fractal characterization [25] to find emerging patterns from a quantitative nonlinear point of view.

EEG signals are measured as a voltage difference between two electrodes. In order to be able to measure such a small signal, the contact between electrode and skin must be correct. Often the skin receives a preparatory treatment, namely oily skin and dead cells are removed from the surface to arrange a conductive gel or paste to improve contact, in order to measure the impedance between the electrode and the skin. To achieve correct results, the impedance should not be much above 5 $k\Omega$.

Usually there are two configurations for the placement of the electrodes: i) in a referential way and ii) in a bipolar way. The first one is also called *monopolar configuration*, the reference is the same for all electrodes, i.e. when two EEG signals are recorded with a 2-channel EEG module, two active and one reference electrodes would be needed in addition to the ground electrode. Whereas for a *bipolar configuration* each channel has its own reference, so that to record two signals, i.e. four electrodes are necessary in addition to the ground electrode. The ground electrode that is added in both configurations is intended to reduce the common mode, e.g. the annoying interference of the electrical network [26].

Generally an EEG signal is characterized by means of its power spectrum. Traditionally the spectrum of an EEG signal is divided into four frequency bands. Besides, an EEG signal is going to be made up of components from all bands to a greater or lesser extent, but under certain conditions one or the other prevails. An EEG signal can be described as follows:

- 1) δ Band (0.5-3.5 Hz): Low frequency and high intensity waves (a few hundred μV). They occur in young children and adults only in a state of deep sleep, unconsciousness or situations that increase intracranial pressure such as brain tumors.
- 2) θ Band (3.5-7.5 Hz): These waves of amplitude less than 20 μV occur during the maturation process in the entire cerebral cortex, although it predominates in the occipital and temporal region and is faster in the frontal area. There are prevailed in children 5-7 aged and are associated in adults and adolescents with creative thoughts, stress or psychic disorders.
- 3) α Band (7.5-12.5 Hz): These waves of amplitude less than 20 μV are known as *alpha rhythm* and are referred to bursts of 20-100 μV of amplitude and great periodicity at those frequencies predominant over the occipital region but appearing throughout brain cortex. Average frequency of the alpha rhythm in an adult population is about 10.2 Hz. These waves are also associated with states of relaxation, inactivity and are very evident in the absence of visual stimuli[27].
- 4) β Band (12.5-30 Hz): These small amplitude signals, below 20 μV , are quite common and predominate during adulthood. There are usually divided into low beta, medium beta and high beta. The low beta rhythm is usually localized in the frontal and

occipital lobes and the other two are less localized. There are more irregular than the alpha rhythm and are associated with psychophysical activity, states of agitation, alertness or mental activity when solving problems.

To record the patient's brain activity or Human-Computer Interaction (HCI) in bands δ , θ , α and β , we use the ThinkGear ASIC Module v1.0 (TGAM1) passive sensor developed by the NeuroSky company (see Fig. 1), measuring the frequency bands of brain waves and generating raw time series, i.e. raw sound signals [28], [29]. These sound signals were recorded from the patient with ISCP by the first frontopolar electrode (F_{P1}) of 10-20 System of Electrode Placement [30].

Fig. 1. Signal acquisition tools: Sensor ThinkGear ASIC module v1.0 (TGAM1)

Fig. 2. Signal acquisition tools: Hydrophone 8103 of Brüel & Kjær

This sensor enables to construct fractal time series to be compared with spectrogram obtained from power analysis of bioacoustic signals, in order to insight relevant information about the dynamics pertaining to the behavior of the patient's brain Before, During and After DAT.

To collect dolphin's bioacoustic signals, a Brüel & Kjær 8103 Hydrophone and its coupling attachments are used to sound card that allows communication with computer equipment. This small and highly sensitive transducer is used to perform absolute sound measurements in frequency ranging from 0.1 Hz to 180 kHz with a reception sensitivity of -211 dB referred to 1V/ μ Pa. It has high sensitivity relative to its size

and good overall characteristics, making it generally applicable for both industrial and educational use. The high-frequency response of Type 8103 is especially valuable when conducting acoustic investigations of marine animals and in measurement of pressure distribution patterns by ultrasound. It is also useful for cavitation measurements. Fig. 2 shows the main external characteristics of the type 8103 hydrophone.

The applied Signal Acquisition Tools are described in detail in [31], while the mathematical tools used in this work are explained in [32].

C. Stimuli

Sonar of dolphins in conjunction with the resonance characteristics of humans are contributing factors to the current interest of this type of alternative therapies by researchers and foundations devoted to the treatment of neurological ailments, mainly in children [15], [16] with developmental disorders .

In [18] is argued that a dolphin orients its sonar by itself to the cranial area of the patient during DAT.

Hence, there is an increment of the Power Spectral Density when dolphin is closer to the patient, and thus a certain resonance frequency is yielded in specific parts of the patient's body (see Table I).

TABLE I. RESONANCE FREQUENCY RANGE OF THE PATIENT'S BODY

Human body parts	Range of Resonance Frequency (Hz)
Arms and shoulders	[2,8]
Chest	[2,12]
Hips	[2,8]
Lower back	[6,12]
Abdomen	[2,14]
Head	[8,27]

Therefore, the main issue is that dolphin's sonar produces resonance of different parts of the human body, yielding effects on the nervous system of the patient via psychological changes [33]. This process is attributed to the generation of endorphin in the brain, bringing about the activation of collagen molecules throughout the body.

Positive effects of DAT have been observed since 1978 in [34], [35], who proposed an experimental model of assisted-therapy to be a starting point for complementing the systematic rehabilitation, highlighting relevant factors in the effectiveness of these alternative therapies such as the type of patient condition, the water temperature, and the time required in a day. Each DAT is different, according to the condition to be treated as well as the patient specific needs [15], [16]. The conclusion of these works is that patient improvement depending only on testimonials explained by parents of the patient to therapists and trainers.

For this reason, some authors in [36] refer to DAT such as a *scientific Heresy* owing there had not a study where the brain activity of patients were measured and explored during DAT from computational and mathematical points of view.

D. Methodology

1) *Model*: The Healthcare Informatics System developed in this works relies on information technology, allowing to

Fig. 3. Four-stage first-order cybernetic model of the healthcare informatics system or HIS-DAT

organize and analyze health (EEG signals) records to measure and evaluate healthcare (effectiveness) outcomes.

Our Healthcare Informatics System is included in a model designed for measuring and assessing the effectiveness of DAT in a patient with ISCP. This model can be summarized in a four-stage first-order cybernetic model (see Fig. 3): i) *Signal Acquisition*, ii) *EEG Processing*, iii) *EEG Exploring* and iv) *Healthcare Informatics System (HIS-DAT)*. The input of this system is the *Signal Acquisition* stage wherein acoustic activity of the dolphin's sonar stimulates the patient's brain activity, considered the *Child-Dolphin Interaction*. In the *EEG Processing* stage, biosignals acquired in parallel in the previous stage are digitized and transformed into the frequency space. Subsequently, an *EEG Exploring* stage is performed as the output of the system, summarizing the behavior of biosignals by means of both a *Power Spectral Density* and a *Self-Affine Fractal Analysis*. Finally, in the fourth stage the *Child-Dolphin Interaction* is contrasted with non-parametric mathematical methods applied, in order to assess how effective the assisted therapies were for the patient, i.e. HIS-DAT focuses on making sense of the feedback or Input / Output interaction of the entire DAT-system.

2) *Procedure*: DAT can be carried out both in a tank and in open sea, contributing to the effectiveness of this kind of alternative therapies. There is no a standardized procedure for this type of assisted-therapies, since they vary to adapt to both patient and location conditions. Hence, depending on the sort of facility, DAT are performed differently, but there are prevailing factors [37], [38].

It is noteworthy mentioning that National Polytechnic Institute of Mexico by means of its Ethics Committee in document number D/1477/2020 approved this methodology for sampling and treating not only patients with ISCP but also female bottlenose dolphin.

In Delfiniti-Ixtapa facilities everything starts with an interview to the parents in order to learn more on their children, including the infants' diagnosis and behavior. This is vitally important in children whose communication skills are limited, and helps adjust therapies to the needs of each patient [39], [40].

Already in the water two specialists are present during the process: i) dolphin trainer and ii) therapist. Dolphin trainer supervises the behavior of dolphin while therapist places dolphin in certain parts of the patient body, especially those points that are located on the patient skull. Since a patient is introduced into the water, his/her motor exercises begin to stimulate the movement of the joints and effort in the muscles for carrying out a treatment focused on diseases that attack the central nervous system, regardless of the type of therapies [41], [42], [43]. Moreover, these exercises are performed as a warm-up before DAT and generate trust between patient and therapist, a crucial element during therapies. For patients with motor severity, water provides support in the body enabling them to perform more postures. Besides, water helps exercise muscles and joints, activating blood circulation to induce the desired state of relaxation.

The introduction of dolphin into the procedure is at discretion of the human specialist, taking place until the patient's confidence enables it. In [16] describes how many times in a day dolphin accepted the presence and the interaction of patient, before and after being trained for that purpose. After training dolphin, patient displayed feelings of joy, acceptance and a state-reflective positive [44].

The Delfiniti-Ixtapa personnel have developed their own Intervention Methodology for performing DAT (*IM4pDAT*). Thus, in the interaction with the dolphin, the patient is guided to caress it with complete movements that stimulate orientation and movement in three dimensions: length, height and depth [44]. To perform effectively DAT, the cooperation of both parties is stimulated by rewards, which is known as conditioned behavior (see Fig. 5). If *IM4pDAT* are done correctly, patient is rewarded by caresses, games and activities with dolphin, while dolphin cooperation is rewarded by attention and food as prizes.

Fig. 4 shows a Therapist who indicates to trainer where to orient the dolphin's nose to specific points on the patient's body until a light-touch is performed. Starting with the upper part of the chest where the thymus is located, a gland that develops T lymphocytes and responsible for the cellular immunity of the human body [45]. The dolphin's sonar emission can be perceived by therapist, either by waves in the water or by a sensation in the area where the body is in contact.

Next points to be in touch with dolphin are the frontal lobe located on the patient's forehead, and later in nape of the neck where the medulla oblongata is located, this latter communicates the peripheral nervous system and the spinal cord with the brain. Subsequently, therapist orients dolphin to the middle of head, in order to locate it in pituitary gland, a gland that is part of endocrine system responsible for producing hormones that carry instructions and information among several cell groups. Dolphin is oriented towards occipital and parietal of patient in an upright position, where it is usual that certain discomfort occurs when dolphin is approached to

left hemisphere of patient's brain. In [46] it is established left hemisphere is dominant for mathematical comprehension and language. In Delfiniti-Ixtapa a therapies last from 15 to 30 minutes, according the patient's needs [44].

Fig. 4. Dolphin-assisted therapies in Mexico: development

Fig. 5. Dolphin-assisted therapies in Mexico: dolphin feeding

As mentioned before, DAT are alternative therapies increasingly recommended by foundations to support children with neurological disorders and rehabilitation centers, in addition to being recommended by the Family Integral Development System (DIF, in Spanish) in Mexico [16], [47].

Nonetheless, there are bad practices when DAT are performed, as in all human activity, since it is still a business goal that increases in popularity over the years. Hence, DAT have been seen as a procedure focused mainly on animal rights and without any scientific evidence on its effectiveness. However, in [16], [48], [15] it is also encouraged the emergence of new research to improve techniques to be carried out, in order to assess the effectiveness of this method in the treatment of several disorders, diseases and ailments.

To understand the origin of benefits of DAT and try to offer scientific evidence about its effect in children with ISCP, a Human-Computer Interaction model is developed for the frequency-analysis in sessions lasting 8 minutes, proposing two sub-types of experiments. On the one hand, one session at a pool without a dolphin for 6 minutes measuring patient's brain activity in four exercises:

- 1) Before therapy in the water (1 min).

- 2) During therapy in the water without a therapist (2 min).
- 3) During therapy in the water with the therapist (2 min).
- 4) After a water therapy (1 min).

On the other hand, one session at the dolphin's tank with salt water, previously informing the completion of DAT and measuring patient's brain activity in five exercises:

- 1) Before DAT (1 min).
- 2) During DAT without therapist and without dolphin (2 min).
- 3) During DAT without therapist and with dolphin (2 min).
- 4) During DAT with therapist and with dolphin (2 min).
- 5) After DAT (1 min).

The above mentioned experiments are designed to independently compare the effect in DAT under different factors such as water, wind or dolphins [49]. To verify the expected outcomes for the experimentation, the raw-results were acquired using *IM4pDAT*.

E. Data Acquisition and Analysis

The correlation analysis between bioacoustic signals emitted by dolphin and an EEG signal from patient with ISCP is performed from a software developed in the programming-language MATLAB because of being a programming language oriented to design scripts, i.e. an interpreted language made-up a set of predefined functions for execution of programs in mathematical language. To perform only the program's final stage, i.e. analysis of collected data, minimum requirements of MATLAB R2016b release are demanded.

Data-acquisition process during DAT requires the following devices:

- Sensor ThinkGear ASIC Module v1.0 (TGAM1).
- 2 Web with Standard or SD Resolution, although it supports high-definition or HD.
- USB-DAQ 8/2-ch production analysis card.
- Charging to Delta Tron converter with integrated TEDS.
- BNC (male) to 10-32 UNF (female) adapter.
- Brüel Miniature hydrophone & Kjør Model 8103 with 10-32 UNF cable (male).

Besides the analysis of biosignals performed in this research, a system programmed in Matlab R2022a is also developed in order to create folders on local disk of computer equipment used for this analysis. These folders store samples collected in each analysis step. Integrated development environments or IDE's are designed for each part of the process to be managed intuitively by users, so that the program execution is divided into modules to provide the user graphical access to system control. Likewise, each module is divided into functions with specific goals for successfully running of the program by dividing the process into sub-sequential processes. Each function is executed by indirect calls, allowing sequential execution of same, as well as transfer of data among

them. Fig. 6 and 7 show both IDE Configuration for signal acquisition and the one for storing Basic patient information, respectively.

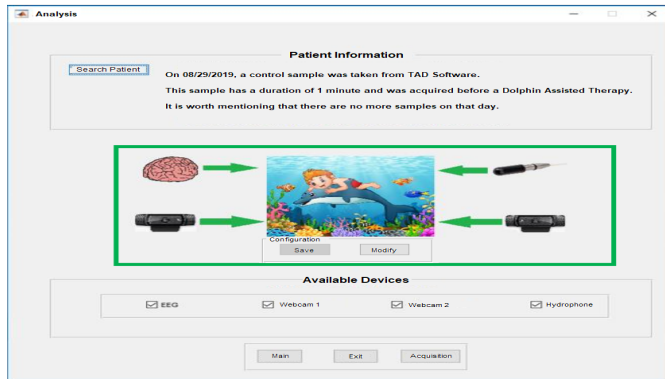

Fig. 6. Data analysis: configuration for signal acquisition

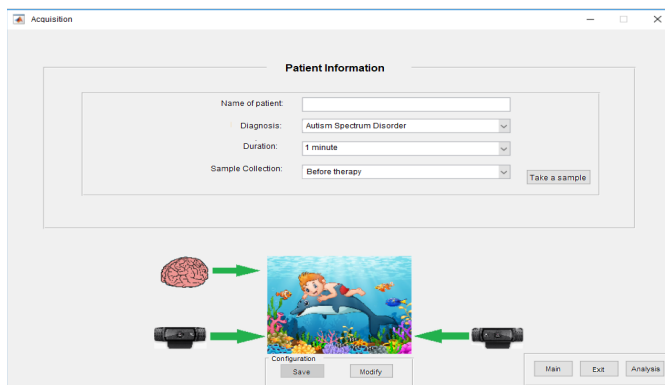

Fig. 7. Data analysis: basic patient information

For the statistical analysis of time series, in this work an Self-Affine (or Fractal) Analysis was performed. A fractal object is scale-invariant or self-affine when it remains invariant under an anisotropic transformation scale (different scales in all directions). Despite their differences, on a transformation scale, directions are not completely independent. If, when zooming in, one of coordinate axes is transformed into a factor b , $x \rightarrow bx$, the rest of coordinate axes must be rescaled into a factor $b^{-1} x_i \rightarrow b^{-ai} x_i$, in order to preserve the invariant set. Exponent ai is called the Hurst exponent (or dynamic scaling exponent) and tell us what the degree of anisotropy or correlation of the set is [50].

Biosignals, specifically EEG signals, representing a fractal system having self-affinity at a macro level and at a micro level. Small changes create a huge variety of patterns at both micro and macro levels. Fractal analysis makes it possible to determine fractional dimension and detect properties of self-affinity in objects or time series subject to investigation and possessing complex characteristics [51], [52].

In this work, we apply Self-Affine Analysis as theoretical basis for evaluating dynamics of EEG signals of patient with ISCP owing this mathematical tool gives us a notion of the behavior of cerebral signals. From EEG time series it is

possible to explore the behavior of many biological complex systems at different time-scales. Expected relationship between values of EEG at time t and at time $t + \tau$ is a correlation relationship in brain activity. Otherwise, a stationary time series has correlation when it depends only on time interval between two observations and falls to zero fast enough while increasing, reflecting the fact that influence of past values decreases with considered delay [50], [53], [51], [52].

Thus, evaluation of Hurst exponent is a first step in recognition and characterization of complex dynamics in EEG time series. This analysis makes it possible to distinguish a random behavior from a non-random one.

Likewise, a EEG time series with some level of pre-visibility will show positive self-correlation. Contrarily, a EEG time series with negative self-correlation has no level of pre-visibility. A Hurst exponent ranging $0.5 < H \leq 1$ corresponds to EEG time series showing a period of growth followed by another analog. This means that one increase is more likely to be followed by a similar one; this is known as positive self-correlation [53].

While values located at $0 < H < 0.5$ correspond to a behavior of one period of growth followed by another of decrease, or vice versa, there is more probability that next period is below average; it has a negative correlation. In addition, $H = 0.5$ corresponds to a random movement; an increase can be followed by a decrease or by a similar one. Finally, the movements do not display any memory, it has auto-correlation equal to zero, namely $H = 0$. All this will give us information about the behavior of patient with ISCP when his/her brain is excited or not by a bioacoustic signal emitted by the dolphin [53].

III. RESULTS

This section is divided into three main parts. The first describes how the performance or test operation of biosignal acquisition equipment is validated. The second explains the Power Spectrum Density results. Finally, the third shows the Self-Affine Analysis results.

A. Performance Validation

A data capture was realized using all the sensors for testing the system operation. This test lasted 5 minutes with the dolphin presence to capture the bioacoustic signal by using the 8103 hydrophone. Additionally, a control subject without any diagnosed condition was positioned on the side of the tank to perform the EEG analysis on it.

Once data acquisition process was completed, *Analyzing* IDE option corresponding to *FFT* option was selected in order to verify whether the use of the hydrophone is part of the saved settings. Hence, an indirect call is made to a function to graph the raw-data, both from the hydrophone and from the EEG. Firstly it is set-up the following: i) the hydrophone's sensitivity, ii) the total sample, iii) the analysis time (in this case, 5 minutes), and iv) the folder for the patient as the destination path for the outcomes. Besides the raw-data collected are plotted to yield the time series corresponding to the Volts referred to Pascals (V/Pa) captured by the hydrophone in each $1/f_s$ seconds (see Fig. 8). Images generated by webcams are saved as image-files in the patient's folder.

A DAT session was studied from the average frequencies obtained for the histogram of this Experiment, both from the EEG and the hydrophone 8103. These frequencies were estimated in an expected range for a patient in a relaxed state and a dolphin with little activity, respectively.

Fig. 8. Time series of the hydrophone resulting from the test

B. Power Spectrum Density

The power density was estimated via an indirect call to a function by adjusting both the minimum frequency to which the hydrophone is sensitive ($f_{min} = 0.1$ Hz) and the sampling frequency ($f_s = 96000$ samples per second). The *pwelch* function is applied inside the MATLAB *Signal Processing Toolbox* to obtain the Welch transform using a Kaiser window of size $(2/f_{min}) \times f_s$. In Fig. 9 is shown the graph resulting from the estimation of the power density expressed in decibels (dB) and referred to Hertz, for each of the frequencies captured by the hydrophone 8103 during the experimentation.

Fig. 9. Periodogram of the hydrophone resulting from the test

Then, the *spectrogram* function is applied inside the MATLAB *Signal Processing Toolbox* with a *kaiser* window of size $(2/0.1) \times f_s$ to calculate the Fourier transform in short-time of the frequencies captured every $1/f_s$ seconds. This is required to define a normalized-vector to the maximum frequency estimated by the hydrophone. As a result, the spectrogram of Fig. 10 is constructed, depicting a heat-map where each column contains the estimate of the power density of frequencies captured while running the experiment. Fig. 10

and 11 show a spectrogram of biosignals from patient's brain activity and dolphin's echolocation, respectively. These graphs are stored with the patient's name as *image files.jpg* in the selected folder as the *Patient Data*.

Fig. 10. Spectrogram resulting from the test from EEG

Fig. 11. Spectrogram resulting from the test from hydrophone

Likewise, Fig. 10 and 11 show three-dimensional graphs where not only whole power given by a frequency is observed, but also the moment when a sample manifested certain frequency. Lighter areas point out higher power of a frequency at a certain moment and, on the contrary, dark areas indicate lower power. Thus, after analyzing these two-spectrograms it is found (in red) a clear activation of the brain of patient with ISCP in $\beta = 12$ Hz frequency band, which are related to a state of alert and conscious attention, at the same time when dolphin emits at approximately 12 KHz. This means an indirect activation of the child's brain caused by dolphin's echolocation during DAT.

Fig. 12 shows the resulting histogram from the average of the power of frequencies captured during the experimentation, in intervals of two octaves. Although the hydrophone 8103 is sensitive until 180 KHz, its maximum frequency can be represented as nineteen octaves. For this experimentation only the first-twelve octaves were considered, ranging from 0 to 4096 Hz due to a greater occurrence of the highest powers from seven to ten octaves.

For the data generated from the EEG signals, we also apply the same functions for graphing and analyzing the hydrophone,

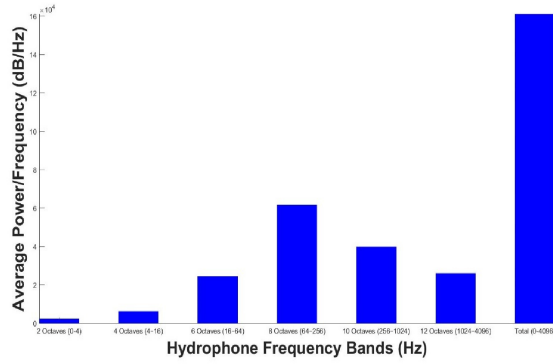

Fig. 12. Histogram of the hydrophone resulting from the test

Fig. 14. DAT given to a patient with spastic cerebral palsy in Delfiniti-Ixtapa, Mexico

and performing a similar analysis to the hydrophone without plotting in octaves but plotting in frequency bands of brain activity, such as δ (0.5-4.0 Hz), θ (4.0-8.0 Hz), α (8.0-12.0 Hz), beta β (12.0-30.0 Hz)[54].

Once data processing is finished, a new IDE is opened (see Fig. 13(a)) to choose between viewing the outcomes of the sensor EEG (see Fig. 13(b)) or the Hydrophone (see Fig. 13(c)). If it is wanted to return to the Analysis IDE, it must be pressed the return button. The high-quality versions are located in the same folder selected as the Patient Data.

Fig. 13. Results of ISCP patient. (a) window of the Integrated Development Environment (IDE), (b) fast fourier transform for EEG signal, and (c) fast fourier transform for hydrophone biosignal

A frequency analysis during DAT is carried out from the signals captured in this cetacean via the 8103 hydrophone and the EEG signal corresponding to a DAT performed on a patient with ISCP (see Fig. 14 [55]).

In Table II is shown the recorded outcomes corresponding to the average of frequencies obtained from the EEG signals. High-frequencies ($\alpha + \beta$ bands) refer to an attention state and low-frequencies ($\delta + \theta$ bands) correspond to a relaxation state in a human. In the case of water therapy without a dolphin, it is observed a decrease at the end of therapy of 72.77% in the power of the patient's brain activity for low-frequencies and 85.33% for high-frequencies. Contrarily, in the case of DAT was found an increase of 9.73% and 6.85%, respectively, at the end of therapy. In both sub-types of experimentation, the

greatest power is recorded when the main factor of change is introduced in each therapy, being the therapist in the case of therapy in the pool and the dolphin in the case of assisted therapy. Thereby, during DAT the greatest power is recorded between both sub-types of experiments. The increase observed is 160.3% in low-frequencies and 143.84% in high-frequencies regarding the frequencies recorded Before DAT.

C. Self-Affine Analysis

Fig. 15 and 16 show the main outcomes for RAW-EEG brain activity. Fig. 15 shows the cerebral activity of patient with ISCP undergo DAT with dolphin and therapist. Fig. 16 presents the results in terms of voltage fluctuations regarding brain activity, estimated by a Self-Affine Analysis. The three-curves depict the voltage fluctuation behavior at different time-scales: i) in red color the sample taken Before DAT, ii) in blue color the sample taken During DAT, and iii) in green color the sample taken After DAT. The resulting values of the Hurst exponent are: i) Before DAT $H = 0.4133$, ii) During DAT $H = 0.3898$, iii) and After DAT $H = 0.4462$; in all cases the behavior of patient's brain activity is antipersistent or displayed negative correlations ($0 < H < 0.5$), i. e. there is a constant change in the patient's brain activity

Fig. 15. Main results for RAW EEG brain activity of the child with ISCP: i) in red color Before DAT, ii) in blue color During DAT, and iii) in green color After DAT

TABLE II. RESULTS FROM PATIENT WITH ISCP, EXPERIMENT CARRIED OUT ON JANUARY 25, 2020. THE BOLD BARS INDICATE THE BEST THERAPEUTIC EFFICIENCY IN TERMS OF POWER DENSITY

Therapy	Bands	Before	During	After	$\delta + \theta + \alpha + \beta$		
					Before	During	After
Pool without therapist	$\delta + \theta$	423.65	256.56	115.36	1097.75	563.28	214.28
	$\alpha + \beta$	674.1	306.72	98.92			
Pool with therapist	$\delta + \theta$	423.65	365.08	115.36	1097.75	771.99	214.28
	$\alpha + \beta$	674.1	406.91	98.92			
DAT without dolphin and therapist	$\delta + \theta$	262.48	222.89	288.02	596.98	649.42	645.43
	$\alpha + \beta$	334.5	426.53	357.41			
DAT without dolphin and with therapist	$\delta + \theta$	262.48	217.5	288.02	596.98	477.77	645.43
	$\alpha + \beta$	334.5	260.27	357.41			
DAT with dolphin and therapist	$\delta + \theta$	262.48	683.26	288.02	596.98	1498.9	645.43
	$\alpha + \beta$	334.5	815.64	357.41			

Fig. 16. Results form self-affine analysis describing the voltage fluctuation behavior at different time-scales: i) in red color before DAT, ii) in blue color during DAT, and iii) in green color After DAT

IV. DISCUSSION

From Table II, it can be observed that the greatest power occurs both at low-frequencies ($0.5 - 8.0 \text{ Hz} \rightarrow \delta + \theta$) and at high-frequencies ($8.0 - 30 \text{ Hz} \rightarrow \alpha + \beta$) when performing DAT with a therapist working on the patient. In addition, when frequencies ranging from 0.5 to 30.0 Hz ($\delta + \theta + \alpha + \beta$), DAT gets the greatest power during therapy. Moreover, a simulated DAT in a pool is working as a relaxant since it has a tendency to reduce the power of brain activity. While tendency of DAT is to enter with a certain power, it increases almost 3-fold the power and produces a greater effect than initial therapy, as well as it keeps high-frequencies responsible for concentration.

In [56] and in [57] have been pointed out that a complete conventional therapy should increase the brain's highest-frequencies in conditions, e.g. Attention Deficit Hyperactivity Disorder since it makes patient's concentration be kept, an effect that does occur in DAT.

Concerning to outcomes resulting from the Self-Affine Analysis, it is observed: i) Before DAT $H = 0.4133$, ii) During DAT $H = 0.3898$, and iii) After DAT $H = 0.4462$. Thus, in the full-session of DAT the patient's brain activity displays only negative correlations at different time-scales, i.e. the patient's brain activity increases and decreases all time long, but the greatest changes occurred During DAT due to it yields the lowest Hurst exponent ($H = 0.3898$), i.e. the most negative correlation displayed.

Finally, it is worth mentioning that it is not possible to

compare the results obtained in this article with those yielded by other related articles on the topic owing non-parametric and non-linear mathematical methods such as this work are not used and are only limited in many cases in the opinions of parents or simply basic descriptive statistics such as the mean or standard deviation. Besides, this work contains just a single case study, which gives a first approximation of what happened with the brain activity of a patient with cerebral palsy during DAT, but it is the basis for future research, which should have at least both control and intervention subjects in order to strength our findings.

V. CONCLUSIONS

Family members of patients with Infantile Spastic Cerebral Palsy (ISCP) appeal to both conventional and alternative therapies such as dolphin-assisted therapies (DAT). This work trials to find scientific evidence about the effect of DAT in a child with ISCP for improving his functional abilities and quality of life. Therefore, we develop a four-stage first-order cybernetic model: i) Signal Acquisition, ii) EEG Processing, iii) EEG Exploring and iv) Healthcare Informatics System (HIS-DAT) to measured the brain activity of this patient by collecting and exploring two passive-sensor types of biosignals: i) Electroencephalographic and ii) Sonar echolocation of a female bottle-nose dolphin.

We found that the Power Spectrum of signals from EEG and Hydrophone signals yield similar densities along all DAT and increases 3-fold higher-frequency brain activity when the therapist-dolphin pair interacts with the patient. Increments in higher-frequencies, ranging from 12 to 30 Hz ($\alpha + \beta$), corresponding to concentration activities can help not only in patients with ISCP but also in other disorders such as Attention Deficit Hyperactivity Disorder. These findings are supported by the Self-Affine Analysis outcomes, pointing out the emergence of negative correlations from the patient's brain activity during the whole session of DAT but the greatest changes occurred During DAT. Usage of a single child as a case study shows first results of how this patient's brain activity behaves when this brain has neuronal disability and it is auto-stimulated by dolphin's sonar.

The proposed HIS-DAT model stores and retrieves all applicable information regarding patients undergone DAT. HIS-DAT also allows doctors, therapists, dolphins' trainers, and parents to have quick, easy, and efficient access to changes in patients' brain activity Before, During and After DAT in order to evaluate its effectiveness.

ACKNOWLEDGMENT

The research described in this work was carried out at Superior School of Mechanical and Electrical Engineering (Escuela Superior de Ingeniería Mecánica y Eléctrica) of the Instituto Politécnico Nacional, Campus Zacatenco. It should be noted that this research is part of doctoral thesis entitled *Modelo sistémico para determinar la eficacia de una terapia asistida por delfines* supported by Erika Yolanda Aguilar del Villar, work directed by Dr. Oswaldo Morales Matamoros and Dr. Ricardo Tejeida Padilla, in addition with *Modelo de sistema viable para organizaciones de turismo de salud, basado en la delfinoterapia*, supported by Abril Pérez Sánchez, work directed by Dr. Oswaldo Morales Matamoros and Dr. Jesús Jaime Moreno Escobar.

Dynamic Light Settings as Data Augmentations for Automated Scratch Detection

GRAVE Valentin¹, FUKUDA Osamu², YEOH Wen Liang³,

Graduate School of Science and Engineering, Saga University, Saga, Japan

Abstract—The manufacture of plastic parts requires a rigorous visual examination of its production to avoid the shipment of some that would be defective to its customers. In an attempt to ease the detection of scratches on plastic parts, the prototype of a computer-assisted visual inspection system was developed. The aim of this paper is to introduce how we explored ways to design a semi-automatic system comprising of a lamp whose orientations and intensities help in revealing irregularities on subjects that would have been missed with a unique light configuration. This process was qualified as “hardware data augmentation”. The pictures collected by our system were then used to train several convolutional neural networks (YOLOv4 algorithm/architecture). Finally, the performances of their models were confronted to evaluate the effects of the different light settings, and deduce which parameters are favourable to capture datasets leading to robust defect detection systems.

Keywords—Augmentation technique; deep neural network; image processing; light emission; object detection

I. INTRODUCTION

The appearance of a product is the first and foremost characteristic that will attract, or repel, a customer. One of the key factors for an “appealing aspect” is the lack of flaws in the final product. Indeed, if defects are visible on an item, it will be considered poorly made. Therefore, it is essential for a manufacturer to carefully design its processes so that irregularities become as rare as possible.

Companies have been striving to produce quality products by implementing verification procedures in crucial stages of their production. In the plastic industry, for example, it is frequent for operators to be tasked with observing the surfaces of plastic parts under some light and comparing them with typical flawless pieces as validation standards. These pieces are moved to different positions, so the incident light may expose defects that would otherwise have remained invisible. However, visually inspecting parts is a fairly laborious and time-consuming burden for a human and the accuracy of its outcome may be unreliable. Among the few factors that can alter the judgment of an operator, their lack of experience or assiduity may certainly be the most common [1].

With the advent of artificial intelligence (AI), mostly deep learning techniques, applied to the detection of elements in pictures or video streams, industries have been trying to develop systems that would automatically notify the presence of defective items in their production lines. Nowadays, the popular method to implement such an AI is via the usage of Convolutional Neural Network (CNN) models [2], [3], [4], whose algorithms and architectures enable them to extract

features from pictures (or videos) and classify their content through pattern matching.

Although current CNNs are quite efficient in detecting familiar categories of objects within pictures, they are still perfectible when used for specific tasks in specialized fields. For example, when integrated as monitoring tools on production lines of plastic or metallic parts, the scarcity of defective training data may lead to poor model performances. A substantial and diverse dataset is often required for a deep learning algorithm, such as CNNs, to produce an efficient model [5]. Moreover, another problem comes from the fact that an operator has to move and orientate the pieces in different positions to reveal flaws that would not be noticeable with a unique point of view and light incidence, since these movements are hardly ever performed automatically by an inspection system.

It is not rare for studies to explore ways that would expand limited datasets or boost the efficiency of deep learning models, but these researches generally involve software solutions revolving around image processing [6], [7]. In our case, we looked into a hardware method to enhance the quality of artificial networks’ trainings through the acquisition of datasets whose elements have undergone physical data augmentations, as opposed to artificial data augmentations. These physical “data augmentations” come as fluctuations of both the brightness and the orientation of a light exposing a target (i.e. the object to be represented in the sets). This concept also aims to be useful to help models in detecting defects, as the visibility of the details of an item may vary with the intensity and the angle of incidence of its illuminating lamp. These multiple lighting conditions act as the movements an operator performs during their inspection: moving items into different positions and adjusting the brightness to facilitate their judgment, but unlike these manual inspections, our concept aims to perform these operations automatically.

II. RELATED WORK

Researchers have investigated numerous means of performing data augmentations for both the expansion of insufficient assortments of pictures and for the creation of robust models. Our study investigates yet another novel approach to collecting and exploiting data targeting computer-assisted visual inspection of surfaces.

In deep learning, the size and diversity of a dataset are critical to creating a decent model [5], in case of a restricted set of training samples circumventing these limitations may be required. Therefore, resorting to data augmentation is a

common preprocessing step in deep learning [6], [7] (geometric transformation, noise addition, mix of images, etc.). Granted that the affinity of the new samples estimates them close to the originals, this artificial inflation of a dataset's population permits reducing the risks of a model overfit while improving its feature extraction capabilities, thus enhancing its adaptability to new data [8].

Data augmentation involving synthetic manipulations of the illumination of a picture is not unusual, whether it be by modifying their "general" brightness [9], or by adding a "synthetic" light source and shifting its position [10]. However, the majority of previous works revolve around software augmentation to generate their data, which often results in unnatural representations that may not be relevant to the models.

Moreover, some softwares and appliances aiding in the inspection of plastic parts already exist, such as the SavvyInspector™ [11] from Savvy Optics Corp., but they often do not include automatic image processing technologies nor consider different lighting configurations. Several studies also aimed at facilitating the examination of surfaces, but their experiments often did not take the orientation of the light into consideration [12], [13], [14].

Our study focused on the creation of a simple system that made possible the acquisition of data that are physically "augmented" through the different light settings used during their capture. This method is useful to generate specimens that are representative of occurrences a model will face in a live setting. Pictures of defective plastic parts were collected to train models, and the performances of these models on common test samples have subsequently been compared.

III. IMAGE CAPTURING SYSTEM

In current industrial environments, visual inspections necessitating rigorous examinations are still predominantly performed manually. So as to expose as many potential defects as possible on products, the common procedure is to scrutinise them under multiple lighting configurations. Operators are required to adjust the positions of the objects' surfaces, such as in Fig. 1, so the angles of incidence of the rays emitted by the light source can reveal deficiencies [15]. They may also modify the brightness of the source, since it has an obvious influence on the global visibility of the subjects they observe. Nevertheless, an equilibrium is to be found: while a dim light makes it difficult to distinguish details -if anything-, a bright light can also alter vision by flooding a defective area, covering its flaws with interfering glares.

In order to observe the effects distinct illumination settings of samples have on the efficiency of a CNN model's training, we have developed a semi-automatic device equipped with a light that automatically rotates around a subject while taking pictures as it reaches a designated set of positions. Its diagram is illustrated in Fig. 2 and its prototype is shown in Fig. 3. However, the current system version still needs the user to change the intensity of the light manually.

This system enables the capture of pictures with subjects illuminated from multiple angles and with different lighting brightness. The current prototype allows 256 levels of luminosity and has an amplitude of about 270°, since the support

Fig. 1. Diagram of a manual inspection

Fig. 2. Diagram of our automatic inspection setup

Fig. 3. View of the actual prototype

of the camera makes a full revolution impossible (as it gets in the way of the arm holding the bar light as it rotates). Because the target observed persists over a given set of light configurations, we qualified the process by which the variety of images was captured using our system as "hardware data augmentations", as opposed to a regular collection of pictures that would have been taken in a unique light setting. The augmentations thus engendered by our system took various forms: appearances/disappearances of scratches, variations of their shapes as well as shifts of their colors (or that of their supports). Several images were thereby collected to train multiple models on data having different light exposures. Their incorporations into datasets are detailed further in a subsequent section.

A. Hardware Components

Our device measures 50 by 50 by 50cm. Its constituting elements, visible on the photograph in Fig. 3, are the following:

- A camera that collects shots of plastic pieces. Created by Logitech, the C920 is a 1080p webcam that permits a stream of 30 frames per second.
- An electrical motor that orientates the light. The KM-1U is manufactured by Keigan Motor. It can be controlled programmatically and has a step resolution of about 0.05° .
- A light that illuminates the subjects that are observed. This light bar, model TLB245x25-22WD-4, is made by Aitec System. It can accept up to 24V and 0.3A, which results in a maximum power of 7.2W.
- An adjustable power supply that regulates the light intensity. The TPDP1B-2450NCW is made by Aitec System. It has 256 (16*16) gradations and it can output up to $24V \pm 0.5V$ and 1.85A.

Thanks to its 256 gradations, the power supply made it possible to fine-tune the luminosity level of the light. Since the latter can accept up to 7.2W, each gradation of the power supply represents a fluctuation of $0.028125W$ ($7.2W / 256$).

Finally, to run the software that operates our prototype and to carry the CNN trainings, we used a laptop whose operating system was Windows 10 and which included an Intel i7-8750H @2.20GHz CPU, an NVIDIA GTX 1060 GPU and 16GB of RAM.

B. Operating Software

A custom software had to be developed to enable a user to control the acquisition device we created. Considering that the operating system of our working station was Windows, we thought that designing a program in C# on Visual Studio was the most practical. The User Interface (UI) of the current version is shown in Fig. 4. This UI is divided into three main sections:

- **Configuration:** in this column are listed the elements related to the establishment of connections with the external peripherals (motor and camera) and the creation of the base file structure where captures will be stored.

Fig. 4. Interface of our image acquisition software

- **Parameters and controls:** this column contains the components that enable the user to parameterize the motor, select how the captures are to be taken (automatically or manually) and control the motor manually (if desired).
- **Data visualisation:** data coming from the system (motor and camera) are shown within this space, so the user can monitor the acquisition process.

This program allowed us to capture a lot of pictures with ease and speed. Indeed, within the **Parameters and controls** division, it is possible to specify the angular spacing appropriate between two successive captures and to define the movement of the camera as "automatic". However, as stated previously, the current prototype necessitates the intensity of the light to be set manually. Despite its resulting semi-automatic nature, the device still fulfils the incommensurable task of rotating the light on its own, only leaving a simple punctual intensity tuning to the operator, which makes for a prompt acquisition process.

IV. EXPERIMENTS

In this section, we will specify the content of the datasets that were gathered thanks to our system and how they were used for experimental purposes. The objective of the tests was to assess the performances of CNN models when the parameters of physical light sources varied during the acquisition of the population of their training/validation sets. From here onward, since each couple of training and validation collections contain similar data, to facilitate the reading, they will be referred to as a single entity: "training datasets".

A. Experimental Conditions

The variables of our experiments were as follows:

- **Independent variables:** The effects of different illumination settings, such as their brightness and their orientation, were observed.

Fig. 5. Samples of training and testing pieces with their lines distributions

- **Dependent variables:** The detection abilities of the different models were measured thanks to the number of True Positives (TP), False Negatives (FN) and False Positives (FP) they output when handling testing data. We also evaluated them through their precision and recall, which are metrics derived from TP, FN and FP.
- **Control variables:** Throughout our experiments, the sizes of the training and validation datasets have been kept at respectively 40 and 5 images. Every model has been trained for 3000 iterations in Darknet, a neural network framework used to train YOLO [16] models. Furthermore, every model has been tested on the same set of 24 pictures to ensure a consistent and reliable baseline to confront the results.

B. Dataset Compositions

We formed 5 datasets based on photographs of six different plastic parts created by cutting sheets of acrylic resin into 100 by 100mm squares. Lines have been etched onto the surfaces of these pieces with a laser engraver, so that they mimic scratches that can usually be found on items on a production line, for example. Every piece comes with its own pattern of lines, carved with determined sets of laser parameters (power, speed and repetition), repeated in four different areas but with decreasing lengths. The lines within the training pieces were 20mm, 15mm, 10mm and 5mm long, while that of the testing pieces were 7mm, 5.25mm, 3.50mm and 1.75mm long. The aim was to obtain synthetic flaws that had different aspects. A visual explanation of the line distributions can be found in Fig. 5, in which features highlighted with a common color were traced with the same laser configurations.

The pictures have all been collected by our semi-automatic visual inspection system. In order to minimize the risks of getting biased datasets, the pictures have been taken at night time when no external source could interfere with the light exposure of the pieces intended by the system.

1) *Training data's characteristics:* Four pieces comprising 16 scratches each, listed in Fig. 6, were used to take 784 photographs. This amount of data is due to the number of combinations possible with:

- 4 pieces whose scratches are tilted: 0°, 45°, 90°, 135°
- 7 light intensities: 0.45W, 0.9W, 1.35W, 1.8W, 2.25W, 2.7W, 3.15W
- 28 light positions: 0°, 10°, 30°, ..., 250°, 260°, 270°

Fig. 6. Base pieces used for training, with the tilt value of their scratches

Fig. 7. Training pieces with different light intensities

Fig. 7 presents one of the plastic parts under different illuminations, while Fig. 8 shows the same sample brightened from distinct angles.

Before being incorporated into any training datasets, these data had to be annotated. Since some of them had scratches difficult to see clearly, especially those taken in low brightness, it was decided to create an algorithm that created copies of the images and turned their pixel black if their respective luminance values were below a given threshold, and white otherwise. This way, we were able to use the black and white pictures to consistently classify what scratch should be

Fig. 8. Training pieces with different light orientations

Fig. 9. Scratch annotation based on their luminance value

annotated (white pixels) or which one should be considered “invisible” (black pixels), as shown in Fig. 9. In our case, a value of 30 for the luminance was chosen, as it was below this point a scratch became hardly perceptible to the naked eye.

2) *Test data’s characteristics:* Two pieces comprising 96 scratches each, listed in Fig. 10, were used to take 24 photographs. This amount of data is due to the number of combinations possible with:

- 2 pieces: test_A, test_B
- 4 light intensities (in watts): 0.45, 1.322, 2.25, 3.122
- 3 light positions (in degrees): 0, 100, 200

3) *Overview of the datasets:* Four training datasets were assembled, whose structures are summarised in Table I. The formations of those batches aimed at getting models trained on images captured in specific light conditions, so as to try to perceive which setting may be the most efficient, when opposing their results. In addition, 1 testing dataset of 24

Fig. 10. Testing pieces

TABLE I. OVERVIEW OF THE TRAINING DATASETS’ CONTENTS

Dataset name	Light intensities (in watts)	Light orientation (in degrees)	Size
TRAIN_intLow_oriQuad	0.45 / 0.9 / 1.35	0 / 90 / 180 / 270	Train: 40 Valid: 5
TRAIN_intHigh_oriQuad	2.25 / 2.7 / 3.15	0 / 90 / 180 / 270	Train: 40 Valid: 5
TRAIN_intMix_oriQuad	0.45 / 0.9 / 1.35 1.8 2.25 / 2.7 / 3.15	0 / 90 / 180 / 270	Train: 40 Valid: 5
TRAIN_intMix_oriMix	0.45 / 0.9 / 1.35 1.8 2.25 / 2.7 / 3.15	0... (increments of 10° ..270)	Train: 40 Valid: 5

TABLE II. OVERVIEW OF THE TESTING SUB-DATASETS, ORGANISED BY LIGHT INTENSITY

Dataset name	Light intensities (in watts)	Light orientation (in degrees)	Size
TEST_intVeryLow	0.45	0 / 100 / 200	6
TEST_intLow	~1.322	0 / 100 / 200	6
TEST_intHigh	2.25	0 / 100 / 200	6
TEST_intVeryHigh	~3.122	0 / 100 / 200	6

distinct pictures was gathered to assess the performances of the models. During the computation of the metrics, to emphasise the hypothetical discrepancies between the models (especially the brightness represented in their training images), it has been considered as 7 sub-datasets: 4 organised by light intensity, outlined in Table II, and 3 organised by light orientation, depicted in Table III. The performances of the models are confronted and reviewed in the next section.

C. CNN Trainings

Finally, once the data was collected, annotated and put together, they were used to train models. For our project, the neural network framework named Darknet, and most especially its algorithm/network architecture YOLOv4 [16], has been chosen to assist in the generation of models. This end-to-end learning algorithm is well-known in the field of image processing, its speed and accuracy held it as a reference among CNNs. Every one of the 4 datasets was fed into the algorithm to output its corresponding model, so experiments could be conducted to analyze their respective abilities to find defects within pictures. The training phases were not started from scratch, **yolov4.conv.137** pre-trained weights were chosen as a base. Since the evolution of the average training loss curves indicated that the models had converged by 3000 iterations, a training session stopped when this count was reached.

TABLE III. OVERVIEW OF THE TESTING SUB-DATASETS, ORGANISED BY LIGHT ORIENTATION

Dataset name	Light intensities (in watts)	Light orientation (in degrees)	Size
TEST_ori0	0.45 / ~1.322 / 2.25 / ~3.122	0	8
TEST_ori100	0.45 / ~1.322 / 2.25 / ~3.122	100	8
TEST_ori200	0.45 / ~1.322 / 2.25 / ~3.122	200	8

TABLE IV. METRICS RESULTING FROM THE TESTS CONDUCTED ON EACH MODEL, ON THE ENTIRE TESTING DATASET (24 PICTURES)

Model	TP	FN	FP	Precision	Recall
<i>TRAIN_intLow_oriQuad</i>	597	1707	2	0,997	0,259
<i>TRAIN_intMix_oriQuad</i>	447	1857	9	0,98	0,194
<i>TRAIN_intHigh_oriQuad</i>	502	1802	6	0,988	0,218
<i>TRAIN_intMix_oriMix</i>	644	1660	3	0,995	0,28

V. INTERPRETATION OF THE RESULTS

As a first step to confront the ability of the models to spot irregularities, we had trained *TRAIN_intLow_oriQuad*, *TRAIN_intMix_oriQuad* and *TRAIN_intHigh_oriQuad* so tests could be conducted with the brightness as an independent variable, as their pictures were taken with similar light orientations. Based on the 24 photographs of test plastic pieces, the total number of True Positives (defects found), False Negatives (defects unexposed) and False Positives (regular areas inferred as abnormal) were counted. Then, the precisions and recalls were derived from these TPs, FNs and FPs.

The precision, whose formula is shown in (1), describes the proportion of “positive identifications” that were actually correct.

$$Precision = \frac{TP}{TP + FP} \tag{1}$$

The recall, whose formula is shown in (2), describes the proportion of correct “positive identifications” that were successfully identified.

$$Recall = \frac{TP}{TP + FN} \tag{2}$$

The values of the various metrics are transcribed in the Table IV. If the header of this table is coloured green, it translates a positive metric for classification of a model, while a red-coloured header is for a negative one. When a metric’s value is written in green, it means that this value is the best of those recorded; if it is red, it is the worst (it takes into account the positive/negative nature of the metric).

When analysing the measures, it has been noticed that the outcomes of the models were relatively close to one another, nonetheless, *TRAIN_intLow_oriQuad* was the most efficient and *TRAIN_intMix_oriQuad* was the less effective. In order to examine the impact of light orientation, it was attempted to increase the diversity of the less reliable dataset: instead of only including images of pieces that were enlightened from a source positioned at either 0°, 90°, 180° or 270°, we decided to pick from 28 angles. In this way, *TRAIN_intMix_oriMix* has been constituted, as *TRAIN_intMix_oriQuad* was the most lacking. The TPs, FNs, FPs, precision and recall obtained are also reported in Table IV. From this new array of values, it has been noted that *TRAIN_intMix_oriMix* not only outperformed *TRAIN_intMix_oriQuad*, it also seemed to slightly surpass the results of the other models.

Though there were differences between the models, they were rather limited and based on a single set of data, which did not reflect their effectiveness at handling data according to their attributes. It was conjectured that it would be pertinent to underline the capabilities of the models at processing images

Fig. 11. Comparisons of the average number of TPs on the test subsets arranged by brightness, grouped by light intensities within their training data

Fig. 12. Comparisons of the average numbers of TPs on the test subsets arranged by brightness, grouped by light orientations within their training data

taken in specific light conditions. Thus, the former test dataset was split into several subgroups consisting of images sorted either by intensity (Table II) or by orientation (Table III). For these new comparisons, it was decided to restrict the metrics to the average of True Positives: within the scope of our experiments, the significance of this measure makes it sufficient to gain a decent appreciation of the quality of a neural network’s training.

The new arrangements of data corroborated the previous experience. Indeed, for the sets containing photographs classified by their luminosity, *TRAIN_intLow_oriQuad* was more efficient than *TRAIN_intHigh_oriQuad* and even more than *TRAIN_intMix_oriQuad*, as shown in Fig. 11. *TRAIN_intMix_oriMix* obtained more satisfactory results than its counterpart trained with four different light orientations, yet again, as visible in Fig. 12. The reason why the models struggled to detect scratches in the case of very low light intensities is that even though most of them were barely discernible, they were annotated as ground truths within the test data, which led to a lot of False Negatives (and, conversely, hardly any True Positives) during the tests that included them. The purpose of these data was to challenge the models on confounding specimens.

Furthermore, similar observations were made for the sets containing photographs classified by the angular positions of

Fig. 13. Comparisons of the average number of TPs on the test subsets arranged by orientation, grouped by light intensities within their training data

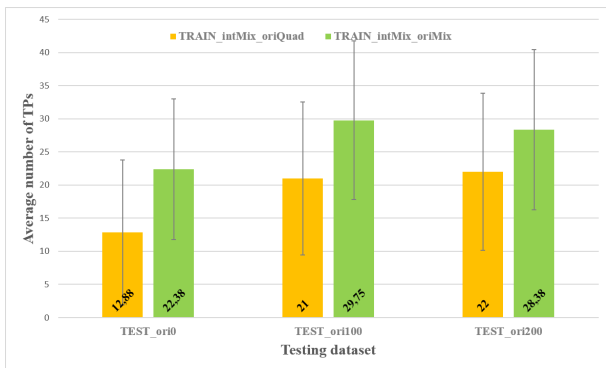

Fig. 14. Comparisons of the average numbers of TPs on the test subsets arranged by orientation, grouped by light orientations within their training data

their light source, as shown in Fig. 13 and Fig. 14.

A few examples of images with their corresponding inferences, output by *TRAIN_intMix_oriQuad* and *TRAIN_intMix_oriMix*, are displayed in Fig. 15.

VI. CONCLUSION

Our study involved the conception of an automatic system that facilitates the acquisition of pictures intended for training/testing datasets, while adding physical data augmentation in the form of variations of light brightness and orientation.

This device was used to gather our own images, which were assembled into datasets that were fed to CNNs. These neural networks generated multiple models, each trained on photographs taken under specific lighting conditions. These models were then opposed to one another to observe if the parameters of their illumination had some effects on their ability to handle new data.

It has been noted that both the independent variables (light intensity/light position) that were experimented on influenced the outcome of the training processes. For instance, a model based on data whose illumination varied, but was limited to four positions, obtained worse results than another model based on data whose illumination also fluctuated, but had a broader array of angular positions.

Fig. 15. A few inferences produced by *intMix_oriQuad* and *intMix_oriMix*

Since the pieces involved in this research have been created to suit a specific scenario: scratches detection on plastic parts, our “hardware data augmentation” technique might only be relevant to this test case. For that reason, future work reiterating the experiments, with larger and more intricate datasets, is expected to confirm (or disprove) the conclusions drawn from the current study. Additionally, the implementation of an automatic light intensity controller, along with the incorporation of YOLO into our software, are objectives envisaged to make our system a fully independent computer-assisted visual inspector.

Abstract—Mobile Edge Computing (MEC) is a new method to overcome the resource limitations of mobile devices by enabling Computation Offloading (CO) with low latency. This paper proposes a multi-user multi-task effective system to offload computations for MEC that guarantees in terms of energy, latency for MEC. To begin, radio and computation resources are integrated to ensure the efficient utilization of shared resources when there are multiple users. The energy consumed is positively correlated with the power of transmission and the local CPU frequency. The values can be adjusted to accommodate multi-tasking in order to minimize the amount of energy consumed. The current methods for offloading aren't appropriate when multiple tasks and multiple users have high computing density. Additionally, this paper proposes a multi-user system that includes multiple tasks and high-density computing that is efficient. Simulations have confirmed the Multi-User Multi-Task Offloading Algorithm (MUMTOD). The results in terms of execution time and energy consumption are extremely positive. This improves the effectiveness of offloading as well as reducing energy consumption.

Keywords—Time execution; energy consumption; computation offloading; mobile edge computing

I. INTRODUCTION

Mobile devices such as tablets and smart phones are becoming more and more popular. This has led to increasing the number of mobile apps, such as augmented Reality, natural language processing and interactive online gaming [1]. These kinds of mobile apps are typically resource-hungry and latency-sensitive, which means they require greater computing capacity and use more energy, but they have serious time constraints. Mobile devices are constrained in size and are limited in resources, such as CPU-cycle frequency and energy consumption, memory. Computing offloading is a viable solution. Mobile users are now able to perform their computing tasks to devices with the right computing resources or a computing server by using the computation offloading.

A new paradigm of computing called MEC was suggested to solve this issue. It is created to relieve mobile devices of massive computing workloads [2]. MEC offers CC capabilities at the edge of the cellular network, near mobile devices. MEC permits mobile apps to run directly on the device or on the MEC servers [3]. The MEC model offers high bandwidth, low latency and high computing speed when compared to traditional MCC. This is because of the smaller distance between mobile devices and the edge servers [4]. Recent MEC paradigm developments [5] shift computation-intensive tasks away from mobile devices and toward nearby MEC servers. Among these advancements is single-user computation. The majority of these technologies have a common objective which

is to reduce energy use, allocate radios and increase computational resources, decrease costs and/or meet the delays required by mobile IoT networks. MEC is a rapidly developing computing model, extends cloud and the services, it provides to the edges of the network for applications that are resource-intensive and require the highest level of performance, MEC network computation offloading is a viable method to allow mobile apps that are resource-intensive. The SMD is a limited source of energy to execute tasks and this is a major issue. Additionally when offloading is utilized specific parts of applications that require computational power are divided into multiple, mutually exclusive offloadable tasks [6]. We believe that mobile users from multiple locations are able to offload computation tasks that they have duplicated to network edge servers and then share the results between them. Edge computing is the process of transferring processing and storage toward the edges of connected devices. Edge computing isn't located in devices.

Edge computing relies on the offloading of computation. It is first utilized in cloud computing and later in edge computing. To transfer computation tasks to servers devices may use computing offloading. In certain situations, all computation tasks are not able to transfer to servers because of limitations on network connectivity restrictions on network connectivity [7]. It is crucial to swiftly determine how many tasks need to be transferred to servers and which ones should remain local. Only when computation tasks are properly offloaded can achieve the QoS and enhance the QoE.

In this paper, we will discuss the allocation of resources, computation offloading to enhance the efficiency of multi-user multi-task offloading computation for MEC. This is the reason behind our research: The most significant factors that impact the effectiveness of multi-user MEC systems are the computational resources on the edge, wireless channel radio resources, and the offloading of computation of mobile device user's tasks. Then, it is essential to develop an approach to these problems. MEC system lets users transfer their application data to the MEC server through the wireless channel. This paper describes an integrated model for resource allocation. The model is based on multi-user, multi-task computing environment that permits MEC within mobile IoT networks. The goal is to decrease the consumption of energy within the computational latency constraints.

This paper is focused on the following aspects: A model that incorporates resource allocation can be described as an optimization issue to reduce the energy consumed under the constraints of computation latency in multi-user, multiple-task MEC systems that are used in mobile IoT networks.

The MUMTOD algorithm is developed to take the most efficient offloading choice for the tasks of computation of every mobile device user in the MEC system. The remainder of the paper is based on these steps: Section II discusses related research regarding computation offloading. Our system model multi-user multitask offloading of computations and problem formulation in section III. Our proposed solution in Section IV. Section V includes simulations to demonstrate our model for computation offloading. The paper concludes in Section VI.

II. RELATED WORK

Task offloading is a crucial method to overcome the limitations of storage for edge computing as well as computing power within the IoT network. Edge devices can outsource some or all of its computing functions to an edge computing server. This can increase the speed of processing, conserve energy, and decrease the time to respond. The research continues to find the most efficient optimization strategy for various situations. MEC is a crucial element of devices. The MEC offers a wide range of storage and computation capabilities to mobile devices. The majority of these research address the problem of offloading computations to a single user such as [8]. Others address offloading of computation in multi-user environments[9].

The researchers [10] looked at three different types of offloading decisions including partial offloading, complete offloading, as well as local execution. The goal of this study is to optimize computational resources and decrease the amount of time needed to complete an independent task within the MEC system. A dynamic offline strategy for single-user computation offloading has been suggested using both deterministic and random methods[11]. This method takes into account offloading computation and resource scheduling to establish the most efficient schedule offloading policy. This method aims to decrease energy consumption while also satisfying the requirements for delay. A scenario where users receive the list of computation tasks to be offloaded. Each task must be handled by the MEC server within a fixed time frame[12]. The proposed optimization problems aim at the reduction of energy usage, the total processing delays as well as the insatiable processing workload.

The authors of [13] investigated multi-user edge computing scenarios that are based on orthogonal frequency division multiple access (OFDMA) and time division multiple access (TDMA). The limitation of computing delay implies that the optimal resource allocation algorithm should be convex. This resolves the issue by minimizing the weighting and power consumption of mobile devices. To simplify the process, a less efficient resource allocation algorithm is recommended for cloud systems with small capacity. The issue of offloading in multi-user situations was investigated by [14]. The authors proposed a simple search algorithm that consists of two segments to determine an optimal conditional time. A method of coordinate descent was designed to improve mode selection.

While the work [15] focused on one server system that fixed local computational resources, as well as the transmission capabilities, this is the first time investigating the real MEC system where some users are subscribers with the highest priority for services that offload computation. This research is

an important expansion of the research [15]. Task offloading serves two primary objectives: to decrease the time required to execute applications that run on user equipment and to save energy. Efficiency of task offloading is a multi-fold issue. MEC servers might not be as efficient as cloud servers, therefore it is crucial to assign the tasks. Transferring offloading of user equipment to the MEC servers should be carried out in this way the MEC servers make use of their resources in a responsible manner.

The MEC Servers hosting on different Base station might not share the identical set of drivers Services, as well as the computational load on MEC servers could also be affected Variable as the passage of time. The optimal allocation of resources to relieve load Tasks, fair and steady load distribution among the MEC servers. The seamless coordination between edge and cloud is just one of the aspects that make up seamless integration. The issue is the difficulty in using of the MEC of the MEC services efficiently [16]. Another aspect The size of the defined remains a problem which is the Tasks that need to be delegated. The QoE requirements will determine the tasks that need to be delegated. The process of running applications can be difficult. It is also possible that the tasks be a matter of distinct priority, the impact of computing overhead, progress and other dependencies[17]. The scheduling, selection, location and the management of work are all a part of the process. A myriad of issues could arise from the task of offloading. This is why the key to optimal task delegation is to select the best correct task to offload to the correct MEC server at the correct time to allow for meeting. The most efficient performance of an app running when using the MEC utilizes resources efficiently. It is clearly an optimization that is multi-objective problem is considered to be NP hard [18]. In the context of this debate, task offloading could be defined Uploading the entire module to an application that contains the Calculation, data required and other libraries that are dependent on it can be delivered to remote locations server, and then receiving the result of the computation from the remote server. It is crucial to talk about the process of offloading, scheduling is crucial to offload tasks, which is a method for executing a list of tasks for a specific number of computer resources that can be utilized to achieve a goal [19].

In [20] an energy-saving, dynamic scheduling strategy and offloading method developed to cut down on energy use and speed up the completion of applications. The problem could be turned into a problem of energy efficiency by reducing task dependence and the time limit for completion. It is broken down into three sub-tasks: controlling the frequency of the clock, transmission power allocation, and calculation offload selection. Wang and coworkers addressed the MEC offloading problem. Wang et al. suggested a new framework for offloading based on deep reinforcement that can be used to automatically identify the most efficient way to load for different scenarios based on the specifics of each offloading job. This reduces the total delay in service [21], and the others concentrated on management of resources in a multi-user MEC system. The research did not offer any insights into the effect of channel-specific information on the devices' consumption of energy. To address these issues we will focus on task offloading process within multi-user MEC systems and provide an energy efficient stochastic framework. The optimization issue is solved with an effective algorithm that doesn't require prior knowledge of the

time of task completion or any statistics about the channel state.

The authors of [22] looked at the possibility that the wireless energy transfer was the main driver of MCC, and developed an energy-efficient framework to increase the probability of computing while balancing the limitations of delay and energy. A majority of these researches relied on the assumption or prediction of the task's timing or channel status. The load-shedding of traffic from IoT devices and the quality of wireless channels are complex and are difficult to predict.

The work [23] focused on a partial computation offloading method, it optimizes computational and communication resources employing the dynamic voltage scaling, an algorithm design is included in the description of this method. The main goal of the method is to reduce energy consumption and delay in execution. This can be accomplished by taking into account computational time, transmission power and the offloading ratio.

An Markov chain theory-based search algorithm that is one-dimensional is described in [24]. The algorithm is presented in [24]. It determines the best strategy for offloading stochastic computations in a single-user MEC system. The perspective of scheduling flow shops is further developed by the work of [23] that has created an optimization issue for task-offloading scheduling and the allocation of power for transmission in an MEC system, which an energy harvesting technique is employed to cut down on the power consumption and energy consumption for data transmissions to enable offloading computation. It uses a simple algorithm to determine the best offloading option for every time slot [24].

III. SYSTEM MODEL AND PROBLEM FORMULATION

This research aims to decrease the use of energy in multi-user edge computing devices that are multi-tasking by deploying the concept of offloading computation. This section is dedicated to a system model adopted during our research.

This paper investigates the concept of a multi-user as well as a multi-tasking system as illustrated in Fig. 1.

Fig. 1. System model and problem formulation

Take $U = \{1, 2, \dots, L\}$ as a set of mobile devices. Each mobile is assigned $T = \{1, 2, \dots, N\}$ which is a set of tasks that must be accomplished, which are linked with a base station. Let's start with the introduction of communication in a MEC. Our environment includes L users. Each user has to complete

computation tasks. Let $x_{i,j} \in \{0, 1\}$ represents the number of integers that are used to compute offloading decisions for the task j of the user of a mobile device i . Particularly if $(x_{i,j} = 0)$, the task j of the user of a mobile device i will be performed locally. in contrast, $(x_{i,j} = 1)$ the task j of the user of mobile devices i is transferred to the MEC server through the wireless channel.

