Editorial Preface

From the Desk of Managing Editor...

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Kohei Arai

Editorial Board

Editor-in-Chief

Dr. Kohei Arai - Saga University

Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation

Associate Editors

Alaa Sheta

Southern Connecticut State University

Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems

Domenico Ciuonzo

University of Naples, Federico II, Italy

Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things

Dorota Kaminska

Lodz University of Technology

Domain of Research: Artificial Intelligence, Virtual Reality

Elena Scutelnicu

"Dunarea de Jos" University of Galati

Domain of Research: e-Learning, e-Learning Tools, Simulation

In Soo Lee

Kyungpook National University

Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning

Krassen Stefanov

Professor at Sofia University St. Kliment Ohridski

Domain of Research: e-Learning, Agents and Multi-agent Systems, Artificial Intelligence, e-Learning Tools, Educational Systems Design

Renato De Leone

Università di Camerino

Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming

Xiao-Zhi Gao

University of Eastern Finland

Domain of Research: Artificial Intelligence, Genetic Algorithms

CONTENTS

Paper 1: A Two-Step Approach to Weighted Bipartite Link Recommendations

Authors: Nathan Ma

PAGE 1 – 5

Paper 2: Hyperspectral Image Segmentation using End-to-End CNN Architecture with built-in Feature Compressor for UAV Systems

Authors: Muhammad Bilal, Khalid Munawar, Muhammad Shafique Shaikh, Ubaid M. Al-Saggaf, Belkacem Kada

PAGE 6 – 13

Paper 3: Design of Personalized VR Short Video Content Distribution Algorithm based on Artificial Neural Network

Authors: Han Zhong, Donghyuk Choi, Wonho Choi, Yu Zheng

PAGE 14 – 21

Paper 4: Modeling and Simulation of a Blockchain Consensus for IoT Node Data Validation

Authors: Bismark Tei Asare, Laurent Nana, Kester Quist-Aphetsi

PAGE 22 – 31

Paper 5: Microcontrollers Programming Framework based on a V-like Programming Language

Authors: Fernando Martínez Santa, Santiago Orjuela Rivera, Fredy H. Martínez Sarmiento

PAGE 32 – 39

Paper 6: Advantages of Digital Transformation Models and Frameworks for Business: A Systematic Literature Review

Authors: Seyedali Aghamiri, John Karima, Nadire Cavus

PAGE 40 – 47

Paper 7: Dynamic Time Warping Features Extraction Design for Quranic Syllable-based Harakaat Assessment

Authors: Noraimi Shafie, Azizul Azizan, Mohamad Zulkefli Adam, Hafiza Abas, Yusnaidi Md Yusof, Nor Azurati Ahmad

PAGE 48 – 54

Paper 8: A Novel Method for Recognizing Traffic Signs using Color and Texture Properties using the ELM Algorithm

Authors: Xiaoda Cao

PAGE 55 – 62

Paper 9: Global Pattern Feedforward Neural Network Structure with Bacterial Foraging Optimization towards Medicinal Plant Leaf Identification and Classification

Authors: Sapna R, S N Sheshappa, P Vijayakarhik, S Pravinth Raja

PAGE 63 – 70

Paper 10: Predicting Employee Turnover in IT Industries using Correlation and Chi-Square Visualization

Authors: Bagus Priambodo, Yuwan Jumaryadi, Sarwati Rahayu, Nur Ani, Anita Ratnasari, Umniy Salamah, Zico Pratama Putra, Muhamad Olong

PAGE 71 – 75

Paper 11: Arabic Location Named Entity Recognition for Tweets using a Deep Learning Approach

Authors: Bedour Swayelh Alzaidi, Yoosef Abushark, Asif Irshad Khan

PAGE 76 – 83

Paper 12: Low Complexity Classification of Thermophilic Protein using One Hot Encoding as Protein Representation

Authors: Mereditha Susanty, Rukman Hertadi, Ayu Purwarianti, Tati Latifah Erawati Rajab

PAGE 84 – 89

Paper 13: Comparison of Naive Bayes and SVM Classification in Grid-Search Hyperparameter Tuned and Non-Hyperparameter Tuned Healthcare Stock Market Sentiment Analysis

Authors: KaiSiang Chong, Nathar Shah

PAGE 90 – 94

Paper 14: Intrusion Detection System using Long Short Term Memory Classification, Artificial Raindrop Algorithm and Harmony Search Algorithm

Authors: Meghana G Raj, Santosh Kumar Pani

PAGE 95 – 103

Paper 15: Social Media Multimodal Information Analysis based on the BiLSTM-Attention-CNN-XGBoost Ensemble Neural Network

Authors: Ling Jixian, An Gang, Su Zhihao, Song Xiaoqiang

PAGE 104 – 111

Paper 16: Design of Human-Computer Interaction Product Interface of Intelligent Service System based on User Experience

Authors: Xiaoli Xiong, Yongguang Hou

PAGE 112 – 121

Paper 17: Age Estimation on Human Face Image Using Support Vector Regression and Texture-Based Features

Authors: Jesy S Amelia, Wahyono

PAGE 122 – 129

Paper 18: A Fast and Effective Method for Intrusion Detection using Multi-Layered Deep Learning Networks

Authors: A. Srikrishnan, Arun Raaza, Ebenezer Abishek. B, V. Rajendran, M. Anand, S. Gopalakrishnan, Meena. M

PAGE 130 – 142

Paper 19: Footwear Sketches Colorization Method based on Generative Adversarial Network

Authors: Xin Li, Yihang Zhang

PAGE 143 – 149

Paper 20: Multi-Exposure Image Fusion based on Window Segmentation and a Laplacian Pyramid for Chip Package Appearance Quality Detection

Authors: Fei Hao, Jiatong Song, Jiahao Sun, Yang Fu

PAGE 150 – 157

Paper 21: Image Matting using Neural Networks

Authors: Nrupatunga J, Swarnalatha K S

PAGE 158 – 162

Paper 22: New Text Steganography Technique based on Multilayer Encoding with Format-Preserving Encryption and Huffman Coding

Authors: Mohammed Abdul Majeed, Rossilawati Sulaiman, Zarina Shukur

PAGE 163 – 172

Paper 23: Secure Palmprint Recognition based on Multispectral Sequential Capture

Authors: Amine AMRAOUI, Mounir AIT KERROUM, Youssef FAKHRI

PAGE 173 – 185

Paper 24: Combining the Characteristics of the Buddha Statue from Photogrammetry and 3D Creation to Simulate the Combination of the Art of Creating Buddha Statue

Authors: Jirawat Sookkaew, Nakarin Chaikaew

PAGE 186 – 191

Paper 25: Hardware Trojan Detection based on Testability Measures in Gate Level Netlists using Machine Learning

Authors: Thejaswini P, Anu H, Aravind H S, D Mahesh Kumar, Syed Asif, Thirumalesh B, Pooja C A, Pavan G R

PAGE 192 – 200

Paper 26: Multi-Objective Optimal Path Planning for Autonomous Robots with Moving Obstacles Avoidance in Dynamic Environments

Authors: Kadari Neeraja, G Narsimha

PAGE 201 – 210

Paper 27: Eye-Vision Net: Cataract Detection and Classification in Retinal and Slit Lamp Images using Deep Network

Authors: Binju Sajju, Rajesh R

PAGE 211 – 221

Paper 28: Fast Comprehensive Secret Sharing using Naive Image Compression

Authors: Heri Prasetyo, Kukul Caezaocta Prayuda

PAGE 222 – 229

Paper 29: The Effect of Blockchain using Big data and the Internet of Things in Healthcare

Authors: Bassant Nabil Mohamed, Hatem Abdelkader

PAGE 230 – 238

Paper 30: Multi Oral Disease Classification from Panoramic Radiograph using Transfer Learning and XGBoost

Authors: Priyanka Jaiswal, Vijay Katkar, S. G. Bhirud

PAGE 239 – 249

Paper 31: Dilated Multi-Activation Autoencoder to Improve the Performance of Sound Separation Mechanisms

Authors: Ghada Dahy, Mohammed A. A. Refaey, Reda Alkhoribi, M. Shoman

PAGE 250 – 257

Paper 32: A Machine Learning Ensemble Classifier for Prediction of Brain Strokes

Authors: Samaa A. Mostafa, Doaa S. Elzanfaly, Ahmed E. Yakoub

PAGE 258 – 266

Paper 33: Feedforward Deep Learning Optimizer-based RNA-Seq Women's cancers Detection with a hybrid Classification Models for Biomarker Discovery

Authors: Waleed Mahmoud Ead, Marwa Abouelkhir Abdelazim, Mona Mohamed Nasr

PAGE 267 – 276

Paper 34: Transfer Learning for Closed Domain Question Answering in COVID-19

Authors: Nur Rachmawati, Evi Yulianti

PAGE 277 – 285

Paper 35: A Cascaded Feature Extraction for Diagnosis of Ovarian Cancer in CT Images

Authors: Arathi B, Shanthini A

PAGE 286 – 294

Paper 36: Big Data and Internet of Things Web Service Management to Support Salt Agriculture Automation

Authors: Muhammad Choirul Imam, Dedi Trisnawarman, Hugeng, Hetty Karunia Tunjung Sari

PAGE 295 – 300

Paper 37: Recognition of Copy Move Forgeries in Digital Images using Hybrid Optimization and Convolutional Neural Network Algorithm

Authors: Anna Gustina Zainal, Chamandeep Kaur, Mohammed Saleh Al Ansari, Ricardo Fernando Cosio Borda, A. Nageswaran, Rasha M. Abd El-Aziz

PAGE 301 – 311

Paper 38: Event Detection and Classification Using Deep Compressed Convolutional Neural Network

Authors: K. Swapnika, D. Vasumathi

PAGE 312 – 322

Paper 39: Estimation of Transmission Rate and Recovery Rate of SIR Pandemic Model Using Kalman Filter

Authors: Wahyu Sukestyastama Putra, Afrig Aminuddin, Ibnu Hadi Purwanto, Rakhma Shafrida Kurnia, Ika Asti Astuti

PAGE 323 – 328

Paper 40: Tracking The Sensitivity of The Learning Models Toward Exact and Near Duplicates

Authors: Menna Ibrahim Gabr, Yehia Helmy, Doaa S. Elzanfaly

PAGE 329 – 338

Paper 41: A Hybrid Optimization Approach with Deep Learning Technique for the Classification of Dental Caries

Authors: Riddhi Chawla, Konda Hari Krishna, Araddhana Arvind Deshmukh, K. V. Daya Sagar, Mohammed Saleh Al Ansari, Ahmed I. Taloba

PAGE 339 – 347

Paper 42: FDeep: A Fog-based Intrusion Detection System for Smart Home using Deep Learning

Authors: Tahani Gazdar

PAGE 348 – 355

Paper 43: A Novel Approach to Cashew Nut Detection in Packaging and Quality Inspection Lines

Authors: Van-Hung Pham, Ngoc-Khoat Nguyen, Van-Minh Pham

PAGE 356 – 361

Paper 44: Improvement Classification Approach in Tomato Leaf Disease using Modified Visual Geometry Group (VGG)-InceptionV3

Authors: Jiraporn Thomkaew, Sarun Intakosum

PAGE 362 – 370

Paper 45: Deep Neural Network Training and Testing Datasets for License Plate Recognition

Authors: Ishiaq Rasool Khan, Saleh M. Alshomrani, Muhammad Murtaza Khan, Susanto Rahardja

PAGE 371 – 379

Paper 46: Prediction of Oil Production through Linear Regression Model and Big Data Tools

Authors: Rehab Alharbi, Nojood Alageel, Maryam Alsayil, Rahaf Alharbi, A'aeshah Alhakamy

PAGE 380 – 387

Paper 47: A Comparison of Pathfinding Algorithm for Code Optimization on Grid Maps

Authors: Azyan Yusra Kapi, Mohd Shahrizal Sunar, Zeyad Abd Algfoor

PAGE 388 – 393

Paper 48: Integrating User Reviews and Issue Reports of Mobile Apps for Change Requests Detection

Authors: Laila Al-Safoury, Akram Salah, Soha Makady

PAGE 394 – 401

Paper 49: Research on Quantitative Security Protection Technology of Distribution Automation Nodes based on Attack Tree

Authors: Yinfeng Han, Yong Tang, Xiaoping Kang, Hao Jiang, Xiaoyang Song

PAGE 402 – 409

Paper 50: Analysis and Detection of Tomatoes Quality using Machine Learning Algorithm and Image Processing

Authors: Haichun Zuo

PAGE 410 – 419

Paper 51: Electricity Theft Detection using Machine Learning

Authors: Ivan Petrlík, Pedro Lezama, Ciro Rodriguez, Ricardo Inquilla, Julissa Elizabeth Reyna-González, Roberto Esparza

PAGE 420 – 425

Paper 52: Machine Learning for Securing Traffic in Computer Networks

Authors: Ahmed BaniMustafa, Mahmoud Baklizi, Khalaf Khatatneh

PAGE 426 – 435

Paper 53: Fish Detection in Seagrass Ecosystem using Masked-Otsu in HSV Color Space

Authors: Sri Dianing Asri, Indra Jaya, Agus Buono, Sony Hartono Wijaya

PAGE 436 – 440

Paper 54: Prioritizing the Factors Affecting the Application of Industry 4.0 Technology in Electrical Appliance Manufacturing using a Fuzzy Analytical Network Process Approach

Authors: Apiwat Krommuang, Atchari Krommuang

PAGE 441 – 453

Paper 55: The Prediction of Pediatric Outpatient No-Show Visits by Employing Machine Learning Framework

Authors: Abdulwahhab Alshammari, Hanoof Alaboodi, Riyad Alshammari

PAGE 454 – 458

Paper 56: Principal Component Analysis Based Hybrid Speckle Noise Reduction Technique for Medical Ultrasound Imaging

Authors: Yasser M. Kadah, Ahmed F. Elnokrashy, Ubaid M. Alsaggaf, Abou-Bakr M. Youssef

A Two-Step Approach to Weighted Bipartite Link Recommendations

Nathan Ma

Adlai E. Stevenson High School Lincolnshire, Illinois, 60069, USA

Abstract—Many real-world person-person or person-product relationships can be modeled graphically. Specifically, bipartite graphs are especially useful when modeling scenarios involving two disjoint groups. As a result, existing papers have utilized bipartite graphs to address the classical link recommendation problem. Applying the principle of bipartite graphs, this research presents a modified approach to this problem which employs a two-step algorithm for making recommendations that accounts for the frequency and similarity between common edges. Implemented in Python, the new approach was tested using bipartite data from Epinions and Movielens data sources. The findings showed that it improved the baseline results, performing within an estimated error of 14 per cent. This two-step algorithm produced promising findings, and can be refined to generate recommendations with even greater accuracy.

Keywords—Bipartite graph; weighted graph; link prediction; two-step algorithm; information retrieval

I. INTRODUCTION

Bipartite graphs [1] are graphs that can be split into two sets of vertices such that, within each set, there are no edges. Edges only exist between the vertices of opposite sets. See Fig. 1, for an example of a bipartite graph. Within a weighted bipartite graph, each edge is also given a weight. Weighted bipartite graphs [2] can be used to model a multitude of real-world relationships such as the product-customer relationship. In this scenario, the weighted edges represent how a customer has rated a product.

This research focused on examining the link prediction problem in the context of weighted bipartite graphs. Though not solely limited to weighted bipartite graphs, the link prediction problem [3] takes in an arbitrary graph network and predicts the possibility of an edge between unpaired vertices. When applied to weighted bipartite graphs, the link prediction problem predicts the weight between unpaired vertices based on the input graph network.

Weighted link prediction has broad applications. For example, it is sometimes analogous to forecasting how customers will rate products based on a network of customer-product ratings. Many platforms, such as Amazon or YouTube, likely employ some form of weighted link prediction algorithm when recommending items to users. The applicability of link prediction can be extended beyond user-item recommendations to image recommendation systems as well [4].

In this paper, I propose an algorithm that performs weighted link recommendation in two steps, which differs from existing multi-step algorithms that utilize techniques derived from the predominant Graph Convolution Networks [5] and Graph Neural Networks [6]. In our two-step approach, the

Fig. 1. Example of an unweighted bipartite graph

confidence in a potential link occurring between two vertices based on common neighbors was first evaluated. Then, weights were determined based on the information derived from these common neighbors. This algorithm was finally tested on existing datasets that could be modeled using weighted bipartite graphs.

II. RELATED WORK

Given numerous real-world applications, prior papers have examined different approaches to link prediction using either weighted [7] or unweighted [8] bipartite graphs.

One approach to unweighted link prediction is to specifically predict internal links [9]. Internal links are defined as an unpaired top and bottom node in which a hypothetical edge between the nodes does not change the bipartite projected graph. Only internal links may be considered for potential edges because being “internally linked” means that two vertices already share some degree of common neighbors. In turn, this indicates that the two vertices are more likely to have an edge develop between them. Whether an internal link would become an actual edge may be determined from several proposed weighting functions that account for factors such as common neighbors and the overall number of neighbors. (See Fig. 2, for an example of an internal link.)

One idea used in weighted link prediction is the Pearson coefficient [10]. The Pearson coefficient does not predict edges, but determines a similarity between two nodes within the same disjoint bipartite set. Similarity is determined by first finding the set of common neighbors between the two nodes. For each of the two nodes, the weight of the edge with the common neighbor is then subtracted from the average weight of all edges extending from that node. These resulting values are multiplied, and this process is repeated for all common neighbors. A positive final value corresponds to a positive similarity and vice versa.

Fig. 2. Example of internal links within a bipartite graph (dotted red edges)

It is also important to note the difference between link prediction and link recommendation. Whereas link prediction involves finding any arbitrary connections that will occur in the future, link recommendation is more specific to the weighted bipartite graph. Instead of dealing with arbitrary connections, link recommendation identifies the most relevant connections between unpaired top and bottom nodes and calculates a weight for a hypothetical edge.

A classical approach specific to link recommendation has been collaborative filtering [11]. The principle underlying collaborative filtering is very similar to that of the Pearson coefficient; if Person A and B rate a product similarly, then Person A should rate another product more similarly to Person B than a randomly chosen person. Thus, collaborative filtering leverages the power of people with mutual interests to generate recommendations.

Collaborative filtering may be applied in many different ways such as: the use of neural networks [12] to establish deeper analysis between the user-user and user-item connections, hybrids between memory and matrix-based ideas [13], and the incorporation of time as a relevant factor in the decision making process [14] [15]. Though collaborative filtering is not the only approach to link recommendation [16], the role of similarity nevertheless plays a vital role.

Traditionally, key factors that affect recommendation algorithms include the size and density of the dataset [17]. This paper builds upon the previous work of both past link prediction and recommendation models to create an algorithm suited for recommendation.

III. METHODOLOGY

This recommendation algorithm is comprised of two steps. First, pairs of currently nonadjacent top and bottom nodes were identified for making a prediction. Second, predictions were made after selecting the pairs. Notably, a recommendation could not be made in the case of insufficient data connecting a top node and a bottom node.

Intuitively, the top nodes can be thought of as products and bottom nodes as customers. For ease of understanding, the terms “bottom node” or “customer” and “top node” or “product” are used interchangeably in this paper. Thus, the weights between the top and bottom nodes represent the ratings a customer has assigned to a product.

For each candidate pairing, let t denote the number of neighbors of the original top node, excluding the original

bottom node. Next, for each of these neighbors, let n define the number of neighbors that have at least one common top neighbor with the original bottom node. Interpreting $\frac{n}{t}$, a value close to 1 indicates that most of the customers who already purchased the candidate product have purchased items the candidate customer has already purchased. The inverse is also true. Thus, a threshold value for $\frac{n}{t}$ was defined such that all values below were classified as “insufficient” for recommendation, and all values above were classified as “sufficient” for recommendation.

This threshold is expected to vary for every dataset. Generally speaking, the threshold should be lower in datasets with a sparser distribution of edges and greater in more compact datasets. Additionally, datasets with many edges may be “sparse” if they also have many nodes.

Thus, the threshold can be given by the equation $\frac{9}{10} - \frac{4}{x+y}$, where x represents the average amount of edges for a bottom node, and y represents the average amount of edges for a top node.

This threshold was set to have a maximum value of $\frac{9}{10}$. Thus, for larger values of $x+y$, the candidate bottom node must have a common neighbor with at least 90% of candidate-top adjacent bottom nodes. The term $-\frac{4}{x+y}$ serves to compensate for smaller datasets with fewer existing edges. The constant 4 was specifically chosen to accommodate smaller datasets such as the Epinions dataset. After performing some initial testing, the constant values 1, 2, and 3 all returned few or no recommendations because the resultant threshold was too high. The constant value 4 was the first number that consistently produced recommendations.

However, this does not prevent cases where the product and customer have sufficient similarity, but have insufficient data to ascertain that level of sufficiency. For example, if the candidate top node has only one bottom neighbor besides the candidate bottom node, and the candidate bottom node has a common top neighbor with the one candidate top-adjacent bottom node, then $\frac{n}{t} = 1$. This will always yield a value above the maximum threshold set; however, this cannot be definitively determined based on a single data point. Therefore, we also required that the original bottom node and bottom nodes adjacent to the original top node have a number of common neighbors at least equal to the average number of edges of a top node.

Once the unpaired nodes with insufficient data were filtered out, we predicted the expected weight between the candidate top node and the candidate bottom node. This was achieved by returning to the bottom nodes that were neighbors of the candidate top node. For the sake of clarity, these bottom nodes were labeled as candidate top adjacent. We defined the *similarity* of one of these bottom nodes and the candidate bottom node by how closely the common neighbors were rated. In other words, the *similarity* represented how closely the preferences of two customers matched based on the products both had bought. Naturally, a higher similarity means that two customers have similar preferences, which in turn, affects the prediction positively.

Similarity was determined by comparing all products rated by both customers. For each common product, the algorithm computed the difference between the ratings assigned by the

$$\begin{cases} (\min(r_1, r_2) - a) \cdot (2 - |r_2 - r_1|) & r_1 \geq a, r_2 \geq a \\ (a - \max(r_2, r_1)) \cdot (2 - |r_2 - r_1|) & r_1 \leq a, r_2 \leq a \\ 2 - |r_2 - r_1| & r_1 \geq a, r_2 \leq a \\ 2 - |r_2 - r_1| & r_1 \leq a, r_2 \geq a \end{cases}$$

Fig. 3. Piecewise function for temporary similarity

candidate bottom and the overall average rating assigned by all of its customers. The process was repeated for the other bottom node. The differences were compared, and a temporary similarity for each common top node between the candidate top adjacent bottom node and the candidate bottom node was calculated. This was based on the absolute difference and whether the signs were the same. The piecewise function in Fig. 3 depicts the exact method employed for calculating temporary similarity (r_1 and r_2 denote the two differences; a denotes the average rating of the common top node).

After iterating through each of the common products, the temporary similarity values were averaged to determine the overall similarity between the candidate bottom node and the candidate top-neighboring bottom node.

For each bottom node neighboring the candidate top node, the algorithm computed similarity with the candidate bottom node using the aforementioned algorithm. The predicted rating p was determined by the following formula:

k represents the number of top-adjacent bottom nodes that share at least one common neighbor with the candidate bottom node. s_i represents the similarity score for the i th product-adjacent bottom node. r_i is the analogue for rating.

$$p = \frac{\sum_{n=1}^k s_i \cdot r_i}{\sum_{n=1}^k s_i}$$

IV. RESULTS

The algorithm was implemented in Python and tested using two datasets, which were obtained from the Epinions website [18] and the MovieLens website [19], respectively. Both datasets can be modeled using weighted bipartite graphs with weights ranging between 1 and 5. Users in the Epinions dataset rated products, while users in the MovieLens dataset rated movies. In both datasets, a 1 represented an utterly unsatisfactory response whereas a 5 represented an extremely satisfactory response.

After reading in the dataset, 80% of the given edges were used to train the algorithm (which provided the averages used in later calculations for similarity) and the remaining 20% of the edges were set aside to test the algorithm.

The algorithm was tested by first running through 20% of edges initially set aside. The first part of the algorithm determined whether the edge had sufficient data to make a prediction. If the edge had sufficient data, the second part of the algorithm was implemented to obtain a predicted weight.

The predicted weight was measured against the actual weight and the percent error was determined. To determine

Fig. 4. Histogram of individual error of epinions recommendations

Fig. 5. Histogram of individual error of movielens recommendations

the overall percent error of the algorithm, the average of all individual percent error values for each prediction was used.

The performance of the algorithm across both datasets is detailed in Fig. 4 and 5 and summarized in Table 1.

Comparing Fig. 4 and 5, we noted that the error in predictions from the Epinions dataset was approximately unimodal, centered between 6 and 18 percent. On the contrary, the error in predictions from the MovieLens dataset was much more right-skewed with no clear center value exhibited. The overall percent error was therefore calculated using the mean value in the Epinions dataset and the median in the MovieLens dataset.

Considering the two datasets, the overall percent error was approximately 14% which improved upon the 20% error of existing algorithms [20]. This attests to the strength of our two-step approach and encourages further exploration into similar link prediction algorithms. However, though this is a promising finding, it must be noted that each recommendation was “screened”; i.e., a recommendation was only made if sufficient data existed in the first place.

V. DISCUSSION

The two-step algorithm performed fairly well; however, outlier recommendations were notable, particularly with respect to the MovieLens dataset. Specifically, the MovieLens recommendations generated error values up to 300%. Further analysis revealed that though both datasets employed a similar 1-5 rating system and modelled a type of product-customer relationship, the most pronounced difference was that the

TABLE I. PERCENT ERROR OF EPINIONS AND MOVIELENS DATASET

Dataset	Percent Error
Epinions	13.8%
MovieLens	14.4%

MovieLens dataset contained nearly 10 times the number of entries than the Epinions dataset. This size difference may have led to greater diversity in opinions, which in turn may necessitate a different approach to the parameters.

With respect to the size of datasets, this algorithm runs in $O(n^3)$ time. Therefore, testing the algorithm on datasets containing more than approximately 100,000 entries is infeasible given the unrealistic run time required. A significant number of existing datasets contain millions of entries, which limits the scope of datasets available for testing. However, given the size of the Epinions and MovieLens datasets, both datasets may provide solid representations of a real-world product-customer relationship. However, the high time complexity is ultimately a limitation compared to other methods which were able to operate on much larger datasets.

An alternative method for calculating $\frac{n}{t}$ may also be considered. In the current algorithm, n was defined as the number of candidate bottom nodes and top-adjacent bottom nodes that share at least one common top node. However, instead of a single common top node, the two bottom nodes may be required to share at least two common top nodes, three common top nodes, or even more common top nodes.

However, it must be noted that adjusting this parameter would likely necessitate changing the $\frac{n}{t}$ threshold. Requiring a greater number of common top nodes would decrease the value of n and warrant lowering the $\frac{n}{t}$ threshold correspondingly. This makes sense as while there might be fewer pairs of sufficient bottom nodes, there would ultimately be a relatively equivalent amount of data to work with as the number of common top nodes was increased.

Additionally, other conditions can be deliberated on in which the $\frac{n}{t}$ value may be deemed sufficient enough to generate a prediction. Examining the threshold, potential edges were sometimes rejected due to insufficient data. Although the $\frac{n}{t}$ value was high enough, the value t might have been too low to instill confidence in making a prediction. However, instead of rejecting those edges outright, the threshold might have been adjusted so that it increased as the number of top-adjacent nodes decreased.

Furthermore, different functions could be explored that determine similarity between the candidate bottom node and a top-adjacent bottom node. In a manner similar to how the Pearson coefficient was calculated, the piecewise function in Fig. 3 rewards the bottom nodes for rating their common top nodes similarly. It does this by taking into account the differences between how the two bottom nodes rated the common top nodes, and how they typically rated a top node. Matching signs (positive or negative) would contribute more positively towards similarity. One could also explore the effect of slightly modifying the constants of the functions.

Finally, this result continues to highlight the value of intuitive implementation within the context of this problem [21]. This follows a recent trend within the documentation of the link prediction problem of simplifying the problem [22]. Whereas previous papers used more involved methods such as neural networks or time series to generate predictions, this algorithm obtains strong results with two intuitive steps: search and calculation.

VI. CONCLUSION

In this paper, we presented a two-step approach to the classical link recommendation problem. Extending ideas from previous papers focused on sign prediction or unweighted link prediction, the algorithm utilized the properties of the weighted bipartite graph to determine two parameters: 1) the most relevant edges that could appear based on pre-existing edges, and 2) the weights of the edges based on the idea of *similarity*.

In the first step, the algorithm considered whether the candidate bottom node had common neighbors with bottom nodes adjacent to the candidate top node. The algorithm proceeded to compare this number against the total number of bottom nodes adjacent to the candidate top node. The algorithm then further determined whether any edges considered sufficient were a result of low sample size. The exact tuning parameters were determined by the density and size of the datasets.