This is why we have chosen $X = \{x_{1,1}, x_{1,2}, \dots, x_{L,N}\}$, as the offloading profile to handle the computing tasks of all users of mobile devices. Frequency Division Multiple Access is (FDMA) is a multi-access technique with higher performance. Every user will be provided with just a portion of the bandwidth that the system provides. This is, the data uplink rate of every mobile user i is as follows:

$$r_i(p_i) = B \log\left(1 + p_i \frac{h^2}{\omega_0}\right) \quad (1)$$

which B is the bandwidth of the channel. p_i represents the mobile's i transmission power, h is the channel's gain, and ω the channel's noise power. If all mobile IoT devices decide to delegate their computing tasks to the wireless access channel at once in a computation offloading time, there is the limit on data rate R .

$$\sum_{i=1}^L \sum_{j=1}^N x_{i,j} r_i \leq R \quad (2)$$

Every smartphone user i is equipped with N computing tasks. The tasks can be completed local on the device, or remotely on the MEC server through wireless communication. We further define $u_{i,j}$ as the user of the mobile device i who is requesting the task of computation j to be executed.

Every computation task j is identified by $(C_{i,j}, D_{i,j})$ in which $C_{i,j}$ refers to the number of CPU cycles needed to complete the task of computation j and $D_{i,j}$ is the total size of data that is able to be offloaded. The time required to transfer the result from the MEC server to the mobile device users is not taken into account in this study. This is because the result is usually smaller than input data [25]. All computations are performed locally using a mobile device for local execution. the total time of the task i that is executed locally can be expressed as:

$$T_{i,j}^{loc} = \frac{C_{i,j}}{F_i^{loc}} \quad (3)$$

where F_i^{loc} represents the computing capacity of mobile i . Different mobile devices may have varying computational capabilities. The energy required to perform the task locally is determined as follows:

$$E_{i,j}^{loc} = y_i C_{i,j} \quad (4)$$

y_i is the value of the energy consumed by CPU cycles. It is determined by [24]. In MEC Server: A user of a mobile device i chooses to transmit computation task j to an edge server through the wireless channel. The time required for task execution when offloading is determined by time of transmission which is the amount of time required for users of mobile devices to offload the task of computation and also

the amount of time needed for the computation task to run in the MEC servers which is task execution.

Furthermore, the energy usage for the offloading process is only measured by the cost of communication for offloading the task information to the MEC server. The total amount of offloading time which is the sum of the transmission time and execution time and energy used in the transmission are calculated using (1).

$$T_{i,j}^{up+exec} = \frac{D_{i,j}}{r_i} + \frac{C_{i,j}}{F_i^s} \quad (5)$$

$$E_{i,j}^{up} = p_i \frac{D_{i,j}}{r_i} \quad (6)$$

F_i^s represents the computing power, measured in the form of CPU cycles per (s) of the edge server which was assigned to the user i . We suppose that all users of mobile devices are part of the edge computing server's computation resources.

This section presents also an optimization problem to achieve efficacy in computation offloading in a multi-user multi-task MEC system. Every user of a mobile device is accountable for the execution time as well as the energy consumed. In addition, the allocation of available compute and radio resources on the edge server is also managed. The problem of offloading is described as a constrained optimization problem:

$$\begin{aligned} (P1) \quad & \min_x \sum_{i=1}^L \sum_{j=1}^N (E_{i,j}^{loc} + E_{i,j}^{up}) \\ & \text{s.t} \\ (C1) \quad & \sum_{i=1}^L \sum_{j=1}^N x_{i,j} \cdot r_{i,j} \leq R \quad \forall i, j \\ (C2) \quad & \sum_{i=1}^L \sum_{j=1}^N x_{i,j} \cdot F_i^s < F \quad \forall i, j \\ (C3) \quad & x_{i,j} \in \{0, 1\} \quad \forall i, j \\ (C4) \quad & \sum_{i=1}^L \sum_{j=1}^N (E_{i,j}^{loc} + E_{i,j}^{up}) < E^{max} \end{aligned}$$

The goal of the optimization problem is to reduce the amount of energy consumed by mobile device users by using task offloading. The capacity for data rates is the constraint C1. The top limit of the CPU's frequency is shown by the constraint C2. Constraint C3 indicates that task-offloading decision variables are binary variables. Constraint (C4) means that both the Edge server and mobile device use less energy than the maximum energy consumption E^{max} .

IV. PROPOSED SOLUTION

This section will introduce our solution (MUMTOD), a multi-user multi-task offloading decision algorithm. It addresses the optimization issue.

This section explains the multi-user multitask offloading decision algorithm. It provides the specifics of the procedure to get the most optimal MEC algorithm for computing offloading. Each computation task is initiated by using $x_{i,j} = 0$ that indicates local execution.

Every mobile device transmits the specifications of every computation task, including $\{C_{i,j}, D_{i,j}, y_i, p_i\}$ along with the computational capability F_i^{loc} to the MEC server. The MEC server then determines the mobile device's uplink data rate

Algorithm 1 Multi-User Multi-Task Offloading Decision Algorithm

- 1: **Initialization:** Each mobile device user i initializes the offloading decision for each computation task with $x_{i,j} = 0$
- 2: **for all** each mobile user i ($i \in U$) **do**
- 3: **for all** each computation task j ($j \in T$) **do**
- 4: **Transmit** the computational capability of each mobile user F_i^{loc} and the requirements of computation task $\{C_{i,j}, D_{i,j}, y_i, p_i\}$ to the edge server
- 5: **end for**
- 6: **end for**
- 7: Based on equation (1): **Calculate** the uplink data rate r_i , for every device.
- 8: **Utilize** Equation (2) to determine the most efficient computation offloading decision value $x_{i,j}$ for all computation tasks. This will reduce energy consumption overall.
Send the decision value $x_{i,j}$ to each device

TABLE I. SIMULATION PARAMETERS

Parameter	Value
Number of mobile device users	100
The background noise	10^{-9}
Task generation rate (seconds)	10
Computational load (millions of CPU cycles)	200
Number of computation tasks	100
Data entry size (MB)	10

using the equation (1). MEC server then determines the most optimal solution for the offloading of computations decision by using the constraint (C2). In the end, MEC server sends the decision to each mobile device, which reducing the energy used in the entire system. The algorithm 1 describes the procedure of offloading multitask multiuser computation the decision.

To demonstrate and assess the model, a simulation of two various scenarios was conducted. They are:

Computation Offloading (CO): The CO policy permits all mobile device users to perform their computations locally on the device or via a MEC server. It is based on the model of optimization described in [26].

The Proposed Solution (PS): considers computation, communication, and the impact on the consumption of energy.

V. SIMULATION RESULTS AND DISCUSSION

In this section in this section, we'll first outline the outcomes of the algorithm we propose and verify its effectiveness. Then, we'll demonstrate the results obtained by the parameters of the system.

The algorithm MUMTOD was implemented within Eclipse IDE version 2022- 03 (4.23.0) and written in the Java programming language. One application was identified as [27] for the experiment as shown in Table I.

The simulation parameters are described as follows, we are considering N=100 mobile devices and 100 independent computation tasks which can be run locally or remotely via

Fig. 2. Execution time for different mobile devices L=100

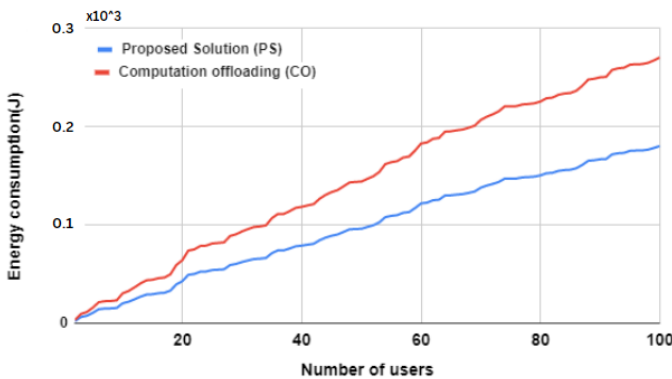

Fig. 3. Energy consumption for different mobile users L=100

the edge server. The following sections provide a summary of the results. The time of simulation was measured in (s) and the scenarios were constructed using a predetermined number 100 tasks.

In Fig. 2, computation tasks are measured in relation to the number of users on the mobile devices. The total time to execute for both scenarios is displayed in the figure in two curves. the execution of our model is nearly as fast or quicker than the time required by the computation offloading scenarios in the case of 24 mobile devices owners. Although as the number of mobile users is growing and our model is more efficient than the scenario that uses computation offloading. This is because the communication channels shared by all users are overloaded. The time required to improve communication speeds due to the growing number of mobile devices has also increased.

Fig. 3 illustrates the amount of energy used to complete the computation tasks in two scenarios. This is then compared to the number of users. It is observed from Fig. 3 that energy consumption significantly increases when the number of users of mobile devices increases the model proposed uses less energy than the alternatives. As the number of mobile devices grows the gap gets bigger. Our model can also help reduce the energy usage.

Offloading scenarios consume more energy than other model. Every mobile device user and information transmitted are competing for the limited resources of communication.

VI. CONCLUSION

This paper proposes a multi-user multi-task offloading algorithm to support MEC in the mobile user. A problem of optimization was designed to determine near-optimal offloading choices for every mobile user. This is done in order to reduce the energy consumed by mobile users of devices. A thorough process was employed to develop an efficient offloading algorithm that could be used to solve the optimization issue. Additionally, our model was more efficient than other computational offloading scenarios in terms of execution time as well as energy consumption which use different simulation settings and has an improved selection of tasks to offload. Our model is able to support multi-user, multiple-task computation offloading within MEC to mobile IoT networks.

For our future work, a secure computation offloading model that ensures the security of edge computing on mobile devices will be examined. This layer safeguards the data transmitted from cyberattacks.

Performance Comparison of Multiple Neural Networks for Fault Detection of Sensors Array in Oil Heating Reactor

Mai Mustafa¹, Sawsan Morkos Gharghory², Hanan Ahmed Kamal³

Electronics and Communication Engineering Department, Cairo University, Giza, Egypt^{1,3}
Computers and Systems Department Electronics Research Institute, cairo, egypt²

Abstract—Fault detection is an important issue for early failure revelation and machine components preserving before the damage. The processes of fault detection, diagnosis and correction especially in oil heating reactor sensors are among the most crucial steps for reliable and proper operation inside the reactor. The fault detection in sensors array of heating reactor is considered as an important tool to guarantee that the controller can take the best possible action to insure the quality of the output. In this paper, fault detection for the temperature sensor in oil heating reactor using different types of faults with different levels is addressed. Multiple approaches based on Neural Network (NN)s such as the classical Fully Connected Neural Network (FCNN), Bidirectional Long Short Term Memory network (BiLSTM) based on Recurrent Neural Network (R.N.N.) and Convolutional Neural Network (CNN) are suggested for this purpose. The suggested networks are trained and tested on real dataset sequences taken from sensors array readings of real heating reactor in Egypt. The performance comparison of the suggested networks is evaluated using different metrics such as “confusion matrix”, accuracy, precision, etc. The various NN are simulated, trained and tested in this paper using MATLAB software 2021 and the advanced tool of “DeepNetworkDesigner”. The simulation results prove that CNN outperforms the other comparative networks with classification accuracy reached to 100% with different levels and different types of faults.

Keywords—Fault detection; sensor array; oil heater reactor; confusion matrix; neural network; recurrent neural network; convolution neural network; bidirectional short term memory

I. INTRODUCTION

Sensor faulty readings is considered one of the major source of industries inefficiencies, detection and diagnosis have a strong ability to improve the operational precision and processes stability inside factories and reduce any inefficiencies in the production cycle. Therefore the objective of fault detection and diagnosis is to reduce the production losses, while assuring the safety to both human and devices.

With the high number of sensors used in monitoring industrial operation, it is very time consuming and a large number of labor is needed to follow whether they work properly or not.

Automatic fault detection is one stage of multi-stage processes system to detect-diagnose-correct any fault at sensors array in a complex control systems. Literature review to some techniques was presented to detect the faults such as serial principal component analysis (SPCA) [1], Decision Tree, Random Forest, Nearest Neighbors [2] Support-Vector Machine

(SVM) [3], [4], Fuzzy Deep N.N (FDNN) [5], principal component analysis (PCA) [6], independent component analysis (ICA) [7], Serial Principal Component Analysis [8], lossless compression method [9], KNN rules [10], Kalman Filter [11], and hidden Markov models (HMM) [12],

and other methods [13], [14], [15], [16], [17], [18], [19] and [20].

In oil heating reactor many sensors are used to monitor and control the processes inside it because any malfunctions in processes inside the heating reactor may lead to the non-quality production and high cost.

Therefore, it is very crucial to detect any sensor anomalies as early as possible to avoid any product defect.

The stages of detection, diagnosis and correction for a faulty sensor reading using N.N-based classification are shown in Fig. 1 and are illustrated as follows:

Fig. 1. Sensor array reading processor

- 1) Fault detection: in this stage, the sensor array processor will review all sensors readings by using a trained NN based classification to determine if there is a fault in the sensor readings or not and define the faulty sensor if there is a fault.
- 2) Fault diagnosis: in which the sensor array processor will use the number of the faulty sensor from the previous stage to compare its reading with all other sensors readings to determine the type of the fault using trained classification NN.

3) Fault correction: in this stage, the sensor array processor will utilize the type of fault from the previous stage and the other sensor readings to predict the true reading value of this sensor and send the corrected value to the controller.

This papers presents three N.Ns for fault detection of temperature sensor from sensors array in oil heating reactor and evaluate their performance through comparison using different metrics. The suggested networks are Fully connected neural network (FCNN),Bidirectional long short term memory(BiLSTM) based on recurrent neural network(RNN) and Convolution neural network (CNN). Where, from the simulation results comparison will be used to assess the best performance one of the suggested networks to be recommended in future work in detecting the faulty sensor.The remaining of this paper is organized as follows:

Section II introduces oil heating reactor and description to its physical functions.

Faults types and their mathematical models are displayed in Section III.

Section IV discuss the suggested networks for fault detection, data sets used and how the data is Prepared to be used

Section V is show the construction of the NNs, training parameter and training/test data.

The simulation results of comparing the suggested networks with their performance evaluation using different metrics are displayed in Section VI.

Finally, Section VII concludes the work and discusses the future work.

II. OIL HEATING REACTOR AND ITS PHYSICAL FUNCTION DESCRIPTION

This section will discuss the physical construction of the reactor, sensor array, and control system. The physical system consists of heating element for oil before it is separated in later stages.the System also has multiple numbers of sensors - for monitoring the temperature and the flow of natural gas - which are illustrated in the following section. The construction of oil heating reactor and the schematic diagram of its control system are shown in Fig. 2 and Fig. 3.

Fig. 2. Oil heating reactor

1) *Sensor array:* The sensor array consists of 37 sensors in total divided into:

- i- 1 oil flow Sensor
- ii- 34 Temperature sensors
- iii- 1 Gas flow Sensor
- iv- 1 Gas Pressure Sensor

Fig. 3. Control system schematic diagram

All these sensors are installed in various places to monitor the temperature and flow of oil and natural gas through the reactor to help the controller to control the flow of natural gas that will be burned to heat the oil that exits the reactor to be at specific temperature.

2) *Heating element:* The heating element consists of two stages:-

- i- Preheating: where the exhaust of heater is used to preheat the oil.
- ii- Main heating:burning natural gas to heat oil passing through some pipes.

III. FAULT TYPES MATHEMATICAL MODELS

This section will discuss the mathematical model of the various types of faults [21], [22], [23], [24].

A. The drift fault

As shown in Fig. 4,

Fig. 4. The drift fault sensor reading

the value of sensor reading will increase in positive feedback loop, so the faulty sensor reading X will be modeled by the following equation:

$$X = X_o + \delta X.t \quad (1)$$

Where $\frac{\delta X}{\bar{X}}$ called fault level, X is the sensor reading, \bar{X} is the average of Sensor readings, t is the time stamp, and X_o is the true reading.

B. The Bias Fault

As shown in Fig. 5,

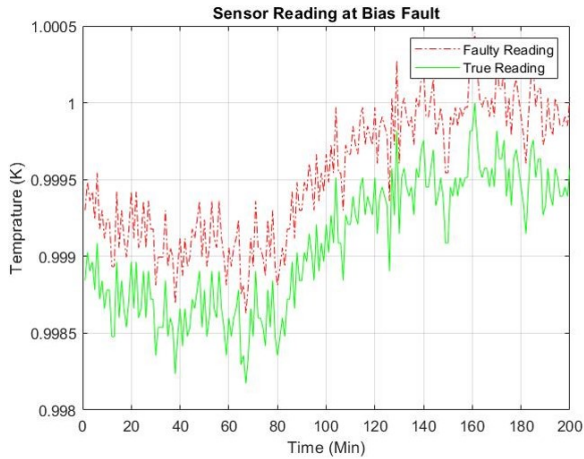

Fig. 5. The bias fault sensor reading

the value of sensor reading will increase by constant value, so the faulty sensor reading will be modeled by the following equation:-

$$X = X_o + \delta X \quad (2)$$

Where $\frac{\delta X}{\bar{X}}$ called fault level, X is the sensor reading, \bar{X} is the average of sensor readings, and X_o is the true reading.

C. The Precision Degradation Fault

As shown in Fig. 6,

Fig. 6. The precision degradation fault sensor reading

the value of sensor readings will be mixed with white Gaussian noise (WGN), so the faulty sensor reading will be

corresponding to the following equation:

$$X = X_o + \delta X.W.G.N \quad (3)$$

Where $\frac{\delta X}{\bar{X}}$ called fault level, X is the sensor reading, \bar{X} is the average of sensor readings, WGN is white Gaussian noise with value varying form (0 to 1), and X_o is the true reading.

D. The Spike Fault

As shown in Fig. 7,

Fig. 7. The spike fault fault sensor reading

the value of sensor readings will be mixed with spike noise [22], [23], [24], so the faulty sensor reading will be modeled according to the following equation:

$$X = X_o + \delta X.W.G.N\delta(t - t_0) \quad (4)$$

Where $\frac{\delta X}{\bar{X}}$ called fault level, X is the sensor reading, \bar{X} is the average of Sensor readings, WGN is white Gaussian noise with value varying form (0 to 1), t is time Stamp X_o is the true reading, and t_0 is the time of the spike.

E. The Stuck Fault

As shown in Fig. 8

the value of sensor reading will be stuck in a certain value, so the faulty sensor reading will be calculated according to the following equation:

$$X = \delta X \quad (5)$$

Where $\frac{\delta X}{\bar{X}}$ called fault level and X is the sensor reading, and \bar{X} is the average of sensor readings.

IV. THE PROPOSED NETWORKS FOR CLASSIFICATION-BASED FAULT DETECTION

In this paper, fault detection stage is implemented by NNs based-classification. After training the networks on series dataset of sensors readings,the network classifies the readings into faulty or non-faulty. The suggested NNs are described in the following section.

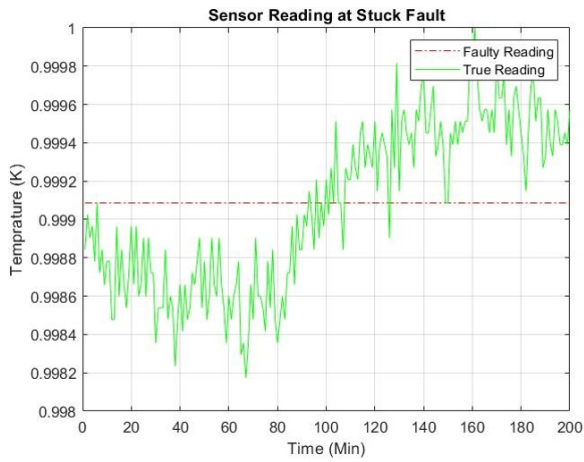

Fig. 8. The stuck sensor reading

A. Description of Suggested Networks

This part is dedicated to show the construction of the used NNs in this Paper.

1) *FCNN*: A FCNN [25] consists of a series of fully connected layers as demonstrated in Fig. 9.

A fully connected (FC) layer is a function from multiple inputs to one output.

Each output dimension depends on each input.

Fig. 9. FCNN construction

2) *BiLSTM*: BiLSTM network has the ability to learn bidirectional long-term dependencies between time steps of time series data which is helpful for a network to learn at each time step from the total time series data.

BiLSTM handles input sequences in two directions using two sub-layers.

It includes two recurrent network layers, in which the first one processes the sequence of inputs in forwards direction while the second processes the inputs sequence in backwards.

Both layers are connected to the same output layer. Thus, BiLSTM network captures the total information about preceding and future sequence of data points [26], [27], [28], [29].

BiLSTM network utilizes the past states to determine the output of the current states as shown in Fig. 10.

Fig. 10. BiLSTM NN construction

3) *CNN*: The structure of CNN is depicted in Fig. 11, which consists of convolution layers, pooling layers, and FCL where these layers adaptively learn spatial hierarchies of features through the back-propagation learning [30], [31], [32] and [33].

Fig. 11. CNN construction

B. Data sets

The real non-faulty data set collected from sensors array of real oil heating reactor in Egypt over a period of one month is used for training the suggested networks.

This stage of the work in this paper focuses on the temperature sensors readings of 34 sensors arranged in a matrix of 42660 rows and 34 columns.

The Faulty data is created using the different types of faulty models mentioned previously. Thus, the suggested network will be trained for classifying the sensor readings into faulty or non-faulty class.

C. Processing Data

The following procedures are conducted for preparing the data-set for classification:

- 1- The data will be divided into test and training data, in which the test data is 25% from the total data.
- 2- Choosing the fault type that will be used to test the NN, where the faulty data is detected from this type.
- 3- Choosing the fault level that will be used to test the NN, where the faulty data is detected from this fault level.
- 4- Label both of the training and test data without and with the corresponding type of fault and its level by using two classes to be inputs to the suggested N.Ns

V. CONSTRUCTION OF USED NN

In this paper, the performance of three types of neural networks based-classification (FCNN, BiLSTM and CNN) are compared for detecting the faulted temperature sensor using various fault types with different levels .

A. FCNN

FCNN used in this paper is consist of the following layers as shown in Fig. 12:

- Input layer consist of 34 input nodes; one for each sensor reading.
- Hidden layer has 70 nodes.
- Output layer consist of 1 output (label) node for the (+ev) result which means that the sensor is faulty and (-ev) result which means that the sensor is not faulty.

Fig. 12. Proposed FCNN construction

The training parameter used in the FCNN will be as follows:-

- Scaled conjugate gradient back propagation “trainscg” [34] is used as the training function.
- Mean Square Error “mse” [35] is used to evaluate the training result by calculating the error between actual and network outputs.
- Maximum of 1000 epoch will be applied.
- 6 validation checks will be used.

The FCNN have 31995 non-faulty readings and 31995 faulty readings.

In test phase, 10665 faulty readings and 10665 non-faulty readings are used for testing each sensor.

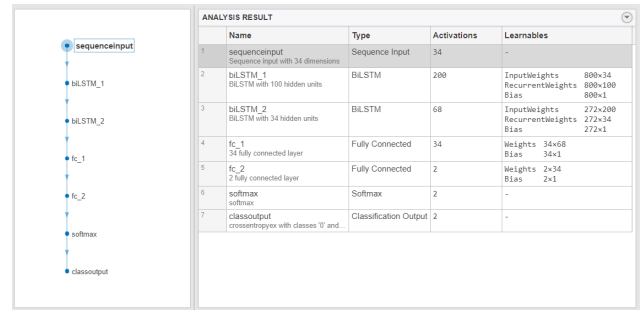

Fig. 13. Proposed BiLSTM RNN construction

B. BiLSTM

BiLSTM is used to classify a Sequence of data as shown in Fig. 13. The BiLSTM network consists of sequence input layer, two BiLSTM layers, two fully connected layers, softmax layer and finally classification layer.

- 1) The data sequences of sensors readings is divided into batches; each batch consists of 15 consecutive readings.
 - 2) Thus, the input data to BiLSTM network consists of array of size (15x1) to each sensor reading where for all sensors are (15x34).
 - 3) 2133 non-faulty and 2133 faulty readings are used for training the network, while 711 readings from each of the faulty and non-faulty data are utilized for test phase.
- There are 34 input nodes; one for each sensor; 15 consecutive reading.
 - The BiLSTM NN uses 200 BiLSTM nodes in one hidden layer.
 - The BiLSTM NN uses 68 BiLSTM nodes in one hidden layer.
 - The BiLSTM NN uses 34 nodes in FCL.
 - The BiLSTM NN uses 2 output nodes; one for (+ve) Faulty sensor and one for (-ev) non faulty sensor.

The training parameter used in the FCNN will be as follows:

- “adam” is used as the training function.
- 40 epochs maximum will be used.
- 30 iterations per epoch applied.

For the BiLSTM training there is 2133 non-faulty reading runs and 2133 faulty reading runs.

For each sensor test there is 711 faulty reading runs, and 711 the non-faulty runs.

C. CNN

The inputs to CNN must be of two dimension matrix as the gray scale picture shown in Fig. 15. The data sequences of sensors readings are divided into batches; each batch consists of 15 consecutive readings. Thus, the input data to CNN network consists of matrix of size (15x34).

Fig. 14. Input picture to CNN

Fig. 15. Proposed CNN construction

Consequently, 2133 non-faulty and 2133 faulty readings are used for training the network while 711 faulty readings and 711 non-faulty readings are utilized for test phase.

The CNN construction is shown in Fig. 14.

so there is 2133 non-faulty and 2133 faulty training runs and 711 non-faulty and 711 faulty test run each consist of (15X34) Reading.

- The CNN has 15x34x1 images as input.
- The CNN has 8 (2x2) convolutions.
- The CNN has (2X2) Max Pooling.
- The CNN has 16 (2x2) convolutions.
- The CNN has (2X2) Max Pooling.
- The CNN has 32 (2x2) convolutions.
- The CNN has (2X2) Max Pooling.
- The CNN has 35 nodes in F.C.L.
- The CNN has 2 nodes in F.C.L.
- The CNN has Softmax Layer.
- The CNN has 2 output nodes one for (+ve) Faulty sensor and one for (-ev) non faulty Sensor.

The training parameter used in the CNN will be as follows:

- The Optimization algorithm named stochastic gradient descent with momentum “sgdm” is used for more efficient neural network weights during the network training [36] is used as the Training Function.

TABLE I. NETWORK PARAMETERS COMPARISON

Parameter	FCNN	BiLSTM N.N	CNN
Input Type	Value	Matrix	Picture
Number Of Layers	3	5	11
Input Layer	34 Node	34 Node	1 Node
Layer-2	FC	BiLSTM	Convolution
Layer-3		BiLSTM	Max Pooling
Layer-4		FC	Convolution
Layer-5			Max Pooling
Layer-6			Convolution
Layer-7			Max Pooling
Layer-8			FC
Layer-9			FC
Layer-10			Soft Max
Output Layer	2 node	2 node	2 node
Maximum Epoch	1000	40	100
Validation Check	6		
Iteration/epoch	1	30	16
Training Points	63990	4266	4266
Training Function	trainscg	adam	sgdm
Test Points	21330	1422	1422

Fig. 16. FCNN performance

- 100 epoch maximum is used.
- 16 iteration per epoch is used.

D. Parameter comparison

Summary combining the comparison between the different neural networks constructions is shown in Table I.

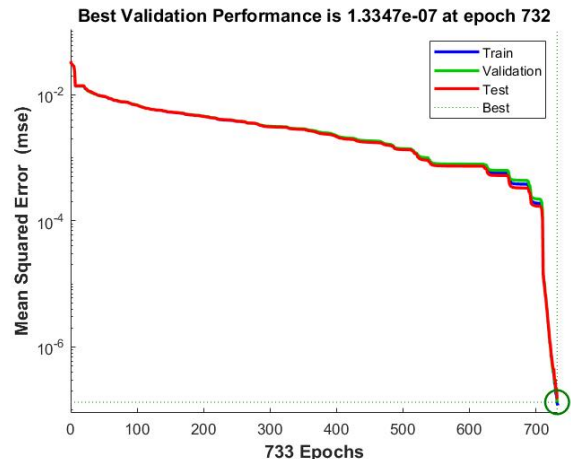

Fig. 17. FCNN training result

VI. NETWORK RESULTS COMPARISON

This section is dedicated to discuss the results of training the N.Ns used in this paper.

A. Performance Metrics for the Suggested Network

The performance of the suggested N.Ns is compared and evaluated using the following metrics [37]:

Fig. 20. BiLSTM training result

Fig. 23. CNN confusion matrix

Fig. 24. CNN training result

Fig. 25. 1% fault level comparison for all NNs

- 1- Accuracy: It is the ratio of correct predictions to total predictions.
- 2- Precision: the ratio of correct fault detection to all fault predictions.
- 3- Recall: It is the ratio of correct fault detection to all true fault readings.
- 4- F-Score: It is the harmonic mean of precision and recall

The results of NNs classification include four types of data samples which are described as follows:

- I) True positive (TP): is the number of samples that the network label as **faulty** while they are in-fact a **faulty** readings.
- II) True negative (TN): is the number of samples that the network label as **non-faulty** while they are in-fact a **non-faulty** readings.
- III) False positive (FP): is the number of samples that the network label as **faulty** while they are in-fact a **non-faulty**

readings.

- IV) False negative (FN): is the number of samples that the network label as **non-faulty** while they are in-fact a **faulty** readings.

The aforementioned metrics according to the four types of classified data are calculated by the given equations as follows:

1- Accuracy

$$= \frac{TP + TN}{TP + TN + FP + FN} \quad (6)$$

2- Precision

$$= \frac{TP}{TP + FP} \quad (7)$$

3- Recall

$$= \frac{TP}{TP + FN} \quad (8)$$

4- F-Score

$$= \frac{1}{\frac{1}{Precision} + \frac{1}{Recall}} \quad (9)$$

5- False positive rate (FPR)

$$= \frac{FP}{TN + FP} \quad (10)$$

6- False negative rate (FNR)

$$= \frac{FN}{TP + FN} \quad (11)$$

B. Results and Discussion Simulation

The suggested networks are trained by all types of fault with different levels which are: [1%, 10%, 50% and 90%]. The performance results of the suggested networks for detecting all types of fault with there different levels in metrics of accuracy, precision and recall are given in Table II:

C. Results

The following results is obtained after the training and testing of the NNs

1) *FCNN performance*: The comparison of classification accuracy of FCNN for detecting the different fault types with its different levels is shown in Fig. 16.

As shown above the FCNN is very weak in detecting spike fault with accuracy of 50% while its good in detecting the other faults with their different levels where the results of detection are acceptable with accuracy ranges from 96% to 100%.

While the mean square error versus the number of epochs in training FCNN is shown in Fig. 17, confusion matrix is shown in Fig. 18.

2) *BiLSTM performance*: The comparison of classification accuracy of BiLSTM network for detecting the different fault types with its different levels is shown in Fig. 19.

As shown above, the accuracy of BiLSTM in detecting Basie, stuck and P.D.E faults is weak at fault levels (1%). On contrast, the accuracy results are acceptable with other faults.

While the network accuracy and the losses versus the number of epochs in training BiLSTM network are shown in Fig. 20, confusion matrix is shown in Fig. 21.

TABLE II. NN RESULTS COMPARISON

NN TYPE	Fault Type	Fault Level	Accuracy	Precision	F-score
CNN	Bias	90%	100%	100%	100%
CNN	Bias	50%	100%	100%	100%

F.C.N.N	Spike	90%	53.1%	100%	11.6%
F.C.N.N	Spike	50%	53.1%	100%	11.5%
F.C.N.N	Spike	10%	53.2%	100%	11.9%
F.C.N.N	Spike	1%	53.1%	100%	11.7%
F.C.N.N	Stuck	90%	100%	100%	100%
F.C.N.N	Stuck	50%	100%	100%	100%
F.C.N.N	Stuck	10%	100%	100%	100%
F.C.N.N	Stuck	1%	100%	100%	100%
F.C.N.N	P.D.E	90%	98.5%	100%	98.4%
F.C.N.N	P.D.E	50%	99.2%	100%	99.2%
F.C.N.N	P.D.E	10%	98.6%	100%	98.6%
F.C.N.N	P.D.E	1%	96.4%	99.8%	96.2%

3) *CNN performance*: The comparison of classification accuracy of CNN for detecting the different fault types with there different levels is shown in Fig. 22.

As shown above the result of the CNN is accepted even at spike fault and low level faults.

While the network accuracy and the losses versus the number of epochs in training CNN network are shown Fig. 23, confusion matrix is shown in Fig. 24.

4) *The networks accuracy comparison at 1% fault level*:: The comparison between all NN performance at various fault types and 1% fault level is shown in Fig. 25.

As shown in this figure, the results demonstrate that the CNN has the best performance in detecting all fault types and levels.

VII. CONCLUSION

In this paper, different neural networks are suggested for detecting the fault in temperature sensor of sensors array in oil heating reactor.

From the given results in this paper, the networks performance in metrics of Accuracy, Precision and Recall are varying depending on the network type, fault type, and fault level.

The CNN performance for fault detection outperforms the other networks, and it is the best so far to detect even very low level faults such as 1% fault level with accuracy reached to 97%.

This results show that the CNN is the best candidate to be implemented for fault diagnosis in future works, that will be focused on fault diagnosis and fault elimination.

The Impact of Peer Code Review on Software Maintainability in Open-Source Software: A Case Study

Aziz Nanthaamornphong¹, Thanyarat Kitpanich²
College of Computing, Prince of Songkla University, Phuket, Thailand

Abstract—Recently, open-source software (OSS) has become a considerably popular and reliable source of functionality corrections. OSS also allows software developers to reduce technical debt in software development. However, previous studies have shown that the main problem within OSS development is the lack of systematic processes and formal documents related to system development, such as requirements, designs, and testing. This feature of OSS development causes problems in the software quality, such as those related to security and maintainability. In this research, the authors focused on the software's maintainability because this attribute has to greatest potential to reduce the cost and increase the productivity of the software development process. There is currently no existing research that examines whether OSS developers pay attention to software maintainability. To better understand how OSS developers improve software maintainability, this research aims to answer the question: "Are developers interested in software maintainability under the modern code review of open-source software projects?" To answer the research question, the authors investigated the code review process in which the OSS developers changed the code based on a review of code comments related to maintenance and collected the sub-characteristics associated with software maintainability from the existing literature. The authors examined the review comments from two OSS projects: Eclipse and Qt. The results suggest that the number of code revisions due to maintenance issues was moderate and that the OSS developers tend to improve source code quality. This direction could be observed from the increasing number of modifications on given maintenance-based comments over the years. Therefore, an implication of this is the possibility that OSS project developers are interested in software maintainability.

Keywords—Open-source software; software maintainability; code review

I. INTRODUCTION

Open-source software (OSS) has received considerable attention from users worldwide, especially among organizations and commercial industries that widely utilize OSS. Notably, OSS is often a key to organizational success for entrepreneurs. OSS can create the opportunity for organizational growth, enhance performance, increase the options for software use, and decrease operating costs. Moreover, users from around the world can use OSS freely without fees, allowing software developers to access the OSS code repository [1] and jointly develop software [2]. OSS projects are being continuously developed and improved by software developers with expertise and experience in system development. Therefore, OSS has become popular and credible in terms of effectiveness and functionality.

A previous study [3] noted that OSS development lacks systematic processes or procedures and formal documents related to system development, such as requirements, design, testing, etc. Considering the aforementioned problems, most software developers working on OSS projects solve relevant problems when they are reported by users or software developers on the same team. One frequent problem is the occurrence of a defect or bug in the system. When the source code is frequently modified, the size of the code increases, and it generally becomes more complex. Moreover, some source codes can be difficult to understand. These issues can lead to serious problems, such as increases in time and development costs. Additionally, software developers and commercial entrepreneurs who want to develop software often cannot comprehend old codes that are complex and poorly described. Thus, accessibility may be poor, and call functions may fail. In addition, poor results or inaccurate information may not meet user expectations, and possible vulnerabilities in the system may lead to the pirating of information or viruses. All of these issues can cause software project development to ultimately fail. The quality of the source code of OSS projects could be improved [4], in particular, the relevant software security and maintainability of these projects [5].

Software maintainability can improve product quality at a low cost and ensure that software development meets the intended objective. Therefore, software maintainability is one of the most important steps in the software development life cycle because most software developers spend approximately 40-50% of their time identifying defects or errors during the development process or after product delivery [6]. Notably, maintainability can solve OSS quality issues and prevent problems that may affect the system in the future. The code review process is an important part of the software development process that ensures the creation of high-quality software and the implementation of successful OSS projects [7]. Thus, many OSS projects use "peer code review" or "modern code review" [8] as a guideline for developing and improving code.

Peer code review is commonly used in software engineering for quality control [9]. Generally, a code change must be reviewed by the software developers on the same development team or reviewers other than the code editor. Generally, the code review process does not have a fixed format, but it prevents problems associated with patch files and helps avoid bugs or errors that can influence the long-term applicability of the software. Moreover, the comments from reviewers can be used to identify bugs or defects in the source code, improve the source code, modify the source code to meet certain standards,

and improve code readability [10]. However, some comments may not be directly related to software quality improvements.

A review of studies on software development in OSS projects indicated that the comments provided via peer code review have not been extensively investigated. Developers should review comments related to software maintainability in OSS projects. These comments are often collected in the Gerrit system, which provides services related to the code review process and facilitates communication and the exchange of ideas about software development among software developers. In this study, two OSS projects: Eclipse (<https://eclipse.org/>) and Qt (<https://www.qt.io/>), are investigated. These projects were selected because they have different purposes and have already been completed. Therefore, extensive comment information is available for both projects. The projects provide the opportunity for researchers in the field of software engineering to access this information and study code reviews. The main research questions posed in this study are as follows:

- 1) How many sub-characteristics are related to software maintainability?
- 2) Are the developers of OSS projects interested in software maintainability under the peer code review?
- 3) What characteristics of software maintainability have the developers considered?

In order to answer these questions, text mining was applied to identify the sub-characteristics related to software maintainability that appear in comments provided by peer code review, and the latent Dirichlet allocation algorithm (LDA) was applied to develop new characteristics related to software maintainability. Quantitative data analysis was performed to identify the trends of developers in software maintainability for OSS projects. In addition to answering the main research questions, the results were used to determine the factors that affect the number of comments related to maintainability, and statistical analysis was conducted to answer the following research questions:

- 1) Does the size of the reviewer pool influence the comments related to maintainability?
- 2) How many comments related to maintainability are given by code reviewers each day?

The results of this study will provide empirical evidence for the research community regarding the software quality of OSS projects. Moreover, this study will shed light on the importance of software maintainability and help software developers understand sub-characteristics related to software maintainability, which usually appear in OSS projects.

The remainder of this paper is organized as follows. Section II provides the necessary background and related work. Section III describes the research methodology. Section IV shows the results of this study. Section V discusses the results. Section VI concludes the paper and outlines our future work.

II. RELATED WORK

In this section, the theories and methodologies used to conduct the research are summarized, including the literature review, which provides the basic framework of this study.

A. Peer Code Review for OSS Projects

Code review is a way to reduce the risk of error and improve the quality of software by checking the source code to identify defects or bugs that may occur during software development. Moreover, such a review can standardize the source code [11]. When organizations or projects that require software development use this code review process, it ensures that the developed code will meet the specifications or needs of the user and that the impacts of source code modifications are minimized. Therefore, code review has been a best practice in software engineering for over 35 years [12]. “Peer code review,” or “modern code review,” is applied by open-source organizations and communities to improve the quality of source code [13]. The source code is standardized by deleting duplicate functions and removing irrelevant or unnecessary code. Moreover, the code review process allows detailed comments from experienced reviewers that can improve the source code. Additionally, peer code review facilitates the sharing of knowledge about system development [11] because code review services often utilize specific communication tools. The most common tools are CodeFlow, Gerrit, Collaborator, Crucible, Review Board, and Upsource.

B. Software Maintainability

ISO/IEC 25010 is the model used by organizations around the world because it has set the software quality standard for code review based on system and software requirements. Furthermore, ISO/IEC 25010 was selected in this study because it includes both quality evaluation for a system or software and the corresponding effects on stakeholders or users. The international standards that are used to assess quality include requirement definition and quality measurement and evaluation [14].

ISO/IEC 25010 defines software maintainability as “the degree of effectiveness and efficiency with which a product or system can be modified to improve it, correct it or adapt it to changes in the environment, and in requirements.” In a previous study on software maintainability, Ghosh et al. [15] identified the 40 sub-characteristics that impact maintainability. These sub-characteristics are used as keywords in this study to obtain comments related to software maintainability.

C. Literature Review

Bakar and Arsat [16] studied the factors that affect the quality of OSS by measuring the quality of the source code using McCall’s Quality Factor model. This model considers maintainability, accuracy, reliability, efficiency, and ease of use. The results indicated the relationships among lines of code and the complexity of the source code based on correlation analysis. The most influential factors were correctness, maintainability, efficiency, and usability. Related research on complexity measurements for source code generally uses Cyclomatic Complexity (CC) as an indicator, although there are newer indicators as well. For example, Walden et al. [17] analyzed code and used complexity metrics to predict the possible density gaps in 14 web applications. The study results could be used by software developers in OSS projects to create a simple system structure and clearly illustrate the development of software, especially security, because the number of gaps

was decreased. Norick et al. [18] studied OSS projects developed in C/C++ to determine whether the number of revisions affected the quality of the source code. This analysis used the CC of each coded function and the density of comments as representatives of source code quality. However, the study did not find a correlation between the number of software developers and the software quality, and the average software quality was satisfactory for all the studied OSS projects. Schmidt and Porter [19] studied the software development process of the “Skoll” OSS project and of closed-source projects. They found that the community of OSS developers could control long-term maintainability procedures and development costs, and these characteristics created confidence and a level of acceptance in the quality of the software. Specifically, users had confidence in the software and corresponding system. Such practices are easier to implement in OSS projects compared to closed-source projects because the disclosure of sources allows software developers who are interested in OSS projects to voluntarily participate in quality improvement tasks.

Successful OSS projects usually participate in peer code reviews to assess the quality of the software [20]. The code review process begins with the software developers creating patch files, which add value to a project. Rigby [21] stated that using supportive tools for peer code review could affect the progress of OSS, and there was a subsequent push for software development that facilitates code review. As noted by Bosu and Carver [7], review tools have been widely used to study comments via platforms such as ReviewBoard. The researchers analyzed the number of participants in the project, the number of requests for code review, and the response time after a request for code review was submitted by comparing MusicBrainz Server and Asterisk. However, Bacchelli and Bird [22] studied motivation and challenge in searching for defects in Microsoft projects using the CodeFlow tool, which records data from code reviews. The comments aiming to guide code modification during the peer code review process were investigated. The results showed that reviewers with expertise in system development and reading and reviewing source code provided the most useful comments for developers.

Baysal et al. [10] studied the factors that affect the modification of patch file defects by extracting code review information for the WebKit project from Bugzilla. Most reviewers denied large patch files because developers modified or developed source code that was too complex, included unnecessary components, and/or affected other functions or modules. Tao et al. [23] proposed a method for developers to code patch files that were accepted by reviewers. They verified the causes of rejected patch files by collecting rejection information for Eclipse and Mozilla patch files. The information was collected and stored based on an online survey of 246 software developers. Considering the issues that caused a code fix to be accepted or rejected, the community can determine how to optimize the peer code review process.

fBosu et al. [10] searched for ways to improve the efficiency of peer code review, which was useful for system development. They analyzed 1.5 million comments from Microsoft projects to identify the characteristics of useful and useless comments. Some comments that software developers received contained incorrect information or comments unrelated to system development, and software developers took time to

respond to these questions and discuss why they did not modify the source code accordingly. Moreover, the study identified the factors that were correlated to beneficial comments, such as review experience, organizational experience, and being on the same team as the code developers. Czerwonka and Greiler [24] found that up to 50% of the comments provided via the peer code review process were related to software maintainability and that very large patch files decreased the benefit of reviewer comments and increased the review time by six hours to a week. Nonetheless, they found that reviewer comments are beneficial and reflect the overall view of software development. Such a review system promotes cooperation in problem resolution and expedites the development and improvement of software. Such systems provide a standardized framework for researchers to better understand peer code review.

Maintainability is a very important factor because software maintenance accounts for 66% of the life cycle and 40-80% of the cost of development [25]. Code smells are among the most important problems that must be urgently solved. A code smell is any characteristic in a source code, such as a poorly designed structure or poor organization, that can lead to larger issues. These factors decrease the quality of software maintainability. Wagey et al. [26] presented a model of software maintainability and applied it to six OSS projects. The results showed that the model improved the structures of the OSS projects. Refactoring [27], a process that involves shortening lines of code or combining similar functions to reduce the complexity of the code [28], has also been used to improve software functionality. Rizvi and Khan [29] used regression analysis to develop a class-level maintainability estimation model called MEMOOD, which facilitated development and reduced the time required to improve or edit code before delivery. This model used the features of understandability and modifiability, which were calculated based on object-oriented metrics, to estimate the maintainability of the code considering its size and structural complexity. Khan and Khan [30] developed a model that was used to measure the quality of analyzability. Multiple linear regression was conducted for the structural design of a system in which complexity might affect the quality of software maintainability, especially its analyzability. However, they found that other factors, such as the size of a file or program, may also make maintainability difficult.

III. RESEARCH METHODOLOGY

This study analyzes the comments related to software maintainability from the peer code review of OSS projects using text mining techniques. The main procedure consists of two parts, as described in the subsequent subsections.

A. Development of Software for Searching and Storing Data from Gerrit

Software was developed for searching and storing data associated with Eclipse and Qt comments that were collected by Gerrit from 2017 to 2021. Before storing the data from Gerrit, tables were designed in the database to support the data used in this study. The stored information is as follows:

- ID - the unique number for each data entry;
- Patch_numbers - the number of patches;

- Created_on - the review request date;
- Uploader - the uploader's ID (Gerrit user name);
- Author - the code author;
- Reviewers - the reviewer's ID (Gerrit user name);
- File - the name of the file with the review request;
- Line - the number of changed lines of code;
- Message - the comment message; and
- Kind - the status of the changed code, such as trivial rebase, no code change or rework.

B. Analyzing a Dataset

In this step, the sub-characteristics related to software maintainability that appear in comments provided via the peer code review of OSS projects were searched using a text-mining technique. This technique also verifies that the comments were related to maintainability. This step is shown in Fig. 1, and each step is shown as follows.

Fig. 1. The data analysis process

Keyword List Building - A set of keywords that are related to software maintainability, such as modularity, analyzability, and testability, was constructed. These keywords were selected based on the sub-characteristics that are related to the definition of “software maintainability”. Previously, Ghosh et al. [31] used these collected keywords to search for comments related to software maintainability. However, they found that the reviewers of OSS projects typically did not use words in comments that matched these keywords. Therefore, the sub-characteristics related to software maintainability are converted to their root forms to reflect the basic meaning of the term; for example, “modifiability” was shortened to the root “modify”. Then, synonyms for each root word, such as “edit”, “improve”, “solve”, and “amend” (for “modify”), were also added to the search set. The words with the same meaning as these keywords were identified using WordNet, a website that provides synonyms for various terms.

Data Cleaning - In this study, R was used for data cleaning. Specifically, the text mining (tm) package was used in this step. In data cleaning, the stop word function was employed to remove terms that were not significant without changing the meaning of the sentence. For example, pronouns, conjunctions, and prepositions usually appear in each comment but could generally be removed. Moreover, whitespace, numbers, and special characters, such as special symbols (, , * , #, and ! were deleted. Then, word stemming was performed by removing prefixes and suffixes. Words with the same root, such as “compatible” and “compatibility,” have similar meanings; therefore, “ible” and “ibility” could be removed to obtain the root “compat”. Another example is “connection”, “unconnected”, “connective” and “connecting”, for which the root is “connect”. Moreover, letters were converted from upper case to lower case to reduce the number of required indices and the processing time.

Comment Retrieval - In this step, a command set was developed to search for comments with keywords or meanings related to software maintainability. At least one word from the constructed keyword list must be matched, and the search results were converted into a file format for easy analysis. In order to search for comments related to software maintainability, we developed a command in R that connects to a MySQL database and searches based on various subcommands. For example, a set of commands is developed to find the word “modify,” and words with the same meaning as “modify” appear in the text of comments in the database.

In order to search for comments containing keywords, we created a command set for each keyword for the convenience of searching and storing. After the comments related to software maintainability were obtained, each comment was reviewed to improve credibility. This check was manually performed to verify that each comment contained a keyword or related term. If the text in a comment did not match a keyword or related word, we deleted the text from the database. After verification, the results were stored in table format, and relations were preserved. The table shows the number of terms, either keywords or related words, that appear in comments and are related to software maintainability.

Unrelated Comment Removal - We analyzed the results from step 3 and determined the number of comments in Eclipse and Qt related to software maintainability. These results could help answer the question of whether the developers are interested in software maintainability in OSS projects based on peer code review. To determine whether a comment was considered in code modifications, a command set was established in R by pairing comments related to software maintainability and comments from Gerrit. Notably, most comments from Gerrit included both the comments from reviewers and the comments of software developers who responded. This code modification assessment considers the type of code modification, such as trivial rebase or rework.

Additionally, the words in the reply related to code modifications, such as “done”, “finished”, or “edited” (as shown in Fig. 2), were considered. After checking the comments based on this procedure, the comments with no replies were removed from the database.

Maintainability Attribute Discovery - Thirty-three sub-

History – Comments in Gerrit		Status
 "Please add a similar test to performTest() where the first two lines are in the header file and the third line is in the source file."		Trivial Rebase
 "Done."		Trivial Rebase

Fig. 2. Example of comment related to maintainability and responses of code authors

characteristics of software maintainability were selected, and other sub-characteristics of software maintainability hidden in comments related to Eclipse and Qt projects were searched using the LDA. This algorithm could be applied to search for topics related to maintainability. The result of the LDA in R presented the frequency of occurrence of words that were related to the keywords, and we were required to determine whether these words should be new keywords. If the answer was yes, the term was added to the keyword set, and steps 3 and 4 were repeated until there were no additional keywords.

IV. RESULTS

Based on our research questions (described in Section I), the results of the analysis are presented.

A. How Many Subs-Characteristics are Related to Software Maintainability?

In Ghosh [31], 40 sub-characteristics related to maintainability were identified and studied. The following criteria were used to select sub-characteristics: 1) the definition of the sub-characteristic must be relevant to the definition of “software maintainability” according to ISO/IEC 25010, and 2) a sub-characteristic keyword cannot be a common or general word. The sub-characteristics of this study that did not meet those criteria were as follows:

- 1) Compliance,
- 2) Conciseness,
- 3) Delivery,
- 4) Documentation,
- 5) Impact Analysis,
- 6) Programming Language; and
- 7) Self-descriptiveness.

The obtained sub-characteristics that met these criteria were converted into verbs or nouns by removing the suffix, and the final keywords were easy to search for in the comments of reviewers on OSS projects. The results of keyword determination are shown in Table I.

We then reviewed the keyword search results to identify potential words that should not be considered keyword synonyms. The criteria for synonym consideration are as follows:

- 1) Cannot be a common term used in the programming language, such as class, function, feature, method, object, or parameter, or a general computer-related

TABLE I. THE LIST OF KEYWORDS

No.	sub-characteristics	Keyword	No.	sub-characteristics	Keyword
1	Accuracy	Accuracy	18	Implementation	Implement
2	Adaptability	Adapt	19	Instrumentation	Instrument
3	Analyzability	Analyze	20	Integrability	Integrate
4	Augmentability	Augment	21	Localization	Localization
5	Availability	Available	22	Modifiability	Modify
6	Changeability	Change	23	Modularity	Modular
7	Completeness	Complete	24	Perfectiveness	Perfect
8	Complexity	Complex	25	Portability	Portable
9	Comprehensibility	Comprehension	26	Readability	Read
10	Consistency	Consistency	27	Reusability	Reuse
11	Correctability	Correc	28	Simplicity	Simple
12	Durability	Durable	29	Stability	Stable
13	Efficiency	Efficient	30	Standardization	Standard
14	Effort	Effort	31	Testability	Test
15	Expandability	Expand	32	Traceability	Trace
16	Extensibility	Extension	33	Understandability	Understand
17	Flexibility	Flexible			

term, such as system, computer, software, file, or command.

- 2) For duplicate synonyms, only synonyms from three root words are selected.
- 3) For different synonyms, all words from three roots are used as keywords.

The search process for the keywords and synonyms that met these criteria is shown in Table II. The software developers that use Eclipse and Qt can consider all characteristics of software maintainability to improve and edit their source codes. Therefore, in addition to the 33 characteristics identified by the LDA, the frequent terms in comments related to software maintainability were also searched. The LDA results in Table III contain keywords and synonyms such as change, adjust, test, and improve. Therefore, to choose the new maintainability characteristics from the LDA, we considered the most frequently used words in each group.

Considering the maintainability characteristic produced by the LDA, some groups did not contain appropriate words. However, Eclipse and Qt contained two new characteristics related to software maintainability: cohesion and duplicate. To define the new maintainability characteristics, the authors used comments provided by the reviewers to search and identify these two maintainability characteristics. The words that typically appear with “cohesion” and “duplicate” had a relationship value of 0.6. Thus, those keywords were associated with software maintainability at least 60% of the time. The words most highly correlated with the new types of maintainability characteristics in comments are considered to define the maintainability characteristics and group the synonyms (as shown in Table IV).

- 1) The cohesion module identifies the modules that work together by connecting the components of the modules. These components may work at the same time or have the same input but different operations.
- 2) The duplicate function combines functions with similar properties or procedures to reduce the duplication of functionality, which can potentially cause confusion in calling.

TABLE II. THE LIST OF KEYWORD AND SYNONYMS

No.	Keyword	Synonym
1	Accuracy	accuracy, exact, truth, certainty, precision, propriety, rectitude, validity, sure, definite, inevitable, rigorous, evident, categorical, explicit, just, lawful
2	Adapt	adapt, adjust, modulate, alter, fine, shape, regulate
3	Analyze	analyze, analysis, diagnose, assay, delineate, muse, anatomize
4	Augment	augment, amplify, spread, inflate, escalate, dilate, enhance, accumulate, increase, suffuse, raise, mount, aggrandize, splay, accrete
5	Available	available, accessible, handiness, obtainable, satisfactory, convenient, usable, benefit
6	Change	change, vary, remodel, permute, convert, transform, re-vamp, purge, reform
7	Complete	complete, full, absolute, plenary, finish, utter, flawless
8	Complex	complex, complicate, sophisticated, elaborate, manifold, labyrinthine, multiple, confuse, entangle, mix, muddle, discursive, tangle, intricate, bewildered, imbroglia, intricacy, jumble, obscurity
9	Comprehension	comprehension, finality, inference, conclusion, notion, realization, savvy
10	Consistency	consistency, coherence, pertinacity, adhesion, invariability, tenacity
11	Correct	correct, rectify, fit, favorable, appropriate, worthy, deserve, suitable, due, rightful, infallible, redress, regularize
12	Durable	durable, lasting, hardy, imperishable, substantial, permanent, long, immune, indissoluble, enduring, strong
13	Efficient	efficient, able, capable, competent, proficient
14	Effort	effort, endeavor, fighting, might, stamina, energy, strength, activity
15	Expand	expand, add, accretion, accrue, develop, flatten, grow, prosper, thrive
16	Extension	extension, flare, connect, continue, broaden, enlarge, widen, magnify, prolong, elongate, protract, proliferate
17	Flexible	flexible, elastic, dexterous, limber, resilient, springy, pliable, stretch
18	Implement	implement, execute, accomplish, achieve, resource, utilize, apply
19	Instrument	instrument, equipment, accessory, apparatus, machinery, appliance, device, gadget
20	Integrate	integrate, gather, collect, compile, assemble, embody, coordinate, cooperate, harmonize, consolidate, sticking, combination, joining, amassing, hoard, compound
21	Localization	localization, limitation, narrowing, restriction, stint, definition, circumscription
22	Modify	modify, customize, edit, improve, solve, repair, amend, qualify
23	Modular	modular, configuration, component, constituent, ingredient, composition, complement, element, procedure, segment
24	Perfect	perfect, excellent, ideal, immense, keen, superb, wonderful, terrific, fantastic, splendid, magnificent, superior, entirety, consummate, faultless
25	Portable	portable, mild, soft, slight, lightweight, feathery, weak, mushy, flimsy
26	Read	read, peruse, pronounce, extrapolate, imagine, speculate, surmise, see, view, interpret, transliterate, look
27	Reuse	reuse, recycle, reiterate, rehash, reclaim, exploit, revise
28	Simple	simple, ease, expedient, facile, easy
29	Stable	stable, still, steady, invariable, constancy, endurance, firmness, fastness, indissolubility, sturdily
30	Standard	standard, formula, archetypal, representative, typical, characteristic, degree, tier, quality, criterion, measurement, imperative, touchstone, property
31	Test	test, verify, check, prove, evaluate, examine, assess, attempt, experiment, inspect, trial, proof, tryout, investigate
32	Trace	trace, pursue, tag, trail, detect, search, seek, probe, meaning, significance, hint, consequence, point, follow, behave, track, extract, transcribe
33	Understand	understand, explain, fathom, grasp, knowledge, perceive

TABLE III. THE LDA RESULTS

Topic 1	Topic 2	Topic 3	Topic 4	Topic 5
change	use	add	work	method
convert	sure	adjust	example	tool
parameter	suggest	file	make	class
patch	implement	test	code	review
index	cohesion	improve	model	package
name	resource	worth	duplicate	commit

TABLE IV. NEW KEYWORDS

No.	Keyword	Synonyms
1	Cohesion	cohesion, sticky, tough, gummy, leathery, tenacious
2	Duplicate	duplicate, repetitive, double, copy, transcript, counterpart, facsimile, reproduce, mimeograph, repeat, replicate

B. Are the Developers of OSS Projects Interested in Software Maintainability Under the Peer Code Review?

The Qt and Eclipse projects had totals of 309,165 and 108,357 comments, respectively. Thirty-five keywords were identified based on the characteristics that were relevant to maintainability. These keywords included 33 previously used terms and two terms obtained from the LDA. A script was developed in program R for text mining. The results indicated that 39,638 and 93,629 comments were related to maintainability in the Qt and Eclipse projects, respectively, based on the keywords (36.58% and 30.28% in Fig. 3). In both projects, the number of comments related to software maintainability was low compared to the total number of comments.

Fig. 3. Rate of comments are related to maintainability and comments are not related to maintainability

The keywords were used 64,616 and 149,610 times in the comments of the Eclipse and Qt projects, respectively. In order to determine the extent to which software developers of Eclipse and Qt prioritized software maintainability, the comments related to software maintainability and code editing were analyzed. Overall, 36,975 and 94,408 comments led to source code modifications for Eclipse and Qt, representing 57.22% and 63.10% of all comments, respectively. Fig. 4 shows that the comments provided to the software developers of Eclipse and Qt resulted in source code edits 50-60% of the time.

We found that software developers of Eclipse and Qt edited

Fig. 4. Ratio of comments to modification code

the source code according to the comments related to software maintainability approximately 50-60% of the time. This result provides empirical evidence suggesting that the software developers of Eclipse and Qt prioritized software maintainability in more than 50% of source code modifications.

The Pearson correlation coefficient was determined in this study at a 95% confidence interval to obtain the relationship between comments related to maintainability and comments related to code changes in these two OSS projects. Based on an analysis in R, the Pearson correlation coefficients of Eclipse and Qt were 0.995 and 0.993, respectively. These coefficients indicate that the number of comments related to software maintainability and the number of comments related to code modifications were highly related. In other words, when the reviewers of Eclipse and Qt provided more software maintainability comments, the software developers made more source code edits.

C. What Characteristics of Software Maintainability have the Developers Considered?

The five most common comments related to software maintainability were investigated, and the number of code modifications related to those comments was determined. Fig. 5 illustrates that the software developers of OSS projects make the most source code edits based on comments that discuss readability, and the rates of related changes are

61.44% for Eclipse and 72.14% for Qt.

D. Does the Size of the Reviewer Pool Influence the Comments Related to Maintainability?

In the two OSS projects, most of the comments that led to code edits were made by reviewers and other software developers. Therefore, the number of comments was compared to the number of comments related to software maintainability each month. Moreover, the sizes of the groups or teams of software developers were considered to determine how many software developers reviewed the code.

R was used to calculate correlation coefficients and obtain the relationship between the number of software developers who provided comments related to software maintainability and the number of comments related to software maintainability. The annual Pearson correlation coefficients in the study period were 0.78, 0.88, 0.72, 0.53, and 0.75 for Eclipse and 0.85, 0.86, 0.57, 0.005, and 0.17 for Qt (as shown in Fig. 6 and 7).

Fig. 6 shows that the group size of reviewers and the number of comments related to software maintainability were highly related in the Eclipse project. Fig. 7 illustrates that the group size of reviewers and the numbers of comments related to the project maintainability in Qt were highly correlated.

Fig. 5. The percentage of addressed comments related to sub-characteristics

Fig. 6. The relationship between the number of reviewers and comments related to maintainability of the Eclipse project

The data were further analyzed to determine the trend in the number of reviewers. Fig. 8 shows that the number of reviewers who provide comments related to maintainability has increased

annually. As observed in the Eclipse and Qt projects, the new generation of software developers is interested in developing high-quality software and providing comments that improve

Fig. 7. The relationship between the number of reviewers and comments related to maintainability of the Qt project

the quality of OSS projects.

E. How Many Comments Related to the Maintainability are Given by Code Reviewers each Day?

The working times of reviewers for each project were evaluated based on ANOVA and posthoc comparisons considering Tukey's honest significant difference (HSD), which compares the average of multiple data pairs. Tukey's HSD was used because hypothesis testing with ANOVA considers multiple averages. Therefore, the results do not indicate which data pair is different. Moreover, Tukey's HSD is a popular statistical test in software engineering research. In this study, the results of the posthoc Tukey's HSD indicate how many comments were made by reviewers on each day of the week on average.

R was used to perform ANOVA at a 95% confidence level for the following hypotheses.

H0: The average number of comments related to software maintainability was the same on each day of the week.

H1: The average number of comments related to software maintainability differed on each day of the week.

The results indicate that Eclipse has a p-value of 0.000649 and Qt has a p-value of 0.0105. The p-values of both projects are lower than 0.05, so H0 is rejected. Therefore, it can be concluded that the average number of comments related to

maintainability provided by reviewers each day varies. To assess the differences, Tukey's HSD is calculated.

R was used to perform the variance for Tukey's HSD calculation at a confidence level of 95%, and the hypotheses of the test are as follows.

H0: The average number of comments related to software maintainability is the same each day.

H1: The average number of comments related to software maintainability is different each day.

Based on the variance of Tukey's HSD, the average number of comments from Monday to Saturday does not vary for Eclipse. While there is a significant difference between the comments related to the maintainability on Sunday compared to those made throughout the rest of the week, the difference is not significant. Moreover, the values on Saturday and Sunday are similar. This finding may indicate that the Eclipse code reviewers usually review code and provide comments related to software maintainability from Monday to Saturday rather than on Sunday. Based on the variance of Tukey's HSD for Qt, there are no significant differences between the number of relevant comments on weekdays and weekends. Therefore, it can be concluded that the reviewers of Qt usually review code and provide comments related to software maintainability every day.

Fig. 8. Boxplot of comments related to the maintainability per day of the week

V. DISCUSSION AND THREATS TO VALIDITY

This section discusses the results and threats to the validity of this study.

A. Discussion

The comments related to software maintainability from the reviewers of OSS projects account for approximately 30% of all comments, and some comments are related to the development of the main functions and subfunctions of the system and to other characteristics, such as stability [32]. In addition to maintainability, stability is a very important characteristic because users around the world want to be sure that OSS can maintain their confidentiality and integrity and prevent accessibility issues or allow software editing without permission. Moreover, published software must be made available. Therefore, software developers who focus on stability mainly try to find possible gaps in code or vulnerable code changes. The results of this study indicate that most comments led to modifications of the code, which is a good sign for software quality. Therefore, it is predicted that the software developer communities of the Eclipse and Qt OSS projects will continue to focus on maintainability in the future.

The results of this study and the applied methodology are of interest in assessing software maintainability. This study differs from other studies in that software engineering researchers have typically investigated Eclipse and Qt based on other maintainability topics and methods, such as using indicators to verify source code and check maintainability. For example, Yamashita et al. [33] checked for files that were vulnerable to size increases and analyzed the complexity of the software. Additionally, Caglayan et al. [34] used indicators to predict

defects in OSS projects, and Counsell et al. [35] calculated the maintainability index based on coupled factors. Therefore, the results of this study related to “software maintainability” may differ from the results of other studies based on various factors, such as the methods, processes, tools, and environments of OSS projects.

B. Threats to Validity

Threats to validity can reduce the accuracy and reliability of studies and lead to inaccurate results. This section presents the threats to the validity of the current study. The threats in this study can be categorized into three classes as follows.

Construct Validity - This research compiled OSS comments from the code review system called “Gerrit”. The storage structure of Gerrit was studied to design and develop searching and storage software. The collected data were sets of text or characters, and some data, such as symbols and figures, may be incomplete. However, the collected data were considered acceptable for analyzing the quality of OSS projects, especially maintainability, which was the objective of the research. In the research process, R was used for text mining, data processing, and data analysis, as well as to search for comments related to software maintainability. Moreover, R was used to conduct various statistical methods, such as variance analysis, correlation analysis, and regression analysis. Therefore, other programs or tools were used for text mining, and the results may be different.

Internal Validity - This study presents the comments related to software maintainability from the code review processes of Eclipse and Qt. In the comment search process, keywords and synonyms related to each sub-characteristic of

software maintainability were selected to provide the support framework for searching. Only comments with one or more of the selected keywords or synonyms were analyzed, and irrelevant comments or those that did not meet specific criteria were removed. Result verification was performed by manually reviewing all comments related to software maintainability before processing. However, this manual may have an inherent bias, and we attempted to minimize this bias by repeating the verification process many times. Moreover, expert code reviewers were asked to verify the results by reading the comments (approximately 30% of all comments). Currently, there is no tool available for the automatic review of comments.

External Validity - The results of this study only provide empirical evidence for the two OSS projects considered. Therefore, the findings are not applicable to every OSS project because each project differs in internal structure, and the code review and software development processes also vary. However, the results of this study can provide preliminary guidelines for other studies related to the quality of similar OSS projects.

VI. CONCLUSION

The objective of this research was to analyze the comments associated with the Eclipse and Qt projects as part of the code review process. The analytical results suggest that the number of changes based on maintainability is moderate. This result can improve the awareness of software developers regarding the importance of code modification related to maintainability. Moreover, the empirical data in this research can benefit source code improvements made by software developer communities in OSS projects. Additionally, the code review trends illustrated in this study can improve decision-making processes among software developers of OSS projects, who should prioritize software maintainability. In addition, these developers should be ready to perform code editing in situations or environments that may change in the future.

Although the results of this research provide only basic conclusions, the existing information is sufficient for guiding the development and improvement of OSS quality. Moreover, the findings can be used by researchers who are interested in software maintainability to study related topics, such as plug-in development, using Gerrit. This comment-related approach could improve code modification and extend beyond maintainability to other topics, such as readability and testability. Additionally, tools or processes could be developed to assess the edits of software developers in OSS projects according to reviewer comments in Gerrit. If such a script or program was developed to automatically check code edits in the Gerrit framework, the reviewers who provide the comments could be notified to facilitate better communication within the software development community and allow for faster subsequent reviews.

School of Computer, Science and Engineering, VIT-AP University
Andhra Pradesh^{1,2}

Abstract—Human activity recognition in aerial videos is an emerging research area. In this paper, an Inflated I3D-ConvNet (Inflated I3D) and Bidirectional Long Short-Term Memory (Bi-LSTM) based human action recognition model in UAV videos have been proposed. The initial module was pre-trained using the Kinetics-400 video dataset, which consisted of 400 classes of human activities and around 400 video clips for each class culled from real-world and arduous YouTube videos. The proposed inflated I3D-ConvNet which was built on 2D-ConvNet inflation learns and extracts spatio-temporal features from aerial video while leveraging the architectural design of Inception-V1. The proposed model employs Bi-LSTM architecture for human action classification on the Drone-Action dataset which is a smaller benchmark UAV-captured video dataset. This model considerably improves the state-of-the-art results in activity classification using the SoftMax classifier and retains an accuracy of about 98.4%.

Keywords—2D-ConvNet; Bi-LSTM; drone-action; inception-V1; inflated I3D-ConvNet; Kinetics-400

I. INTRODUCTION

Drone technology has advanced rapidly in recent decades. Unmanned aerial vehicles (UAVs), or drones, are proving very useful in areas that humans cannot reach or cannot reach quickly and effectively. Drone technology has much greater potential, scope, and size when used in a variety of settings, including businesses, governmental institutions, military installations, etc. They take little effort, energy, or time and can travel to even the most remote locations where fewer people are needed.

In the next generation of drones, the key characteristics of size, autonomy play, and propulsion are crucial. The type of drone is determined by the technologies used to operate it. Multirotor is the most prevalent type of drone extensively used by most of the professionals. Video surveillance, aerial photography, etc. are some of the multirotor drone applications. Multirotor is easy to manufacture and most economic to fly. With a multirotor, you can position and frame the camera more precisely for good aerial shots. The most popular and commonly used multirotor aircraft are quad-copters. Multirotors have many drawbacks such as limited speed, reduced endurance, and less flying time. With light cargo, the maximum flight time for a multirotor is 20 to 30 minutes. Due to this, multirotors are not appropriate for applications involving long-distance travel, inspection, or mapping.

Understanding how a human body is articulated in an image and identifying human movement in videos taken by these types of drones [1] is a challenging research problem. Sometimes in many situations such as those including visual

blur, perspective distortion, low-resolution scenes, occlusions, etc., it is highly challenging to discern human motions.

With the swift advancement of deep learning algorithms and neural network architectures, numerous great accomplishments have been made in image recognition tasks on various datasets [2], [3], [4]. The CNN model pre-trained on ImageNet [5] has already achieved significant performance in image recognition. The same methods can be adopted in the existing action recognition mainstream models for extracting temporal and spatial features from frames of RGB video and optical flow subsequently. Although great video-based action recognition performance can be attained, our research work discovered that pre-train on still image dataset ImageNet is not an optimal preference. Since still images differ from video sequences to a significant extent, the novel dataset known as Kinetics for human action recognition [6] was released. This dataset is appropriate for pre-training the architectures for video recognition. The outcome of the experiment [7] shows that every convolutional neural network architecture pre-trained on this dataset outperforms the architectures pre-trained on ImageNet. In action recognition, an important factor along with image recognition is sequence modeling. In sequence modeling problems, compared with RNN (Recurrent Neural Network) and unidirectional LSTM [8], bidirectional LSTM [9], [10], [11] is broadly used architecture because it can address the most resilient problems such as vanishing gradient and exploding gradient up to some extent.

The majority of existing techniques suffer from a high false alarm rate. Furthermore, while these techniques perform well on simple datasets, their performance is restricted when dealing with real-world scenarios. To address these issues, we present in this paper a robust and efficient model that learns visual features from a sequence of frames by integrating them as spatiotemporal information from raw video. The following are the key contributions of current work:

- For drone-based outdoor surveillance networks, we propose a reliable ConvNet-based sophisticated paradigm. For deep spatiotemporal feature extraction, we use a pre-trained inflated inception-V1 architecture, followed by a sequential learning method that outperforms state-of-the-art approaches in terms of accuracy.
- The proposed framework employs a multi-layer Bi-LSTM architecture. Because of the forward and backward passes applied at each layer of the LSTM model, this improves the capabilities of effective learning. As

a result, the final trained model is not limited to the data used for training, but it can also be used in video surveillance networks.

- In this paper, we proposed a novel network that combines the advantage of a sophisticated ConvNet feature extractor pre-trained on Kinetics and robust sequence modeling tools such as Bidirectional LSTM. Initially, like I3D Inception 3D-CNN [12], [13], [14] pre-trained on Kinetics is exercised as the feature extractor. Next, to capture high-level temporal features, the feature vectors created by I3D are input into a bidirectional LSTM network. Finally, to create useful predictions of these high-level features, a SoftMax classifier is used. We can train the network on an end-to-end basis.

The rest of the paper is structured into sections as follows: Section II presents the overview of the existing models for action recognition, Section III gives the problem definition, Section IV describes the proposed methodology, Section V reports the datasets adopted for the proposed work, experimental results, performance evaluation, comparison with the state-of-the-art models and discussion. Section VI concludes the proposed work. Section VII provides the future work. Finally, Section VII gives the acknowledgments.

II. LITERATURE SURVEY

A. 3D-ConvNet for spatio-temporal feature extraction

Since 3D-CNN was first introduced for action recognition tasks, it has always been a prevalent research method. Using this method, spatial and temporal data are directly extracted from raw surveillance video. C3D [15] is one more predominant research effort. Using a simple linear classifier on four main-stream benchmarks, C3D can outperform other algorithms by learning spatial-temporal properties from 3D-CNN. Recently, large-size datasets such as Kinetics and ActivityNet [16] have been introduced. After pre-training on a large video dataset, a few other works incorporating a 3D-CNN model outperform leading-edge models. Before 3D-CNN came into existence, due to its ability to directly extract spatial characteristics using 2D convolution, which is more effective and exact than creating features by hand, 2D-CNN models totally rule the image recognition domain.

The previous research study says that for the action recognition task, very deep 2D-CNN models can be outperformed by very shallow and Kinetics pre-trained 3D-CNN models to a great extent. A novel model called inflated I3D-ConvNet has been proposed that enhances kernels of inception module [17] such as convolution and pooling in GoogleNet [18] into 3D. In the UCF-101 dataset [19], this model has achieved maximum accuracy.

B. Bi-LSTM for Action Recognition

In sequential modeling tasks like human action recognition in videos, RNN is a very powerful and widely used network architecture. LSTM (Long Short-Term Memory) is an RNN-based network that is extensively used in video-based action recognition for learning motion features. This also can be used to prevent gradient explosion problems and gradient

vanishing problems up to some extent during the training process. Another research work [20] has suggested a video as an ordered sequence based on LSTM architecture. In this, the underlying CNN network generates the output features which are fed to the LSTM network yielding an exceptional performance in the UCF-101 dataset. Another model LRCN [21] is very broad in both spatial & temporal dimensions. In this, we utilized CNN for spatial feature learning and LSTM for temporal feature learning. Also, the LRCN model has different input and output lengths.

Bidirectional RNNs are initially addressed in [22], later for speech recognition tasks, the work [23] has been proposed by using the bidirectional RNN to outperform the unidirectional RNN. Next, bidirectional LSTMs were introduced to predict frame-wise phoneme classification [24], network-wide traffic speed [25], etc. In terms of prediction bidirectional LSTMs give good results than unidirectional LSTMs. In various tasks involving videos like object segmentation in video [26], video-super resolution [27], fine-grained action detection [28] and spatio-temporal feature learning for gesture recognition [29] bidirectional LSTM architecture has been leveraged. Another research work [30] extends the idea of coupling the convolutional module with the RNN module. This architecture leverages the element-wise max pooling and BiConvLSTM and includes the temporal encoding in forward temporal directions and backward temporal directions as well because in most heterogeneous datasets accessing the forthcoming details from the present state is very much advantageous for accurate predictions.

CNNs are capable of extracting local features whereas Bi-LSTMs are very good at handling long-term dependencies. Unlike LSTMs (which utilize only past information), when complete time-series sequence data is at hand Bi-LSTMs make use of both past and future information which permits the network to make more accurate predictions. In sequential data, to capture the different temporal local dependencies, this model employs different sizes of convolutional kernels. Datasets such as WISDM, UCI-HAR, and PAMAP2 are adopted to calculate the performance of the proposed multiple human activities identification model. Merits and demerits of the existing research works are described in the below Table I.

It is possible to reach a conclusion by utilising some of the constraints and potential improvements learned from previous research. Existing approaches were insufficiently effective. This is primarily due to the algorithm's complexity and potential. Our proposed approach is used to fill gaps in the existing scientific literature. For this, we introduced a novel model named I3D-BiLSTM that employs inflated I3D-CNN pre-trained on the Kinetics dataset and bidirectional LSTM architectures for learning spatio-temporal features of adjacent video frames. This approach achieved considerably highest performance in terms of accuracy compared to existing works.

III. PROBLEM DEFINITION

Human activity recognition in a fixed camera-based surveillance system is relatively one of the well-studied areas of interest whereas human activity recognition in UAV-based surveillance systems is comparatively less studied [31], [32], [33]. This area of research has drawn a great deal of attention

TABLE I. MERITS AND DEMERITS OF RELATED WORKS

Method	Dataset	Merits	Demerits
C3D [15]	UCF-101	Effective approach for spatiotemporal feature learning using deep 3D ConvNets	Achieved less accuracy
ActivityNet [16]	ActivityNet	Provides largescale video benchmark for human activity understanding	Needs more categories and samples per category to unveil new challenges in understanding and recognizing human activities in present scenarios
Inception-v3 [17]	ILSVR 2012	Enhances the kernels of inception module such as convolutional and pooling in GoogleNet into 3D	Lack of verification of ensemble result on the test set as the test and validation set error tends to correlate very well
GoogleNet [18]	ILSVRC14	Improved utilization of the computing resources inside the network	Improvement needed in classification of groundtruth predictions
UCF-101 [19]	UCF-101	Large benchmark dataset consists of unconstrained videos	Less number of classes and categories, below baseline action recognition results
CNN+LSTM [20]	Sports-1M+ UCF-101	Yields good performance using CNN and LSTM for video classification	Deeper integration of the temporal sequence information into the CNNs is required
LRCN [21]	Flickr30k+ COCO2014	Achieved good results in CNN special learning and LSTM temporal feature learning with different input and output lengths	Needs more investigation on perceptual problems with time-varying visual input or sequential outputs

BiConvLSTM [30]	Hockey Fights+Movies+Violent Flows	Leverages the element-wise max pooling and BiConvLSTM, includes the temporal encoding in forward temporal directions and backward temporal directions for the detection of violence in videos	Further investigation is needed for the best results on more dynamic and heterogeneous datasets

in recent years as drones are becoming more popular and extremely beneficial in different applications such as military, agriculture, search and rescue, security monitoring systems, etc [34]. Human activity recognition in aerial videos is a challenging task because of various factors such as environmental background, camera motion, object distances and variety of cameras, longitude, the latitude of the UAV flight, etc. [35], [36], [37]. Another challenging task is human activity recognition in a video (sequence of frames) where each frame has different variations such as spatio-temporal features loss, background clutter, occlusion, low inter-class and high intra-class variances for some classes, background lighting change, image distortion, and a person pose variation [38], [39], [40], [41]. We need to develop a sophisticated model that addresses these issues and accurately classifies the human activities in UAV captured video datasets.

IV. PROPOSED METHODOLOGY

A. 3D-ConvNet

In the realm of computer vision, Convolutional Neural Network (CNN/ConvNet) is one of the well-known deep learning neural networks that can handle massive volumes of data in the early 1980s. It is a feed-forward neural network

with multiple layers that agglomerates many convolutional layers called grouping layers, hidden layers, and activation layers on top of each other in a particular order. This sequential design allows ConvNet to learn hierarchical attributes using the multi-layers of artificial neurons. An artificial neuron or perceptron is the function that evaluates the weighted sum of one or more inputs and passes this value to the non-linear function called the activation function which produces the output as an activation value.

Initially, 2D-ConvNet was pre-trained on ImageNet for image recognition. When an image is passed as an input to the 2D-ConvNet, it generates different activation functions that are directed to the next layers. During the convolution, a kernel/filter of fixed size should be applied to the input image to obtain convolved features. The initial layer extracts primitive information such as diagonal or horizontal edges. The next layer takes hold of the output from the previous layer and extracts more intricate features such as amalgamated edges or corners. Hence, the deeper layers of the network can extract even more complex features such as faces, objects, etc. The terminal convolutional layer generates the activation map. Based on this, the confidence score (between 0 and 1) will be produced by the classification layer to classify the image. 2D-ConvNet architectures pre-trained on ImageNet and other

datasets failed to recognize the objects in the images or videos which are having different angles and different illumination conditions. Later on, Carreira and Zisserman introduced a new 3D-ConvNet architecture pre-trained on Kinetics for human action recognition to extract spatio-temporal features in videos.

In this work, we proposed a novel architecture shown in Fig. 1 where each short video clip classification is treated as an action recognition problem. For this subject, 3D-CNN has traditionally been a popular strategy for facilitating spatio-temporal learning. A substantial amount of training data is often required to train a 3D-CNN from scratch. Carreira and Zisserman introduced a new model that inflates a pre-trained 2D-CNN on ImageNet architecture along the temporal dimension to produce an inflated I3D-ConvNet. They used the Kinetics human action dataset to train the inflated I3D-ConvNet to address the action recognition challenge. Based on their work, we exercised Inception-v1 I3D for our challenge and fine-tune it on our Drone-Action dataset [42]. In this paper, we have chosen the pre-trained weights of the RGB stream as the initial weights are publicly accessible for Inception-v1 I3D.

In this model architecture, we manifested the evolution of 3D-ConvNet from ImageNet-based 2D-ConvNet architecture. Like standard conventional networks, 3D-ConvNet is a natural video modeling approach with spatio-temporal filters explored previously in [43], [44], [45]. Inflating 2D-ConvNets into 3D implies converting successful image classification models such as deep 2D-ConvNets into 3D-ConvNets by inflating all the filters and pooling kernels of size 'n × n' into 'n × n × n' with a supplementary temporal dimension. One important characteristic of these models is that they precisely generate hierarchical illustrations of the spatio-temporal data. Compared to 2D-ConvNet, it has many parameters due to the added kernel dimension, which makes training very difficult but results have proven that they have produced promising results for evaluation on the larger benchmark dataset (e.g. Kinetics). Fig. 2 depicts the feature extraction process for an inflated I3D-ConvNet architecture.

We used a modest modification of C3D for this research, which contains 14 convolutional layers, 27 BatchNormalization layers, 27 ReLU layers, 13 DepthwiseConv layers, 4 ZeroPadding layers, one GlobalAveragePooling layer, and A top layer with 4 fully connected layers. As in the original version, short clips of 244 × 244 pixels each with a crop of 112 × 112 pixels make up the model's inputs. After all convolutions and completely connected layers, we used batch normalization. Another variation of the original model is, that instead of using a temporal stride of 1 stride 2 is used. This moderates the memory usage and permits greater batch sizes. When fully connected layers without weight bindings have been constructed, batch normalization is very crucial at this stage.

B. LSTM

Long Short-Term Memory (LSTM) deep learning architecture was first developed by Hochreiter and Schmidhuber in 1997. It is a gated Recurrent Neural Network (RNN) architecture. RNN network works on the present input by considering the previous output as feedback and stores the information in its memory for future prediction. Unlike RNN, it is capable

of handling long-term dependencies. LSTM networks address the following issues that RNN fails to solve:

- Preserving the information for a long period or handling long-term dependencies to predict the current output.
- Fine control over carrying forward the important information and forgetting the unnecessary past information.
- Removal of exploding and vanishing gradient problem which occurs during the network's training phase, backtracking is used to reduce loss and achieve the best outcomes.

C. LSTM Architecture

LSTM works very similar to RNN but it has a key feature that differs it from RNN that is it preserves information for a long period for future cell processing. Three gates make up an LSTM cell: Forget gate, Input gate, and Output gate. The internal process of an LSTM cell is depicted in the following Fig. 3:

It has a memory pool that has two key vectors of states.

- 1) Short-term state: It is also known as a hidden state. This state keeps the output at the current time step. The short-term state of the previous timestamp is represented with S_{t-1} and the current timestamp is S_t .
- 2) Long-term state (L_{t-1}): It is also known as the cell state. This state reads and rejects the information while passing through the network which is meant for long-term storage. The long-term state of the previous timestamp is represented with L_{t-1} and the current timestamp is L_t .

Here, the cell state contains all timestamps and information as well. As depicted in the figure, the decision of reading, writing, and storing depends on the activation functions whose outputs are in between (0, 1).

1) *Forget gate*: This is the first state in the cell of the LSTM network. This gate decides whether to store the information of the previous timestamp or forget it. The Forget gate Eq. (1) is as follows:

$$F_t = \sigma(C_t * U_f + S_{t-1} * W_f) \quad (1)$$

Where,

- C_t = Current timestamp t input,
- U_f = Weight connected with the input,
- S_{t-1} = Previous timestamp's short-term state or hidden state,
- W_f = The weight matrix for the short-term state.

Next, the activation function i.e. the *sigmoid* function is applied to it which gives the value of f_t in between (0, 1). It is then multiplied by the previous timestamp's long-term state, as shown in the calculations below by using Eq. (2) and (3).

$$L_{t-1} * f_t = 0, \quad \text{if } f_t = 0 \quad (2)$$

Fig. 1. Framework of the proposed Inflated I3D-ConvNet-BiLSTM for action recognition

Fig. 2. The feature extraction workflow of Inflated I3D-ConvNet architecture

$$L_{t-1} * f_t = L_{t-1}, \quad \text{if } f_t = 1 \quad (3)$$

If the f_t value is 0 it forgets everything, otherwise, it forgets nothing.

2) *Input gate*: This is employed to manage the input value flow and quantifies the importance of the latest information in the cell. The Input gate Eq. (4) is as follows:

$$I_t = \sigma(C_t * U_i + S_{t-1} * W_i) \quad (4)$$

Where,

- C_t = Current timestamp t input,
- U_i = Matrix of weights associated with the input,
- S_{t-1} = Previous timestamp's short-term state or hidden state,
- W_i = The weight matrix for the short-term state.

Next, the activation function is then subjected to the *sigmoid* function, resulting in the value of 'I' at timestamp 't'. The value lies between (0, 1).

In LSTM, the latest information also known as new infor-

Fig. 3. Long short-term memory architecture

mation in Input Gate is used to update the long-term state.

Latest Information (or New Information):

$$N_t = \tanh(C_t * U_c + S_{t-1} * W_c) \quad (5)$$

This latest information shown in Eq. (5) is a function of the short-term state at the previous timestamp 't-1' & input 'C' at the timestamp 't'. This information is necessary to pass it through the long-term state. After the activation function, \tanh is applied over it, therefore the value of the latest information lies between (-1, 1).

If N_t is negative, this information is subtracted from the long-term state; if N_t is positive, this information is added to the long-term state at the current timestamp. The following Eq. (6) is an updated equation to add N_t to the long-term state.

$$L_t = F_t * L_{t-1} + I_t * N_t \quad (6)$$

Where L_{t-1} represents the long-term state at the current timestamp and others represent previously determined values.

3) **Output gate:** This is used to control the cell utilization for calculating the output activation of the LSTM unit and is used to determine the generation of the output from the current internal long-term state to the next short-term state. The Output gate Eq. (7) is as follows:

$$O_t = \sigma(C_t * U_o + S_{t-1} * W_o) \quad (7)$$

This equation is similar to Forget gate and Input gate. The output value of this equation lies between 0 and 1 when the *sigmoid* activation function is applied to it.

Next, the following Eq. (8) will be used to compute the current short-term state O_t and \tanh of the updated long-term state:

$$H_t = O_t * \tanh(L_t) \quad (8)$$

That is, the short-term state is the function of present output and \tanh of the long-term state. Then apply the SoftMax activation function to the short-term state L_t to get the output of the present timestamp using the following Eq. (9):

$$Output = SoftMax(S_t) \quad (9)$$

In this, the token with the highest score in the output is the prediction.

D. Bidirectional LSTM

Bidirectional LSTM or Bi-LSTM is an extension of the LSTM model. Bi-LSTMs, unlike baseline LSTMs (trains a model in unidirectional i.e., forward direction and use only past information), train the model in two directions called forward direction and backward direction as depicted in the following Fig. 4.

In the forward direction, the model learns a sequence of inputs from past to future whereas in the backward direction model learns from future to past when the complete sequence of time-series data is available. This denotes that the calculation of the output frame at timestamp 't' depends on the preceding frame at time 't-1' and the subsequent frame at time 't+1' because it performs processing in both directions.

This approach uses two hidden states, one for the forward pass and another for the backward pass, to preserve the past and future information. To enable the network to make more accurate predictions, these states should be combined

and this mechanism is called merging. This can be achieved through the functions called sum, averaging, multiplication, and concatenation. Among these functions concatenation is the default mechanism.

Fig. 4. Bidirectional LSTM architecture

V. EXPERIMENTAL RESULTS AND DISCUSSION

First, we briefly described the datasets that are utilized to evaluate the models in this segment. Secondly, we provided the classification outcomes after implementing the Inflated I3D-ConvNet model with Bi-LSTM for recognizing human actions. In the performance evaluation section, charts of model accuracy and loss are provided. We finally reported the comparison results of existing models with the proposed model in the following section. All these experiments are performed on the anaconda platform.

A. Overview of the Datasets

1) *Kinetics-400*: The below Table II presents an overview of the Kinetics-400 dataset.

TABLE II. SUMMARY OF KINETICS-400 DATASET

Feature	Value
Actions	400
Clips per class	min 400
Total clips	306,245
Repetitions per clips	3-5
Each clip length	10 Sec

In this paper, we used a human action video dataset called Kinetics-400. It contains 400 human action classes, with at least 400 video clips per action, each clip lasting 10 seconds, for a total of 306,245 videos. Each clip in this dataset is retrieved by first searching YouTube for suggestions and then using AMT (Amazon Mechanical Turkers) to determine if the clip contains an action. At least three or more out of five confirmations were needed to accept the clip. Next, we ran de-duplication on the dataset and verified that the clips were retrieved from each video and that the clips did not share common video footage. Finally, the noise reduction and overlap of the class were reviewed.

Rather than activities or events, the dataset is focused on a broad range of classes and human actions. Some of the human actions are drinking, drawing, pumping fist, laughing, etc., human-human actions such as shaking hands, hugging, kissing, etc., as well as human-object actions such as washing dishes, opening a present, mowing the lawn, etc.

Some actions in the Kinetics-400 dataset are fine-grained and require emphasis on an object to categorize, e.g., playing various kinds of wind instruments. Some other actions require temporal reasoning to categorize e.g., various kinds of swimming. There are also different Parent-Child groupings like Personal Hygiene (cutting nails, washing hands, Brushing teeth, ...), Music (trombone, playing drums, violin, ...), Cooking (peeling, frying, cooking, ...), Dancing (macarena, ballet, tap, ...), etc.

2) *Drone-Action*: The dataset consists of 13 actions, each action having 10-20 clips, a total of 240 clips, and 66919 frames. All videos in the dataset were delivered in HD format (1920 × 1080 resolution) and recorded at 25 fps, with an average duration of 11.15 seconds for each action. Midway through a wheat field, actions were recorded on an unsettled road while the hover and follow modes were active. The actions were divided into three categories called following, side-view, and front-view based on the camera movement and the viewpoint. The video recording camera was 10 MP, A 3DR SOLO rotor-craft served as the unmanned aerial vehicle, and the camera was a GoPro HERO 4 Black with 5.4 mm, IR CUT anti-fish eye replacement, and a 3-axis Solo gimbal. The flight ended between 8 and 12 metres low altitude and was slow. The following Table III provides an overview of the Drone-Action dataset.

TABLE III. SUMMARY OF DRONE-ACTION DATASET

Feature	Value
Actions	13
Actors	min 10
Clips	240
Clips per class	10-20
Repetitions per class	5-10
Mean clip length	11.15 Sec
Total duration	44.6 min
Frames	66919
Frame rate	25 fps
Resolution	1920 × 1080
Camera motion	Yes (hover and follow)
Annotation	Bounding box

In this research work, out of 13 action classes, only 5 classes [clapping, waving hands, walking (front, back, left, right), jogging (front, back, left, right), running (front, back, left, right)] with a minimum of 20 video clips for each action class and an average duration of 11.15 seconds for each action were utilized for classification of human actions.

B. Results

Initially, to make your I3D-ConvNet network a strong feature extractor, pre-train it with the Kinetics-400 video dataset. Referring to the RGB I3D model [12] and using the open-source I3D model, we attempt to emulate the results to achieve

97.6% accuracy on the Drone-Action dataset with RGB modality. With reference to the previous work, to represent high-level temporal features, we integrated the Bi-LSTM network with I3D and used the Drone-Action dataset to validate the proposed model and attempt to obtain an accuracy of 98.4% which outperforms the other mainstream models and also the original I3D model.

Below Table IV provides instances of sequences that correlate to various types of actions and scenarios in the Drone-Action dataset and Table V shows some of the sample results with a percentage of accuracy after validating the model using the Drone-Action dataset.

C. Performance Evaluation

The evaluation measure we have chosen for this experiment was accuracy. The action classifier returns scores based on this the accuracy was evaluated. The Drone-Action dataset was divided into train-to-test split sets. Each train-to-test split set was randomly generated at a ratio of 70:30.

The two measures which we considered to assess the proposed model’s accuracy trained on Kinetics-400 are as follows:

- Firstly, freeze the network weights and utilize it to generate features for the Drone-Action video dataset, and then train the SoftMax classifier for the Drone-Action dataset classes that use train data to evaluate a test set.
- Secondly, fine-tune the network for classes of the Drone-Action dataset by utilizing its training data and re-evaluating its test sets.

This clearly says that the proposed inflated I3D-ConvNet architecture with Bi-LSTM perks from pre-training on the Kinetics-400 dataset and also after pre-training on the Kinetics dataset training only the model’s last layers yield much better performance. The proposed model’s model accuracy and model loss per epoch is depicted in the Fig. 5.

1) *Comparison with classical models:* We compare the performance of I3D models to earlier classical approaches in Table VI, on HMDB-51 & UCF-101 datasets and the bar chart of the various model’s average accuracies is shown in the following Fig. 6. We provide the findings while pre-training on miniKinetics and the complete Kinetics dataset.

D. Discussion

All activities were correctly recognised with a high classification performance using the proposed approach. The bidirectional LSTM ability to use past and future inferences in the signal allows for accurate differentiation of the dynamic activities like clapping, jogging, wavinghands, running, walking.

The results of this work are comparable to the best related works using the same datasets. In contrast to earlier 3D-ConvNets (C3D) models, Kinetics’ pre-trained I3D models

(a) Model accuracy

(b) Model loss

Fig. 5. Performance of the proposed model

Fig. 6. Bar chart of the average accuracies of the various models

demonstrate a far higher difference. This could be due to Kinetics higher quality, but it could also be due to I3D’s superior architecture. The I3D RGB stream on HMDB-51 improves after switching from miniKinetics to Kinetics pre-training, indicating that 3D-ConvNets may permit a massive volumes of information to understand robust motion characteristics. The two streams achieve equal performance after Kinetics pre-

TABLE VI. COMPARISON WITH CLASSICAL MODELS AVERAGED OVER THREE TRAIN/TEST SPLITS ON HMDB-51 & UCF-101 DATASETS

Model	HMDB-51	UCF-101
RGB-I3D, miniKinetics pre-trained	66.4%	91.8%
RGB-I3D, Kinetics pre-trained	74.5%	95.4%
Flow-I3D, miniKinetics pre-trained	72.4%	94.7%
Flow-I3D, Kinetics pre-trained	74.6%	95.4%
Two-Stream I3D, miniKinetics pre-trained	76.3%	96.9%
Two-Stream I3D, Kinetics pre-trained	80.2%	97.9%
Inflated I3D-ConvNet + Bi-LSTM, Kinetics pre-trained	88.9%	98.2%

training, but they're still good together. When their predictions are averaged, the results range from 74.6% to 80.2%.

The average accuracy over the three common train/test splits was used to compare our techniques. When pre-trained on Kinetics, a model from our RGB-I3D or RGB-Flow lineup outperforms any model combination or any previously published performance by any model. Our proposed model significantly improves on previous models, bringing overall performance to 88.9% on HMDB-51 and 98.2% on UCF-101 respectively.

VI. CONCLUSION

In this paper, we introduced a new architecture known as inflated I3D-ConvNet with Bi-LSTM pre-trained on the Kinetics-400 video dataset. First, on the Kinetics-400 dataset, we initially model the low-level features of successive frames using a pre-trained I3D model, and then we learn high-level special features using a Bi-LSTM network. The leading performance of inflated I3D-ConvNet pre-trained on the Kinetics-400 video dataset also corroborates that this novel model is more advanced and efficient than other mainstream models. The proposed model can serve as an alternative solution to the data loss and long-term dependency problems that arise as the training data size increases. This architecture uses various convolutional filter sizes by capturing different local dependencies to enhance feature extraction and also can able to classify simple activities like waving hands, walking, clapping, jogging, and running with outstanding accuracy. The suggested model uses the inflated process as a domain adaptation job for 3D-ConvNets, and the input structure of split video segments outperforms the standard sequential input structure.

VII. FUTURE WORK

In the proposed model we utilized Kinetics-400 large-scale and high-quality video dataset which includes 400 human action classes for pre-training the architecture. As a future plan, we plan to rerun all the experiments using other benchmark datasets such as Kinetics-600 and Kinetics-700 that cover 600 & 700 human action classes consequently with and without pre-training, explore inflating operation on 3D-ConvNets and also examine the efficacy of implementing our inflated I3D-ConvNets into two and three-stream architectures.

ACKNOWLEDGMENTS

We would like to extend our profound gratitude and sincere appreciation to everyone on the Kinetics dataset project, especially Tim Green and Brain Zhang for creating data that

can be used for experiments and also we would like to express our profound gratitude to Asanka G.Perera, Yee Wei Law and Javean Chahl for sharing Drone-Action dataset for our experiments.

Abstract—Public opinion is important for decision-making on numerous occasions for national growth in democratic countries like Bangladesh, the USA, and India. Sentiment analysis is a technique used to determine the polarity of opinions expressed in a text. The more complex stage of sentiment analysis is known as Aspect-Based Sentiment Analysis (ABSA), where it is possible to ascertain both the actual topics being discussed by the speakers as well as the polarity of each opinion. Nowadays, people leave comments on a variety of websites, including social networking sites, online news sources, and even YouTube video comment sections, on a wide range of topics. ABSA can play a significant role in utilizing these comments for a variety of objectives, including academic, commercial, and socioeconomic development. In English and many other popular European languages, there are many datasets for ABSA, but the Bengali language has very few of them. As a result, ABSA research on Bengali is relatively rare. In this paper, we present a Bengali dataset that has been manually annotated with five aspects and their corresponding sentiment. A baseline evaluation was also carried out using the Bidirectional Encoder Representations from Transformers (BERT) model, with 97% aspect detection accuracy and 77% sentiment classification accuracy. For aspect detection, the F1-score was 0.97 and for sentiment classification, it was 0.77.

Keywords—Sentiment analysis; Bengali sentiment analysis; Aspect-Based Sentiment Analysis (ABSA); Bengali ABSA; deep learning; Bidirectional Encoder Representations from Transformers (BERT)

I. INTRODUCTION

Online communication has grown extremely prevalent all around the world due to the internet. Social media is used by about 51% of the world's population overall. They use social media on a daily basis for an average of 2.5 hours [1]. Social media platforms, for example, Twitter and Facebook have made it simple to convey comments. Online newspapers have replaced traditional newspapers, and readers now even share their opinions about many news stories in the news portal's comment section. People express their perspectives and ideas on a wide range of topics, including politics, business, and international issues. As a result, a significant volume of data is created daily and contains many insightful opinions on a variety of subjects on those online sites. For many widespread applications, it's vital to comprehend opinions from user comments. For instance, the quality of goods or services can be improved by studying client feedback from comments on e-commerce sites. Also, People frequently voice

their opinions on many national issues in democratic nations like Bangladesh, India, USA on social media or news websites, which must be taken into consideration for a country's development. Studying all the text manually and trying to understand what the individuals are feeling is difficult. So, all of this data must be automatically studied to provide useful information as it is quite beneficial to understand the viewpoints of the general public on a particular topic. ABSA is a popular method for obtaining such useful data.

Sentiment analysis, often referred to as opinion mining, is a technique for determining if a given expression is negative, positive, or indifferent. There are three layers of sentiment analysis to consider, the first one to evaluate is the document level, the second is the sentence level, and the third is the level for aspect. At document level, the text is analyzed to see if it has a favorable or unfavorable sentiment. The polarity of every sentence is determined by sentence level. These two layers of analysis don't indicate what people liked and didn't like in particular. This shortcoming of earlier layers is resolved by the third layer. Sentiment analysis is known as ABSA on the aspect label. The main objective of ABSA is to find out the correlation of a piece of text with a set of aspects and deduce their sentimental polarities in the process. The most comprehensive version for document-level SA to retrieve key information is ABSA. ABSA consists of two key tasks. 1) Extricating the specific aspects addressed in the text. 2) For each aspect, identify the sentiment's polarity [2]. For example, "The fabric has decent quality, but the price is excessive." This evaluation focuses on two factors: 'price' and 'fabric'. 'Positive' feeling is indicated with the 'price' aspect, whereas a 'negative' feeling is shown with the 'fabric' aspect. Aspect categories are stated specifically inside this review. However, reviews can be implicit at times. For instance, "I asked the waiter three times for tomato sauce, but he didn't bring any". The implicit aspect here is a restaurant's 'service'.

Bengali is spoken by around 226 million people worldwide, with a large proportion of them using the internet [3]. There are very few ABSA datasets available in Bengali language. Not many Bengali-based ABSA works are available, to the extent that we are aware, and the insufficiency of Bengali ABSA datasets is one of the key barriers to the development of Bengali ABSA. The present Bengali ABSA research is based on a variety of deep learning and machine learning strategies, for instance: Support Vector Machine (SVM), Random Forest (RF), and Convolutional Neural Network (CNN). BERT is

well-known for resolving many shortcomings of these machine learning and deep learning techniques. In a self-supervised fashion BERT learns the language model by utilizing Transformer's encoder. But to the best of our knowledge, BERT was never used in any prior ABSA works for Bengali text.

As we previously discussed, there isn't much research done on ABSA in Bengali. We committed our work to the Bengali language by making the following contributions:

- For implementing ABSA in Bengali text, we collected heterogeneous Bengali data from news portals, YouTube channels and comments from social media.
- We annotated the collected dataset in five aspects: Technology, Corruption, Economy, Politics, and Sports, and three sentiment categories: Neutral, Positive, and Negative.
- We performed aspect detection and sentiment classification using our dataset by implementing BERT, which provided the best performance in terms of Bengali ABSA to the best of our knowledge.

The paper is organized as follows. The literature review is covered in Section II, and the research procedures for our experiment are described in Section III. We present and analyze the experimental results in Section IV. Finally, Section V provides the conclusion along with potential future directions.

II. LITERATURE REVIEW

A fast-growing and improving sub-field of Natural Language Processing (NLP) is sentiment analysis. Subramaniam *et al.* conducted a sentiment analysis-based survey in their research [4]. They studied the IMDB dataset and observed that sequence neural models had the best results, but they come at a high cost in terms of classifier complexity. By comparison, CNN had a preferable performance with less complexity over models of sequence neural. YouTube videos were used for a study on sentiment analysis by Alhujaili *et al.* in their research work [5]. The development of sentiment analysis is being accelerated by cutting-edge deep learning techniques like LSTM and BERT. Althobaiti suggested an automated technique for extracting coarse-grained hate speech and offensive language from Arabic tweets [6]. BERT was contrasted with two traditional machine learning methods SVM and Logistic Regression (LR). Along with the textual content of the tweets, the use of sentiments and text-based emoji descriptions was also looked at. They had an F1-score of 84.3% for offensive language detection, 81.8% for hate speech detection, and 45.1% for fine-grained hate-speech recognition by applying BERT. BERT was used by Nijhawan *et al.* for sentiment classification in their research [8]. Experiments revealed that, despite its comparatively simpler structure, the BERT model outperforms many prominent models in this subject.

The majority of Bengali sentiment analysis works are based solely on determining the text's polarity. Recurrent Neural Network (RNN) with Long Short-term Memory (LSTM) was used to analyze sentiment in Bengali data to avoid long-term reliance by Ahmed *et al.* [3]. Demonstration of the benefits of tuned hyper-parameter and how it can aid sentiment analysis on a dataset was given in their paper. An attention-based CNN algorithm was proposed by Basri *et al.* for analyzing sentiment

on the Bang-lish Disclosure in their paper [10]. Islam *et al.* introduced two fresh datasets for sentiment analysis in Bengali in their research that was manually tagged [11]. *BERT_{BSA}*, which is a deep learning method of sentiment analysis for the Bengali language that surpassed all the previous models, was also introduced in their research.

ABSA was first discussed as a chapter in Liu, B.'s research paper. There were discussions of ABSA's methods and related issues [12]. The goal of SemEval2014's Task 4 was to advance the field of ABSA. Pontiki *et al.* developed and published benchmark datasets for ABSA with manually labeled reviews from the restaurant and laptop sectors [13]. Four subtasks, Aspect term extraction, Aspect category detection, Aspect term polarity, and Aspect category polarity—were used to analyze the 163 entries from 32 teams. Karimi *et al.* research on adversarial training in ABSA was discussed in their paper [14]. The studies with the proposed architecture show that using adversarial instances during network training enhances the efficiency of the common purpose BERT, while BERT which is in-domain and post-trained, brought better results for feature extraction and sentiment classification. Suciati *et al.* suggested a methodology to ensemble aspect extraction focused on Part-of-speech (POS) tagging, dependency parsing, and dense neural networks [7]. They found that deep learning integrated with conventional methods can yield better outcomes than lexicon-based approaches. The aspect-agnostic issue, which is pervasive in the context modeling of ABSA, was identified and discussed by Xing *et al.* [9]. They claimed that during context modeling, the semantics of the provided aspect should be taken into account as a new indication outside the context. In order to produce the aspect-aware masked states specifically designed for the ABSA work, they presented context encoders that are aspect-aware, such as Aspect-Aware BERTs (AABERTs), Aspect-Aware Graph Convolutional Networks (AAGCN), and Aspect-Aware LSTM (AALSTM).

Rahman *et al.* constructed two freely accessible datasets, 'Cricket' and 'Restaurant', to be used for the ABSA in Bangla, which function as a benchmark for the Bangla ABSA field [15]. It was the first ABSA work in Bengali. Customer reviews of restaurants make up one of the datasets, while manually labeled user comments on cricket make up the other. 2900 comments about cricket in five aspect categories are included in the 'Cricket' dataset, while 2600 restaurant reviews are included in the 'Restaurant' dataset. They designed an aspect category extraction model which is based on CNN architecture in the same year [2]. They used their suggested datasets [15] to compare their model with well-known machine learning techniques. For the 'Cricket' dataset, they achieved 51% F1-Score while KNN, SVM, and RF classification only achieved 35%, 34%, and 37% accuracy, accordingly. For the 'Restaurant' dataset, KNN, SVM, and RF classification achieved 42%, 38%, and 38% F1-Score, respectively, while CNN outperformed them with 64% F1-Score. In [16], Boidini implemented three stacked Auto-encoders (AEs) models based on the datasets from [15] to categorize aspects in the Bengali text. The stacking network's layers were individually trained to comprehend the encoded data of the layer that came before them. The three layers that were trained in a stacked manner were AE, Sparse AE (SAE), and Contractive AE (CAE). In comparison to the studies of Rahman *et al.* [2,15], all of the suggested models exhibit improved precision, F1 score, and

recall. The CAE model especially generated the best F1-score on the ‘Restaurant’ and ‘Cricket’ datasets with 0.87 and 0.91 respectively. Based on the dataset provided by Rahman *et al.* [15], Haque *et al.* constructed the Bangla ABSA model [17]. The traditional supervised aspect classification machine learning approach was employed in this work with minimal preprocessing. They observed that if the data is less pre-processed, then the result has a higher F1 Score. To perform aspect extraction on the dataset provided by Rahman *et al.* [15], F.A. Naim presented a novel technique called PSPWA (Priority Sentence Part Weight Assignment) [1]. PSPWA is a phase of the data pre-processing process that leads to better performance. CNN and traditional supervised learning methods were utilized to show the performance. Compared to other learning algorithms, CNN performed best. CNN’s F1-score for the ‘Cricket’ dataset was 0.59, and for the ‘Restaurant’ dataset it was 0.67.

The summary of this literature review is presented in Table I.

TABLE I. SUMMARY OF LITERATURE REVIEW

Author	Year	Dataset	Used Method	Result
Ahmed <i>et al.</i> [3]	2020	Prothom Alo, Cricket [15], etc.	LSTM	94%
Subramaniam <i>et al.</i> [4]	2021	IMDB dataset	RNN,CNN-LSTM, etc.	CNN-LSTM: 96%
Althobaiti [6]	2022	Data set from [20]	LR, SVM, BERT	Offensive language: 84.3%, Hate speech: 81.8%, Fine-grained hate speech: 45.1%
Suciati <i>et al.</i> [7]	2020	from PergiKuliner platform	SVM, LR, DT,ET	Food:GRU: 88.16%, BiLSTM: 88.16% Price:RF: 89.54%, Service: BiLSTM: 89.03% Ambience: BiLSTM: 84.78%
Nijhawan <i>et al.</i> [8]	2022	100042 tweets	RF,DT, LR,BERT	97.78%
Basri <i>et al.</i> [10]	2021	Dataset with 5000 short paragraphs	Attention -based CNN	Funny sentiment: 90% Multiclass data: 83%
Islam <i>et al.</i> [11]	2020	Prothom alo	Multi-lingual BERT	3-class: 60% 2-class: 71%
Pontiki <i>et al.</i> [13]	2014	Restaurant and laptop sectors reviews	CRF with features extracted	Laptop: 74.55% Restaurant: 84.01%
Karimi <i>et al.</i> [14]	2020	SemEval-2016, SemEval-2014	BERT	Laptop: 85.57% Restaurant: 81.50%
Bodini <i>et al.</i> [16]	2019	Cricket Restaurant [15]	AE, SAE, CAE	Cricket- CAE: 0.88 Restaurant- CAE: 0.87
Naim <i>et al.</i> [1]	2021	Cricket Restaurant [15]	CNN, RF, SVM etc.	Cricket-CNN: 0.59, RF: 0.41 Restaurant- CNN: 0.67, RF: 0.35
Haque <i>et al.</i> [17]	2020	Cricket Restaurant [15]	SVM, RF, LR etc.	Cricket- SVM: 0.35, RF: 0.37 Restaurant- LR: 0.43, RF: 0.35
Rahman <i>et al.</i> [2]	2018	Cricket Restaurant [15]	CNN, RF, SVM etc.	Cricket-CNN: 0.51, RF: 0.37 Restaurant- CNN: 0.64, RF: 0.38

III. METHODOLOGY

This work can be divided into two subtasks: determining a Bengali sentence’s aspect and identifying sentiments. For the first subtask, five aspects can be defined: Technology, Corruption, Sports, Politics, and Economy. As for the second subtask, there will be three sentiment categories: Positive,

Neutral, and Negative. BERT was used for both subtasks due to its exceptional features and efficiency. We began by collecting data, then labeled it and cleaned the dataset by removing stop words, punctuations, and decimal values. Following that, we preprocessed the dataset using tokenization and special token addition because BERT requires the data in a specific format. The training dataset was then fed into the BERT model, and the model was tested using the test dataset. Other deep learning models, such as CNN, Bidirectional LSTM (BiLSTM), LSTM, RNN and Gated Recurrent Unit (GRU) models, were also built, trained, and tested on our dataset to cross-validate the BERT model’s results. Our model’s performance is evaluated using a variety of performance metrics. The process as a whole is depicted in Fig. 1 below.

Fig. 1. Aspect-based sentiment analysis process

A. Data Collection

The dataset is a critical component of a machine learning algorithm since it determines the outcome based on its size and quality. Data was collected from social media, news portals, and Youtube comments of Bangladeshi users on five topics: Technology, Corruption, Sports, Politics, and Economy. The comments were stored in a Microsoft excel file.

B. Data Labeling

Some multi-lined sentences were simplified to single sentences by removing unnecessary sentences manually. Following that, 10042 sentences were left to be labeled. After that each author individually annotated the dataset. Each sentence was assigned to one of the five aspect categories—technology, corruption, sports, politics, and the economy—and was then annotated for sentiment polarity into three categories: positive, negative, and neutral. Each participant added an annotation to every comment. To figure out the ultimate aspect category and

the polarity of a statement, voting percentage was calculated. In the final dataset, there are three columns for 10042 annotated sentences. One is for text or comments, the second one is for aspect and the final one is for sentiment category. Fig. 2 contains a sample of our dataset.

Text	Category	Polarity
রক্তে রক্তে জড়িয়ে পড়েছে যে দেশে দুর্নীতি ও সুদ ঘুষ কিছুতেই জেন লাগাম টানা যাচ্ছেনা!!!!	Corruption	Negative
ইলিশ রন্ধানি করে প্রচুর বৈদেশিক মুদ্রা অর্জন করা সম্ভব হচ্ছে	Economy	Positive
দুর্নীতি দমন কমিশন ক্ষমতাবানদের বিরুদ্ধেও স্বাধীন তদন্ত করবে এমনই আমাদের প্রত্যাশা	Corruption	Positive
গ্রামে আমরা টাজি নেটওয়ার্কই তিকমতো পাইনা, তারা আবার আসছে ফোরজি নিয়ে। যত্নসব।	Technology	Negative
আওয়ামীলীগ জনগণের জন্য কাজ করে বলেই তারা সফল।	Politics	Positive
আর কোন দিন বাংলাদেশ ক্রিকেট দল জয় এর মুখ দেখবে না যত দিন পাপন সভাপতি থাকবে।	Sports	Negative

Fig. 2. Sample of the labeled dataset

The Zipf’s law was implemented in our dataset. According to Zipf’s Law, there should be an inverse relationship between the frequency of various words in the dataset and their positions [18]. Fig. 3 demonstrates how Zipf’s Law applies to our dataset. It suggests that the words in our dataset are not arbitrary.

Fig. 3. Word frequency of our dataset using Zipf’s law

Every effort was made for balancing the dataset, however for the chosen topics, people are more likely to comment on negative instances than positive ones, and comparatively less comments were without opinion. Because of this there are a few more negative comments with sentiment labeling and number of Neutral comments is comparatively less. As for the aspect labeling, all five aspects have nearly identical numbers of comments. Tables II and III display the dataset’s statistics for aspect labeling and sentiment labeling, respectively.

TABLE II. STATISTICS OF ASPECT LABELING

Aspect category	No. of data
Technology	2003
Economy	2011
Corruption	2001
Sports	2021
Politics	2006
Total	10042

TABLE III. STATISTICS OF SENTIMENT POLARITY LABELING

Sentiment polarity	No. of data
Positive	3507
Negative	3909
Neutral	2626
Total	10042

C. Data Cleaning

NLP relies significantly on data preparation. To adapt the machine learning algorithm to the Bengali data, data cleansing is necessary. To clean the dataset, a few procedures were used.

Step 1: The dataset was first changed to lowercase.

Step 2: Several unnecessary decimal digits appeared in the text. So, they were taken out.

Step 3: We eliminated all types of punctuation, extra characters, and components.

Step 4: Bengali stop words come in a variety of forms. These cause issues when the data was examined. Therefore, all stop terms from the dataset were eliminated using a corpus of Bengali stop-words.

Fig. 4 displays the flow chart for data cleaning.

Fig. 4. Flow chart for data cleaning

D. Data Preprocessing

Text preprocessing is an important step in achieving better accuracy in Natural language processing tasks. The dataset should be preprocessed in a particular way for pre-trained models like BERT. Two steps were followed for preprocessing, tokenization and special token addition. The BERT model was trained to transform sentences into tokens. WordPiece tokenization was used in this case. This type of tokenization is useful when dealing with words that are not in our dictionary. After that special tokens, like [CLS], [SEP] were included in the data. The main dataset was then divided into two subsets: the training dataset and the test dataset. Data splitting was carried out in this research using the scikit-learn library’s Train test split function.

E. Model Development

For both of our subtasks, aspect detection and sentiment classification, we used the BERT model. We began the aspect

detection task by training the BERT model with training data and testing the model with test data. We used the same method to detect sentiment. By fully understanding both the left and right context, BERT aims to pre-train from the unlabeled text. Making use of Transformer's attention mechanism, BERT learns contextual relationships between words.

BERT: BERT is an acronym that stands for Bidirectional Encoder Representations from Transformers [20]. It is a free and open-source NLP framework. Transformer serves as an inspiration for BERT as it studies the connections between words in a sentence. Transformer comes with an encoder and a decoder that reads the input data and predicts the outcome. BERT only requires the encoder component of the transformer to complete its task. In order to clarify the meaning of vague terms in data, BERT attempts to provide context to the surrounding data. The BERT framework was pre-trained using a large volume of Wikipedia texts. BERT considers the context of each word of the text. A word's vector in early word embedding techniques was always the same, regardless of where the word appeared in the text. Contrary to them, BERT provides different vectors for the same words depending on their position. For input representation, the first sentence starts with a classification token, [CLS], and each subsequent sentence ends with a separation token, [SEP]. BERT includes two steps, pre-training and fine-tuning.

a. Pre-Training: In this step, the model is trained on unlabeled text data. Masked Language Modeling (MLM) and Next Sentence Prediction (NSP) are associated with the pre-training task. MLM and NSP are applied together to reduce the total loss function of the two methods [26].

- **Masked Language Modeling (MLM):** The first step is to arbitrarily mask out 15% words in the input text data and replace them with [MASK] tokens [26]. The BERT attention-based encoder is then applied to the entire sequence, which only predicts the masked words based on the context that the other, non-masked words in the sequence provided. Next, the attention-based encoder of BERT processes the input. It only predicts masked words using the context given by the other non-masked words in the sentence.
- **Next Sentence Prediction(NSP):** NSP predicts the connection between two sentences [26]. The primary task of NSP is to determine whether the second sentence comes after the first sentence or not. If the second sentence comes after the first sentence, it is referred to as IsNext; otherwise, it is referred to as NotNext. The sentence is IsNext 50% of the time and NotNext 50% of the time.

b. Fine Tuning: BERT can be fine-tuned to perform a variety of language tasks. By simply placing a single layer over the base model, we can adjust the base model according to our own dataset [26]. The pre-trained parameters are used to initialize the BERT model at first. Then, using annotated data from the required tasks, all of the parameters are fine-tuned. Multilingual BERT is trained in 104 languages using Masked Language Modeling (MLM) [27], and Bengali is one of them. In our work, we used the multilingual BERT model to identify aspects and sentiments in order to gauge the scope of this language model. The pre-trained model weights and

implementation for HuggingFace's Transformers have been made public, and it was used in our work. The two parts of BERT are encoding and decoding, respectively. Encoding is used to read text data, and decoding is used to make predictions. The classification layer is then placed over the encoding layer. In our work, in the classification layer, the loss function was computed using binary cross entropy, and the Adam optimizer was applied. The ktrain library was used to calculate the proper learning rate. The model was fed with training data. Then, the model was trained with the previously calculated learning rate, weight, and 10 epochs. Then, testing was done using the test dataset. Fig. 5 depicts how BERT processes a Bengali sentence.

Fig. 5. BERT processing on Bengali text

Along with BERT, a number of deep learning models were also used in this ABSA work. Word2Vec [28] preprocessing technique was used in those models for feature extraction. Some brief descriptions of the algorithms are given below:

- **CNN:** CNN is a member of the family of ANN in deep learning. Using a variety of building pieces, including convolution layers, fully connected layers, and pooling layers, CNN is intended to adaptively and instinctively grasp spatial feature hierarchies by backpropagation [21].
- **RNN:** The outcome from the prior step is provided as input to the ongoing step in an RNN, a form of neural network [22]. In contrast to conventional neural networks, RNN input and output are interdependent. Many times, when forecasting the upcoming word of a statement, the prior words are necessary, and thus the preceding words must always be memorized. RNN was designed to address this issue by utilizing a Hidden Layer. The Hidden state is the most essential characteristic of RNN. It stores some sequence information in memory.
- **LSTM:** An RNN variant that can pick up dependency of order in predicting sequence issues is the LSTM network [23]. Every step uses the output from the previous one as its input in this technique. It resolved the problem of RNN long-term reliance, which is

that RNN can anticipate words looking at recent data but cannot predict words kept in long-term memory. The substantial number of memory cells and 4 neural networks, which are arranged in a chain pattern, make up the LSTM. The four components of a typical LSTM unit: Cell, Input gate, Output gate, Forget gate. Three gates regulate the data flow in and out of the cell, as well as the cell retains contents for arbitrary time periods. Time series with indeterminate duration can be examined, categorized, and predicted with the LSTM algorithm.

- **BiLSTM:** Two models are integrated into the bidirectional LSTM rather than training only one [24]. The input sequence is acquired by the first model, while its reverse is understood by the second model. Context from both sides enhances the performance of language-based models in numerous applications, including language translation, speech recognition, etc. Bi-Directional LSTMs are employed to use those features.
- **GRU:** GRU is a variant of RNN [19]. Similar to LSTM, it was created to address the vanishing gradient issue with RNN. It only has three gates, as opposed to the four in LSTM, and it doesn't keep track of the internal state of the cell. The hidden state of the GRU incorporates similar information as from the internal cell state of the LSTM recurrent unit. This set of information is sent to the subsequent GRU.

IV. EXPERIMENT AND RESULT

A. Preparing Environment

Deep learning-based experiments need powerful CPU and GPU. In order to conduct experiments, a system with a core i5 processor with 8 GB of RAM was used. KERAS has been programmed in Python while TensorFlow has served as the backend.

B. Result

The results were evaluated for both subtasks using well-known evaluation matrices. They are F1-score, accuracy, recall, and precision. They are assessed using True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN). Equations for accuracy, precision, recall, and F1-score are [25]:

$$Accuracy = \frac{TP + TN}{TP + FP + TN + FN} \quad (1)$$

$$Precision = \frac{TP}{TP + FP} \quad (2)$$

$$Recall = \frac{TP}{TP + FN} \quad (3)$$

$$F1 - score = \frac{2 * (Recall * Precision)}{Recall + Precision} \quad (4)$$

Both aspect detection and sentiment classification are multi-label classification. Tables IV and V display the findings of our analysis of the dataset for aspect extraction and sentiment classification.

TABLE IV. ASPECT DETECTION RESULT

Algorithm	Accuracy	Precision	Recall	F1-score
BERT	0.97	0.97	0.97	0.97
BiLSTM	0.95	0.95	0.96	0.96
LSTM	0.94	0.95	0.94	0.95
GRU	0.88	0.94	0.90	0.92
RNN	0.71	0.85	0.75	0.78
CNN	0.91	0.93	0.92	0.93

TABLE V. SENTIMENT CLASSIFICATION RESULT

Algorithm	Accuracy	Precision	Recall	F1-score
BERT	0.77	0.78	0.77	0.77
BiLSTM	0.74	0.78	0.74	0.75
LSTM	0.73	0.78	0.74	0.75
GRU	0.62	0.77	0.64	0.69
RNN	0.52	0.68	0.51	0.58
CNN	0.63	0.74	0.67	0.69

Tables IV and V show that BERT got the highest score in both subtasks. Its F1-Score was 0.97 and it had a 97% accuracy rate for aspect detection. As for sentiment classification BERT accurately classified 77% sentiments, with an F1-Score of 0.77. BiLSTM achieved a 95% accuracy in aspect detection, closely followed by LSTM at 94%. Their respective F1 scores for these subtasks were 0.96 and 0.95. In terms of sentiment classification, BiLSTM predicted 74% sentiment correctly, while for LSTM it was 73%. CNN and GRU performed almost similarly in both subtasks. Their F1-score for those subtasks were same (0.75). Despite having the same F1-score in sentiment classification (0.69), CNN outperformed GRU in aspect detection (0.93). The subtasks with the poorest performance were completed by RNN. It achieved an F1-Score of 0.78 and an accuracy of 71% for aspect detection. Only about half of the sentiments were correctly predicted by RNN (accuracy: 52%). The RNN's F1-Score for detecting sentiments was 0.58.

C. Discussion

Based on the findings in the result section, the BERT model outperformed every other deep learning algorithm, in the both subtasks of ABSA, aspect detection and sentiment classification. They achieved the best scores in all the evaluation matrices due to its "self-attention" quality. Other classifiers' use of the word embedding method, which is not context-based, led them to miss some of the word's context and produce some inaccurate predictions. Contextual embedding, used by BERT, ensures that words are understood in relation to one another. It is one of the main factors influencing BERT's exceptional performance.

The results of LSTM and BiLSTM were close, but BiLSTM outperformed LSTM in terms of its ability to accurately detect more aspects and sentiments due to its capacity to understand the context from both sides of a statement, whereas LSTM only comprehends context from the beginning of a sentence. GRU and CNN performed comparably. RNN performed rather poorly as a result of vanishing gradient issues.

It can also be seen that aspect detection produces better results than sentiment classification since the dataset is evenly

distributed in terms of aspects but slightly unbalanced in terms of sentiments.

D. Comparison with Previous Works

The results of this study were compared with four earlier Bengali ABSA based papers, [1], [2], [15], [17] and [18]. Table VI shows a comparison of our dataset to datasets used in their studies. Tables VII and VIII, respectively, provide performance comparisons for aspect detection and sentiment classification among them.

TABLE VI. COMPARISON OF BENGALI ABSA DATASETS

Dataset	Total comments	Aspect category	Sentiment polarity
Cricket [15]	2958	Batting, Bowling, Team, Team management, Other	Positive Negative Neutral
Restaurant [15]	2053	Food, Price, Service, Ambiance, Miscellaneous	Positive Negative Neutral
BAN-ABSA [18]	9009	Politics, Sports, Religion, Others	Positive Negative Neutral
Our Dataset	10042	Technology, Economy, Corruption, Sports, Politics	Positive Negative Neutral

TABLE VII. COMPARISON OF ASPECT DETECTION WORKS FOR BENGALI ABSA

Research	Dataset	Algorithm	Accuracy	F1-score
Rahman <i>et al.</i> [2, 15]	Cricket	RF	0.25	0.37
		SVM	0.19	0.35
		CNN	0.81	0.51
Rahman <i>et al.</i> [2, 15]	Restaurant	RF	0.30	0.33
		SVM	0.29	0.38
		CNN	0.83	0.64
Haque <i>et al.</i> [17]	Cricket	RF	-	0.37
		SVM	-	0.35
		LR	-	0.34
Haque <i>et al.</i> [17]	Restaurant	RF	-	0.35
		SVM	-	0.39
		LR	-	0.43
F. A. Naim [1]	Cricket	RF	-	0.41
		SVM	-	0.48
		CNN	-	0.59
F. A. Naim [1]	Restaurant	RF	-	0.35
		SVM	-	0.52
		CNN	-	0.67
Masum <i>et al.</i> [18]	BAN-ABSA	RF	-	0.65
		SVM	0.69	0.66
		CNN	0.79	0.75
		LSTM	0.77	0.76
This Research	Our Dataset	BiLSTM	0.80	0.78
		CNN	0.91	0.93
		RNN	0.71	0.78
		GRU	0.88	0.92
		LSTM	0.94	0.95
BiLSTM	0.95	0.96		
BERT	0.97	0.97		

Tables VI, VII, and VIII clearly show:

- Among all the datasets, the CNN algorithm gave the best accuracy and F1-score (0.93 and 0.93) in aspect

TABLE VIII. COMPARISON OF SENTIMENT CLASSIFICATION WORKS FOR BENGALI ABSA

Research	Dataset	Algorithm	Accuracy	F1-score
Masum <i>et al.</i> [18]	BAN-ABSA	SVM	0.65	0.41
		CNN	0.72	0.60
		LSTM	0.70	0.61
		BiLSTM	0.71	0.62
This Research	Our Dataset	CNN	0.63	0.69
		RNN	0.52	0.58
		GRU	0.62	0.69
		LSTM	0.73	0.75
		BiLSTM	0.74	0.75
		BERT	0.77	0.77

detection for the dataset used in our research. A clear illustration of the performance of CNN algorithm in these datasets can be found in Fig. 6.

Fig. 6. Representation of CNN performance in research works for aspect detection

- It also can be seen that for the BiLSTM algorithm, that was applied by Masum *et al.* [18] and in our work for aspect detection, it scored better in this work with an accuracy score of 0.95 and F1-score of 0.96.
- To the best of our knowledge, among all Bengali ABSA works, for subtask 1, aspect detection, this research got the best accuracy score and the best accuracy and F1-score for BERT (0.97 and 0.97). Fig. 7 depicts the best aspect detection scores from the research works for clear comparison.
- To the best of our knowledge, this research received the best accuracy and F1-score for BERT (0.77 and 0.77) for subtask 2, sentiment classification, in comparison to the only other ABSA subtask 2 work that has been done in [18]. The comparison of the highest sentiment classification scores from the research works is shown in Fig. 8.
- When it comes to performance of the model, the dataset’s richness and quality are important. Given that the dataset used in this research is larger than the Cricket, Restaurant, and BAN-ABSA datasets and includes more diversity, the same algorithms (e.g. CNN, BiLSTM) scored higher in this dataset.