In the second step, the idea of *similarity* was used. Similarity between the candidate bottom node and candidate top adjacent bottom nodes was calculated by taking into account how closely common neighbors were rated. The weight of the edge between the candidate bottom node and the candidate top was more heavily influenced by higher similarity pairings and less influenced by lower similarity pairings.

This algorithm was tested using the MovieLens and Epinions datasets, and it performed well compared with existing algorithms. Further work will refine and improve the results of the proposed algorithm. In particular, future work can explore means to optimize its performance on larger datasets as well as how to fit the constant terms better for each particular datasets.

ACKNOWLEDGMENT

I would like to thank Dr. Zhiliang Xu, professor of Applied and Computational Mathematics and Statistics at the University of Notre Dame, for introducing me to this topic and providing invaluable guidance and support during the research.

Abstract—Hyperspectral image segmentation is an important task for geographical surveying. Real-time processing of this operation is especially important for sensors mounted on-board Unmanned Aerial Vehicles in the context of visual servoing, landmarks recognition and data compression for efficient storage and transmission. To this end, this paper proposes a machine learning approach for segmentation using an efficient Convolutional Neural Network (CNN) which incorporates a feature compressor and a subsequent segmentation module based on 3D convolution operations. The experimental results demonstrate that the proposed approach gives segmentation accuracy at par with conventional approaches based on Principal Component Analysis (PCA) to reduce the feature dimensionality. Moreover, the proposed network is at least 35% faster than the conventional CNN-based approaches using 3D convolutions.

Keywords—Hyperspectral images; CNN; dimensionality reduction; segmentation; PCA

I. INTRODUCTION

Remote sensing is an important field which has helped urban and rural planning as well as environmental studies. Originally initiated as a satellite-based technology, it is being fast adopted to be used via sophisticated multispectral sensors that can be installed on Unmanned Aerial Vehicles (UAV) [1]. Other than being equipped with a standard RGB camera [2], several hyperspectral imaging (HSI) sensors [3] are now being deployed on-board these platforms to serve various applications in the field of security surveillance, town management, wild fires and agriculture etc. Another important application is to supplement the on-board navigation algorithms via visual servoing [4]. The spectral information provided by HSI is extremely rich and powerful. However, this raw information has to be processed extensively. Specifically, segmentation (classification) of each spatial data point in HSI has to be performed. Overall, the spatial and spectral data points constitute an information ‘cube’ [5]. Various researchers have put forward multiple segmentation methods of hyperspectral images to this end [6]. Various open-source datasets have also been made available to facilitate the research and development in this field [7]. Conventionally, HSI

segmentation has been done through well-known machine learning methods such as Bayesian [8] distance, nearest-neighbor classification [9] and hand-coded features (e.g. Local Binary Pattern) [10] etc. Although, these methods have shown satisfactory performance on the standard datasets, recently CNN-based methods have shown exceptionally better results with near optimal segmentation [11, 12]. In this regard, ‘Indian Pines’ is a well-known HIS dataset [7] captured through Airborne Visible Infrared Imaging Spectrometer (AVIRIS) [13]. This scene (Fig. 1) consists of 145×145 pixels (spatial data points) and 224 spectral reflectance bands captured in the wavelength range [0.4 2.5] μ meters. This scene is marked by regions consisting of common agricultural land, a forest as well as wild natural vegetation. Other than this, highways, a railway line and some urban construction also exist. The ground truth (intended segmentation output) consists of sixteen classes (Table I).

Some earlier works have suggested reducing the number of spectral bands to 200 by removing bands corresponding to [104-108], [150-163], the so-called ‘water absorption bands’ to improve segmentation accuracy [14]. Moreover, it has been observed that there is a considerable spectral redundancy i.e. the observations in different spectral are highly correlated [15]. Thus, it has been found beneficial to consider dimensionality reduction through PCA before application of segmentation algorithms. Furthermore, it has been suggested to employ the spatial variations in spectral data, especially in the case of high-resolution data, to improve the segmentation accuracy. While, the former approach helps in increasing the inference time (lower computational load), the latter adds further computational complexity to the segmentation task. However, in order to improve segmentation performance, it has been proposed to use both spectral and spatial data while segmenting a particular data point [6]. Spatial information improves the segmentation accuracy because further discriminating information could be found in the texture and shape of geological structures. To illustrate this point, we have trained two classifiers on Indian Pines dataset. The results have been given in Table II.

TABLE II. REFERENCE SEGMENTATION CLASSIFIER ON INDIAN PINES DATASET

Classifier	Dimensionality	Segmentation Accuracy
SVM	220	96.0%
SVM	30	96.1%
CNN	30	99.6%

The first classifier is based on a conventional machine learning classifier, i.e. Support Vector Machine (SVM) [16]. In order to verify the strong redundancy in the spectral bands, two different versions have been trained. The first version uses all 220 hyperspectral bands (including noisy bands) while the second reduces the dimensionality of these spectral bands through PCA. PCA works by projecting the d dimensional data to m dimensional data where $m < d$.

$$\mathbf{x}_i \in \mathbb{R}^d, i = 1, 2, \dots, N$$

$$\mathbf{z}_i \in \mathbb{R}^m, i = 1, 2, \dots, N$$

The projection works by exploiting the eigen values and corresponding eigen vectors to build the transform as follows.

$$S\mathbf{u}_d = \lambda_d\mathbf{u}_d \quad (1)$$

Where S is the normalized covariance matrix of the input features, λ_d are the eigen values while \mathbf{u}_d are the corresponding eigen vectors. The transformation is then given by.

$$\mathbf{z} = \mathbf{u}_m^T \left(\frac{\mathbf{x}_i - \mu}{\sigma} \right) \quad (2)$$

As can be noticed from the data given in Table II, the segmentation accuracy with and without dimensionality reduction is almost identical with the minor difference being without any statistical significance. The accuracy results have been obtained with the provided ground truth as benchmark.

Fig. 2 shows the original first twelve bands in the Indian Pines data as well as the twelve most significant bands after PCA has been applied. It can be clearly seen that the most information is contained within the first three bands only. Thus, the dimensionality reduction through PCA is merited to facilitate the further segmentation task. However, it should be noted that PCA does not ensure that the segmentation accuracy will remain intact in all the cases.

Fig. 2. Application of PCA on HIS data from Indian Pines a) First twelve original bands b) Twelve transformed bands after PCA.

The second classifier considered in Table II is a CNN [6] classifier which also incorporates the spatial information while performing segmentation. In order to reduce the computational load, CNN has also been fed the same PCA-compressed spectral bands as for SVM classifier. It can be seen that this classifier almost achieves 100% accurate results. For both classifiers, 70% data points have been used for training while the remaining have been used for validation. Moreover, for CNN classifier, image patch size of 25×25 has been used to learn spatial information.

This approach of reducing the spectral information before applying the classifier has been considered by various early researchers [17]. The other approach of inferring spatial information before incorporating spectral data has also been considered in some works [18]. Adaptive Markov Random Fields [19] and graph cut [20] algorithms have also been considered to regularize the segmentation results in the spatial domain. Joint processing of spatial and spectral features has been considered by Zhon et al. [21] and Guijarro et al. [22]. These efforts to combine spatial and hyperspectral data to extract joint features is especially important since latent redundancy could be exploited. As noted earlier, HIS data cube hold valuable information in the local neighborhoods both with respect to spatial and spectral dimensions. However, this also presents a challenge in terms of computation complexity. This is especially relevant for on-board processing of data on battery-powered UAVs.

In contrast to the conventional machine learning models, deep learning or CNN-based approaches have been shown to be exceptionally well in exploring the data dependencies and discriminating features. Thus, several approaches have been proposed by researchers in the recent years related to this technique [23-25]. In this regard, U-Net [26-28] is of special interest because it has been successfully applied to image segmentation tasks other than HSI. However, since like other CNN-based segmentation frameworks, the computational load is a consideration for these methods, PCA is generally applied to reduce the HSI data dimensionality as shown above. However, since PCA and the subsequent CNN deep feature extraction modules are separate, the joint spatial-spectral redundant information [27, 29] may not be captured for optimal segmentation. To this end, Ying et al. [6] proposed using 3D CNN operations for HSI segmentation. 3D convolution kernels can learn the patterns found in both the spatial and the spectral dimensions of the HSI cube in local neighborhoods. This information has been shown to be of crucial value for segmentation. This structure can take the full advantage of all structural similarities within the HIS cube. 3D CNNs have shown promise in a variety of computer vision applications where the input is simple RGB images. Moreover, they have been applied to video frames to make the best use of temporal information. While using 3D CNNs for HSI segmentation, not only the pre-processing (PCA) overhead is reduced, but also the spectral and spatial features are learnt jointly. However, this presents a computational overhead since 3D convolutions are even more complicated than their 2D counterpart. In this paper, we have proposed an approach to circumvent this problem by adding an 'Encoder' stage before 3D CNNs. The 'Encoder' stage is inspired by the autoencoders

[30] which have been shown to infer even non-linear statistical dependencies. In contrast PCA can only infer linear correlations. The proposed 'Encoder' stage compresses the spectral features, just like PCA, but in tandem with the subsequent segmentation stage based on 3D CNN. In this regard, Khan et al. [31, 32] have proposed using a traditional Autoencoder for the segmentation of HIS but they do not explicitly target the improvement in the inference speed. On the other hand, the experimental results demonstrate that the proposed architecture works at par with the state of the art while being up to 35% faster.

The remaining paper has been structured as follows. Section II describes the proposed architecture in detail with respect to the inclusion of encoder section before a 2D CNN. Section III has been devoted to the provision of results of the proposed architecture on standard datasets followed by a discussion. Section IV concludes the discussion by summarizing the results and contributions of the current work.

II. PROPOSED ARCHITECTURE

Autoencoders have been extensively used in computer vision applications to learn the underlying data dependencies and have been shown to work better than PCA in the presence of non-linear structures. Autoencoders are made up of two parts i.e. encoder and decoder. The encoder finds a compressed representation of the input while the decoder replicates the input using the compressed (low dimensional) encoding. Inspired by their architecture, we propose adding only the 1D encoding stage before a 3D CNN stage for HIS cube processing. The idea is to find non-linear data dependencies in the spectral bands data which is then subsequently processed by the 3D CNN architecture to exploit spatial information as well. However, since the two modules are part of one learnable architecture, both spatial and spectral information are learnt jointly. Moreover, it is faster since the early part of the network (closer to the input) only processes the spectral dimension. In contrast the 3D CNN architecture proposed in [6] processes the whole cube starting from the input which leads to a high computational load.

The proposed architecture depicted in Fig. 3 consists of two stages as mentioned earlier. The 'Encoder' stage reduces the spectral dimension in two stages. The first stage uses 3×3 convolutions with a stride of two to reduce the dimensions from 220 to 110. The second stage uses 3×3 convolutions with a stride of four to reduce the dimensions from 110 to 27. The spatial dimensions (25×25) remain the same. Thus, at the end of the 'Encoder' stage, a $25 \times 25 \times 27$ cube is presented the 3D CNN stage for further segmentation. This network consists of four 3D convolutional layers i.e. $3 \times 3 \times 7$, $3 \times 3 \times 5$, $3 \times 3 \times 3$ and $3 \times 3 \times 1$. There are 8, 16, 32 and 8 filter kernels for these layers respectively. A 256 long vector is generated through a fully connected layer followed by another fully connected layer generating a 128 long vector. The final vector (16 output classes) is generated through another fully connected layer. Thus, the $25 \times 25 \times 220$ HSI input cube is gradually processed through convolutions to generate the final segmentations. The hallmark of this architecture, as mentioned earlier, is that the 'Encoder' stage is light-weight since it only processes the spectral data. However, despite only processing spectral data, it

is connected with the subsequent spatial processing layers as well through the forward propagation. Thus, the whole network learns spectral and spatial information jointly without being computationally complex. The proposed architecture has been implemented using the Matlab Deep Learning Toolbox and trained in the same environment using NVIDIA GeForce 940 MX GPU on a intel i7 powered CPU (3.48 GHz) with 12 GB RAM. For training and testing of the proposed architecture, Indian Pine, Salinas, SalinasA, Pavia and PaviaU datasets [7] have been used. A sample training session has been shown in Fig. 4. It can be clearly seen that the training process quickly converges for both training and validation sets. Thus, not only is the proposed architecture suitable for the task at hand but also does not overfit showing excellent harmony between spatial and spectral data points.

Fig. 4. Training of the proposed network in Matlab environment depicting fast convergence without overfitting.

III. RESULTS AND DISCUSSION

The proposed architecture has been trained and tested on Indian Pine, Salinas, SalinasA, Pavia and PaviaU datasets. The former three datasets have been captured by AVIRIS sensor with 220 bands. The latter two datasets are captured by ROSIS sensor and have 102 and 103 bands respectively. To cater for the fewer number of bands on ROSIS datasets, the first stage of the ‘Encoder’ uses 3×3 convolutions with a stride of two to reduce the dimensions from 102/103 to 50. The second stage uses 3×3 convolutions with a stride of two to reduce the dimensions from 50 to 25. The rest of the architecture remains same.

The test results have been reproduced in Table III. It can be seen that the proposed network either performs better or at par with the 3D CNN network. Moreover, it is worth mentioning that this particular network has been tuned for each dataset separately by the authors [6] while we have used the same universal architecture for all cases. Thus, the proposed architecture is universally applicable to all scenarios.

It is worth mentioning that the proposed architecture also operates faster than the competing 3D CNN architecture due to its simpler ‘Encoder’ stage. On average, the proposed network processes an HSI cube of size 145×145×220 in 7.14 s while a 3D CNN without encoder stage processes the same in 9.64 s. Thus, the proposed approach is at least 35% faster while being equally accurate.

Fig. 5 shows the reconstruction of spectral data for four example data points in Indian Pine dataset. This data has been generated by a reference Autoencoder with both ‘Encoder’ and ‘Decoder’ parts for visualization. It can be seen that the spectral information can be fairly accurately recovered even after being compressed to 27 channels from original 220 (12%). However, it must be noted that the purpose in the application at hand is not reconstruction but use in subsequent segmentation where upto 100% accuracy has been achieved on SalinasA dataset even with this much compression. Visual results using pseudocolors for segmentation results on the mentioned datasets have been depicted in Fig. 6, Fig. 7, Fig. 8 and Fig. 9 respectively.

TABLE III. SEGMENTATION ACCURACY ON TEST DATASETS

Architecture	Indian Pine	Salinas	SalinasA	Pavia	PaviaU
3D CNN [6]	99.07%	-	-	-	99.4%
Proposed	99.6%	94.3%	100%	98.0%	98.3%

IV. CONCLUSION

This paper has proposed a 3D convolution-based segmentation architecture for hyperspectral images. The proposed architecture achieves detection accuracy at-par with the state-of-the-art with the added benefit that it achieves up to 35% higher speed due to a feature compressor module at the input. Moreover, this module works almost as good as conventional PCA in compressing the spectral information while being trained in tandem with the spatial data. Thus, the network has the ability to jointly learn spatial and spectral information. In conclusion, the proposed architecture provides a better alternative than both PCA-CNN and 3D-CNN architectures, combining the best of both approaches in terms of computational speed, learning flexibility and segmentation accuracy. For future work, the proposed technique could be applied to HS images from more satellite imagers to test the generalization of the approach.

Abstract—In order to improve the video quality, reduce the number of video jams, and improve the video transcoding rate, a new personalized distribution algorithm of VR short video content based on artificial neural network is proposed. BP neural network is used to compress the original video and determine the execution mode and cache location of VR short video cache file; Transcoding cached high bit rate VR short video stream to generate low bit rate video stream to meet the needs of different network bandwidth; Build a video distribution model, and build a multicast distribution tree based on this model, that is, add some relay servers to minimize the video distribution cost; Finally, through the algorithm of minimizing the distribution cost of VR short video, the bandwidth loss and response delay are effectively reduced to achieve the goal of minimizing the distribution cost. The experimental results show that the video blocking times of this method are always less than six times, which effectively reduces the video blocking times. The PSNR value is high, the increase is large, up to 0.5, and the video transcoding rate is improved, up to 92%.

I. INTRODUCTION

With the rapid development of network information technology, people rely more and more on the Internet and smart phones for entertainment. The emergence of various short video applications has met the needs of users for fragmented reading, social interaction and personalized expression, but problems have also arisen [1, 2]. At present, the short video industry is still in the rapid development stage. In view of the current situation of the industry environment, it is necessary to analyze the environment of the short video distribution platform to provide a reference solution to the problem. Traditional wireless network access and transmission modes are single, and usually rely on network infrastructure such as base stations and core networks to provide services. Once network congestion or force majeure occurs, users will not be able to obtain corresponding services [3, 4]. In this context, the growing user demand for content services and the limited network carrying capacity have become the main contradiction restricting the development of video. In order to meet the requirements of high quality and low latency for the development of short video, and reduce the network load at the

same time, it is important to study the personalized distribution method of short video content.

II. LITERATURE REVIEW

Literature [5] proposed an online short video content distribution method based on federated learning. First, based on the federated learning method, the user group interest vector prediction algorithm is proposed by training the interest prediction model using the user group's local album data, and the user group interest vector representation is obtained; Then, with the user group's interest vector as the input, the corresponding short video content distribution strategy is designed in real time based on the combined confidence upper bound algorithm. The experimental results show that the short video content distribution strategy can effectively improve the accuracy of short video distribution, and help to improve the profits of video content providers. Literature [6] proposed a video distribution method based on QoE awareness. According to the characteristics of optical wireless fusion network structure, considering link state information and scalable video coding structure, a QoE evaluation model was established. Particle swarm optimization algorithm is used to select the optimal video transmission rate, and then analyze the node transmission capacity and node matching degree, so as to select the transmission path for the service and ensure the reliable transmission of the service. The experimental results show that this method can effectively improve the utilization of network resources and reduce network congestion while enhancing the quality of user experience. Literature [7] proposed a video distribution method based on random linear network coding. The source node uses RLNC to segment the video files to be distributed, and the encoded data pieces are distributed to mobile devices on the road. After receiving the data slice, each mobile device will re encode and distribute it to other devices. When the device receives a certain amount of linearly independent data, it will decode the data slice to obtain the original data. Three strategies are designed: mode switching, wireless access point selection, and active re coding to reduce the delay of video distribution. Experimental results show that this method has higher distribution efficiency.

From the above analysis, we can see that the existing methods improve the video distribution effect to a certain extent. In order to further improve the video quality, reduce the

*Corresponding Author.

number of video blocks, and improve the video transcoding rate, this paper proposes a personalized VR short video content distribution algorithm based on artificial neural network. The main research contents of this method are as follows:

- 1) Solve the problem of VR short video cache reuse by reasonably deploying and placing VR short video files.
- 2) The drift error adaptive fast video transcoder transcodes the buffered high bit rate VR short video stream to generate a low bit rate video stream to meet the needs of different network bandwidth.
- 3) Improve the video distribution model, generate a multicast distribution tree, and conduct personalized distribution of VR short video content to effectively reduce bandwidth loss and response delay, so as to minimize the distribution cost.

III. VR SHORT VIDEO PREPROCESSING

A. Video Compression

In recent years, with the development of artificial neural network theory and technology, its application in video compression has gradually attracted people's attention. Compared with some traditional compression methods, the artificial neural network technology [8, 9] has good fault tolerance, self-organization and adaptability. Therefore, it is not necessary to use some predetermined data coding algorithm in the video compression process, but can independently complete the video compression completely according to the information characteristics of the video itself. BP neural network [10] is a typical and commonly used network structure in artificial neural network. This paper mainly introduces a video compression method based on BP neural network.

BP neural network refers to a multilayer feedforward network using BP algorithm. Fig. 1 is a simple feedforward network, which consists of an input layer, an output layer and a

hidden layer (middle layer). Where, w_{zh} and w_{vh} are the weighted values between the input layer and the intermediate layer (hidden layer), hidden layer and output layer respectively. The neurons in the hidden layer and the output layer first sum the input signals of the previous layer by weighting, and then perform the pre specified transformation to generate the output signals. The output of the hidden layer neurons is also connected to the output layer neurons by weighting.

Let the input vector of the network be $Z = \{z_1, z_2, \dots, z_n\}$, where n represents the number of neurons in the input layer. The transformation function adopted by neurons is:

$$D(n) = 1 + \frac{1}{\exp(w_{zh} - w_{vh})} \quad (1)$$

Fig. 1. Multilayer forward network.

The output vector corresponding to Z is $V = \{v_1, v_2, \dots, v_m\}$, where m represents the number of neurons in the output layer. If the expected output of the network is required to be $F = \{f_1, f_2, \dots, f_m\}$, the error function can be defined as:

$$E(n) = \sum_{i,j=1}^m (f_{ij} - v_{ij})^2 \quad (2)$$

In the formula, f_{ij} represents the network training speed; v_{ij} represents the network convergence rate.

The BP algorithm uses the gradient descent method to adjust the network weight to reduce the above error function, namely:

$$\eta(n+1) = \eta(n) - \alpha \frac{E(n)}{\lambda(\eta)} \quad (3)$$

In the formula, $\eta(n)$ represents the approximation error of the neural network; $E(n)$ represents the difference function between the actual output and the expected output; $\lambda(\eta)$ represents generalization capability of neural network; α represents the weight adjustment rate, usually $0.01 \leq \alpha \leq 1$.

The general weight adjustment formula is:

$$\Delta \alpha = \sum_{i=1}^m E_{ij} |G_{ij} - H_v| \quad (4)$$

In the formula, G_{ij} represents the weight correction from the i -th node of a layer to the j -th node of the next layer; H_v represents the output of the node; E_{ij} represents the endpoint equivalent error of node i and node j , which is equivalent back transmitted from the error of the output layer:

$$\eta_v = \Delta\alpha(v_i - f_i) \quad (5)$$

In the formula, v_i represents that node i is located in the output layer; f_i represents that node i is in hidden layer.

For a VR short video with N frame, when BP neural network is used for compression, the number of neurons in the input and output layers of the network is required to be n^2 , while the number of neurons in the hidden layer is much less than that in the input layer. When VR short video is transmitted in the network, the state of each neuron in the hidden layer, as some transformation result of the input information, must contain some information of the original VR short video. Therefore, when the output unit can reproduce the original VR short video, it can be considered that the output of hidden layer neurons is the compression result of the original input VR short video. Fig. 2 describes the VR short video compression process [11].

B. Video Cache

This section will focus on solving the problem of VR short video, and solve the problem of VR short video cache reuse by reasonably deploying and placing VR short video files. After the VR short video compression is completed in Section 2.1, determine the execution mode of the VR short video cache file and whether the cache location is appropriate [12].

Suppose user videos are stored in K clusters, $K = \{k_1^1, k_2^1, \dots, k_L^1, \dots, k_1^r, k_2^r, \dots, k_L^r\}$, where k_l^i represents

the VR short video file l stored in user cache k^i . Update VR short video files and store them in each blank cache. Among them, cluster member k_l^i only stores some files in the VR short video library. Due to storage restrictions, these files cannot contain all VR short video files. Therefore, it is expected to deploy more file contents in k_l^i and cache and reuse them.

For each cluster, selecting the video file to update is also an important issue. In each cluster, cluster file library L_p represents all video file records in the cluster, and $L_p = z_1 \cup z_2, \dots, \cup z_l$ represents an independent cluster popularity distribution. On this basis, collect the VR short video file statistics cached by the whole cluster members in the cluster, and then update the missing videos. It is not difficult to find out which VR short video files are missing in the cluster according to the VR short video file statistics [13].

At the same time, considering the problem of video storage capacity, the storage formula of VR short video files is expressed as:

$$V_f = Z \subseteq C_m, m = 1, 2, \dots, M \quad (6)$$

Among them, the maximum possibility of updating the number of VR short video files is as follows:

$$\mu_{\max} = M - C_m \quad (7)$$

Therefore, to update the VR short video file library L_p , assume that each file requested to be updated is equal to:

$$\phi_{L_p} = \{p \notin L_p, \mu_{\max} \leq M\} \quad (8)$$

Fig. 2. VR short video compression process.

In the video cache, the most popular VR short video file ϕ_{L_p} , which is not in the original cluster, may be selected to offset the request. At the same time, a popular VR short video file is arranged and stored in the cluster head and the cluster center to facilitate user access and make the user's viewing experience better and smoother. And through constant iteration and change, users can obtain the latest VR short video information without requiring additional micro cache or auxiliary devices to simplify VR short video cache.

C. Video Transcoding

It is one of the most important applications of VR short video transcoding to generate low bit rate video streams to meet the needs of different network bandwidth [14]. Generally, the simplest and most direct way to realize VR short video transcoding is to use the so-called full decoding and full encoding scheme, that is, first decode the encoded video stream to generate a video sequence, and then re encode them to generate a new video stream. Because the recoding process requires a very complex motion estimation and mode selection process, this scheme is difficult to achieve real-time video transcoding, which greatly limits the practical application of this scheme.

To solve these problems, researchers have proposed various video transcoding structures, among which the most influential are the so-called open loop structure and closed loop structure. The open loop structure and the closed loop structure completely reuse the macroblock mode and motion vector information in the original bitstream, so there is no need for high complexity motion estimation and mode selection. Among them, the open-loop structure can directly transcode in the compressed domain (DCT domain) [15]. The transcoding speed is very fast, but due to the existence of drift error, the transcoded video frames are seriously distorted. The closed-loop structure introduces a closed loop in the encoding part to eliminate drift error, which basically eliminates the impact of drift error on the video quality after transcoding. However, the introduction of a closed loop also increases the complexity of the transcoder, making the speed of the closed-loop structure lower than that of the open loop structure. To solve these problems, this paper designs a fast video transcoder with drift error adaptive.

The closed loop for eliminating drift error in the closed-loop video transcoder can be divided into two parts, in which the part before the error buffer input completes the accumulation of drift error; the part after the error buffer output completes the drift error compensation. Suppose Y is the DCT coefficient obtained by decoding in the original code stream, and W is the DCT coefficient obtained by error compensation operation. The new quantized DCT coefficient T obtained by quantization operation is obtained as follows:

$$T = \frac{(Y+W)^2}{Q^2} \tag{9}$$

In the formula, Q^2 represents quantization operation. If $0 \leq |Y+W| < Q^2$, then the non-zero error W does not affect the value of T . Therefore, if a threshold θ is given in advance, the error compensation operation can be determined according to the size of error W and threshold θ . Based on this idea, this paper proposes the working principle of the drift error adaptive fast video transcoder as shown in Fig. 3 [16]. For VR short video stream, there are three different types of coded video frames (A frame, B frame and C frame). The transcoder of this structure operates as follows:

- 1) The current transcoding video is A frame: no error compensation operation is required, but error accumulation operation is required.
- 2) The current transcoding video is a B frame: error compensation and error accumulation operations are required, but error compensation for B frame is performed in blocks.
- 3) The current transcoding video is C frame: in order to speed up the transcoder, C frame requires neither error compensation nor error accumulation.

Fig. 3. Working principle diagram of video transcoder.

IV. VR SHORT VIDEO DISTRIBUTION ALGORITHM CONSIDERING COST OPTIMIZATION

The development of video applications has put forward higher requirements for video distribution in terms of real-time, mobility and interactivity. How to efficiently distribute video, alleviate the contradiction between bandwidth pressure and response delay, and reduce the cost of video distribution has become a difficult and hot spot in video distribution application research. Based on the above video compression, video caching and video transcoding results, this section proposes a cost optimized VR short video distribution method. This method can effectively reduce the bandwidth loss and response delay, thus minimizing the allocation cost. In the process of video distribution, a multicast distribution tree is built to realize the communication and video distribution between the source server and the proxy server.

A. Video Distribution Model

In the VR short video distribution framework, it mainly includes source server, proxy server and relay server. This article assumes that the source server stores all video streaming media, and each proxy server manages at least one area. Users can request and download videos from proxies that are closer to them. In order to meet the needs of users, a VR short video distribution method combining active distribution and passive distribution is adopted. The VR short video distribution model is shown in Fig. 4.

In Fig. 4: 0 represents the source server, 1 represents the relay server, 2 represents the request server, and 3 and 4 represent the proxy server. The directed bold line segment in the figure represents the VR short video distribution process; the directed virtual line segment represents the process that the proxy server sends a request to the source server when there is no video requested by the user; the black directed solid line represents the distribution link.

As shown in Fig. 4, when a user sends a video streaming media request to the local proxy server, the source server quantifies the video based on the user's interest in the video.

H_ε represents the maximum number of requests for video streaming media in the streaming media distribution system, H_ω represents the number of requests for video streaming media from the proxy server, and the source server quantifies the user's interest in video streaming media in the proxy server through the H_ε / H_ω ratio.