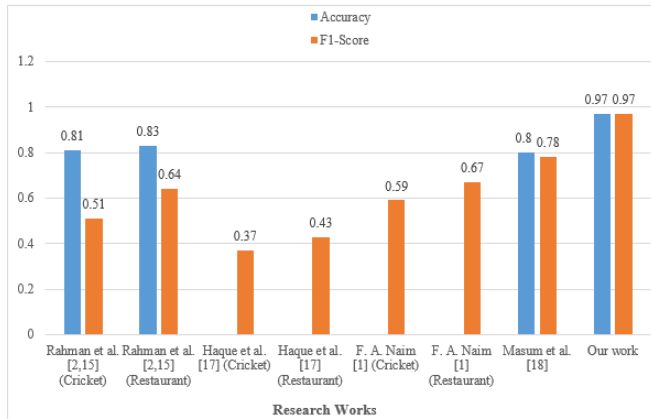

Fig. 7. Comparison of best performances of research works for aspect detection

Fig. 8. Comparison of best performances of research works for sentiment classification

V. CONCLUSION AND FUTURE WORK

A. Conclusion

Since there are very few ABSA research works on Bengali text currently available, more Bengali language research in this field is still needed. Our model to perform ABSA was built by applying BERT, which is known for getting over the limitations of the algorithms used in prior Bengali ABSA works. Also, a new Bengali dataset was introduced that is annotated with five aspect categories (Technology, Politics, Sports, Economy, and Corruption) and three sentiment categories (Negative, Positive, and Neutral), and these aspects and categories are particularly popular in our everyday life. After comparing it to five additional models that were applied in this study, it is evident that our BERT-based model outperformed the others. Due to BERT's ability to understand words in relation to each other in a phrase, which CNN, RNN, GRU, LSTM, and BiLSTM lack, it received the highest score in both subtasks. For aspect detection, BERT accurately detected 97% of the aspects and the F1-Score was 0.97. As for sentiment analysis, the F1-Score was 0.77 and accuracy was 77%.

B. Future Work

Our future research will be concentrated on researching hybrid methodologies, which will integrate a number of models and practices to improve the efficacy of this research. The models used in this study adhere to supervised techniques. We'll use unsupervised techniques like Latent Dirichlet Allocation (LDA) in the future as well. We will focus more on reducing time complexity and memory space requirements. To more effectively train our models, we will conduct our study in the future using more sophisticated equipment. In order to enhance this dataset and add further preparation steps, we will add extra data before training models. Romanized Bengali and code-switched Bengali data will also be added to increase the diversity of the dataset. The sentiments can be classified into a wider variety of human emotions, including joy, sorrow, hate, and anxiety.

Drought Forecasting in Alibori Department in Benin using the Standardized Precipitation Index and Machine Learning Approaches

Rodrigue B. W. VODOUNON¹, Henoc SOUDE², Ossénatou MAMADOU³
Department of Computer Science^{1,2}, Department of Physics³
Institute of Mathematics and Physics (IMSP), Porto-Novo, Benin

Abstract—Drought forecasting provides an early warning for the effective management of water resources to avoid or mitigate drought damage. In this study, the prediction of droughts is carried out in the department of Alibori in Benin republic using the standardized precipitation index (SPI) where two Machine Learning approaches were used to set up the drought prediction models which were Random Forest (RF) and Extreme Gradient Boosting (XGBOOST). The performance of these models was reported using metrics such as: coefficient of determination (R^2), root mean square error (RMSE), mean square error (MSE), and root mean absolute error (MAE). The results revealed that XGBOOST models gave better prediction performance for SPI 3, 6, 12 with coefficients of determination of 0.89, 0.83 and 0.99, respectively. The square root mean square error (RMSE) of the models gives 0.29, 0.40 and 0.07, respectively. This work demonstrated the potential of artificial intelligence approaches in the prediction of droughts in the Republic of Benin.

Keywords—Droughts; forecasting; machine learning; SPI

I. INTRODUCTION

Droughts come after floods and represents one of the most dangerous natural disasters affecting many countries in the world, especially the countries of West Africa which includes Benin republic [1]. Generally caused by a lack control over precipitation, droughts are very complex and difficult to identify because of their ability to occur in any climate, anywhere on earth [2]. Losses caused by droughts between 1900 and 2013 worldwide are estimated at 135 billion dollars. Moreover, in 2018, a total of 281 climatic and geophysical events were recorded with 10,733 deaths and more than 60 million people affected worldwide [3]. According to [4] and [5], climate change would be a factor in the aggravation of drought situations and their frequency in the world. Several vital sectors such as agriculture sectors, food security, hydroelectricity production, human and animal health, industrial activities [2] are seriously affected by the adverse effects of droughts.

Benin republic, like the other West African countries, is not on the sidelines and has suffered the harmful consequences of climate change. According to [3], Benin has recorded more than half a dozen droughts with ever-increasing disasters, from the 1960s to date. One of the most impacted sectors of the economy is the agricultural sector, which contributes 1/3 of the Gross domestic product (GDP) and holds up to nearly 70% of jobs in Benin republic [6]. Despite the significant impacts of drought, Benin republic, like most African countries, has no tool to either monitor or predict it's occurrence.

According to their effects and duration, droughts are classified into three categories: meteorological, agricultural and hydrological droughts. Several indices have been developed to predict and forecast the different types of drought. Gokhan et al. [7] drew up in their bibliometric analysis an exhaustive list of the various indices used in the literature as well as the conditions in which to use them. We can mention: the Standardised Precipitation Evapotranspiration Index (SPEI) dedicated for determining the onset, duration and magnitude of drought conditions; the Standardized Precipitation Index (SPI) to monitor and predict droughts on several timescales including 3, 6 and 12 months corresponding to SPI 3, SPI 6 and SPI 12, respectively. The SPI 3 is dedicated for the meteorological drought prediction, the SPI 6 is used to predict agricultural drought and the SPI is dedicated to the prediction of hydrological drought.

Abhirup et al. [8] also used artificial neural networks to understand the effect of droughts in New South Wales (NSW) using the SPEI drought index. The performance results revealed a coefficient of determination of 0.86. On the other hand, Abhirup et al. [9] used Long Short Term Memory (LSTM) to predict SPEI at 1 and 3 months time scales in New South Wales. The results of this study revealed a coefficient of determination of more than 0.99 for SPEI 1 as for SPEI 3. Poornima et al. [10] on the other hand compared the predictive capacities of SPI and SPEI in China by the LSTM and the model ARIMA at time scales of 1, 3 and 6 months. In all cases, the LSTM outperformed the capabilities of the ARIMA model. Other studies such as [11] have used Random-Forest to predict SPI at 3 and 12 month timescales in the Haive River Basin in China. These models showed good prediction accuracy. Lotfirad et al. [12] also used Random-Forest to predict SPI and SPEI at time scales of 3, 12, 48 months in Iran. The results obtained showed that in temperate climates, such as northern Iran, the correlation coefficients of SPI and SPEI were 0.94, 0.95 and 0.81 at time scales of 3, 12 and 48 months, respectively while it was 0.47, 0.35 and 0.44 in arid and hot climates.

In spite of the multitude of works, Africans are less concerned and among them we can cite the work of Mulualem et al. [13] where they used Artificial Neural Networks to predict the Normalized Precipitation and Evapotranspiration Index (SPEI) for seven stations in the upper Blue Nile (UBN) basin in Ethiopia. The results obtained found that the coefficient of determination and root mean square error of the best model ranged from 0.820 to 0.949 and 0.263 to 0.428, respectively. As

in the most studies on drought forecasting, they use satellite data sources without first assessing their reliability; satellite data may not reflect the reality.

The objective of this work is to propose a prediction tool of meteorological, hydrological and agricultural droughts in the Alibori department (BENIN), using the SPI 3 SPI 6 and SPI 12 indicators respectively. The first time we focus on using satellite sources. Indeed, in the concern to have a model close to reality, we carried out an analysis of similarities between satellite data and measured data. We then proposed two models based on the algorithms random forest and XGBoost. Finally, we presented a technique to improve the performance of the model based on the XGBOOST, by combining the different variables present in our dataset.

The rest of the document is organized as follows: Section II presents study area and drought indicators. Then we described our prediction approach in Section III. In Section IV we presented and discussed our results then we concluded with Section V

II. BACKGROUND

In this section, we first presented our study area followed by the description of the indices chosen for the prediction of drought in our study area. Then, we presented the algorithms used for the implementation of the different models.

A. Study area

Fig. 1. Cartography of the alibori department (6)

Geographically located between 11°19' north latitude and 2°55' east longitude, Alibori is a department located in the northeast of the Republic of Benin. It is bordered to the north by the Republic of Niger, to the northwest by the Republic of Burkina Faso, to the east by the Federal Republic of Nigeria, to the west by Atacora and to the south by the department of Borgou [14]. Covering an area of 26 242 km² (nearly 23% of the national territory), Alibori is subdivided into six (06) municipalities as shown in Fig. 1. These are: Malanville, Karimama, Segbana, Gogounou, Banikoara and Kandi, comprising 41 districts and 229 villages and city districts [14]. According

to [6], the department of Alibori is the area most vulnerable and most at risk to droughts in Benin republic. [15] confirms this finding by stating that drought is more recurrent in the northern part of Benin, particularly in the municipalities of Karimama, Malanville and Segbana.

B. Standardized Precipitation Index (SPI)

The standardized precipitation index was developed in 1993 by Mc Kee, N.J. Doesken and J. Kleist of Colorado State University. Its role is not only to determine rainfall deficits for a given period [16] but also to improve the detection of drought episodes at both local and regional scales [17]. Its calculation is based solely on historical rainfall data. To calculate the SPI more efficiently, [2] suggests that it is desirable to have monthly precipitation data over a period of 20 to 60 years. The mathematical expression for calculating the standardized precipitation index is as follows:

$$SPI = \frac{P_i - P_m}{\sigma} \quad (1)$$

with:

$$\begin{cases} P_i : \text{the total rain of month } i; \\ P_m : \text{the average rainfall of the series on the time scale} \\ \quad \text{considered;} \\ \sigma : \text{the standard deviation of the series on the time scale} \\ \quad \text{considered.} \end{cases}$$

The seasons can be classified according to the values of the SPI as shown in Table I.

TABLE I. CLASSIFICATION OF SEASONS BASED ON SPI VALUES [18]

SPI values	Season classes
2.0 and more	Extremely wet
from 1.5 to 1.99	Very humid
from 1.0 to 1.49	Moderately humid
from -0.99 to 0.99	Near normal
from -1.0 to -1.49	Moderately dry
from -1.5 to -1.99	Very dry
-2 and less	extremely dry

C. Machine Learning Approaches

1) *Random forest*: Random forests represent a supervised learning method based on decision trees [19]. This method generates multiple trees for prediction. Thus, at the end of the individual predictions, these are averaged to give a final prediction of the model. Each tree being weak, the aggregation of all the weak trees compensates for this shortcoming [20] and creates a more robust model. According to [21], the mean makes a random forest better than a single decision tree, thus improving its accuracy and reducing overfitting. The functioning of Random Forests is illustrated by Fig. 2.

2) *Extreme gradient boosting*: Extreme Gradient Boosting, also called XGBOOST, is an optimized implementation of the gradient boosting tree algorithm [22]. It is often the winning algorithm in competitions on Kaggle [23]. Unlike the Random Forest, the XGBOOST works sequentially. In other words, the algorithm is based on previous predictions to improve the results of other estimators. Thus, we rely on the predictions of the “weak learners” to build a “strong learner” [23]. XGBoost minimizes a regularized objective function (L1 and L2) that combines a convex loss function (based on the difference between predicted and target outputs) and a penalty term for model complexity. The training proceeds iteratively, adding new trees that predict the residuals or errors of the previous trees which are then combined with the previous trees to make the final prediction [24]. Fig. 3 further illustrates how the XGBOOST algorithm works.

Fig. 2. Structure of a random forest (Random forest) [25]

Fig. 3. How XGBOOST works [24]

3) *Performance assessment*: The mean absolute error (MAE), mean square error (MSE), root mean square error (RMSE) and coefficient of determination (R^2) are five typical performance indicators used to assess the models performance. The following mathematical expressions illustrate how to calculate these metrics.

$$MAE = \frac{1}{n} \sum_{i=1}^n |Actual - Predicted| \quad (2)$$

$$MSE = \frac{1}{n} \sum_{i=1}^n (Actual - Predicted)^2 \quad (3)$$

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (Actual - Predicted)^2} \quad (4)$$

$$R^2 = 1 - \frac{Squared\ sum\ error\ of\ regression\ line}{Squared\ sum\ error\ of\ mean\ line} \quad (5)$$

with n : The number of samples.

III. PREDICTION APPROACH

A. Methodology

Fig. 4. Methodology of the study conducted

Our solution consists in predicting droughts in the department of Alibori using the drought index SPI{3, 6, 12}. The prediction is performed using machine learning algorithms, as shown in Fig. 4. First, we collected satellite data covering our entire study area over a period of 30years. Then, we carried out the validation of these data using observation data from a station of the AMMA-CATCH program (Multidisciplinary Analysis of the African Monsoon-Coupling of the Tropical Atmosphere and the Hydrological Cycle) [26]. After that, we built our dataset and our models based on the Random Forest and XGBOOST algorithms. Finally we selected the best of the models and tried to improve them using a variable scenario method described in [27]. It consists of identifying the most useful variables when predicting indicators. First, we determined the correlation between the variables using the Pearson correlation matrix, then we defined the different combinations of variables, starting with the most correlated variables. After construction of the variable scenarios, the models were retrained and re-evaluated on the basis of each variable scenario.

B. Data

The use of Machine Learning in the prediction of drought indicators requires data over a period of at least 30 years. Unfortunately, we do not have any data for such a period. So as an alternative, we therefore opted for the use of satellite data from NASA’s Power Data Access Viewer platform(<https://power.larc.nasa.gov/>) which has data over a period

of 36 years (1985-2021), covering the entirety of our study area and containing all the variables allowing the calculation of the SPI: Temperature, total precipitation, wind speed, wind direction, surface pressure, relative humidity, cloud amount, soil moisture, Top-Of-Atmosphere Shortwave Downward Irradiance and all sky and All Sky Surface Shortwave Downward Irradiance. In addition to this, its use is reported in several works [28], [29], [30] to quote only those.

1) *Validation:* It consists in evaluating the reliability of satellite data before using them. To this end, we considered the Bellefougou station (Benin) [31] for which we already had in situ data over (08) years and we collected satellite data corresponding to this region and the same period. We then used the Taylor diagram and the Pearson correlation matrix to study the similarity between in situ and satellite data. The results of this validation phase are presented in Fig. 5 and 6. As shown in Fig. 5, there is a strong correlation (0.91) between observation data and satellite data. Fig. 6 also reveals that there is a strong correlation (0.91) between observation data (represented by the white circle on the x-axis) and satellite data (represented by the blue dot). This figure also shows that the difference in the standard deviation between the observation data and the satellite data is not very high (approximately equal to 0.3) and the error between these data is above 0.5. From all the above, it can be seen that there is a strong similarity between observational data and satellite data.

Fig. 5. Correlation matrix of the total precipitation variable

Fig. 6. Taylor diagram of the total precipitation variable

2) *Construction of the dataset:* By exploiting the precipitation data, the calculation of the SPIs at the time scales of 3, 6 and 12 months corresponding respectively to SPI 3, SPI 6 and SPI 12 has been implemented according to the formula 1 presented in the Section II.

After calculating the different SPIs, observations with missing data were removed. Once the datasets were purged of missing values, the data from the (06) municipalities were merged together in order to have a single dataset (Table II).

C. Model Building

We used the approaches described in the subsection II-C to implement models for the prediction of SPI 3 (meteorological drought), SPI 6 (agricultural drought), SPI 12 (hydrological drought). The different models have been implemented using the python programming language as well as different data science libraries such as: NumPy, Pandas, Scikit-learn, Matplotlib and Seaborn.

TABLE II. DETAILS OF THE SATELLITE DATASET

VARIABLES	UNITS	TIME SCALE
Surface Pressure	KPa	Monthly
Total Precipitation	mm	Monthly
Air Temperature at 2 meters	C	Monthly
Relative Humidity at 2 meters	%	Monthly
Wind Speed at 2 meters	m/s	Monthly
Wind Direction at 2 meters	Degree (°)	Monthly
Soil Moisture	-	Monthly
Cloud Amount	%	Monthly
Top-of-Atmosphere Shortwave Downward Irradiance	MJ/m ² /day	Monthly
All Sky Surface Shortwave Downward Irradiance	MJ/m ² /day	Monthly

In order to effectively train and validate the developed models, the dataset was divided into two parts: the training data (77%) and the test data (23%). We also used GridsearchCV to obtain the best hyperparameters for the models (see Tables III and IV).

TABLE III. RANDOM FOREST MODEL HYPERPARAMETER VALUES

Index	Hyperparameters	Values
SPI 3	n_estimators	70
	random_state	15
SPI 6	n_estimators	100
	random_state	9
SPI 12	n_estimators	100
	random_state	9

TABLE IV. XGBOOST MODEL HYPERPARAMETER VALUES

Hyperparameters	Values
Subsample	0,7
colsample_bytree	1
eta	0,1
max_depth	10
n_estimators	100
booster	gbtree
verbosity	0

IV. RESULTS AND DISCUSSION

We first evaluated the different models based respectively on Random-Forest and XGBOOST to identify the best models and then we improved them using variable scenario.

A. Random Forest Evaluation

Considering all the variables whose data were collected, prediction models for SPI 3, 6 and 12 were implemented and evaluated using the performance metrics presented in Section II. As it can be seen in the Table V, the models gave SPI 3, SPI 6 and SPI 12, respectively for performance R^2 of 0.832 (83%), 0.742 (74%) and 0.992 (99%).

After evaluating the models, it can be seen that the SPI 3 prediction model gives errors RMSE = 0.379, MAE = 0.276 and MSE = 0.143 respectively. As for the prediction model of SPI 6, we had the following errors: RMSE=0.479, MAE=0.344 and MSE=0.230. The SPI 12 prediction model gave the lowest errors with RMSE= 0.082, MAE = 0.041

and MSE = 0.006 values, respectively. This would mean that the variables considered are more relevant for predicting hydrological drought (SPI 12).

B. XGBOOST Evaluation

The Table VI presents the evaluation results of the prediction models of SPI 3, 6 and 12 based on the XGBOOST algorithm. This table shows good performance for all models with coefficient of determination R^2 respectively equal to: 88% for the SPI 3 prediction model, 81% for the SPI 6 prediction model and 99% for that of the SPI 12.

As for the errors made by the models, the results of the evaluation revealed that the prediction model of the SPI 3 gave the values RMSE = 0.317, MAE = 0.221 and MSE = 0.100, respectively. The SPI 6 prediction model gave the following results: RMSE = 0.423, MAE = 0.301 and MSE = 0.179. The SPI 12 prediction model provides the best performance and minimizes all errors the most with errors RMSE = 0.076, MAE = 0.041 and MSE = 0.005.

By comparing the performances of the Random Forest models and those of XGBOOST, we find that the XGBOOST algorithm is much more efficient in the case of the present study.

TABLE V. RANDOM FOREST MODEL EVALUATION RESULT

Index	R ²	RMSE	MAE	MSE
SPI 3	0.832	0.379	0.276	0.143
SPI 6	0.742	0.479	0.344	0.230
SPI 12	0.992	0.082	0.041	0.006

TABLE VI. XGBOOST MODEL EVALUATION RESULT

Index	R ²	RMSE	MAE	MSE
SPI 3	0.882	0.317	0.221	0.100
SPI 6	0.817	0.423	0.301	0.179
SPI 12	0.993	0.076	0.041	0.005

C. Variable Scénario

Fig. 7. Correlation matrix between input variables and SPI 3

According to the Fig. 7, the highest correlation is equal to 0.2 and this corresponds to the correlation between the total precipitation and the SPI 3. We also note a correlation

of 0.17 between the humidity of the ground and SPI 3. Then follow weaker positive correlations respectively equal to 0.038, 0.026 and 0.014 corresponding respectively to the correlations between SPI 3 and surface pressure, relative humidity and wind speed. In addition to the positive correlations, some variables have a negative correlation with the SPI 3. These are the amount of cloud (-0.036), All Sky Surface Shortwave Downward Irradiance (-0.05), wind direction (-0.057), Top-Of-Atmosphere Shortwave Downward Irradiance (-0.066), Air temperature (-0.15). This correlation matrix made it possible to identify the variables that have a strong correlation with the SPI 3. This is the variable: total precipitation. It can be deduced that the total precipitation represents a relevant variable for the prediction of SPI 3 (meteorological drought). The same approach was adopted for the cases of SPI 6 (agricultural drought) and 12 (hydrological drought).

The Tables VII, VIII and IX respectively present the different variable scenarios according to the type of drought. Indeed, these scenarios are only combinations of the variables obtained from the Pearson correlation matrices. For the experimentation phase, they were successively used as input parameters to the XGBOOST models. These matrices made it possible to construct 11 scenarios per type of drought. The presence of a (✓) symbol in the cell of a column means that the variable concerned is part of the scenario corresponding to this column. For illustrative purposes, scenario 1 of the Table VII consists only of the Total precipitation variable. Scenario 3 consists of the variables: soil moisture, total precipitation and surface pressure.

TABLE VII. SCENARIOS OF VARIABLES FOR THE PREDICTION OF SPI 3 (METEOROLOGICAL DROUGHT)

Variables	Scenarios										
	1	2	3	4	5	6	7	8	9	10	11
Soil moisture		✓	✓	✓	✓	✓	✓	✓	✓	✓	✓

Once the variable scenarios were established, the XGBOOST models were trained and validated by considering each variable scenario. Then, these models were evaluated using previously used performance metrics to identify not only the most accurate model but also the scenarios that provide better prediction performance. The performance results of the models according to each scenario of variables for each SPI

All Sky Surface Shortwave Downward Irradiance								✓	✓	✓	✓
Air temperature										✓	✓

(SPI 3, SPI 6 and SPI 12) are presented in the Tables X, XI, XII. The Table X, reveals that scenario 9 is the one that provides the best results with a determination coefficient R^2 equal to 0.898 (89%), an RMSE of 0.29, an MAE of 0.211 and an MSE of 0.087. This table also reveals two important elements. First, it can be noticed that the more one adds a variable to a scenario, the more the precision of the model increases (even the variables having a weak correlation with the SPI 3) with the exception of the variables soil humidity and air temperature. Secondly, when we use as input parameters, scenario 2 which contains only the variables most correlated to SPI 3, the performance of the model deteriorates completely with a negative R^2 (-0.241). This actually means that the fact that the variables are the most correlated to the SPI 3, does not necessarily mean that they are the most essential for the prediction of the SPI 3. Moreover, a variable having a negative correlation (quantity of cloud for example) with SPI 3 can increase the predictive performance of the model. As for the Table XI, it shows that scenario 9 is still the one that provides the best results for the prediction of SPI 6 with a coefficient of determination R^2 equals to 0.830 (83%), an RMSE of 0.408, an MAE of 0.289 and an MSE of 0.167. This table also shows two other key pieces of information. We can also notice that the more we add a variable to a scenario, the precision of the model increases (even the variables having a negative correlation with the SPI 6) with the exception this time of the temperature variable of the air whose addition lowered accuracy and increased errors. Although the total precipitation and soil moisture variables constituting scenario 2 are the most correlated with SPI 6, the performance of the model was only 0.017 for this scenario. This actually shows that the fact that the variables are the most correlated to the SPI 6, does not necessarily mean that they are the most essential for the prediction of the SPI 6. Moreover, a variable having a negative correlation (wind speed per example) with SPI 6 can increase the predictive performance of the model.

The performance results of the XGBOOST model for the prediction of SPI 12 are presented in the Table XII. Unlike SPI 3 and SPI 6, this time it is scenario 8 that gives the best results with a determination coefficient R^2 equal to 0.994 (99%), an RMSE of 0.073, an MAE of 0.039 and an MSE of 0.005. Several other relevant information can be extracted from this table. Firstly, as in the case of SPI 3 and SPI 6, it can also be seen that the more a variable is added to a scenario, the more the precision of the model increases (even the variables having a negative correlation with the SPI 12) with the exception this time variables: Top-Of-Atmosphere Shortwave Downward Irradiance, wind speed, air temperature, the addition of which decreased accuracy and increased errors. Secondly, considering

the three variables most correlated to SPI 12 which are: total precipitation, soil moisture and relative humidity forming scenario 3, the performances are already starting to be good ($R^2 = 86%$). This is not the case for the prediction of SPI 3 and 6. This actually shows that the total precipitation, soil moisture and relative humidity have a strong influence on the prediction of SPI 12. Having a negative correlation with the SPI 12, only the addition of the variable All Sky Surface Shortwave Downward Irradiance slightly increased the performance of the model 0.994 (99%).

The variation of predicted SPI values and calculated SPI values is illustrated in Fig. 8, 9 and 10. As it can be seen, the predicted SPI (in blue) have a similar variation as the calculated SPIs 3 (in red). By considering these three figures, it can be noticed that the predicted SPI 12 is very close to the calculated SPI 12. This justifies the 99% accuracy of the SPI 12 prediction model. It can therefore be said that the XGBOOST is better suited to the prediction of hydrological drought in the department of Alibori.

TABLE X. PERFORMANCE RESULTS OF THE SPI 3 PREDICTION MODEL BASED ON THE XGBOOST ALGORITHM

Fig. 8. Comparison of predicted SPI 3 and target SPI 3

V. CONCLUSION

This study consisted in designing prediction models of SPI 3 (meteorological drought), SPI 6 (agricultural drought) and SPI 12 (hydrological drought) in the department of Alibori based respectively on the Random forest and Extreme Gradient Boosting (XGBOOST) algorithms. Performance results

Fig. 9. Comparison of predicted SPI 6 and target SPI 6

Fig. 10. Comparison of predicted SPI 12 and target SPI 12

indicated that XGBOOST performs better than Random forest in predicting SPI 3, SPI 6 and SPI 12 with respectively the coefficients of determination R^2 égal to 88%, 81% and 99%. To further improve the performance of XGBOOST models, 11 variable scenarios were designed. These scenarios were then used respectively to train, validate and evaluate the models in order to identify the scenarios that allow good prediction performance. At the end of this improvement step, the best performances obtained are respectively 89% for SPI 3, 83% for SPI 6 and 99% for SPI 12. The use of this technique based on the scenarios of variables allowed to deduce that the air temperature was not relevant for the prediction of the SPI 3. Similarly the variables air temperature and wind speed were not essential for the prediction of SPI 12. Future prospects consist of using other drought indices like SPEI in order to compare their results with those obtained in the present study in order to see the drought index that lends itself to drought prediction in Benin in general and in the Alibori in particular).

VI. PERSPECTIVES

In the future works, historical data will be used to predict future droughts, which would be useful to meteorological decision makers in developing drought mitigation measures and actions.

Abstract—One of the major tools of the new era of digital transformation is Internet of Things (IoT) through which, one can look forward to exploring the new technologies in the digital world as well as how they help in improving the real world. This work provides an overview of the approach used to deploy a surveillance system for monitoring any indoor space in general and specifically for agricultural spaces. The entire process starts after motion detection by motion sensors using Machine Learning techniques. This requires coverage and response processing algorithms implemented in the electronic chain. The electronic part of the system relies on the micro-controllers, sensors and communications between them. A mobile application has been developed to allow competent authorities to receive alerts for real-time intervention with the aim of preventing the destruction of crops slaughtered near herds passage. The monitoring system' synoptic diagram and its operation along with the power modules description are introduced. Prototype has been designed and performance evaluation performed to show the system' responsiveness.

Keywords—Monitoring system; agricultural space; machine learning; herds passage; motion detection

I. INTRODUCTION

A thriving society offers myriad benefits: joy, peace, and security. Yet, security continues to be critical. This is true whether the safe space is for people, items, or animals. It makes sense to send out a team of guards to monitor and police a safe space. Therefore, having a monitoring system [1], [2], [3] remains the best engagement solution for well-being. Moreover, thanks to the development of the Internet of Things (IoT), one can now keep in real-time, an eye out for its own assets remotely [4].

Despite the crucial importance and active participation of livestock in the Beninese economy, their producers are less protected from the serious threats that often accompany the search for animal feed, especially in the dry season, which leads to loss of the plantations. With this in mind, a monitoring system that is intended to be able to adapt itself to the user needs, has been designed. The service produced by the system, allows receiving alerts when intrusions occur. Recently, in [5], a multi-layered architecture that is useful for various stakeholders (breeding producers, farmers, and policymakers) has been proposed to support Smart Agriculture and Smart Livestock. Transhumance related issues have been targeted, as those issues gain further expansion in developing countries. Indeed, during the transhumance process, passages dedicated to animals, usually referred to as corridors may not be followed

by the breeders. This can cause deadly clashes between herders and farmers. In this paper, the above issues are addressed by extending the architectural solution provided in [5], to the implementation of a monitoring system to detect intrusion when the cows are too close to the farmers field, as well as to send alert message on the phone of the authorities that can try to anticipate the conflicts.

Machine Learning is being intensively used to solve real-time computer vision and image processing problems [6], [7]. Our solution is built using Machine Learning techniques associated with OpenCV library [8], [9] and a pre-trained library of objects and animals from Coco (Common Object in Context) dataset [10], [11] that is large-scale object detection, segmentation, and captioning dataset. Thanks to this trained library, the proposed intrusion detection system, based on Raspberry Pi, will allow recognizing some objects and animals such as cows, oxen and persons, using DNN (Deep Neural Network) algorithm [12], [13].

The specific objectives of this work are: i) use IoT to set up a monitoring system that detects intrusion of cows using a training model, ii) carry out the processing of the captured image and ensure the identification of the cows or oxen, iii) trigger an alarm after the detection of cattle movement at the entrance of the field and send an alert message and details about the field' location to authorities who can take appropriate decision in real-time. Sending alerts to the farmers, is avoided to reduce the direct conflicts before authorities intervention.

The remaining of this paper is set as follows. Section II discusses problem statement and motivation. Section III presents the novel IoT-based intrusion detection system followed by section IV that discusses experimental results. Sections V and VI, respectively focus on related work and conclusion, followed by perspectives.

II. PROBLEM AND MOTIVATION

Although the rules of arable land are carefully codified, the roads are delimited and respected by the sedentary, the level of destruction caused by the traditional movements of pasture increases day by day. Land degradation has been a constant challenge for farmers and ranchers as it accompanied the spread of agriculture in prehistoric times. It can create dangerous outcomes like death when large herds enter in neighboring fields, making it necessary for authorities to be alerted to their presence, anywhere in the land [5], [14]. In order to reduce deadly outcomes and large herds of animals

roaming fields, pioneers need to lessen the conflict between agricultural experts. This work aims to alert authorities as soon as herds of livestock are advancing toward neighboring ranches. In today's world, surveillance systems are predominantly based on more traditional equipment, such as closed-circuit cameras. Unlike, the proposed system not only monitors herds' passage, but is also able to send the exact position of the concrete place where the intrusion takes place. In addition to this, the image processing is done to decipher whether the movement is actually animals or if it is men or otherwise.

III. IOT-BASED DETECTION SYSTEM

Our monitoring system can be divided into two main parts, namely, the electronic component and the mobile application. The first part, dealing with electronic, covers the communication between the various modules and the electronic devices used. When the motion sensor at the entrance of the field, detects the movement of an object, the camera is activated and the object is identified. If there is a cow or oxen among these identified objects, an alarm will be triggered, when it is less than 2 meters from the system, positioned at the entrance of the agricultural domain. This is called pre-intrusion. However, if the cow crosses the border by entering in the domain within 1.5 meters from the system, the same treatment process is followed. Again, for cows and oxen, it sends an alarm message to authorities and assigns them the location of the sensor that detected the movement, reporting the intrusion.

The second important part of the work, is mobile application design. This application acts as intermediary between electronic system and users. Therefore, it receives alerts, displays alerts, displays the history of intruders, and allows administrators to know the status of components of the system.

This section highlights the system architecture along with its functional requirements. Moreover, electronic details have been underlined, as well as the OpenCV library description.

A. Intrusion Detection System Architecture

Our intrusion detection system is based on a client/server architecture. All processing tasks are performed through the server. It is therefore, the brain of the system, which consists mainly of two parts, as shown in Fig. 1.

- Electronic components consisting of motion sensor, ultrasonic sensor, camera, Raspberry Pi 3, NEO-6M GPS module.
- The mobile application obtains information sent by electronic system regarding the intrusion' detection.

B. Detection Processing Steps

Fig. 2 shows the process of pre-intrusion and intrusion detection in agricultural domain. First, when the PIR motion sensor detects motion at the entrance to the monitored area, it triggers the camera, which is in standby mode by default, to identify objects whose presence has been notified by the sensor. For cows and oxen, ultrasonic sensors assess the distance between the object and the system. If the distance between them is less than 1.5 meters, the system will sound an alarm (buzzer). This is the pre-intrusion detection. When

the PIR sensor placed in the field, detects movement within the detection area, an ultrasonic sensor is activated and the distance between the system and the trigger object is also calculated. Then, when the distance between the system and the object is less than 1.5 meters, the camera will be activated to check if it is a cow/oxen. In the case of cow or oxen, the system sends notification to the authorities. This is an intrusion detection. If not, no action is required.

Fig. 1. System architecture

Fig. 2. System operations steps

C. OpenCV Library Usage

The recognition of objects, in particular an ox or a cow, was done using the OpenCV library [8], [9], which makes it possible to manipulate the objects and animals predefined in the Coco dataset [11]. The Coco (Common Object in Context) library is a large-scale object detection, segmentation, and captioning dataset. This library is designed from a large collection of images of each object and animal in different shapes and various landscapes. It allows the Raspberry Pi to

identify 91 unique objects/animals and to provide a constantly updated confidence score. The OpenCV library along with Coco dataset are set up on the Raspberry.

Object recognition, specifically, cow and oxen, was performed using the OpenCV library [8], [9]. As library, it allows manipulating predefined objects and animals in the Coco dataset [11]. Coco (Common Object in Context) is a rich object detection, segmentation and captions dataset. It was designed from a large collection of images of each object and animal in different shapes and different landscapes. This allowed the Raspberry Pi to identify 91 unique objects/animals and provide a constantly updated confidence score. An OpenCV library along with a Coco dataset are set up on the Raspberry Pi.

D. Use Cases

Use case diagrams are provided in terms of actions and reactions, allowing to visualize system behavior from the user's point of view and give a complete overview of the functional behavior of a system. Fig. 3 shows "what" the proposed system provides by illustrating the possible interactions with the actors.

After authentication, authorities can:

- Comment on intrusions
- Visualize alerts
- Consult intrusions history

After authentication, administrator can manage the system as follows:

- Add or remove users in the system
- Check system status
- Consult intrusions history

E. Prototyping

Several tools were used in order to design the monitoring system. The following materials/tools are used to set up the prototype:

- Raspberry Pi 3, which is a computer reduced to its simplest form with a single ARM processor card, a bit larger than a credit card.
- Camera Pi, Raspberry Pi Night Vision Camera, that supports all versions of Raspberry Pi.
- PIR sensor, is a motion sensor used to determine whether a human or an animal has entered or left the module's detection field.
- Ultrasonic sensor that evaluates the distance between the object and the system.
- SIM800L GSM module, is the smallest and powerful GSM module which can automatically start and look for network connectivity. It allows SMS exchange, calls and data recovery in GPRS 2G+.
- The NEO-6M GPS module, is a GPS receiver, which has a high performance built-antenna to provide powerful satellite search capability.

- Solar panel kit, which is composed by a 10W 12V solar panel, a 5A 12/24V charge regulator and a 12V 12Ah battery. It is used to power on the monitoring system.

Fig. 4 shows the connections between system components. In fact, all the used components are directly connected to the main element, the Raspberry Pi. Main wires are used to connect various components and circuit boards. Each component has a specific role.

The system also includes a mobile application that allows getting intrusions notifications and consulting the history of intrusions. Thus, authority can consult the history of all the intrusions that take place in different agricultural areas and for which he has been alerted.

Fig. 5 shows what the surveillance system box looks like. At the top, 3 LEDs are positioned: one to signal the powering up of the device, the second to indicate an object detection and the last to highlight data transfer to the remote database. In the middle, the Pi camera and the motion sensor can be identified. Further down, an ultrasonic sensor is positioned to calculate the distance between the system and the detected object. In the profile view, you can easily distinguish the start button and the power plug.

Fig. 6 gives in one view, the proposed system from the implementation to the deployment. It shows: a) intrusion detection system prototype, b) system mounting on 1.5 meters high support covered by a solar panel, c) system deployed in real environment. The system is powered by a 30WATT solar panel, mounted on a 12V-9AH battery. The two elements are interconnected by a charge controller.

IV. EXPERIMENTAL RESULTS AND VALIDATION

The designed prototype is experimentally evaluated and validated through the system deployment along a field in order to know the accuracy of the intrusion detection. The passage of cows is simulated in a real environment. A herd of ten cows circulate in front of the device, a hundred times. Each time, how accurately the device reported the intrusion is noted. For the simulation, three significant hours of the day are chosen to perform measurements over three days: Morning on day 1, noon on day 2, and evening on day 3. Fig. 7 shows the simulation results for three different time periods selected. Fig. 8 summarizes the measurements taken statistically.

Fig. 3. System' Use Cases

Fig. 4. Electronic circuit' wiring

Fig. 7 shows that the proposed system gives better results in the morning and noon, while Fig. 8 shows an accuracy between 0.5 and 1 with averages between 0.74 and 0.82 for morning and noon. Indeed, the evening measurements show an average of 0.53, with detection failing half the time along with a significant value of 0.29 for the standard deviation.

In conclusion, one can notice that noon measurements are more accurate than morning and evening measurements. Detection accuracy in the evening is not so high, although, the system box is equipped with a night vision camera. It turned out that this was due to the brightness and quality of the camera and the low processing power of the Raspberry Pi 3 micro-controller. Future version of the prototype should be equipped with a better camera to improve recognition quality using more powerful Raspberry Pi. This will reduce processing time for cow recognition from images sent by the camera.

V. RELATED WORKS

Many studies focused on different aspects of transhumance in Benin and worldwide. From this, it is first possible to draw some solutions about cows' movements monitoring along a specific way called corridor [15]. Secondly, some publications analyzed the effects of constantly greater cattle overflows on total biomass productivity [16]. Thirdly, other relevant research works focus on providing an IoT-based architecture to develop a Smart, Sustainable Agriculture platform as a solution [17]. Finally, some other studies discussed the importance of a good agricultural practice in contrast to forests establishment as a way to increase both rangeland' productivity and the appreciation of its use and management. From the outputs of these studies, one can be able to determine the importance of transhumance and its pipelines in Benin as well as in some countries which have the same challenges.

Endorsements have also been made about how a corridor can be materialized by identifying the factors that contribute to define transhumance routes and analyze the perception of transhumant herders on the determinants of these routes in

Fig. 5. Monitoring system box

Fig. 6. Monitoring system in one view

Fig. 7. Accuracy of intrusion detection over time

Fig. 8. Statistics on accuracy measured by the system

order to take better decisions in the management of grazed ecosystems [18], [19]. Other solutions are based on monitoring system [20] to manage selected physical conditions and behaviors of livestock across long distances and over large grazing areas in open pastures, as well as in fenced in areas [21], [22]. The solution proposed in [23] is to monitor cows using an IoT enabled sensor installed on the collar of each cow, which associated to the cow, a unique identifier. Livestock farming is assisted more and more by technological solutions such as a vision-based module that allows to automatically detect predators and distinguish them from other animals in order to prevent damages and respecting biodiversity [24]. Sensor technologies are also used to monitor animal health and ensure animal well-being in the fast changing conditions. In addition, authors of [25] try to show relevance of digital technologies for health and welfare monitoring usage and the management of livestock, kept in large pasture areas. Authors of [22] illustrate IoT technology for farmers and use sensors to gather and transfer data using parameters, like temperature, humidity and heartbeat. Once data are collected, they are sent to the Arduino Uno controller.

Moreover, authors of [26] have proposed a farmland surveillance-alert system using unmanned aerial vehicles for cattle presence detection on farmlands as a solution to curbing the problem of farm invasion and destruction. The system, upon detecting cattle presence, higher than a threshold level, sends SMS to farmer's selected number.

In [5], as a previous work, we have focused on a proposal of a multi-level architecture that is able to help through the implementation of a smart guidance system based on IoT Technologies, where herders can better control their livestock following the predefined corridors. Unlike all existing technological solutions, the current work is not intended to identify the cows before tracking them. This is explained by the fact that transhumants often do not adhere to this practice, because they fear that their livestock will be counted. Furthermore, the idea of automatically sending alerts to the farmer upon intrusion detection is rejected, as this does not resolve commonly recorded deadly conflicts. The designed system uses DNN Machine Learning algorithm, to detect intrusion and send alert to the authorities. The system achieved an average accuracy score that varies from 0.53 to 0.82 in real-life test environment.

VI. CONCLUSION

In this work, we succeeded in prototyping an intrusion detection system for spaces monitoring. The system consists of several modules, that each, plays an important role. The main objective of the project is to send the information collected after processing, to a remote database, specifically Firebase, when there is an intrusion in a monitored space. A test bed has been provided for livestock and agricultural domains. Upon detection, a generated alert is sent to a mobile application to allow visualization and decision-making by authorities. In future work, the prototype will be improved by putting the ultrasonic sensor on a servo motor in order to turn it in the direction of the moving object. Moreover, performance tests will be extended and will include, among other, the evaluation of the time taken to detect the intruding object.

Measurement Tool for Exposure Techniques in X-ray Ionizing Radiation Equipment

Edwin Arley Cortes Puentes¹, Andres Gomez Rodriguez², Fernando Martinez Santa³
Universidad Distrital, Francisco Jose de Caldas
Bogotá, Colombia

Abstract—This article shows the development of an instrument for measuring the exposure parameters used to take radiographic studies in living beings; such as kilovoltage, current and time, since radiation protection is a fundamental pillar in the care of patients and operators of ionizing radiation equipment, it is necessary to calibrate these parameters in equipment that produce X-rays. For the manufacture of the measuring instrument is used an ESP32 microcontroller which is programmed using the Python syntax using the project micropython, in addition to current, distance and light sensors. The results of these measurements will be displayed through output devices such as organic light-emitting diode (OLED) displays, liquid crystal (LCD) displays, and a Web server, in order to perform the measurements safely from the control room and thus avoid exposure to radiation as much as possible. The kVp measurement performed in this article is for equipment operating at 60 [Hz], for high frequency equipment a new parameterization must be performed in order to obtain results as close to reality as possible. By using the web server for the transmission of measurement data, the radiation exposure was reduced and the calibration times of the equipment were improved. This article presents the measurements, and also the calculation of the error of each of the different exposure parameters of conventional X-ray equipments, such as kVp, mA, mAs and time. The errors obtained in the measurements were made assuming that the X-ray equipment used has a 0 error, i.e. assuming that the X-ray equipment is calibrated and that it is a standard equipment.

Keywords—Voltage; current; X-Ray; kVp; mA; mAs radiation; ESP32; OLED microcontroller

I. INTRODUCTION

The discovery of X-rays dates back to 1895 in the city of Hamburg, Germany and is due to experiments conducted by the physicist Wilhelm Conrad Röntgen, this contribution has been of great importance and usefulness in both industry and medicine. Radiation is emitted energy that is transferred through space with or without influence on the atomic structure of matter, it is classified into non-ionizing radiation and ionizing radiation according to the effects produced by corpuscular contact [1]. Non-ionizing radiation includes ultraviolet (UV), infrared (IR) and microwave radiation. In cells, the possibility that they can generate heat decay has been considered, but it is not yet known whether they can generate microscopic effects. Ionizing radiation includes X-rays, gamma, alpha and beta rays. These types of radiation are capable of creating damage or not in human cells [2]. In our body, ionizing action is evidenced by chromosome breaks, where changes may include consequent deletions or abnormal translocations, these effects can be seen during cell division resulting in abnormal cell development or death. The action of X-rays on sex cells can generate alterations in the transmission of hereditary characters

known as mutations. X-rays are electromagnetic radiation generated by the excitation of electrons in the internal orbit of an atom, with the ability to pass through opaque bodies. The wavelength range of X-rays is between 0.01 nm and 10 nm, which corresponds to an energy range of approximately 1 keV to 150 keV.

X-rays have been used extensively by humans in the fields of industry, veterinary medicine and medicine. In medicine they are used to obtain diagnostic images. As an example of its use we have panoramic and periapical equipment. Panoramic radiography is used to obtain a single image of the teeth and their supporting structures. Periapical radiography shows a more detailed image of the dental structure, it is used to explore the dental structure and the surrounding tissue. [3], mammograms: Mammography is one of the most important methods for detecting breast lesions. By means of this technique small anomalies can be identified which, if prevented in time, can be treated in a better way [4]. TACS “Computerized Axial Tomography” is a method that uses imaging technology for medical diagnosis, it allows to analyze the interior of the human body through millimetric transversal cuts to the cephalo-caudal axis, all this is done through the use of X-rays [5], C-arms, fixed and mobile X-ray equipment (they are used to obtain general X-rays of organs and bones), among others; These types of examinations, being non-invasive, represent a vital instrument for the analysis, study and care of animal and human health. Due to the imminent risk presented when using X-rays on living beings, it is essential to supervise and control the doses administered for such examinations.

However, in the process of diagnostic imaging, X-rays are used, which are dangerous, as it has been shown that they can generate negative eventualities to people. For this reason, and according to one of the pillars of radiation protection “as low as reasonably achievable” known as optimization, this indicates that the control elements of these devices must have the highest quality standards to obtain a good quality image with the lowest radiation dose [6].

Embedded systems work based on a processor, microprocessor, microcontroller or programmable logic devices, usually perform repetitive functions [7], therefore, we can find a variety of applications in practically all fields, from applications in bioengineering [8], as well as image processing [9], to industrial and educational levels as applications in industrial preventive maintenance [10] and control of didactic robots, respectively [11].

Since the beginning of mankind, human beings have sought their welfare in many ways, therefore any advance in technology has had approaches in medicine, embedded

systems have not been alien to this, have been developed applications as simple as drug dispensers [12] and others a little more complex, as is the control of vital signs [13] to the physiological emulation of the lung [14].

Speaking specifically of applications focused on everything related to X-rays, we can find various studies such as FPGA-based ionizing radiation detection [15], sample alignment devices for the diffractometer [16].

Thanks to all these advances in electronics in terms of sensors and embedded systems applied to the medical field [17], it is possible to perform increasingly faster and more precise measurements of X-ray exposure parameters (kVp,mAs,t) [18].

It is then intended to implement a system for measuring the exposure parameters kVp, mAs and time based on an ESP32 microcontroller, this in order to monitor and control the calibration of X-ray equipment and ensure the doses delivered to patients, thus this article is organized as follows: Section I gives an introduction on the parameters of exposure, the importance of X-rays and how embedded systems have been used in the area of medicine, Section II presents the design, which takes into account the electrical and mechanical characteristics that must be taken into account for the design of the same, Section III shows the data obtained from the measurements of the measurement system implemented, finally, Section IV presents some conclusions and recommendations that should be taken into account for future research.

II. DESIGN

This section explores the electrical, mechanical and electronic characteristics to be taken into account for the development of the measurement equipment, such as connectivity, power, voltage range, current range, time, materials, among others.

A. Measurement of Exposure Parameters

When a specific radiographic study is required, it is necessary to vary the parameters of peak kilovolts [kVp], current as a function of time [mAs] and time [t], because each patient has a different contexture, and each bone or organ of the body requires these parameters to be varied in order to obtain a good quality image that allows an accurate diagnosis.

1) *Exposure parameters influence on the acquired image:* Each exposure parameter varies the quality of the image to be acquired as follows:

kVp= Penetration "More or less opaque an organ" The higher the kVp applied, the higher the penetration of the X-rays and vice versa. mAs= Definition "Contrasts, grays" Allows to define the borders of the organs and to be able to distinguish between them [19]. t= Radiation exposure time. The longer an X-ray beam is the more penetration can be obtained in the image, however this parameter should be as low as possible without sacrificing the definition of the image, since the shorter the radiation exposure time of a patient the lower the risk of affecting the health of individuals.

Fig. 1. kVp sensor box

B. Current Measurement

Conventional X-ray equipment generates a current in the range of $25[mA]$ to $500[mA]$, periapical and panoramic equipment uses lower values in the range of $3[mA]$ – $15[mA]$, the current in mammographs ranges from $20[mA]$ – $150[mA]$.

1) *Current sensor INA219:* The INA219 sensor allows current measurements from 0 to 400 [mA] and uses an I2C communication protocol compatible with the ESP32 microcontroller, which is why it is the current sensor module used by the measurement device proposed in this article.

C. High Voltage Measurement

Conventional X-ray equipment generates a voltage in the range of $30[kV]$ to $150[kV]$ with variations of $1[kV]$, mammographs operate between $20[kV]$ to $35[kV]$ because air at these voltages is ionized [20] To measure these voltage magnitudes, there is specialized equipment such as a blider or voltage dividers that allow an indirect measurement [21]. The phosphor screens used to take radiographs emit an intensity of light that is proportional to the kVp applied, this feature is used so that the measuring instrument designed in this article obtains the measurement of [kVp] indirectly.

1) *Light sensor for indirect kVp measurement:* The TSL-2591 sensor allows the measurement of the visible and infrared light spectrum separately, taking advantage of the light emanating from the phosphor screens and the sensor at the time of exposure, obtaining a digital constant that will be greater the higher the kVp applied and vice versa.

2) *Sensor box design:* Since the wavelength of light to be measured is in the visible light range, it is necessary to manufacture a box where the sensor and the phosphor screen are isolated from the light signals that may interfere with the measurement process. For this, the design is made in the AutoCAD software Fig. 1 and the .stl file is obtained, in this kVp sensor box is housed the light sensor, the phosphor screen that performs the measurement of kVp indirectly, plus a distance sensor installed in order to perform all measurements at the same distance and an OLED screen as user interface.

D. Time Measurement

Since the radiation from this equipment is ionizing, the exposure time is a parameter to be controlled, since the less time without sacrificing image quality the less radiation a patient will receive, it is necessary to measure the exposure time.

1) *ESP32 internal timer*: To perform the time measurement is used the *timer0* of the microcontroller *ESP32* that will use the signal emitted by the sensor *TSL2591* to start and end the trigger time count. This measurement is performed in the range of [ms], by tests performed the microcontroller can measure signals in the order of 15 [us].

E. Distance Measurement

Since the distance between the X-ray tube and the phosphor plate can be a factor in the measurement error, a distance sensor is used to ensure that the data acquisition is always at the same distance.

1) *HCSR04 sensor*: The *HCSR04* distance sensor is an ultrasonic type sensor that provides the possibility to measure distance in a range from 0 to 4 m with a sensitivity of 1 cm. It is installed next to the *Kvp* sensor in order to ensure that all measurements are made at the same distance and thus guarantee repeatability of the measurements made.

F. 20X4 OLED and LCD Display

After data acquisition, it is necessary to exchange information with the user, so that the user can acquire measurement information. Due to the practicality, size, low power consumption and connectivity with the *ESP32*, a 0.96" *OLED* screen will be used to display results on the *kVp* measurement device. In addition, the main control will use a 4x20 *LCD* coupled to an *I2C* module which facilitates the connection to the *ESP32* for the same purpose of being a user interface.

G. Web Server

Using the *Wifi* connectivity provided by the *ESP32* microcontroller, the measurement data obtained with the sensors is transmitted via a web server to a cell phone or laptop connected to the same network as the microcontroller. [22] This reduces the exposure to radiation and speeds up the verification and calibration process of the X-ray equipment, since the data transmission will be instantaneous via *wifi*.

H. ESP32

For the development of the measurement tool a development board is used that has integrated the *ESP32* family microcontroller that are manufactured by *espressif*, because this family of microcontrollers has *bluetooth* and *wifi* connection [23], By having *wifi* it is possible to create a web-server for the exchange of information *ESP32-Mobile* device, which is an advantage, since this allows to reduce the risk of exposure to X-rays by being able to exchange information from the control room of the X-ray equipment with the study room where the measurement equipment is located. Communications with the sensors and output peripherals are handled by *I2C* communication protocol [24]. Fig. 2 shows a

general diagram of the communications between the sensors, the microcontroller and the output peripherals. The flowchart shown in Fig. 3 shows the programming logic of the *ESP32*.

Fig. 2. General operating diagram

1) *Control box design*: In the control box is the current sensor (*INA219*), the *LCD 4x16* and the *ESP32* microcontroller, in turn is connected to the other sensors and peripherals output via *I2C* communications [25] with the sensor box *kVp*, *ESP32* processes the data obtained by the sensors and output signals are issued to the *OLED*, *LCD* and web server. For the design of the control box the *Autocad* software is used and the *.DWG* file is obtained, with which the cuts are made on a laser cutting machine, the cuts are shown in Fig. 4 The design of the box is shown in the Fig. 5.

III. RESULTS

This section shows the results obtained from the measurements made with the measurement equipment to an *Ameri-*

Fig. 3. General operating flow diagram

comp X-ray equipment model TXR-325, which operates in kVp from 30[kV]to150[Kv], in current from 0to500[mA] and in time from 0 to 5 [s], also are shown in this section the prototypes manufactured for the control box and sensor box kVp.

A. Case fabrication on 3D printer

Using a 3D printer, the kVp sensor box shown in the Fig. 6 is manufactured. First the design was made using the autoCAD software, the measures are 9x8x4 cm, once finished, it was exported to the 3D printer. The figure is recreated in a plastic, known as polylactic acid or PLA.

Fig. 4. Laser cuts

Fig. 5. Box Control

B. Laser Cutting Machine Control Box Manufacturing

Using a laser cutter, the kVp control box shown in the Fig. 7 was manufactured. First, the design was made using the autoCAD software, it was generated in 2D, the measurements are 7x12x3.5 cm, once finished, it was exported to the laser cutter. The figure is recreated in a 3 mm thick acrylic.

C. measurements Performed

The Fig. 8 shows the complete measurement prototype, with which the measurements presented in this article were performed, the results are displayed on the OLED, LCD and a Web server that displays the results; the Fig. 9 shows an example of how the data is viewed from the control room on the Web server from a device that can be a laptop or a Smartphone, thus the measurement is performed safely without exposure to radiation.

Since there is no standard equipment, the measurements presented in the article are made assuming an error of zero, i.e. assuming that the Americomp model 325 X-ray equipment on which the tests were performed is the standard equipment and it is assumed that it is calibrated.

Similarly, the mean absolute error is calculated for each measured variable, using the formula in equation 1.

$$MAE = \frac{1}{n} * \sum_{i=1}^n |Y_i - X_i| \quad (1)$$

The analyzed measures are as follows:

1) Time measurement:

The time measurement is performed non-invasively by taking the TSL2591 sensor signal as the trigger start and termination signal for the ESP32 internal timer that keeps track

of the trigger duration time. The results of the measurements performed are shown in the Table I, where t_s is the set time and t_m is the time measured by the ESP32 internal timer.

The mean error for the calculated time is shown in equation 1, taking t_s as Y_i and t_m as X_i .

$$MAE = 2 \text{ ms}$$

2) *Current Measurement:* The current measurement is performed invasively by placing the INA219 sensor in series with

TABLE I. TIME MEASUREMENTS

t_s	t_m	Error
100[ms]	101[ms]	1%
200[ms]	199[ms]	0.5%
300[ms]	299[ms]	0.33%
400[ms]	402[ms]	0.5%
500[ms]	501[ms]	0.2%
800[ms]	803[ms]	0.37%
1000[ms]	1005[ms]	0.5%

the secondary of the high voltage transformer and communicating the measurement to the ESP32 via I2C communication. The results of the measurements are shown in the Table II, where I_s is the set current and I_m is the measured current.

TABLE II. CURRENT MEASUREMENTS

I_s	I_m	Error
50[mA]	51[mA]	2%
55[mA]	53[mA]	3,64%
60[mA]	57[mA]	5%
70[mA]	69[mA]	1,43%
80[mA]	78[mA]	2,5%
90[mA]	91[mA]	1,1%
100[mA]	99[mA]	1%
150[mA]	147[mA]	2%

The calculated mean current error is shown in equation 1, taking I_s as Y_i and I_m as X_i .

$$MAE = 1,75 \text{ mA}$$

3) *mAs Measurement*: Having the current and time measurements we can find the measured *mAs* using the equation 2, where I_m and t_m are the results of the current and time measurements respectively, the results obtained from the calculated *mAs* measurements are shown in the Table III where mAs_s is the $mAs_{selected}$ and mAs_m is the $mAs_{measured}$.

$$mAs = I_m * t_m \quad (2)$$

TABLE III. MAS MEASUREMENTS

mAs_s	mAs_m	Error
50[mAs]	51[mAs]	2%
100[mAs]	104[mAs]	4%
200[mAs]	203[mAs]	1,5%
300[mAs]	302[mAs]	0,67%
400[mAs]	397[mAs]	0,75%
500[mAs]	496[mAs]	0,8%

The mean error for the calculated mAs is shown in equation 1, taking mAs_s as Y_i and mAs_m as X_i .

$$MAE = 2.83 \text{ mAs}$$

Fig. 10 shows a diagram of the general operation of the kVp meter. The kVp measurement is done indirectly, to find the kVp value the microcontroller makes use of the digital value in binary number delivered by the visible light sensor and making use of the equation 3 calculates the measured kVp value. In the equation 3, N_{binary} is the binary number read by the sensor at the time of exposure and K is the constant found through testing. The results of the kVp measurements performed are shown in the Table IV where kVp_s is the kVp

set in the X-ray equipment, kVp_m is the kVp measured with the measuring equipment.

Fig. 10. General operation of kVp meter

$$kVp = N_{binario} * K \quad (3)$$

TABLE IV. kVp MEASUREMENTS

kVp_s	kVp_m	Error
50[kVp]	51[kVp]	2%
55[kVp]	53[kVp]	3,64%
60[kVp]	57[kVp]	5%
70[kVp]	69[kVp]	1,43%
80[kVp]	78[kVp]	2,5%
90[kVp]	91[kVp]	1,1%
100[kVp]	99[kVp]	1%
150[kVp]	147[kVp]	2%

The mean error for the calculated kVp is shown in equation 1, taking KVps as Y_i and KVpm as X_i .

$$MAE = 1,75 \text{ kVp}$$

4) *Distance measurement*: The distance measurement made by the ultrasonic sensor between the collimator and the

fabricated sensor is compared with the measurements taken with a flexometer, the results of the measurements made are shown in the Table V, it should be noted that the kVp measurements were made at a distance of 1[m].

TABLE V. DISTANCE MEASUREMENTS

Distance	Distancie _m	Error
10[cm]	9, 8[cm]	2%
20[cm]	19, 9[cm]	0, 5%
35[cm]	35, 1[cm]	0, 28%
50[cm]	49, 7[cm]	0, 60%
80[cm]	80, 2[cm]	0, 25%
90[cm]	89, 9[cm]	0, 11%
100[cm]	99, 8[cm]	0, 2%

The mean error for the calculated distance is shown in 1, taking distance as Yi and measured distance as Xi.

$$\text{MAE} = 0,17 \text{ cm}$$

The measurement instrument designed allows to have an impact in favor of the health of the operators and users of the machines in charge of generating the X-rays, due to the fact that the exposure to radiation decreases when carrying out the measurements in short times and also through of the webserver tool and an IP to transmit and view them in a control booth.

IV. LITERATURE REVIEW

The articles used as reference in this research are in common agreement on how important it is to minimize the time and distance of exposure to X-rays, finally, we can find concepts, methodologies and proposed applications focused on different areas such as biomedicine for means of embedded systems.

That is why applications have been proposed that seek to be less exposed to these rays, such as the one created through Atmega328p, with the limitation that it is only for Android devices, since it is implemented under an application or the one designed by means of the intel386EX for the real-time communication system of a moving vehicle but only for a closed network.

V. CONCLUSIONS

The impact of the media system designed in the field of medicine is very important and improves because it allows monitoring the X-ray equipment from a mobile device keeping a prudent distance from it, which generates a positive benefit for patients and operators, the first they could have a more optimal and efficient team, and the latter would avoid the recurring exposure to which they are immersed

It is common knowledge that exposure to X-rays generates short, medium and long term damage to health, therefore it is of vital importance to seek solutions that allow users and operators to mitigate these health consequences, that is why from our branch, we thought and implemented a measurement system that can be operated and monitored remotely.

The specification of the controller is vital for the desired application, in this case an ESP32 was selected, as it has the advantage of connecting to WIFI natively, which makes it ideal for Internet of Things (IoT) type projects such as the one developed, likewise its low cost is another added value.

This measuring equipment allows measurements in conventional equipment operating at 60 [Hz], since in high frequency equipment additional factors must be considered. By the fact that the tests showed the importance of having sensors with a high response speed, because to sample a signal with a frequency of 60[Hz], you must have a sensor module that performs the measurement and makes the transmission of information at least 2[ms], in order to reconstruct a signal.

For this type of measurements it is important to have sensors with a high response speed, since it is necessary to sample signals in the order of [ms], in the implementation of the proposed measurement system was one of the problems presented, because it was not possible to generate the expected signal, simply obtaining measurement points that did not indicate anything, the solution was a sensor with higher speed performance, thus the rectified signal was acquired.

As a future improvement for the proposed media system, it is recommended to use a sensor that is faster in terms of data processing, as this could make the data acquisition for the kVp variable more accurate.

For future research where it is required to implement a control or measurement prototype, it is recommended to have the appropriate protective equipment for work with X-rays.

It is important to keep the traceability of the error of the designed measurement system, for this, it is proposed as an improvement for the future, to use a standard equipment, since with a calibrated instrument we can know the real error of the equipment, and then compare it with our system.

ACKNOWLEDGMENT

I thank the ARMOS research group of the Universidad Distrital Francisco José de Caldas, especially the engineer Fernando Martinez Santa who as a teacher directed the project and also the company Ingenieria Biomedica Setroc for allowing us to run experimental tests under the direction of Daniel Cortes who provided his knowledge and experience in the area for the realization of this project.

Encrypted Storage Method of Oral English Teaching Resources based on Cloud Platform

Tongsheng Si

School of Culture-Tourism and International Education, Henan Polytechnic Institute, Nanyang, China

Abstract—With the development of the times, the secure storage of educational resources has become one of the key security problems faced by colleges and universities. On the one hand, the cost of traditional resource storage is too expensive, on the other hand, its encryption and access efficiency are low. To solve this problem, this research takes the cloud platform serves as the main carrier for the encrypted storage of school teaching resources. On this basis, the convolutional neural network is encrypted and optimized, and the argmax algorithm is improved to improve the access efficiency of encrypted data. Finally, the effectiveness and superiority of the design method are compared and analyzed through the method of performance detection. The results show that the maximum consumption time of encryption and decryption of the encrypted storage model is no more than 20000ms, which is significantly less than that of the traditional model. The running time of the argmax output encryption module is 1.76ms and the running loss is 0.26 MB, which is less than that of the traditional model. It can be seen that the encrypted storage model has stronger encryption performance and access performance, and has a better application effect in the encrypted storage of oral English teaching resources with a large amount of access data and frequent updates.

Keywords—Cloud platform; oral language; encryption; resource storage

I. INTRODUCTION

With the development of modern network technology, the cloud platform, as a new cloud service model, can provide more secure and efficient services for users who need computing and storage services through the deployment of a cloud machine learning model [1]. The development of cloud platform technology provides customers with services that need a high budget and high-tech support in the actual environment more conveniently and economically. Encrypted storage is one of the main types [2]. For modern colleges and universities, the security of teaching resources is one of the main security problems in the teaching process. Oral English teaching resources themselves have the characteristics of fast replacement speed and a large amount of stored data. As a network grafting service platform, the cloud platform has a stronger fit with the encrypted storage of oral English teaching resources [3]. As a special resource containing multilingual voice and text contrast materials, oral teaching resources are diversified and integrated. At the same time, the resource reserve is large and the real-time update speed is fast. Therefore, the encryption system for oral teaching resources needs higher data processing efficiency and a more robust and easy architecture. Applying cloud platform encrypted storage technology to the encrypted storage of oral English teaching

resources can effectively improve the economy and quickness of the encrypted storage of school teaching resources, and provide teachers and students with better teaching and learning experience while improving security [4]. This research applies convolutional neural network, a robust deep learning model, to cloud platform encryption. On the one hand, it provides a theoretical path for the formation of an economic and practical teaching resource encryption system in colleges and universities, and on the other hand, it provides a new idea for the application research of deep learning algorithm in the field of data encryption.

II. RELATED WORKS

In recent years, the research on encrypted storage has developed more deeply from the perspective of encryption details and user experience. Li M et al. constructed an encrypted storage scheme using a searchable symmetric encryption method and used locally sensitive hash and bloom filter with high search accuracy. The results show that the encryption efficiency of this method is higher than that of the traditional method [5]. Xue K et al. proposed a method to protect encrypted cloud storage from EDOS attacks. This method reduces the resource consumption cost of cloud computing users and can comply with any access policy of cp-abe. The results show that this method has higher security and practicability [6]. Kumar G K's team proposed an encrypted storage algorithm using symmetric encryption keys for the same set of keys. The results show that the algorithm can reduce the data burden of cloud storage in the form of eliminating duplicate data, and can provide more efficient data access by using access policies [7]. Rao E et al. provided a secure data search method for encrypted user data. The results show that this method can provide users with different types of online data while ensuring users' privacy and data security [8].

On the other hand, the research based on cloud platform is gradually diversified. Farhadi H et al. used the cloud platform to quickly and automatically detect the time series image of measuring the burn area, so as to obtain the accurate information of the density and distribution of the combustion area in the large vegetation coverage area. The results show that this method has stronger dynamic real-time performance and can greatly improve the accuracy of the map of the combustion area [9]. Taking the cloud platform as the basic framework of smart education, Liu steam proposed a dual high-precision cooperation strategy to accurately perceive the needs of smart teaching and resource supply. The results show that this method not only improves the effectiveness of communication between teaching resources and learning

needs, but also provides teachers and learners with a more personalized and secure data access strategy [10]. Liu P proposed an EV battery voltage evaluation strategy based on cloud platform, and used the spatial clustering method with noise to improve the calculation efficiency of outlier detection. The results show that this method not only maintains high recognition ability, but also reduces the complexity of calculation and has higher calculation efficiency [11]. Choi S et al. Built a digital twin data platform based on cloud platform to facilitate novices to build digital twin data schemes more quickly and easily. An example shows that this method is fast and effective [12]. This research applies the cloud platform, which has compatibility and diversified development direction, to the encrypted storage of teaching resources, and provides the school with a more economical and reliable security scheme of teaching resources through the encrypted storage service of cloud platform.

III. DESIGN OF ENCRYPTED STORAGE METHOD OF ORAL ENGLISH TEACHING RESOURCES ON CLOUD PLATFORM

A. Design of Cloud platform Storage Encryption Method based on Convolutional Neural Network Algorithm

Modern teaching resource storage is divided into three

main ways. One is that users graft and train the encryption storage module of teaching resources by themselves. For the school that lacks practical and technical talents in network and intelligent computing technology, the cost of designing the encryption storage system of teaching resources alone is too high, and it is technically impossible to achieve to a certain extent [13]; the second is to use it by renting a third-party encrypted storage model. Although this method can solve its own technical shortcomings, the maintenance cost is still relatively high, and the encrypted storage process is controlled by the third-party organization in the whole process, which has a certain risk; the third is to use cloud platform services for teaching resource storage [14]. For oral English teaching, which needs to constantly update a large number of oral interactive resources, cloud platform encrypted storage is a more secure, economical and real-time encrypted storage method. However, there are still some risks in cloud platform encrypted storage. This risk is mainly reflected in the infrastructure of cloud platform. The infrastructure of cloud platform encrypted storage is shown in Fig. 1.

Fig. 1. Cloud platform based encrypted storage architecture

Fig. 2. Convolutional neural network

Fig. 1 shows the basic encrypted storage architecture of the cloud platform. It can be seen that users communicate with the cloud platform mainly through interactive channels. This way of user operation, channel communication, and cloud encrypted storage is easy to form the risk of resource leakage in two parts. One is the security and privacy protection of the cloud platform itself, that is, whether the encrypted storage model used by the cloud platform is reliable; the other is the data transmission security problem that may occur in the process of user interaction with the cloud platform. In this study, the two storage security issues are studied respectively. For the security and privacy protection of the cloud platform itself, this research optimizes the convolutional neural network algorithm based on the characteristics of encrypted storage of spoken English teaching resources. This is mainly because the convolutional neural network itself has strong deep learning ability and structural stability. For the college encryption application scenario, the convolutional neural network has lower application costs, is economical, and requires less maintenance consumption. Colleges and universities can implement the application without consuming a lot of technical support. The specific schematic diagram of the architecture is shown in Fig. 2.

The convolution neural network model in Fig. 2 is divided into three main parts: input part, convolution part and output part. The main input content of the input part of the optimized encrypted storage convolution neural network model in this study is to store the ciphertext used for encryption. This part of ciphertext can be divided into two specific ciphertexts, both of which are $w \times h \times c$ in size. The two ciphertexts are expressed as real part $[F(x)_R]$ and imaginary part $[F(x)_I]$ respectively. At this time, the number of plaintext slots of the system is n , and the convolution kernel parameter of plaintext of the system is k . At this time, the convolutional neural network encrypted storage model performs the operation by means of fast Fourier transform, and the real part operation result can be obtained:

$$[F(y)_R] = [F(x)_R] \otimes [F(f_i)_R] \oplus [F(x)_I] \otimes [-F(f_i)_I] \quad (1)$$

In formula (1), y represents the convolution result of the algorithm, x represents the input data, \otimes represents homomorphic multiplication, and \oplus represents homomorphic addition. Calculate the imaginary part of the ciphertext in the same way to obtain formula (2):

$$[F(y)_I] = [F(x)_R] \otimes [F(f_i)_I] \oplus [F(x)_I] \otimes F(f_i)_R \quad (2)$$

$F(f_i)_I$ and $F(f_i)_R$ represent the Fourier transform results of convolution kernel respectively. The cloud platform will automatically generate random variables r after calculation. The size of the random variable r is $w \times h$. On

this basis, the cloud platform encrypts the results of the fast Fourier transform and sends the ciphertext to the user. The real encryption formula is shown in formula (3):

$$[F(y-r)_R] = [F(y)_R] \oplus [-F(r)_R] \quad (3)$$

In formula (3), $[F(y-r)_R]$ represents the real content of the ciphertext sent by the cloud platform to the customer, and $[-F(r)_R]$ represents the real fast Fourier transform encryption result. The imaginary part ciphertext can be obtained by adopting the same calculation method:

$$[F(y-r)_I] = [F(y)_I] \oplus [-F(r)_I] \quad (4)$$

In formula (4), $[F(y-r)_I]$ respectively represents the virtual part ciphertext content sent by the cloud platform to customers, and $[-F(r)_I]$ represents the virtual part fast Fourier transform encryption result. After the user decrypts the ciphertexts at both ends respectively, the two short ciphertexts can be combined to form a complete $F(y-r)$, and then the $(y-r)$ can be obtained by inverse fast Fourier transform. At this time, the cloud platform and the user can share the state of additivity. The common setting formula is:

$$\begin{cases} x^s = r \\ x^c = y - r \end{cases} \quad (5)$$

Where s represents the cloud platform, c represents the client, and r represents that the cloud platform will automatically generate random variables after operation. The plaintext convolution kernel parameters of the convolution neural network model are encrypted and stored. The calculation flow of the encryption process is shown in Fig. 3.

Fig. 3. Encrypted convolutional neural network flow

In the practical application of encrypted storage of teaching resources, due to the requirements of oral English teaching storage and real-time update, more complex operations are often required. In this case, the convolution cores of the convolution layer must participate in the independent input and convolution process, so as to obtain their own convolution results. Here, it can be assumed that there are C convolution cores and the same number of data channel inputs in the convolution layer. At this time, the system needs to treat each input and filtering calculation process as a separate data operation group in the ciphertext domain, carry out parallel operation through the operation method in a simple case, obtain C ciphertext individual

results at the same time, and then accumulate a large number of ciphertext individual results to form the final overall ciphertext results. In addition to the convolution layer, this study also optimizes the activation layer of the encrypted storage product neural network model. Since the encrypted storage design conducted in this study requires the convolutional neural network model to perform nonlinear calculation, it is necessary to select the nonlinear function of the activation layer. The commonly used convolutional neural network activation functions include tanh function and relu function. The comparison of the function images of the two functions is shown in Fig. 4:

Fig. 4. Function image comparison

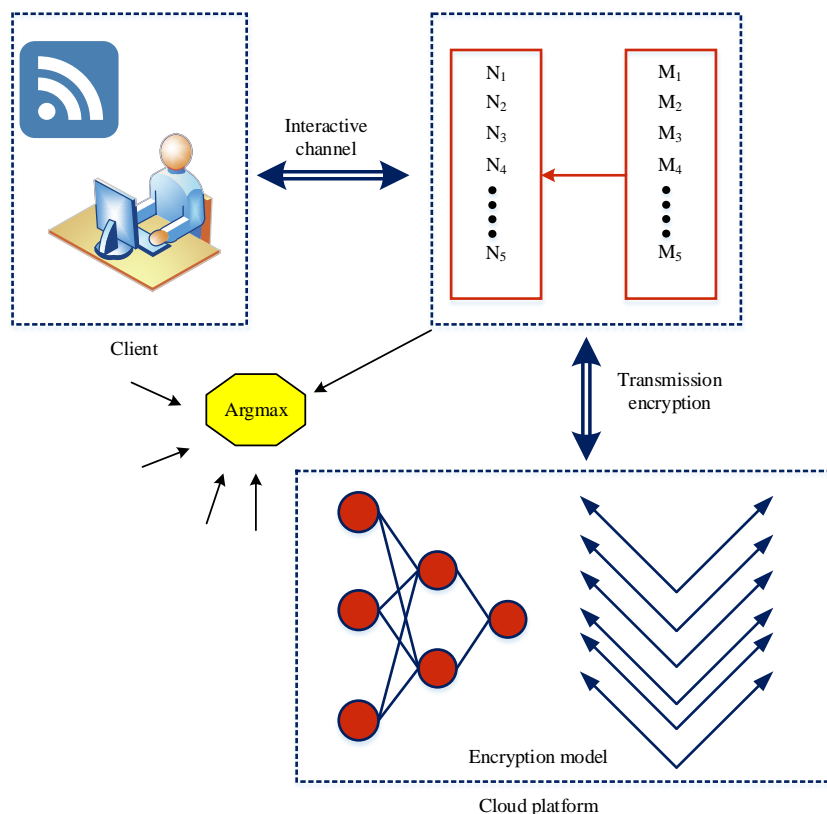

Fig. 5. Storage data transmission optimization

Tanh function formula is shown in formula (6):

$$\tanh(x) = 2 \cdot \text{sigmoid}(2x) - 1 \quad (6)$$

As shown in the calculation formula of Lu power division, it is more difficult to select and activate the Lu power division function (Reh) in the design process, so it is more difficult to activate the two kinds of operation formulas:

$$f(x) = \max(0, x) \quad (7)$$

Relu activation function can clear all nonpositive terms in the input data center, balance the size relationship between input data and output data on this basis, enable each neuron to be activated in the process of input and output, and continuously transfer this activation state downward. This method can help the model improve its input sparsity and model activity, and improve the operational performance of the model. Design of cloud platform output encryption method based on argmax algorithm

The ultimate purpose of the encrypted storage model of cloud platform oral English teaching resources designed in this study is to effectively ensure the security of teaching data in the two operations of customer storage and data transmission. Therefore, after the optimization design of the storage model, the research will also carry out the security design for the data transmission part of the cloud platform encrypted storage model, which is mainly optimized by the argmax algorithm, the overall optimization position is shown in Fig. 5:

It can be seen from Fig. 5 that the Argmax algorithm

mainly acts on the transmission channel established when users communicate with the cloud platform on the channel, and improves data security by strengthening the reliability in the process of data input and output. In the cloud platform encryption storage algorithm designed in this study, cloud platform has encrypted the oral English teaching resources. When users need to take out or input data from the cloud platform storage, they need to access the data through the common protocol between the client and the cloud platform. This research mainly uses the optimized convolution neural network algorithm as the main storage encryption technology. The output of the last convolution layer in the convolution neural network is called Logits, which represents the weight difference between different categories in the input process, and the main function of the softmax layer is to convert Logits into the vector form representing the probability values of different categories. The softmax function is shown in formula (8):

$$f(x)_k = \frac{e^{x_i}}{\sum_{k=1}^K e^{x_k}} \quad (8)$$

Where $i = 1, 2, \dots, K$, K represents the length of Logits vector. The final classification result can be expressed as:

$$t = \arg \max(\log its) \quad (9)$$

The model connection between softmax layer and argmax algorithm is shown in Fig. 6.

Fig. 6. Model connection

In this study, the improved argmax algorithm is used to encrypt the data access part. The Logits vector obtained from cloud platform encryption can be expressed as:

$$Enc(x) = (Enc(x_1), Enc(x_2), \dots, Enc(x_n)) \quad (10)$$

Where x represents the generated random vector. The cloud platform extracts two ciphertexts arbitrarily from the ciphertext set and performs homomorphic subtraction calculation for the ciphertext to obtain $n \cdot (n-1)$ new ciphertexts. The specific matrix is shown in formula (11):

$$\begin{bmatrix} [x_1 - x_2] & [x_1 - x_3] & \dots & [x_1 - x_n] \\ [x_2 - x_1] & [x_2 - x_3] & \dots & [x_2 - x_n] \\ \dots & \dots & \dots & \dots \\ [x_n - x_1] & [x_n - x_2] & \dots & [x_n - x_{n-1}] \end{bmatrix} \quad (11)$$

Since the optimized convolutional neural network encryption storage model used in this study adopts the combined encryption mode of real part ciphertext and imaginary part ciphertext, after obtaining the basic Logits vector matrix, it needs to be transformed into the form of double encryption matrix corresponding to the double ciphertext mode. The estimated size of the ciphertext matrix is n , and each individual ciphertext contains $n-1$ plaintext data different from each other, Ciphertext matrix itself has the dual commonalities of cloud platform and client. After the $n-1$ subhomomorphic subtraction, the cloud platform needs to perform random inter row conversion on the ciphertext matrix to obtain the row random matrix formed by the combination of double ciphertext matrices. The specific formula is shown in formula (12):

$$\begin{bmatrix} [x_{\psi_1} - x_{\pi_{\psi_1}(2)}] & [x_{\psi_1} - x_{\pi_{\psi_1}(3)}] & \dots & [x_{\psi_1} - x_{\pi_{\psi_1}(n)}] \\ [x_{\psi_2} - x_{\pi_{\psi_2}(1)}] & [x_{\psi_2} - x_{\pi_{\psi_2}(3)}] & \dots & [x_{\psi_2} - x_{\pi_{\psi_2}(n)}] \\ \dots & \dots & \dots & \dots \\ [x_{\psi_n} - x_{\pi_{\psi_n}(1)}] & [x_{\psi_n} - x_{\pi_{\psi_n}(2)}] & \dots & [x_{\psi_n} - x_{\pi_{\psi_n}(n-1)}] \end{bmatrix} \quad (12)$$

Where $(\psi_1, \psi_2, \dots, \psi_n)$ represents a random arrangement of $(1, 2, \dots, n)$, and on this basis, $(\pi_{\psi_1}(2), \pi_{\psi_1}(3), \dots, \pi_{\psi_1}(n))$ can be obtained by removing ψ_1 from the arrangement, while $(\pi_{\psi_2}(1), \pi_{\psi_2}(3), \dots, \pi_{\psi_2}(n))$ represents the nonrandom arrangement after removing ψ_2 from the arrangement. After the cloud platform analogizes the matrix, it then randomizes the matrix of formula (12) with two matrices to obtain:

$$\begin{bmatrix} r_2^1 & r_2^1 & \dots & r_n^1 \\ r_1^2 & r_3^2 & \dots & r_n^2 \\ \dots & \dots & \dots & \dots \\ r_1^n & r_2^n & \dots & r_{n-1}^n \end{bmatrix}, \begin{bmatrix} \varepsilon_2^1 & \varepsilon_2^1 & \dots & \varepsilon_n^1 \\ \varepsilon_1^2 & \varepsilon_3^2 & \dots & \varepsilon_n^2 \\ \dots & \dots & \dots & \dots \\ \varepsilon_1^n & \varepsilon_2^n & \dots & \varepsilon_{n-1}^n \end{bmatrix} \quad (13)$$

Formula (13) represents a random positive number r_j^i , $\varepsilon_j^i \in [0, r_j^i]$. The first ciphertext matrix and the row random matrix are multiplied by homomorphic multiplication, and then the matrix is interleaved with the second ciphertext matrix by homomorphic subtraction to obtain a fully random ciphertext matrix. The specific matrix is shown in formula (14):

$$\begin{bmatrix} [r_2^1 \cdot (x_{\psi_1} - x_{\pi_{\psi_1}(2)}) - \varepsilon_2^1] & \dots & [r_n^1 \cdot (x_{\psi_1} - x_{\pi_{\psi_1}(n)}) - \varepsilon_n^1] \\ [r_1^2 \cdot (x_{\psi_2} - x_{\pi_{\psi_2}(1)}) - \varepsilon_1^2] & \dots & [r_n^2 \cdot (x_{\psi_2} - x_{\pi_{\psi_2}(n)}) - \varepsilon_n^2] \\ \dots & \dots & \dots \\ [r_1^n \cdot (x_{\psi_n} - x_{\pi_{\psi_n}(1)}) - \varepsilon_1^n] & \dots & [r_{n-1}^n \cdot (x_{\psi_n} - x_{\pi_{\psi_n}(n-1)}) - \varepsilon_{n-1}^n] \end{bmatrix} \quad (14)$$

This operation process requires n sub homomorphic subtraction, homomorphic addition and homomorphic multiplication. When different types of homomorphic addition operations are carried out, it is necessary to change the setting mode in the operation process to ensure that the random number generated in the calculation process will not affect the symbol corresponding to the encrypted plaintext, that is, in the homomorphic encryption operation process, its influence on the symbol data is limited by the value range of the associated random number. After the cloud platform obtains the random ciphertext matrix, it can send the matrix information to the access user. The access user decrypts the ciphertext matrix using the common protocol to obtain the plaintext matrix. The specific matrix is shown in formula (15):

$$\begin{bmatrix} r_2^1 \cdot (x_{\psi_1} - x_{\pi_{\psi_1}(2)}) - \varepsilon_2^1 & \dots & r_n^1 \cdot (x_{\psi_1} - x_{\pi_{\psi_1}(n)}) - \varepsilon_n^1 \\ r_1^2 \cdot (x_{\psi_2} - x_{\pi_{\psi_2}(1)}) - \varepsilon_1^2 & \dots & r_n^2 \cdot (x_{\psi_2} - x_{\pi_{\psi_2}(n)}) - \varepsilon_n^2 \\ \dots & \dots & \dots \\ r_1^n \cdot (x_{\psi_n} - x_{\pi_{\psi_n}(1)}) - \varepsilon_1^n & \dots & r_{n-1}^n \cdot (x_{\psi_n} - x_{\pi_{\psi_n}(n-1)}) - \varepsilon_{n-1}^n \end{bmatrix} \quad (15)$$

The access client finally counts and classifies the matrix plaintext symbols of each line, and obtains the corresponding real value at the cloud platform.

IV. EFFECT ANALYSIS OF ENCRYPTED STORAGE METHOD OF ORAL ENGLISH TEACHING RESOURCES ON CLOUD PLATFORM

A. Analysis of Storage Encryption Effect of Neural Network

In the part of the effect analysis of the encrypted storage method of oral English teaching resources on the cloud platform, this study will be divided into two parts: cloud platform storage encryption and cloud platform storage and

transmission encryption according to the cloud platform structure of oral English teaching resources. The cloud platform storage encryption part takes the optimized convolutional neural network storage encryption model as the main encryption storage tool. Therefore, this research will analyze the connection layer performance of the model, the running time and overhead of the model, and the efficiency of encryption and decryption. In order to explore the performance change of the model when the user input demand increases but the model output is stable, the performance of the model connection layer is analyzed. The performance analysis of the connection layer of the model is shown in Fig. 7.

Fig. 7 shows the operation performance changes of the connection layer under different input levels when the output level is fixed. Here, the operation performance changes are measured mainly by running time. As can be seen from Fig. 7, the operation efficiency of the model running time in the setting stage and the operation stage is significantly different. Under almost all input variables, the operation efficiency of the model connection layer in the operation stage is significantly higher than that in the setting stage. On this basis, observing the operation efficiency caused by the change of input variables, it can be found that when the value of input variables is between 2000 and 2500 and between 4000 and 4500, the operation efficiency of the connection layer has changed greatly. When the input variable value is between 2000 and 2500, the running time of the connection layer in the setting stage increases from 5.4ms to 7.8ms, while the running time of the connection layer in the setting stage increases from 2.9ms to 4.1ms, and the running efficiency decreases significantly. This is because the plaintext slot size of the model in this study is 2048, that is, a ciphertext in the model can support 2048 plaintext at the same time when it is most saturated, Therefore, when the amount of input data exceeds this amount, the operation efficiency of the model connection layer is greatly affected. In addition, in the stage where the value of the input variable is between 4000 and 4500, it is the

node when the number of inputs exceeds twice the number of plaintext slots, so the impairment of operational efficiency is more obvious. To sum up, when the number of inputs does not exceed the number of plaintext slots, the performance of the connection layer of the model involved in this time is relatively reliable, but after exceeding, the performance will be affected to some extent, which is a normal phenomenon. In this study, the overall running time and running cost of the model is tested by distinguishing the storage encryption scheme from the convolution neural model. The convolution neural model selects the MNIST model and cifar-10 model respectively, and the storage encryption scheme selects minions and gazelle. The specific test results are shown in Fig. 8.

Fig. 7. Performance analysis of connection layer

Fig. 8. Data set performance test

Fig. 8 compares and analyzes the models from the perspectives of running time and running cost. The results show that the running time of the model optimized in this study is 0.64ms under the small data set, 0.18ms online, and 0.82ms overall. The overall running time is less than 9.34ms of the minion model and 1.35ms of the gazelle model, and the running time in the setting stage and online stage is smaller; In terms of running cost, the model optimized in this study sets the running cost to 40.4 MB under the small data set, the online running cost to 21.8 MB, and the overall running cost to 61.8 MB. The overall running cost is less than 657.5 MB for the minion model and 67.0 Mb for the gazelle model, and the running cost is less in the setting stage and online stage; Under the large data set, the set running time of the model

optimized in this study is 10.4ms, the online running time is 3.30ms, and the overall running time is 13.7ms. The overall running time is less than 543.3ms of the minion model and 19.86ms of the gazelle model, and shows significant advantages in the running time of the setting stage and online stage; In terms of running cost, the model optimized in this study sets the running cost as 897.1 MB under large data set, 343.4 MB on-line running cost and 1240.5 MB overall running cost. The overall running cost is less than 9272.0 MB for the minionn model and 1278.7 MB for the gazelle model, and the running cost in the setting stage and online stage is smaller. The analysis of the encryption and decryption efficiency of the model is shown in Fig. 9.

Fig. 9. Analysis of encryption and decryption efficiency

It can be seen that the encryption time and decryption time of the traditional model and the model optimized in this study show a positive proportional trend with the increase of the data scale. In terms of encryption time, taking the 512KB data scale as the starting point, the encryption time of the traditional model and the model designed in this study has increased significantly, but the encryption time of the model optimized in this study on each data scale node is relatively less, and the highest time point is no more than 20000ms; The decryption time of each node of the traditional research model is not less than 2m, but the decryption time of each node of the traditional design model is not less than 2m. It can be seen that the optimized models have higher operation efficiency in the process of encryption and decryption.

B. Analysis of Output Encryption Effect of argmax Algorithm

In the cloud platform storage and transmission encryption analysis part, this research first analyzes the running time and transmission efficiency of optimizing the traditional module of argmax. In the analysis process, the research will take the category parameters and precision values as the main distinguishing dimensions. The correlation analysis of category parameters is shown in Fig. 10.

It can be seen that the operation time and operation consumption data of the optimized argmax output encryption module under the three category parameters of 10, 100, and 1000 are 0. It can be seen that the optimized argmax output encryption module does not need to operate in the setting stage. In the online operation stage, when the category parameter is 10, the operation time of the system is 0.21ms;

When the category parameter rises to 100, the running time of the system is 2.01ms; When the category parameter rises to 1000, the running time of the system is 20.01ms; It can be seen that the running time of the optimized argmax output encryption module shows an increasing trend with the increase of category parameters. In terms of system operation consumption, when the category parameter is 10, the system operation consumption data is 0.59 Mb; When the category parameter rises to 100, the consumption data of the system is 5.92 Mb; When the category parameter rises to 1000, the consumption data of the system is 59.21 Mb; It can be seen that the amount of data transmitted by the optimized argmax output encryption module shows an increasing trend with the growth of category parameters. It can also be seen from the growth law of the two indicators that with the increase of category parameters in the order of 10 times, the running time and the amount of transmitted data of the system also increase in the order of 10 times. This indicates that the operation efficiency and loss of the system are relatively stable and will not exceed the expected additional loss with the increase in operation demand, which proves that the overall system is still stable in the face of the excessive operation. As different precision operations will lead to different system operation costs, if the system has a large difference in operation costs between high precision and low precision, the overall system operation stability will be insufficient, which will easily lead to higher performance consumption and resource waste. Therefore, the research will analyze the system costs under different precision. The specific accuracy analysis results are shown in Fig. 11.

Fig. 10. Category parameter analysis

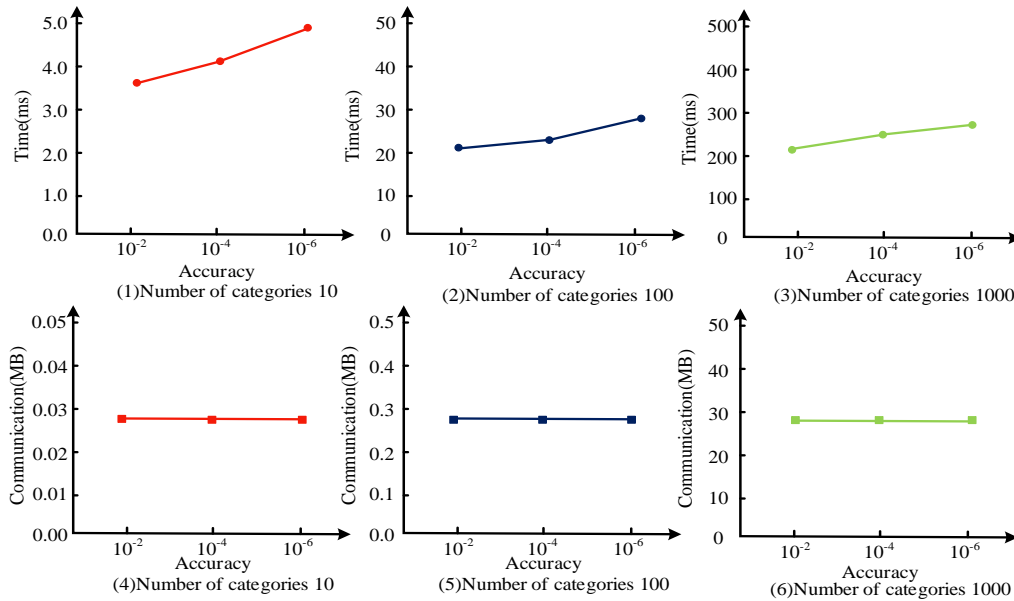

Fig. 11. Accuracy analysis

Fig. 12. Performance comparison of overall transmission module

Fig. 11 analyzes the running time and running consumption of 10, 100, and 1000 parameters under the accuracy conditions of 10-2, 10-4, and 10-6. The results show that when the category parameter is 10, the running time of the system increases gradually with the increase of accuracy, the overall range is between 3.0 and 5.0, while the running consumption does not fluctuate, and remains at 0.028 under all

accuracy; When the category parameter is 100, the running time of the system also shows a gradually increasing trend with the increase of accuracy, the overall range is between 0.2 and 0.3, while the running consumption does not fluctuate and remains at 0.28 under all accuracy; When the category parameter is 1000, the running time of the system still shows a gradually increasing trend with the increase of accuracy, the

overall range is between 20 and 30, while the running consumption does not fluctuate and remains at 28 under all accuracy. It can be seen that the setting and online operation efficiency of the system increase with the increase of accuracy, but the overall operation cost does not change with the change of accuracy but maintains the overall consistency, and the overall operation resource consumption is relatively stable. The comparative analysis of the overall system performance is shown in Fig. 12.

Fig. 12 compares the optimized argmax output encryption module with the traditional argmax output encryption module. The results show that the optimized argmax output encryption module in this study will not produce running time and running consumption in the system setting stage, which is because the optimized argmax output encryption module does not need to be calculated in the setting stage. From the perspective of online operation, the running time and running loss of the optimized argmax output encryption module are relatively small. The running time of the traditional argmax output encryption module is 2.63ms, while the running time of the optimized argmax output encryption module is 1.76ms, the running loss of the traditional argmax output encryption module is 0.29mb, and the running time of the optimized argmax output encryption module is 0.26mb. In addition, from the perspective of system processing time, with the increase of parallel number, the overall system processing time of the optimized argmax output encryption module is less than that of the traditional argmax output encryption module, and with the increase of parallel number, the system processing time of the optimized argmax output encryption module shows a certain downward trend. It can be seen that the optimized argmax output encryption module has stronger encryption processing performance.

V. CONCLUSION

To solve the budget problems and technical difficulties caused by the localized encrypted storage of oral English teaching data, this study takes the cloud platform as the main encrypted storage platform of teaching resources, optimizes the convolutional neural network from the perspective of ciphertext encryption and decryption, and takes it as the main model of cloud platform data storage encryption. On this basis, it studies the encryption improvement of argmax algorithm, makes it more efficient in storing encrypted data, and finally tests the computing performance of the main part and transmission part of the encrypted storage model of the cloud platform. The results show that the overall running time of the encryption model is 0.82 MS under small data sets; the overall running cost is 61.8 MB, and the overall running time is 13.7ms under large data sets; the overall running cost is 1240.5 MB, which is less than other comparable models. The longest consumption time of encryption and decryption of the research and design encryption model is no more than 20000 MS, which is significantly less than that of the traditional model. In terms of encrypted data transmission, the running

time of the optimized argmax output encryption module is 1.76ms and the running loss is 0.26 MB, which is less than the traditional encryption model. It can be seen that the encryption model designed in the research has higher security and higher encryption and decryption efficiency in the encrypted storage and transmission of oral English education resources. At the same time, the cloud platform itself also has strong realizability and economic advantages, which is more suitable to help the school carry out the encrypted storage of oral English education resources and improve the security and access efficiency of educational resources.

Denoising Method of Interior Design Image based on Median Filtering Algorithm

Tao Li

School of Design, Chongqing Industry Polytechnic College, Chongqing, China

Abstract—Interior design image generation process is prone to the interference of many factors, resulting in the interior design image denoising effect decreases, denoising time increases, so the interior design image denoising method based on median filtering algorithm is proposed. The architecture of interior design image collection is set up, including video signal conversion module, compression coding module, programmable logic chip module and power module. The interior design image collection is realized by using sensors to collect interior design related video information and converting video signals. Based on the results of image acquisition, the median filtering algorithm based on rough set theory is used to realize the denoising of interior design images. Experimental results show that the denoising effect of the proposed method is better, the average signal-to-noise ratio of interior design images is 54.6dB, and the denoising time is always lower than 0.3s, which can be widely used in practice.

Keywords—Median filtering algorithm; interior design; image denoising; image acquisition architecture; the rough set

I. INTRODUCTION

Interior design is a comprehensive discipline that studies the artificial environment. It is “a rational creative activity that takes science as the functional basis and art as the form of expression in order to shape an indoor environment where spiritual wealth and material wealth coexist” [1]. With the application of computer image digital interior decoration design technology, the design drawing is no longer an abstract design drawing, but can fully and truly present the design effect and improve the design quality. Before the formal start of interior design, designers should make full preparations. First of all, the designer should build a complete interior design layout in his mind. Based on this layout, the framework should be gradually enriched by collecting data and understanding customer needs [2]. According to the information provided by the customer, the decoration design concept map is sorted out and used as the design framework, which is constantly modified and optimized to form an interior design image. Therefore, the rise of computer image digitization technology has provided great help for interior design. This technology makes designers say goodbye to the traditional manual drawing method and improves the efficiency of drawing work [3]. On the other hand, each detail of interior space can be expressed in a dynamic way, which improves the expressiveness of design drawings. Therefore, the digital work of design drawings has gradually become the mainstream direction of the development of the industry, with high market potential. However, due to the influence of many factors in the process of interior design digitalization, interior

design images include noise, resulting in the deterioration of interior design quality, so it is urgent to study a method of interior design image denoising.

Research for indoor design class image denoising is not much, much more to the rest of the research achievements in the field of migration to the interior design in the image denoising to reference [4], for example on at night, such as indoor under low illumination scene image sensor collected video images are widespread low signal-to-noise ratio and poor visual effect, In order to improve the de-noising effect, a video de-noising method based on time-space frequency(TSF) domain set is proposed. First, a digital gain low illumination image noise model is established, and then, according to the theory of the original video before and after two adjacent frames, finish the image registration based on the optical flow method, get the displacement map, in time-space domain to high frequency image denoising and reconstruction, and then realize the infinite impulse response combined with subsequent noise image processing, at the same time in the airspace for noise reduction, the output after a frame denoising image. However, this method has low signal-to-noise ratio and poor image quality for interior design images, so the practical application effect is not good. In reference [5], an image denoising method based on deep learning is proposed in order to make the noise image clear and obvious, as the image will be polluted by noise due to imperfect equipment and lose the details of the original image. The structure of image denoising network based on convolutional neural network is constructed, and the back propagation algorithm in convolutional neural network is optimized, so as to accelerate the training speed of the model and improve the denoising effect effectively. In order to solve the problem of poor image denoising and rendering in interior design system and consider data rendering, a research method of interior design system combining digital processing technology and image processing technology is proposed, which transmits the image after data processing to the logic layer, by digital processing module using the new threshold function of image denoising algorithm of energy distribution into consideration, Image denoising is realized by multiplying the denoising factors with the same wavelet coefficients. In the image processing module, the bidirectional reflection distribution function model is used to simulate the diffuse reflection of objects, and the Torrance-Sparrow microplane model is used to simulate the specular reflection of objects to achieve image rendering. The logic layer transfers the processed interior design image to the application layer, and displays the interior design result through PC or browser interface, so as to improve the image denoising effect [6]. However, this method is too complicated

and has the problem of long denoising time for interior design images.

In order to solve the problems of the above methods, this paper proposes a denoising method of interior design image based on median filtering algorithm, and verifies the effectiveness of the proposed method through experiments.

II. STANDARD IMAGE ACQUISITION

A. Interior Design Image Collection

In order to improve the quality of interior design class image acquisition, this paper designed image acquisition architecture interior design class, including video signal conversion module, compression module, a programmable logic chip module, power supply module, mainly through the use of sensors to collect interior design related video information, and transformed the video signal processing, image acquisition in interior design class.

1) *Video signal conversion module*: DMD sensor is used to collect interior design related video information, and the video signal is converted. The conversion of video signals is realized by a dedicated video processing chip [7]. This paper uses special video processing chip SAA7113, is a powerful and simple operation of the bit video input processing chip, the chip adopts technology, through the bus and or microcontroller connected to form an application system. It contains two analog processing channels, which can realize video signal source selection, anti-aliasing filtering, conversion, automatic box position, automatic gain control, clock generation, multi-standard decoding, brightness contrast saturation control and multi-standard data decoding.

After the SAA7113 is turned on, the chip does not immediately collect analog video signals for A/D conversion processing and output digital signals. It must be initialized by the front-end processor through the serial bus to set up its internal register before it can operate normally. LLC is the output of line locking clock, which is twice the frequency of pixel clock, and 27MHz is used to synchronize the whole interior design image acquisition architecture. One CYCLE of LLC generates one byte of image data, and the rising edge of LLC can be used as the write signal of frame storage after being inverted in CPLD [8-9]. The function of RTS0 and RTS1 is determined by programming the internal register. RTS0 and RTS1 are thresholds for different routers. The interface is set RTS0 as the horizontal output reference signal line effective signal, and RTS1 as the vertical output reference signal and parity field signal. RTS0: high level means a row of valid pixels, low level means field blanking signal. The rising edge of RTS0 represents the beginning of the effective singular field image, and it is also used to represent the beginning signal of the frame image. The falling edge of RTS1 indicates the start of output of a valid even field image. SAA7113 and its peripheral circuits are shown in Fig. 1.

Fig. 1. SAA7113 and its peripheral circuit

2) *Compression coding module*: The JPEG compression and coding part adopts THE JPEG special codec chip ZR36060, which can realize the image compression and decoding function. In this paper, only its compression and coding function is used [10-11]. ZR36060 is specially designed for computer video acquisition and editing applications, which can easily realize real-time compression and decompression of video signals. During compression, ZR36060 receives digital video signal and encodes it as JPEG stream period; during decompression, it receives a JPEG stream and decodes it into digital video output. The internal structure of ZR36060 is shown in Fig. 2.

VCLK and VCLK×2 are the external clock input. External clock input is connected to the machine terminal by using external oscillation pulse. VCLK×2 is the video clock. For CCIR digital video format, it is connected to the 27MHz clock. VCLK is half the frequency of VCLK×2 and requires synchronization with VCLK×2. SATRT and FRAME are external control signals. The interface of ZR36060 can be divided into video interface, host interface and code interface. The video signal is input and output by the video terminal, the control word of the chip is written and read by the host interface, and the JPEG code is input and output by the code in the activation mode.

Fig. 2. ZR36060 internal structure

3) *Programmable logic chip module:* The microcontroller AT89S52 is the transaction control core of this paper [12]. It will enter the working state after power-on and will run continuously. Therefore, the reset circuit of the microcontroller part adopts power-on reset. Interior design image acquisition architecture does not have high requirements for the running speed of the microcontroller. The clock circuit of the microcontroller is composed of 12mb external crystal and grounding capacitor. Reset circuit and clock circuit are shown in Fig. 3.

The communication between the microcontroller and GPRS network is realized through the universal asynchronous serial interface (UART), and its level standard is RS-232, which is a serial physical interface standard developed by the American Electronics Industry Association. The RS-232 has the fastest transmission speed and the maximum transmission distance of 30m. The serial port adopts MAX232 level conversion chip and DB9 interface. The interface circuit is shown in Fig. 4.

4) *Power module:* The front-end circuit of interior design image acquisition architecture includes digital part and analog part. The interface level of each chip consist of 5 volts and 3.3 volts. To reduce the interference of digital signals with analog circuits, the digital and analog power circuits need to be separated and connected to a point on the circuit board. Considering the power consumption of image acquisition, a three-terminal voltage stabilizer power supply of 5V to 3.3V is utilized. The circuit of the power supply is shown in Fig. 5.

III. INTERIOR DESIGN IMAGE DENOISING METHOD

A. Image Denoising based on Median Filtering Algorithm

As a representative of nonlinear filtering methods, standard median filtering technology can protect image edges while reducing noise, but it only considers the sorting information of data in the filtering window, not the timing information of data, so it will produce edge jitter in image processing. It is possible to remove important image details such as points, corners, and thin lines [13-14]. Considering the problems existing in the standard median filtering, national and international scholars have improved it from many aspects, and produced many improved median filtering algorithms, which make full use of the sorting and timing information of data and improve the filtering quality. Therefore, this paper applies it to interior design image denoising process to improve the effect of denoising.

The basic idea of median filtering is to replace the value of a point in interior design images or digital sequences with the median value of each point in a neighborhood of the point [15]. The median is defined as follows:

For a group of numbers x_1, x_2, \dots, x_n , which are expressed as $x_{t_1}, x_{t_2}, \dots, x_{t_m}$ in order of size, then:

$$y = \text{Med} \{x_1, x_2, \dots, x_n\} = \begin{cases} x_{\lfloor (n+1)/2 \rfloor}, n \in 2n+1 \\ [x_{\lfloor n/2 \rfloor} + x_{\lfloor n/2 \rfloor + 1}] / 2, n \in 2n \end{cases} \quad (1)$$

y is called the median of sequence x_1, x_2, \dots, x_n .

A neighborhood of a particular size or shape of a point is called a window. In the one-dimensional case, the median filter is a sliding window with an odd number of pixels. The value of the center pixel of the window is replaced by the median value of each pixel in the window [16-17] for filtering.

Suppose $\{x_{i,j}, (i,j) \in I^2\}$ represents the gray value of each pixel of interior design images, then the two-dimensional median filtering with a filtering window of A can be defined as:

$$y_{i,j} = \text{Med} \{x_{i,j}\} = \text{Med} \{x_{i+r,j+s}, (r,s) \in A(i,j \in I^2)\} \quad (2)$$

Median filtering also has the following main features:

1) The output of median filter is related to the density distribution of noise, and it has obvious effect on the interference of narrow pulses with small pulse width and long distance.

2) Through the observation of the overall test, it is found that the spectrum characteristics of the median filter have little fluctuation and the mean value is relatively stable. Therefore, it can be considered that the spectrum of the signal after the median filter is basically unchanged [18].

3) Some specific input signals can remain unchanged after median filtering, such as monotonically decreasing or monotonically increasing sequences.

For interior design image processing, standard median filtering mainly has the following deficiencies:

1) From the perspective of signal estimation theory, because the standard median filter is a non-parametric estimation, it does not make full use of the statistical knowledge of the observation model available in practice during processing, so it is quite blind and conservative.

2) Although median filtering has a good suppression effect on long trailing probability distribution noise, such as impulse noise, it has a less ideal suppression effect on short trailing distribution noise and medium trailing distribution noise, such as uniform distribution noise and Gaussian distribution noise.

3) When the number of interference samples in the filtering window is larger than half of the window length, median filtering has no effect. In this case, increasing the size of the filtering window can improve the noise filtering ability, but will destroy the image details.

4) After the median filtering of the image, some thin lines or sharp edges and corners may be eliminated, which destroy the geometric structure of the image.

5) Edge jitter will occur after median filtering for nonconstant signals disturbed by pulse. Even in low noise area, edge displacement still exists.

In order to further improve the filtering effect of standard median filter, rough set theory is used. For noisy interior design images, the effect and quality of early processing often determine the quality of subsequent processing (such as feature extraction, image segmentation, etc.) [19-20]. The complexity and strong correlation of image information cause incompleteness and uncertainty in image processing. Rough set theory has been successfully applied to image processing, among which image filtering is a key research direction in the future. Its basic idea is to treat the information expressed in each image as a knowledge system, and to detect and process the noise pixels in the image by using the approximate set concept of rough set. In this paper, a median filtering algorithm based on rough set theory is proposed to denoise interior design images.

An interior design image can be regarded as a knowledge system. Image I and equivalence relation R constitute an approximate space of interior design image, which is represented by $K = (I, R)$. For a filtering window, an approximate space is formed by the pixels in the window (W) and equivalence relation R , and is represented by $K = (W, R)$.

Rough set theory includes conditional and decision attribute. The conditional attribute set $C = \{c_1, c_2\}$, where c_1 is the extreme value attribute and c_2 is the region attribute of the pixel (hereinafter referred to as the region attribute).

Let the extreme value attribute $c_1 = \{0, 1\}$, where 0

represents that the current pixel is the extreme point, that is, its gray value is greater than or equal to the maximum or less than or equal to the minimum gray value of the neighborhood pixel, and 1 represents that the current pixel is not the extreme point. Generally, it is assumed that the gray image to be processed consists of flat region and detail region. If the gray value of the current pixel is close to that of most neighboring pixels, it indicates that the pixel is located in a flat region. Otherwise, it indicates that it is in the detail area. Let the region attribute be $c_2 = \{0, 1\}$, where 0 means that the current pixel is in the flat region and 1 means that the current pixel is in the detail region. According to the equivalent concept of the irresolvable relation, draw the molecular diagram, classified by attribute C .

1) Drawing the molecular diagram according to c_1 . Let x represent image pixel, and the equivalence relation R_{c_1} is defined as the following:

If the gray values of the two pixels are greater than or equal to the maximum or less than or equal to the minimum gray values of the neighboring pixels, then the two pixels are related, that is, they belong to the equivalence class and can be described by the following formula:

$$R_{c_1}(x) = \left\{ x \mid f_{ij} \geq \max(f_w) \text{ or } f_{ij} \leq \min(f_w) \right\} \quad (3)$$

Where, f_{ij} is the gray value of the corresponding pixel, $\max(f_w)$ represents the maximum gray value of pixel in neighborhood x , and $\min(f_w)$ represents the minimum gray value of pixel in neighborhood x . $R_{c_1}(x)$ represents the set composed of all pixels with extreme gray value, and the complement of R_{c_1} represents the set composed of all pixels with non-extreme gray value.

2) Drawing the molecular diagram according to c_2 . R_{c_2} is defined as a small difference between the gray value of a pixel and its adjacent pixels. $R_{c_2}(x)$ represents the set of pixels in all plane areas, and R_{c_2} is complement represents a group of pixels in all detail areas. The difference of gray values is measured by introducing fuzzy membership degree. For a certain pixel point x , the following fuzzy membership function is defined as its degree of belonging to surrounding points:

$$u_z(x) = \left[1 + \frac{(f_{ij} - f_z)^2}{f_z + \lambda} \right]^{-1} \quad (4)$$

Where, z represents the point in the neighborhood of x , f_z represents the gray value of the neighborhood pixel of pixel x , and λ is a constant, which is the square of the mean gray value of the image. According to the definition of membership function, the larger $u_z(x)$ is, the more similar x and z are, and the more likely x and z are to be

classified into the same category. Therefore, we can use fuzzy membership function to judge the similarity of gray values between pixels.

The flatness pixel area to be processed for the current pixel (i) is determined based on the above analysis, can choose the current pixel as elements to be processed, calculate the fuzzy membership degree, on the other a pixel the sum of membership degree, the greater the means of each pixel gray value are more close to, on the basis of pixel gray similarity to measure area, To judge the flatness of the region. Therefore, for any point in the image, the following conditions can be used to determine whether it is located in the detail region or flat region: If the sum of the membership degree of the point to be processed relative to all neighborhood points is greater than or equal to a threshold value, the point is considered to be located in the flat region; otherwise, it is considered to be located in the detail region.

To sum up, it can be concluded that:

$$R_{c_2}(x) = \left\{ x \mid \sum_{z \in Z} u_z(x) \geq T \right\} \quad (5)$$

Where, W represents the selected window centered on the current pixel, that is, a neighborhood of the current pixel, and T represents the preset threshold.

After combining the subgraphs, we can get:

$$W = R_{c_1}(x) - R_{c_2}(x) \quad (6)$$

The pixel in A is median filtered, while the gray values of the other pixels remain unchanged.

In the interior design noisy image, the pixel at position (i, j) is represented by x , and its gray value is f_z . A_{ij} is the filtering window for median filtering of pixel point x , the neighborhood pixel of x is represented by z , and the gray value of pixel z is set as A_{ij} . T is the preset threshold.

The denoising process of interior design images based on median filtering algorithm is as follows:

Step 1: Determine the gray maximum value $\max(f_w)$ and minimum value $\min(f_w)$ of the neighborhood pixel of pixel x in the filtering window A_{ij} ;

Step 2: Judge the extreme value attribute of pixel point x . If $\min(f_w) \leq f_{ij} \leq \max(f_w)$, When the pixel point x is a signal point, directly output f_{ij} , and execute step 6; Otherwise, when the pixel x is an extreme point, the fuzzy membership function is used to further judge its regional attributes.

Step 3: Calculate the fuzzy membership of pixel x with respect to its neighbor pixel z according to the fuzzy

membership function $u_z(x)$, and sum it.

Step 4: Compare the summation result $\sum_{x \in Z} u_z(x)$ with threshold T . If $\sum_{x \in Z} u_z(x) \geq T$, pixel point x is located in the flat area and is the signal point. Output f_{ij} directly and go to step 6. If $\sum_{x \in Z} u_z(x) < T$, pixel x is a noise point, and median filtering is performed on it.

Step 5: According to the standard median filtering principle, replace the gray value f_{ij} of pixel x with the gray median of pixel in the filtering window;

Step 6: If all pixels in the image are processed, complete the process; otherwise, go to the first step to continue to process with the next pixel, so as to achieve interior design image denoising.

IV. EXPERIMENTAL DESIGN

In order to verify the effectiveness of the interior design image denoising method based on median filtering algorithm designed in this paper, experimental tests were carried out. The proposed test parameters are shown in Table I.

In order to verify the application effect of different methods, LYX's method, HCX's method, LYF's method and the method designed in this paper are selected as experimental methods. By selecting multiple interior design scenes, collecting interior design images with sensors, and taking the collected data as experimental sample data, by comparing the denoising effect of interior design images of different methods. The signal-to-noise ratio of interior design images and the denoising time of interior design images are used to verify the practical application effects of different methods.

1) *Comparison of denoising effects of interior design images:* The indoor design image denoising effects of LYX's method, HCX's method, LYF's method and proposed method in this study are compared in 50 experimental scenes. The comparison results are shown in Fig. 6-7.

TABLE I. EXPERIMENTAL ENVIRONMENT PARAMETERS

Runtime environment	Parameter	Explanation
Hardware environment	CPU	Intel(R) Core (TM)i5-9400
	Frequency	2.90GHz
	RAM	16.0GB
	Operating system	Windows 10
Software environment	Version	18362.1082 pro
	Digits	64bit
	Analog software language	APDL
	Simulation software	Matlab 7.0

By analyzing the results of Fig. 6 and Fig. 7, it can be seen that the image denoising effect of HCX's method is the worst of the four methods, and the image denoising effect of LYX's method and LYF's method is better than that of HCX's method. Compared with the three experimental comparison methods, the image denoising effect of this method is better.

(b) HCX's method

(c) LYF's method

(d) Proposed method

Fig. 7. Scene 2 image denoising effect

2) *Comparison of signal-to-noise ratio of interior design images:* The signal-to-noise ratio of interior design images of LYX's method, HCX's method, LYF's method and this proposed method are compared. The results are shown in Table II.

By analyzing the data in Table II, it can be seen that the maximum signal-to-noise ratio of interior design images in LYX's method is 39.7dB, the minimum value is 32.7dB, and the average value is 35.9dB; The maximum signal-to-noise ratio of interior design image in HCX's method is 28.9dB, the minimum value is 23.1dB, and the average value is 26.4dB; The maximum signal-to-noise ratio of interior design image in LYF's method is 39.6dB, the minimum value is 29.7dB, and the average value is 33.1dB; Compared with these methods, the maximum signal-to-noise ratio of interior design image in this method is 58.4dB, the minimum value is 50.6dB, and the average value is 54.6dB, which shows that the signal-to-noise ratio of interior design image processed by this method is higher, the image is clearer, and the practical application effect is better.

TABLE II. SIGNAL TO NOISE RATIO OF INTERIOR DESIGN IMAGES

Number of experiments	Image signal-to-noise ratio/dB			
	LYX's method	HCX's method	LYF's method	Paper method
10	35.1	25.6	30.6	50.6
20	34.2	28.9	31.2	51.4
30	36.9	27.6	35.6	52.3
40	39.7	24.7	30.7	56.4
50	36.4	25.6	35.4	58.4
60	35.6	28.7	29.8	53.2
70	34.1	23.1	29.7	56.7
80	32.7	25.8	32.8	58.2
90	38.5	26.7	35.7	53.6
100	35.7	27.5	39.6	54.7
average value	35.9	26.4	33.1	54.6

Fig. 8. Comparison of denoising time of interior design images

3) *Comparison of denoising time of interior design images:* The denoising time of interior design images of LYX's method, HCX's method, LYF's method and proposed method in this study are compared. The results are shown in Fig. 8.

By analyzing the data in Fig. 8, it can be seen that the denoising time of interior design image of LYX's method is between 2.1s and 3.4s, the denoising time of interior design image of HCX's method is between 1.0s and 2.9s, the denoising time of interior design image of LYF's method is between 0.3s and 1.8s, The denoising time of this method for interior design images is always less than 0.3s, which shows that the denoising time of this method for interior design images is shorter and more effective.

Fig. 9. Comparison of denoising time of interior design images

4) *Comparison of image denoising time with the latest method:* The method proposed in this paper and Goyal's method are used to denoise the interior design image. The results are shown in Fig. 9.

By analyzing the data in Fig. 8, it can be seen that the denoising time of Goyal's method for the design image is between 0.35s and 0.98s, and the overall time required is still greater than that of the research method. This shows that the method has shorter and more effective noise reduction time for interior design images.

V. CONCLUSION

With the development of computer technology, the functions provided by digital interior design software have become more and more abundant. The application of relevant software can completely replace the traditional manual design method. Digital room design software can quickly and conveniently complete sketch design. In short, it is to process the two-dimensional plane image through computer software, so that it can be presented in a digital way, so that people can understand the content of the image in a more intuitive way. However, in the process of interior design image generation, interior images are easily interfered by various external factors, resulting in the rise of image noise. Therefore, this paper proposes an interior design image denoising method based on median filter algorithm. The experimental results show that the image denoising effect of this method is better. The average signal-to-noise ratio of interior design image is 54.6dB, and the denoising time of interior design image is always less than 0.3s. It can realize accurate and rapid denoising of interior design image and improve image quality.

Application of CAD Aided Intelligent Technology in Landscape Design

Juan Du

Department of Architectural Engineering, Shijiazhuang University of Applied Technology, Shijiazhuang, China

Abstract—The current landscape design methods ignore the depth rendering of scene elements, resulting in low spatial utilization of landscape plant diversity index and landscape spatial pattern. Therefore, this study explores the application of CAD in landscape design. AutoCAD aided intelligent technology is adopted to display the scene in multiple directions and from all angles with terrain design, planning design and planting design as the main contents. Using 3D graphics engine to render landscape elements. On this basis, the spatial coordination planning model of plant landscape is established. The color attribute of landscape space staggered pattern is added to 3D visual reconstruction model by image library function, and the CAD intelligent technology is applied in landscape design. The results shows, the method scored higher in graphic refresh rate, visual brightness and visual contrast, a higher plant diversity coefficient in multiple iterations, and a higher spatial utilization ratio of the landscape pattern than the other two design methods, and the spatial utilization ratio of the landscape pattern of the proposed method is higher than that of the reference method.

Keywords—Landscape design; CAD intelligent technology; engine rendering; image library function; 3D visual reconstruction; digital design; landscape architecture

I. INTRODUCTION

Landscape design requires consideration of relevant theories, based on landscape planning and the integrated use of scientific, technology and art means to create and protect the outdoor environment. The design work needs to be both aesthetically pleasing and coherent [1]. These landscape elements provide a lot of material for creating a high-quality urban spatial environment, but to form a unique urban landscape, it is necessary to organize various landscape elements systematically and combine them with the layout to make them form a complete and harmonious landscape system and orderly spatial form. Regardless of the scale of landscape design, it is expected to achieve a step-by-step effect in space organization. Therefore, it is very important for designers to express their works in an all-round, real and even dynamic way. Current landscape design process mostly uses AutoCAD to draw the 2D construction drawings [2].

Contemporary society with the development of information technology, production methods from the past empirical to knowledge-based, scientific and information direction transition, as the human habitat of the landscape because of the impact of computer network technology, multimedia technology, electronic communication technology is showing unprecedented changes. The landscape design is also deeply engraved with the brand of information technology. Multimedia technology, computer network technology and

other information technology are becoming an indispensable part of contemporary landscape design, and they are also an important driving force of landscape design changes. Through the use of information technology and from the information expression of the landscape, people feel the comprehensive impression of the landscape's efficiency and smoothness [3]. As the most widely used CAD software at present, it has rich drawing and editing functions, and provides convenient operation under friendly user interface, so it has a good reputation in the design industry. In particular, AutoCAD software can also provide various editing interfaces and tools, and strengthen the function of 3D modeling and image processing, supporting ActiveXAutomation program design interface.

The study [4] puts forward the reconstruction method of landscape spatial staggered pattern based on the coupling mechanism of pattern and process, analyzes the connotation and extension between landscape spatial pattern and ecological development process, considers that human activities will interfere with and control the reconstruction of landscape spatial pattern, and reveals the external performance and internal mechanism of landscape spatial pattern from the aspects of function and connectivity of landscape spatial pattern. Finally, the steps of landscape spatial pattern optimization are summarized to realize the optimization of landscape spatial pattern. The research [5] proposed a landscape spatial staggered pattern reconstruction method based on remote sensing image, analyzed the landscape spatial pattern characteristics of northern rural areas by using remote sensing image technology, reflected the characteristic changes of northern rural spatial pattern, and calculated the forest land area of northern rural areas by using the patch density and type of landscape spatial pattern, experiments show that proposed method can improve optimization effect of landscape spatial pattern.

The existing methods ignore the depth rendering of scene elements, which leads to the low spatial utilization of landscape plant diversity index and landscape spatial pattern. Therefore, this study explores the application of CAD in landscape design. Therefore the study uses CAD as the development platform.

II. APPLICATION OF CAD INTELLIGENT TECHNOLOGY IN LANDSCAPE DESIGN

A. CAD Software in Landscape Image Processing

AutoCAD (hereinafter referred to as "CAD") [6]: developed by Autodesk, USA, is the core software of choice

for landscape design. It has powerful 2D graphics editing function and powerful 3D drawing and solid modeling function. It assisted intelligent technology to generate vector graph, its main feature is to generate a variety of editable straight lines, circles, text and size. It has many other editing features, such as copy, pruning, mirroring, and rotation. Mainly used for the drawing of landscape plans, elevations, sections, construction drawings, so that the main line of landscape graphics. Before making landscape, it is better to collect and set up various elements of the library system, which is of great significance to the completion of image processing quickly and beautifully. Different software needs different atlas types, according to the mountains, rocks, plants, architecture, sculpture, sketching and other related factors, you can establish different atlas system. In addition, thinning classification can improve the efficiency of graphics processing.

CAD has become an important technology for landscape designers, and CAD technology is widely used in the landscape design process because of its convenience, creativity and visual impact. It has become a mainstream technology for landscape design due to its easy modification and fast and beautiful drawing. At present, the methods applied to landscape design are mainly divided into two categories: one is the application of GIS technology; the other is the application of traditional image processing software. The former is mostly used in the planning and design of scenic spots, which can generate real topography, landscape and background, and manage and analyze geographic data. And the latter is more widely used in garden planning, elevation drawings, section drawings and rendering, which can draw more beautiful effects. The software can be divided into several modules of modeling, editing, terrain design, planning design, planting design, sprinkler design, data statistics, construction drawing production, rendering and animation production, and the overall structure of the software is shown in Fig. 1.

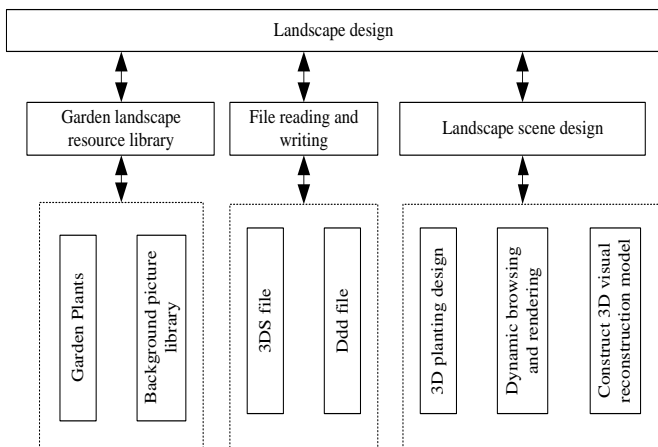

Fig. 1. Application of CAD in landscape architecture design

B. Scene Multi Feature 3D Rendering

In the digital technology of garden design, the system through three-dimensional animation, three-dimensional rendering, virtual scene design, the design intention is well expressed, so that the design technology of garden landscape from the original two-dimensional construction drawing stage gradually upgrade, really reach the stage of three-dimensional simulation, so that the efficiency of garden design greatly improved, in China has been applied as a commercial software, its development prospects are very promising [7-8]. 3D graphics engine is a set of functional modules that allow building full-fledged graphics applications with minimal effort. The visualizer has the ability to extend the architecture, so developers can create their own object classes, inherit them from existing objects, and thus place their own properties and rules in them. Classes can be set up as needed until the objects in the scene are rendered. 3D graphics engine creates graphics applications that use a geometric representation of the scene, i.e. lines, surfaces, edges and other objects drawn in the active window. The direct interaction of the user with the graphics application has some kind of representation of the scene display. This can complicate the use of efficient methods if the view does not have a hierarchical structure, but is represented, for example, by a simple linear array of objects. Using hierarchical scene views has several advantages. In this case, scene objects have very similar functionality and can be grouped into individual groups and then combined into higher-level groups. The advantages that platform has over 2D design drawings are shown in Table I.

Platform can be used to build the texture and transparency of water body, but it cannot reflect the refraction and reflection of the dynamic water body under the illumination of light. Static water body needs to be built by platform software first, and then the refraction and reflection of water body can be realized by animated walkthrough software, so that the water body model has strong vividness and authenticity [9, 10]. There are a large number of tree models in landscape design. If the number of trees is too large, the data and rendering consumption will be too large. TreeEngine engine can be used to load and render tree models in landscape. The tree model rendering consumption can be effectively reduced by adding the branch and leaf information of the tree model to the hierarchical detail model and building the leaf information with the Billboard model. The TreeEngine engine effectively draws and renders parameterized tree models, and includes all the functions of the OSG scene. Load the created tree model into the rendering process of the created 3D terrain scene model, as shown in Fig. 2.

TABLE I. COMPARISON WITH PREVIOUS METHODS

	2D design drawings	Platform
/	2D	3D
Models	Possible detail errors	Realistic restoration
Similarity	Inheritance is strong and conducive to innovation	Inheritance is not possible
Reuse		

Fig. 2. Tree model rendering flow chart

The tree model is read into the TreeEngine engine, the tree format is parameterized, and the tree multi-level detail is obtained. When the multi-level detail level is more than one, the tree trunk and the whole texture and mesh are established.

C. Spatial Coordination Planning Model of Plant Landscape

According to the analysis results of landscape pattern, the following formula is used to extract the spatial information characteristics of ecological plant landscape in green city:

$$Q(x, y) = Q^n(x, y) + \mathfrak{R} \quad (1)$$

In the formula, $Q(x, y)$ represents the feature information existing in the landscape group space, $Q^n(x, y)$ represents the feature information existing in the landscape group space in block n , \mathfrak{R} represents the feature extraction coefficient, and (x, y) represents the position of the landscape group in the whole ecological plant landscape space.

Combining the information of decision variables, the relationship between landscape spatial planning and different decision variables was determined. The utility function is used to solve the problem of ecological plant landscape spatial planning from the perspective of ecological plant landscape spatial coordination planning. Through the above analysis, the following formula is used to describe the spatial planning of green urban ecological plant landscape:

$$\max R = \sum_{i=1}^I \mathfrak{S}_i \cdot Q(x, y) \cdot \delta \quad (2)$$

Formula (2) satisfies the following formula:

$$\mathfrak{S}_i = Q_i(x, y), i = 1, 2, \dots \quad (3)$$

In the formula, I represents the number of planning objectives, \mathfrak{S}_i represents the importance of i corresponding to ecological plant landscape management objectives, δ represents the rationality coefficient of spatial planning, and q_i represents the value of i corresponding to the objective variable.

Utility functions generally consist of sub-efficacy functions (Fig. 3), restrictive efficacy functions (Fig. 4), evenly increasing efficacy functions (Fig. 5) and evenly decreasing efficacy functions (Fig. 6).

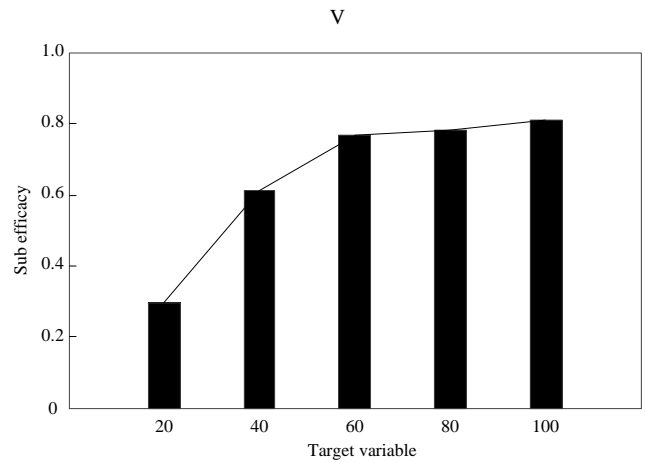

Fig. 3. Sub efficacy function

Fig. 4. Restricted efficacy function

Fig. 5. Uniformly increasing efficacy function

Fig. 6. Efficacy function of uniform decline

Taking green urban ecological plant landscape planning as an object, a green urban ecological plant landscape coordination and planning model is established by maximizing the utility function combined with basic model and utility function theory:

$$U = \frac{W_1 + W_2 + W_3 + W_4}{\delta \cdot \sum_{i=1}^I \mathcal{J}_i} \quad (4)$$

Where, W_1 , W_2 , W_3 and W_4 represent the weight of sub objectives.