In the active video distribution strategy, the source server distributes the video streaming media through the multicast distribution tree, and caches it to some proxy servers according to the quantitative proportion. The user directly obtains the video content from the proxy server. The passive video distribution strategy aims at sending video access requests to the proxy server by users, but when they fail to hit, the proxy server sends video requests to the source server. According to the received video request, the source server distributes the video to the request proxy server through the multicast distribution tree, and then forwards it to the requesting user. In the process of multicast distribution, some relay proxy servers

can be added to minimize the cost of video distribution. VR short video distribution can effectively reduce user access delay and bandwidth loss.

B. Multicast Distribution Tree

With the rapid increase of types and quantities of VR short videos, users have put forward higher requirements for network bandwidth and access delay. In the process of VR short video distribution, this paper comprehensively considers the impact of personalized demand, link bandwidth and delay on the video distribution cost. In the VR short video distribution model, the source server distributes the video to the proxy server by building a multicast distribution tree. During the construction of multicast distribution tree, based on the 4VR short video distribution model shown in Fig. 4, some relay servers can be added to minimize the video distribution cost. The multicast distribution tree model is shown in Fig. 5, where node 0 represents the source server, node 1, 3, 6, 7, 8 represents the proxy server, and node 2, 4, 5 represents the relay proxy server. The directed line segment between two points represents the communication link between servers. The number on the directed line segment represents the link cost when bandwidth and delay are considered comprehensively. In this paper, we want to find an optimized video distribution path from the source server to the proxy servers to minimize the cost of video distribution.

C. VR Short Video Distribution Cost Minimization Algorithm

In the process of VR short video distribution, the problem of cost minimization is proposed for satisfying users' best experience of video requests and minimizing distribution costs. The performance of the video distribution network discussed in this paper does not calculate the delay and bandwidth cost between the proxy server and the end user. Since users request video from proxy servers in their regions, access time and bandwidth costs will not be affected by video copy allocation.

Fig. 4. VR short video distribution model.

Fig. 5. Schematic diagram of multicast distribution tree model.

The video in the source server is divided into β different video streaming objects. Each video streaming media object is represented by the symbol U , so the video streaming media object set is $U = \{u_1, u_2, \dots, u_\beta\}$. The storage limit of each proxy server is I_a , and ϑ_a represents the number of video streaming media objects requested by proxy server a . During the active distribution of VR short videos, δ_a represents the degree of interest of users in proxy server a in video streaming media objects, and κ_a represents whether proxy server a caches video streaming media objects:

$$\kappa_a = \begin{cases} 1, & a \in U \\ 0, & a \notin U \end{cases} \quad (10)$$

In the formula, 1 shows that the video object is actively distributed to the proxy server; 0 that the video object is passively distributed to the proxy server.

The cost function of VR short video distribution delay is as follows:

$$C_a = \sum_{a=1}^n \sum_{i=1}^m k^i (1 - \kappa_a) - d_t \quad (11)$$

In the formula, d_t represents the unit retrieval delay of the proxy server for video streaming media objects.

The bandwidth cost function of VR short video distribution is as follows:

$$C_a^2 = \sum_{a=1}^n \sum_{i=1}^m (\zeta_{ai} + \chi_{aj})^2 \quad (12)$$

In the formula, ζ_{ai} represents the size of the video streaming media object; χ_{aj} represents the unit bandwidth of the video streaming media object requested by the proxy server.

When bandwidth and delay are considered at the same time, coefficients φ_1 and φ_2 are used to balance the delay and bandwidth costs to meet the needs of multiple applications and systems. Therefore, the cost minimization function of VR short video distribution is as follows:

$$C'_{\min} = \varphi_1 C_a + \varphi_2 C_a^2 \quad (13)$$

The constraints of formula (13) are as follows:

$$\sum_{a,i=1}^n \kappa_a k^i \leq \tau_i \quad (14)$$

$$\chi_{aj} \leq \chi_{\max} \quad (15)$$

$$0.1 \leq \varphi_1 < 1; 0.1 \leq \varphi_2 < 1 \quad (16)$$

$$\varphi_1 + \varphi_2 \geq 1 \quad (17)$$

Formula (14) is the storage capacity limit of the proxy server. Formula (15) indicates that the link bandwidth between the proxy server and the video streaming media object cannot exceed the maximum bandwidth between two points. Formulas (16) and (17) are the constraints of balance coefficients φ_1 and φ_2 .

This paper summarizes the problem of minimizing the distribution cost of VR short video, that is, giving the size of different video streaming media objects and the number of video streams requested, whether there is an allocation strategy to minimize the total cost in formula (13), and whether the video capacity stored in the proxy server is full of formula (14), the size of the link bandwidth meets formula (15), and the relationship between the balance coefficients meets the restrictions of formulas (16) and (17).

V. EXPERIMENTAL VERIFICATION

In order to verify the application effect of personalized VR short video content distribution algorithm based on artificial neural network, experimental analysis is carried out. The methods in literature [5] and literature [6] are used as comparison methods and compared with the proposed methods.

A. Experimental Samples and Indicators

In the simulation experiment, the experimental hardware platform is Pentium IV 2.4GHz CPU with 8GB of memory. The experimental data comes from the COIN (Comprehensive Interactive Video Analysis), an open-source tutorial video dataset, which contains 11827 tutorial videos involving 180 tasks in 12 fields of daily life. Video test sequences are selected from this dataset, all of which are standard test sequences. When analyzing the performance of simulation results, this paper uses Matlab software to convert the experimental data comparison into specific images, which provides strong evidence for the conclusions of this paper.

When comparing the proposed method with traditional methods, the following three performance indicators are mainly considered:

- 1) *Stuck times*: the number of times a video stream is stuck during transmission and playback.
- 2) *PSNR*: A function of the square difference of pixels between the original video file and the received video file, which is a standard objective indicator to measure the video picture quality.
- 3) *Transcoding rate*: it can directly reflect the complexity of video transcoding and indirectly reflect the rate of video distribution.

B. Analysis of Experimental Results

1) *Stuck times*: The comparison results of the stuck times of the methods in literature [5], literature [6] and the proposed method in the video distribution process are shown in Fig. 6.

VI. DISCUSSION

Through the above experiments, conclusions can be drawn as follows:

1) As shown in Fig. 6, the number of video clicks of the proposed method is always less than six times, while the maximum number of clicks of the method in literature [5] reaches 20 times, and the maximum number of clicks of the method in literature [6] reaches 19 times. Compared with traditional methods, the proposed method can provide users with a higher quality user experience during video distribution, that is, improve the video quality level of users when the video is played smoothly. This is because the design method can select the most popular VR short video files not in the original cluster in the video cache to offset the request. At the same time, the copies of popular VR short video files are stored in the cluster header to facilitate user access, thus making the user's viewing experience smoother.

2) It can be seen from Fig. 7 that although the PSNR values of the three methods have an overall improvement trend, the variation range of the methods in literature [5] and literature [6] is small. The PSNR value of this method is high, with a large increase, up to 0.5, indicating that the average video quality level obtained by users is high, indicating that the video distribution quality is high. The reason for this result is that the design method uses BP neural network to compress the original video and determine the implementation mode and cache location of VR short video cache files; Convert and cache high bit rate VR short video streams to generate low bit rate video streams, which not only meets the needs of different network bandwidth, but also improves the PSNR value.

3) It can be seen from Fig. 8 that the video transcoding speed of this method is significantly higher than that of [5] and [6], and the maximum can reach 92%. There are two main reasons for this result: on the one hand, the new coding coefficients and drift errors in the conversion encoder structure are calculated mainly through look-up tables rather than complex multiplication and division operations, which greatly reduces the overhead of the converter and improves the speed of the converter; On the other hand, the improvement of the speed of fast transcoding structure also comes from the selective error compensation operation of video frames. If the error compensation operation is performed, the table lookup structure cannot be used to calculate new coding coefficients and drift errors. Instead, the table lookup structure can be used to perform corresponding operations. It can be seen that the adaptive drift error control method greatly reduces the complexity of video frame transcoding, and can also improve the speed of video transcoding.

VII. CONCLUSION

In order to meet the requirements of high quality and low delay in short video development and reduce network load, this paper proposes a personalized distribution algorithm of VR short video content based on artificial neural network. Firstly, the original video is compressed by BP neural network, and the

Fig. 6. Comparison results of stuck times.

2) PSNR: The PSNR comparison results of literature [5] method, literature [6] method and the proposed method are shown in Fig. 7.

Fig. 7. Comparison results of PSNR.

3) Transcoding rate: Fig. 8 shows the video transcoding rate comparison results of three different methods.

Fig. 8. Transcoding rate comparison results.

implementation method and cache location of VR short video cache file are determined; Secondly, the cached high bit rate VR short video streams are converted to generate low bit rate video streams to meet the needs of different network bandwidth; Third, establish a video distribution model, and build a multicast distribution tree based on this model, that is, add some relay servers; Finally, the minimum allocation cost of VR short video is realized through the algorithm of minimizing the allocation cost of VR short video. The experimental results show that the video blocking times of this method are always less than six times, which effectively reduces the video blocking times. The PSNR value is high, the increase is large, up to 0.5, and the video transcoding rate is improved, up to 92%. The application effect of this method is fully verified, which shows that it has certain application value. However, in the process of experimental analysis, the design method has not been compared with other more methods, and there are still some deficiencies. In the next research process, supplementary research will be carried out to further improve the application effect of this method.

Abstract—The classical blockchain developed for the Bitcoin cryptocurrency has evolved since its introduction more than a decade ago. Blockchain exists in different forms for different purposes and operational contexts. There has been a significant growth in the business use cases of blockchain which is based on the unique attributes of the distributed ledger technology. Blockchain provides peer-to-peer distribution of data in a traceable and decentralized architecture that attains data authentication using consensus protocols. Blockchain as a distributed ledger is the fusion of cryptography, peer-to-peer networking technology, distributed system technology, and consensus mechanism to assure information security and digital asset management. Consensus mechanisms are applied to the distributed ledger that operates in a peer-to-peer network where message transmission between peers is validated and stored across all active peers. Reaching an agreement to validate message transmission and maintaining the correctness of the state of data in a network for critical wireless sensor networks have become a necessary requirement for networks that span several subsystems covering a large operational area. Due to the resource constrained nature of the active actors of wireless sensor networks, any cryptographic solution to be adopted must be lightweight and efficient as well. This paper proposes a blockchain-based decentralized mechanism for authentication of node data for storage onto a distributed ledger. The coloured Petri net was used to model and simulate by detailing the critical attributes of the workings of the system that is based on cyber-physical IoT architecture.

Keywords—Blockchain consensus; ripple consensus algorithm; coloured petri net; cyber-physical system; IoT architecture; node data security

I. INTRODUCTION

Reaching agreements to validate the authenticity of node data and subsequent transmission and storage of such network resources for cyber-physical systems have been a challenging and interesting domain for academia and information security industry players in recent times. Distributed ledgers use consensus algorithms to reach agreement among all connected active nodes to validate message transmission in a peer-to-peer approach. Recent advancements in connectivity, artificial intelligence, machine learning approaches although have provided an advantage for the expansion of network coverage and prediction and visualization of network resource sharing for enterprises and institutions, these available passive

technologies in the hands of bad actors and hackers could render sophisticated cyber-attack exploitations to networks and user accounts resulting in breaching data, corrupting data, and compromising the security of such network systems [1].

Reaching an agreement to validate messages as well as authenticate the state of a distributed ledger have been the requirement for networks whose major components are resource constrained.

Distributed consensus research has become popular since the Nakamoto Satoshi introduced the Bitcoin blockchain cryptocurrency more than a decade ago. Internet of things have provided a platform for expanding the network resources to secure a new value proposition for scaling the scope of an enterprise's network. Available reports support that the technological and cybersecurity budgets for business and institutions have increased allocations and are making efforts to include internet-of-things integration, expansion, and management [2].

Cybersecurity investments and the annual budgetary allocations across most enterprises have increased largely due to the increasing number of cyber-attack incidences on enterprise systems which have resulted in data corruption, data theft and huge revenue losses in some cases [3].

During the COVID-19 lockdown period, most businesses and institutions adopted telecommuting as a measure to regulate and manage people in observing physical distancing to avoid possible person-to-person infection. There were reported cases of cyber-attacks during this period where personal and enterprise data were breached as a result [4].

Cascading effect of cyber-attacks on heterogeneous systems for wireless sensor networks like the internet of things has a wide and costly impact due to the critical messages that the resource-constrained devices in such networks transmit [5].

The effect of cyber-attacks on heterogeneous wireless sensor networks resulting in the compromise of critical data in enterprise networks have taken an alarming trajectory due to the complexity of the interconnectedness of the components of the subsystems that make up the internet of things architecture [6].

Availability of pervasive applications and their integration in enterprise networks that have most of its component relying on internet of things architecture could make the security management of such wireless sensor systems a complex challenge to undertake.

A consensus algorithm for decentralized authentication and distributed ledgers for an IoT with heterogeneous system architecture requires a blockchain-based agreement mechanism that operates with relatively less energy, fully scalable and most importantly byzantine fault-tolerant [7].

Wireless sensor networks achieve privacy and integrity for message transmissions using either third-party trust enforcement systems that adopt a centralized entity to authenticate devices and validate messages or a decentralized mechanism for authentication of devices and validating messages. The centralized authentication mechanism is prone to several attacks including single point of failure attacks. In a distributed system that rely on decentralized authentication mechanism, agreement is reached by all active nodes on the network using consensus. Since the introduction of Bitcoin cryptocurrency, several consensus algorithms have been developed. The Bitcoin cryptocurrency uses a distributed consensus mechanism that is based on proof of work [8].

The Coloured Petri Net (CPN) is a modeling and simulation tool for modeling and simulating systems, and verifying their properties (real-time, behavioral, security properties ...).

The CPN modeling, simulation, and validation of critical security properties of an efficient blockchain-based consensus mechanism that does not compromise the security requirements of a cryptographic solution and offers low latency with improved resistance to the Byzantine fault tolerance is presented by this paper.

The rest of the paper is structured in sections and represented as follows. In Section II, related work describing the state of the art for CPN in modeling and simulating security protocols for networks, node data security and critical security challenges in cyber-physical systems is presented. In Section III, the Ripple consensus algorithm is described. Section IV outlines the implementation of the consensus algorithm in establishing agreements for storing messages on the distributed ledger. Section V concludes the paper.

II. RELATED WORK

A. Consensus Algorithm

In a stand-alone system, validating transmitted message or any transaction is vested in a dedicated centralized node. Consensus algorithms are useful in networks that do not have a dedicated node to singularly authenticate users, processes and transmitted messages or transactions. A consensus algorithm was employed by the system to agree on a single data among multiple processes and agents. To ensure that situations of some multi-agents failing to agree or be unreliable by not being available for consensus to actively reach agreement, a consensus protocol must adopt mechanisms to make them flexible and fault-tolerant [9].

In [10] a decentralized multi-agent system achieved consensus using consensus problem to control these multi-agents. More than half of all the multi-agents and processes agreed by voting on the state and integrity of a process.

B. Blockchain Consensus Algorithm

Blockchain as a cryptocurrency framework for Bitcoin has evolved since its introduction. Blockchains are uniquely categorized based on the type of consensus algorithm in use. In a Proof-of-Work (PoW) consensus, agreement on the validity of a process was achieved using the computing power challenge. The node that had more computing power achieved consensus through a completely decentralized approach. There is Proof-of-Stake (PoS) consensus that is based on financial power competition where the node that controls more than a third of all the resources within the network gets to validate processes within the blockchain. PoS operates by selecting validators to authenticate transactions within the blockchain based on the quantity of the cryptocurrency holdings forming a stake by a node. The more stake a node possesses the higher the chance of being selected to validate transactions. In a PoS, less computational power is involved since it takes shorter time to reach consensus than in PoW. In Delegated Proof-of-Stake (DPoS), consensus is reached based on election and voting process to guard malicious usage and centralization of blockchain. In DPoS, less computing power and time are involved in achieving consensus [11].

A consensus mechanism must provide a trade-off between performance, fairness, and security. There is Proof-of-Activity (PoA) that is a fusion of PoW and PoS. The PoA operated on an economic phenomenon with the assumption of "Tragedy of the Commons" which described a situation where a limited resource for several agents could be ruined in situations where there is uncontrolled use [12].

C. Ripple Consensus Algorithm

The Ripple consensus algorithm is a permissioned blockchain consensus algorithm that requires access permission for nodes in the network because it is not publicly accessible, and operates in rounds using active nodes as servers. It adopts an approach of closing an active ledger updating session once a consensus is reached to store and maintain an identical state of the ledger on all active nodes. For each round within the ripple protocol consensus algorithm (RPCA) [13];

- End users of the server forwards all new transactions to each server. These valid transactions are compiled and made public in the form of a list to constitute the "candidate set".
- All the candidate sets from several servers are merged on every server's unique node list (UNL), to authenticate these transactions.
- The transactions that do not pass the authentication minimal percentage of "Yes" votes are either discarded or included in the candidate set at the commencement of the consensus process for the next ledger. Conversely, transactions that obtain the minimal

percentage of “yes” votes are passed onto the next round of consensus.

The minimum percentage of 80% of a server’s UNL is a requirement for agreeing on a transaction and that constitutes the final round of consensus. The final round of transaction closes the ledger after appending the authenticated transactions onto the ledger.

1) *Composition of the ripple consensus protocol:* The Ripple Consensus Protocol consists of several components: Server, Ledger, Last-closed ledger, Open-ledger, Unique node list (UNL), Proposer.

The server is an entity that runs the Ripple server software.

Ledger is an append only record of the amount of currency in each user’s account and represents the ground truth of the network. The ledger grows with updating transactions using the consensus protocol.

The last-closed ledger describes the most recent state of the ledger after the consensus protocol has validated transactions and appended the validated transaction onto the ledger.

The Open ledger is used to represent the current operating status of a ledger on a node.

2) *Correctness of the consensus:* There is the likelihood of a validating node being compromised to form a cartel of corrupt validating nodes to comprise the byzantine-fault-tolerance integrity of the consensus. The ripple consensus protocol maintains correctness for agreements and resistive to Byzantine failures by adopting a mechanism where a transaction is approved only when 80% of the validating nodes agree using the consensus algorithm. Dishonest agreement to validate a message transmission is possible only after the number of faulty validating nodes exceed 80% of the unique node list. The consensus protocol with honest nodes in the UNL will maintain correctness if the unique node list UNL of n nodes in the network meets this condition:

$$f \leq (n - 1) / 5$$

Where f is the number of Byzantine failures. In situations of $(n - 1)/5 + 1$ Byzantine failures, the correctness of the consensus is maintained. The consensus will only confirm a fraudulent transaction when there are $(4n + 1)/5$ failures or more. The probability of occurrence p^* hereafter, points to the likelihood of growing the size of the nefarious cartel below the maximal threshold of Byzantine failures.

$$p^* = \sum_{i=0}^{\lfloor \frac{n-1}{5} \rfloor} \binom{n}{i} p_c^i (1 - p_c)^{n-1}$$

Where p_c denotes the probability of any node colluding with other nefarious cartel.

In Fig. 1, the process for the Ripple consensus is outlined.

The validation nodes are IoT sink nodes from several local IoT networks.

Fig. 1. Ripple consensus data flow diagram

Fig. 2. Smart contract dataflow diagram

In Fig. 2, the smart contract data flow is presented. The smart contract operates between the sink node and the cloud network. The IoT gateway runs the blockchain smart contract. The smart contract ensures that users, devices, and data are verified and validated for data storage operations on the distributed ledger. Data from the sink node get stored onto the distributed ledger through the IoT gateway. The sink node registers itself on the blockchain in step 3a. The IoT gateway always verifies the state of the blockchain using the internal storage distributed ledger as input to validate the integrity of the blockchain using the cloud or remote. Connected sink nodes constitute the consensus nodes for performing user, device and data integrity checking before either writing onto the blockchain or access data from the blockchain. Data writing operations on the blockchain are done by the sink nodes, to append data onto the blockchain. They are referred to as data write operations in step 2a. The hash and encrypted data from the sink node are used in the next phase. The *writedata* function in the smart contract is used to append the hash of the sink node data onto the blockchain. The encrypted data is then written to the gateway internal memory in steps 4a-8a. The Ecall/Ocall wrapper communicates with the gateway internal memory as illustrated in the step 5a. The hash of the data from the sink node is verified by recalculating the hash-based message authentication code (HMAC) based on the encrypted and comparing the given hash with the derived hash. The Integrity Checker verifies and validates IoT data by ensuring that the given hash and the derived hash are the same,

the encrypted data is sealed and written to disk in step 7a. If the report from the Integrity Checker shows a difference in the string structure of the derived hash from the given hash, that will result in discarding the data including the hash from the sink node. Step 7a and Step 8a are used in validating the hash and proceeding to either write the encrypted data to disk or disproving the hash and discarding the data from the sink node.

Data accessing activities from the blockchain is done using the data read module. A user module first registers third-party users using the *allowAccess* method with the smart contract. The user calls the *revokeAccess* function to revoke access for a user. Step 1b outlines the interaction of the third-party user with the smart contract in obtaining the hash of the data generated by the sink node after providing the device ID of the sink node. The smart contract checks if the third-party user device ID and the address have the validation necessary to access the data after doing integrity checking for the third-party user ID and address. The hash of the sink node data is only returned from the cloud storage after the integrity checker grants the access permission to the third-party user to enable it to access the data from the IoT gateway persistent storage (IoT gateway internal memory) that represents local storage of the data. The smart contract uses the *READDATA* API as illustrated in step 4b, to confirm if the third-party user has the access permission to read the data hash identifier supplied by the third-party request. In step 5b, it illustrates how data is retrieved from the secured internal gateway storage once data access permission is granted. The data is unsealed in step 6b, and the integrity of the data is checked in step 7b, after recalculating and verifying the digital signature by comparing the given and the derived digital signatures. The sensor data stored in the gateway internal memory is read and returned by the user only after the digital signature verification is completed. Steps 9 and 10 illustrate the data flow for this operation [14].

In Table I, the pseudo-code for the smart contract is presented.

Where:

OwnerAddress: Sink node identity (SNI_d)

Device: Sensor

DeviceID: SensorID (Ss_{Id})

In [15] five main blockchain consensus protocols were examined using the unique properties of type (probabilistic or absolute finality), level of fault-tolerance, power consumption, scalability, and application. The five consensus protocols are: Proof-of-Work (PoW), Proof-of-Stake (PoS), Delegated Proof-of-Stake (DPoS), Practical Byzantine Fault Tolerance (PBFT) and Ripple.

The ripple consensus proved to have a good scalability, involved negligible power consumption, low fault tolerance and operated using permissioned application. In ripple consensus, the entire network will continue to function to support correct consensus even if 20% of the nodes are attacked by Byzantine generals problem [16].

D. Modeling Languages for Verification Systems

Modeling systems exist to provide opportunity for designing, developing, and implementing critical systems. Although there are several kinds of tools and platforms for modeling, simulation, and verification of systems, the coloured petri nets (CPN) is distinguishable in the following aspects: CPN offers several functions and provides a flexible manipulation of the functions in developing a model. The CPN tool has been improved and tested to support the modeling of complex systems [17].

Study [18] surveyed several modeling tools for checking, validating, and some cases improving the design requirements of systems. Notable modeling systems mentioned included the Practical Robust Implementation and Sustainability Model (PRISM), Numeric Symbolic Model Verifier (NuSMV), UPPAAL, Symbolic Analysis Laboratory (SAL), SPIN, Beryl, D-Finder.

The related works showed available research on IoT solutions that is based on blockchain. It however confirmed the absence of an implementation for a blockchain-based solution to authenticate and protect IoT data transmitted between actively connected network elements of the IoT gateway and the cloud.

Additionally, there is an implementation gap for a formal model for IoT systems that directly involved the sensor, sink node, IoT gateway, and the cloud elements in a blockchain-based IoT architecture.

In the next section, the methodology for the paper is presented.

III. METHODOLOGY

The target and design principles that formed the basis for the chosen methodology to support a blockchain-based consensus mechanism for authentication of node data for IoT systems are hinged on a security solution appropriate for an environment where the devices are resource-constrained.

The design principles for the methodology are the usage of decentralized authentication, smart contract for consensus among sink nodes, lightweight cryptographic solution, digital signature, smart contract with lightweight cryptographic function, a formal modeling tool that allows for dynamic behavior modeling, and the provision of a visual simulation tool.

The design goals on the other hand involved the elimination of a single point of failure, stronger security, extending data protection with a lightweight cryptographic solution, enforcing authentication with smart contract, the proposal of a formal model for a generic blockchain-based IoT solution, and the validation of a blockchain-based IoT solution through simulation.

A. Heterogeneous IoT Architecture

An architecture consisting of several subsystems was adopted for the implementation of the blockchain-based authentication mechanism.

Fig. 3. An IoT architecture

In Fig. 3, an IoT architecture with components for a heterogeneous cyber-physical network is displayed. The architecture has three components involving a local IoT network which consisted of sensor end devices and sink nodes, an overlay network that employs blockchain-based distributed ledger, and a cloud network (remote storage) to receive and store the hash values of the sensor data. The local IoT networks amalgamate validated sink nodes with their validated data and

transmit them through an IoT gateway to be stored on the distributed ledger [19].

The local IoT sub model is composed of elements that consist of security management, devices and sensors, internet connectivity things, Application Programming Interface (API) libraries, System Development Kits - SDK. Distributed systems that operate based on a decentralized authentication mechanism is prone to attacks such as the double spending instances where validated messages that represent independent transactions have the possibility of getting used in simultaneous transfers without considering the output of each transfer in the simultaneous transactions [20].

B. Coloured Petri Net

The coloured Petri Net (CPN) is a graphical mathematical modeling language. It is used to describe and check system properties, security requirements and synchronization characteristics for real-time distributed systems, and more generally event-driven systems. CPN comprises essential tools for analyzing boundedness, reachability, resource conflicts, deadlock as well as the structural properties of a real-time system [21].

The formalization of CPN is composed of nine tuples.

$$CPN = (P, T, A, \Sigma, V, C, G, E, I)$$

Where:

$P = \{P_1, P_2, \dots, P_m\}$ represents a finite set of places.

$T = \{T_1, T_2, \dots, T_n\}$ denotes a finite set of transitions.

A : Directed arc set

Σ : A finite set of colour set types

V : Denotes a finite set of variables whose type $\in \Sigma$.

C : It represents the colour set function from P to Σ .

G : Denotes the set of guard functions of transitions.

E : It represents a function that associates an arc expression to each transition.

I : denotes the function that gives the initial marking of each place.

The graphical representation of Petri net comprises of rings representing Places, rectangles denoting Transitions, arrows symbolizing Arcs.

A coloured Petri net is composed of variables, values, and expressions. CPN objects are described using colour domain that comprises variables, data values, operators, a syntax for expressions, and typing rules. An abstract colour domain consists of : Data values \mathbb{D} , Variables \mathbb{V} and Expressions (\mathbb{E}) [22].

- \mathbb{D} is the set of data values; These data values include integer values, Boolean values (True and False), and special undefined value \perp ;
- \mathbb{V} is a set of variables, that are represented using single letters x, y, \dots , or as subscripted letters x_1, y_k, \dots

- \mathbb{E} is the set of expressions, that are composed of values, variables, and suitable operators.

Variables or values may form a basic expression. Thus, $D \cup V \subset E$. For example, let $e \in E$, the expression $vars(e)$ denotes the set of variables from V involved in e .

A binding is a restricted function $\beta : V \rightarrow \mathbb{D}$. Let $e \in \mathbb{E}$ and β be a binding. $\beta(e)$ represents the evaluation of e under β ; if the domain of β does not include $vars(e)$ then $\beta(e) \stackrel{\text{def}}{=} \perp$.

Both sets and multisets of expressions are subjected to binding evaluations.

For example, if $\beta \stackrel{\text{def}}{=} \{x \mapsto 1, y \mapsto 2\}$, we have $\beta(x + y) = 3$. With $\beta \stackrel{\text{def}}{=} \{x \mapsto 1, y \mapsto 2\}$, according to the colour domain, we may have $\beta(x + y) = \perp$ (no coercion), or $\beta(x + y) = "12"$ (coercion of integer 1 to string "1"), or $\beta(x + y) = 3$ (coercion of string "2" to integer 2), or even other values as defined by the concrete colour domain.

Two expressions $e_1, e_2 \in \mathbb{E}$ are said to be equivalent which is represented as $e_1 \equiv e_2$, if for all possible binding β , the binding for both expressions are the same $\beta(e_1) = \beta(e_2)$. For example, $x + 1, 1 + x$ and $2 + x - 1$ are pairwise equivalent expressions for the usual integer arithmetic.