D. 3D Planting Design

a) *Description of planting method:* 3D graphics engine can provide a lot of drawing tools, such as grass point filling, garden corridor, water barge, slate road, gravel road, hedge line, forest edge line, etc., and can also be used to mark plants, positioning line, elevation, garden road, angle, radius and area, etc. The system also has similar to AutoCad fill pattern function and rich content of the two-dimensional library, and the corresponding effect can be printed. The system also has similar functions to AutoCad and a rich library of 2D drawings, and can print out the corresponding effect drawings. In general, the system is used for parameterization, definition of plots, road planning, generation of steps, fences and walls, ponds, planters, planters, ramps, curbs, and other landscape models and design of mountain roads. The design function also provides a rich plant database and pictures, and records the various plant habits, providing a variety of planting methods such as mixed planting, piece planting, column planting, and solitary planting, as well as modifying the number and properties of some already planted plants, and expanding the planting on flat surfaces to undulating terrain. The expression of plantation plan should meet the standard of landscape design. It should be shown according to plantation legend or plantation point and plant contour. In order to achieve the unity of 2D and 3D planting design, the planar planting plan is displayed in the top view and the plantation plan is displayed in the perspective view.

b) *Methods of representation for plants:* In landscape construction, many plants may be used. If a 3D model is used to represent plants, then a plant will use a large number of patches, which back use a larger system space and even cause the software to crash. Based on the above reasons, the system provides another plant representation, using platform bulletin board, using pictures to simulate the plant. Bulletin board is a very useful technology, it can be a simple way to achieve a lot of special effects, but it is most attractive to achieve these effects with very low system resources. So for each plant entity, it only needs to store its location and the index information of the picture, instead of the storage cost of the 3D model, so it saves the system space greatly. In the display effect, the system will collect nearly a thousand kinds of plants in the south and north of the picture have done the hollow processing, using platform expansion function to achieve the hollow texture display effect, the results more realistic.

E. Dynamic Browsing and Rendering Technology

After the creation of a 3D model, after assigning materials to entities and setting up light sources and viewpoints (cameras), dynamic browsing can be conducted at any time, 3D realistic rendering or animation can be made, and the rendering effects and texture can be reflected by the rendering effect pictures. As can be seen, the difficulty of building a three-dimensional model is that it is difficult to achieve a large volume and a large amount of data for the implementation of the model to browse. The landscape design software uses a more cost-effective display card and its mature interface language for acceleration. At the same time, data processing is greatly reduced by smoothing the special 3D mesh. Landscape design software rationally uses the triangle belt and triangle fan mode provided by platform to reduce the repetition of records on nodes and reduce number of nodes representing stereotyped objects [11-12].

In addition, the use of a specific 3D mesh surface smoothing processing also greatly reduces the data processing, in practical applications played a significant effect. Since the platform requires the map to be a power of two in size. Therefore, it will be sorted when it is passed to the platform. Considering the characteristics of landscape design, we cannot use a simple cutting method, but a combination of color compression, color combination and softening technology to achieve the desired results.

Through reading transparent channel information of 32-bit color bitmap and combining with application of platform template, the hollowed-out texture display technology is realized. The tree image is mapped by hollowing out, and the tree image size is set to power of two to improve the display accuracy. In the aspect of realistic rendering and rendering algorithm, by comparing the depth buffer, ray tracing and radiance, the improved radiance algorithm is used to solve the problem of low rendering speed. The light module in the platform can realize the whole scene, and can display various effects such as daytime and nighttime scenes. In a daytime environment, ambient lighting consists of “parallel light”, “light” and “sky light” by way of simulated sunlight. The camera is equivalent to another point and determines the final rendering type. The landscape design software can drag and modify the position of the camera, display the position and angle of the camera in real time, and display the observation range of the camera in the camera view to achieve a WYSIWYG effect. Meanwhile, the software also supports six types of light sources, including point light source, cone light source, parallel light source, column light source, surface light source and sunlight source. Each light source can be interactively set and modified.

F. Construct 3D Visual Reconstruction Model

Based on the index of landscape spatial staggered pattern, the characteristic points of landscape spatial staggered pattern are mapped into the 3D visual reconstruction model, and the 3D visual reconstruction model is established [13-14]. If there are A points in the 3D visual reconstruction model, the space coordinate of the scanning base station of texture mapping is (X, Y, Z) , and the a point coordinate of the

staggered pattern of A points and landscape space is E , the mapping relationship between (x, y) points and a points of the staggered pattern of landscape space in the 3D visual reconstruction model is as follows:

$$\begin{cases} x = h_1(X, Y) \\ y = h_2(X, Y) \end{cases} \quad (5)$$

$$\begin{cases} x = \sum_{i=0}^n \sum_{j=0}^{n-i} a_{ij} X^i Y^j \\ y = \sum_{i=0}^n \sum_{j=0}^{n-i} b_{ij} X^i Y^j \end{cases} \quad (6)$$

Because of the error of data transmission and the noise in the feature data of landscape pattern, the coordinates of X and Y axes are different, but the coordinates of Z axes are the same. In order to make the mapping result more accurate, the threshold σ is introduced, and the A_i is assumed to be a point in the 3D visual reconstruction model. The threshold σ is used to find A 's adjacent point \dot{A}_i in the A_i -point range. By expanding formula (6), the mapping model of A and \dot{A} from 3D visual reconstruction model to point a can be obtained:

$$\begin{cases} h_1(X, Y) = x = A_{00} + A_{10}X + A_{01}Y + A_{20}X^2 + A_{11}XY + A_{02}Y^2 \\ h_2(X, Y) = y = B_{00} + B_{10}X + B_{01}Y + B_{20}X^2 + B_{11}XY + B_{02}Y^2 \end{cases} \quad (7)$$

$$\begin{cases} \dot{h}_1(\dot{X}_i, \dot{Y}_i) = C_{00} + C_{10}\dot{X} + C_{01}\dot{Y} + C_{20}\dot{X}^2 + C_{11}\dot{X}\dot{Y} + C_{02}\dot{Y}^2 \\ \dot{h}_2(\dot{X}_i, \dot{Y}_i) = D_{00} + D_{10}\dot{X} + D_{01}\dot{Y} + D_{20}\dot{X}^2 + D_{11}\dot{X}\dot{Y} + D_{02}\dot{Y}^2 \end{cases} \quad (8)$$

In the formula, A represents the landscape autocorrelation coefficient; B represents landscape heterogeneity coefficient; C represents the basic characteristics of landscape pattern; D represents the global characteristics of landscape pattern [15].

Using formula (7) and formula (8), it can be obtained that the mapping model includes 24 positions. When the number of 3D visual reconstruction model and its corresponding landscape spatial staggered pattern is greater than 12, the 3D visual reconstruction models of $h_1(X, Y)$, $h_2(X, Y)$, $\dot{h}_1(\dot{X}_i, \dot{Y}_i)$ and $\dot{h}_2(\dot{X}_i, \dot{Y}_i)$ can be calculated according to the principle of least square method.

Substituting $\dot{A}_i(\dot{X}_i, \dot{Y}_i, \dot{Z}_i)$ into formula (7), respectively obtain that the coordinates of \dot{a}_i are (\dot{x}_i, \dot{y}_i) and the distance between \dot{a}_i and a is d_1 ; Substitute $A(X, Y, Z)$ into formula (8) and obtain that the coordinate

of a' is (x', y') and the distance between a' and a is d_2 .

Comparing the size of d_2 and d_1 , the size of the sum is compared and the corresponding polynomial with smaller distance is selected to express the mapping relationship of the 3D visual reconstruction model.

III. EXPERIMENTAL DESIGN OF PERFORMANCE TEST OF THE PROPOSED METHOD

A. Presentation of Landscape Design Effect

Select Visual Studio 2021 as the development platform, using VC+ language as the development language to develop this landscape design software. The landscape design of a residential quarter in a certain city is selected as the verification object. The residential quarter is located in the southeast of the city and is a newly developed ecological residential quarter. The total area of the residential quarter is 38759m², the total construction area is 16748m², and the residential quarter includes eight residential buildings, including villas, multi-storey areas and high-rise areas. The landscape design requires that the green area within the residential quarter shall be more than 40%.

As can be seen in Fig. 7, the 3D model built using the platform can contain all the architectural information needed in the relevant landscape project, and the 3D terrain scene model and the actual building can be presented in a 1:1 scale, which makes the design drawings more intuitive and easy to modify.

Fig. 7. Reconstruction of 3D terrain scene model

Fig. 8. Final effect of landscape design

The final effect drawing of landscape design for this residential area is shown in Fig. 8.

The simulation results of Fig. 8 show that the proposed method can effectively reduce the labor intensity of landscape designers and shorten the design cycle. Compared with the 2D landscape design, the 3D terrain scene model is more accurate. Because the 3D terrain scene model is 1:1, the accuracy of landscape design is improved effectively. The method of this paper can be used to design landscape in 3D scene model.

Analytic Hierarchy Process is selected to evaluate the effect of landscape design in this paper. Analytic Hierarchy Process is a quantitative and qualitative multi-objective decision analysis method. The results of AHP evaluation of the landscape designed by this method are shown in Table I.

TABLE II. LANDSCAPE DESIGN RESULTS OF THIS METHOD

Evaluating indicator	Weight	Evaluation results / score
Illumination	0.08237	94
Visual contrast	0.09263	98
Resolving power	0.08356	94
Visual brightness	0.06657	91
Shadow processing	0.16849	98
Graphics refresh rate	0.26478	99

As can be seen from Table II, the AHP method can be used to evaluate the final effect of the landscape design using the 10 indicators listed in the table to rate each indicator, and the average of each score sought is 93.7. The result shows that the method has high design effectiveness.

B. Application Performance Test of the Proposed Method

In order to the overall effectiveness of the proposed method, it is necessary to test the analysis method of green urban ecological plant landscape spatial coordination planning model. This test is completed in Simulink platform. Set the plant diversity coefficient in the interval [0,1]. The larger the plant diversity coefficient, the more categories of plants in the landscape space, and the better the diversity. The proposed method, the landscape spatial design method based on pattern coupling mechanism proposed in study [4] and the landscape spatial design method based on remote sensing image proposed in research [5] are tested respectively.

The plant diversity coefficients of different methods are shown in Fig. 9.

By analyzing the data in Fig. 9, it can be seen that the plant diversity coefficient obtained by the proposed method in multiple iterations is more than 0.8, and the plant diversity coefficient obtained by the landscape spatial design method based on pattern coupling mechanism proposed in study [4] fluctuates around 0.5. The plant diversity coefficient obtained by research [5] method in multiple iterations fluctuates around 0.5. Comparing the test results of different methods, it can be seen that the plant diversity coefficient of the proposed method is high in multiple iterations.

Fig. 9. Plant diversity coefficients of different methods

Fig. 10. Rationality coefficients of different methods

The above methods are further tested through the rationality coefficient of green urban ecological plant landscape spatial planning. The rationality coefficients of different methods are shown in Fig. 10.

According to the data in Fig. 10, when the proposed method is used to design the ecological plant landscape space of green city, the rationality coefficient is more than 8, When the landscape space design method based on pattern coupling mechanism proposed in study [4] and the landscape space design method based on remote sensing image proposed in research [5] are used to plan the ecological plant landscape space of green city, the rationality coefficients obtained are within the interval [4, 8]. The comparison shows that the rationality coefficients of the proposed methods in multiple iterations are higher than those in references. Because the proposed method uses 3D graphics engine to render garden landscape scene elements. Based on this, the spatial coordination planning model of plant landscape is constructed. Color attribute of landscape spatial staggered pattern is added to 3D visual reconstruction model through image library function, which improves the planning rationality of the proposed method.

The landscape spatial design method based on pattern coupling mechanism proposed in study [4], the landscape spatial design method based on remote sensing image proposed in research [5] and the proposed method are used to calculate the utilization rate of landscape spatial pattern. The calculation formula is as follows:

$$\eta = \frac{S_0}{S} \quad (9)$$

Fig. 11. Comparison results of landscape spatial pattern utilization

In the formula, S_0 represents the area of the utilized landscape spatial pattern; S represents the area of reconstructed landscape spatial pattern. The results are shown in Fig. 11.

As can be seen from the results in Fig. 11, the spatial utilization rate of landscape spatial pattern is significantly higher than that of the other two design methods, indicating that the design method has advantages in spatial utilization rate and can effectively improve the spatial utilization rate of landscape spatial pattern.

IV. CONCLUSION

This study explores the application of CAD in landscape design. It has powerful 2D graphics editing function and powerful 3D drawing and solid modeling function. In this paper, platform technology is used to generate landscape vector map. Topographic design, planning design and planting design are main contents. Landscape can be dynamically browsed and displayed. After reconstructing terrain and environment information of landscape to be designed by binocular stereo vision camera, landscape elements are rendered by 3D graphics engine. Based on this, coordination and planning model of plant landscape space is constructed by maximizing utility function combined with basic model and utility function theory. The color attribute of landscape space staggered pattern is added to the 3D visual reconstruction model by using image library function, and the platform intelligent technology is applied in landscape design. The results show that the design evaluation index score of the

proposed method is higher, the plant diversity coefficient is higher, and the spatial utilization ratio of the landscape spatial pattern is higher.

Filtering and Enhancement Method of Ancient Architectural Decoration Image based on Neural Network

Yanan Wang

Architectural Engineering Institute, Sanmenxia Polytechnic, Sanmenxia, China

Abstract—Due to poor ambient light or uneven lighting, the old decoration image acquisition methods are easy to cause the image blur. To solve this problem, this paper proposes a neural network-based filtering enhancement method for ancient architectural decoration images, which preserves image details by enhancing contrast, smoothing noise reduction and edge sharpening. Based on the convolutional neural network which is composed of encoder, decoder and layer hop connection, the residual network and hole convolution are introduced, and the hole U-Net neural network is constructed to fuse the pixel feature blocks of different levels. This method enhanced the image contrast according to the gray level and frequency histogram, and aiming at the gray value of the pixel to be processed in the image. And the middle value of the gray value of the neighborhood pixel is used to filter the noise of the ancient building decoration image. The paper also analyzes the joint strength of beams and columns in ancient buildings, and calculates the elastic constants of beams and columns and the stress at the joint of them, considering the image texture characteristics of the wood in ancient buildings with the mortise and tenon connection of beams and columns. Experimental results show that the proposed method has good noise suppression performance, can effectively obtain image detail features, and significantly improve the subjective visual effect of ancient architectural decoration images.

Keywords—Neural network; decorative images of ancient buildings; filter enhancement method; encoder; decoder; pixel gray value

I. INTRODUCTION

Ancient buildings are one of the most important cultural heritages left over by the history of various countries, marking the national civilization, the pride of various countries and the wealth of all mankind [1-2]. The comprehensive protection of ancient buildings is conducive to the promotion of national traditional culture and can benefit future generations of mankind. On the vast land, there are many distinctive ancient villages and residential buildings, as well as many magnificent royal ancient buildings, which can be said to be countless. These buildings integrate ancient folk culture and architectural art, and are the witness of history and the crystallization of culture [3-4]. Its existence not only leaves exquisite evidence

for the development of architectural history and human civilization history, but also provides diversified development reference for contemporary architectural art [5]. With the substantial improvement of people's living standards and cultural level, tourism has developed very rapidly around the world, in which the visit of ancient buildings has become more and more popular, and more places of interest have begun to be open to the public and for the public to visit. More and more developers began to explore the cultural connotation and historical value of ancient buildings, followed by the birth of a series of antique buildings, trying to restore the ancient architectural style in terms of layout and building materials. In recent years, people pay more and more attention to the protection of ancient buildings [6], especially China, which has a long history and many ancient buildings. But after years of erosion, most China ancient buildings have been weathered, corroded and even man-made damage to varying degrees. How to reconstruct the damaged ancient buildings and ensure the high degree of restoration after reconstruction has become the main research problem in the field of ancient building restoration [7]. Image filtering and enhancement processing is an enhancement strategy to improve the decorative features of ancient buildings. It can improve the overall image quality from the aspects of pixel definition, contrast and brightness. However, in daily life, because of the photographer's photography level and surrounding environment, the initial image quality is usually poor. Therefore, it is imperative to design a reasonable and complete image filtering and enhancement processing method.

The body of the study consists of six parts. In Section III, the convolutional neural network is introduced and modified into U-Net neural network, which establishes the basic framework for the proposed method. In Section IV, the beams and columns of ancient buildings are introduced, and their properties such as handover strength, elastic constant and connection stress are calculated. The characteristics of the application objects of the proposed method are investigated to make the method more suitable for this kind of image. In Section V, the image filtering enhancement method based on neural network is introduced in detail. The validity of the proposed method is verified by experimental analysis in the Section VI. Conclusion and prospect are described in Section VII.

II. RELATED WORKS

There are many research types in the field of filtering and enhancement of ancient architectural images. The study [8] proposes a quantitative evaluation of the architectural style of Agora, an ancient Greek city in Athens based on image correlation and fractal dimension analysis. Agoras is the center of Western European life and can be called the starting point of western European civilization. In previous studies, image processing technology was used to restore the initial shape of buildings and cities. Then, each building in the three-dimensional model of the square is built around the formation of the square. In this study, the 3D model of temple focuses on temple buildings and corridor extracts the facade of each building, quantitatively evaluates the similarity by performing fractal dimension analysis and image analysis, and considers the correlation of the two analysis results. The research [9] pointed out the evolution of Vladivostok's spatial structure and architectural image, and the problems and contradictions existing in the modern stage of the development of Far East maritime cities, which is the result of insufficient consideration of the basic principles of its formation and development. The solution to these problems is to analyze their spatial structure and architectural image from the perspective of evolution. This method can reveal all the existing shortcomings and contradictions, and formulate the main direction, principles and means of urban environmental construction, so as to improve and humanize the urban environment. From the perspective of evolutionary method and complex analysis method proposed by the author, the development of Vladivostok urban spatial structure and architectural image is considered. In the latest research, the performance of machine learning has been further optimized. The authors [10] proposed a new NA-DE hybrid neural network algorithm. It incorporates NNA and differential evolution algorithms. In the experiment, the controller optimized by this algorithm has better performance. In addition, it shows better robustness to the uncertainty of parameters in the system. The literature [11] proposes a trainable network framework based on attention mechanism. The framework combines model training, feature extraction and band selection. The experimental results show that the model constructed based on this framework has higher regression R^2 value and classification accuracy, and the original spectral space information can be used to effectively select the band while training the model.

Although the above research has made some progress, because only the feature information is enhanced and the enhanced information is not matched, the visual effect of image filtering and enhancement is poor, and it is easy to lose the local detail information of the image. Therefore, this study proposed a neural network-based filtering and enhancement method for ancient architectural decoration images. In this method, residual network and hole convolution are introduced to build hole U-Net neural network, which can fuse pixel feature blocks of different levels, enhance the contrast of decorative images of ancient buildings, and filter the noise of decorative images of ancient buildings.

III. NEURAL NETWORK

Using cavity convolution with different convolution rates, a neural network [12] is constructed to obtain more and more detailed image information of ancient architectural decoration, provide as perfect a visual image as possible for image filtering and enhancement, and further improve the image enhancement effect.

The neural network composed of encoder, decoder and layer hopping connection is shown in Fig. 1. The encoder is similar to the feature extraction layer, while the decoder mainly carries out an operation similar to deconvolution. In the process of decoding, image features extracted during encoding are also added. Jump joins can bridge the semantic gap between the encoder and the decoder, and it can also recover fine-grained details of the target object. The image is first down-sampled by the encoder to obtain the high-level semantic feature map, and then up-sampled by the decoder to restore the feature map to the resolution of the original image. Each time the decoder is upsampled, the jump connection will fuse the feature maps corresponding to the same resolution in the decoder and the encoder in a splicing way to help the decoder recover the details of the target better.

Fig. 1. Neural network architecture

As can be seen from Fig. 1, the encoder and decoder have symmetry, and the number of ancient building decoration image channels and resolution and other parameters correspond one by one. They are respectively composed of two convolution modules. Each convolution module contains two convolution stages, and its functions are to extract the deep features of ancient building decoration image and repair the details of ancient building decoration image; The function of layer hopping connection is to associate the image feature blocks between codec and decoder, and further optimize the image restoration effect of ancient architectural decoration of decoder by using the deep features extracted by encoder feature blocks.

The process of using neural network filtering to enhance the image of ancient architectural decoration is described as follows:

1) Based on the gray level and single channel initial ancient building decoration image, the encoder uses the maximum pool of two steps for down sampling processing, so

that the ancient building decoration image channel is multiplied by 2 and the resolution is divided by 2;

2) After the decoder uses the same step deconvolution of 2*2 convolution kernel for up sampling, it also performs the same processing on the ancient building decoration image and resolution. Finally, the number of compression channels is the number of types to be output, and the segmentation result of the ancient building decoration image is obtained.

3) Layer hopping connection integrates the semantic information and orientation information contained in different levels of features through splicing, so that the number of feature channels is one fourth of the input, and accurately segment the ancient building decoration image.

The semantic information and orientation information of ancient architectural decoration image have certain randomness, so the deep and shallow feature weights change constantly with the image content; Moreover, the decoration image of ancient buildings will change with the passage of time, which increases the probability of problems such as blurred boundary, uneven illumination and high noise in the visual image [13], which brings great difficulty to the subsequent processing and application of the image. Therefore, in order to balance the feature weights of different levels of neural network and improve the image quality of ancient architectural decoration, the residual network and cavity convolution are integrated into the neural network to construct the cavity neural network, so as to remove the network gradient and fully extract the multi-scale features of the image.

Assuming that based on the neural network with convolution layers of n , the following formula is used to derive the gradient of the network whose first layer weight is w_1 , and the calculation formula is:

$$\frac{\partial Q}{\partial e_1} = \frac{\partial Q}{\partial q_n} \cdot \dots \cdot \frac{\partial q_3}{\partial q_2} \cdot \frac{\partial q_2}{\partial q_1} \cdot \frac{\partial q_1}{\partial e_1} \quad (1)$$

In formula (1): Q represents the loss function, $Q(y, f(x)) = |y - f(x)|$, q_i ($i = 1, 2, \dots, n$) represents the activation function output with the number of layers of i , and ∂ represents the sign of partial derivative. When the partial

derivative of $\frac{\partial Q}{\partial q_n}$ satisfies $\frac{\partial Q}{\partial q_n} < 1$, the more network layers, the faster the network gradient decreases, and infinitely approaches 0.

According to the correlation between the output value of the simultaneous loss function and the number of network layers, the residual network structure composed of convolution layer and curve is used to remove the network gradient. The input items reach the network output through the curve and convolution layer respectively, so the definition formula of residual network structure is as follows:

$$W_a = D(n) + n \times Q \quad (2)$$

In formula (2): W_a represents the network output part, $D(n)$ represents the residual network part, and n represents the input item or direct mapping structure.

Neural network hole convolution is to increase the convolution rate index in the convolution core of convolution layer, expand the field of view of convolution layer and prevent the loss of down sampling information. Based on the 3*3 cavity convolution with the expansion rate of 1, when the expansion rate increases to two, insert a zero between the two adjacent points of the convolution core to make it 7*7; when the expansion rate increases to four, insert three 0 between the two adjacent points of the convolution core to make it 15*15, and so on. Thus, a positive correlation between the field of view of cavity convolution and the expansion rate is established.

After the convolution of residual network and hole, the neural network is improved into hole U-Net neural network, as shown in Fig. 2.

According to Fig. 2, the operation process of U-NET is shaped like "U", which can be divided into two parts: code and decode, including input and output layer, convolution layer and pooling layer, but not full connection layer. Through the network structure, pixel feature blocks of different levels in the decoration images of ancient buildings are fully integrated. Published in 2015, U-Net is a variant of FCN. Its original intention is to solve the problem of biomedical images. Due to its good effect, it has been widely applied in various directions of semantic segmentation, such as satellite image segmentation, industrial defect detection, etc [14]. Its structure is simple but effective, and it can recognize multi-scale features of image features. Therefore, it is selected in this study to expand the neural network.

IV. BASIC CHARACTERISTICS OF BEAMS AND COLUMNS IN ANCIENT BUILDINGS

A. Orthotropic

In general, wood is constructed according to cells with different shapes, sizes and arrangement order. This construction characteristic also determines the anisotropy of wood. The anisotropy of wood elasticity is obtained by applying the principle of orthogonal symmetry to wood. When wood materials in ancient buildings are cut from different directions, they will show inconsistent texture characteristics. Specifically, they can be divided into four characteristics: along grain direction, chord direction, radial direction and tangent direction. The longitudinal cutting of wood refers to the direction parallel to the wood fiber in the process of actual operation, that is, the cutting direction of the trunk from the bottom line, which becomes the direction along the grain; Chord direction and radial direction refer to the direction perpendicular to wood fiber, which can be called transverse grain direction; In general, after the wood is cut, the center of the trunk will show an annual ring like a concentric circle, while the radial cutting and chord cutting are perpendicular to the annual ring. The only difference is that the radial direction passes through the tangent direction of the tree center, and the chord direction does not pass through the tangent direction.

B. Mechanical Properties of Beams and Columns in Ancient Buildings

1) *Flexural strength*: Since the bending strength of wood is higher than the strength under external force, in general, the external force strength and bending strength along the grain of wood can be improved respectively, and on this basis, it conforms to the following formula:

$$W_{sd} = \left(3 \frac{\sigma_l}{\sigma_y} - 1 \right) / \left(\frac{\sigma_l}{\sigma_y} + 1 \right) \quad (3)$$

In formula (3), σ_l and σ_y represent the external force strength and bending strength of wood samples respectively.

When the wood in ancient buildings is damaged by bending, the wood fiber under external force on the cross section of the material will be unstable and wrinkled. With the strength of cyclic load, the position of fiber instability will develop to the neutral axis of the section, and finally the wood will break.

2) *Bearing strength*: In ancient buildings, wood bearing pressure refers to the performance of transmitting load on the cross section of the intersection of beams and columns when they intersect into nodes. The intersection point of force is called bearing stress on this cross section, and the corresponding resistance is called bearing strength. However, because the actual intersecting section is unstable, the bearing capacity along the grain of wood is lower than that along the grain.

When the cross grain of the whole surface is under pressure, the appropriate maximum proportion will be selected as the measurement standard of the bearing strength. The bearing pressure of part of the cross grain is consistent with

that of the whole surface. However, due to the bearing pressure of the cross grain on the length of some wood, it is necessary to consider the improvement of the strength caused by the fiber action of the wood on both sides of the bearing pressure point.

In general, the elastic characteristic constants of wood include: elastic modulus E_i , Poisson's ratio μ_{ij} and shear elastic modulus G_{ij} . The elastic modulus of longitudinal L , radial R and chord T of wood cutting is the elastic modulus in the main direction. Assuming $E_L = E_1$, $E_R = E_2$ and $E_T = E_3$, E_L , E_R and E_T represents the elastic modulus of wood cut longitudinally, radially and vertically, respectively. And it is determined that there is only one normal stress in the main direction, the ratio of normal stress to linear strain in the corresponding direction can be written as:

$$E_i = \sigma_i / \varepsilon_i \quad (i = L, R, T \text{ or } i = 1, 2, 3) \quad (4)$$

According to the ratio of formula (4), Poisson's ratio μ_{ij} is the normal stress, and σ_i acts alone in the L direction; when the corresponding bearing stress is zero, the opposite number of the ratio of stress in L direction to strain in R direction is:

$$\mu_{i,j} = -\varepsilon_j / \varepsilon_i \quad (i = L, R, T \text{ or } i = 1, 2, 3, j = 1, 2, \dots, 3) \quad (5)$$

According to formula (5), $G_{L,R}$, G_{RT} and G_{TL} can be described as shear elastic modulus in bearing plane LR , RT and TL respectively.

C. Characteristic Analysis of Beam Column Joints

1) *Characteristic points of mortise and tenon structure*: Mortise and tenon connection is a semi-rigid connection between rigid connection and hinge connection. Because most ancient building structures adopt straight mortise connection, the straight mortise is mainly analyzed, and the finite element numerical simulation analysis of mortise and tenon connection of building structure is carried out [15]. According to the unique characteristics of the building structure in this technology, the virtual spring element will be used to simulate the semi-rigid structure. In practical application, this spring element has no substantial mass and element.

2) *Analysis of tenon joint intersection*: In order to calculate and solve the stress effectively and simply, assuming that the shear capacity of wood along the x axis and y axis is the same, and the bending and torsion capacity in different directions is the same, the simplified $k_x = k_1$, $k_y = k_z = k_2$ and $k_{\theta_x} = k_{\theta_y} = k_{\theta_z} = k_3$ can be obtained. Only these three unknown variables need to be solved, and there are:

$$k_x = \frac{F_x}{\Delta_x} \quad (6)$$

According to formula (6), similarly, the load F_z treatment along the z axis can be carried out on the model to obtain the shrinkage strength of the mortise joint along the z axis:

$$k_z = \frac{F_z}{|\Delta_z^4 - \Delta_z^5|} \quad (7)$$

In formula (7), Δ_z^4 and Δ_z^5 are respectively described as the average value of all nodes on section A_4 and section A_5 moving along the z axis.

According to the calculation result of formula (7), the torque M_y rotating around the y axis is applied to the surface A_3 of the mortise joint, and the state is determined after multiple iterative calculations, the moving distance of i node in the upper surface A_1 along the x axis is solved, where Δ_z^4 and Δ_z^5 are expressed as the average value of multiple nodes on FF and A_4 moving along the A_5 axis respectively. According to the simplified expression of formula (7), the value of stress in each direction of mortise and tenon joint can be obtained.

V. FILTERING AND ENHANCEMENT OF ANCIENT ARCHITECTURAL DECORATION IMAGE BASED ON NEURAL NETWORK

A. Filtering and Enhancement of Ancient Architectural Decoration Image

Using the hollow U-Net neural network, after fusing the different levels of features in the ancient building decoration image, the image is transformed into a mode more convenient for automatic analysis and visual observation through the stages of enhancing contrast, smoothing and noise reduction and edge sharpening, so as to realize the filtering enhancement of the ancient building decoration image and improve the visual effect.

1) *Contrast enhancement*: The pixel gray variable θ of the ancient building decoration image is any integer between 0 and 255. When processing the image, the gray variable is normalized to the interval of 0 to 1. If the gray variable is continuous, the initial gray distribution of the image can be described by using the probability density function $S(\theta)$. The decoration image of ancient buildings is usually discrete, and the discrete gray level can be expressed by Z_x . The

corresponding gray level distribution is A_{qw} , and the calculation formula is:

$$A_{qw} = S(\theta) \times Z_x \times R_{as} \times V_{av} \quad (8)$$

In formula (7): R_{as} represents the total number of image pixels, and V_{av} represents the number of gray pixels. Randomly select a normalized gray variable θ and convert the gray value using the following expression:

$$H_{dz} = M(\theta) \times S_{ab} \times A_{qw} \quad (9)$$

In formula (8): H_{dz} represents the new gray value after conversion, $M(\theta)$ represents the monotonically increasing conversion function, and S_{ab} represents the probability of occurrence of the converted gray value.

Most ancient architectural decoration images have fixed shapes, so histogram regularization processing needs to be carried out on the basis of equalization processing to further enhance the image contrast [16-17]. For the converted gray value function H_{dz} , the equalization result is T_k . After replacing the inverse gray u with uniform gray s , the calculation formula for contrast enhancement of ancient building decoration image is as follows:

$$D_{bd} = H_{dz} \times T_k \times T(\theta) \times u \times s \quad (10)$$

$$T(\theta) = T^{-1}\left(\frac{1}{\theta}\right)$$

If there is $T(\theta) = T^{-1}\left(\frac{1}{\theta}\right)$, the histogram regularization completes the contrast enhancement of ancient architectural decoration image.

2) *Smooth noise reduction*: In the process of collecting, transmitting and quantifying the ancient building decoration image, the noise of fuzzy image information will be formed. Therefore, the median filter method is used to remove the noise of the ancient building decoration image on the premise that the image edge contour and line can be well preserved.

For the gray value of the pixel to be processed in the image, the intermediate value of the gray value of the pixel in its neighborhood is used to complete the replacement. The implementation form is as follows:

$$Z_{JZ} = med\{M(\alpha_1, \beta_1), M(\alpha_2, \beta_2), \dots, M(\alpha_n, \beta_n)\} \quad (11)$$

In formula (10): Z_{JZ} represents the intermediate value of the neighborhood gray of the pixel to be processed, med represents the median value, $M(\alpha_n, \beta_n)$ represents the pixel whose coordinate is (α_n, β_n) , α represents any integer, and β represents the number of rows and columns

of the pixel.

3) *Edge sharpening*: A gradient method is designed to sharpen the pixels with significant changes in image edge and gray level. Based on the field theory, set a vector field as $t = t(\alpha, \beta, \gamma)$, and obtain the vector field gradient according to the extreme value of directional derivative at any point, as shown below:

$$A_{grad}(t) = \frac{\partial O}{\partial \alpha} a + \frac{\partial O}{\partial \beta} b + \frac{\partial O}{\partial \gamma} c \quad (12)$$

In formula (11): a , b and c represent arbitrary constants.

Given the pixel $O(\alpha, \beta, \gamma)$, the following vector formula is used to define the corresponding gradient of the coordinate (α, β, γ) :

$$B_{grad} [O(\alpha, \beta, \gamma)]^T = \begin{bmatrix} \frac{\partial O}{\partial \alpha} \\ \frac{\partial O}{\partial \beta} \\ \frac{\partial O}{\partial \gamma} \end{bmatrix} \quad (13)$$

The amplitude of the vector is $G[O(\alpha, \beta, \gamma)]$, and the following absolute value operation method is used for approximate calculation:

$$G[O(\alpha, \beta, \gamma)] = |O(\alpha, \beta, \gamma) - O(\alpha + 1, \beta, \gamma)| + |O(\alpha, \beta, \gamma) - O(\alpha, \beta + 1, \gamma)| \quad (14)$$

In order to simplify the complexity of edge sharpening, the obtained gradient $G[O(\alpha, \beta, \gamma)]$ is used to describe the pixel $O(\alpha, \beta, \gamma)$ and obtain the gradient image.

B. Filtering and Enhancement of Ancient Architectural Decoration Image

Before realizing the filtering and enhancement of ancient building decoration image, obtain the ancient building decoration image data through tilt photography technology and preprocess it. Obtain the ancient building decoration image data through three-dimensional laser scanning system and preprocess it [18]; Then, based on the preprocessed tilt image data and point cloud data, ICP algorithm is used to register the tilt image data and point cloud data; Finally, according to the registration results, the filtering and enhancement of ancient architectural decoration image is realized by using CGA rules.

1) *Image preprocessing of ancient architectural decoration*: The acquisition of ancient building decoration image needs to determine the UAV aerial photographing area, route and time according to the target ancient building and UAV elevation information, set the UAV flight take-off and landing points, and obtain the ancient building decoration image by controlling the UAV. In tilt photography, the vertical ground shooting method is adopted, also known as central projection. In order to ensure the accurate expression of the target ancient architecture, the central projection image is converted into the map projection mode of Orthophoto projection, and the conversion formula is as follows:

$$\begin{cases} x = -j \frac{a_1(X - X_g) + b_1(Y - Y_g) + c_1(Z - Z_g)}{a_3(X - X_g) + b_3(Y - Y_g) + c_3(Z - Z_g)} \\ y = -j \frac{a_2(X - X_g) + b_2(Y - Y_g) + c_2(Z - Z_g)}{a_3(X - X_g) + b_3(Y - Y_g) + c_3(Z - Z_g)} \end{cases} \quad (15)$$

In formula (14), j represents focal length, $a_1, a_2, a_3, b_1, b_2, b_3, c_1, c_2$ and c_3 represent the parameters of external orientation element matrix, (X, Y, Z) represents point cloud data coordinate information, g represents ranging observation value, and (X_g, Y_g, Z_g) represents the coordinate information of a point of the target building in the ground coordinate system.

The obtained target ancient architecture decoration image has multiple perspectives, such as left perspective, right perspective, front perspective, rear perspective and positive perspective. The inclined image of each perspective contains rich geographic information of the target ancient architecture. The definition of the target ancient architectural decoration image plays an important role in image filtering and enhancement. Tilt images from different perspectives will produce large overlapping areas, resulting in some deviation between tilt image data and real data, which will affect the accuracy of filtering and enhancement of ancient architectural decoration images. Therefore, it is necessary to preprocess the target ancient building decoration image data to improve the filtering and enhancement accuracy.

Tilt image preprocessing is mainly divided into two stages, as follows:

Stage 1: Configure relevant information, such as sensor pixel information and parameter information, so as to reduce the displacement deviation during filtering and enhancement of ancient building decoration image;

Stage 2: uniform light and color processing, so as to ensure the filtering of ancient architectural decoration image and enhance the consistency of hue. The hierarchical diagram of point cloud data of ancient building decoration image preprocessing is shown in Fig. 3.

Fig. 3. Hierarchical diagram of point cloud data of ancient building decoration image preprocessing

Fig. 4. Image preprocessing point cloud data partition storage graph

As shown in Fig. 3, the image preprocessing point cloud data in each sub cube is still stored hierarchically with the Z axis coordinate value from small to large. The maximum and minimum values of coordinates X and Y are used as the point cloud data segmentation points, the plane data is divided into four parts and stored as a point cloud data linked list. The above point cloud data preprocessing process is shown in Fig. 4.

According to Fig. 4, calculate the cube space containing all point cloud data, and the calculation formula is:

$$\begin{cases} L_{abc} = roundup(X_{max} - X_{min}) \\ W_{abc} = roundup(Y_{max} - Y_{min}) \\ H_{abc} = roundup(Z_{max} - Z_{min}) \end{cases} \quad (16)$$

In formula (15), L_{abc} represents the length of the cube and W_{abc} represents the width of the cube; H_{abc} represents the height of the cube; $roundup(\cdot)$ represents the upward rounding function; $(X_{max}, Y_{max}, Z_{max})$ represents the maximum coordinate of cube space; $(X_{min}, Y_{min}, Z_{min})$ represents the minimum coordinate of cube space.

According to the above calculation results, the point cloud data of ancient buildings are simplified, and the specific steps are as follows:

Step 1: Combine the point cloud data to segment points, and cluster and sort the point cloud data of each layer;

Step 2: Set an appropriate reduction step according to the filtering and enhancement requirements of ancient architectural decoration images;

Step 3: Based on the point cloud data reduction standard, retain the point cloud data that meets the reduction standard, and delete the point cloud data that does not meet the reduction standard;

Step 4: If the point cloud data is in the layer, return to step 1; If the point cloud data is not in the layer, proceed to step 5;

Step 5: If the point cloud data is in the cube, update the point cloud data segmentation points; if the point cloud data is not in the cube, the point cloud data reduction is completed and the reduced point cloud data is output.

2) *Filtering and enhancement of ancient architectural decoration image:* According to the above preprocessing results of ancient building decoration image, the filtering and enhancement of ancient building decoration image is realized under the neural network by applying CGA rules. The specific process is as follows:

CGA rule is a computer language that can automatically build models and has the characteristics of target description and visual observation. The basic idea of the rule is to replace a shape symbol with a certain number of new shapes. By inserting extruded taper and scatter, rendering texture and so on, the decorative details of ancient buildings can be modeled [19]. Nowadays, CGA rules have been integrated into the CE platform, and the rule programming has been completed in collaboration with C++ language to realize the filtering and enhancement of ancient architectural decoration images with numbering programs. The CGA rule commands are shown in Table I.

Based on the registration results of the ancient building decoration image and the point cloud data, execute the CGA rule command shown in Fig. 1, and finally complete the filtering and enhancement of the ancient building decoration image through the conversion operation. The expression is:

$$V_{fg} = (X_g, Y_g, Z_g) \times R_s + H_t \times Y_r \quad (17)$$

	InnerRect	Inner rectangle
Subtraction operation	Shape L;shape U;shape O	Deformation
	Convexity	De convexity
	Setback	Back off
	Offset	Deviation
	Comp split	Decompose
	Mirror;mirrorScope; Reverse Normals	Image
	Texture	Mapping
Conversion operation	T(scope translate) translateUV	Move
	AlignScope ToAxes center	Alignment
	R(scope rotate) rotateUV	Rotate
	S(scope size) sizeUV	Zoom
	Set	Set up
	Color	To color

In equation (16), R_s represents the image scaling coefficient, H_t represents the image motion vector, and Y_r represents the rotation coefficient. Through the above conversion operation, the research on the filtering and enhancement method of ancient building decoration image under neural network is realized, which not only provides a means to solve the contradiction between opening and protection of ancient building decoration image, but also provides accurate and complete data support for ancient building management and repair.

VI. EXPERIMENTAL ANALYSIS

In order to verify the performance of the filtering and enhancement method of ancient architectural decoration image based on neural network in practical application, an experiment is designed. The specific experimental process is as follows:

A. Selection of Experimental Objects

A Hutong in Beijing, China is selected as the experimental object of ancient architectural decoration image, which is a quadrangle in the Ming and Qing Dynasties. The South and east of the ancient building are qilinbei Hutong and scissors Lane Hutong respectively. Opposite is Fuxue primary school. It can be seen that the experimental object has a strong flavor of old Beijing life. The experimental object covers an area of about 15000 square meters and is now a key unit of cultural relics protection in Beijing. With the change of history, the owner of the experimental object has changed for several

generations, but the shape and architectural layout of the main house have not changed significantly, and the original appearance of ancient buildings in the Ming and Qing Dynasties is basically retained. The schematic diagram of experimental objects of various ancient architectural decoration images is shown in Fig. 5.

Fig. 5. Schematic diagram of experimental object

B. Experimental Instrument Setting

The experiment is carried on Matlab 7.1 platform and runs on the microcomputer platform configured with Genuine Intel(R) CPU T1600 1.66 GHZ and 1GB RAM. The effects of the decorative image filtering and enhancement methods of this method, literature [8] method, literature [9] method and literature [10] method are compared. In the experiment, the UAV camera and three-dimensional laser scanner are mainly used to obtain the information data of the experimental object. In order to ensure the accuracy of the obtained information, the parameters of the experimental instrument are reasonably set, as shown in Table II and Table III. In addition, the superparameter of the neural network as shown in Table IV is set, so that the maximum iteration of the network is 1000 times, and the training will stop when the set accuracy is reached.

TABLE II. CAMERA PARAMETER SETTING

Camera Parameters	Numerical Value	Image Parameters	Numerical Value
Camera model	ILCE-QX1	Image size	5462 * 3632 pixels
Time of exposure	1/1000 秒	Ground resolution	5cm
Aperture value	F/5.6	Horizontal resolution	350dpi
Focal length	16mm	Vertical resolution	350dpi
Maximum Aperture	2.96875	Image overlap	80%-90%
ISO speed	ISO-200	Image bit depth	24

TABLE III. PARAMETER SETTING OF 3D LASER SCANNER

Parameter Name	Numerical Value	Company
Scanning principle	Pulse	-
Field of view range	360×270	Degree
Ranging range	1-350	m
Angle measurement accuracy	±60	mrad
Single point ranging accuracy	±6(50)	mm
Maximum scan rate	5000	Spot/s

There are about 30 courtyards and 60 houses, including rockeries, shrubs, gardens, etc.

TABLE IV. HYPERPARAMETER SETTING OF CONVOLUTIONAL NEURAL NETWORK

Parameter Name	Numerical value
Learning rate	0.001
Batch_size	128
Iterations	1000
Step size	1

C. Result Analysis

The signal-to-noise ratio is used to measure the noise suppression performance of the four methods in the process of image enhancement. Generally, the higher the signal-to-noise ratio, the smaller the noise contained in the ancient building decoration image, and the better the image quality. The calculation process of signal-to-noise ratio is as follows:

$$X_{SNR} = \sum_{i,j}^n x_{ij}^2 / \sum_{i,j}^n y'_{ij} - x'_{ij}{}^2 \quad (18)$$

Different Gaussian white noises are introduced into the image, and four methods are used for enhancement respectively. The enhanced images' signal-to-noise ratio is compared. The results are shown in Table V.

TABLE V. COMPARISON RESULTS OF SIGNAL-TO-NOISE RATIO OF THREE METHODS

White Gaussian Noise	Reference [8] Method	Reference [9] Method	Reference [10] Method	Paper Method
1	11.15	11.44	13.12	14.52
2	10.20	10.43	12.20	12.42
3	9.73	9.91	11.33	11.89
4	7.82	8.99	9.96	10.92
5	7.57	7.82	9.69	10.45
6	7.18	7.54	9.10	9.99
7	7.11	7.43	8.84	9.85
8	7.07	7.24	8.52	9.75
9	6.92	7.04	8.13	8.99
10	6.76	6.94	8.21	8.77

It can be seen from Table V that under the same Gaussian white noise, the signal-to-noise ratio of the method in this paper is greater than that of the methods in literature [8], [9] and literature [10], which can effectively suppress the adverse impact of noise on the image. This is because this method uses the median filter method to remove the noise of ancient architectural decoration image on the premise of better preserving the image edge contour and lines. For the gray value of the pixel to be processed in the image, the intermediate value of the gray value of the adjacent pixel is used to complete the replacement, which is helpful to suppress the adverse effect of noise on the image to a certain extent.

Fig. 6 is a comparison diagram of ancient building decoration image after filtering and enhancement processing under three methods.

Fig. 6. Image filtering and enhancement processing effect under three methods

It can be seen from Fig. 6 that the images processed by the methods of literature [8] and literature [9] can only get gray images, and the processing of image target details is relatively rough, resulting in blurred image edge feature extraction. However, the filtering enhancement processing effect of ancient building decoration image under this method is very close to the original image, and the color is consistent. Visually, the image obtained by this method is clearer than that obtained by the literature method. This method can show more detailed information in the image, greatly improve the image contrast, enhance the processed image content, and has strong practicability and robustness. Mainly because most of the ancient architectural decoration images in this method have fixed shapes, histogram regularization processing is carried out on the basis of equalization processing to further enhance the image contrast.

VII. CONCLUSION AND PROSPECT

The filtering and enhancement method of ancient architectural decoration image based on neural network can effectively suppress the adverse impact of noise on the image, show more detailed information in the image, greatly improve the image contrast and enhance the processed image content. It has strong practicability and robustness. Although the work has achieved preliminary results, there are still many

deficiencies, and a large number of technical problems need to be further studied and solved. Although this work has achieved preliminary results, it only has a good adaptability to the decorative images of Chinese ancient buildings, and cannot be well adapted to other types and styles of decorative images. In the following work, other types of decorative images of ancient buildings should be studied, and the information acquisition problem of some colored images that are not covered and exposed to light and wind and rain for a long time will be studied.

A Neural Network-Based Algorithm for Weak Signal Enhancement in Low Illumination Images

Dawei Yin^{1*}, Jianwei Li²

General Affairs Office, Laiwu Vocational and Technical College, Laiwu, China¹

Department of Information Engineering, Laiwu Vocational and Technical College, Laiwu, China²

Abstract—There is noise interference in low-illumination images, which makes it difficult to extract weak signals. For this reason, this paper proposes a low-illumination image weak signal enhancement algorithm based on neural network. Multi-scale normalization is performed on low-light images, and multi-scale Retinex is used to enhance weak signals in low-light images. On this basis, the GAN artificial neural network is used to detect the weak signal of the weak signal in the image, the normalization of the weak signal of the low-illumination image is completed based on the residual network, the self-encoding parameters of the depth residual are generated, and the weak signal enhancement result of the low-illumination image is output. The experimental results show that the method in this paper has better enhancement effect on low-illumination images and better image denoising effect. When the scale value is large, the low-contrast area of the low-illumination image has a better enhancement effect. The saturated area of the low-light image has a better enhancement effect.

Keywords—Artificial neural network; GAN neural network; low-light image; weak signal enhancement

I. INTRODUCTION

With the advancement and development of science and technology, the methods of image acquisition are becoming more and more abundant, and people's requirements for image quality are getting higher and higher. However, the process of image acquisition will be affected by many factors. Under special lighting conditions, optical imaging equipment may cause uneven exposure of the obtained image, loss of scene details, and unclear recognition of weak and small targets due to uneven lighting. Since the dynamic range of the shooting equipment is limited, if you just adjust the exposure rate of the equipment, it still cannot solve the problem of overexposure or oversaturation in some areas. Under the conditions of lack of light and low visibility such as at night and dusk, the image collected by the image acquisition device not only has dark areas, but also the brightness and contrast of the image will be seriously reduced, making it difficult to distinguish the details of the image or even unable to see any details. The identification and judgment of images and the extraction of information in project management and control have a certain impact. Therefore, it is the current focus in the field of image processing to study and enhance the detail features of low-light images and ultimately improve the overall quality of the image [1].

Image weak signal enhancement is to perform specific processing on a given image, purposefully emphasizing the overall or local characteristics of the image, making the

original unclear image clear or emphasizing some interesting features, and expanding the difference between the characteristics of different objects in the image. To meet some special application requirements [2], the difference between them can be suppressed, and the features that are not of interest can be suppressed. Low-illumination images are generally images collected in scenes with insufficient ambient light. The gray levels of such images are concentrated in a lower gray-scale range, and the details of the images are not obvious. In addition, the image will also contain a lot of noise, which seriously affects the image quality. To make the low-illumination image have a better display effect or meet the input requirements of other image processing algorithms, it is necessary to carry out enhancement and noise reduction processing to emphasize the useful information in the image and effectively suppress the interfering information such as noise [2].

Study [3] proposes a low-light image adaptive enhancement algorithm based on maximum difference map decision. First, the concept of a maximum difference map is proposed, and the initial illumination component is roughly estimated by the maximum difference map; then, an alternate guided filtering method is proposed. The algorithm uses alternating guided filtering to correct the initial illumination components to achieve accurate estimation of the illumination components; finally, an adaptive gamma transform for image brightness is designed, which can adaptively adjust the gamma transform parameters according to the acquired illumination components to enhance the image, also eliminates the effects of uneven lighting. Research [4] proposes a recurrent image enhancement network based on generative adversarial networks (GAN). An unsupervised learning method is introduced to estimate the original illumination of low-light images by reducing the loss of cycle consistency and adversarial loss. The image enhancement model formula is used to enhance the brightness of the images collected under insufficient illumination. Finally, the synthetic low-light image data set and the real natural low-light image data set are evaluated qualitatively and quantitatively. Liu Y's team proposed a GAN model that can perceive the lighting details. This model can fine-tune the image lighting effect in the case of high noise and loss of texture details, and use residual dense encoding and decoding strategy to suppress noise. The performance results show that the model is better in the ultra-low light image data set [5]. Jung E's team proposed a multi-frame GAN concept that can enhance stereo vision image sequences under low light conditions. This method is based on the reversible generation of the confrontation

*Corresponding Author

network, which can transfer the features of bright lighting scenes to the bottom lighting scenes. The research results show that this method has great advantages in visual mileage [6]. Ma Y et al., focusing on the field of medical images, proposed a GAN model that can add terms to the circular structure and illumination constraints of medical images. This model can learn the overall and local details of images. The research results show that this method is better than traditional methods [7]. The above methods are all effective to a certain extent, but it is difficult to ensure the details of the image while realizing the enhancement of the low-illumination image, and the visual perception of the enhanced image still needs to be improved. To this end, this paper proposes a low-light image weak signal enhancement algorithm based on a neural network.

II. RESEARCH ON WEAK SIGNAL ENHANCEMENT OF LOW ILLUMINATION IMAGE

A. Multi-Scale Normalization of Low-Light Images

For low-light images, normalization can reduce the probability of image distortion during the enhancement process and improve the ability to retain details. Through the unified management of image features, the misjudgment rate of target information is reduced and the enhancement efficiency is improved. However, in most cases, the original low-light image contains a large number of isolated discrete pixels, and there is no spatial correlation between these pixels, but the pixels follow the Gaussian distribution, indicating that the data of the original image has a certain influence of noise. To this end, the image is denoised first and then normalized [8].

In this paper, the wavelet transform method is used to denoise the data points in the multi-frequency domain in the image, which helps to deepen the pixel signal characteristics in the image, and can ensure the processing effect of signal noise even in the state of different resolutions. The key to wavelet transformation lies in the selection of the transformed threshold. There are two commonly used thresholds: one is the hard threshold, which is closer to the actual situation and retains the edge information of the image better, but the noise reduction effect for Gaussian white noise is poor. The second is the soft threshold, which has a certain continuity, which can improve the low-light enhancement performance and make the visual expression more natural. In contrast, the latter is more suitable for low-light image processing [9].

By establishing a unified Gaussian frequency division noise reduction model, the original low-light image is used as the input value of the model. In the model, the transform value of each wavelet packet frequency band depends on the frequency band value of the image, and the complex wavelet packet is decomposed. It is assumed that X is the initial value of the image, P is the noise, and Z is the observation image with noise. The expression formula is as follows:

$$Z = X + P \quad (1)$$

If each noise in the image follows the Gaussian

distribution of its frequency band, its mean value is 0, and its variance value is σ_k^2 . The variance value can be calculated according to statistical values [10].

After determining the frequency band parameters of the image, use the multi-scale method to quickly estimate the noise reduction model, and then use the soft threshold to correct the estimated value ξ to obtain the actual output value e^2 . The correction formula is:

$$\begin{aligned} e^2 &= |\xi|^2 / 4 - \sigma_k^2 & |\xi| \geq 4\sigma_k^2 \\ e^2 &= 0 & |\xi| < 4\sigma_k^2 \end{aligned} \quad (2)$$

From the corrected output value, derive the noise value in all frequency bands in the image:

$$\xi = e^2 / (e^2 + \sigma_k^2) \quad (3)$$

Finally, the estimated value is restored to the original decomposition domain by wavelet packet transform to realize image noise reduction.

Calculate the multiple scale values of the denoised image, and divide the size threshold of the image normalization process according to the scale value. The algorithm framework is as follows.

Given a low-light image of size $P \times Q$, where Q is the sampling factor, M is the scaling factor of the image, and $m = 1, 2, \dots, M$. Pixel sampling according to $\frac{P}{q} \times \frac{Q}{p}$, pixel point $i \in C$.

The constraint function is:

$$C_{s-1,s}(i, j) = \frac{1}{|N_i|} \quad \forall j \in N_i \quad (4)$$

In the formula, N_i is the neighborhood of image sampling point i .

Calculate the refraction value W_s^c of the image passing through the light, the radius is r , and the multi-scale value of the image is calculated by $(W_s^c, C_{s-1,s})$:

$$W = \begin{bmatrix} W_1^c & & \\ & \ddots & \\ & & W_s^c \end{bmatrix} \quad (5)$$

$$C = \begin{bmatrix} C_{1 \square 2} - I_2 & & & \\ & \ddots & & \\ & & \ddots & \\ & & & C_{s-1, s} - I_s \end{bmatrix} \quad (6)$$

In the formula, W represents the multi-scale weight. Calculate the image projection value Q :

$$Q = I - AC^T (CA^{-1}C^T)^{-1} CA \quad (7)$$

In the formula, A represents a multi-scale normalized matrix:

$$A(i, i) = \sum_{i, j=1}^n W(i, j) \quad (8)$$

The low-light image is substituted into the matrix, and the final normalized result can be obtained by multiple iterative calculations.

B. Weak Signal Enhancement of Low-Light Images based on Multi-Scale Retinex

1) Low-light sub-image segmentation based on LIP model:

In image processing, general arithmetic operations are not suitable for some actual image processing work, and the result obtained by directly adding (or multiplying) two images has a certain gap with the human visual effect, and will produce “hyper-interval value” problem, the LIP model provides a new arithmetic construct that defines new vector operations such as addition, subtraction, multiplication, etc. The gray values of the images applied with this model are all in the (0, M) interval, so as to avoid the problem of exceeding the interval value, which is also consistent with the saturation characteristics of the human visual system [11].

In order to make the enhancement effect of the proposed method more obvious, when the low-illumination image is denoised, it is decomposed in two dimensions according to the background intensity and gradient information.

Let $I(x, y)$ be the background intensity, which is obtained by calculating the weighted mean of the pixels in the field, as shown in the following formula:

$$I(x, y) = m \otimes n \left(2 \otimes \sum_L f(x, y) \right) \quad (9)$$

In the formula, the set of neighborhood pixels in the four directions of the pixel to be processed is L ; the weights are m and n ; the set of domain pixels on the diagonal of the pixel to be processed is L' .

If the gradient $G(x, y)$ of the pixel value of the low-light image is used as the information transition rate, the maximum difference value of the low-light image pixel needs to be defined. The calculation method is as follows:

$$Id = [\max(f(x, y)) \ominus \min(f(x, y))] \quad (10)$$

Let I_i be the threshold of the background intensity; G_i be the threshold of the gradient, and use the following formula to divide the low-light image into regions:

$$\begin{cases} I_1 = a * Id; I_2 = b * Id; I_3 = c * Id \\ GG_1 = 0.01\beta \max(GG(x, y)I(x, y)) \\ GG_2 = GG_1 I_2 \\ GG_3 = GG_1 I_3 \end{cases} \quad (11)$$

Pixels in saturated regions of low-light images satisfy the following equation:

$$\begin{cases} I(x, y) \geq I_3 \\ \begin{cases} GG(x, y) \\ I(x, y) \end{cases} \geq GG_3 \end{cases} \quad (12)$$

Pixels in the de Vries region of a low-light image satisfy the following equation:

$$\begin{cases} I_2(x, y) \geq I(x, y) \geq I_1 \\ \begin{cases} GG(x, y) \\ I(x, y) \end{cases} \geq GG_2 \end{cases} \quad (13)$$

Pixels in the Weber region of a low-light image satisfy the following equation:

$$\begin{cases} I_3(x, y) \geq I(x, y) \geq I_2 \\ \begin{cases} GG(x, y) \\ I(x, y) \end{cases} \geq GG_1 \end{cases} \quad (14)$$

The proposed method decomposes the low-illumination image into several sub-images and then merges the remaining pixels into the low-contrast area uniformly, which completes the division of each area of the low-illumination image and realizes the purpose of image enhancement for different sub-images [12].

2) *Local multi-scale Retinex algorithm*: The Retinex theory believes that an image can be divided into incident components and reflection components. First, the low-illumination image is segmented by the area division method of the above LIP model. Then, according to the illumination characteristics of each sub-image after segmentation, Retinex of different scales σ is used to highlight the advantages of Gaussian functions of different scales are enhanced, and the specific process of the method is shown in Fig. 1.

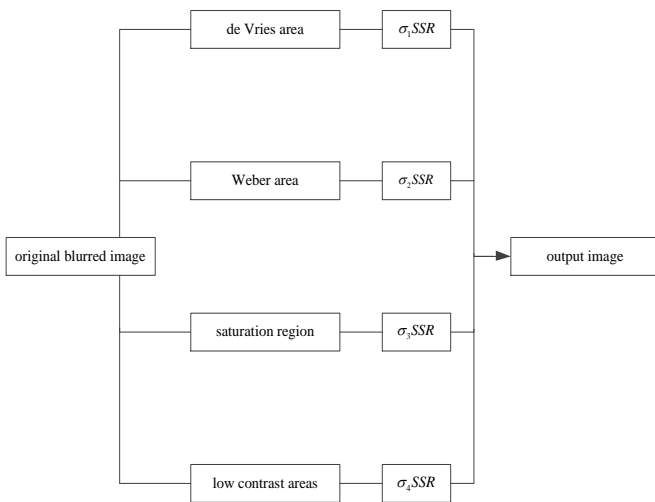

Fig. 1. Local multi-scale Retinex algorithm process

The pixels in the low-contrast area are filtered using Gaussian template $F_1(x, y)$ with scale σ_1 .

First, the incident component of the image in this area is estimated, and then the reflection component is discarded to complete the enhancement of the low-contrast area in the low-illumination image, as shown in formulas (15) and (16):

$$F_1(x, y) = 2 \frac{1}{\pi} \sigma_1 \exp\left(-\frac{x^2 + y^2}{2\sigma_1^2}\right) \quad (15)$$

$$R_1(x, y) = \lg S_1(x, y) - \lg [S_1(x, y) * F_1(x, y)] \quad (16)$$

In the formula, the Gaussian function with a scale of σ_1 is $F_1(x, y)$; the pixel in the low-contrast area is $S_1(x, y)$, and the processing result of the low-contrast area in the original image is $R_1(x, y)$.

Use Gaussian filters of different scales to estimate the incident components of the remaining de Vries area, Weber area, and saturation area, and complete the enhancement of each area according to the above calculation method. The calculation method is as shown in formulas (17) and (18). Show:

$$F_k(x, y) = 2 \frac{1}{\pi} \sigma_k \exp\left(-\frac{x^2 + y^2}{2\sigma_k^2}\right) \quad (17)$$

$$R_k(x, y) = \lg S_k(x, y) - \lg [S_k(x, y) * F_k(x, y)] \quad (18)$$

Through the above calculation, three sub-images $R_2(x, y)$, $R_3(x, y)$, $R_4(x, y)$ are obtained in the same way for the other three regions, and the sub-images $R_1(x, y)$, $R_2(x, y)$, $R_3(x, y)$, $R_4(x, y)$ are combined together to

obtain the final enhancement effect.

Because the pixel contrast in the low-contrast area of the low-illumination image is low, choosing a relatively small σ -value can better highlight the details of the image and achieve an enhanced effect. Among them, σ_1 , σ_2 , σ_3 , σ_4 are different scales selected in the four regions decomposed in the low-illumination image by using the Gaussian function.

The de Vries region represents the low-light region of the low-light image, the Weber region represents the medium-light region of the low-light image, and the saturated region represents the high-light region of the low-light image. Therefore, the scale can be selected according to the rule of $\sigma_2 < \sigma_3 < \sigma_4$. At the same time, through the improved multi-scale Retinex algorithm, the proposed method satisfies the enhancement requirements for different specific pixel regions in low-illumination images, so that low-illumination images can obtain better color fidelity and detail enhancement effects.

III. IMPROVED ALGORITHM FOR WEAK SIGNAL ENHANCEMENT OF LOW-LIGHT IMAGES BASED ON NEURAL NETWORK

A. Weak Signal Detection of Weak Signal in Image based on Artificial Neural Network

Before designing the low-light image weak signal enhancement algorithm, extract the weak signal of the image, apply the mathematical model and other techniques to plan the image edge data into a set of multi-dimensional data structure [13], and then use the random process of the data and the feedback in the artificial neural network. The mechanism divides the weak signal of the image into functional regions and non-functional regions [14], and its noise function expression is as follows:

$$g(y) = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{(y-\mu)^2}{2}\right) \quad (19)$$

In the formula, y represents the gray value of the noisy edge image, and μ represents the expected value of the image edge noise on the gray value. The formation of Rayleigh noise is mainly caused by other elements in the edge data collection environment during the image generation process, and the noise is relatively high. The complex data edge environment, and then the formation of noise, the function representation is as follows:

$$g(y) = \frac{2}{b} (y-a) \exp\left[-\frac{(y-a)^2}{b}\right], y \geq a \quad (20)$$

In the formula, a represents the high probability complex factor existing in the weak signal data environment of the image, and b represents the correlation between the weak signal data of the image and the original data of the image edge. In order to observe the influence of different noises on the image edge more intuitively, this paper extracts

the noise data of the original image edge, and then the Matlab software is used for model simulation processing. The obtained weak signal detection processing results of different types of images are as follows:

The application of artificial neural network technology to extract image weak signal edge noise data requires the application of various types of algorithms and filtering techniques [15-17]. As the feedback object and data extraction library of artificial neural network, the filtering algorithm formula used in this paper is as follows

$$f(x, y) = \frac{1}{M \times N} \sum_{M, N \in R} f(m, n) \quad (21)$$

In the formula, M and N respectively represent the average noise wave value of different types in the image weak signal edge data, which can produce a certain degree of defense against the image edge noise data, and complete the image edge noise without losing the original image clarity. Data detail processing and extraction will not affect the post-processing of images such as missing data.

After filtering and classifying the relevant data in the weak signal of the image by applying filtering technology, two parts of noise coefficients are generated, which respectively exist in the image edge database with different noise frequencies. Initialize the data information at the edge of weak signal. The specific change expression is as follows:

$$w_{j,k}^n = \begin{cases} w_{j,k} & |w_{j,k}| \geq \lambda \\ 0 & |w_{j,k}| < \lambda \end{cases} \quad (22)$$

In the formula, λ represents the image edge noise threshold, and $w_{j,k}$ represents the noise coefficient in the neural network. To accurately extract the noise coefficient, the data connection state in the artificial neural network has been

in a continuous mode, resulting in obvious threshold division and easy to make other noise factors. Reshape the details of the weak signal edge of the image.

B. Create a Normalized Processing Structure for Weak Signals in Low-Light Images

GAN technology is actually a low-light image weak signal confrontation processing program, which mainly processes the weak signals of low-light images one by one according to the corresponding steps. First, we need to prepare a low-light image weak signal discriminator and a generator. The discriminator mainly makes a corresponding judgment on whether the weak signal of the low-illumination image belongs to the real data distribution, and calculates the respective probability values of the data input and output. The generator captures relevant data and indirectly forms a similar data distribution. Calculate the objective function of the GAN. Calculated as follows:

$$G\{F(a, b)\} = E\left[Lg(1 + \sqrt{5})\right] \quad (23)$$

In the formula, G represents the value of the objective function, F represents the set range of the function, a represents the maximum value of the function, b represents the minimum value of the function, and E represents the corresponding separation function of the GAN objective function. Through calculation, its objective function is obtained. Then, a model is generated using the objective function and balanced optimization is performed on it. In a specific low-light image weak signal processing environment, use SRGAN to build a GAN network architecture processing structure, as shown in Fig. 2:

Fig. 2 shows the related process of the low-light image weak signal processing structure of the created GAN network. After that, a normalized processing relationship is established between the weak signal loss function of the low-illumination image obtained in the model and the adversarial function, as shown in the following formula:

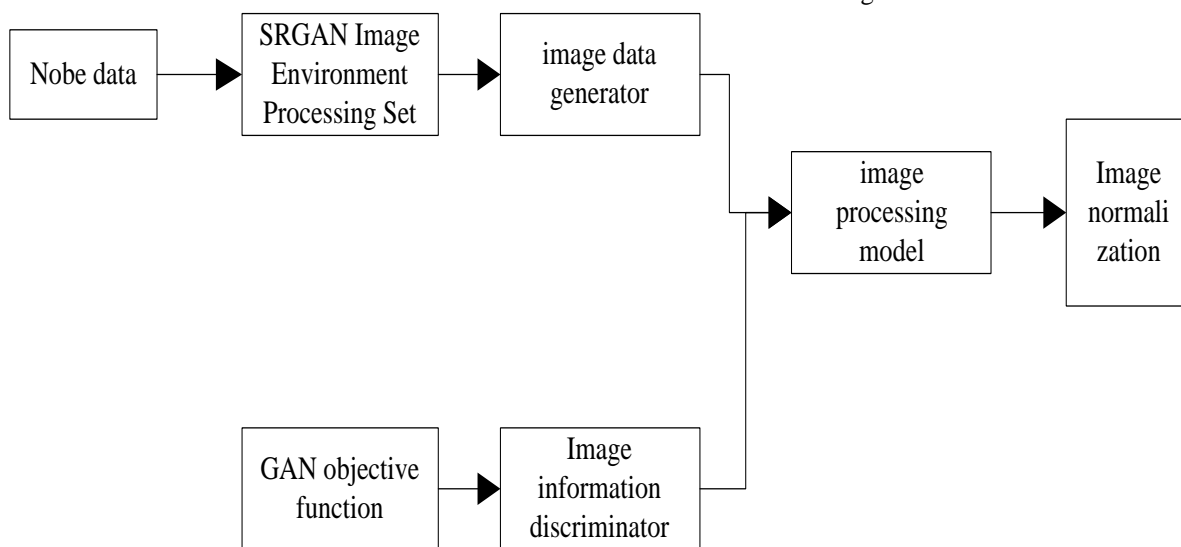

Fig. 2. GAN network low-light image weak signal processing architecture

$$Y = B - C + r \quad (24)$$

In the formula, Y represents the relationship between the loss function and the adversarial function, B represents the directional processing distance, C represents the target processing distance, and r represents the error distance. After the processing relationship is established, the weak signal of the low-illumination image is imported into the processing system, and the generator is used to first obtain the data information corresponding to the weak signal of the low-illumination image, and then a convolution layer of the weak signal of the low-illumination image is established to improve its resolution. Subsequently, the convolutional layer is activated using the ReLU activation layer in the discriminator, and then 10 residual network modules are constructed through the processing steps, and these modules are skip-connected. At this time, the connection surfaces of each layer are superimposed on each other and continue to be superimposed under the action of the convolution layer. Such a low-light image weak signal processing mode can prevent the low-level low-light image weak signal features from being generated. loss, and expand the size, length, width, and area of weak signals in low-light images. In general, it can be expanded to about four times the weak signal of the original low-light image, and finally, a picture with four times the resolution is obtained. Then, the discriminator is used again to superimpose the weak signal of the low-illumination image processed above by using the processing path again to superimpose the connection surface. This time, multiple convolution structures need to be repeated, and their lengths are separated into two types, one and two, using different processing types used to process low-light images, weak signals, and pictures in different formats. Subsequently, the image scale was changed to 1/16 in the original image processing system. Adjust the number of channels to 612, activate the discrimination result, output the result in another system dimension, and set the sigmoid function to perform the final processing on the weak signal of the low-light image, to use the related technology of GAN to create a low-light image. Normalized processing structure for weak signals.

C. Low-Light Image Weak Signal Enhancement Algorithm based on Residual Network

After the normalization of the weak signal of the low-illumination image is completed, next, a low-illumination residual network is constructed to enhance the weak signal of the low-illumination image. First, the auto-encoding parameters of the depth residual are generated. Auto coding is a neural network control value that uses a backpropagation algorithm to process data information. It compresses the weak signal of a low-light image to an editable size, hides its spatial representation, and then outputs it through the representation. Next, the low-light processing coefficient of the residual processing model is established in a low-light processing environment. The calculation formula is as follows:

$$X = (\alpha + \beta) - \frac{1}{l} \quad (25)$$

In the formula, X represents the low-light processing coefficient of the model, represents the processing distance, represents the straight-line processing distance of the model, and one represents the number of inertial protons. Through the above calculation, the low-light processing coefficient is obtained. On this basis, next, the total iteration value of the discrimination of the weak signal of the low-light image is calculated. The calculation formula is as follows:

$$K = \frac{\Delta i}{\Delta j} - \frac{1}{v} \quad (26)$$

In the formula, K represents the total iterative value of discrimination for weak signal processing of low-illumination images, i represents the total distance of calculation iterations, j represents the number of iterations, and v represents the objective function. After obtaining the iterative value of the weak signal processing of the low-illumination image, next, the processing system is used to establish an enhancement relationship between the weak signal of the original low-illumination image and the weak signal of the target low-illumination image to enhance its versatility.

The cyclic residual neural network is used to enhance the weak signal of the low-light image. First, optical color analysis needs to be performed on the low-light image that needs to be processed, and the color that cannot be edited is recorded. Then, use the residual neural network technology to amplify the weak signal of the low-light image to a size that can be processed, separate the color replacement factors in the low-light image, and adjust the color of the low-light image to a single mode, and turn on the intelligent color in the system processing. Adjustment function, a kind of original low-light image weak signal, restores the color and increases the control parameters of its saturation so that the low-light image weak signal overall is more three-dimensional. Then, set the residual coefficients that satisfy the weak signal enhancement processing of low-illumination images in the system, add auxiliary graphics processing programs, and change the processing mode of the system to multiple-simultaneous loop processing. Then, in the low-light and low-light image processing environment, the corresponding low-light image weak signals and photos are enhanced at various levels, to complete the low-light image weak signal enhancement processing by the cyclic residual neural network.

IV. EXPERIMENTAL ANALYSIS

A. Experimental Conditions

To verify the effectiveness of the low-light image weak signal enhancement algorithm based on a neural network, a simulation comparison experiment was carried out. Select the images in the Joint Video Stitching and Stabilization from Moving Camer (http://www.liushuaicheng.org/TIP/VideoStitching2016/index.html) dataset, and the schematic diagram of the low-light image is shown in Fig. 3.

Fig. 3. Schematic diagram of low-light image

TABLE I. GAN NEURAL NETWORK PARAMETERS

Index	Parameter
The number of network layers	3
The number of iterations	94
The weight of the first layer	0.5
The offset term	0.7
The learning rate	0.001

The parameters of the GAN neural network are set as shown in Table I.

Under the above experimental conditions, the method of studies [3] and [4] are used as experimental comparison methods to test the effectiveness of the low-light image weak signal enhancement algorithm.

B. Analysis of Experimental Results

Fig. 4 is a low-illumination image enhancement effect diagram obtained by applying the method of study [3], the method of research [4] and the method of this paper to the low-illumination image enhancement operation.

(a) Reference [3] method

(b) Reference [4] method

(c) This paper method

Fig. 4. Low-light image enhancement effect diagram

As can be seen from the above figure, the original low-illumination image is dark in brightness and the blurring phenomenon is serious. The enhancement effect of the method in studies [3] and [4] is poor, while the low-illumination image enhanced by the method in this paper has low brightness and sharpness. It shows that the application of this method can realize the enhancement of low-light images, and the enhancement effect is better, which can better meet the needs of practical work.

Clarity and information entropy are two important indicators that reflect the enhancement effect of weak signals in low-light images. Table II shows the values of sharpness and information entropy at different scales obtained by performing sub-image enhancement operations on saturated areas of weak signals and low-contrast areas of low-illumination images using the method in this paper.

TABLE III. CLARITY AND INFORMATION ENTROPY AT DIFFERENT SCALES

Scale value	low contrast area		saturation area	
	sharpness	information entropy	sharpness	information entropy
0.6	20.52	6.21	23.63	8.63
1.2	21.52	6.59	22.52	8.52
1.8	22.03	7.03	22.02	8.01
2.4	22.96	7.42	21.96	7.56
3.0	23.65	7.86	21.56	6.98
3.6	24.52	7.99	20.32	6.23
4.2	25.63	8.09	19.56	5.56
4.8	26.66	8.33	18.96	4.98
5.4	27.33	8.86	18.23	4.88
6.0	27.86	9.01	17.63	4.35

It can be seen from Table II that with the increase of the scale value, the sharpness and information entropy value of the low-contrast area of the low-illumination image both show an increasing trend. When the value is 0.6, it is increased by 34%; the sharpness and information entropy of the saturated area of the low-light image shows a decreasing trend with the increase of the scale. When the scale value increases from 0.6 to 6.0, the sharpness of the image decreases by 25%. Description: When the value of the scale is large, the low-contrast area of the low-light image has a better enhancement effect, and when the value of the scale is small, the saturated area of the low-light image has a better enhancement effect. Therefore, when applying the method in this paper to perform image enhancement on low-illumination images, large-scale and small-scale combined operations should be performed in the low-contrast and saturated regions of the low-illumination image to achieve better image enhancement effects.

Fig. 5 shows the sharpness curves under different signal-to-noise ratios obtained by applying the method in this paper, the method in study [3] and [4] to perform weak signal multi-scale enhancement operations on low-illumination images respectively. In Fig. 5, with the increase of the signal-to-noise ratio, the sharpness curves of the three methods all show an upward trend, but the sharpness curves of the method in this paper are higher than those of the methods in researches [3] and [4] from the beginning, and with the increase of the signal-to-noise ratio, the sharpness curve obtained by applying the method in this paper to perform the image enhancement operation on the low-illumination image has an obvious upward trend. Increased by 50% and 65%. Prove: Applying the method in this paper to perform image enhancement operations on low-light images can obtain higher image clarity, and the advantages of low-light image enhancement are more obvious.

Fig. 5. Comparison of sharpness curves

Fig. 6. Peak signal-to-noise ratio curves of different methods

In order to verify the advantages of the method in this paper in denoising low-illumination images, the peak signal-to-noise ratio curves under different noise variances obtained by applying three methods to perform denoising operations on low-illumination images are shown in Fig. 6.

Analysis of Fig. 6 shows that the peak signal-to-noise ratio curves obtained by applying the three methods to perform denoising operations on low-illumination images all gradually decrease with the increase of noise variance, but the peak signal-to-noise ratio curves obtained by applying the method decrease from one to one. In the beginning, it is higher than the methods of [3] and [4], and with the increase of noise variance, the downward trend of the curve is very insignificant. Experiments show that the method in this paper is used to perform denoising operation on low-illumination images, and the denoising effect is better than the methods in [3] and [4], and it has more advantages in denoising low-illumination images.

V. CONCLUSION

This paper proposes a low-light image weak signal enhancement algorithm based on a neural network. The experimental results show that the method in this paper has a better enhancement effect on low-light images. When the scale value is large, the low-contrast area of the low-light image has a better enhancement effect. When the scale value is small, the saturation area of the low-light image has a better effect. It has a better enhancement effect, and the image-denoising effect of this method is better.

Digital Intelligent Management Platform for High-Rise Building Construction Based on BIM Technology

Rui Deng¹, Chun'e Li^{*2}

School of Building Management, Chongqing Metropolitan College of Science and Technology, Chongqing, China^{1,2}

Abstract—In this study, the digital intelligent management platform of high-rise building construction based on BIM technology is used for real-time monitoring and management of construction progress and quality. In the data acquisition and processing layer, construction site data is obtained through RFID technology. After processing such as cleaning and integration, it is input to the BIM model layer to dynamically generate various real-time BIM models, and these real-time BIM model information is input to the application layer to query, monitor and correct the construction progress and quality. The results are presented by the display layer. The actual application results show that the real-time BIM models generated by the platform have clear details and can realize the query, monitoring and correction functions for the construction progress of high-rise buildings, and effectively correct the construction progress according to the construction progress monitoring query results to achieve the unification with the planned progress. It can effectively realize the visual measurement of the size of each component in construction and monitor the construction quality in real time.

Keywords—BIM technology; high-rise building construction; digitization; intelligent management; BIM model; RFID technology

I. INTRODUCTION

With more and more complex high-rise construction and longer construction cycle in recent years, it makes the control of construction progress and quality more and more difficult. Therefore, the collaborative management of construction progress and quality of high-rise buildings has become a very important research topic in the field of engineering construction [1]. Many studies have been done by scholars at home and abroad for this purpose. At present, most of the studies are exploring the working principles of management and platform for comprehensive monitoring of progress and quality implementation in the construction phase. However, such management platforms lack specific responses in case of changes in project construction and are not effective in ensuring that high-rise buildings proceed as planned [2, 3]. Therefore, there is a need to create a platform that can adapt to this change.

J. Zhang et al. (2021) study the project critical chain schedule monitoring method based on project resource segmentation, and determine the early warning state value by multi-objective fuzzy comprehensive evaluation method, solve the overdue minimization objective function, and finally use

BPNN to predict the next phase of the project so as to deal with the problems in the project implementation process in a timely manner. In order to realize the monitoring and management of project progress, this monitoring method of construction project progress can effectively predict the project risk situation and has good effect on reducing the overdue completion rate and overcapacity rate, but it does not implement monitoring and management of construction quality of the construction project [4]; Zhou, C et al. (2020) proposed that the digital construction management platform in EPC mode is mainly from EPC mode starting from the EPC model to solve the key problems in the digital construction of large enterprises, so as to analyze the necessity of applying the EPC model in digital construction. Although this platform can realize the basic digital management in construction, it lacks the function of real-time correction and adjustment according to the plan in the actual construction process [5]; Ma, G et al. (2019) proposed an engineering construction schedule optimization model based on improved genetic algorithm, constructed the overlapping strategy decision model of engineering schedule, combined with the optimization algorithm to output the overlapping strategy with precise overlapping rate, and obtained the overlapping strategy in meeting the premise of schedule requirements, the optimal schedule plan is obtained. This model can achieve the optimal management of project construction schedule, but does not have the ability to control the project construction quality [6]. In recent decades, information simulation technology has been widely used in the construction industry, especially the Building Information Modeling (BIM) technology. This technology is considered as an essential tool for construction project management. All project participants can share and exchange information with each other with the help of BIM technology platform, which is also an upgrade of CAD technology. In a real sense, it realizes industrialization, refinement, digitization, informatization, and intelligence in the construction industry [7, 8]. It not only reflects the geometric information of building entities, but also shows a large amount of building information such as structure type, material type, manufacturer, construction quality, etc. during the whole life cycle of a construction project. It not only provides a unified data and information source for the collaborative management of all project participants, but also promotes the reform process of building construction progress and quality management [9]. Obtaining 3D models through BIM technology can enhance the interactivity of manual models [10]. However, due to the large volume and high investment in the construction of high-rise

*Corresponding Author

buildings, the wide range of specialties and long period, the impact on the surrounding environment and complex construction organization and other challenges. Therefore, in the construction process of high-rise buildings, we need to adopt BIM technology to solve the problems of construction progress and quality management in real time. For the pre-processing of the data, RFID technology is required. This technology, also known as radio frequency identification, is a communication technology [11]. This technology allows the identification of specific targets and the reading and writing of relevant data through wireless communication without the need to establish mechanical or optical contact between the identification system and the specific target.

Based on the above analysis, this paper innovatively proposes a digital intelligent management platform for high-rise building construction based on BIM technology. The digitalization of construction progress and quality in the construction process of complex high-rise buildings is visually and intelligently monitored and managed, which improves the comprehensive management level in the construction process of high-rise buildings and ensures the construction progress and quality of high-rise buildings. Firstly, RFID technology is used for data collection, and then the data is input into the BIM model proposed in this study.

II. DIGITAL INTELLIGENT MANAGEMENT PLATFORM FOR HIGH-RISE BUILDING CONSTRUCTION

A. Overall Architecture Design of the Platform

Architecture design of the digital intelligent management platform for high-rise building construction based on BIM technology. The key objective of the platform is to realize the visual digital intelligent management of the construction progress and quality of high-rise buildings, as well as to ensure the construction quality and progress. The overall architecture design of the platform is shown in Fig. 1.

The intelligent management platform is mainly composed of data acquisition and processing layer, BIM model layer, application layer and display layer. The data of high-rise building's construction site is collected through the data acquisition and processing layer. After processing the collected data, the BIM model layer uses the processed high-rise building's construction site data to build terrain BIM model, high-rise building's BIM model, high-rise building's construction information BIM model, construction machinery and equipment's BIM model and the 4D BIM model of high-rise building construction. Various BIM models are introduced into the application layer to prepare the progress plan and progress report of high-rise building construction, monitor and correct the construction quality and progress in time, simulate and optimize the construction process, and present various application results in the application layer to the construction manager in real time through the display layer, so as to complete the digital intelligent management of high-rise building construction progress and quality.

Fig. 1. Overall architecture diagram of digital intelligent management platform for high-rise building construction based on BIM technology

B. Design of Data Acquisition and Processing Layer in Digital Intelligent Management Platform for High-Rise Building Construction

In the digital intelligent management platform for high-rise building construction designed in this paper, the data acquisition and processing layer mainly realizes the collection and processing of building and mechanical equipment data on the high-rise building construction site. Therefore, this layer can be divided into two parts: data acquisition and data processing. The key contents of the two parts are as follows:

1) *Data collection part*: mainly using RFID technology to collect construction site data of high-rise buildings in real time. It provides strong data support for the realization of digital intelligent management of the building. In terms of applicability, RFID technology has technical advantages in the field of building management. Its superior non-contact reading and writing function can be used to quickly identify information such as high-rise building construction [12]. In this study, RFID technology is used to quickly identify and collect information from each instrument and equipment in high-rise buildings and construction, and to complete the storage and transmission of the collected information. Its structure is shown in Fig. 2.

Fig. 2. Structure diagram of data acquisition part of RFID technology

The realization process of RFID technology in the data acquisition part is as follows: i) identification and information acquisition of buildings and mechanical equipment: the RFID technology in the data acquisition part is mainly composed of RFID tag, RFID reader and antenna. In the on-site construction process, RFID tag is generally placed in mechanical equipment, and RFID reader and writer are placed in each floor of buildings; when the RFID reader scans the RFID tag, the antenna of the RFID reader transmits radio waves, and the antenna of the RFID tag receives the transmitted radio waves, activates the RFID tag, and collects the existing building and mechanical equipment and other information, such as building and mechanical equipment ID; for mechanical equipment with motion range on the construction site, RFID can not only collect its construction information, but also realize the accurate positioning of mechanical equipment according to the collected information. ii) Information storage and transmission of buildings and mechanical equipment: after the RFID reader obtains the actual construction information of buildings and mechanical equipment on the construction site in real time, it can write the information into the RFID tag, decode it and transmit it to the RFID background database for storage by GPS or wireless network, or directly to the data acquisition terminal.

2) *Data processing part*: the data processing part is the intermediate filter layer for effective information transmission from the data acquisition part to the BIM model layer. The amount of information collected by RFID technology in the data acquisition part is huge and miscellaneous. It must be further processed by data analysis, data cleaning and data integration, so as to provide efficient data information flow for the management of high-rise building construction. Since a large amount of complex data will be generated during the construction of high-rise buildings, NoSQL, Sybase, Oracle and other databases can be selected for data storage of the information of buildings and mechanical equipment on the construction site obtained by RFID technology in the data acquisition part [13]; At the same time, due to the non-standard data form, data conflict, data duplication and other situations in the obtained information, in order to effectively manage the construction progress and quality of high-rise buildings in the digital intelligent management platform, it is necessary to

analyze and clean such complex and diverse information data. Through the statistical analysis and network analysis of such information data, the classification and standardized processing of such information can be realized [14]; The cleaned and re-selected data cannot be directly applied to the intelligent management platform. It is necessary to sort out such data forms through data integration, so that the BIM model layer in the intelligent management platform can directly extract and use these data, and use these data to obtain various corresponding BIM models, so as to lay a foundation for the application and implementation of the management platform.

C. Design of BIM Model Layer in Digital Intelligent Management Platform for High-Rise Building Construction

1) Structure Design of BIM Model Layer

Based on its own characteristics, if the traditional construction management mode is adopted, the management efficiency is not only low, but also easy to cause the loss of information and other problems. In this paper, the BIM model layer is designed by using BIM integration technology in the digital intelligent management platform of high-rise building construction, which can effectively solve the above problems. According to the digital intelligent management requirements of high-rise building construction, the BIM model layer structure of the digital intelligent management platform for high-rise building construction is designed. This layer uses different software to build three-dimensional terrain's BIM model, high-rise building's BIM model, construction machinery and equipment's BIM model, high-rise building's construction information BIM model and the 4D BIM model of high-rise building construction. Through the application layer of the digital intelligent management platform of high-rise building construction, the integration and application of this BIM model are realized, so as to realize the digital visual intelligent management of high-rise building's construction progress and quality. The structural design of BIM model layer is shown in Fig. 3.

Fig. 3. Structure design drawing of BIM model layer

Various BIM models in the BIM model layer are described as follows:

a) *Three-dimensional terrain's BIM model*: this model is a three-dimensional real scene model, which can well reflect the terrain and geomorphic characteristics of the high-rise building's construction area. It is intuitive, vivid and realistic. The model is composed of terrain mapping data and real image. After collecting the terrain image of the area where the high-rise building construction is located, the three-dimensional digital model of surrounding buildings, terrain and geomorphic vector data and other information, it is imported into BIM software for processing, to obtain the three-dimensional BIM model of terrain and landform.

b) *BIM model of high-rise building*: in order to maximize the coincidence between the construction simulation and the actual construction process, taking the construction process of high-rise building as the goal and based on the construction scheme plan, the construction project of high-rise building is divided into different construction areas for modeling. The model is the basis of realizing digital intelligent management of high-rise building construction. It integrates physical and functional characteristics, including the spatial location, shape structure and material properties of high-rise building's construction projects. BIM model construction of high-rise building mainly includes two parts: terrain surface solid model and high-rise building's partition solid model. Whether it is terrain surface solid model or high-rise building's partition solid model conforming to partition, the multi-level of detail accuracy of components generated by BIM component assembler directly determines the accuracy of partition solid model of high-rise building construction [15-17]. BIM software editor can be used to improve the overall accuracy of generated components. The specific process is shown in Fig. 4.

Fig. 4. BIM model assembly flow chart of high-rise building

c) *BIM model of high-rise building's construction information*: the BIM model of high-rise building's construction information based on BIM technology mainly includes construction progress and construction quality information, which has better visibility. This model can be created with the help of Microsoft Project (MSP), and the bar chart of on-site construction progress can be prepared according to the created model.

d) *BIM model of construction machinery and equipment*: the information data of various construction machinery and equipment on the high-rise building's construction site obtained and processed by the data acquisition and processing layer in the platform is used to import into the BIM software to generate the real-time BIM model of construction machinery and equipment in the operation of the construction site.

e) *4D BIM model of high-rise building construction*: the 4D BIM model of high-rise building construction is the integration of BIM model and high-rise building's BIM model of high-rise building's construction information.

2) Design of Dynamic Modeling Process in BIM Model Layer

The accuracy of traditional manual modeling methods cannot be guaranteed, and it is time-consuming and laborious. It costs a lot in practical application. Due to many uncontrollable factors in the intermediate process of automatically creating BIM model, it is easy to miss or deviate from the model. Therefore, in the digital intelligent management platform of high-rise building construction, the dynamic modeling process of BIM model layer combines time series and planning model to realize the dynamic generation of various BIM models. In the design stage before the construction of high-rise building project, the pre generated BIM model corresponding to the construction plan of high-rise building project [18] is the planning model. According to this planning model, various BIM models can be dynamically created, which can make full use of the planning model to complete the verification of the real-time creation model, ensure the accuracy and integrity of high-rise building construction, and reduce the complexity of automatic modeling.

The dynamic modeling method used in the BIM model layer in this paper is to obtain the spatial position and orientation of each model component in the actual high-rise building's construction project by using the processed on-site construction data on the basis of the data acquisition and processing layer, and change the planning model to obtain various actual BIM models according to this kind of actual information. This way of creating the actual BIM model based on the planning model can not only ensure the accuracy of the BIM model, but also reduce the complexity and workload. For

the convenience of description, U_a is defined as the actual BIM model generated by the BIM model layer, and U_b is defined as the plan model. Then the relationship between the two is:

$$U_a = \delta(U_b) \quad (1)$$

Where, δ represents the model change function, which aims to transform the planned model components according to the information of the actual high-rise building's construction site, such as rotation, clipping, spatial position movement and so on. The planning model U_b can be described by a series of elements C_b and the relationship H_b between elements, that is:

$$U_b = \langle C_b, H_b \rangle \quad (2)$$

Therefore, only a certain transformation of C_b and H_b is needed to generate U_a . The transformation equation used here is:

$$\max^l [fit(B, U_b^l)] \rightarrow \tilde{U}_b \sim U_a \quad (3)$$

Where, B represents the characteristics of the obtained construction site data; U_b^l represents the BIM planning model modified by l iterations; $fit(B, U_b^l)$ represents a function for calculating the similarity between B and U_b^l ; \tilde{U}_b represents an approximate solution of U_a and the optimal solution of fit function. This dynamic modeling method of real-time generating BIM model based on planning model not only has high modeling efficiency, but also has high precision, and can reconstruct the covered part. The dynamic modeling process of BIM model layer combining time series and planning model is shown in Fig. 5.

Fig. 5. Dynamic modeling process diagram of BIM model layer combined with time series and planning model

The detailed steps of dynamic modeling process of BIM model layer combining time series and planning model are as follows:

1) *Format conversion of high-rise building's information model*: in order to obtain the detailed information in the BIM model, it is necessary to convert the irregular geometry in the BIM model into triangles, that is, convert the parametric BIM model into STL data format [19]. Relatively complex planes or surfaces can be represented in detail by triangles.

2) *Rough model registration*: rough registration of the converted model is carried out based on the spherical coordinate system. The converted model is an entity to be pseudo scanned in the coordinate system. In the matching process, it is necessary to select the datum points of high-rise building's construction engineering facilities to obtain more than three point pairs, and then rough registration is carried out.

3) *Fine model registration*: for each scanning point in the data generated after laser scanning of the solid parts of the converted model, the model points of the corresponding parts can be found in the planning model after mapping, to record the included angle in the horizontal direction and the inclination angle in the vertical direction when the laser scanner scans the solid parts of the converted model. These two angles can determine the direction of the ray for the pseudo scanning of the converted model; Then, by calculating the intersection and distance between the triangular surface of a part in the planning model and the previously determined ray, the obtained intersection is the model point matching the scanning point; The vertices and corresponding intersections of STL triangles in the converted model need to be represented by spherical coordinate system, so the horizontal included angle and vertical inclination of the boundary of each triangle element can be identified.

4) *Model point matching*: in the construction of high-rise buildings, each model point of each component can be matched with the corresponding scanning point. The previous coarse registration and fine registration ensure that each model point has the same angle with the actual scanning point. Therefore, it only needs to compare the distance ΔD between the model point and the scanning point to determine the relationship between this distance and the preset threshold ΔD_{max} . If $\Delta D \leq \Delta D_{max}$, it is considered that the two-point pairing is successful. Therefore, the definition of D2 directly determines whether the automatic matching can be successful. ΔD_{max} is defined as:

$$\Delta D_{max} = \varepsilon_1 + \bar{\varepsilon}_2 \quad (4)$$

Where, ε_1 represents the acceptable construction error in the actual high-rise building construction; $\bar{\varepsilon}_2$ represents the average value of registration error.

5) *Recognition of model components after conversion*: for the point matching method, as long as a certain number of

point pairs are judged to match, it can be considered that the components are recognized, but its stability depends on the number of point pairs sought [20]. Here, a method with higher stability is combined to judge whether the object is recognized more effectively. The process of the method is as follows: i) define parameter A_e as the surface area of the model, that is, the sum of the areas formed by the equal division of the distance between adjacent discrimination points. ii) Define the model's surface area threshold S_e as:

$$S_e = n \tan \alpha \tan \beta \text{dist}_{\max}^2 \quad (5)$$

Where, n represents the minimum number of model recognition point pairs; $\tan \alpha$ and $\tan \beta$ represent the tangent functions of the horizontal included angle and vertical inclination of the model components respectively; dist_{\max}^2 represents the highest distance function of the distance between adjacent discrimination points. The accuracy of component identification is guaranteed by setting an appropriate threshold S_e . When the threshold S_e is less than or equal to A_e , the component can be considered to be successfully identified.

6) *Spatial position calculation of model components after identification:* after the components of the converted model are successfully identified, the position and orientation of such components need to be calculated. After the third step of fine registration, the converted model will be paired with the real-time high-rise building's state data points, so that the spatial position information such as the position and orientation of the components that have been successfully identified can be calculated. According to the spatial position information of such actual components, various real-time BIM models in high-rise building construction can be obtained by adjusting the parts of the plan model, such as rotation and clipping.

D. Construction Progress and Quality Monitoring Process of Application Layer in Digital Intelligent Management Platform for High-Rise Building Construction

In this paper, the application layer of the digital intelligent management platform for high-rise building construction mainly realizes the functions of construction progress planning, report generation, monitoring, correction, construction quality monitoring, and the optimization and simulation of the whole construction process, etc. Among them, construction progress monitoring and construction quality monitoring are particularly keys. Therefore, the design is implemented for the monitoring process of high-rise building's construction progress and quality. Fig. 6 shows the details.

Fig. 6. Monitoring process diagram of construction progress and quality

Construction progress and quality monitoring is based on the construction plan. The BIM model layer is used to import various BIM models in the actual construction of high-rise buildings in the application layer, so as to visually and intelligently supervise whether the actual construction progress and quality of high-rise building projects under construction are consistent with the construction plan, so as to achieve the purpose of digital intelligent management of high-rise building's construction progress and quality. The management of high-rise building's construction progress and quality realizes the input of time nodes and construction tasks of high-rise building's project construction. In the management process, the generated construction progress chart and construction quality model chart can be reviewed to observe whether they meet the construction requirements, and the construction progress and quality can be checked and recorded in real time.

In the digital intelligent management platform of high-rise building construction, the construction progress and quality report is generated according to different time periods. Through the comparative analysis of the current construction progress and quality and the planned construction progress and quality, the report is formed and output through the display layer to realize the supervision and reminder of high-rise building's construction progress and quality; At the same time, it can query the completion of high-rise building's construction tasks according to the time, content, cycle and other keywords of construction tasks, and adjust the construction progress and quality of high-rise buildings in real time to avoid the waste of time, manpower and economic cost. So far, the design of digital intelligent management platform for high-rise building construction based on BIM technology has been completed.

III. ANALYSIS OF EXPERIMENTAL RESULTS

Taking a high-rise building project under construction in an area as an example, this platform is applied to the construction management of the high-rise building project to test the practical application effect of this platform. The high-rise building project is divided into 10 partitions, each partition is numbered a ~ j. Digital intelligent management is implemented for the construction progress and construction quality of each partition through the platform of this paper. The specific inspection process and results are analyzed as follows:

A. Construction Progress Management Process and Result Analysis

Firstly, two partitions c and f are randomly selected from the 10 partitions of the experimental high-rise building project, and the real-time BIM models of the two selected partitions are obtained through the platform in this paper. The presentation results are shown in Fig. 7.

Fig. 7. Real-time BIM model of each partition of experimental high-rise building presented by this platform

It can be seen from Fig. 7 that the real-time BIM model of each partition of the experimental high-rise building presented by the platform in this paper can show the internal information and layered information of the building in detail, and the visualization effect is clear, which is convenient for users to view and monitor the construction progress in real time, so as to realize the digital intelligent management of high-rise building construction.

The real-time construction progress of partitions c and f of the experimental high-rise building is obtained through the platform in this paper. The deviation between the obtained real-time construction progress and the planned construction progress is compared and analyzed to realize the real-time monitoring of the construction progress. The bar chart of deviation comparison and analysis is shown in Fig. 8.

According to the analysis of Fig. 8, the real-time construction progress of each partition of the experimental high-rise building can be obtained through the platform. After comparing the implementation deviation between the real-time construction progress of each partition obtained by the platform and the planned construction progress, it is found that the real-time construction progress of partition c of the experimental high-rise building is basically consistent with the planned construction progress, and there is almost no deviation; The real-time construction progress of partition f is different from the planned construction progress, and the deviation between the two is obvious. The actual construction progress of the partition is one day later than the planned partition. Therefore, the platform in this paper can monitor the actual construction progress of experimental high-rise buildings in real time, so as to provide guarantee for correcting the construction progress in time and ensuring the completion of the overall construction on schedule.

Through the platform in this paper, the real-time construction progress of all partitions of the experimental high-rise building is obtained according to the above methods, and compared with the implementation deviation of the planned construction progress of each partition respectively, the obtained data are stored in the background database of the platform in this paper, and the number of each partition is used to query the planned and actual construction progress data of each partition to complete the construction progress query task. The query results are shown in Table I.

TABLE I. REAL-TIME QUERY RESULTS OF CONSTRUCTION PROGRESS OF THE PLATFORM IN THIS PAPER

Partition number	Plan time	The actual time	Schedule analysis	Delays
a	March 10, 2021	March 15, 2021	The required progress has been reached, but the progress is delayed	Delay 5 days
b	March 13, 2021	March 12, 2021	Arrive ahead of schedule	Without delay
c	March 8, 2021	March 8, 2021	According to the original schedule to reach the specified progress	Without delay
d	March 15, 2021	March 18, 2021	The required progress has been reached, but the progress is delayed	Delay 3 days
e	March 20, 2021	March 24, 2021	The required progress has been reached, but the progress is delayed	Delay 4 days
f	March 6, 2021	March 7, 2021	The required progress has been reached, but the progress is delayed	Delay 1 day
g	March 5, 2021	March 5, 2021	According to the original schedule to reach the specified progress	Without delay
h	March 17, 2021	March 18, 2021	The required progress has been reached, but the progress is delayed	Delay 1 day
i	March 1, 2021	March 3, 2021	The required progress has been reached, but the progress is delayed	Delay 2 days
j	March 25, 2021	March 31, 2021	The required progress has been reached, but the progress is delayed	Delay 6 days

(a) Comparison between real-time construction progress and planned construction progress in c partition

(b) Comparison between real-time construction progress and planned construction progress in f partition

Fig. 8. Horizontal chart of deviation between real-time construction progress and planned construction progress in each partition

It can be seen from Table I that the platform in this paper can query the actual construction progress of each partition of high-rise building in real time. From the query results, it is known that the actual construction progress of three partitions b, c and g of the experimental high-rise building project is not delayed compared with the planned construction progress, and the construction progress of the other seven partitions is delayed to varying degrees.

Based on the above query results, under the management of the platform in this paper, the construction progress correction is implemented for the seven partitions with construction progress delay. Taking three partitions a, f and j as examples, the bar chart of the real-time construction progress and planned construction progress of each partition after the correction of this platform management is presented to test the correction effect of construction progress management of this platform. The construction progress bar chart of each partition is shown in Fig. 9.

As can be seen from Fig. 9, after the construction progress correction is implemented under the management of the platform in this paper, the actual construction progress and planned construction progress of each partition with construction progress delay in the experimental high-rise building project can be gradually unified. The construction progress management effect of the platform in this paper is remarkable, which can provide effective guarantee for the construction period of high-rise buildings. The data processing efficiency and progress error of this method, digital twin (DT) technology and EPC mode digital building management platform in construction progress are compared and analyzed. The results are shown in Table II.

Fig. 9. Horizontal chart of real-time construction progress and planned construction progress in each partition after correction of platform management in this paper

TABLE II. COMPARATIVE ANALYSIS TABLE

Comparison Items	BIM	DT	EPC
Data processing efficiency	91.89%	78.93%	79.97%
Progress advancement error	0.156	0.342	0.459

It can be seen from Table II that the data processing efficiency of BIM model is 91.89%, and the progress error is 0.156, which is better than the processing progress of digital twin (DT) technology and digital building management platform under EPC mode. The construction progress management of BIM technology platform has a remarkable effect, which can provide an effective guarantee for the construction period of high-rise buildings.

B. Construction Quality Management Process and Result Analysis

Based on the platform in this paper, the parts of the real-time BIM model of the two partitions c and f of the experimental high-rise building are obtained. Using these parts, we can measure whether the size of the internal components in the construction of each partition of the experimental high-rise building meets the construction requirements in real time, so as to achieve the purpose of real-time visual monitoring of the high-rise buildings' construction quality. Taking the random components in the real-time BIM model of partitions c and f obtained by the platform in this paper as an example, the real-time measurement is shown in Fig. 10.

Fig. 10. Real-time measurement of BIM model components in each partition of experimental high-rise building obtained by the platform in this paper

As can be seen from Fig. 10, the internal details for the BIM model components of each partition of the experimental high-rise building obtained by the platform in this paper are clear, which can be used to realize the real-time visual measurement of the dimensions of each component in the component, so as to achieve the purpose of real-time monitoring the quality of each component in the construction of high-rise building.

IV. DISCUSSION

This paper mainly analyzes the practical application effect of the platform in this paper from two aspects: the first aspect is the management effect of this platform on the construction progress of high-rise buildings; The second aspect is the management effect of the platform on the construction quality of high-rise buildings. Among them, the management effect of this platform on the construction progress of high-rise buildings is mainly tested through the actual construction progress monitoring, query and correction. The test results show that this platform can realize the functions of real-time progress monitoring, query and correction in the actual construction of high-rise buildings, and has a significant effect on the comprehensive management of construction progress; The management effect of this platform on the construction quality of high-rise buildings is only tested by the quality monitoring in the actual construction. The test results show that this platform can realize the real-time monitoring function of each component quality in the actual construction of high-rise buildings, but it is not verified for other functions of construction quality. This part needs to be further carried out in the future research, in order to improve the verification of the comprehensive management effect of high-rise building construction quality.

V. CONCLUSION

With the development of science and technology, infrastructure construction is developing rapidly, and also showing the development trend of scale and complexity. In order to ensure that building construction can be put into use properly, it is necessary to ensure that the project can be completed on time as planned. Therefore, this paper proposes a digital intelligent management platform for high-rise building construction based on BIM technology to achieve comprehensive management of progress and quality during high-rise building construction by integrating the processes of data collection and processing, dynamic generation of BIM models, and construction progress and quality monitoring. The application effect of the platform was tested through practical engineering applications. The results show that the data processing efficiency of the BIM model proposed in the study is 91.89%, and the progress error is significantly lower than that of the digital construction management platform model under digital twin (DT) technology and EPC mode, and the application effect in construction progress monitoring, query, correction and construction quality monitoring is significant, which can realize the digital, visualization and intelligent management of high-rise building construction. In the future, we will continue to study the energy consumption and cost management in high-rise construction and further expand the practical application of this platform. This research can track

the construction progress and monitor the construction quality in real time, which has significant effect compared with other technologies.

College of Architecture and Civil Engineering, West Anhui University, Lu'an, China²

Abstract—The intelligentization of building interior decoration construction is of great significance to the construction of smart city, and robot automation has brought an opportunity for this. Robot self-decoration is the development trend in the future. One of the key issues involved, is the self-planning of mobile path. In this regard, the research adopts the proximal policy optimization algorithms (PPO) to improve the self-planning path ability of the decoration robot. For the information of lidar and robot status, the Full Connect Neural Network (FCNN) is used to process it. In addition, the reward function and the corresponding Credit Assignment Problem (CAP) model are designed, to accelerate the learning process of path planning. Aiming at the dynamic uncertainty in the actual environment, the adaptive loss function is used to build an auxiliary model to predict the environmental change. The simulation results show that the research and design strategy significantly improves the learning efficiency and path planning success rate of the decoration robot, and shows good adaptability to the dynamic environment, which has important reference significance for the practical application of the decoration robot.

Keywords—Interior decoration; path planning; deep reinforcement learning; reward function; credit allocation

I. INTRODUCTION

Smart city is the universal vision of urban development in various countries. It uses modern technologies such as the Internet, big data and the Internet of things to solve urban governance problems, involving many fields such as architecture, transportation, medical treatment and smart home [1]. Intelligent robot is indispensable in the comprehensive environment of smart city [2]. In smart city architecture, the building scale is gradually expanding, but the number of labor is decreasing. Building construction automation has become an inevitable trend to improve production efficiency and quality. Robot technology provides new conditions and foundation for this [3]. On the whole, the development of construction robots is still at an early stage. The main robots that have been put into use at home and abroad are wall construction robots, decoration robots, facade maintenance robots, 3D printing robots, etc. [4-6]. The decoration robot has realized the plastering, painting, door and window installation and other processes of interior decoration, which has promoted the automation of interior decoration. The decoration robot mainly includes sensor, positioning system, control system and other parts. The sensor combined with the positioning system enables the decoration robot to realize the movement

path planning, positioning, obstacle avoidance and other actions. Traditional robots use simultaneous localization and mapping (SLAM) to construct prior knowledge to avoid obstacles [7]. Therefore, the degree of intelligence is not high, and automatic identification cannot be carried out. Faced with the uncertainty of the actual indoor environment, the adaptability to the dynamic environment is not high, and the ability of path planning and obstacle avoidance needs to be improved. Therefore, a path planning strategy based on PPO deep reinforcement learning algorithm is proposed, which enables the decoration robot to obtain external information through the sensor system, make path selection decisions through autonomous learning, and improve the intelligent degree of the robot. Through the auxiliary model based on adaptive loss function, the adaptive degree of the robot is improved, providing a new way for the practical application of the indoor decoration robot.

II. RELATED WORK

Interior decoration is an important part of urban construction, and its construction automation is an important direction of future development. In this regard, robot technology is a key technology, in which the research on robot path planning is an important issue and research hotspot. Using voxel space modeling and vector field path optimization, Min JK et al. proposed a new method for planning the robot's three-dimensional obstacle avoidance path to realize the robot's three-dimensional obstacle free path planning in the factory environment [8]. Guo X et al. proposed a robot intelligent assembly path planning scheme based on the improved Q-learning algorithm by adding a dynamic reward function to accelerate the convergence speed and design a trap avoidance scheme. Experiments show that the six joint robot UR10 has a good three-dimensional path optimization ability under this algorithm [9]. Zhang S et al. used information entropy to describe the population diversity of ant colony algorithm, thus improved an adaptive ant colony algorithm and improved the optimization ability of the algorithm. Through evaluation and significance test, it is proved that the algorithm is feasible in mobile robot path planning and has good performance [10]. Zhao W et al. proposed a heuristic search path planning method to solve the defects of traditional path planning methods in high demand environments. The experimental results show that more robots in narrow and long channels can run in a coordinated and

*Corresponding Author

orderly manner and have better path planning ability [11]. Jing et al. designed an intelligent interactive system for home robots, so that the robot has a perception and positioning system, and can realize autonomous navigation and obstacle avoidance. Experiments show that the robot using this system can better adapt to the family dynamic environment, and the human-computer interaction effect is good [12]. Islam M R et al. reset and introduced a new basic operator of chemical reaction optimization algorithm, and proposed an improved meta heuristic path planning algorithm. The experimental results show that the algorithm has good performance and can effectively improve the robot's path optimization ability in complex tasks [13].

Sharma K and Doriya R use the intelligent distance measurement method to improve the path planning ability of multi robot systems when performing tasks in large warehouses. This method has achieved good results in the coordinated operation and path optimization of multi robot systems [14]. Kang J G et al. designed a rerouting method using trigonometric inequality to improve the Rapid Exploring Random Tree (RRT). The simulation results show that, compared with RRT and RRT connection algorithm, the planning ability and path optimization ability of this algorithm are improved [15]. Zhang Z et al. proposed a path planning method based on the improved A* algorithm according to the special kinematic characteristics of the spherical motion robot, which improved the search efficiency of the robot and could find the optimal path in a short time [16]. Zhang TW et al. proposed an improved firefly algorithm (FA) combined with genetic algorithm (GA) to solve the defect of local optimal solution of FA algorithm. The experimental results show that the performance and accuracy of the improved algorithm are improved, and good results can be achieved when applied to robot path planning [17]. Chi W et al. proposed a heuristic path search method by using the feature extraction algorithm of Generalized Voronoi Diagram (GVD) to improve the path planning ability of fast robots in obstacle environments. The results show that this method is highly efficient, the results of one-time feature extraction can be reused, and the robot can efficiently search the obstacle free path [18]. Yang Y et al., based on the global and local levels, used the two-level path planning method to enable the robot to effectively avoid obstacles in a multi obstacle mobile environment. The results show that the actual application effect is good [19]. Xu T et al. perceived the shape of obstacles and planned the obstacle avoidance path of the robot arm under specific circumstances by improving the artificial potential field method. The results show that the method is highly adaptable to the environment and can effectively avoid obstacles [20]. In spherical tank inspection, Li J et al. planned the path of their inspection robot by improving Fleury algorithm, and recognized the welding line through depth learning network. The results show that the application effect of the path planning method is good [21].

From many researches on robot path planning, it can be seen that the current common path planning methods mainly include graph planning algorithm, spatial sampling, deep reinforcement learning and so on. The deep reinforcement learning method combines the deep learning and reinforcement learning, so that the robot can realize the

autonomous learning of path planning in the interaction with the external environment. Compared with the traditional methods, it has obvious advantages, and is more suitable for the path planning of indoor construction of decoration robots. However, previous studies have mostly used the existing algorithm framework to build models, neglecting the design of the algorithm itself, especially the shaping of the reward function, and the quality of the reward function is directly related to the effect of robot learning. The novelty of this paper is to optimize the algorithm through the construction of reward function, aiming to improve the ability of robot autonomous planning. In this regard, this research focuses on the shaping and use of reward function, and deeply discusses the deep reinforcement learning method of robot path planning, hoping to propose an effective autonomous planning learning scheme.

III. DESIGN OF SELF PLANNING LEARNING SCHEME FOR MOBILE PATH OF DECORATION ROBOT

A. Learning Method of PPO Algorithm and FCNN Neural Network

With the development of smart cities, intelligent interior decoration has become a new direction of interior decoration development. Robots replace manual workers to carry out relevant decoration operations. During this period, the robot path planning problem needs to be solved. In this paper, PPO algorithm is used as the basic algorithm of path planning learning for decoration robot. This algorithm is a gradient optimization algorithm based on policy gradient and off policy. It combines the advantages of strategy and value function, and performs well in tasks with continuous control and continuous scenarios. Generally, a reinforcement learning process can be described as a Markov Decision Process (MDP) [22]. This process can be expressed as a four tuple $M = (S, A, R, P)$, S is the environment state set, A is the action set, R is the reward function, and P is the state transition function. In the interactive environment, at each time step t , the agent's status is s_t and the action is a_t . It gets a reward r_{t+1} and moves to the next state s_{t+1} . When the cumulative reward reaches the maximum G_t , as shown in equation (1), the agent enters the termination state.

$$G_t = \sum_{n=0}^{T-t-1} \gamma^n R_{t+n+1} \quad (1)$$

In equation (1), $\gamma \in [0,1]$ is the attenuation coefficient. PPO algorithm is based on Actor-Critic algorithm. The Actor-Critic algorithm combines two reinforcement learning methods, value based and policy based, and is divided into two different network structures, Actor and Critic [23]. The idea of the algorithm is to use Actor network to generate actions to interact with the environment, and Critic network to evaluate actions. In the strategy π_ϕ , the state estimation of Critic output is shown in equation (2):

$$Q_\rho(s, a) \approx Q^{\pi_\phi}(s, a) \quad (2)$$

In equation (2), ρ is the parameters of Actor network, φ is the parameters of Critic network. Therefore, as a Policy Gradient (PG), the calculation of Actor-Critic algorithm is shown in formula (3):

$$\nabla_{\varphi} J(\varphi) \approx E_{\pi_{\rho}} \left[\nabla_{\varphi} \log \pi_{\varphi}(s, a) Q_{\rho}(s, a) \right] \quad (3)$$

The Policy Gradient has a high square difference, which can be solved by subtracting a Baseline [12]. During actual operation, you can select a Baseline function and add an Advantage function in the form of $A^{\pi_{\varphi}}(s, a) = Q^{\pi_{\varphi}}(s, a) - B^{\pi_{\varphi}}(s)$, so as to obtain a new calculation formula of Actor-Critic algorithm, as shown in (4):

$$\nabla_{\varphi} J(\varphi) \approx E_{\pi_{\varphi}} \left[\nabla_{\varphi} \log \pi_{\varphi}(s, a) A^{\pi_{\varphi}}(s, a) \right] \quad (4)$$

According to formula (4), the Actor-Critic algorithm adopts online update, that is, it needs to collect data again after completing an update, which is inefficient. In this regard, PPO algorithm introduces Importance Sampling into the existing framework, so that samples can be reused and offline updates can be realized. In this method, when it is impossible to obtain the expected $e(x)$ of a variable x subject to a continuous random distribution m , a distribution n with close values is set, and the expected $f(x)$ of the distribution is calculated to obtain the expected score distribution m , as shown in formula (5):

$$\begin{aligned} E_{x \sim m} [e(x)] &= \int f(x) m(x) dx = \int f(x) \frac{m(x)}{n(x)} n(x) dx \\ &= E_{x \sim n} \left[e(x) \frac{m(x)}{n(x)} \right] \end{aligned} \quad (5)$$

Therefore, the Actor-Critic gradient calculation formula of Importance Sampling is introduced, that is, the gradient calculation formula of PPO algorithm is shown in (6):

$$J^{\bar{\varphi}}(\varphi) \approx E_{(s, a) \sim \pi_{\varphi}} \left[\frac{m_{\varphi}(a_t | s_t)}{m_{\bar{\varphi}}(a_t | s_t)} A^{\bar{\varphi}}(s_t, a_t) \right] \quad (6)$$

The path planning training flow chart of PPO algorithm is shown in Fig. 1.

Fig. 1. PPO training process

FCNN neural network is used to process the state information of laser radar and robot. The algorithm has good fitting effect on nonlinear data. The full connection layer is converted into a convolution layer, which can be classified at the pixel level. However, it is not precise enough in the sampling process and is insensitive to some details. FCNN consists of input layer, hidden layer and output layer. The basic unit is neurons. There is no correlation between neurons in each layer, but all neurons in the other layer are associated. Information propagates unidirectionally from input layer to input layer. Its structure is shown in Fig. 2.

Fig. 2. Structure of FCNN

The propagation mode of FCNN can be expressed as formula (7):

$$\begin{cases} L_i = K_{i-1} H_i + C_i \\ K_i = F_i(L_i) \end{cases} \quad (7)$$

In equation (7), L_i represents the linear input of layer, K_i represents the output after layer activation, H_i represents the weight matrix from layer to layer, C_i represents the offset vector of layer, and F_i represents the activation function of layer. In deep learning, a reverse algorithm is usually used to make FCNN propagate from the output layer to the input layer to update the neuron weight matrix and bias vector. The principle is to bring the data set $I = \{(x^p, y^p)\}_{p=1}^P$ into FCNN training so that the output layer get \hat{y}^p as shown in formula (8):

$$\hat{y}^p = FCN \left[(x^p, \varphi) \right] \quad (8)$$

In Eq. (8), $FCN[]$ represents a FCNN neural network and φ represents the training parameters of the FCNN network. After we get \hat{y}^p , we can use the cost function to calculate $Loss(y^p, \hat{y}^p)$, and the gradient of the network can be obtained according to the partial derivative and learning rate σ of the loss function to the weight and offset. Finally, the inverse algorithm updates the weight H and offset C of the network, as shown in equation (9):

$$\begin{cases} H - \sigma \frac{\partial Loss(H, C)}{\partial H} \Rightarrow H \\ C - \sigma \frac{\partial Loss(H, C)}{\partial C} \Rightarrow C \end{cases} \quad (9)$$

B. Design and Optimization of Reward Function

In the process of deep reinforcement learning, the learning goal is to achieve the maximum cumulative reward, so the setting of reward function is directly related to the realization effect of learning goals [24]. The research aims at the problem of autonomous planning of the robot's indoor moving path, which involves two key abilities, namely, the ability of path optimization and the ability of obstacle avoidance. Therefore, two potential energy reward functions can be created respectively, and an initial reward function can be combined to get a better training effect. The initial reward function $R(s, a, \bar{s})$ is shown in equation (10):

$$R(s, a, \bar{s}) = \begin{cases} 40 & \text{if } \delta_d < 0.25m \\ -20 & \text{if } \delta_0 < 0.2m \\ -0.15 & p(\text{every step}) \end{cases} \quad (10)$$

In Eq. (10), $\delta_d < 0.25m$ means that the robot successfully reaches the target within 0.25m, successfully completes the task, and the reward value is 60, and starts the next round of training; $\delta_0 < 0.2m$ means that if the robot reaches within 0.2m of the obstacle and the task fails, the reward value is -30 and the next round of training starts; P is punish, motivating robots to perform training tasks. For the path optimization capability, it involves the distance from the end of the task and the angle of the travel direction. First, set the potential energy function F_r for the target distance as shown in equation (11):

$$\begin{cases} F_r(s, a, \bar{s}) = \delta_r(\bar{s}) - \delta_r(s) \\ \delta_r = F_\varepsilon(r_{ax} - r_{rx}, r_{ay} - r_{ry}) \\ F_\varepsilon = \sqrt{(\nabla rx)^2 + (\nabla ry)^2} \end{cases} \quad (11)$$

In Eq. (11), r_{ax} , r_{ay} indicates the position of the target position on the x-axis and y-axis; r_{rx} , r_{ry} indicates the position of the trolley in the x-axis and y-axis; δ_r represents the distance between the robot and the target; ∇rx , ∇ry represents the difference between the target position and the trolley position in the x-axis and y-axis; δ_r represents Euclidean distance; s indicates the current status; a indicates the action taken in the current state; \bar{s} indicates the next state to move to. Set the potential energy function F_a for the robot travel direction angle δ_g as shown in equation (12):

$$\begin{cases} F_g(s, a, \bar{s}) = \delta_g(\bar{s}) - \delta_g(s) \\ \delta_g = \begin{cases} \pi/4 & \text{if } g \leq \pi/4 \\ abs(g) & \text{if } g > \pi/4 \end{cases} \end{cases} \quad (12)$$

In Eq. (12), g represents the orientation angle between the robot and the target position, and $abs(g)$ represents the absolute value. Within the range of 2 meters in diameter centered on the robot, the distance δ_d between the obstacle

and the robot sets the potential energy reward function F_d as shown in Eq. (13):

$$\begin{cases} F_d(s, a, \bar{s}) = \delta_d(\bar{s}) - \delta_d(s) \\ \delta_d = \begin{cases} otr & \text{if } otr \leq 1 \\ 1 & \text{if } otr \geq 1 \end{cases} \end{cases} \quad (13)$$

In Eq. (13), otr is the distance between the current robot and the obstacle. Adding the three potential energy reward functions set to the initial reward function $R(s, a, \bar{s})$ is the new reinforcement learning reward function, as shown in Eq. (14):

$$\dot{R}(s, a, \bar{s}) = R(s, a, \bar{s}) + F_r + F_g + F_d \quad (14)$$

In the training scheme adopted in the study, every time the robot reaches the target point or fails to avoid obstacles, it will re-enter the new training process, and each round will obtain a training path t_s , including reward sequence r_s , as shown in Eq. (15):

$$t_s = s_1, a_1, r_1, s_2, a_2, r_2, \dots, s_n, a_n, r_n \quad (15)$$

This training process is carried out in rounds until the cumulative reward reaches the maximum G_r . The global training in this way involves a credit allocation problem [25]. Generally speaking, in the whole process of robot path selection, the final selection step is relatively more Critic. However, as the number of training steps increases, the discount coefficient decreases exponentially. Therefore, the correlation between the reward return performance of the previous steps and the number of subsequent steps is very low, so that the variance of the final cumulative return is too high. This has a great impact on the update of the strategy gradient, and the sample utilization and training efficiency are therefore low. In order to solve this problem, we can build a credit allocation model, reallocate the reward value at the end of the decision sequence, and obtain the cumulative return value with smaller variance, so as to make the gradient update of reinforcement learning algorithm more stable and accelerate the training speed. The training structure of adding credit allocation model is shown in Fig. 3.

In Fig. 3, S_d is the lidar information, S_s is the self-status information, $V_\eta(s)$ is the status output value of the critical network, $\pi_t(a)$ is the action distribution of the actor network, and $V_\phi(s)$ is the status output value after credit allocation. After a complete path planning training, the robot can obtain three different reward values, namely, the positive reward value 60 for completing the training, the negative reward value -30 for collision obstacles, and the common reward value [-2.0, 2.0] for reaching the maximum number of training steps. Each reward is shown in Fig. 4.

Fig. 3. Training model after adding credit allocation

Fig. 4. Credit allocation models

The core of the problem to be solved is to allocate the reward impact of the later stage to the reward of the previous stage. First, the whole sequence needs to be segmented. The operation requirements are shown in formula (16):

$$P_t = \text{round}(S_t / N_t) \quad (16)$$

In Eq. (16), S_t is the reward sequence length, N_t is the credit allocation indicator, that is, the sequence length divided, N_t is the number of divided sequences, and $\text{round}(\)$ refers to rounding. On the basis of the new segmented sequence, the reward of the later segment of the original sequence is redistributed in the direction from the back to the front and the discount coefficient γ is taken as the criterion, so as to update the reward sequence r_s and recalculate the cumulative reward G_t . Then, the advantage functions AF_{old} and AF_{new} of the original sequence and the updated sequence are introduced respectively, and their values are the respective maximum cumulative reward G_t and the state output value of the Critic network. The two advantage functions are multiplied by the coefficients κ and λ respectively, so obtain the final form AF of the reward function, as shown in formula (17):

$$AF = \kappa AF_{old} + \lambda AF_{new} \quad (17)$$

In addition, in order to make the credit allocation perceived by the algorithm, a CACritic network is introduced to output additional credit allocation status. Finally, the loss functions of CACritic network, Critic network and Actor network are calculated by PPO algorithm respectively, so as to complete the shaping of the reward function.

C. Auxiliary Model Construction of Adaptive Loss Function

In the static environment, because the elements of the environment are fixed, the ‘‘State-Action-Reward’’ of machine training is fully responsive. As long as the time and strategy

required for training are met, the robot can tend to repeat training on a successful path or finally retain the training state related to all environmental elements, so it is easy to obtain the optimal path and achieve the maximum reward. However, in the real decoration scene, the environmental state will change constantly, and new structures and elements will be generated. Taking the same action at different times of the same path may result in different reward situations, which requires more adaptation to costs and has a negative impact on machine learning. The change of this environment is accidental. Therefore, the study assumes that the uncertain s-a-r condition obeys the Gaussian distribution, and then constructs an auxiliary model to predict this distribution. In the training process, the uncertainty of s-a-r is transformed into the uncertainty of obtaining rewards to affect the robot's decision-making. Therefore, the core of the auxiliary model is to connect two FCNN on the basis of the training model to predict the mean and variance of s-a-r distribution, so as to represent the mean of the reward and measure the uncertainty of the reward, and then use the adaptive regression loss function to compare the predicted value with the actual reward value. The reward uncertainty perceived by the robot with the help of the auxiliary model can be used as a reference for the next path planning decision-making, so as to improve the adaptability of the robot and speed up the speed of completing the learning task. The training structure with auxiliary model is shown in Fig. 5.

Fig. 5. Training model after adding credit allocation auxiliary task

In Fig. 5, τ_α is the s-a-r distribution mean predicted by the auxiliary model, and v_α^2 is the distribution variance. The specific method to build the model is to set the S-A-R data set of the dynamic environment, which follows the Gaussian distribution, described as $Trend(s, a, r)$, as shown in Eq. (18):

$$Trend(s, a, r) \in N(\tau_\alpha, v_\alpha^2) \quad (18)$$

In Eq. (18), τ_α is value of distribution, v_α^2 is variance of distribution, used to measure the uncertainty of reward. FCNN is used to predict the mean and variance of S-A-R distribution. The prediction results are compared with the actual reward situation for regression training, and then the adaptive loss function W_α is used to calculate the difference between the two, as shown in equation (19):

$$W_\alpha = \frac{1}{n} \sum_{j=1}^n \frac{1}{2v(s_j)^2} \|h(s_j) - r_j\|^2 + \frac{1}{2} \log v(s_j)^2 \quad (19)$$

In Eq. (19), s_j represents the state of the path, r_j is the reward obtained in this state, $h(s_j)$ is the predicted mean value obtained by the auxiliary model, $v(s_j)^2$ is the variance obtained by the prediction model, and $\log v(s_j)^2$ is the constraint added to prevent the gradient turbulence caused by too high variance. Finally, the loss functions of CACritic network, Critic network and Actor network are calculated by PPO algorithm respectively, so as to complete the addition of auxiliary model.

IV. EFFECT ANALYSIS OF SELF PLANNING LEARNING STRATEGY FOR MOBILE PATH OF DECORATION ROBOT

A. Simulation Experiment Setup

The common robot operating system (ROS) is used as the programming framework of the robot running program, and the simulation environment is built in combination with the Gazebo simulation platform. Gazebo can perform simulation independently of ROS, or install ROS related function packs to build an environment model as a node of ROS. In addition, the turtlebot3 of the turtlebot series robots is selected as the simulation robot. It has high support for ROS, strong modularity and flexibility, and has a large number of relevant resources in the ROS community, which brings great convenience to the research. The ROS simulation training framework thus established is shown in Fig. 6.

Fig. 6. Framework of ROS simulation training

In Fig. 6, /ppo refers to the algorithm used in the experiment/ cmd_Vel is the moving speed command sent to the robot/ gazebo and /gazebo_GI refers to the Gazebo simulation program/ gazebo/set_md1_States and /gazebo/mel_States means setting obstacles and robot states/ Odom and /scan refer to mobile state sensor and laser ranging sensor/ obstacle_1~/obstacle_N means moving obstacles. Firstly, the experiment simulation environment is built by using Gazebo software. The research is aimed at the indoor movement of the decoration robot. Therefore, considering the actual situation and the needs of experimental training, two kinds of square enclosed spaces including static obstacles and dynamic obstacles are built. The plan is shown in Fig. 7.

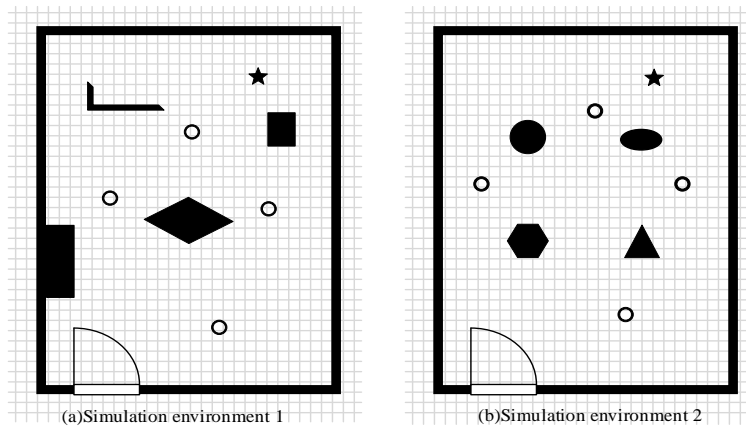

Fig. 7. Gazebo simulation environment

In Fig. 7, the closed block represents the static obstacle, the circular graph represents the dynamic obstacle, and the five pointed star represents the target position. Secondly, the linear velocity and angular velocity at different levels are set for the action parameters of the robot; For the running environment of the experimental program, the operating system is Ubuntu20.04 LTS, the processor is Intel i5 12600K, the graphics card is NVIDIA RTX2070Ti, python version 3.9, and pytoch version 1.9.1; The machine status includes real-time distance to the target, travel direction angle, travel speed information and completed action information; The ranging system adopts light detection and ranging (LIDAR).

B. Path Planning Ability Test and Performance Analysis of Decoration Robot

Firstly, the training effect of path planning for decoration robot is compared between the initial reward function training model PPO and the improved reward function training model. The improved reward function training model is divided into improved reward function PPO-S and added credit allocation model PPO-SC. In static simulation environment 1, the path planning training effect of each model is shown in Fig. 8.