Definition 1 (Petri nets). A Petri net is a tuple with several elements such as (S, T, l) where:

- S is the finite set of places; S is also represented as P
- T , disjoint from S , is the finite set of transitions;
- l is a labelling function such that:

for all $s \in S, l(s) \subseteq \mathbb{D}$ is the type of s , i.e., the set of values that s is allowed to carry,

for all $t \in T, l(t) \in \mathbb{E}$ is the guard of t , i.e., a condition for its execution,

for all $(x, y) \in (S \times T) \cup (T \times S), l(x, y)$ is a multiset over \mathbb{E} and defines the arc from x toward y .

Definition 2 (Markings and Sequential Semantics) Let $N \stackrel{\text{def}}{=} (S, T, l)$ be a Petri net.

A marking M and N is a function on S that maps each place s to a finite multiset over $l(s)$ representing the tokens held by s .

A transition $t \in T$ is enabled at a marking M and a binding β , which is denoted by $M[t, \beta]$, iff the following conditions hold:

- M has enough tokens, i.e., for all $s \in S, \beta(l(s, t)) \leq M$;
- the guard is satisfied, i.e., $\beta(l(t)) = \text{True}$
- place types are respected, i.e., for all $s \in S, \beta(l(t, s))$ is a multiset over $l(s)$.

If $t \in T$ is enabled at marking M and binding β , then t may fire and yield a marking M' defined for all $s \in S$ as $M'(s) \stackrel{\text{def}}{=} M(s) - \beta(l(s, t)) + \beta(l(t, s))$. This is denoted by $M[t, \beta]M'$.

The marking graph G of a Petri net marked with M is the smallest labelled graph such that:

- M is a node of G
- if M' is a node of G and $M'[t, \beta]M''$ is also a node of G and there is an arc in G from M' to M'' labelled by (t, β) .

The definition of marking graphs allows the addition of infinitely many arcs between two markings. If $M[t, \beta]$, there might exist infinitely many other enabling bindings that differ from β only on variables not involved in t . Finally only firings $M[t, \beta]$ such that the domain of β is $vars(t) \stackrel{\text{def}}{=} vars(l(t)) \cup \bigcup_{s \in S} (vars(l(s, t)) \cup vars(l(t, s)))$ is considered.

In the next section, the results and discussion for the proposed methodology is presented.

IV. RESULTS AND DISCUSSION

The use of the mathematical and visualization features of CPN provided the set of mathematical foundations necessary for representing and describing the elements and security properties of the proposed solution that is based on the IoT architecture.

In this section, the simulation results for the blockchain consensus using CPN tools are presented and discussed.

Fig. 4. CPN modeling of the blockchain consensus protocol

In Fig. 4, the CPN modeling of the blockchain consensus mechanism with validators is presented. The validators are an amalgamation of the current sink node which presents the data to be validated as well as other external sink nodes within the hierarchical IoT network. The external sink nodes form the external validators. The sink node whose data is to be validated through the consensus assumes the local validator status. The

validators (local and external) reach agreement to validate data if and only if the number of the positive feedbacks are more than half of all the total decisions from the validation voting by all the validators. Once a message does not get at least more than half of the total decisions to be positive feedbacks, that message is discarded. A session for the consensus by the validators is considered closed once the decision on a message has been made in accordance with the consensus correctness criterion of the adopted blockchain consensus. The correctness criterion of the consensus is critical to make the algorithm byzantine fault tolerant.

Fig. 5. Local validator feedback decision

In Fig. 5, the consensus commencement for validators is illustrated. The blockchain consensus starting with the local validator to decide by voting by on the feedback of the data under validation is presented. There are two feedback options (0, 1) to be selected by a validator. Option 1 symbolizes positive feedback whereas option 0 denotes non-positive feedback. The “start validation transition” has not been fired yet. Selecting a choice for the feedback will fire the transition. The token (1`1) on the local validator symbolizes a single node data and the specific data to be validated is 1. The update on the number of proposals “nbprop” of 1` (0, 0) shows that voting on the decision feedback on the data under validation has not started (0, 0).

Fig. 6. Local validator feedback decision proposal update

In Fig. 6, a feedback decision of ‘1’ on the data under validation is presented. The feedback from the local validator confirms that the “start validation transition” has been fired. The update on the number of proposals “nbprop” of 1` (1, 1) shows that voting has started on the decision feedback on the data under validation. That only 1 validator has voted on the decision feedback. That decision is a positive decision (1 – ‘Number of decisions’, 1-‘number of positive decisions’).

Fig. 7. External validator1 feedback decision

In Fig. 7, the feedback decision from external validator1 on the data under validation is illustrated.

The update on the nbprop place 1` (2,2) shows that there have been two voting decisions and all the decision are positive decisions.

Fig. 8. External validator2 feedback decision proposal update

In Fig. 8, the feedback decision from external validator2 on the data under validation is shown.

The decision feedback voting update on the number of proposals “nbprop” – 1` (3,3) shows that there have been three

feedback decisions with all three being positive feedback decisions.

Fig. 9. External validator3 feedback decision proposal update

In Fig. 9, the feedback decision from external validator3 on the data under validation is illustrated. The local validator, external validators 1, 2, 3 have all voted on the decision and have the feedback updated and stored on the nbprop place. The token value has been updated to 1(4,3) to show that there have been four votes (local validator, external validators 1,2,3). And that three out of the four votes are positive feedback decisions.

Fig. 10. External validator4 feedback decision proposal update

In Fig. 10, the feedback decision from external validator4 on the data under validation is depicted. Additionally, it provides the update as illustrated in the place for the number of proposals “nbprop” for a total of five decisions, with three positive feedback decisions. The EndValProcess transition is highlighted to show that it is the next action or step to be taken for the simulation.

Fig. 11. Decision result after the proposals

In Fig. 11, the data flow CPN simulation on the decision feedback results at the end of the decision voting process is represented. The token value on the nbprop 1(5,3) and the summary information on the transition confirm that there was one data identity that represented 1 data element to be validated and that there were 3 positive decision feedbacks.

Fig. 12. Consensus decision

In Fig. 12, the decision on the data at the end of the consensus process is shown. The initial token element 1(1) on the local validator place has been moved to the place for the ValidatedData. Additionally, the consensus session is closed and the nbprop token element is reset to 1(0,0).

The firing of the EndValProcess transition ends and session for the consensus activity. The data is then validated and the colour token 1(1) on the ValidatedData place finalizes the consensus.

TABLE II. DESCRIPTION OF CPN MODELING FEATURES FOR THE BLOCKCHAIN CONSENSUS MECHANISM

Abbreviation	Description	CPN Component
LocalValidator	It represents an internal sink node. The container for keeping a sink node data prior to a validation operation	Places
ExValidators	It denotes external sink nodes that form the external validators. These are all the other sink nodes within the hierarchical IoT network. They join the internal validator to reach an agreement on a message through a blockchain consensus.	
nbprop	A container for keeping all the decisions resulting from validators using the consensus rule to vote on a data under validation.	
ValidatedData	It represents the results after the voting decisions undertaken by all the validators have ended. When the number of positive feedbacks where at least 60% of the total decisions by the validators, the data will be moved to a new state of ValidatedData.	
DataUnderValidation	It denotes a place that specifies the current data being validated is kept. It is represented by the identity of the data which is captured as (*cpt) on the arc inscription.	
StartValProcess	It is an event that signifies the start of the consensus session. The local validator is an input to this event. It fires the data from the local validator to the external validators as well as updates the DataUnderValidation and the "nbprop" places.	
EVDDecision	It is a transition label for the CPN event that fires the decision of each external validator as feedback on a data. The input of the transition is the external validator and the data to be validated based on the consensus rules. The output for this transition is the number of decision feedbacks and the number of positive decision feedbacks.	
EndValProcess	It is a transition to signify the close of a consensus session. It has DataUnderValidation, and	

Abbreviation	Description	CPN Component
	nbprop as input. The output of this transition is the ValidatedData.	Variables
cpt	A token for describing the identity of data under validation. The data under validation is submitted by the local validator to the validators where the consensus mechanism is applied on the data using other established rules in the consensus to vote on the data in validating it.	
EVi (i = 1 .. 4)	The token identifying the external validator i.	
data	A data element representing the data under validation by the external validator.	
nboffeedbacks	It is a counter that records the decisions of voting activities by providing an update on the total number of feedback decisions	
nbofposfeedbacks	It is a counter that records the total number of positive feedback decisions. Both the number of feedbacks and the number of positive feedback decisions are stored as a token in the "nbprop" place and are updated each time an external validator decision is taken.	

In Table II, the CPN simulation components for the consensus mechanism for the system are presented. The components for the simulation consisted of CPN places, transitions, arc expressions, and initial marking of places using coloured tokens. The various components used in the simulation of the consensus mechanism were described in the table.

The use of the proposed IoT architecture is an improvement on a related work that used blockchain mechanisms for IoT data security. In [19] the blockchain solution did not indicate how the node data from the sensor was protected as well as an approach to maintain the integrity of the data communicated between the sensor and the sink node. The proposed blockchain-based IoT architecture used a centralized approach with a lightweight-cryptographic mechanism to protect the content of data between the sensor and the sink node. Additionally, the use of a non-monetary-based blockchain consensus mechanism where only the IoT gateway and other sink node clusters formed the consensus nodes is used to implement a smart contract with a lightweight cryptographic function for decentralized authentication of node data.

The use of the decentralized consensus ensured the elimination of a single point of failure situation for the IoT network and supported a distributed ledger that guaranteed the availability of validated node data on the IoT internal storage and the cloud for authorized users in the IoT system.

In the next section, the general conclusion of the work is presented.

V. CONCLUSION

Distributed systems that rely on decentralized processing for authentication and validation of processes like the blockchain system use agreements through consensus mechanisms to assure and maintain the correctness of decisions, and to guarantee stable systems. For a blockchain mechanism to be deployed in an IoT network where the devices are resource-constrained, an architecture was designed that factored in the challenges regarding memory, computational processing, and energy limitations of sensors and sink nodes. The distinctive security features in the proposed consensus mechanism enabled the core elements of the IoT architecture to reach an agreement among the sparsely fragmented network elements in the IoT architecture. The use of the IoT gateway, PKI, and cloud network in the architecture supported a security solution that provided a trade-off between performance, fairness in load balance, and security.

Additionally, the ripple consensus mechanism provided a byzantine fault-tolerant approach with good scalability to support a large network consisting of several subsystems.

The modeling and simulation of the blockchain-based authentication mechanism provided the possibility of validating the security properties of an IoT security solution that is based on a decentralized authentication approach. The CPN features including places, transitions, arcs, expressions, and initial markings of places with tokens were used to represent the entities or physical attributes of the system as well as the design decisions of the system. The design decisions and the dynamic nature expectations of the distributed ledger system were represented using places, transitions, arc expressions, and tokens.

Abstract—This paper describes the design of a programming framework for microcontrollers specially the ones with low program and data memory, using as a base a programming language with modern features. The proposed programming framework is named *Aixt Project* and took inspiration from other similar projects such as *Arduino*, *Micropython* and *TinyGo* among others. The project's name is inspired on the weasel pet of the *V* programming language and at the same time it is a tribute to *Ticuna* people who live in the Amazon rain-forest, just between Colombia, Perú and Brasil. *Aixt* comes from *Aixtü* or *Aitü rü* which means otter in *Ticuna* language. The proposed programming framework has three main components: the *Aixt* language based on the *V* syntax, a transpiler that turns the defined V-like source code into *C*, and a generic cross-platform Application Programming Interface (API). The target of this project is obtaining a cross-platform programming framework over the same language modern language an the same API, for programming different microcontrollers especially the ones with low memory resources. *Aixt* language is based on the syntax of *V* programming language but it uses mutable variables by default. *V* language was selected to be used as base of this project due to it is a new compiled programming language with interesting modern features. In order to turn the *Aixt* source code into *C*, a transpiler is implemented using *Python* and the some specialized libraries to design each part of its translation process. The transpiled code is compiled by the native *C* compiler of each microcontroller to obtain the final binary file, that is why the API has to be adapted for each native *C* compiler. The complete project is released as a free and open source project. Finally, different application test were done over the XC8 and XC16 compilers for the PIC16, PIC18, PIC24 and dsPIC33 microcontrollers families, demonstrating the correct working of the overall framework. Those tests show that the use modern language framework to program any microcontrollers is perfectly feasible using the proposed programming framework.

Keywords—*Microcontroller; transpiler; API; programming language; V; V-lang; Aixt project*

I. INTRODUCTION

The different processor architectures used by the commercial microcontrollers, make the programming process dependent on those architectures and thus not universal. Even, when the microcontrollers are programmed on high level languages, tasks such as peripherals, timers, setup registers, and others, keep depending on the programmer's knowledge of the processor's architecture [1], [2]. There are some different projects which pretends to generate cross-platform programming frameworks [3], using different programming languages like *JavaScript* [4], and other implementations using virtual machines [5], [6], [7]. An example of those programming frameworks (and one of the most popular) is *Arduino*[8], [9],

[10], which is based on *C* language in addition to an API which makes the programming process easier. That API works on a predefined hardware setup to reduce the setup process by the programmer. Another popular programming framework for microcontrollers is *Micropython* which implements on several devices a subset of *Python* language. *Micropython* has specific relatively high memory requirements which makes it impossible to run on small microcontrollers, but it has been ported to a large number of different architectures [11] mainly in internet of things IoT implementations. *Arduino* is compiled but its *C* syntax lacks modern features, on the other hand *Micropython* is interpreted and therefore non time optimized as compiled language, but there is an intermediate framework named *Tinygo* which implements *Go* language on Microcontrollers, offering modern features like *Python* and the advantage of being compiled [12] like *Arduino* (*C*). However, most of the microcontroller with limited memory features does not fit to the memory requirements of the projects previously described, so for those ones it is necessary to use their native *C* compiler.

In order to obtain the best execution times and the best code optimization level [13], [3] it is necessary to use the native *C* compiler of each architecture. Then, if there is a programming framework with an upper modern language layer, a transpiler to *C* and the native *C* compiler as a part of the framework, this could have high level language features along with optimization levels similar to the ones reached with only the native compilers. The described programming framework needs to have a transpiler [14], which is a translator from the upper layer language to the native *C* [15]. Transpilers are highly utilized nowadays [16], [17], in several languages both compiled and interpreted [18], [19], [20], and even in languages based on virtual machines [21]. Those transpilers are mainly used in order to reuse source code that comes from another different language [18], or improve the execution times or another performance feature of the program [22], [23] changing the platform or language (for instance turn *Python* (interpreted) into *Rust* (compiled) [19]), even translating source code to gate-based hardware [24] like FPGAs or other processor-less devices.

Several new programming languages have emerged nowadays, mainly to solve some of the issues of the traditional ones such as safety, memory management among others. Among these new languages are *Go*, *Swift*, *Dart*, *F#* and *Rust*, being this last is one of the most preferred ones[25], having even implementations on microcontrollers [26], [27], [28]. There are some other other languages such as *Peregrine* which is based on the *Python's* syntax and the *V* programming language [29]

wish is inspired on *Rust* and other languages. *V* is an statically-typed programming language with several modern features that make the development easy, and a better learning curve than other modern languages like *Rust*.

This paper proposed a programming framework for micro-controllers that is composed by a high level language based on *V* as the main language, a transpiler from this *V-like* language named *Aixt* to *C*, and the microcontrollers' native *C* compiler which finally generates output binary file. In order to generalized the programs across the different microcontrollers, a general API is designed, which is implemented on each *C* compiler of the supported devices (in this first stage for XC8 and XC16 compilers). For the transpiler implementation *Python* and the module *SLY* were used, to write the lexer analyzer and the Parser. This project is based on a previous one named *Sokae* [30] developed by the same authors.

The paper is organized as follows: Section II presents the methodology for implementing the overall proposed programming framework, including the *Aixt* language definition (Section II - A), the *Python* implementation of the *Aixt*-to-*C* transpiler (Section II - B), and the API implementation for the XC16 compiler and PIC24 microcontrollers family (Section II - C). Section III shows the *Aixt* language functionality by implementing several examples, as well as it presents the results of implementing the proposed programming framework by several test source codes. Finally, Section IV shows the conclusions about this research's main ideas, including possible future jobs.

II. METHODOLOGY

With the name *Aixt Project*, a microcontroller programming framework is implemented. This framework uses an homonym language which is based on the *V* programming language. A transpiler from *Aixt* language to *C* is the most important block of this framework, as well as an Application Programming Interface (API) written in both languages. As part of the proposed structure, the native *C* compiler of the specific micro-controller finally generates the output binary file, as shown in Fig. 1. Using the proposed framework, the users will be able to write the source code in *Aixt* language using a standard API and obtains the binary file for a specific microcontroller or board without having further knowledge of the programming architecture. This framework pretends to be highly modular and relatively easy to include other microcontrollers or boards. The Fig. 1 shows the general structure of the programming framework indicating that for each new microcontroller to be supported it is necessary to adapt the API (Fig. 1 right) to this and invoke its specific native *C* compiler (Fig. 1 left down). The specific test done for this paper were implemented on some different Microchip® microcontroller families such as PIC16, PIC18, PIC24 and dsPIC33 using the XC8 and XC16 compilers, these microcontrollers were selected because their limited amount of implemented memory.

A. Aixt Language

Aixt is the name given to the proposed language and the overall programming framework. This language is based on the *V* programming language [29] and shares most of its syntax. Due to its relatively short learning curve, *V* language was

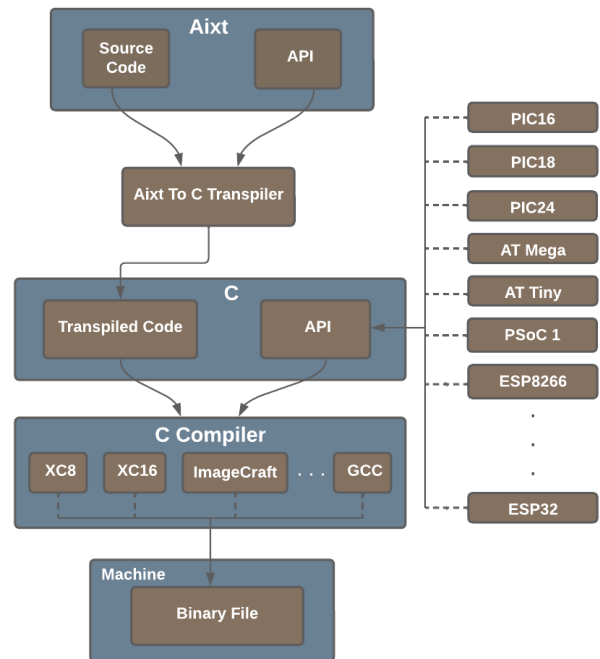

Fig. 1. General programming framework diagram

selected for this implementation instead other new languages like *Rust* [30]. The framework and language name is inspired in the Weasel pet of *V* Language, and at the same time is a tribute to *Ticuna* people who live in the Amazon rain-forest in the borders between Colombia, Brasil and Perú. Weasels are mustelids just like otters, so the name *Aixt* comes from *Aixtũ* or *Aitũ rũ* which is a way to say otter in *Ticuna* language.

Aixt is a compiled and statically typed programming language based on the *V* syntax. This is designed to be used on a wide range of microcontrollers no matter their memory limitations. *Aixt* syntax shares some feature with languages such as *Rust* and *Go*, therefore also it shares syntax features with *C*, which makes *Aixt* easy to understand and transpile.

Listing 1 shows an example code using *Aixt* language and API, which makes blinking a LED for a specific microcontroller's pin. Likewise, the Listing 2 shows the *C* equivalent of the same *Aixt* source code.

Some of the basic features of *Aixt* language are listed as follows:

- the `:=` operator is used for declaring variables.
- Unlike *V*, variables are mutable by default in *Aixt*.
- `ix`, `ux` and `fx` variable types for regular integers, unsigned integers and floating point variables.
- `isize` and `usize` for integers with same size of the processor.
- `rune` type for character variables.
- Default type inference in declaring.
- Underscore character in literals for improving its readability.

- The `main` function is the first entry of a *V* program. In case of having only one source code, the main function definition can be omitted.
- All instructions end with a new line character, whit a semicolon or with a curly bracket close.
- The semicolon is optional. It has to be used when having two simple instructions in the same code line.
- All the code blocks are delimited by curly braces.
- All function declarations start with the reserved word `fn`.
- The names for all the identifiers (variables, constants, functions, etc.) prefer to use snake case as in *V*, for instance the function `pin_low()`. This feature is implemented in order to keep a standard format for all the *V* source code.
- There is only a loop instruction which is used for implementing all the supported loops, changing only its input parameters syntax.
- The reserved word `import` is used for including different complete modules or libraries.
- In order to reduce the *C* obtained code, it is possible to include individual components from a global module using the curly braces following the syntax: `import module { comp1, comp2, ... }`

Listing 1: Blinking LED example in *Aixt*

```
import machine { pin }
import time { sleep_ms }

pin(A6,OUT)
for {
    pin_high(A6)
    sleep_ms(500)
    pin_low(A6)
    sleep_ms(500)
}
```

Listing 2: Resultant *C* code for the Blinking LED example

```
#include "../settings.h"
#include "../machine/pin.h"
#include "../time/sleep_ms.h"

int main(void) {
    pin(A6,OUT);
    while(true) {
        pin_high(A6);
        sleep_ms(500);
        pin_low(A6);
        sleep_ms(500);
    }
    return 0;
}
```

B. Transpiler

A transpiler is a program that translates source code between programming languages with the same abstraction levels, by contrast a compiler translate source code generally to another low level language. The proposed programming framework does not compile directly the *Aixt* source code but transpile it to *C*. The Transpiler from *Aixt* language to *C* is implemented with *Python* and using the *PLY* module in order to implement the lexer analyzer and parser for the input source code. The complete working diagram of the implemented transpiler is shown in Fig. 2, where an input file with `.v` extension get in to the transpiler and it generates the output `.c` file. The transpiler implementation is based on part of the *V* language grammar, the Listing 3 shows an extract of that grammar in Backus-Naur form (BNF). This part of the grammar shows the definition of the four different ways to do loops in *Aixt* using the reserved word `for`, including infinite loops.

Fig. 2. Transpiler diagram

Listing 3: *Aixt* language BNF definition (extract)

```
...
forStmt ::= for block
        | for expr block
        | for forClause block
        | for inClause block

forClause ::= simpStmt ; expr ; simpStmt

inClause ::= exprList in IDENTIFIER
...
```

For the implementation of the lexer analyzer, all of the tokens of *V* language are supported, such as keywords, operands and other punctuation symbols, as shown in the code extract of Listing 4.

Listing 4: *Aixt* Lexer implementation (extract)

```
...
tokens = {
    I8 , I16 , I32 , I64 , ISIZE ,
    ...
    F32 , F64 , BOOL , RUNE ,
    IMPORT , IN , MAP , MATCH , RETURN ,
}
```

```

...
}
BOOL      = r'bool'    # Types
RUNE      = r'rune'
...
IDENTIFIER = r'[a-zA-Z_][a-zA-Z0-9_]*'
...
BINARY_LIT = r'0b[01_]+ '
...
literals = { '(', ')', '{', '}', '[',
             ']', ';', ',', '.',
             }
...

```

Once the Lexer analyzer reduced the character flux of the source code to an token flux, the parser analyzes the syntactic rules of language in order to find possible syntactic error and transpile it to C. The most of the syntactic rules of *V* are implemented in *Aixt* using the SLY module as shown in the extract source code of Listing 5, which matches with the BNF definition shown in Listing 6.

Listing 5: *Aixt* Parser implementation (extract)

```

...
@_( 'identList_DECL_ASGN_exprList',
    )
def varDecl(self, p):
...
    return ret_value

@_( 'IDENTIFIER',
    'identList ',' IDENTIFIER'
    )
def identList(self, p):
...
    return p[0]
...

```

Listing 6: *Aixt* BNF rules (extract)

```

varDecl ::= identList DECL_ASGN exprList
identList := IDENTIFIER
           | identList "," IDENTIFIER

```

SLY library uses *Python's* function decorators to implement the syntactic rules of the language to be compiled or transpiled, applying them to each syntactic production, for example the production `varDecl` is the implementation of variable declarations in *Aixt* language.

As previously said, the transpiler reads the source code written in *Aixt*, which for compatibility with standard source code editors, the `.v` file extension.

C. Application Programming Interface

One of the main goals of the proposed framework is designing a cross-platform API, which includes the basic features and peripherals of most microcontrollers. In order

to make the microcontroller's programming process easier, a general Application Programming Interface is implemented in both the *Aixt* programming language and C for the specific native compiler. This API includes the peripherals and features shown in Tables from I to IV.

TABLE I. GENERAL PURPOSE INPUT/OUTPUT

Description	Function name
pin type declaration	pin()
setting high and low	pin_low() pin_high()
setting specific binary value	pin_value()
reading an input value	pin_value()

TABLE II. ANALOG TO DIGITAL CONVERTER (ADC)

Description	Function name
ADC setting up	adc()
ADC reading value	adc_read()

TABLE III. UNIVERSAL ASYNCHRONOUS RECEIVER TRANSMITTER (UART)

Description	Function name
UART setting up	uartx()
single byte transmitting	uartx_put()
single byte receiving	uartx_get()

TABLE IV. TIMING FEATURES

Description	Function name
delays in microseconds	sleep_us()
delays in millisecond	sleep_ms()
delays in second	sleep()

Table I shows the pin and GPIO functions like setup, input capture and output set. Some devices even could support exchange state functions (`pin_toggle`). The rest of API functions follow the same rules:

- The setup function has the same name of the module.
- The rest of name functions of the same module follow the syntax: `module_function()`. For instance: `adc_read()` function of `machine { adc }` module (Table II).
- Devices with more than one peripheral of the same time follow this name function syntax: `modulex_function()` where the `x` refers to the number that identify each peripheral. For instance: `uart2_get()` as shown in Table III.
- Some API modules refers to a inner features of the device different to hardware peripherals, for instance software delays (Table IV).

The Fig. 3 shows the folder structure designed for the overall API, this structure has to be followed for each of the supported microcontrollers and boards to maintain the compatibility across all the hardware devices. Following strictly this folder structure allow the transpiler to correctly redirect the module including tasks when it is necessary to include to the project isolated components of a module.

As previously mentioned, the module including follows the next syntax in *Aixt*: `import module`

for complete modules, which will be transpiled as `#include \./module.h`". Likewise, the sub-modules or module components including follows the syntax: `import module { sub1, sub2, ...}`, which will be transpiled to `#include \./module/sub1.h`" etc. That is very important to optimize the resultant binary file. On the other hand, when a complete module is included, the `./module.h` header file has to include all of the `.h` files in the correspondent folder on the folder's API structure.

Fig. 3. General API structure

III. RESULTS

The overall project including the *Aixt* language definition, the transpiler from *Aixt* to *C* and the API, is published by the authors as a free software project at the URL <https://gitlab.com/fermarsan/aixt-project>. The authors hope this project works as a starting point of a great free programming framework for microcontrollers or as seed for other similar projects.

The complete programming framework was successfully tested using some of the 8-bit and 16-bit PIC microcontroller families from Microchip®. Those devices were selected due to their low amount of implemented data and program memories.

Several different working tests have been performed to check the correctness of most *Aixt* features. Listings 7 and 8 show a comparison of the variable declarations in *Aixt* and the corresponding transpiled *C* code for XC8 and XC16 compilers. In *Aixt* the variable declaration is always along with an assignment. The declaration and assignment process uses the operator `:=` to differentiate with only assignment `=`. At the same time it is necessary to use the conversion predefined functions such as `i8()`, `u32()` and `f64()` among others, in order to specify the number of bits and the type of integer and floating point variables. One of the benefits of using the conversion functions of *V* for the variable definitions is that each variable is bit-width explicit, independent of hardware device. Listing 7 shows too the use of the underscore symbol `"_"` for improving the large numbers readability. Also the special notations for hexadecimal, octal, and binary literals,

are shown. The only difference with *C* is the octal literals beginning with the sequence `"0o"` (zero + o), instead of only `0` as in *C*.

Listing 7: *Aixt* variable declaring and assignment example.

```
var2 := i8(129)
var3 := i64(-6_835_292)
var4 := u8(0b0011_0101)
var5 := u16(0o073452)
var7 := u64(0xA AFF_7625)
var8 := f32(1_342.56)
var9 := f64(-34.035_440)
```

Listing 8: *C* resultant variable declaring and assignment example.

```
int8_t var2 = 129;
int64_t var3 = -6835292;
uint8_t var4 = 0b00110101;
uint16_t var5 = 0073452;
uint64_t var7 = 0xA AFF7625;
float var8 = 1342.56;
long double var9 = -34.035440;
```

Modern programming languages like *V* has some useful features such as the type inference, which simplifies programming in most cases. Type inference gives programmers peace of mind about variable types when they are not needed, thereby reducing development time. The implementation of this feature in *Aixt* is reached by using the standard types for integer and floating point variables. In the case of XC8 compiler the standard integer type is `int8_t` and for XC16 compiler `int16_t`. For the floating point variables the default type is `float`. Listings 9 and 10 show the transpiling result for some variable declarations by inference, including Boolean, character (named runes), integer and floating point literals, for the XC8 compiler.