(a)Reward effect of PPO

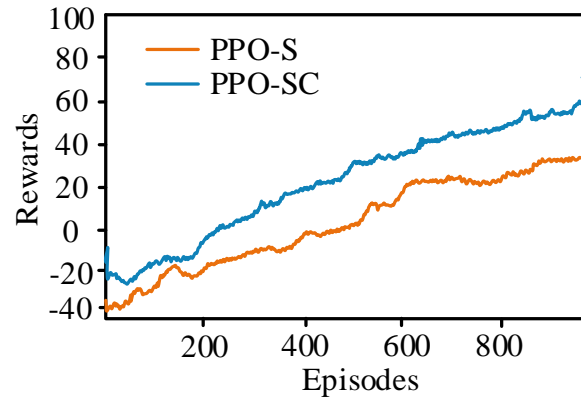

(b)Reward effect of PPO-S & PPO-SC

Fig. 8. Simulation environment 1(Static state)

(a)Reward effect of PPO

(b)Reward effect of PPO-S & PPO-SC

Fig. 9. Simulation environment 1(Dynamic state)

The results show that the PPO model robot has more collisions with its random exploration route, and gets some negative rewards. Finally, in order to avoid collision, it stays in place, and the reward remains at -15, and the task fails. PPO cannot guide the robot to complete the training task. In the PPO-S and PPO-SC models, the robot can complete the learning of path planning, and the PPO-SC model has faster rising speed and higher success rate. Therefore, in static environment 1, the new reward function and credit allocation model improve the robot's path planning ability. In dynamic environment 1, the training effect of each model is shown in Fig. 9.

The results show that compared with the static environment, the robot collision situation of PPO model increases and gets more negative rewards. In the simulation environment, the robot will still collide with the dynamic obstacles when it is stationary. In PPO-S and PPO-SC models, the training efficiency of the robot is significantly lower than that of the static model, and the stability is poor, but the training effect of PPO-SC is still better. To sum up, PPO-S with potential energy function can effectively guide the robot to achieve the goal and complete the training task, and the learning ability is improved and the training effect is better after credit distribution and reward sequence redistribution. However, the dynamic environment adaptability is poor and

the training effect is average. In order to verify the effect of auxiliary tasks on improving the adaptability to dynamic environment, the training effect of PPO-S model and PPO-SA model combined with auxiliary tasks is compared. The results are shown in Fig. 10.

The results show that in both static and dynamic environments, PPO-SA model has better reward performance than PPO-S model. The reward rises faster and the learning efficiency is higher. In the dynamic environment, the robot training effect under PPO-S model is significantly worse than that in the static environment, the number of collisions has increased significantly, the training effect is poor, and the reward curve fluctuates greatly. In the PPO-SA model, through early learning, the auxiliary model in the middle and late stages can effectively predict the reward distribution, so that the robot can avoid obstacles in advance in route selection, the training effect has been significantly improved, and the reward curve is relatively stable. In order to further verify the effect of the research and design strategy in robot path planning, the deep deterministic policy gradient (DDPG) algorithm, A-star algorithm and RRT algorithm are used to design the robot indoor path planning model. Conduct training in static environment 1, and compare the percentage of the difference between the completed path and the optimal path. The results are shown in Fig. 11.

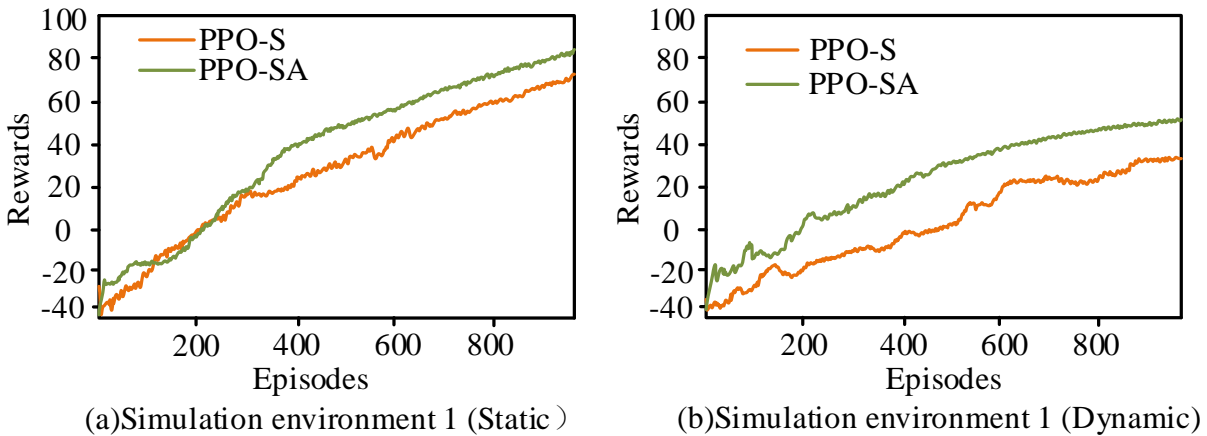

Fig. 10. Reward effect of PPO-S & PPO-SA

Fig. 11. Ratio of path difference in simulation environment 1

Fig. 12. Ratio of path difference in simulation environment 2

It can be seen from the figure that in the static simulation environment 1, the path optimization ability of the PPO-S model studied and designed is better, the curve rises fastest, and the time to find the optimal path is the shortest. Conduct training in the static simulation environment 2, and compare the proportion of the difference between the completed path and the optimal path. The results are shown in Fig. 12.

It can be seen from the figure that in the static simulation environment 2, the path optimization ability of the PPO-S model studied and designed is better, the curve rises fastest, and the time to find the optimal path is the shortest. Each model is used to train robots in dynamic environment 1 and dynamic environment 2. Compared with PPO-SA model, the

results show that the designed training model has achieved good training effect, while other algorithms used for comparison are not applicable in dynamic environment. It shows that the traditional common path planning algorithms are usually placed in static environment, and it is difficult to deal with dynamic environment without adding improvement measures. In the static simulation environment 2, 50 simulation experiments were conducted, and the statistics of the success times and success rates of different models are shown in Fig. 13.

TABLE I. SUCCESS TIMES AND SUCCESS RATE OF THE MODE

Model	Success times (times)	Success rate (%)
PPO-S	47	94
DDPG	40	80
RRT	21	42
A*	33	66

In Table I, from the success times and success rates of different models, PPO-S model has the highest success rate of 94%, significantly higher than other models, while DDPG model takes the second place, with a success rate of 80%. The success rate of A* model is the lowest, with only 21 successful times. It can be seen that the adaptability of PPO-S model is relatively optimal.

V. CONCLUSION

In order to promote the application of decoration robot in automatic decoration construction, it is a key problem to solve the autonomous planning of mobile path. In this paper, FCNN neural network is introduced into PPO algorithm and applied to interior decoration path planning. Aiming at the two core problems of path planning, a potential reward function is established. The reward function is redesigned based on the initial reward function. In order to solve the problem that the variance of cumulative reward returns is too large due to the difference between the front and rear reward values, a credit allocation model is constructed. By predicting the distribution of rewards through the auxiliary task model, the robot can predict the distribution of dynamic obstacles through training,

and avoid obstacles in advance. The simulation results show that compared with the training model of the initial reward function, the learning efficiency of the robot is significantly improved and there are fewer negative rewards in the training of the new reward function after adding credit allocation; In a dynamic environment, the reward curve is more stable, the learning efficiency is higher, and the adaptability is better. Compared with other common path planning algorithms, PPO-S model has better performance in path planning, with the highest success rate of 94%, 14% higher than DDPG. Therefore, the research and design of deep reinforcement learning algorithm for indoor mobile path planning of decoration robot is feasible, and the training effect is also very good, which has important practical significance. Applying this scheme to the actual environment is the next research direction.

Abstract—Face recognition technology is the core technology of the subway ticketing system, which is related to the efficiency of people's ticket purchase. In order to improve people's experience of taking public transport, it is necessary to improve the performance of face recognition technology. In this study, the Back Propagation (BP) algorithm is used to optimize the parameters of the SoftMax classifier of the convolutional neural network, and the branch structure is added to the structure of the SphereFace-36 convolutional neural network to extract the local features of the face. Based on the improved neural network, the face recognition system of the subway automatic ticketing system is established. The results show that the area under the ROC curve is the highest for validation and identification of the optimization model; The recognition accuracy of the optimized model in different data sets is 1.0%, 0.7%, 1.1%, 0.9% and 0.6% higher than that of SphereFace-36 respectively, and its specificity is higher than that of SphereFace-36, with the maximum difference of 9%; The average accuracy of global feature extraction and recognition of the optimized network model is 83.01%. In the simulation experiment, the optimized model can accurately recognize facial features, which has high practical value and can be applied to the automatic ticketing system.

Keywords—Automatic ticketing system; BP; CNN; deep learning; face recognition; SphereFac; SoftMax classifier

I. INTRODUCTION

Face authentication does not require physical contact with other systems, has a high false acceptance rate and false rejection rate, and can minimize errors [1]. Because of these unique characteristics of face recognition systems, it is considered one of the effective methods of data protection. Face recognition technology is widely used in many fields such as security, medical care, education, etc., and face recognition is required in various social places, which is very important for security, transportation, etc. [2]. Face recognition is mainly divided into appearance recognition and feature recognition. By extracting facial features, it is judged whether it matches the face information in the image or video stream, to identify the identity [3]. However, in the real environment, face recognition technology will be affected by posture, gender, lighting, and other conditions, so it is necessary to improve and optimize the method to improve face recognition's accuracy [4]. Changes in head posture will bring challenges to face recognition technology, and an unconstrained environment will increase the difficulty of face recognition in the field of human-computer interaction.

Researchers designed a tool to collect key pose samples from face datasets and then identify changing head poses through cascaded convolutional neural networks [5]. With the continuous development of society, people have higher and higher requirements for travel quality. Face recognition technology can help people save time cost of transportation. In the subway automatic ticketing system, fast ticket purchases can be realized by scanning the face. The application of face recognition technology has significantly improved the service efficiency and quality of the subway ticketing system. Due to factors such as the new crown epidemic, wearing masks for self-protection in public places is necessary, which makes the face recognition technology of the automatic ticketing system of the subway more difficult. As an important factor, the occlusion problem can affect the accuracy of facial landmark detection in face recognition, and the occlusion of the face affects the application of face recognition [6]. To improve the face recognition technology of the subway automatic ticketing system, the neural network was optimized in this experiment, and the accuracy of the face recognition system was improved through deep learning technology, hoping to meet people's travel needs. To improve the face recognition technology of the subway ticketing system, the neural network was optimized in this experiment. The research content of this paper is mainly to optimize the parameters of the SoftMax classifier of the convolutional neural network using the Error Back Propagation (BP) algorithm, and add a branch structure on the basis of the structure of the SphereFace-36 convolutional neural network to extract the local features of the face. Then, based on the improved neural network, the face recognition system of the subway ticketing system is established. Finally, the performance of the optimized neural network and face recognition system is simulated and analyzed. It is hoped that the accuracy of face recognition system can be improved through deep learning technology to meet people's travel needs.

II. RELATED WORK

In promoting the development of machine learning and deep learning, the application of CNN plays an important part and can reduce the complexity of feedback nerves. With in-depth research of scientific research, CNN has been continuously optimized and improved, and it has been effectively applied in various fields such as medicine, autonomous driving, and face recognition. In the technical research of heartbeat detection in the medical field, Chandra B

*Corresponding Author.

et al. applied a convolutional neural network for multimodal data analysis, and CNN can effectively improve the robustness and accuracy of heartbeat detection [7]. In disease classification, the bilateral CNN method can effectively distinguish dystrophic scoliosis from non-dystrophic scoliosis. This method has good classification accuracy, has strong application value, and provides a great deal for clinical diagnosis. Good technical support [8]. O Elharrouss and other scholars cascade the CNN technology, perform pose estimation, face segmentation, and recognition through three CNN models, and realize face recognition from the left, front and rear directions of the human face. The model training results show that the new model has high robustness [9]. As one of the ways of people's daily communication, image data shows explosive growth with network technology's continuous development. Machine vision is based on image recognition. CNN can perform feature extraction and recognition of image information, thereby extracting and analyzing different images. However, when recognizing face images, CNN may lose some image feature information during propagation and computation, and the multi-level information fusion method can further recover the information lost in CNN propagation and computation [10]. SoftMax classifier is the main technology of convolutional neural network to realize feature classification. The enhanced algorithm based on SoftMax classifier can effectively improve the accuracy and processing time of face recognition [11]. BP algorithm can be used to train artificial neural network to realize face recognition process. To improve the performance of face recognition system, artificial neural network is combined with the famous meta heuristic optimization algorithm, namely harmony search algorithm (HSA) [12]. Genetic algorithm, particle swarm optimization algorithm, etc. are heuristic algorithms, which can effectively solve the combination problems by examples. In recent years, researchers have obtained meta heuristic algorithm by combining random algorithm with local search algorithm. This algorithm can explore the solution space more thoroughly, so as to obtain a better solution. For example, Dwarf Mongoose Optimization Algorithm [13], the arithmetic optimization algorithm [14], Reptile Search Algorithm (RSA) [15], and other optimization algorithms are all improvements to heuristic algorithms, which can be independent of problems. Although meta heuristic algorithm has certain advantages, its intrinsic parameters still need to be adjusted and further studied in order to make the technology better used for problem solving.

Led by the rapid development of computer science and other fields, face recognition technology has become increasingly sophisticated and perfected. In various industries and fields, face recognition technology has been well applied. For example, based on face recognition technology such as neural networks and UAV, the online attendance system for students in the education industry is designed, and the research on the estimation of long-distance absolute distance and target tracking of face recognition technology is designed [16-17]. Some literature has conducted in-depth discussions on the lateralization of face recognition. The study believes that although the left hemisphere has achieved language evolution and is also the realization area of facial recognition, there is no

evidence that the right hemisphere does not correlate with face recognition [18]. Image feature extraction is a key technology for face image classification in face recognition systems. Nejr S et al. applied two-dimensional discrete Fourier transform technology to face image classification. The performance difference comparison method based on the correlation coefficient is effective. The classification accuracy of the target image reaches more than 90%, which proves that the classification result of the new model method is accurate [19]. Face recognition technology includes the recognition of facial expressions, and some scholars use machine learning algorithms to optimize face recognition technology. By using the gradient direction histogram to collect facial emotion data, and then applying the fast learning network algorithm to classify the extracted features for facial emotion recognition, the recognition of people's facial expressions and emotions is realized [20]. CNN is an efficient and accurate technical method in face recognition method and has high robustness [21]. To improve the distinguishing degree of feature extraction in face recognition technology, researchers use the optimized loss function to train the existing neural network and use the multi-action form supervision force to supplement the origin loss, which promotes the feature learning of face recognition [22]. Face recognition technology is easily affected by factors such as illumination and environment, which reduces the accuracy of face recognition. Chen C et al. proposed to use the fuzzy discriminant analysis method to establish a face recognition system, which can reduce the influence of the environment on the face recognition technology to a certain extent. This method calculates the fuzzy membership degree of the sample, calculates the fuzzy mean value, and then establishes a new model to achieve face feature extraction [23]. Some scholars have established a face beauty prediction model with a simple structure and suitable for embedding in small devices. The model uses CNN technology to extract facial features and expands the face database to predict facial beauty [24].

Facial sign detection is an important step in face recognition technology. Under the influence of the COVID-19, masks have become a necessity for people's daily travel, and mask occlusion has brought challenges to facial sign detection. Based on the above research, it can be seen that CNN technology has a good application effect in face recognition technology. At the same time, in order to improve the efficiency of CNN face recognition, other methods can be introduced to optimize the parameters. In this experiment, BP neural network is introduced to optimize the weight matrix and bias parameter of SoftMax classifier in CNN algorithm, and branch structure is added to the structure of SphereFace-36 convolution neural network to extract local features of face. It is hoped that the optimization and improvement of the method can improve the efficiency of the subway ticketing system and provide convenience for people to purchase tickets.

III. FACE RECOGNITION TECHNOLOGY OF SUBWAY AUTOMATIC TICKETING BASED ON NEURAL NETWORK AND DEEP LEARNING

A. Face Recognition Technology based on Neural Network and Deep Learning

Due to the impact of the epidemic, people are required to wear masks when choosing public transportation, which puts forward higher requirements for the face recognition technology of the subway ticketing system. The face recognition system needs to achieve high accuracy of face recognition when ticket buyers wear masks and other facial masks. In the existing CNN face recognition systems, the extraction of individual facial sign features can improve the accuracy of face recognition and better classify features [25-28]. CNN is a feedforward neural network model, and convolutional neural networks can be used to detect targets in face recognition technology. CNN can repeatedly cut the target image through different sliding windows and then perform feature extraction and recognition. The CNN network layer includes three network layers: convolutional layer, downsampling layer, and fully connected layer. The weight matrix W and bias term b parameters in the convolutional layer need to be trained and learned, and formula (1) is the calculation formula of convolution.

$$y_{nm} = f\left(\sum_{j=0}^{J-1} \sum_{i=0}^{I-1} x_{m+i,n+j} W_{ij} + b\right) \quad (1)$$

i in formula (1) represents the i th parameter, j th parameter is represented by j , and the samples' total number is represented by m . The subsampling layer can use a nonlinear downsampling method to reduce the amount of input data, thereby the feature map's scale is reduced without affecting the feature extraction of the target. If the size of uniform sampling is $S_1 \times S_2$, then the convolution formula (2) can be obtained.

$$y_{nm} = \frac{1}{S_1 S_2} \sum_{j=0}^{S_2-1} \sum_{i=0}^{S_1-1} x_{m \times S_1 + i, n \times S_2 + j} \quad (2)$$

As a CNN classifier, the fully connected layer can be implemented by convolution operations in practical applications, and is widely used in deep learning network models, but there is also the problem of parameter redundancy. When performing multi-classification, the SoftMax multi-classification layer is added to the convolutional neural network. Assume that the training set sample $T = \{(x^{(1)}, y^{(1)}), \dots, (x^{(m)}, y^{(m)})\}$, which $x^{(i)}$ represents the sample i , $y^{(i)}$ is the label of the sample. For the training set T , the SoftMax classifier can determine the category of the samples in it. In the case of rule restrictions, the probability $P(y = j|x), (j = 1, \dots, k)$ of converting to the k th sample is calculated by the formula, and then the sample category is calculated for face recognition, and the calculation formula of SoftMax can be obtained, see formula (3).

$$f(x^{(i)}|\theta) = \frac{1}{\sum_{j=1}^k e^{\theta_j^T x^{(i)}}} \begin{bmatrix} p(y^{(i)} = 1|x^{(i)}, \theta) \\ p(y^{(i)} = 2|x^{(i)}, \theta) \\ \vdots \\ p(y^{(i)} = k|x^{(i)}, \theta) \end{bmatrix} = \frac{1}{\sum_{j=1}^k e^{\theta_j^T x^{(i)}}} \begin{bmatrix} e^{\theta_1^T x^{(i)}} \\ e^{\theta_2^T x^{(i)}} \\ \vdots \\ e^{\theta_k^T x^{(i)}} \end{bmatrix} \quad (3)$$

$\theta = [\theta_1^T \theta_2^T \dots \theta_k^T]$ representation learning parameters in Eq. (3). The network model is continuously trained in the data set T , and the optimal one is obtained through iterative calculation and fitting θ . Formula (4) is the loss function used in the training.

$$J(\theta) = -\frac{1}{m} \left[\sum_{i=1}^m \sum_{j=1}^k 1\{y^{(i)} = j\} \log \frac{e^{\theta_j^T x^{(i)}}}{\sum_{i=1}^k e^{\theta_j^T x^{(i)}}} \right] \quad (4)$$

In the formula (3), $1\{y = j\}$ means that its value is 1 in case of $y = j$, and 0 in case of $y \neq j$. By calculating network prediction and real value's error, the loss function's value can be obtained and the optimization process of the neural network can make the loss function minimize. The direction of signal transmission is forward, and the propagation direction of the error is opposite to it, which are BP's characteristics. The parameters' reverse adjustment in the network layer can be achieved by BP. Fig. 1 shows the BP network's structure.

Fig. 1. Structure diagram of BP neural network

Through the continuous adjustment of the network weights in the BP neural network, the final network output close to the expected output can be obtained, that is, the error between the network prediction result and the given label is continuously reduced. Assuming that there are a total of n samples with a given label in the training set $\{(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)\}$, the neural network's training method is gradient descent. The variance loss function of the model is shown in formula (5) for the samples (x_i, y_i) in the training set.

$$L(w, b; x_i, y_i) = \frac{1}{2} \|h_{w,b}(x_i) - y_i\|^2 \quad (5)$$

In formula (5), w represents the weight and b represents the bias. The variance loss function can calculate the error, which can be used to evaluate the convergence situation. The loss function of n samples can be derived by formula (6).

$$L(w, b) = \left[\frac{1}{n} \sum_{i=1}^n L(w, b; x_i, y_i) \right] + \frac{\lambda}{2} \sum_{l=1}^{n_l-1} \sum_{i=1}^{S_l} \sum_{j=1}^{S_{l+1}} (w_{ji}^{(l)})^2 \quad (6)$$

$$= \left[\frac{1}{n} \sum_{i=1}^n \|h_{w,b}(x_i) - y_i\|^2 \right] + \frac{\lambda}{2} \sum_{l=1}^{n_l-1} \sum_{i=1}^{S_l} \sum_{j=1}^{S_{l+1}} (w_{ji}^{(l)})^2$$

In formula (6), i represents the i th parameter, j represents the network layer unit of the previous layer, l represents the l th layer of the neural network, and S represents the variance. The parameters λ are introduced to adjust the loss value of the variance loss function and the proportion of the attenuation term. In the process of BP neural network training, it is necessary to continuously fine-tune the size of parameters w and b . The derivation formula of parameter w is shown in formulas (7) and (8).

$$w_{ij}^{(l)} = w_{ij}^{(l)} - \alpha \frac{\partial}{\partial w_{ij}^{(l)}} L(w, b) \quad (7)$$

In formula (7), α denotes the learning rate, and the step size of gradient descent can be controlled by adjusting the learning rate. The derivation formula of parameter b is shown in formula (8).

$$b_i^{(l)} = w_{ij}^{(l)} - \alpha \frac{\partial}{\partial b_i^{(l)}} L(w, b) \quad (8)$$

Through formulas (7) and (8), the partial derivatives of all sample parameters w and b can be deduced, and the formula for partial derivatives of all sample parameters w is shown in formula (9).

$$\frac{\partial}{\partial w_{ij}^{(l)}} L(w, b) = \left[\frac{1}{n} \sum_{i=1}^n \frac{\partial}{\partial w_{ij}^{(l)}} L(w, b; x_i, y_i) \right] + \lambda w_{ij}^{(l)} \quad (9)$$

The partial derivative formula of all sample parameters b is shown in formula (10).

$$\frac{\partial}{\partial b_{ij}^{(l)}} L(w, b) = \left[\frac{1}{n} \sum_{i=1}^n \frac{\partial}{\partial b_{ij}^{(l)}} L(w, b; x_i, y_i) \right] \quad (10)$$

In the BP neural network, according to the input sample signal of forward propagation, the two parameters of weight and bias are randomly initialized, and the loss value is calculated. The partial derivatives of the optimization function to the neuron weights in the neural network of each layer can be obtained in the process of backpropagation, to obtain the error signals of all neurons, as the basis for modifying the parameters w and b . Through the construction of a multi-layer neural network, the basic neural network can be continuously developed to form deep learning. In the field of image recognition, underlying features of the image can be detected by deep learning in the low-level neural network layer, then integrate and abstractly combine to generate the corresponding high-dimensional image features, and finally realize the

classification of high-dimensional features at the top layer. When the deep neural network propagates forward, the corrected weight value and bias value of the neural network can be obtained by calculating the error, and then the weight and bias item are corrected by backpropagation.

B. Face Recognition Technology for Subway Automatic Ticketing based on Neural Network and Deep Learning

The application of face recognition technology in many scenarios is limited by many conditions, and the clarity of photos is one of the limiting factors. In the actual subway automatic ticketing face recognition scene, the face recognition technology will reduce the accuracy of face recognition due to the influence of masks, glasses, hats, and other obstructions, expressions, light, and other factors. To make the robustness of the face recognition technology for subway ticket vending improve, CNN was optimized in this experiment. A branch structure was added to the structure of SphereFace-36 to get the face's local features. Fig. 2 shows the network structure after the fusion of local features and global features. The resolution of facial details can be improved after local and global features are fused.

Fig. 2. Structure diagram of a network

One branch in the network structure diagram is the SphereFace-36, which can get the face's global features, and the other branch divides the feature image into upper and lower parts, which can get the face detailed features. The loss functions applied in these two branch network diagrams are CA-SoftMax (Center Angular SoftMax Loss) and SoftMax Loss respectively. In the original SoftMax Loss, it needs to be satisfied $w_1^T x > w_2^T x$, ie $\|w_1\| \|x\| \cos(\theta_1) > \|w_2\| \|x\| \cos(\theta_2)$. To achieve the effect of increasing the distance between classes, the variable m was added in this experiment to strictly limit the decision boundary of the classification, see formula (11).

$$\|w_1\| \|x\| \cos(m\theta_1) > \|w_2\| \|x\| \cos(\theta_2) \quad (11)$$

In the range of $[0, \pi]$, since the \cos function decreases monotonically, the larger the value of variable m is. Under the condition that x are unchanged, when the classification is correct, the smaller the angle of θ_1 , the smaller the angle between the sample feature vector and w_1 , increase the distance between classes. The separability of the feature angle is a key part of Angular SoftMax Loss, and weight normalization can improve the separability of samples. After the parameter w is normalized by the weight, the value is 1, that is $\|w_i\| = 1$, the bias term b is 0, and formula (12) is the loss function.

$$L = \frac{1}{N} \sum_i -\log \left(\frac{e^{\|x_i\| \phi(\theta_{y_i})}}{e^{\|x_i\| \phi(\theta_{y_i})} + \sum_{j \neq y_i} e^{\|x_i\| \cos(\theta_j)}} \right) \quad (12)$$

$$\phi(\theta_{y_i}) = (-1)^k \cos(m\theta_{y_i}) - 2k, \theta_{y_i} \in \left[\frac{k}{m}\pi, \frac{(k+1)}{m}\pi \right], k \in [0, m-1], m \geq 1$$

In Angular SoftMax Loss, the expression effect of facial features can be improved, but the convergence speed of the function is slow during training, and it is easy to fall into a local minimum. The experiment updated the weights in Angular SoftMax Loss, that is, the sample center, named CA-SoftMax Loss. In formula (13), at time $t+1$, the expected weight value is the mean value of all sample features and their weight values that conform to $y_i = j$ at time t .

$$w_j^{t+1} = \frac{w_j^t + \sum_{i=1}^m \delta(y_i = j) \cdot (x_i)}{1 + \sum_{i=1}^m \delta(y_i = j)} \quad (13)$$

The mean value of Euclidean distance is approximately equal to the mean value of angular distance after weight normalization. The updated value of the sample center can be obtained by formulas (14) and (15).

$$w_j^{t+1} - w_j^t = \frac{\sum_{i=1}^m \delta(y_i = j) \cdot (x_i) - \delta(y_i = j) \cdot w_j^t}{1 + \delta(y_i = j)} = \frac{\sum_{i=1}^m \delta(y_i = j) \cdot (x_i - w_j^t)}{1 + \delta(y_i = j)} \quad (14)$$

$$\Delta w_j = w_j^{t+1} - w_j^t = \frac{\sum_{i=1}^m \delta(y_i = j) \cdot (w_j^t - x_i)}{1 + \delta(y_i = j)} \quad (15)$$

To control the step size of the sample center update, a parameter is introduced during the update α , and it is set to 0.5, which achieves the purpose of preventing the jitter of the class center, see formula (16).

$$w_j^{t+1*} = w_j^t - \alpha \Delta w_j \quad (16)$$

Based on neural network and deep learning, the face recognition system of subway automatic ticketing was designed and developed in the experiment. The process flow of the face recognition system is shown in Fig. 3. The overall framework of the system includes four modules: video image acquisition, face detection, normalization, and face recognition. The system needs to perform face registration first, and then extract the face features, and then save the acquired information and features into the database. When performing face recognition, it should extract the face information and features in the video and make it compared with the database's information and features to determine whether they belong to the same person.

Fig. 3. Flow chart of face recognition

IV. SIMULATION ANALYSIS OF FACE RECOGNITION SYSTEM FOR SUBWAY AUTOMATIC TICKETING

To improve the classification performance of the improved CNN, the improved method is trained in the BLUFR general data set, and the training is completed in the training set and the test set respectively. It can be seen from Fig. 4 that the accuracy rate of the optimized CNN model tends to be stable when it is trained to about 8000 times. The final accuracy rate in the training set is 98.5%, and the final accuracy rate in the test set is 97.6%. The loss function value of the optimized CNN model tends to be stable when it is trained to about 5000 times. The loss function value in the training set is 0.09, and the loss function value in the test set is 0.18. It shows that the optimized CNN model can get higher accuracy and lower loss function value after training, and the algorithm has better

performance.

In the process of neural network training, each weight value needs to be assigned in advance, that is, weight initialization. The method of weight assignment is very important to the convergence speed of the neural network model and the performance of the model. In this study, the original Angular SoftMax Loss has been updated with weights, and the form of the original function has not been changed. The weights can be updated faster and more efficiently after the weights are updated. In the data set WebFace, the loss function in the face recognition system is compared, and SphereFace-36 is selected as the test neural network, the parameter settings are consistent, and the initial learning rate is 0.01. The difference between the optimized CA-SoftMax Loss and the original loss function is shown in Fig. 5.

Fig. 4. Performance verification diagram of improved CNN model

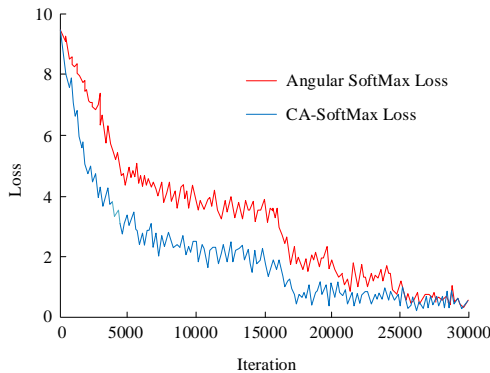

Fig. 5. Loss function curve

From Fig. 5, the initial Loss value of the optimized CA-SoftMax Loss and Angular SoftMax Loss is about 9.2. With the iterations number and pictures number increased, the Loss value decreases rapidly. The optimized CA-SoftMax Loss converges faster than the original Angular SoftMax Loss loss function, and the Loss value does not change or increase abnormally due to network gradient dissipation or gradient explosion during the descent process. In the experiment, we chose to test the model accuracy in the BLUFR general data set, LFW general data set, AgeDB-30 general data set, CFP-FP general data set and YTF general data set, and compared SphereFace-36, Caffe-Face, and optimization. The verification rate and recognition rate of the post-branch network structure are shown in Fig. 6.

Fig. 6 (a) and Fig. 6 (b) are the validation ROC curve and the identification ROC curve of the validation model, respectively. The area under the optimized branch network structure verification ROC curve and identification ROC curve is higher than that of the SphereFace-36 and Caffe-Face models, indicating that the optimized network structure proposed in this experiment has a better Good face recognition effect. In BLUFR general dataset, LFW general dataset, AgeDB-30 general dataset, CFP-FP general dataset and YTF general dataset, SphereFace-36, Center Loss, Angular SoftMax Loss, Caffe-Face. In this experiment, the optimization model is used to compare the algorithm recognition performance, and the results are shown in Table I.

The "-" in Table I indicates that the algorithm has not been tested for recognition performance in the corresponding dataset. It can be seen from the results in different datasets that the accuracy of the basic SphereFace-36 algorithm is lower than that of the optimized network model. In the BLUFR dataset, LFW dataset, AgeDB-30 dataset, CFP-FP dataset, and YTF dataset, the recognition accuracy of the optimized model is improved by 1.0%, 0.7%, 1.1%, 0.9%, and 0.6%, respectively. The evaluation indicators of the performance comparison in the experiment selected the true rate, false positive rate, prediction accuracy rate, and average accuracy rate, respectively in the BLUFR general data set, LFW general data set, AgeDB-30 general data set, CFP-FP general data set Compared with the YTF general data set. Table II shows the test results of SphereFace-36 and the optimized model in this experiment.

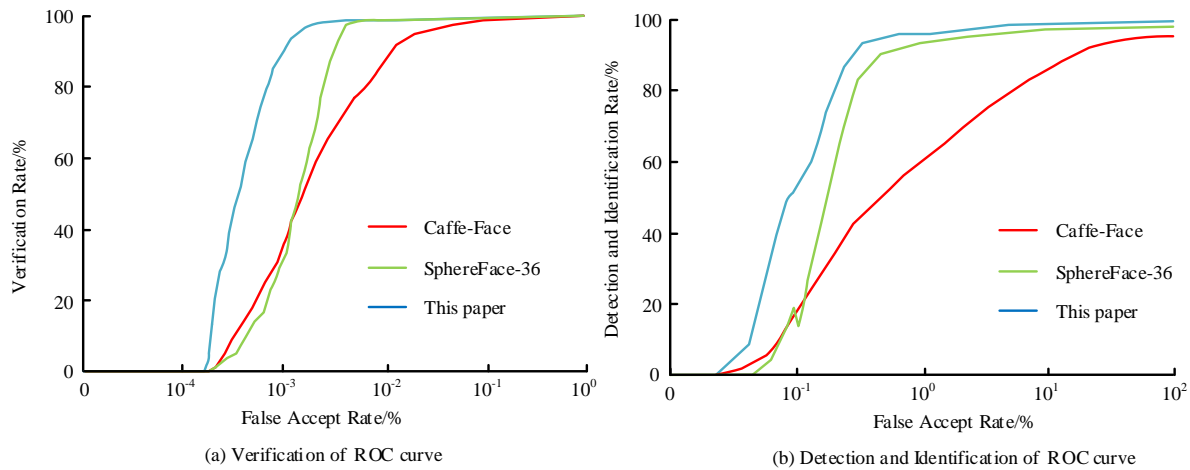

Fig. 6. ROC curve

TABLE I. ALGORITHM PERFORMANCE CONTRAST

Method	BLUFR	LFW	AgeDB	CFP	YTF
SphereFace-36	98.70%	93.25%	94.33%	92.01%	95.17%
Center Loss	98.31%	93.01%	-	92.57%	93.62%
Angular SoftMax Loss	98.12%	-	93.58%	-	94.83%
Caffe-Face	99.13%	92.87%	94.27%	92.33%	95.10%
This paper	99.70%	93.95%	95.43%	93.11%	95.77%

TABLE II. INDEX COMPARISON RESULTS

Data set	Method	True positive (%)	False positive (%)	Prediction accuracy (%)	Average accuracy (%)
BLUFR	SphereFace-36	84.84	9.79	90.59	87.87
	This paper	93.93	4.04	96.85	94.94
LFW	SphereFace-36	83.14	9.60	88.78	86.11
	This paper	92.05	3.95	94.92	93.04
AgeDB-30	SphereFace-36	78.98	9.12	84.34	81.80
	This paper	87.44	3.76	90.17	88.38
CFP-FP	SphereFace-36	86.88	10.03	92.78	89.98
	This paper	96.19	4.13	99.19	97.22
YTF	SphereFace-36	84.84	9.79	90.59	87.87
	This paper	93.93	4.04	96.85	94.94

From Table II, in BLUFR, LFW, AgeDB-30, CFP-FP, and YTF general data set, the true rate of optimizing the branch network structure is 93.93%, 92.05%, 87.44%, 96.19%, 93.93%. In the BLUFR general dataset, the LFW general dataset, the AgeDB-30 general dataset, the CFP-FP general dataset, and the YTF general dataset, the false positive rates of the optimized branch network structure are 4.04%, 3.95%, 3.76%, and 4.13%, 4.04%, respectively. In BLUFR, LFW, AgeDB-30, CFP-FP, and YTF general data set, the prediction accuracy of optimized branch network structure is 96.85%, 94.92%, 90.17%, 99.19%, 96.85%, respectively. In the BLUFR general dataset, the LFW general dataset, the

AgeDB-30 general dataset, the CFP-FP general dataset, and the YTF general dataset, the average accuracies of optimizing the branch network structure are 94.94%, 93.04%, 88.38%, 97.22%, and 94.94%, respectively. In each general dataset, the true rate, prediction accuracy, and optimized network model's average accuracy are higher than those of the basic SphereFace-36; in each general dataset, the false positive rate of the optimized branch network is lower than that of the basic SphereFace-36. In Fig. 7, the sensitivity and specificity of the basic SphereFace-36 and optimized network models are tested on the BLUFR general dataset, the LFW general dataset, the AgeDB-30 general dataset, the CFP-FP general dataset, and the YTF general dataset.

Fig. 7. Comparison results of sensitivity and specificity

Fig. 7 describes the comparison results of specificity and sensitivity between the basic SphereFace-36 and the optimized network model. In terms of specificity, the specificity of the optimized network model is higher than that of the basic SphereFace-36, and the difference can be up to 9 %.

Fig. 8. Test results of global feature recognition and extraction

From Fig. 8, in the global feature extraction and recognition test of the two sample images, the optimized network model proposed in this experiment recognizes the number of feature points and the accuracy rate is higher than the basic SphereFace-36. Among them, the average accuracy rate of the optimized method is 83.01%, and basic SphereFace-36's average accuracy rate is 67.98%. The above results can show that the optimized network model has higher performance in global feature extraction and recognition of face images performance.

V. CONCLUSION

In the results of this research on face recognition technology, the area under the ROC curve for verification and recognition of the optimized model is the highest; The recognition accuracy of the optimized model in different data sets is 1.0%, 0.7%, 1.1%, 0.9% and 0.6% higher than that of SphereFace-36 respectively, and its specificity is higher than that of SphereFace-36, with the maximum difference of 9%. The average accuracy of global feature extraction and recognition of the optimized network model is 83.01%. The results show that the optimized method can accurately recognize facial features, and has high practical value, which can be applied to the automatic ticketing system. In a word,

complexity of the data is low, the specificity of the optimized network model is significantly higher than that of the basic SphereFace-36; as the complexity of the data increases, the specificity gap between the basic SphereFace-36 and the optimized network model gradually narrows. In the sensitivity comparison of the methods, when the data complexity is low, the difference between the basic SphereFace-36 and the optimized network model is not significant, but as the data complexity increases, the optimized network model's sensitivity declines significantly less than the basic one. Fig. 8 shows the global feature recognition and extraction effects of different methods. Two sample images are chosen to optimize network model and the basic SphereFace-36 global feature's performance comparison.

the improved method has good performance and plays a positive role in the establishment of face recognition system. Although the face recognition technology in this study has a good recognition effect, the running time of the algorithm is relatively long in the experimental process, which affects the running speed of the algorithm. In the later research, it is necessary to further improve the optimization of parameters. In addition, in actual application scenarios, face recognition may be affected by environmental factors, resulting in the inability to recognize low resolution faces. Therefore, in subsequent research, specific analysis of problems in the actual scene is required to improve the performance of face recognition technology.

Research on Improved Xgboost Algorithm for Big Data Analysis of e-Commerce Customer Churn

Li Li

Department of Economics & Management, Sichuan TOP IT Vocational Institute, Chengdu, China

Abstract—With the increasing cost of acquiring new users for e-commerce enterprises, it has become an important task for e-commerce enterprises to actively carry out customer churn management. Therefore, based on the distributed gradient enhancement library algorithm (XGBoost), this research proposes a big data analysis study on e-commerce customer churn. First, it conducts an evaluation analysis on e-commerce customer segmentation and combines the random forest algorithm (RF) to build an RF XGBoost prediction model based on customer churn. Finally, it verifies the performance of the prediction model. The results show that the area under receiver operating characteristic curve (AUC) value, prediction accuracy, recall rate, and F1 value of the RF-XGBoost model are significantly better than those of the RF, XGBoost, and ID3 decision trees to build an e-commerce customer churn prediction model; The average output error of RF-XGBoost model is 0.42, and the average output error is relatively good, indicating that the model proposed in this study has a smaller error and higher accuracy. It can make a general assessment of the customer churn of e-commerce enterprises, and then provide data support for the customer maintenance work of e-commerce enterprises. It is helpful to analyze the relevant factors affecting customer churn, to Equationte targeted customer service programs, thus improving the economic benefits of e-commerce enterprises.

Keywords—E-commerce; customer churn; random Forest; XGBoost; big data

I. INTRODUCTION

At present, domestic e-commerce enterprises and websites are also gradually increasing, and people are getting used to buying goods and services online [1]. Most traditional industries have built their e-commerce platforms, and the opportunities for customers to choose products are gradually increasing [2]. For e-commerce companies, they must face fierce competition for customer resources from other companies, and companies that fail to compete will face elimination from the market. Therefore, finding a suitable method to more accurately predict the purchase behavior and churn of users, and taking effective measures to reduce the loss rate has become a hot topic in related industries. In the absence of new customer resources, some e-commerce companies began to focus on old customers, and used data mining-related technologies to analyze the shopping behavior of old customers to mine useful data. By formulating marketing plans based on these data, enterprise can avoid the loss of old customers and increase more economic benefits [3]. Some scholars have pointed out that enterprises will accumulate massive amounts of data in the daily operation process, from which valuable information can be mined and customers who are about to be lost can be accurately predicted

[4]. For e-commerce companies, when they find customers who are about to be lost, taking corresponding retention measures can effectively reduce the loss rate of corporate customers and make customers active on the company's e-commerce platform [5]. Therefore, this research takes e-commerce enterprise customers as the research object, analyzes the relevant behavioral data recorded by the background when customers purchase online, subdivides them according to customer value, combines the distributed gradient enhancement library algorithm (XGBoost) with the random forest algorithm (RF), and constructs a big data analysis model for e-commerce customer loss.

II. RELATED WORK

Janabi S and his team proposed an integrated system, in recent years, under the global economic downturn under the new crown epidemic; all walks of life are competing for customer resources. Therefore, the analysis of big data for enterprise customer churn has attracted people's attention. Janabi S and his team proposed an integrated system to help telecom companies achieve intelligent prediction of customer churn, use training data to build an intelligent predictor of customer churn, and use a genetic algorithm (GA) algorithm to group customers for decision-making. The integrated system is superior to the system built by traditional methods and has high accuracy [6]. Li W et al. used feature extraction technology to analyze lost customers and proposed a customer loss prediction method. The online test shows that the proposed customer churn prediction method can effectively predict customer churn, which is superior to the traditional prediction technology [7]. Gu Y et al. studied the effect of the decision tree algorithm in customer churn prediction. Each performance index of this algorithm is superior to other traditional algorithms. After applying this method, it can help enterprises retain old customers and avoid the loss of old customers [8]. Jiao G and his team predicted telecommunication customer churn and compared four prediction models on a telecommunication dataset, and found that the model built by XGBoost and RF algorithm has the best prediction ability among many algorithms [9]. Eria K's studio studied the relevant characteristics of customer data, and on this basis proposed a customer churn prediction method, that reduces the data according to missing values and irrelevant variables, which helps reduce churn analysis. The computational cost is incurred by teachers using big data in churn prediction and analysis [10].

Sharma T and other researchers propose an improved XGBoost algorithm as a model to address customer churn in the telecom industry. Compared with non churning customers,

the previous model paid more attention to prediction accuracy, and the proposed model correctly classified all churning customers, having better performance [11]. Swetha P et al. designed a data characteristic function model to judge and predict the loss rate of enterprise customers. In the process of research, the loss function is constructed and combined with the XG_Boost method. The proposed model is helpful to identify correct and wrong classification examples of South Asia's global mobile communication system service providers [12]. Scholars such as Naser AM built a customer churn prediction model to determine whether each customer is a churned customer and get more opinions about serving customers and use the extreme gradient to boost the classification model of "XGBoost", which is added to the original network by computing A centrality measure for the new attribute of the dataset to evaluate model performance. Experiments show that the proposed clustering-based churn detection method combining social influence and web content significantly improves the prediction accuracy of telecom datasets [13].

Although a large number of studies have focused on enterprise customer churn, there are still few studies on e-commerce enterprise customer churn. And the prediction accuracy needs to be improved, and the application of the XGBoost loss prediction model is not flexible enough. Therefore, based on the improved XGBoost algorithm, this study proposes a prediction method for e-commerce customer churn, to contribute to the development of e-commerce enterprises.

III. E-COMMERCE CUSTOMER SEGMENTATION EVALUATION AND CUSTOMER CHURN PREDICTION MODEL CONSTRUCTION

A. E-commerce Customer Value Segmentation Evaluation

The "28" law proposed by the Italian economist Pareto shows that in any group of things, the most important part is only a small part, accounting for about 20%, and the remaining 80%, although the majority, is secondary. Its core content is that 80% of the results in life almost all come from 20% of activities. According to the famous "28" law, nearly 80% of the benefits of an enterprise are brought by 20% of the main

customers [14]. Therefore, in the current situation that resources are getting smaller and smaller, e-commerce companies need to further subdivide customers, and at the same time customize different service plans for different customers, to avoid the loss of customers. Based on the traditional customer behavior analysis model (RFM), this study analyzes the customer value evaluation indicators of e-commerce companies [15]. The period indicator (T) of the first online activity and the last online activity in the observation period is introduced through the RFM model, and the RFM model (RFMT) based on the time factor is constructed. It mainly includes four key indicators in the observation period, namely the time interval (R) between the last time the customer had consumption behavior and the observation point of analysis, the total consumption times (F), the total consumption amount (M) and T .

The customer segmentation process is shown in Fig. 1. The first step is to build an index system, mainly using expert scoring to evaluate four key indicators; the second step is to evaluate customer value (V), by calculating the normalized index weight value used to obtain the corresponding V value; the third step is to classify the customer groups. The V value is analyzed through K-means, customer types are divided, and the indicators of each type of center point are analyzed to get the category labels of various customers, and set the value threshold, so that the enterprise can further identify the customers with special value.

According to the actual situation of the research, and according to the method in the literature, a single-layer indicator system for e-commerce customer segmentation is proposed, the target layer is "customer value evaluation", and the indicator layer is four key indicators [16]. Then sort the four key indicators proposed, calculate the weight of each indicator, and realize the calculation of customer value V .

According to the single-level indicator system of e-commerce customer segmentation, the four key indicators are compared with each other in pairs and graded. From the comparison results, the feature discriminant matrix can be constructed $X = (x_{ij})_{n \times n}$, as shown in Eq. (1).

Fig. 1. Customer segmentation model framework

$$X = \begin{pmatrix} x_{ij} & X_1 & X_2 & \dots & X_n \\ X_1 & x_{11} & x_{12} & \dots & x_{1n} \\ X_2 & x_{21} & x_{22} & \dots & x_{2n} \\ \dots & \dots & \dots & \dots & \dots \\ X_n & x_{n1} & x_{n2} & \dots & x_{nn} \end{pmatrix} \quad (1)$$

It can be seen from Eq. (1) that x_{ij} the contrast between the $x_{ij} = 1/x_{ji}$ representation feature i and the feature exists at the same time j . According to the characteristics of the matrix in Eq. (1), to obtain the weight of each index, it is necessary to use the expert scoring method to score X the eigenvectors. Then, the consistency test is performed by the largest eigenroot λ_{\max} pair X , as shown in Eq. (2).

$$CI = (\lambda_{\max} - n) / (n - 1) \quad (2)$$

To be able to better evaluate X the consistency, this study introduces an index X related to RI . Use the CR value to judge X whether it passes the test, if $CR > 0.1$ it fails the test, otherwise it passes the test, see Eq. (3).

$$CR = CI / RI \quad (2)$$

In the classification of customer groups, the scores of each customer in the RFMT model are compared with the average of the indicators, and those higher and lower than the average are marked as "+" and "-" respectively. Based on this, customers are divided into 16 sub-categories, and then through expert analysis, the e-commerce customers are finally divided into four groups, namely core customers, important customers, important development customers, and general customers. After the customer is preprocessed, the customer's score on the four indicators will be obtained, and the weight value of each indicator will be obtained by using the expert scoring method. Finally, the customer's V value will be calculated by the Eq. (4). Among them, W represents the feature vector obtained by expert scoring.

$$V = W_R \times \frac{1}{R} + W_F \times F + W_M \times M + W_T \times T \quad (4)$$

B. Improved XGBoost Prediction Model

First of all, we need to measure the data characteristics of customers. This research is implemented through random forests (RF). When the RF algorithm randomly selects the training subset applied to the decision tree algorithm, the unselected data are out-of-bag data [17]. The error rate of the out-of-bag data evaluation model is named $E1$; then random interference terms are added to the out-of-bag data, x and the evaluation model error is $E2$. If $E2 > E1$, then the importance of feature x (I) is higher, and I , the higher the value, the more important the feature is. Assuming that the number of training decision trees generated by the RF algorithm is k , then I the calculation Eq. is shown in Eq. (5).

$$I = \frac{\sum (E1 - E2)}{k} \quad (5)$$

The introduction of the feature importance measure is convenient for the RF algorithm to select a better feature set [18]. In the process of screening important features through the RF algorithm, a tree-building process will be carried out at the same time. This process mainly includes four processes: one is I to calculate the value of the I features in the data set by Eq. (5). Sort by size, and output the I values of all features; the third is to select the previous x_i feature in the output to regroup into multiple feature sets, input each combined feature set into the RF model, and then calculate the out-of-bag error rate of each feature set, among them $i = 1, 2, 3, \dots, x_1 < x_2 < x_3, \dots$; Fourthly, all out-of-bag error rates are obtained by comparison, and the feature set whose out-of-bag error rate does not change continuously is selected as the optimal feature set, so as to facilitate subsequent empirical analysis and research.

The XGBoost algorithm belongs to a classic ensemble algorithm, which implements part of the generalized linear machine learning algorithm based on the boosted decision tree (GBDT) [19]. XGBoost model can use CPU multithreading to realize parallel operation and obtain the best parameters. See Eq. (6) for the calculation of its objective function.

$$Obj(\theta) = L(\theta) + \Omega(\theta) \quad (6)$$

In Eq. (6), θ is the model parameter and $L(\theta)$ is the loss function. The higher the value, the higher the model accuracy. However, the model is easy to regard noise as a learning sample, which leads to overfitting. Overfitting refers to the phenomenon that the model predicts the known data well, but the prediction effect on the unknown data is poor, which will reduce the robustness of the model.

The regularization term ($\Omega(\theta)$) can improve the generalization ability of the model and the complexity of the evaluation model. Let the number of ensemble trees in the XGBoost model be k .

$$y_i = \sum_{k=1}^K f_k(x_i), f_k \in \rho \quad (7)$$

In Eq. (7), f_k is a base classifier, K and ρ respectively represents the number and space of the base classifier. If y_i represents the class i mark, the calculation of the objective function is shown in Equation (8).

$$Obj = \sum_{i=1}^n L(y_i, \hat{y}_i) + \sum_{k=1}^K \Omega(f_k) \quad (8)$$

The XGBoost model is a boosted tree model with a special form, and its essence is an additive model. To solve the objective function of the model, it is necessary to obtain each tree f_k . However, all trees f_k cannot be obtained at one time, so it is necessary to train according to the model that has been iterated several $t-1$ times to obtain the first t tree. After iteration t times, the loss function of the model is expanded by second-order Taylor expansion, and then the constant term is removed, and a regular term is added to constrain the loss function, to control the complexity of the model. Based on the above content, t the objective function of the first iteration

can be obtained, as shown in the Eq. (9).

$$Obj^{(t)} \approx \sum_{i=1}^n \left[g_i f_t(x_i) + \frac{1}{2} h_i f_t^2(x_i) \right] + \Omega(f_t) \quad (9)$$

For the objective function, g_i and h_i are their first and second derivatives respectively. After minimizing the objective function, the model can achieve the best classification effect, thus improving the prediction accuracy [20]. The loss function when not optimized is drawn in Fig. 2. From the analysis of the curve gradients in the graph, it is found that the gradients of the first two types of curves are consistent, indicating that the losses of the two types of errors are regarded as the same, and the positive examples are misclassified more than the negative ones after optimization, which is consistent with the actual situation.

Fig. 2. Comparison diagram of loss function before and after optimization

Due to the serious loss of e-commerce customers, this

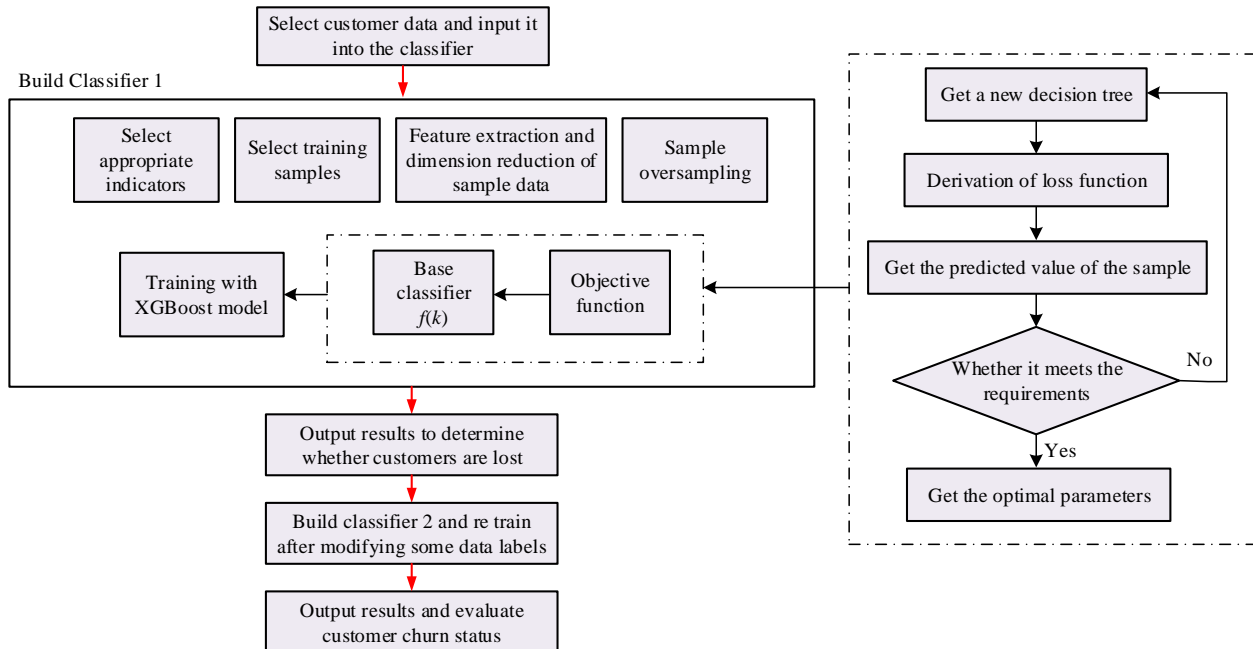

Fig. 3. Customer churn prediction model proposed in this study

study judges the loss of customers by studying the basic data and behavioral data of customers and uses the RF feature selection method combined with the XGBoost algorithm to build a prediction model, to better handle the relationship between e-commerce companies and customers. This research combines RF and XGBoost to build a prediction model, and its process is shown in Fig. 3. In classifier 1, if the customer is not lost, the output is 0; if the customer is lost, the output is 1. In classifier 2, the customers who have not lost the e-commerce company are predicted. If there is a possibility of losing customers, the output result is 1; otherwise, the output is 0.

Firstly, the model should be trained through the data test set, and each parameter in XGBoost should be tuned to obtain the optimal parameters of the algorithm, to make the model prediction effect in the later stage the best. In addition, each tree structure in the algorithm needs to be made simpler. For the detailed process of training the objective function, see Eq. (10).

$$\begin{cases} \hat{y}_l^{(0)} = 0 \\ \hat{y}_l^{(1)} = f_1(x_i) = \hat{y}_l^{(0)} + f_1(x_i) \\ \hat{y}_l^{(2)} = f_1(x_i) + f_2(x_i) = \hat{y}_l^{(1)} + f_2(x_i) \\ \dots \dots \\ \hat{y}_l^{(t)} = \sum_{k=1}^t f_k(x_i) = \hat{y}_l^{(t-1)} + f_t(x_i) \end{cases} \quad (10)$$

The process of training the model and obtaining the optimal parameters proposed in this study mainly includes four steps: first, obtaining a new decision tree, second, deriving the loss function, third, obtaining the predictive value of the sample, and fourth, returning to the first step until the result of parameter optimization is optimal.

IV. MODEL PERFORMANCE ANALYSIS

This study selects the data of an e-commerce platform from April 1, 2020, to April 1, 2022, and analyzes the performance of the model constructed in this study. Take the data from April 1, 2020, to February 19, 2022, as the training set, and the data from the rest of the dates as the test set. The data mainly includes the original sample skeleton data, advertising information attribute description, user information data, and user behavior log data. After the cleaning and conversion of the selected data with missing values and abnormal values, we selected 121949 effective users, a total of 4488519 user behavior data for customer churn prediction research. Based on the above customer segmentation results, Table I shows the churn rate of each type of customer.

The results in Table I show that corresponding to the characteristics of each type of customer after customer segmentation, the order of customer churn rate from high to low is: general customers, important development customers, important customers, and core customers. Moreover, the churn rate of general customers exceeds 90%, which is much higher than that of core customers, indicating that general customers may just consume on the platform by accident, and can be identified as temporary customers, which is very easy to lose.

The core customer churn rate is the lowest, indicating that such customers have the highest loyalty to the company and stronger customer stickiness. The difference between the churn rate of important customers and core customers is 6.46%, and the difference between the churn rate of important development customers and important customers is 4.06%, indicating that the difference in churn rate between them is relatively stable, but the churn rate of general customers is more important. The churn rate of development customers has increased by 43.47%, which makes managers see the fundamental difference between general customers and the other three types of customers, and reminds managers to give up properly and invest more energy in this part of customers.

Build two prediction models (Model A and Model B) based on RF-XGBoost. Among them, the training of model A is mainly through the pre-processed data; Model B uses the original data set for training. See Fig. 4 for the training iteration process. For the accuracy rate and loss curve, the curve of model A is relatively stable, while model B has large fluctuations. It shows that data preprocessing can improve the stability of the model and prediction accuracy.

TABLE I. CUSTOMER CHURN RATE OF CUSTOMER SEGMENTS

/	Customer volume	The number of customers lost	Loss rate
Core customers	23975	8983	37.47%
Key customers	24316	10683	43.93%
Important development customers	26812	12865	47.99%
General customers	46705	42723	91.46%

Fig. 4. Data preprocessing effect

Fig. 5. ROC curve of four models

The prediction models are built based on RF-XGBoost, RF, XGBoost, and ID3 decision trees, which are represented as models 1 to 4 respectively. The performance of the built multiple models is evaluated by the receiver operating characteristic curve (ROC), as shown in Fig. 5. The results showed that model 1 had the largest AUC value, significantly exceeding the other three models. It shows that the performance of the model proposed in this study is better than several traditional prediction models, so it has high practicality and can provide accurate and scientific data support for enterprise customer churn management.

The training results of each model are compared as shown in Fig. 6. The number of iterations required for Model 1 to reach the best accuracy is 45, which is significantly less than the other three models. After iteration to the best accuracy, the error is 0.08, which is the best among all models. Therefore, the proposed model has better convergence and training effects, which is better than the other three models.

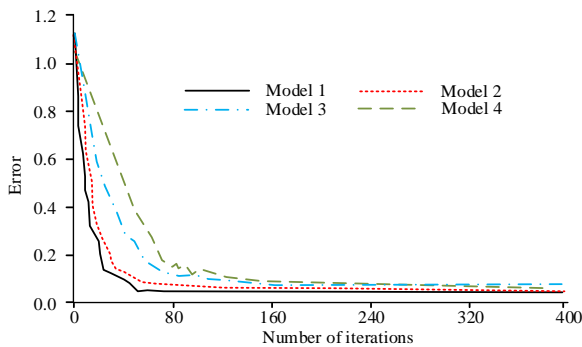

Fig. 6. Training results of each model

TABLE II. PERFORMANCE TEST RESULTS OF FOUR MODELS

Model	Index			
	Accuracy / %	Recall / %	F1	Detection time / s
1	92.15	0.93	0.91	12.7
2	85.34	0.89	0.84	33.5
3	86.19	0.87	0.82	48.3
4	83.48	0.80	0.76	36.9

Test sets are used to test the performance of each model, as shown in Table II. For the accuracy rate, Model 1 has the highest prediction accuracy, reaching 92.15%. For the recall rate, Model 1 has the highest recall rate, reaching 0.93. For the F1 value, model 1 is the highest, reaching 0.91. In addition, the prediction time of model 1 is the shortest, 12.7s.

Further, we analyze the changes of F1 indicators and prediction accuracy of the four models in the iterative process, and the results are shown in Fig. 7. In Fig. 7 (a), after 300 iterations of model 1, the value of F1 reaches the maximum, and the value of F1 in the whole iteration process also remains optimal. In all models, this study proposes that the value of F1 in the model is optimal. In Fig. 7 (b), the accuracy of all models will decrease with the increase of test data. On the whole, no matter whether the number of samples increases or decreases, the prediction accuracy of model 1 is the best. It is said that the model proposed in this study has excellent prediction accuracy, which can accurately predict customer churn based on user data, thus guiding e-commerce enterprises to Equatointe customer maintenance plans.

Divide the selected test set data into 25 pieces, test the four models respectively, and compare the average error between various models and the real output results. After 25 tests on four models, see Fig. 8. The average output error of model 1 is 0.42, which is the lowest among all comparison models, suggesting that the model proposed in this study has a smaller error and higher accuracy.

V. CONCLUSION

The prediction model proposed in this study has excellent performance, including prediction accuracy, stability, and convergence. It can make a rough assessment of customer churn, thus providing data support for e-commerce enterprises' customer maintenance work, helping to analyze the relevant factors affecting customer churn, to Equatiente targeted customer service programs, thus improving the enterprise's revenue.

In view of the importance of the model proposed in this study to other models in the application process, the ROC curve is selected for comparative study of model performance. It can be seen from the Fig. 9 that the AUC area of the optimized model proposed in this experiment is larger than that of the non-optimized model, which can significantly improve the accuracy of the method.

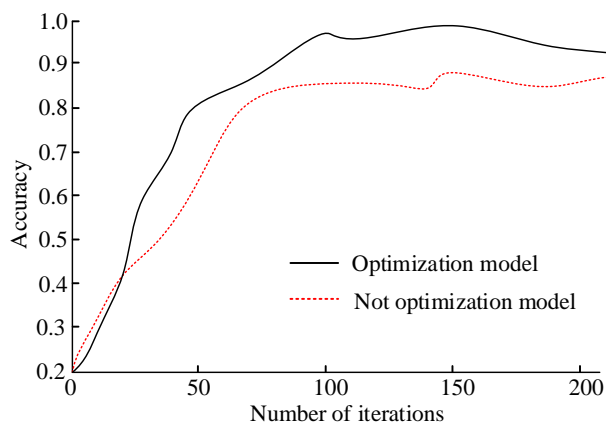

Fig. 9. Performance comparison between different models

For e-commerce enterprises, they must face fierce competition for customer resources from other enterprises. While enterprises that fail in the competition will be eliminated from the market. This research takes e-commerce enterprise customers as the research object, analyzes the relevant behavioral data recorded by the background when customers purchase online, subdivides them according to customer value, combines the distributed gradient enhancement library algorithm (XGBoost) with the random forest algorithm (RF), and constructs a big data analysis model for e-commerce customer churn. The results show that the AUC value of model 1 is the largest, which shows that the performance of the model proposed in this study is significantly better than several traditional prediction models, so it has high practicality and can provide accurate and scientific data support for enterprise customer churn management. The number of iterations required for Model 1 to reach the best accuracy is 45, which is significantly less than the other three models. After iteration to the best accuracy, the error is 0.08, which is the best among all models. Therefore, the proposed model has better convergence and better training effect. For the accuracy rate, Model 1 has the highest prediction accuracy, reaching 92.15%; for the recall rate, Model 1 has the highest recall rate, reaching 0.93; For F1 value, model 1 is the highest, reaching 0.91; In addition, the prediction time of model 1 is the shortest, 12.7s. After 300 iterations of model 1, the value of F1 reaches the maximum, and the value of F1 in the whole iteration process also remains optimal. In all models, this study proposes that the value of F1 in the model is optimal. The prediction accuracy of model 1 is the best, indicating that the model proposed in this study has excellent prediction accuracy. Since the data obtained in this study are preliminary data of e-commerce customers, deeper

customer behavior data such as evaluation, sharing, return and exchange cannot be obtained, which leads to the too one-sided prediction of customer behavior. We will try to get more customer behavior data.