Listing 9: *Aixt* variable declaring and assignment by inference example.

```
var0 := true
var1 := false
var2 := 1345
var3 := 71.4
var4 := -457
var5 := -10.445
var6 := 'd'
```

Listing 10: *C* resultant variable declaring and assignment by inference example.

```
bool var0 = true;
bool var1 = false;
int8_t var2 = 1345;
float var3 = 71.4;
int8_t var4 = -457;
float var5 = -10.445;
char var6 = 'd';
```

On the other hand, *Aixt* language syntax provides support for some of *V*'s looping statements, such as: condition for (while in *C*), bare for or infinite loop (while(true) in *C*), infinite loops, regular for loop and C-like for loop. Listing 10 shows an example of the loop statements currently supported by the *Aixt* syntax and Listing 11 shows the *C* equivalent of each one. The *Aixt*-like for loop includes and integer range notation with the syntax: *i..f*, where *i* is the initial value and *f* is the final value.

Listing 11: *Aixt* available loops.

```
// condition for
for a < 10 {
    a += 1
}
// bare for
for {
    a += 1
}
//range for
for i in 0..10 {
    arr[i] = 0
}
//c for
for i:=0; i<=10; i++ {
    arr[i] = 0
}
```

Listing 12: *C* equivalent loops.

```
while(a < 10){
    a += 1;
}
while(true){
    a += 1;
}
for(int i=0, i<10, i++){
    arr[i] = 0;
}
for(int i=0, i<=10, i++){
    arr[i] = 0;
}
```

A. Microcontrollers Setting Up

In order to setup a specific new microcontroller or board added to the *Aixt* programming framework, a configuration file has to be written. The chosen format for this configuration file is *YAML* which means Yet Another Markup Language, and is a very simple format to implement setup file for software projects. In that configuration file the designer can setup features such as: type equivalences between *Aixt* and the native *C* compiler, the microcontroller fuses or configuration bytes, the part or device number, the default header files among others. This configuration file is expected to be modified once by the designer and not to be modified by a regular user. The Listing 12 shows an extract of the configuration file for a PIC24FJ device.

Listing 13: *YAML* microcontroller or board configuration file (extract).

```
i8:      int8_t
...
u16:     uint16_t
...
default_int:  int16_t
...
device:    p24FJ128GA010
...
headers:
  - <xc.h>
  - <stdint.h>
...
configuration:
  - "POSCMOD = XT"
  - "OSCIOFNC = ON"
...
```

On the other hand, a batch file has to be included for each new device. This file works as a Makefile, following the steps and invoking the different component of the framework, in order to obtain the final binary file starting from the *Aixt* source code. The batch file has to be provided in *.ps1* (PowerShell) format for Windows and in *.sh* format for Linux.

IV. CONCLUSION

Using the proposed programming framework, the micro-controllers programmer can utilize a modern high level language programming environment, using a compiled language with its benefits and at the same time taking advantage of the modern features of the language. *Aixt* Language pretends to be a highly level programming language for microcontrollers with a short learning curve due to its simplicity compared with other modern languages. *Aixt* utilizes modern *V*-based features such as type inference but at the exact same time obtains binary files with similar optimization degrees of standard compiled languages such as *C* and similar execution times. *Aixt* Language and the proposed programming framework could enable programming microcontrollers with ease, as long as they have a native *C* compilers. At the same time *Aixt* does not need a fixed amount of memory to work, the finally binary file depends only the source code. So it has not the problem of the memory needed to run a program written with an interpreted language such as *MicroPython* or *Javascript*.

The transcompilation process between *Aixt* and *C* is successful because both languages are similar, mainly due to all variables in *Aixt* are mutable by default like in *C*, and some other similar features like curly braces and others. Transpile another language such *Python* to *C* for instance, would be a little bit difficult because the differences between both languages.

Aixt Language and programming framework could allow individuals with little electronics know how to program easily embedded systems, just like *Arduino*, *mbed*, and *MicroPython* among other frameworks. Likewise, *Aixt* could enable experienced embedded system programmers only learning one programming language and API, to program a wide variety of microcontrollers no matter their memory sizes.

All of the features in the proposed programming framework was completely tested, however not all the modern features of

the V programming language were implemented. That means this project can highly improve implementing more features and adapting it to other microcontrollers and boards. It is perfectly able to use Aixt language and this framework in the classroom in Basic courses of microcontroller and embedded systems, due to currently this project is highly functional.

In spite of the short learning curve of V and therefore Aixt languages, it is possible to explore another simple languages to improve the proposed programming scheme, or even giving support to another main languages maintaining the same API. One of the candidates is the Peregrine Language who is based on the Python syntax.

As future work, the development of other useful features of V language are proposed. For example, the array definition, direct array indexing using the array for loop, array interpolation, matching statements among others. Likewise, it is important to keep giving support to other MCUs and board especially those with low program and data memories, which are the motivation for this project. For instance Atmel ® AT mega and AT tiny will be included to the project soon due to they use also the XC8 compiler. Finally, it is possible to combine PC graphical application developed in V with embedded application developed in Aixt, taking the advantage of learning only one programming basis to develop a complete embedded-based graphical application.

Computer Information Systems Research and Technology Centre, Near East University, 99138 Nicosia, Cyprus^{1,3}

Abstract—Digital Transformation (DT) is a vital change in the way an organization utilizes processes, people, and technology to provide value to its ever changing customer expectations over products and services. Researchers developed models and frameworks to tackle concerns in this area, and existing literature improved our understanding of digital transformation. However, there are not enough comprehensive systematic literature reviews to picture a clear portrait of the advantages of related works and point out the major gaps for future studies. This study aims to evaluate how these models and frameworks affect business while highlighting their advantages and pointing out their gaps for future improvements and studies. A Systematic Literature Review (SLR) applied and collected and reviewed seven models and nine frameworks over five years between 2017 and 2021 from four databases of IEEE, Web of Science, Scopus, and Science Direct. These models and frameworks were reviewed and their advantages for researchers and practitioners were pointed out while picturing a clear vision of what is done in the Digital Transformation development of models and frameworks. The findings in this SLR indicated that the rising trend of DT studies has increased by 275% solely from 2020 to 2021 with 62% of those studies conducted in Europe.

Keywords—Digital transformation; digitalization; model; framework; business; SMEs

I. INTRODUCTION

Digital Transformation (DT) is a vital change in the way an organization utilizes processes, people, and technology to provide value to its ever changing customer expectations of products and services [1]. Corporations that effectively use DT appreciate enhanced yields of resources and therefore received higher profits [2]. The DT concept was announced in the year 2000 [3], as the DT can be characterized in a broad sense as the adoption or modification of business models or frameworks as an outcome of the fast quotient of technological progress and innovation, which triggers alterations in customer and social behavior. It is necessary to point out that a framework, also called a model in the literature, is a graphical depiction of an occurrence comprising its main factors, variables, and the interactions among them [4]. Today's DT trends are transforming the business landscape, over the past decade, researchers have focused more on designing DT models and frameworks and provided guidelines on how these models and frameworks can function in various businesses [4], mainly the previous studies in this area were to develop or modify DT modes and frameworks to

address business needs while explaining the implementation process of DT as a whole or a part of the business model. This study was focused on a novel perspective and hoped to fill the gap between prior studies by gathering the latest DT models and frameworks and identifying their advantages for businesses by tending to the business needs while examining the offered value and applicability of DT models or frameworks in today's business ecosystem. The literature showed that there are numerous DT models and frameworks and it is important to choose the most suitable among all the proposed models, however, this SLR can be a guideline for the leaders and decision-makers in the organization who are responsible for approaching the DT to select the most suitable DT model or framework for their organization based on their DT strategy. As society is leaning toward digitizing countless aspects, businesses feel the rising significance of DT. Small Medium Enterprises (SMEs) may approach DT for numerous causes, DT has the power to enhance customer experience by bringing extra data-based insights for business decision-making. Another reason for taking on DT is the superior collaboration that it brings to the business by offering noble opportunities, agility, and alignment throughout the body of the firm, however, this study approached an unsolved gap in this area, and gathered the most recent DT models and frameworks developed by the researchers [4], [9-23] for businesses and analyzed them to bring their advantages to the surface, this approach helps the practitioners to address related concerns more swiftly, also it will provide the researchers with a more clear vision for their future studies in this area.

The purpose of this systematic literature review (SLR) is to collect and review the proposed models and frameworks for DT and encapsulate their approaches toward businesses, additionally offering a better understanding of the DT for future studies. The significance of improving the DT lies within the modifications of business models or frameworks for responding to technological, digital, and social changes [5], as it can be viewed as a revolution to a fresh organizational arrangement that matches better performance in the digital economy with the rapid growth of digital properties. On the other hand, the scope of this study is to find the answers to the following research questions.

RQ1: What is the distribution of publications over time?

RQ2: What is the geographical distribution of the studies?

RQ3: What are the latest developed models and frameworks for business?

RQ4: What advantages are embodied in each model and framework?

RQ5: How future studies can improve the DT models and frameworks?

II. LITERATURE REVIEW

A considerable amount of literature has been published on Digitalization in SMEs and Industry 4.0 (I 4.0) to determine the salient recommendations for their adoption [27], [30]. They made use of the Technology Organization Environment (TOE) framework and determined that SMEs must place a high priority on integration IT systems along the entire value chain and human capital with a focus on proficiency in data analysis and knowledge exploration. A comparative literature review by [28] looked into the DT for transportation with regard to the product-service system lifecycle. Another study [29] only focused on the links between digitalization, company culture, and sustainability in SMEs, researchers were able to identify ten such interdependencies and develop a new analytical framework in the process. The researchers derived six key propositions to aid SMEs in their quest for sustainable digital development via corporate culture development, such as having managers raise awareness and positively shape employee perceptions of the prospect of DT, practicing leadership, culture, and digitalization for sustainability, and prioritizing the integration of DT into the SMEs culture by having the organization's mission and vision statements reflect DT commitments. Another existing study [30] explained the requirements necessary to implement DT in the Smart Manufacturing assessment models. The study [31] undertook a literature review of 204 articles to determine how Big Data and the Internet of Things affect businesses and how they carry out DT. They noted that the growing prevalence of Big Data and IoT increased the amount of disorganized knowledge available to businesses and companies seeking to implement them should learn how to make sense of this noise.

However, these researches do not take into account the advantages of the most recently developed and redefined DT models and frameworks for businesses, also they did not point out the presence of the numerous existing DT models and frameworks waiting to be tested and improved by the practitioners and the enthusiast researchers in this area, this systematic literature review aims to fill this gap.

III. METHODOLOGY

The research made use of a systematic literature review to find and choose relevant articles while simultaneously minimizing the chances of conducting the review process [6]. The study consisted of a systematic search undertaken in April 2022. Table I showed a keyword search was employed with the selected keywords being relevant to the subject matter of the study. The keywords used were "digital transformation" OR "digitalization" AND "framework" AND "business" OR "enterprise" in tandem with the synonyms listed in the following table. These keywords were then used to search through four high-quality databases, namely ScienceDirect, Web of Science, Scopus, and IEEE. These were selected as

they adequately covered the fields of digitalization, management, and entrepreneurship.

TABLE I. KEYWORDS SEARCH QUERY

	Keyword	Synonyms
MAIN	"digital transformation" OR	"digitalization"
AND	"model" OR.	"framework"
AND	"business" OR	"enterprise"

Table II portrayed inclusion and exclusion criteria used as part of the selection process to identify articles that were relevant to the research's aims. The inclusion criteria stated that only documents published within the last five years were to be utilized in the study. As it was merely after 2014 that the DT expression was rapidly nurtured in recognition both by experts and researchers [7]. The business world concentration has reformed significantly for facing the businesses DT from 2017 to 2021 [4]. In order to narrow down the search results to the most recent and cutting-edge research in the field of DT, the inclusion criteria are set to be restricted to only journal articles that were published in English and open access type. Records that did not meet these criteria were excluded from the review.

TABLE II. INCLUSION AND EXCLUSION CRITERIA OF THE STUDY

Inclusion Criteria
Documents published within the last 5 years from 2017 to 2021. Journal articles published in the English language. Documents that are related to the "Business" and "Management" subject areas. Full-text studies that are accessible and downloadable (open access). Studies that present models or frameworks for digital transformation. Studies that include matching keywords with our research.
Exclusion criteria
Any records published before the year 2017 and after 2021. Only published journal articles and review articles. Journal articles published in any language other than the English language. Relevant studies in which the focus areas are business or management. "Digital transformation" OR "Digitalization" OR "Digitalisation" don't exist in the title, abstract, or keywords of the studies.

The PRISMA statement was used to screen records for the primary study selection process. The acronym PRISMA is an abbreviation of, the "Preferred Reporting Items for Systematic Review and Meta-Analyses" [6]. In [8] author stated that it is capable of exclusion of duplicated studies between databases. It also enabled the researcher to remove studies without clearly defined aims, studies that are not relevant to the research questions, and studies that only focused on one keyword as opposed to all of them, e.g. digitalization, model, and business. In this SLR the updated version of PRISMA, PRISMA 2020 is utilized.

A total of nine thousand, eight hundred and ninety-six (n=9896) articles were retrieved from a preliminary search of the four databases, with the individual databases contributing records as follows: Scopus (n=3921), IEEE (n=5888), ScienceDirect (n=71) and Web of Science (n=16). No duplicate records were found via automation tools, although two duplicate records (n=2) were removed manually by the researchers. Out of these results, records published before

2017 and after 2021 summed four thousand seven hundred and forty-seven (n=4747) were removed. Records other than journal articles were also removed, and these totaled three thousand four hundred and forty-two (n=3442). Records whose full text was not accessible on the Internet totaled eight hundred and forty-three (n=843) and these were excluded as well. Records were excluded as they did not have the main keywords in the abstract or title or keywords section of them were ninety in number (n=90). Records not in the English language totaled nine (n=9), and these were removed in the process. A combined master list of the remaining retrieved articles summed 238 which three (n=3) could not be retrieved over the internet, this left us with 235 studies in number that were consolidated on a Microsoft Excel report after the articles were selected beside the inclusion and exclusion criteria. At this stage, the researchers independently assessed the articles to make sure that they were relevant to the study topic, search terms, and research questions. In order to deal with disputes in the selection process, the researchers conducted video conference sessions for reviewing critical materials and also used a WhatsApp chat discussion to supplement this. As the final results of the screening and eligibility scan following records were excluded, Records that don't have main keywords in abstract/title/keywords (n = 47), Records that are not in the field of business and management (n = 58), Records that do not present a digitalization model or framework (n = 114), ultimately a total of sixteen (n=16) studies remained as principal studies for examination (Fig. 1).

Data extraction was carried out on the remaining articles that met the selection criteria. This was conducted in accordance with a number of parameters as shown in Table III. After the data was collected and extracted from the articles, it was synthesized through the construction of a summary table and subsequently evaluated to better perform a literature review.

TABLE III. DATA EXTRACTION

Data Item	Description
Source	Name of the database the article is from
Author, Year	Give the author names, year of publication
Proposed Model OR Framework	What model or framework was proposed in the study
Aspects and Activities	What aspects and activities were featured in the proposed model or framework
Key findings	Show the main results from the articles
Advantages	Show the advantages of each study for business maturity
Recommendations	Show research gaps and areas of improvement

IV. RESULTS

A. The Distribution of Publications over Time

Fig. 2 showed the compiled set of selected studies that dealt directly with DT and proposed a framework or a model. However, in the screening and selection process this SLR didn't find any paper within the research criteria from "IEEE" and "Web of Science", and all the 16 records that were included in the study for further analysis were from "Scopus" and "Science Direct". In the past five years ranging from 2017 to 2021, the trend identified in Fig 2 depicted that within the criteria of this SLR no models or frameworks were proposed in 2017 and 2018. On the other hand, an increase in the number of publications over time from 2019 to 2021 is indicated, with the quantity peaking at 11 total publications in 2021 alone, this shows the focus of researchers on this topic amplified 275 % only over 1 year from 2020 to 2021. Also, displayed that DT and its relationship with businesses and SMEs was a particularly rich area of study for researchers, and deducing this to later years suggests continued interest in the topic. Indeed, [4] highlighted that DT has grown to the point of becoming critical to the survival of companies, with a survey conducted concluding that 84% of such organizations regard it as a necessity for their continued operations in the coming five-year period.

Fig. 2. Publication distribution over time.

B. The Geographical Distribution of the Studies

It is depicted in Fig. 3, the studies included in this SLR were a cosmopolitan blend, the 16 proposed frameworks and models presented in the findings were from 5 continents, with studies being authored in eleven (n=11) different countries. Germany was the country with the highest number of articles, with a total of three (n=3) published studies, followed by Italy,

Fig. 1. PRISMA 2020 flow diagram of the study.

Austria, and Brazil each producing two (n=2) studies apiece, also, Finland, Poland, China, Spain, Vietnam, South Africa, and the USA each published one (n=1) study on the subject. This SLR noticed a trending focus on the subject more in European countries with 62% of them conducted in Europe.

Fig. 3. Geographical distribution of the studies.

C. The Latest Developed Models and Frameworks

The results of this SLR showed that various DT models and frameworks were developed, and widely the focus was on tackling the related issues by proposing a novel model and framework, also revising the prior versions to address other concerns in this area. However, there were not enough comprehensive systematic literature reviews to point out their advantages for businesses or organizations or to picture a clear portrait that enables the comparison among the existing models and frameworks. Table 4 depicted the name of the proposed models, and showed the main aspects and activities that researchers presented in their studies on DT models [9–15]. Moreover, Table V portrayed the name of the proposed frameworks, and displayed the main aspects and activities that researchers presented in their studies on DT frameworks [4], [16–23]. Aspects and activities in the mentioned tables are stages, or phases that the researchers suggested in their studies, these are the steps to be taken by the practitioners in order to implement the model or framework.

TABLE IV. DIFFERENT ASPECTS AND ACTIVITIES OF DT MODELS

Proposed Model	Aspects and Activities	Ref
A “Unified” Framework of Competing Forces From COVID-19	“Digitalization, Processes, Cost Reduction, Business Opportunities, Risk and Negative Consequences, Surveillance”	[9]
Econometric Model to Assess A Company’s Preparedness Levels for Digital Transformation.	“Enterprise Management, Productivity Management, Digital Transformation Platform, Smart Manufacturing”	[14]
The Refined Model of Organizational Competence for Digital Transformation	“Vision and strategy, Digital leadership, Organizational learning process and organizational knowledge, Organizational alignment and organizational structure, Digital maturity, Personal competencies, Importance of personal characteristics, Technology selection, acceptance and use, Information culture, Organizational effectiveness”	[10]
A Digital Competence Maturity Model (DigiCom)	“Digital Content, Human-Machine, Human-Human, Personal”	[11]
Model of The Impact of DT on Project Management	“Disruptions: New technologies, Customer expectations, Competitive landscape, Data and analytics, Change process, Projectification of activities, Effects: process automation implementation of new technologies remote cooperation world sourcing new structures, Virtual project teams Online, constant communication Agile methods, Customer orientation and incremental product delivery, Project manager as a facilitator, Optimization of processes of project delivery, Constant access to data, IT tools”	[12]
Digital Transformation Model	“Positioning, Roadmap, Implementation, Current State Review”	[13]
Development Approach Industry 4.0 Maturity and Realization Model	“Definition, Maturity model’s scope, structure and design, Research and population with maturity items, Development assessment tool and structure of maturity report, Transformation maturity items into realization paths, Definition procedure and rules for deriving action-field, Testing and creation of final step-by-step realization model”	[15]

TABLE V. DIFFERENT ASPECTS AND ACTIVITIES OF DT FRAMEWORKS

Proposed Model	Aspects and Activities	Ref
I 4.0 Emerging countries’ DT strategy framework (ECDTS)	“Digital platforms, Ecosystems”	[16]
Interpretative Framework	“Business driver, Supply view, Entrepreneurial model”	[17]
Digitainability Conceptual Framework	“Digitalization, Sustainability”	[18]
Multi-Dimensional Framework	“Contextual Conditions, Mechanisms, Outcomes”	[19]
Digital transformation patterns	“Lean Production, Industry 4.0”	[20]
Conceptual Framework of open innovation to support digital transformation.	“Managerial Strategic and Social Drivers, Digital Technology Enablers, Business Partners, Scientific Partners, Facilitating Factors, Limiting or Challenging Factors, Contribution of collaboration for Digital Innovation”	[21]
The interaction-based digital transformation framework	“Digital Technologies, Business, Society”	[4]
Digitalization and public crisis responses theoretical framework	“Digitalization, Dynamic Capabilities, Response Strategies, Response Performance”	[22]
Construct Map Conceptual Framework	“Digital Transformation, Digitalization, Business Model Innovation”	[23]

D. Advantages that Embodied in each Model and Framework

One of the main goals of this SLR was to find the advantage of the proposed models and frameworks, in order to do that this SLR reviewed and summarized the purpose of these studies. Since the Covid-19 pandemic began it affected all aspects of our environment, and DT is one of these areas. One study recognized the disruptive nature of the pandemic and seeks to utilize its pressure in a way that benefits businesses, i.e. by using it as a catalyst for digital transformation, digitalization drivers and barriers are identified and the study gives organizations a clear picture of the benefits and drawbacks of such a shift, the Conceptual Model proposed by this study offers a roadmap that tackles digitalization in the field of uncertainty i.e. the state of the economic crisis during the Covid-19 pandemic [9]. The research [22] examines the correlations between DT, disaster management strategies during the Covid-19 pandemic, and SMEs' disaster response ability. Using online survey data of 518 Chinese SMEs, the findings in the research perfectly illustrate that, in the long term, digitization may assist SMEs in deploying disaster response as well as responding tactically to public crises, contributing to an increase in SME's capability, an advantage the enormous data set of 518 SMEs in China was used for structuring the presented theoretical framework which is considerable and valuable, especially in times of crisis.

Besides the model and framework development, tool development was also an area that received attention from the researchers. One study developed a useful tool for gauging the preparation of an enterprise for Digital Transformation, classifying them as either Newcomer, Learners, or Leaders. This model was used in conjunction with operational efficiency figures and data on the movement of personnel to determine the impact of DT preparation on the sustainability of companies. The analysis showed different results across the three classifications of companies. overall, businesses benefit from tight integration of Digital transformation in the long run as this yields the greatest operational efficiencies and personnel utilization, the benefit is that this model allows for the assessment of a business's preparation and readiness for Digital Transformation on the sustainability of a company [14]. The [10] research led to the creation of an OCDT model that may assist SMEs in identifying and developing DT strengths in order to progress their enterprise model's DT, moreover, the model is more appropriate to the needs of SMEs than other models that enable digital readiness advancement but were intended for large firms, the advantage of this model will enable SMEs to assess and create digital skills that are now lacking, moreover, it will assist in the digital transformation of business models in order to develop competencies that will enable SMEs to effectively adjust to the changing competitive atmosphere created by digital technologies and marked by innovation and rapid change.

This SLR was able to find solely one research that focused on the impact of DT on project management. The author [12] developed a model that is known as the "Model of the Impact of Digital Transformation on project management" and analyzed thoroughly the manifestation of change that was formed into a model explaining the model, things like the

"Change Process" which includes objectification of activities, "Disruptions" which includes the following, "Novel technologies", "Competitive landscape", "Customer expectancies", "Data and analytics", and "Outcomes" which includes procedure automation new technology adoption new architecture in the field of distant collaboration, as well as the most essential pro and con characteristics of the changes and identified the influence of Digital Transformation on Project. Moreover, the researchers found that Digital Transformation acts as a significant aspect that is an important element determining contemporary project management, the model that was used in this article has great significance in digital transformation in a general social context, there are several advantages in this study: a. Project effectiveness, which includes cost savings, time reduction on activities that are not useful, proper management and allocation of resources. b. It makes it possible to be able to use the time already saved as a result of the elimination process that took place on repetitive activities and gives more room for more creativity and adding value activities. c. Decrease the delivery time of the project. d. Automation has enabled the duration of delivery projects to be reduced to a minimum through the usage of new automation tools. e. Capacity to depletion of a huge number of existing data, real-time access, and quick and easy data handling. f. Possibility of work and results to remain flexible.

When it comes to DT a significant aspect to focus on is employees, in this regard [23] study has proven that human resources as magnitudes of National Intellectual Capital are cogent features of Digital Transformation and shall be reinforced to enhance Europe's capability to survive the digital world, also it constructed a map towards more robust Business Model Innovation. On the other hand, [11] Construct Map Conceptual Framework provides a historical outlook on European Union Countries in totality and focuses more on working talents as modules of human resource, with more focus on employee training and qualitative vocational training. Also, in another paper researchers proposed the Digital Competency Maturity Model (DigiCom) which consists of 49 attributes in four dimensions which are Digital Content, Human - Machine, Human - Human, and Personal to measure the maturity of individual employee levels in industrial enterprises with five steps developmental methodology in use. The proposed model approach used, makes digital competencies more visible, realistic and measurable and modify the basis for competence development in employees that will enhance the performance of their enterprise. The DT DigiCom model focuses deeply on the digital competency of employees in industrial enterprises because it's essential in the manufacturing sector to have digitally equipped clients with the knowledge of managing machines.

Some researchers worked their idea around Industry 4.0, for instance, Digital Transformation Patterns Framework, pointing out that lean production is a concept that is not considered as often as it should be when it comes to digital transformation, this study is an important step in this new area and shows that I4.0 and LP are related when it comes to transformation and that firms committed to lean achieve better digitalization outcomes than those that are not, and the framework takes into account Lean Production

implementation level as a dimension, a novel metric to inform companies on digital transformation patterns with regards to Lean Production [20]. On the other hand, one study proposed an innovative industry 4.0 realization model i.e. industry digital transformation model which proposes a ten steps method that leads the company in a systemic way from their initial interaction by industry 4.0 (transformation model) till industry 4.0 (transformation model) the planning is well defined by roadmaps, action-field, and realization projects, which benefits to the industrial digitalization through its model by creating well-defined structure and enabled the collection of valuation data from manufacturing businesses to amplified precision when benchmarking the company's maturity among others [15]. The third group of researchers focused on digital transformation in emerging countries of Brazil, Russia, India, China, and South Africa, laying out a novel framework for firms to follow that yielded strategic capabilities to the firm, the I4.0 ECDTS framework was backed by a robust analysis of prior research, though its newness could benefit from the application of the proposed framework in the field, the study also reduces the research legwork with regard to policy features in use for strategic pivots. The I 4.0 ECDTS framework enables firms to evaluate the steps taken toward digital transformation, and the framework increased competitive advantage due to flexibility brought on by digitalization and enables strategic capabilities within the firm [16]. However, [21] examined cooperation between scientists and business partners as a key contributor to fostering Industry 4.0 and enhancing digital transformation, plus drawing attention to the fact that technology collaboration drag more benefit on the business success front than technologies developed and adopted solely internally by practitioners, as a benefit this framework analysis how innovation collaborations with different business and scientific partners integrate with digital transformation and Industry 4.0.

In contrast, some researchers followed by another study that they did in 2017 and proposed the model for tackling the DT and in this study, they focused on the step-by-step implementation of the DT model by providing clear explanations and tools and procedure for this purpose, the DT model is an iterative model and needs to be broken down into small pieces of plan and action to be implemented and is not expected to be a model for tackling all the DT difficulties all at once as they have piloted the DT model in 19 SME's and got brilliant results, the presented DT model is a 4 step which is iterative and can be divided into small steps to be taken by the company, also three tools are provided for better guidance and implementation of the DT model, these tools are The DigiMaturity tool, which answer the question, what is the maturity level of the business, the DigiSWOT tool that provides the questions for analyzing the digitalization strengths, weaknesses, opportunities and threats, and The DigiTriangle tool to let the company categorize their vision priorities [13]. Another study by [17] proposed Interpretative Framework investigates the primary legacy from prior industrial revolutions with a particular focus on business drivers, supply view, and entrepreneurial model. The study hopes to act as a guide for international manufacturing SMEs as they tackle digital transformation by providing a comprehensive framework of prior industrial revolutions from

them to draw lessons, the features considered crucial were those of business drivers, supply view, and entrepreneurial model, the Interpretative Framework provides a historical outlook on the process of past industrial revolutions and may be used to extrapolate lessons for carrying out digital transformation in the present.

Nevertheless, [19] formed a Multi-Dimensional Framework that seeks to bring together all the aspects of Digital Transformation ranging from contextual conditions, mechanisms, and outcomes of the process, the study proposed a far-reaching conceptual framework that builds on past knowledge of the organizational change, as a result, it identified trends in digital transformation and came up with perspectives on digital transformation perspectives namely holistic co-evolution, systemic shift, technology impact, and compartmentalized adaptation, the Multi-Dimensional Framework identified trends that allow for greater understanding of Digital Transformation, namely, the shift towards malleable organizational designs and their integration into digital business ecosystems. This SLR found another research [4] that proposed a novel framework that works on the understated areas by combining the numerous models discovered in the literature, plainly incorporating the role of society, emphasizing the evolution over time, and incorporating the drivers of digital transformation classified in 23 digital transformation interfaces throughout 6 groups, eventually, this study can be the initial stage of a unified concept of digital transformation, because the researchers looked at the evolution of 41 DT models and found four different research possibilities, they pay homage to the DT research by organizing their findings into a fresh, all-encompassing framework that integrates important shifts in business, society, and technology, also, they further emphasize the processes' diversity by categorizing the drivers of DT into 23 DTI and 6 categories, this research brings a clear perspective on DT research, this could aid in a deeper understanding of how change happens and where certain changes interact with each other, by bridging the gap between business and society.

From a different perspective, [18] acknowledged the dark side of digitalization such as increased carbon footprints and energy consumption by firms, and seeks to mitigate these negative effects through its conceptual framework that lends greater weight to sustainability, as an advantage the Conceptual Framework gives greater focus to sustainability in digitalization, provides new findings for sustainability research and regulations and overall offers companies a greater chance at achieving sustainable digital transformation.

E. How Future Studies can improve the DT Models and Frameworks

To answer the last proposed research question, this SLR took a deep dive into the literature and reviewed the papers to find the most promising areas for future studies. Expansion of the studies to other countries and developments for a more international organizational environment [14], [16-17]. Monitoring and assessment of the applicability of the model/framework is a crucial area to look into, due to the novel nature of these models/frameworks [9-10]. More

corporate studies including extending the research to different phases of DT models/frameworks as well as establishing tools, procedures, and methodologies, also trying for linking different understandings of different perspectives of the DT [13], [20]. [10], [12], [21] found another area to conduct research for future studies is an expansion of scope through more interviews and expanding the research through quantitative surveys or consolidation of prior quantitative studies, and trying to catch up with technology as AI is increasingly advancing.

V. DISCUSSION

The results of the SLR found that there are some challenges that affect the success of digital transformation success in businesses. For example, digital technologies [10], the digital skills of employees, the digital transformation strategy [32], and leadership. The business and its employees should have the necessary innovative devices, and digital technologies for the digital transformation process, and of course, the digital skills of the employees should be sufficient to use new technologies effectively. In addition, the business must prepare an effective digital transformation strategy and leadership for digital transformation so that digital transformation processes can be carried out successfully.

The digital world globally needs to achieve smart sustainable development while creating value and wealth for society [24]. Therefore, this SLR took a deep dive into the literature and presented a clear picture of what has been done in terms of DT model/framework development searched for by the researchers. This shortage was one of the reasons why this SLR was carried out so as to fill this gap in the literature, it helps the researchers understand the status quo of DT and enabled them to visualize a clear vision of previous studies in this area. This study was able to identify an uptick in the trend of research papers published in the field of Digital Transformation over the past five years (from 2017 to 2021). The papers steadily increase in number, with the total number peaking at 11 papers published in 2021, which is more than the prior four years combined, which adds up to 5 papers. This growth may be attributed to an increased awareness of the extent to which DT impacts the organization [4]. Put forward the argument that DT is not just a passing trend, but may prove to be key to the continued operation of companies, with several companies acknowledging the new DT status quo, it stands to reason those organizations and researchers alike would take an increased interest in the area, resulting in a rise in the number of published articles over time.

Papers originated from a spread of 11 countries. As 62% (n=11) of studies came from Europe, which is remarkable, as the term Digital Transformation itself was coined in North America, one would deduce that the bulk of research would stem from their [3]. However, this peculiarity is better framed when looked at through an economic lens. Germany alone counts for 25% of Europe's Gross Domestic Product and constitutes the largest market in Europe [25], also, it is the third-largest exporter globally, after the United States and China. These factors may contribute to its organizations swiftly taking up DT so as to survive and thrive in the global marketplace. Researchers may also have been drawn to

publish from the country as it is a hub of small and medium-sized enterprises, forming an ideal study and testing ground for proposed DT frameworks [25-26]. It is worth mentioning that the two terms may be used interchangeably when it comes to Digital Transformation [4]. This interchangeability of these terms caused this SLR target search broader than expected which made it harder to find needed results in the literature, but this SLR put both terms in the research agenda to maximize the efficiency of the study and make the road smoother for further studies around the DT area.

Therefore, one limitation, the researchers faced was to conduct this SLR from 4 databases (Scopus, IEEE, Science Direct, Web of Science) meaning that there are other databases that are not covered yet. Another limitation in this SLR was the time boundary, despite the concentration of the studies in recent years we suggest further research on a wider time boundary to collect more relevant studies from before the year 2017. This study focuses on finding the advantages of DT models and frameworks to businesses while gathering proposed models and frameworks that are developed for DT, this can be beneficial to the businesses that are not sure which DT strategy is more suitable to take and also the researchers will have a more clear vision of the road ahead to conduct future studies about DT. We suggest to other researchers who will study this topic, to focus on the negative effects of DT models /frameworks on SMEs and businesses and to utilize this SLR and take additional actions for the development of the DT models and frameworks.

VI. CONCLUSION

Previous studies in this area mainly focused on the development of DT models and provided guidelines and procedures for the adoption of their presented model. The aim of this SLR was to review and analyze existing DT models and frameworks to point out their advantages for businesses to help them to approach the most suitable DT model or framework for their organization based on their strategy. Moreover, the results of this SLR provide a clearer vision for future studies in this area. This SLR found 16 studies in a period of five years from 2017 to 2021 in four databases of IEEE, Web of Science, Scopus, and Science Direct. The results showed an incremental trend in the time distribution of discovered studies, interestingly only from 2020 to 2021 number of related studies raised by 275% percent. Also this study indicated that 10 out of 16 discovered studies were conducted in Europe. However, the DT area is still seeing novel models and frameworks that are not deeply tested and refined. We hope that the results of this SLR will help researchers and practitioners in this field in their future work and studies.

Abstract—The use of technological speech recognition systems with a variety of approaches and techniques has grown exponentially in varieties of human-machine interaction applications. The assessment for Qur'anic recitation errors based on syllables utterance is used to meet the Tajweed rules which generally consist of *Harakaat* (prolonging). The digital transformation of Quranic voice signals with identification of Tajweed-based recitation errors of *Harakaat* is the main research work in this paper. The study focused on speech processing implemented using the representation of Quranic Recitation Speech Signals (QRSS) in the best digital format based on Al-Quran syllables and feature extraction design to reveal similarities or differences in recitation (based on Al-Quran syllables) between experts and student. The method of Dynamic Time Warping (DTW) is used as Short Time Frequency Transform (STFT) of QRSS syllable feature for *Harakaat* measurement. Findings from this paper include an approach based on human-guidance threshold classification that is used specifically to evaluate *Harakaat* based on the syllables of the Qur'an. The threshold classification performance obtained for *Harakaat* is above 80% in the training and testing stages. The results of the analysis at the end of the experiment have concluded that the threshold classification method for Minimum Path Cost (MPC) feature parameters can be used as an important feature to evaluate the rules of Tajwid *Harakaat* embedded in syllables.

Keywords—Speech processing; short time frequency transform; dynamic time warping; human-guided threshold classification

I. INTRODUCTION

The Tajweed Al-Quran guidelines [1], which outline the laws of Makhraj, Sifaat and Harakaat (MSH) scientifically have shown the comprehensiveness of rules and requirements for the proper pronunciation and articulation [2] of each syllable, forming precise recitation for each verse for Al-Quran recitation. This unique information is often embedded inconsistently in the Quranic recitation digital signal, due to different signal representation circumstances and recitation of the Quran by different readers [3]. The preparation of this recitation signal for further analysis, involving Digital Signal (Speech) Processing (DSP) up to the classification of Tajweed rules digitally, is not an easy task as it involves technical solutions, moreover religious opinions and sensitivity need to be factored in.

Difficulties in managing the complexity of recitation signals[3], especially in selecting a reasonable DSP method for the smooth implementation of every stage involved, are among the aspects of the study emphasized in this paper. The

discovery of the error of Tajweed-based recitation [4] was completed by contrasting the comparability properties of the discourse signal between the learner and the expert recitation signal. Stochastic reading discourse is a very interesting issue for a person to show or evaluate reading errors based on technology. The specific model should be able to deal with even a relatively miniature form of differences.

The ability of DSP to reveal important features and classification approaches is very promising and becomes an important pillar in facing and solving the complexity of speech or voice signal analysis. Phoneme duration features and speech models are used to recognize some rules of reciting the Quran [5]. Therefore, an approach to reveal the characteristics and classification of time series to represent speech or voice using DSP techniques will be highlighted in this paper.

Harakaat, as one of the Tajweed rules in the recitation of the Qur'an [6], is the process of prolonging the pronunciation of syllables. In general, the law of Harakat Tajweed requires the prolonging to be performed on the particular syllable pronunciation guided by the character of ζ (Ya), $\text{'}^{\text{}}$ (Alif) and $\text{'}^{\text{}}$ (Wau). In addition, the prolongation of the syllable pronunciation [7] at the end of a sentence also involves 2, 4 or 6 *Harakaat*. The *Harakaat* rules, known as *Madd* [8] are generally divided into 12 types.

The structure of this paper begins with Section I which explains about the introduction to the complexity in speech or the nature of the voice in reciting the Qur'an. Section II explains about the type of reading rate of the Al-Quran that specifically involves the law of Tajwid *Harakaat*. Next, the work related to *Harakaat* analysis is explained in Part III. This is followed by a discussion about the Dynamic Time Warping (DTW) method for feature vectors in Part IV. Descriptions of the extraction design work and a description of the relevant experiments that have been carried out are included in Section V and VI respectively. Part VII of this paper explains the experimental results and the discussion of issues related to the results of the analysis. Finally, the conclusions from the research results in this paper are summarized in Section VIII.

II. AL-QURAN RECITATION SPEED RATE

Islam requires its followers to read the Qur'an in an orderly and prudent manner. Furthermore, reading it with melodious and serious appreciation while following Tajweed rules [5] is very much demanded. There are four types of recitation speed rate which relate to *Harakaat* Tajweed [9].

A. At-Tahqiq (التحقيق)

This is a common reading type for beginners who are just learning Tajweed. The way it is read is similar to at-Tartil, but at-Tahqiq is identified as slower and calmer. The recitation of at-Tahqiq is also as practiced and considered as an initial stage for a novice reciter before the recitation improves to the next level.

B. At-Tartil (الترتيل)

In terms of terminology, at-Tartil carries the meaning of slow reading. This is in line with the tafsir stated in Tafsir Ibn Katsir, where tartil means reading the Qur'an in accordance with the law of Tajweed.

This means each of these readings is given the rights and properties of the letters that should be. Basically, reading with the al-Tartil approach allows the reader to understand and reflect on the verses of the Qur'an.

C. At-Tadwir (التدوير)

At-Tadwir is a type of reading in which the reading rate is intermediate between slow reading and fast reading. Usually, at-Tadwir recitation is practiced in congregational (Jama'ah) prayers, where the reference can be observed easily based on the recitation of Harakaat, known as Mad Munfasil which is recited not more than 6 Harakat.

D. Al-Hadar (الحدس)

Al-Hadar is defined as a way of reading at a relatively fast pace within the laws of Tajweed. In fact, Al-Hadar is the fastest level of reading and usually practiced by memorizers of the Qur'an who requires repetition in the process of memorization. A simple reference can be observed when the reading involved in the law of Tajweed namely Mad Munfasil, the reading is read with only two Harakat only. However, even though the whole recitation is read quickly, the reader adheres to the relevant Tajweed laws in every verse read.

In this paper, the collection of data is implemented for the at-Tadweer category. This important Harakaat attributes are evaluated in the experimental works taking into account the differences in recitation speed rate in every category, producing different Harakaat duration requirements.

III. RELATED WORKS

One of Tajweed rules is the prolongation, which is related to rhythm of recitation. There are various types of prolongation or Harakaat. The approach of Harakaat analysis concerns on sequences of voiced or unvoiced sound because of recitation are related to the prosody. The production of voice or speech involves the movement of air from the lung to vocal tract towards the lips. The combination of voice production mechanism produces a variety of vibration and spectral-temporal composition that produce different speech sound and its prosody. Apparently, the Arabic phonetic sound was produced from the specific articulation places or regions in the vocal tract.

MFCC features are widely used to determine the type or error for Al-Quran word pronunciation or Tajweed rules [10]. In addition, there are further discussion on the uses of MFCC as features in Harakaat recognition or identification [11], [12]

and the prosody characteristics of speech signals associated with Harakaat [13]. All this emphasizes that it has a high potential to be used to obtain important characteristics. Among the successes reported, one of them is encouraging results in the assessment of English pronunciation [14]. Likewise with the successful use of prosody features in identifying the correct recitation of the Qur'an [15].

IV. DYNAMIC TIME WARPING

Speech is a time varying process [16] in which the duration of a word and its sub-words varies randomly. Time alignment may be applied in recitation which is required to find the best alignment and ratio between utterance sequences of expert and learner [17]. The recitation feature vectors represent the syllable similarly length on time occurrence. Dynamic Time Warping (DTW) is used to warp two feature vector sequences in time. DTW is well known in speech recognition to cope with different speaking speeds [18].DTW is used as feature matching with the deployment of the technique of minimum Euclidean distance or another distance-based approach [19]. DTW measures the similarity between the two temporal sequences which may vary in time [17]. This technique is also been used for finding the optimal alignment between the two-times series if one time series may be "warped" non-linearly by stretching or shrinking it along its time axis [20][21]. The recitation is also re-mapped as if all utterances were produced from the same vocal channel. The recitation speech signal produced by the learner is warped with respect to the Quranic speech signal that belonged to the expert by using the DTW algorithm. As a result, the sequence of Quranic speech signal of expert reference, X , with the length of $|X|$, and the learner, Y , with the length of $|Y|$ can be expressed as in equation 1.

$$X = x_1, x_2, \dots, x_i, \dots, x_{|X|}$$

and

$$Y = y_1, y_2, \dots, y_j, \dots, y_{|Y|} \quad (1)$$

The warp path, W , is then can be constructed as,

$$W = w_1, w_2, \dots, w_K$$

where

$$\max(|X|, |Y|) \leq K < |X| + |Y| \quad (2)$$

where K is the length.

And, k th element of the warp path is $w_k = (i, j)$

where i = index of time series of X , and j = index of time series of Y .

The optimal warp path is presented as 'local match' scores matrix by getting the lowest-cost distance warp path and the first frame optimal warp start at $w_1 = (1,1)$ where the distance of a warp path is given by,

$$Dist(W) = \sum_{k=1}^{k=K} Dist(w_{ki}, w_{kj}) \quad (3)$$

$Dist(W)$ is the cosine distance of warp W , and $Dist(w_{ij}, w_{kj})$ is the distance between the two data frame indexes of X and Y in the k th element of the warp path.

The lowest-cost path for the first frame is $D(1,1) = 0$ and can be calculated by,

$$D(i, j) = Dist(i, j) + \min[D(i-1, j), D(i, j-1), D(i-1, j-1)] \quad (4)$$

The minimum-cost alignment is determined from the optimal warp path that ends at $D(|X|, |Y|)$ by looking at the lowest-cost warp path. The lowest-cost warp path is indicated by the ratio of STFT features vector between expert and reciter recitation signals. The search grid is used as a one-to-one monotonic transformation of the time axis in which all the movements have equal weight.

V. FEATURES EXTRACTION DESIGN FOR HARAKAAT

To represent the parameters of measurement for the duration of syllable pronunciation, DTW of minimum path cost parameters coefficient is used. DTW calculates the local stretch on the time axis for two-series objects to optimally map one (query) to the other (reference) by calculating the distance between unequal sequences of length [19]. Minimum path cost alignment calculation uses the cosine distance [17] to determine the optimal warp path from the start point of syllable utterance until the end of an utterance. For each of syllable's utterance the search grid is used with one-to-one monotonic transformation along the time axis. The lowest-cost path is calculated from the optimal warp and known as minimum path cost alignment parameters co-efficient (refer to equation 4). The comparison between Quranic syllable-based Recitation Speech Signal (QRSS) syllables is done by the recitation ratio calculation between the expert and the learner recitation based on Short Time Frequency Transform (STFT) features. The STFT is given by

$$X(k, m) = \sum_{n=0}^{N-1} x(n+m)\omega(n)W_N^{nk}$$

Where $k, m = 0. 1. \dots, N-1$

$\omega(n)$ = time shifted window function.

m = the amount of shift. (5)

The value of the sequence distance represents as the Minimum Path Cost (MPC) for evaluating the syllable characteristics in each period referring to the Harakaat Tajweed rule feature. The minimum path cost (MPC) is used to obtain the optimal alignment by computing all the possible cost path and determine the lowest overall cost from the path to achieve high similarity between the two temporal recitation speech signals. Fig. 1 shows the minimum path cost (MPC)

parameters with optimal path. The steps to calculate the minimum path cost parameters are given as follows [22]:

- 1) Load the QRSS from the expert as a reference template and followed by learner waveform of the same syllable.
- 2) Calculate the STFT features for both QRSSs (with 25% window overlaps).
- 3) Construct the 'local match' score matrix as the cosine distance between the STFT magnitudes.
- 4) Use dynamic programming to find the lowest-cost path between the opposite corners of the cost matrix.
- 5) Find the cost of minimum path cost parameters of the two signals of recitation speech.

Fig. 1. The minimum path cost (MPC) parameters with optimal path.

The minimum path cost parameters value increases when the duration between two QRSSs is increased. Referring to the optimal DTW path in the similarity matrix, it can be observed that the darker grey scale shows a high similarity between the two QRSS readings. Thus, at the optimal DTW level in the minimum path cost, a lighter grey scale indicates a lower cost path (indicated in red) between the two QRSSs. The minimum path cost parameter is taken at the last value of the lowest cost path.

VI. EXPERIMENT

In the context of significant features of QRSS-syllable, the motivation of miniature feature creation remains towards the enrichment of the property characteristics by prosodic features that extracted by DTW. In this section, the *Harakaat* measurement is based on the time length for each syllable measured by using the DTW technique. Firstly, the QRSS-syllable is segmented into a number of frames and uniquely offering the Short Time Frequency Transform (STFT) feature [22] to be extracted using DTW technique. The cosine distance value for each frame is then calculated as the STFT miniature feature property (power energy). Later, the minimum cosine distance is obtained for every frame with the application of dynamic programming.

The minimum cosine distance is finally selected as the minimum path and is represented as the Minimum Path Cost (MPC) value. This means that the MPC parameters are

selected to measure the Harakaat for QRSS-syllables. Fig. 2 shows the different values of MPC for different syllables recited by 54 reciters for the Harakaat measurement performed.

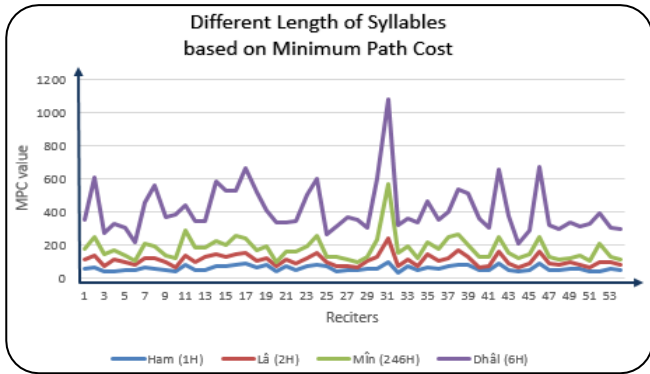

Fig. 2. Different syllables length based on Minimum Path Cost (MPC).

For example, the syllables *Ham*, *Lâ*, *Mîn* and *Dhâl* clearly indicate the lengths of time that differ from each other, which are one Harakaat (1H), two Harakaat (2H), four Harakaat (4H) and six Harakaat (6H) respectively. This is in line with the rule of Harakaat Tajweed for each of these syllables, which have different length of Harakaat respectively.

From the graph shown in Fig. 2, the syllable value of 1H has the lowest MPC value compared to 6H. As for 4H, the MPC values are between 2H and 6H, most of which are in the Tadweer category of speed. The speciality of syllable *Min* in having the multiple choices of Harakaat (2H, 4H and 6H) is limited to the two, four or six Harakaat (4H) for the measurement simplification.

The computational engine score threshold process is used to evaluate the similarity and the dissimilarity based on human-guided threshold process [23]. This successful threshold process shows how a conventional Talaqi process (experts evaluate the recitation by learners based on how to pronounce syllables in the verses of the Quran) are transformed to a machine evaluation approach. Computational engines must have salient features that can distinguish between correct and incorrect readings. Therefore, in determining the score, analysis of salient features, and matching process is used to obtain reading assessment based on the actual assessment by experts called a human-guided or Talaqi-like assessment [24].

Talaqi-like approach and process have been applied in the training and testing phases in the development of computational engine. This is to ensure that the assessment made by the machine are always guided by the human expertise. In this process, MPC parameters are used as representations to each syllable recited by the learners. Initially, the MPC values from recitations by experts were used as primary references in the threshold range assuming that all MPCs generated by expert readings were within acceptable thresholds by the system. Thereafter, learner's recitations were assessed by comparison based on this reference threshold range.

In the training phase, the recitation results by learners were also evaluated by experts to confirm whether learners' recitation is acceptable or not, considering that everyone is still able to comply with the Law of Tajweed despite recitation with different levels of voice. Therefore, the initial value of the threshold originally set for the machine will continue to change (i.e. not necessarily fixed) as long as the expert evaluating the recitation complying with the applicable Tajweed Law.

The training process on this machine with human-guided assessment continue to be repeated until all MPC data have been evaluated by a leading expert (human). After the training process is over, the value of the threshold range has been fully obtained and can be used as a benchmark for the recitations made by learners, that is, whether it is correct or otherwise (within or outside the range). The range for this threshold values is then used and tested for accuracy in the testing phase. The testing performance of this Talaqi-like approach is be measured and justified. Fig. 3 shows the Talaqi-Like assessment flow process.

For Harakaat validation, there are four types of classes are tested, namely as 1H, 2H, 4H and 6H according to their prolongation types.

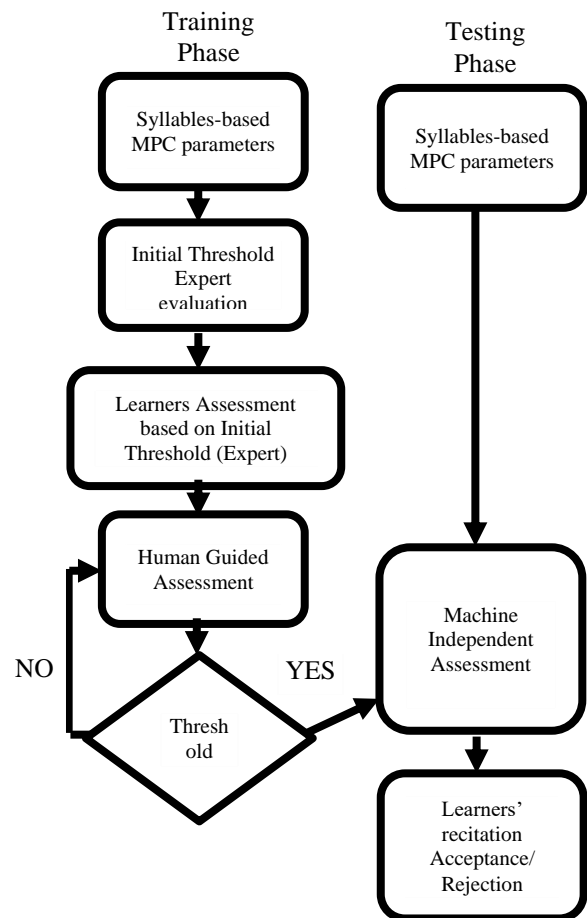

Fig. 3. The Talaqi-like assessment (Human Guided) flow process for Harakaat assessment.

In this classification approach, cross-validation is used to avoid overfitting of the model or class prediction [25]. Cross-validation is a resampling procedure that used to evaluate machine learning models on a limited data sample. It protects the overfitting by partitioning the data set into the fold and estimating the accuracy of each fold. This classification procedure used is k-fold cross-validation which data is divided into k-number of groups. The number of k-group that used in this classification is 5-fold.

The performance of classification is shown with the use of confusion matrix [26] by finding the True Positive Rate (TPR) and False Negative Rate (FNR). Both TPR and FNR are used to indicate the MPC parameters belong to the class or out from the class for each syllable Tajweed rules group or type. TPR shows that the true parameters of MPCs are included in a positive class. While FNR shows that true parameters of MPCs are included in a negative class. In other words, TPR and FNR indicate that parameters of MPCs are classified in the right or wrong classification, respectively.

Confusion matrix is a relatively popular measurement in summarizing the ability or performance of a group of algorithms in classification tasks [26]. In fact, in many cases, the accuracy of a classification result, can produce confusion if it has inconsistencies in the observations that need to be implemented for each classification. The main idea of employing the confusion matrix remains as commonly practice in any machine learning application. The result of the calculation of the confusion matrix is not only able to provide a better perspective on the modelling of a classification, but also at the same time able to identify the form or type of mistakes that have been made. Table I shows the classification performances by Linear Discriminant (LD), Support Vector Machine (SVM) and K-Nearest Network (KNN) for Harakaat measurement using MPC.

TABLE I. CLASSIFICATION PERFORMANCE OF HARAKAAT USING DIFFERENT CLASSIFICATION

Harakaat	LD (%)	SVM ((%)	KNN(%)
1H	98	99.4	96.8
2H	0	1.4	72.6
4H	7.4	13.5	75.5
6H	84.6	94.2	92.3

VII. RESULT AND DISCUSSION

The acquisition of MPC values can be considered as similarity parameters representing MPC the unique significant features of STFT features. Therefore, the training and testing phase classification are developed to assess the *Harakaat* Al-Quran recitation. However, the assessment of this *Harakaat* is limited to recitation from Malay adults because the data used in establishing the threshold range involves only Malay experts and students. This means that the threshold used is limited to the entire voice of Malay adults only.

In this training phase of the classification stage, the initial parameters of MPC are taken from the calculation of 12 Malay

expert recitations to create an initial threshold range along with maximum and minimum values. As a result, the Acceptance Threshold (AT) is defined as,

$$\text{MinMPC} \ll y \ll \text{MaxMPC} \quad (6)$$

while y = accepted threshold MPC parameters.

Each syllable is represented by MPC parameters. These parameters are used to determine the pronunciation of the syllable is pronounced correctly or not, based on the rules of Harakaat Tajweed. These AT values are used based on the minimum and maximum value ranges of MPC to evaluate the syllables related to Harakaat. The starting point of training phase is when the input given to this designed system begins to create a change of pattern or minimum and maximum value that limits the correctness of a Tajweed in the reading of the surah. This is seemingly caused by the changes of the acceptable lowest and highest values of MPCs that correspondingly due to the variability demonstrated by various reciters but remains accepted (Acceptance Threshold) by the expert.

The process of correcting (or training) the minimum and maximum values (threshold range) is firstly performed on the group of experts' MPCs data. This is the initial threshold range and used as reference values to be compared with the learner recitations. Secondly, the MPCs values obtained from the recited syllables of 40 learners are matched with the expert threshold range. Besides the setting of minimum and maximum values, the indication of True Acceptance (TA), False Rejection (FR) and False Acceptance (FA) of the calculated MPCs are counted and accumulated.

Table II tabulates the MPCs values of syllables verse-2 of Al-Fatihah recited by 40 learners that have been matched with the threshold range of expert's recitations. Referring to the data shown, performance on Harakaat assessment for each syllable are highly accepted for syllable S5. It shows that the assessment based on expert and learners MPCs parameters are acceptable by using this approached.

TABLE II. TABULATES THE MPCs VALUES OF SYLLABLES VERSE-2 OF AL-FATIHAH

Range and Result Indication	Expert Max	Expert Min	TA	FR	FA	Performance (%)	
Syllables of Verse-2	S1	68	25	34	6	0	85
	S2	77	39	30	10	0	75
	S3	63	16	36	4	0	90
	S4	53	14	31	8	1	78
	S5	69	25	22	17	1	55
	S6	60	22	33	7	0	83
	S7	36	14	31	9	0	78
	S8	75	17	36	4	0	90
	S9	89	44	31	7	2	78
	S10	61	27	29	11	0	73
	S11	152	30	33	6	1	83

In the testing phase, the main objective is to test the computational engine (from the training phase) that has been designed from the context of reliability of the miniature salient feature, extractor and classifier. The trained range of MPC is used to assess the performance of test data. Each syllable is tested according to the threshold determined based on MPC (maximum and minimum value). A total of 40 different learners from the training phase took their readings and the readings of each syllable in Al-Fatihah were extracted and matched with the reference MPC from the training phase. Each test data is also evaluated manually by an expert and the performance of the reading truth that refers to Tajweed rules is calculated in a technical context, namely true and false positive (TP and FP), false rejection (FR) and false acceptance (FA).

The comparison of errors was made and analyzed between the machine evaluation and human evaluation. From the results, the performance of the machine as an evaluator is then compared with respect to human expert performance.

Table III shows the performance of the parameters of MPCs that can be accepted, which consists of true acceptance (TA) and false acceptance (FA) in the testing phase. From that table, each syllable has been evaluated in terms of good of pronunciation (GOP) [25] for the testing data from Al-Fatihah verses based on Human Guided Assessment threshold from training phase.

In the test phase, the average performance show that each verse in the testing data is lower than training data. However, the average performance for testing data is still above 80% for each MPCs parameter and still shows good performance of Al-Quran recitation assessment. Fig. 4 visualizes the comparison between the performance percentages of training phase and testing phase where the testing gives a lower percentage in performance.

TABLE III. SHOWS THE PERFORMANCE OF THE PARAMETERS OF MPCs TESTING PHASE

Syllables verse 2	Human Machines Performance (%)
S1	87
S2	62
S3	92
S4	85
S5	95
S6	92
S7	85
S8	79
S9	64
S10	85
S11	64
Overall Score (%)	81

Fig. 4. The performance percentages of training phase and testing phase.

VIII. CONCLUSION

The classification performance using the threshold method for these MPC parameters can be used to evaluate syllable - based Al-Quran recitation where Tajweed Harakaat rules are embedded in the syllable. These features show good performance over 80% in testing phase for representing Tajweed Harakaat rules using DTW distance-features. The threshold method is very reliable in the training and testing phases giving a 90.34% and 80.47% respectively. For future work, the range of thresholds from various countries that are experts in reciting the Qur'an with the best Tajweed-based recitation can be included in experiments to improve computerized evaluations that are guided or learned from human expertise. In addition to that, the threshold for the entire verses of the Qur'an can be expanded.

ACKNOWLEDGMENT

The authors would like to express greatest appreciation to Universiti Teknologi Malaysia (UTM) and Ministry of Higher Education (MOHE), Malaysia for the financial support (grant number: Q.K130000.2456.08G28). We also acknowledged the support from the Cyber-physical Research Group and Advanced Informatics at Razak Faculty of Technology and Informatics (FTIR), UTM in this research work conducting this research.

A Novel Method for Recognizing Traffic Signs using Color and Texture Properties using the ELM Algorithm

Xiaoda Cao*

Laboratory Management Department
Northeast Agricultural University, Harbin, Heilongjiang, 150030, China

Abstract—Road accidents cause a lot of financial and human losses every year. One of the causes of these accidents is human error, and the driver ignores traffic signs. Therefore, accurate detection of these signs will help to increase the safety of drivers and pedestrians and reduce accidents. In recent years, much research has been done to increase the accuracy of panel recognition, most of which are problems that affect the diagnosis, such as adverse weather conditions, light reflection, and complex backgrounds. In the present study, considering the diversity of traffic signs' geometric shapes, the sign detection part has been done using a torsional neural network. Then, in the feature extraction section, we used LBP and HOG techniques, and at the end, the section was identified and classified using the ELM algorithm. The results obtained on 12569 images, 75% of which were used for training and 25% for experimentation, show that the accuracy of this research has improved by 95% compared to the essential work by 93%.

Keywords—Traffic sign recognition; torsional neural network; HOG Feature; LBP Feature; ELM Algorithm

I. INTRODUCTION

One of the most critical issues in car vision and pattern recognition, which has attracted the attention of many researchers today, is detecting traffic signs through images. Ignoring traffic signs is a disservice; many people die in accidents or disabilities yearly. With the advancement of technology and the competition of car factories, much research and work has been done on smart cars. Traffic signs increase traffic safety on roads and streets by giving drivers warnings. Therefore, automatic identification of traffic signs is one of the important components of a driver assistance system. The next generation of vehicles can also be considered an important component of automatic reduction vehicles. This system must have high speed and accuracy and perform real-time detection of symptoms in natural scenes.

Automatic detection of traffic signs is one of the problems of intelligent transportation systems today, which facilitates the recognition and interpretation of signs for users. It helps drivers identify traffic signs and pedestrians by warning them [1, 2].

In recent years, a great deal of research has been done to identify signs by intelligent vehicles. Factors such as bad weather, unfavorable weather conditions, light reflection and misdiagnosis of signs, placement of traffic signs and driving in the shade, placement of signs between leaves of trees, and very

complex backgrounds such as the location of buildings, trees, and animals that complicate the background and the background is similar to the panel for detecting problematic symptoms. Because it takes a long time to separate the images from each other and correctly identify the traffic signs, the traffic sign recognition system must be prompt.

The challenge of recognizing traffic signs is their accuracy and short detection time. Much works have been done to detect traffic signs [1, 2], and due to the noise in the image, camera slip, and image quality, all of them have been aimed at accurately detecting traffic signs. In the research reviewed [1, 2], a traffic sign recognition system consists of three main identification steps: image reception, pre-processing, and detection of the area of traffic signs in the image. Early detection of traffic signs and their accuracy can help reduce accidents and human mortality [23], so if traffic signs can be detected intelligently by vehicles, it can be a great help in reducing road accidents.

The motivation of this study is that with the idea of recognizing traffic signs from standard data images. Since traffic sign detection is still a challenging task because of adverse weather conditions, light reflection, and complex backgrounds, it is required to establish a method to provide high accuracy in diagnosis by finding different features in traffic sign images.

The main purpose is to increase the accuracy of existing methods and to detect traffic signs according to the characteristics of color and texture. On the other hand, the use of ELM classification has been used to identify the shape of the symptoms better as well as to extract and pay attention to features such as color, shape, and texture [3].

The major contributions of this study are as, a) proposing a novel feature representation algorithm using color and texture features for finding different features to represent the traffic sign images, b) presenting a method for classifying traffic signs using color and PHOG features the SVM algorithm, c) developing a sign traffic detection method to deal with adverse weather conditions, light reflection, and complex backgrounds.

The rest of this paper is consisted of as, Section II presents the related works. The proposed method is described in Section III. Experimental results and performance analysis are discussed in Section IV. Finally, this paper concludes in Section V.

II. RELATED WORKS

Zhang et al., [29] proposed a cascaded R-CNN to extract the multiscale features in pyramids in order to address undetection and erroneous detection. With the exception of the first layer, each layer of the cascaded network fuses the output bounding box of the preceding layer for joint training. This technique aids in the identification of traffic signs. In order to highlight the features of traffic signs and increase the accuracy of traffic sign detection, a multiscale attention approach is presented to extract the weighted multiscale features using dot-product and softmax. Finally, to reduce the influence from a complicated environment and comparable fake traffic signs, we increase the amount of challenging negative examples for dataset balance and data augmentation in the training.

Avramović et al., [30] presented a traffic sign detection approach based on “You Only Look Once” (YOLO) architectures as baseline detectors for improving the speed and accuracy of traffic sign identification and recognition in high-definition photographs. To meet the real-time performance requirement, a number of preprocessing techniques were suggested. To evaluate the method, tests on a big dataset of traffic signs demonstrate the ability of the method to recognize high-definition images in real time with high recognition accuracy.

Cao et al., [31] proposed an algorithm for traffic sign detection and dealing with the poor real-time performance of deep learning-based traffic sign recognition techniques. In this method, spatial threshold segmentation is firstly performed using the HSV color space, and traffic signs are successfully identified using shape features. Second, utilizing the Gabor kernel as the initial convolutional kernel, adding the batch normalization processing after the pooling layer, and choosing the Adam method. As their results show, the model is much improved over the original LeNet-5 convolutional neural network model. The German Traffic Sign Recognition Benchmark serves as the foundation for the classification and recognition experiments on traffic signs.

III. PROPOSED METHOD

Initially, after downloading images from the GTSRB database [5-8], a torsional neural network is used to detect traffic signs. Extraction of shape properties by HOG technique which is a shape descriptor, based on histogram and statistical information of image spectra as well as its inclination and angles, and finally by extracting texture properties along with shape properties by LBP technique which can increase the sensitivity of HOG, extract light reflections and improve cluttered and complex backgrounds. The features are categorized using the ELM algorithm by forming a feature matrix to detect the panel type and normalizing this matrix, which is also the input matrix to the category. Finally, the accuracy is checked [9-14]. Fig. 1 shows the steps of the proposed method as a flowchart.

A. Torsional Neural Network

Twisted neural networks are very similar to artificial neural networks. These networks consist of neurons with learnable

(adjustable) weights and biases [15]. Each neuron receives several inputs and then calculates the product of the weights multiplied by the inputs and finally presents a result using a nonlinear conversion (activation) function [16-22]. The entire network also provides a derivative score function, with raw input image pixels on one side and points for each category on the other. These types of networks still have a fully operational cost function (SVM, Softmax) in the last layer, and all the points about conventional neural networks are also valid here. Given the above, the difference between a torsional neural network and an artificial neural network is that torsional neural network architectures explicitly assume that their inputs are images, assuming certain features can be embedded within the architecture. With this action, the forward function can be implemented more optimally, and also, by doing so, the amount of network parameters is significantly reduced [24-26].

Neural networks receive an input (in the form of a vector) and then pass it through several hidden layers. Finally, an output resulting from hidden processing layers appears in the network output layer. Each hidden layer is made up of some neurons that are connected to all the neurons in the previous layer. The neurons in each layer act independently and have no connection. The last layer plays the role of representing the score of each class [27, 28].

B. Characteristics of Texture and LBP Technique

The texture is the measurement of changes in the brightness of surfaces, which determines the quantity level for properties such as smoothness and order. An essential feature of the texture is that it is less sensitive to changes in light intensity than the color feature. Compared to color, texture requires a preprocessing step to produce texture descriptors. There are different texture descriptors. Gray Level Cooccurrence Matrix is a two-dimensional histogram that expresses simultaneous events expressing image intensity values in a given direction and distance.

The local binary pattern (LBP) operator was first proposed by Ojala et al. [26]. Experiments have shown that the LBP operator has a high ability to represent tissue. The LBP algorithm is a local feature extraction algorithm. The LBP algorithm is one of the most potent feature extraction algorithms in machine vision science, and many developments based on this algorithm have been proposed.

As shown in Eq. (1), the local properties of LBP are usually symmetrical circles in a neighborhood, comparing images with its neighbors.

$$\text{LBP}(P, R) = \sum_{i=0}^{P-1} u(g_i - g_c) 2^i \quad (1)$$

In Eq. (1), p is the number of neighborhoods, R is the neighborhood radius, g_i is the brightness of the i -th pixel ($i = 0, \dots, P-1$), g_c is the brightness of the central pixel, and $u(x)$ is a step function that has the relation (Eq. 2) is defined.

$$U(x) = \begin{cases} 1 & \text{if } x \geq 0 \\ 0 & \text{otherwise} \end{cases} \quad (2)$$

Fig. 1. Flowchart steps of the proposed method.

Suppose eight neighborhoods are used to extract LBP patterns. In this case, 56 uniformly significant patterns and two patterns for the state where the brightness of the neighborhoods is all more or less than the central pixel, and a pattern for the other states is considered. In total, image pixels are tagged with 59 patterns. The normalized histogram of the repetition of these patterns constitutes the LBP features. The minimum amount of binary pattern produced is used to make the patterns

more resistant to rotation; therefore, the LBP pattern is resistant to the period in the form of Error! Reference source not found is defined.

$$LBP^{riu2}(P, R) = \begin{cases} \sum_{i=0}^{P-1} u(g_i - g_c) & \text{if } U(LBP(P, R)) \leq 2 \\ P + 1 & \text{otherwise} \end{cases} \quad (3)$$

In this case, the number of significant patterns will be seven. As a result, image pixels are tagged with 10 patterns. This paper uses period-resistant LBP patterns. In recognizing traffic signs, searching for a way that is easy to identify and has good accuracy is of great importance. In this paper, the torsional neural network method is used for detection, and then using LBP and HOG; the features were extracted after normalization of the feature matrix as input to the ELM algorithm for classification.

IV. ANALYSIS AND INTERPRETATION OF EVALUATION RESULTS

This research was implemented with MATLAB software version 8.3 and on a system with Intel Core i7 specifications with 2.2GH processing power and 6GB of main memory. The database used in this article is the GTSRB database [5-8]. Considering that the essential work [1] has been implemented on 1000 images from this database while implementing on 1000 images to compare with the essential work on 12569 images in the GTSRB database [5-8], the proposed method has been implemented.

A. Evaluation Data Set

The data used in this study compared with the essential work of 1000 images, of which 800 are noise-free images and 200 are noise-free images to implement the proposed method on all images. The database contains 12569 images downloaded from the GTSRB [5-8], among which 60 are related to speed limit data of 20 km / h, and 720 are related to traffic signs. The speed limit is 30 km / h, 750 pieces of data are related to traffic signs, the speed limit is 50 km / h, 450 pieces of data are related to traffic signs, the speed limit is 60 km / h, and 660 pieces are data. Traffic signs are a speed limit of 70 km / h, 600 pieces of data are related to traffic signs' speed limit of 80 km / h, and 120 data are related to traffic signs with a speed limit of 80 km / h, 480. The number of data related to traffic signs is 100 km / h, 450 of the data related to traffic signs. The speed limit is 120 km / h, 480 pieces of data are related to traffic signs, overtaking is prohibited, 660 images are related to prohibited truck overtaking, 420 pieces of data are related to a two-way intersection, 690 Images of the main street, 720 images of a right of way, 240 pieces of data related to traffic stop signs, 210 pictures of no entry signs, 120 pieces of data related to traffic signs of no-entry trucks, 360 pieces of data related to no-entry traffic signs, 390 pieces of data related to traffic signs, 60 pieces of data related to traffic signs to the left, 120 pieces of data related to traffic signs to the right, 90 images of left turn on the road, 120 pieces of data Bump traffic signs, 150 data slippery road traffic signs, 90 road images approaching from the right, 480 data from workers' traffic signs working, 180 warning images to traffic lights. As we approach the traffic, 60 pieces of data related to traffic signs at the crossing Cloud pedestrian, 180 warning pictures of children playing, 90 warning pictures of cyclists, 150 pieces of data related to frozen road data, 240 pieces of data related to traffic signs for animal crossings, 60 stop signs, 209 number of data related to right-turn traffic signs, 120 data related to left-turn traffic signs, 390 data related to traffic signs for forwarding movement, 120 pieces of data related to two-way intersection traffic signs, 70 news images of entering the street from the

right, 690 news images of the one-way road from the right, 90 images of the one-way road from the left, 120 pieces of data related to traffic signs, 60 pieces of data related to traffic signs allowed overtaking, 60 images No truck overtaking is prohibited.

B. Analyze and Evaluate the Results

First, the images are detected using a torsional neural network described in detail. As described in the previous sections, the torsional neural network is an improved version of the artificial neural network. There is a difference in the structure and operation of this type of network. Unlike an artificial neural network, the input matrix is the intensity of image brightness in a torsional neural network. The features are extracted by mapping and reducing the dimension of this matrix, and classification and detection operations are performed. If the feature extraction operation is performed separately in the artificial neural network, the classification operation will be performed after the feature extraction and normalization of the features. In fact, in torsional neural networks, the spatial dependence of the data is essential for network training and feature extraction from the input matrix. Therefore, this type of network can be used in problems where neighborhood information and spatial dependence make sense. Fig. 2 shows how this detection occurs. After the segmentation of images and detection of traffic signs by the torsional neural network, features are extracted from the detected areas to determine the shape of the traffic sign. Properties are extracted using the texture method and LBP technique, and also the HOG method is used to extract the properties and form the properties matrix. In this paper, we compare the primary article method [1], which uses the PHOG method and different color channels for extraction and SVM algorithm for classification [4], and the proposed method, which uses LBP and HOG for feature extraction and ELM for classification. The baseline work used 1000 images for evaluation, using 800 images with noise or negative images and 200 non-noise images or positive images. Table I shows the comparison of the two methods.

In Table I, as can be seen, four different shapes are presented with different proposed methods and different categories, and the results show that the proposed method has very acceptable accuracy.

The following matrix, called the perturbation matrix, has five rows and five columns of the number of data tested, and their results are shown. In this matrix, the horizontal axis of the actual output or the class label is given, and the vertical axis of the output estimated by the category is shown.

TABLE I. COMPARISON OF THE PROPOSED IDEA AND THE BASIC WORK

Row	Shape type	Color channel method and PHOG with SVM classification [1]	LBP and HOG methods along with ELM algorithm
1	circular	93.52%	100%
2	Triangle	96.45%	95.8%
3	Inverted triangle	94.50%	100%
4	Diamond	95.16%	100%
5	Average	95.02%	98.95%

Fig. 2. Sample GTSRB database images.

An example of the output of a traffic sign detection algorithm is shown in Fig. 3.

Fig. 3. Traffic signs detected by the proposed method.

		Confusion Matrix						
		1	2	3	4	5		
Output Class	1	30 20.4%	0 0.0%	0 0.0%	0 0.0%	1 0.7%	96.8%	3.2%
	2	0 0.0%	6 4.1%	0 0.0%	0 0.0%	0 0.0%	100%	0.0%
	3	0 0.0%	0 0.0%	6 4.1%	0 0.0%	0 0.0%	100%	0.0%
	4	0 0.0%	0 0.0%	0 0.0%	23 15.6%	1 0.7%	95.8%	4.2%
	5	0 0.0%	0 0.0%	0 0.0%	1 0.7%	79 53.7%	98.8%	1.2%
		100%	100%	100%	95.8%	97.5%	98.0%	2.0%
		1	2	3	4	5		
		Target Class						

Fig. 4. The proposed method perturbation matrix is based on the basic paper data.

As shown in Fig. 4, in the first 30 categories of data related to circular traffic signs, the category correctly places the data in its group, and the classification accuracy for this group is 100%. In the second group, which is related to rhombus-shaped traffic signs, category six has correctly categorized the data related to this category. The classification accuracy is 100% for this group. In the third group, which is related to triangular traffic signs, and vice versa, six data are categorized correctly, and the classification accuracy for this group is 100%. In the fourth group, related to simple triangular traffic signs, out of 24 data, one case was incorrectly classified in group five and the rest correctly. The classification accuracy for this group is 95.8% out of which 81% data is related to the background model. One case is incorrect in category four. One data is incorrectly categorized in category one, the rest of the data is categorized correctly, and the classification accuracy for this group is 97.5%. The absolute accuracy in this category is 98%. Also, in the following Fig. 5, the ROC diagram of the proposed method is shown on the data set introduced in [5].

Given that in the primary working method [1], the data used is selected. In order to prove the suitability of the proposed methods of extracting the proposed feature and

algorithm, extracting all the images related to the GTSRB site, which contains 12569 images, has been used for implementation. A base of 1000 images has been used. After image detection by the torsional neural network, the properties are extracted by LBP and HOG. After normalizing the images and forming the feature matrix, the obtained matrix is given as input to the ELM classifier for classification and then output in 43 classes. In this study, 75% of the images were used for training, and 25% were used for experiments. Table II shows the execution times of the different parts of the proposed algorithm.

As shown in Table II, in addition to the appropriate accuracy and high generalizability of the Maximum Learning Machine category, the speed of immediate implementation of this category has been measured, which has not been considered in the essential work. Another criterion used to evaluate the algorithm's performance is the classification accuracy, which in the proposed method for classifying data into 43 accuracy classes is 95.31%.

For this evaluation, the k-fold approach was used, where the value of k was considered equal to 10. At each stage, 90% of the data is set aside for training and 10% for testing. This process is repeated 10 times to consider all the data for testing and training the system which will be averaged on the accuracy obtained. The ROC diagram for this category is shown in Fig. 6. In this diagram, the larger the area under the curve, the higher the classification accuracy. The pivotal components of this chart are the Misdiagnosis Rate (FPR) and the True Diagnosis Rate (TPR).

Fig. 6. ROC diagram of the proposed method.

V. CONCLUSION

In this paper, a novel method for classifying traffic signs is presented. The primary work with 1000 images in four classes using color and PHOG features using the SVM algorithm has reached an average accuracy of 95.03%, while the proposed method uses detection. Torsional neural network and feature extraction using tissue feature with LBP technique and HOG feature with ELM classification in 1000 images reached 98.95%, considering that the baseline work did not use all the data related to GTSRB. In this method, extraction of texture properties along with shape properties by the LBP technique can improve the sensitivity of HOG to light reflections and tangled and complex backgrounds. Therefore, feature of the texture is that it is less sensitive to changes in light intensity than the color feature. To prove the superiority of the proposed method, the proposed method is implemented on all data of the GTSRB site, and the results obtained from 12569 images in 43 classes have achieved 95.3% accuracy. Lastly, this study intends to propose a novel feature representation algorithm using color and texture features for finding different features to represent the traffic sign images, presenting a method for classifying traffic signs using color and PHOG features the SVM algorithm, and developing a sign traffic detection method to deal with adverse weather conditions, light reflection, and complex backgrounds. The advantages of this method include the appropriateness of the selected features and the appropriate classification algorithm. However, the weakness is sensitivity in tough light condition and complicated background. For future study, the proposed method can be extended to deal with the tough variation in complex background and light conditions.

VI. ACKNOWLEDGEMENT

This work was supported by Yinhe Metaverse Foundation.

Abstract—Medicinal Plant species help to cure various diseases across the world. The automated identification of medicinal plant species to treat disease based on their structure is much required in pharmaceutical laboratories. Plant Species with a complex background in the field will make the detection and classification more difficult. In this paper, optimization of bacterial foraging technique has been employed towards medicinal plant prediction and classification architecture based on feed-forward neural network. It is capable of identifying both complex structures of medicinal plants. Feed-forward Neural Networks are considered to have good recognition accuracy compared to other machine learning approaches. Further bacterial foraging has been implemented to minimize the feature search space to the classifier and provides optimal features for the plant classification. The experimental outcomes of the proposed approach has been analysed by employing the medley dataset and evaluating the performance of the proposed approach with respect to dice similarity coefficient, Specificity and sensitivity towards medicinal plant classification. The findings are very positive, and further research will focus on using a large dataset and increased computing resources to examine how well deep-learning neural networks function in identifying medicinal plants for use in health care.

Keywords—Medicinal plant; feed-forward neural networks; linear discriminant analysis; bacterial foraging

I. INTRODUCTION

Most individuals around the world utilise traditional medicines made from medicinal herbs. India is known as the world's botanical garden as well as the country that produces the most medicinal herbs. Due to their natural origins and lack of side effects, herbal medicines have experienced an exponential surge in popularity during the last several years across both developed and developing nations. Plant species have medicinal value and it is considered as the essential resource for curing various diseases around the world [1]. These medications are more widely used since they aim to treat illnesses devoid of causing any negative effects. Indian traditional medicine is renowned for using Naturopathic remedies, Ayurvedic medicine, Unnani, breathing exercises,

meditation techniques, yoga, homoeopathy and many more. There are about 8,000 herbal remedies used in these traditional medicines. As per surveyed findings, approximately 75% of migrants utilize herbal plants for medicinal reasons [2, 3].

Manually identifying medicinal plants is still the most used way. Humans gather information about the entire plant or certain parts like leaves, flowers, fruits, or bark using their eye, nose, fingers, or other human organs [4, 5]. Depending on either individual perspectives or referrals, they will decide which species of medicinal plants to use. It has been demonstrated via practise, nevertheless, that this type of identification strategy is time-consuming, inefficient, and heavily dependent on the expertise and subjective experience of the persons using it.

Mainly to determine the variety of medicinal plants, automated models using image processing approaches [6] has been employed to assist botanists in the early identification of plant by employing machine learning architectures [7]. However, machine learning techniques reveal the structural and texture appearance of the plant along with its discriminative visual symptoms. Further detection and classification of the plant species suffer from the noise and illumination effects of the images [8]. In addition, it is mandatory to discriminate the different growth stages of the plant along the virus and disease involvement which was found to be highly complex in identification.

In order to manage these challenges, various image processing steps such as Image segmentation of the seed region [9], feature extraction on the segmented region [10] and optimal feature selection [11] have to be aggregated to achieve high recognition accuracy in prediction and classification of the medicinal plants from large sizes of input images. In this paper, bacterial foraging optimization has been employed to feed forward neural network towards plant classification on basis of pathological properties.

Among numerous machine learning architecture, feed-forward neural networks produce high recognition accuracy in

classifying the image dataset. Initially, region-growing segmentation [12] techniques are applied to group the seed points having similar pixel values as the segmented region. The segmented region is analysed using linear discriminant analysis which is considered as a feature extraction technique. Shape descriptors and Texture features are extracted. That extracted feature is reduced using the bacterial foraging technique to generate the optimal features. Finally, feed-forward neural network classifier is employed to optimise features to classify into linear plant classes.

The balance part of the article is sectioned into the following form; Section II provides the review of literature containing similar mechanisms of machine learning for plant identification. Section III defines the proposed architecture containing the Feed Forward Neural Network and bacterial foraging based optimization. Section IV highlights the experimental solutions of the proposed approach along with performance evaluation and at the last, summary of the article with conclusion and future work is provided.

II. BACKGROUND STUDY

A. Literature Work

This part of the work describes the problem statement of the research, a review of literature related to the current problem and various deep learning models applied to plant identification using various image datasets has been detailed as follows. The medicinal plant identification model which performs similarly with respect to the proposed architecture has been discussed below.

The Artificial Neural Network Model [ANN] segments the leaf into subfields on different growth stages of the plant. The affinity propagation model computes the variation of the leaf on pixel parameters with reference to plant pathologies and produces the affinity set containing similar leaf properties. Sparse Principle component analysis considered as a feature extraction technique is employed to affinity set to gather the sparse feature and its associations are represented as covariance and correlation matrix [13]. Further Artificial Neural Network is projected to produce the class labels for the sparse features in the feature set. ANN [14, 15] uses a normalization technique to smoothen the edges of the class labels in order to separate plant types.

A Random Forest classifier is implemented to classify the plant on basis of the specified medicinal properties. A classified plant can be employed for disease treatment purposes. Initially, feature extraction methods such as SIFT technique have been employed towards shape extraction, color extraction and texture feature extraction from the plant images. Further genetic algorithm has been applied as a feature selection technique to select effective features towards classification purposes using a Random forest classifier [16].

Convolution Neural Networks (CNN) can be used for the classification of medicinal plant species and they contain built in feature extraction functionality. The shape and texture characteristics are contained in the feature. It classifies the features with respect to the activation function and multiple layers to obtain the effective classes [17]. CNN is also used in various identifications and analysis of images like spatial data,

eye tracking data, networks attack and many more [18, 19, 20, 21].

B. Problem Statement

As a critical problem for the preservation, authenticity, and production of herbal medicines, the automatic classification of medicinal plants needs further study [22]. Owing to the difficulties due to illumination effects, shadow effects, nonlinear seed points, overfitting issues and accumulation of reconstruction error in the processing of medicinal plant datasets, the identification and classification of plant leaves will face significant challenges in employing machine learning algorithms. These necessitate a better approach to be developed for identifying and classifying medicinal plants.

III. PROPOSED MODEL

This section defines the design procedure towards optimization of Feed-Forward Neural Networks using the bacterial foraging technique to classify the medicinal plant in the Mendeley dataset. In addition, the design procedure of the region growing segmentation approach is to segment the medical plant and linear discriminant Analysis to feature extract is also provided in detail. It is as follows:

A. Image Pre-processing

Image preprocessing is used to increase the image pixel properties on the normalization approach and contrast enhancement approach. A further large number of learning parameters of the modelled have been managed for dataset processing. Image Normalization is employed using histogram stretching. Further to eliminate the image noise and image blur, Contrast enhancement [23] is used in addition to the image thresholding approach [24] to improve the image details which contains an important factor for image classification.

B. Region Growing Segmentation

In this part, seed points illustrating the discriminate image parts of the medicinal plant have been analysed and it is grouped into vectors representing the similar seed points to the entire image. Similar points of the medicinal plant are computed with respect to the homogeneity pixel. Vector represents the segmentation results as a growth process on verification of the homogeneity rule among the pixels. The growth process for the selected regions at every stage S is defined as in (1).

$$G_{p,i}(s) \text{ where } i=1, 2 \quad (1)$$

Homogeneity of the pixel is computed for the seed pixel to verify the presence of unfermented pixels in the neighborhood of the remaining pixel in the particular region. The computation rule is as follows in (2).

$$\text{If } (H(G_{p,i}(s)) \text{ for each pixel} = \text{True}) \quad (2)$$

Then compute the Mean M and Standard deviation of each pixel in region R_i is as follows as in (3) and (4).

$$\text{Mean } M = \frac{1}{n} \sum_{i=0}^n R(i) \quad (3)$$

$$\text{Standard deviation } SD = \frac{\sqrt{(1/n)R(i)}}{G_{p,i}(s)} \quad (4)$$

Employ strategy to group two regions $G_p(1)$ and $G_p(2)$ on conditions as in (5) and in (6)

$$\text{If } ((\text{Mean of region 1} - \text{Mean of Region 2}) < \text{Standard Deviation of Region 1}) \quad (5)$$

Verification of the homogeneity of seed points

Else if (pixel intensity of the region 1 is close to mean value of the threshold T_i) (6)

Where Threshold is as in (7)

$$T_i = \{1 - \frac{SD_i}{M_i}\} \quad (7)$$

Threshold T_i depends on the variation of the region R_n and the pixel intensity P_1 .

Resultant segmentation outcomes are represented as image vectors containing the seed points which are further processed for feature extraction and classification process.

C. Linear Discriminant Analysis

Linear Discriminant Analysis (LDA) has been employed to exploit a feature from the image projection using the fisher criterion function [25]. The feature extraction projection in a specific direction extracts properties of homogeneous seeded points in the segmented region vector. Properties of the seed points are represented as a feature. Initially, the homogenous seed point is transformed into scatter matrix to reduce the feature space. Scatter Matrix SM of the vector undergoes the following computation.

Mean of the Vector is as in (8)

$$M_i = \frac{1}{n} \sum_{x \in C} x, nI \quad (8)$$

Total Mean of the Vector is as in (9)

$$TM = \frac{1}{n} \sum_{x \in C} x, N \quad (9)$$

$$\text{Scatter Matrix } S_w = \sum_{i=1}^c s_i \frac{n_i}{n} \quad (10)$$

$$\text{Scatter Matrix } S_b = \frac{1}{2} \sum_{i=1}^c P_i P_j (f_{vi} - f_{vj}) (f_{vi} - f_{vj})^T \quad (11)$$

where $(f_{vi} - f_{vj})$ is vector feature variation.

The covariance of Mean is as in (12)

$$S_i = \frac{1}{n} \sum_{x \in C} (x - m_i) (x - m_i)^T \quad (12)$$

Aggregate Covariance of Scatter matrixes is to produce an optimal feature set is as in (13).

$$S_T = \frac{1}{n} \sum ((f_{vi} - f_{vj}) (f_{vi} - f_{vj})^T) \quad (13)$$

Reducing the Feature space is a vital part of the LDA. It can be generated by improving the scatter ratio $|S_b| / |S_w|$. Further, scatter ratio weight will improve on eigenvectors of $S_b S_w$ producing the projection matrix with column matrix W as in (14).

$$W = [W_1, W_2, \dots, W_{c-1}] \quad (14)$$

Where W_i are the Eigen Vector of the Scatter matrix S_b and S_w and its value corresponds to reducing Eigen values λ_i

The linear discriminant analysis produces the feature of processing the scatter matrix of the seed points. It is further treated as a reduced feature set on the fusion of two or more vectors. However, this reduced feature set has been employed for feature selection to obtain the optimal feature for classification.

D. Feed-Forward Neural Networks

Feed Forward Neural Network (FFNN) is to determine the plant classes of the image. FFNN is employed to process the spatial and temporal features obtained from the segmented region of the image. An FFNN model is composed of many processing states. FFNN produces the plant classes by representing the feature vector in Direct Acyclic Graph (DAG) structure. In FFNN, seed point features of the segmented region are contained in each layer of the graph network. Table I shows the FFNN parameter components. Extracted spatial and temporal features undergo various computations in a graph structure.

TABLE I. HYPER PARAMETER OF FEED-FORWARD NEURAL NETWORKS

Tuning of Hyper Parameter	Values
Class Batch Size	200
Feature Learning Rate	0.09
Attribute Size	85
Maximum No of pixels to each layer	1000
Length of the pixel in sublayers	250
Loss function	Cross entropy

- Abstraction layer

In this layer, the Abstraction layer is used to collect high-level features in the plant. Vector structure contains the feature. Vector is processed in the activation function. It generates a new state from the old state using epoch functions and a few parameter functions. Matrix Feature weight and Vector feature bias are computed by aggregating the input vectors with output vectors extracted hidden layer. The feature weight of the matrix is computed as in (15).

$$A_t = \text{Sigmoid}(W(c(t)) + h(t-1)) \quad (15)$$

Where A_t represents the feature weight of the Input vector $c(t)$ and hidden vector $h(t-1)$ of the seed points of the plant region.

- Hidden Layer

In this layer, hidden feature information is extracted from the input layer vector seeded point and it is represented as the hidden vector H . The FFNN model uses the hidden layer to compute the feature to be represented in the output layer for a period of data availability. Stored Seeded region will be forgotten in the subsequent process. The FFNN model includes the sigmoid function as an activation function to compute the feature weight to eliminate the less-weighted features. Fig. 1 illustrates the proposed research architecture.

The FFNN hidden layer is concealed with the output information of the output layer illustrated in (16).

$$O(f(t)) = \sigma(G_p [A(t) C^{n-k} + h(t-1)] + W_f) + \sum_{k=1}^n \binom{n}{k} m^k \quad (16)$$

The Hidden layer information of the FFNN is identified as an important process to analyse the structural changes and temporal changes of the plant on various growths stage and disease stages. This information is helpful to classify the medicinal plant. The hidden layer of FFNN identifies which input accommodating the plant features and its concealing is provided by (17).

$$H_f = \sigma B_v (W_m G_i(s); W_m d_i(s)) + \sigma B_v (W_m G_i(t); W_m d_i(t)) \quad (17)$$

Where H_f represents the model outcome containing features of growth stage and disease stages along the matrix feature weight W_m and bias of feature vector B_v . It is further interpreted with pathological information. σ is considered as a sigmoid activation function to extract the disease and growth stages features.

- Activation function

The activation function set the decision point of the learning rate of the proposed model to manage and change the feature weights of the growth and disease feature of the plant of various stages from the hidden layer on employing the sigmoid function [26]. FFNN model activation function is illustrated in form of a tree structure which has a high ability in parsing the feature using the sigmoid function. The activation function is optimized using a hyperparameter to improve the output layer representing the plant classes. The activation function is as follows in (18).

$$A_f = \text{Sigmoid} (F_s) * \sum_{n=1}^{\infty} \left(a_n \cos \frac{n\pi w}{B} + b_n \sin \frac{n\pi w}{B} \right) \quad (18)$$

Activation functions of the hidden layer process the feature set to identify the plant classes on basis of distance measures on feature weight.

- Output Layer

The output layer generates the plant classes. The output layer interprets the feature set of the hidden layer with reference to the pathological information to discriminate the plant classes with high recognition accuracy. Plant classes of the output layer are discriminated using the output function. Function $Z(t)$ uses the feature vector on various stages to classify effectively with the activation function. Output Function is given by (19).

$$\text{Output Function } Z(T) = \text{Sigmoid} (G(f) * D(f)) \quad (19)$$

The output function of the FFNN contains the sigmoid function to differentiate the growth and disease stage features of the plant. These outcomes are stored as classes with reference to the output function.

- Loss Layer

The loss layer is employed to assure the classification accuracy of plant classes. It is assured on the processing the image data with various folds using the cross entropy function. On identification of irregularity or reconstruction error on the processing layer of the model, hyperparameter tuning is carried out on each layer of the network to reduce the error in the hidden layer, input layer and output layer. The loss function for hidden and output layers are given by (20) and (21) respectively.

$$\text{Loss function } L_f \text{ for hidden layer} = \text{Softmax} (A_t * E_r * H_t) \quad (20)$$

$$\text{Loss function } L_f \text{ for output layer} = \text{Softmax} (A_t * E_r * Z_t) \quad (21)$$

Fig. 1. Proposed architecture.

An accurate neural network model for classification is obtained with the inclusion of the loss function in the layer.

Algorithm Description:

The classification algorithm initiates with image pre-processing approaches with histogram normalization and contrast stretching for noise removal and image normalization in the Medley dataset. Region-growing segmentation is employed for the preprocessed image. Linear Discriminant Analysis (LDA) has been employed as a Feature extraction approach. Obtained features are processed to classify the feature into classes using Feed Forward Neural Network on the computation of the features in the activation layer of the network using the sigmoid function.

E. Bacterial Foraging Optimization

In this section, bacterial foraging optimization is employed to the hidden layer to obtain the optimal feature space from the hidden layer to enhance plant classification accuracy in processing the features of various plants. The bacterial foraging uses the fitness criteria on the feature space from the hidden layer of the FFNN model [27]. Bacterial Optimization computes the optimal features to classify the plant into categories, especially it is found effective to classify various patterns. The optimal feature set has to be determined using the following fitness function (22).

$$\text{Fitness Function} = \sum_{m=k}^{n-1} \text{Correlation}(\delta_i^j(f_k) - \delta_i^j(f_{m+1})) + O(f_n) \tag{22}$$

Feature set given by fitness function is F(s)

IV. EXPERIMENTAL RESULTS

Experimental analysis has been carried out in the Mendeley plant dataset [28]. The proposed architecture is simulated in Matlab (version 2017). In processing of the model, training data and validating data have been partitioned. In that, 60% of the image has been utilized for model training and 20 % of the image has been fixed for validation and rest 20% of the image has been fixed for model testing. In 10-fold cross-validation of the learning model, the performance of the classification and segmentation of the leaf region has been enhanced.

In this work, the proposed neural network model achieves high recognition accuracy on the identification of plant classes. The model provides excellent outcomes in computing the leaf region with different image sizes and image characteristics evaluated against conventional methods. Model performance has been evaluated with Dice coefficient, sensitivity and specificity against the conventional approaches for medicinal plant detection with volumetric changes of the plant at various stages of the plant growth.

- Dice similarity Coefficient

It is accessed on basis of the variation of classified results against the pathological classes. This difference computation is carried out using a confusion matrix. The confusion matrix yields True Positive (TP), False Positive (FP) and False Negative (FN) values on the class results. It is denoted as in (23).

Dice Similarity Coefficient

$$= \frac{2 \text{ True Positive}}{2 \text{ True Positive} + \text{ False positive} + \text{ False Negative}} \quad (23)$$

- Sensitivity

It is considered as the ability of a test to correctly classify the plant in terms of various features. It is denoted as in (24).

$$\text{Sensitivity} = \frac{\text{ True Positive}}{\text{ True Positive} + \text{ False Negative}} \quad (24)$$

- Specificity

It is considered as the ability of a test to correctly classify the plant without various features. It is denoted as in (25).

$$\text{Specificity} = \frac{\text{ True Positive}}{\text{ True negatives} + \text{ False Negatives}} \quad (25)$$

The Mendeley medicinal plant leaves dataset containing image samples has been analysed to determine the medicinal plant class using machine learning approaches. The learning model has been assessed using the Dice coefficient measure, Sensitivity and Specificity measures. Its performance value is represented in Table II.

The proposed model exhibits good performance in segmenting the plant regions. Optimization of Feed Forward neural Network has been carried out with bacterial foraging illustrating the excellent outcomes on relating with conventional approaches such as Artificial Neural Networks and Convolution Neural Networks.

The Dice Coefficient generates the best outcomes on accessing with a classification accuracy of plant classes, generated using the machine learning model has been illustrated in Fig 2.

TABLE II. PERFORMANCE EVALUATION OF MEDICINAL PLANT CLASSIFICATION TECHNIQUES

Samples	Technique	Dice Coefficient	Sensitivity	Specificity
1 st Fold Validation Set	Bacterial foraging optimized Feed-Forward Neural Network- Proposed model	0.9788	0.9485	0.9792
	Artificial Neural Network - Existing Model	0.9578	0.9122	0.9689
2 rd Fold Validation set	Bacterial foraging optimized Feed-Forward Neural Network 1 - Proposed model	0.9777	0.9194	0.9798
	Artificial Neural Network - Existing Model	0.9665	0.9014	0.9271
3 rd Fold Validation set	Bacterial foraging optimized Feed-forward Neural Network - Proposed model	0.9771	0.9115	0.9785
	Artificial Neural Network - Existing Model	0.9656	0.9015	0.9365

Fig. 2. Performance comparison of the learning model with respect to the dice coefficient.

Regarding the measure of sensitivity, it measures the excellent results in the optimization of the learning model through bacterial foraging to produce optimal features. Fig. 3 shows the performance outcome of the sensitivity measure on the plant classification.

Fig. 3. Performance comparison of the learning model with respect to sensitivity.

The performance of the trained network is adapted to the target domain on producing better outcomes. Fig. 4 illustrates the performance outcome of the specificity. The proposed model is capable of classifying five medicinal plants effectively such as Basella Alba (Basale), Carissa Carandas (Karanda), Citrus Limon (lemon), Ficus Auriculata (Roxburgh Fig) and Rosa-Sinensis (Hibiscus).

Fig. 4. Performance comparison of the proposed model in terms of specificity.

V. CONCLUSION

In this work, an optimized framework of Feed Forward Neural Network using bacterial foraging has been designed and implemented to classify the medicinal plant from the medley dataset. The model initiates the segmentation operation to the pre-processed image dataset in order to obtain the segmented region containing seed points in the image. The segment images are further processed using the linear discriminant to extract the spatial and temporal features. The extracted feature set is applied to the feed-forward neural network classifier. The classifier composed of the input layer, hidden layer, output layer and loss layer has fine-tuned with objective and activation function to discriminate the results with high recognition accuracy. The proposed model produces excellent outcomes even presence of image artifacts and volumetric changes in images. Further it is capable of handling the variability in anatomical properties and contrast variations of the dataset in analyzing the modalities and pathologically changed tissues. Further, different posing and structural changes have to be computed to minimize the interpretation issues and enhance the classification accuracy using Gaussian and quantum models on the features of the images to discriminating the medicinal plant classes of leaf images.

The results are very encouraging, and future studies will concentrate on using a huge dataset and more computational power using Quantum Computing to assess how effectively deep learning neural networks work in identifying medicinal plants for use in healthcare [29]. Whilst deep learning is a paradigm for analysis, linked data can be selected as the optimal practice for data representation [30]. The confluence of linked data with the proposed work can further take this study towards more accuracy.

Abstract—Employee turnover in the IT industry is among the highest compared to other industries. Knowing factors that influence the turnover may help reduce this issue in future. One of these factors is job satisfaction, which are composed of two important factors, status and seniority. In this study, the correlation and chi-square visualization are utilized to determine the factors that affect employee turnover. The experiment was carried out to predict turnover using a private IT consultant dataset comparing three classification algorithms (decision tree, Naïve Bayes, and Random Forest). The result shows that job duration and positioning are factors that influence employee turnover in a software company.

Keywords—Employee turnover; turnover factors; chi-square; classification algorithm

I. INTRODUCTION

According to the information and communications technology (ICT) workers survey, 43.6% of ICT professionals work in IT Industries, with an annual growth rate of 14.7% [1]. Given the sharp increase in demand for skilled IT professionals, supply of qualified computer specialists, especially college graduates, is on the rise [2]. This situation has given the IT industry a competitive advantage in hiring an ever-growing number of professional software engineers, as each company tries to lure the best employees by offering them better opportunities in terms of pay, expertise, and working atmosphere. The IT industry therefore has one of the highest turnover rates in comparison to other industries [1].

Poor financial compensation, management style, and career opportunities are the main factors contributing to dissatisfaction with current employer and their decision to leave [3]. Staff turnover is a major disadvantage for the company on direct and indirect costs. The direct costs are related to the time and resources spent on recruiting, hiring and training employees [4]. The indirect costs include the decrease in production and services caused by the company failing to find replacements. Hiring and training new employees is also a large investment because the higher the turnover rate, the higher the cost [5].

In general, turnover is due to employee dissatisfaction with a number of factors, including working conditions, salary, support quality, co-workers, nature of work, employment security, and career prospects. The factors that affect job satisfaction are divided into two factors, namely

organizational factors - which include company policies and work environment - and individual factors [6]. The status and seniority are one of these individual factors that affect job satisfaction, as a perception that a lack of employment status causes many workers seeking another job [6]. In addition, attitudes toward human resource management indirectly affect turnover, which is fully mediated by job satisfaction [7].

In this paper, visualization and feature selection are proposed to identify factors that influence employee turnover. The paper is organized as follows. In Section II, this paper first gives an overview of previous work on this topic. This is followed by a presentation of the method used in Section III, followed by a discussion of the experimental results in Section IV. Finally, the paper is summarized in Section V.

II. RELATED WORK

Some turnover studies suggest using machine learning to design retention policies [8]. A study was carried out by [9] to predict employee turnover in one of Indonesia's renowned telecommunication company, comparing three classification algorithm (Naïve Bayes, Decision Tree and Random forest) based on 12 attributes. Another study by [10] implemented twelve features to predict employee turnover, while other use 19 attributes [8]. Similar study by [11] evaluate six classification algorithm (KNN, SVR, Naïve Bayes, Decision Tree, Random forest) to predict employee turnover using a dataset from Kaggle. In contrast to the previous study, this study will evaluate the individual and seniority factors, which are represented by length of service and job level as factor of employee turnover in IT consultant firm.

A. Naïve Bayes

In supervised machine learning [12][13][14][15], Naïve Bayes is a widely used model of classification due to its simplicity and efficiency. Naïve Bayes computes the posteriori probability for a class by observing the churn problem, i.e., the churn and non-churn observation probabilities. The posteriori probabilities are computed by using the rule of Bayes and the assumption of naive Bayesians with unique employee backgrounds for each class. The goal of the Bayesian decision rule is to set a record of a new hire to the class with the highest probabilities posteriori as [16] suitable model for predicting employee turnover.

B. Decision Tree

A decision tree is divided by decision rules into some classes [17]. It represents a fluctuating graph resembling a tree structure that implies a test in an attribute for each internal node (not leaf node). A branch represents a test result, with a class label for each leaf node (or end node). The root node is the top node in a tree [18]. The C4.5 decision tree classifier is employed to build predictive models due to its ability to segment dynamic decision processes [19].

C. Random Forest

Random Forest (RF) proposed by Brieman [20], uses aggregation and bootstrap ideas to introduce random forests based on a decision tree [21]. The trees are constructed separately in RF, using bootstrap samples of various data sets. The concept of RF is to construct multiple decision trees using only a subset of attributes based on sample data [16]. Predictions are taken by taking a simple majority decision by dividing the individual nodes into a subset of predictors using the best distribution. At that node, the predictors are selected randomly and this randomness makes it robust against overfitting [22][23].

III. METHODOLOGY

In this section, a proposed framework is presented, which includes preprocessing, relationship visualization, chi-square calculation, correlation, and prediction (Fig. 1).

A. Sourcing and Pre-processing

This is the initial phase of the framework. The purpose of preprocessing the data is to convert the raw data into an easier and more efficient format to use for future processing steps. In the first phase, a min-max method is used to normalize the data. Normalization can shorten the training time as all the data used for training share the same scale. Collecting the dataset from private IT consultants between January 1, 2015 and December 31, 2018, the data consists of gender, entry and exit dates, job title, and department, as shown in Table I.

Fig. 1. Framework of predicting employee turnover by identifying the two most influence factors in turnover, i.e., work duration and department.

TABLE I. ATTRIBUTE EMPLOYEE TURNOVER

No	Gender	Date of accession	Date of withdrawal	...	Job title
1	Male	01/12/2016	05/05/2017	...	Head of the Finance Department
2	Female	16/08/2017	29/03/2018	...	Accounting officer
3	Male	01/03/2016	14/01/2017	...	Driver
4	Female	19/09/2016	14/07/2017	...	Recruiter
149	Male	01/07/2015	-	...	Functional consultant
150	Male	01/07/2015	-	...	Software platform manager

B. Visualization of Correlation between Turnover and All Factors

The correlation across pairs of time series indicates the degree to which the variance in one time series may be the same as the variance in the other. This alone does not imply a causal relationship between the two series. However, this is generally grounds for further investigation of a possible relationship. Relationships of correlation are often expressed as values between -1 and 1, figures close to 1 indicating a high correlation, figures close to 0 indicating a low relationship, and figures close to -1 indicating an inverse relationship. An analysis is made of the correlation between turnover and all factors. The visualization is selected to analyze the most correlated factor with the resignation factors.

C. Calculation of the Chi-Square between Turnover and All Factors

For classification problems having both categorical input and output, a chi-square test ("chi") is useful in determining how relevant the input variables are to the output variable. In this study, the correlation between turnover and all factors is analyzed using chi-square, calculating the *p-value* to determine which factor has the lowest *p-value*. The formula for the chi-square is shown on (1).

$$X^2 = \sum \frac{(O-E)^2}{E} \tag{1}$$

Σ means summarize

O = any observed (actual) value

E = any expected value.

D. Predict Turnover

In classification, a mean value of grouping data based on a label or target class is calculated in the study. The three classification algorithms are used to compare the impact of the proposed framework on classification performance. Using Decision Tree, Naive Bayes, and Random Forest as pilot methods, all of them are used to predict turnover based on all factors. Next, a forecast of sales based on selected factors is also made using these three algorithms. Both results are then compared to determine which has the better performance.

IV. RESULT AND DISCUSSION

A. Pre-Processing

Experiments are conducted using several machine learning algorithms with additional tests on the preprocessed data and feature selection to achieve better accuracy. The preprocessed data for job level, department and gender category are converted into numbers as shown in Table II.

B. Visualize the Correlation between Turnover and All Factors

The correlation between gender, department and degree of resignation is visualized in a bar chart (Fig. 2). The correlation between duration and turnover factor (resignation) is visualized by a boxplot. As shown in Fig. 3, gender does not have a significant impact on employee turnover. The trend of gender is similar for terminated and non-terminated employees.

TABLE II. DATA SET AFTER PRE-PROCESSING

No	Duration (month)	Job level	Department	Gender
1	5	5	13	1
2	7	1	1	0
3	10	1	8	1
4	9	1	17	0
...
149	42	1	14	1
150	42	5	41	1

Fig. 2. The relationship between gender and the turnover Factor (resignation).

Fig. 3. The relationship between the department and the factor of turnover (resignation).

Fig. 3 shows the relation between the department and the turnover factor and reveals that department factors have a significant impact on employee turnover. The trend of the employee leaves and the employee stays are different from various departments.

Fig. 4 shows the relationship between the workplace level and the turnover factor. It indicates that the workplace level has no significant influence on employee turnover. Further, the trend of the job level is similar for terminated and non-terminated employees.

However, the boxplot relationship between duration and turnover (resignation) factor from Fig. 5 shows that the length of employment (duration) has a significant impact on employee turnover.

Fig. 4. The relationship between the workplace level and the turnover factor (resignation).

Fig. 5. The relationship between duration and turnover (resignation) factor.

C. Calculate the Chi-Square between Turnover and All Factors

The term statistically significant has become synonymous with a *p-value* <= 0.05. The table of *p-values* shows that the *p-value* for duration (length of work) and department is less than 0.05, as shown in Fig. 6. Table III and Fig. 6 show that duration of work (length) and department are factors that affect employee turnover.

D. Turnover Forecast and Result Evaluation

The dataset is divided by 80% for training data and 20% for testing data. The result is shown in Table IV. The result of prediction with all factors is shown in the first column (with all factors) and the result of prediction with only selected factors is shown in the second column (only selected factors). Based on the visualization of the correlation between the turnover and all factors and the calculation of the chi-square. Duration and department factor have high correlation with employee turnover. The prediction result shows that the prediction using only selected factors has better performance compared to the prediction using all factors.

TABLE III. P-VALUE BETWEEN TURNOVER AND ALL FACTORS

No	Factors	<i>p-value</i>
1	Gender	0.94
2	Duration	<0.01
3	Level Job	0.36
4	Department	<0.01

Fig. 6. Bar chart of the *p-value* between turnover (resignation) and all factors.

TABLE IV. THE PREDICTION RESULT OF THE EMPLOYEE TURNOVER

	With all factors	Selected factors only
Random forest	0.833	0.867
Naïve Bayes	0.77	0.77
Decision tree	0.83	0.90

V. CONCLUSIONS

In this study, correlation and chi-square visualization are applied. Its key idea is based on a two-step process. A correlation between pairs of time series is first used for further investigation of possible relationships. Secondly, Chi-Square is used to determine how relevant the input variables are to the output variables. By forecasting employee turnover - compared to Decision tree, Naïve Bayes, and Random forest - predictions using only selected factors (duration of employment and department) indicated a notable improvement in various performance parameters compared to predictions using all factors. Using a dataset of IT consulting employees in Indonesia, the key factors affecting employee turnover were identified using the chi-square algorithm; specifically, years in the company, job level, department placement, and gender as the most important factors. Therefore, duration of employment and department are unarguably among the most influential factors for retaining employees.

By predicting upfront, the likely turnover of employees, companies are able to prepare plans and initiate measures to reduce that likelihood, hire replacements swiftly, and make other adjustments aimed at retaining individuals in important positions. By using correlation and chi-square visualization approaches, HR managers may anticipate employee turnover better and take action in a timely manner. Similar applications of this algorithm are possible for imbalanced data classification problems such as predicting customer attrition, preventive cancer care, and anomaly detection. These issues share common characteristics, like a focus on minority classes and the condition that "it is preferable to test wrong than to detect wrong." Future work would be to analyze theoretically the characteristics of the data in these areas and to verify and optimize the approach further.

Due to the limitations of the study, the extra process of feature selection and weight calculation implies that the cost of modeling is higher in time compared to other algorithms. Improvements to the operational efficiency and accuracy of the entire prediction can be analyzed in future research. Furthermore, for industries with high turnover rates, the algorithm is based on unbalanced data and therefore may not be suitable. Details on increasing the universality of the algorithm are yet to be studied.

Arabic Location Named Entity Recognition for Tweets using a Deep Learning Approach

Bedour Swayelh Alzaidi, Yoosef Abushark, Asif Irshad Khan

Department of Computer Science, Faculty of Computing and Information Technology
King Abdulaziz University, Jeddah, Saudi Arabia

Abstract—Social media sites like Twitter have emerged in recent years as a major data source utilized in a variety of disciplines, including economics, politics, and scientific study. To extract pertinent data for decision-making and behavioral analysis, one can use Twitter data. To extract event location names and entities from colloquial Arabic texts using deep learning techniques, this study proposed Named Entity Recognition (NER) and Linking (NEL) models. Google Maps was also used to obtain up-to-date details for each extracted site and link them to the geographical coordination. Our method was able to predict 40% and 48% of the locations of tweets at the regional and city levels, respectively, while the F-measure was able to reliably identify and detect 63% of the locations of tweets at a single Point of Interest.

Keywords—NER; Named Entity Recognition; NEL; named entity linking; event; location; deep learning; Arabic

I. INTRODUCTION

In today's world, information gathering plays an important role in reducing the effects of urgent events, so business managers or emergency agents always focus on gathering up-to-date information to help them make better decisions. So, to assure more precise dealing with situations, different resources of information must be used such as the data posted on social networking sites. The research introduces Twitter as an additional information source, but there are some difficulties and restrictions when using this Information such as data reliability and quality, as tweets may be in different languages and may contain hash tags, internet links, images, or even videos. Also, the geospatial feature of the information is important for disaster response. As for the techniques used to gather information such as Keyword monitoring which is subject and biased and more likely to contain false data. Many models have been developed to extract location-named entities from an informal text [1],[5], however, those models are applied to English text only, And the Arabic language recognition models are not linked to its geographical coordinates and are low accuracy compared to English or other languages that is because there are no functions or converters available to convert the dataset to a format that a model can use it for training. In this paper, we propose a method to extract event location names from unstructured Arabic text documents via NLP methods using the Deep Learning technique [6], first by collecting text data from Twitter and pre-processing it to fit inside the deep learning model and utilizing an Arabic location named-recognition model. In addition, each extracted location will be linked with

geographical coordination by using existing knowledge such as Google Maps.

There are several ways to acquire Twitter data which can be divided into two main groups: First way: Purchasing the data from third-party or commercial data vendors [7], which provides a user-friendly GUI and visual environment for better use of the gathered data. Such an option is not recommended for the academic context due to the expenses. Also, users cannot modify the algorithms used for different operations which is a major drawback. Second way: Direct data collection through Twitter API which provides a straightforward way to query and retrieve publicly available tweets.

There are three main types of APIs provided by Twitter which are: REST API [6], Streaming API [9], and Ads API. Both REST API and Streaming API are very similar and provide access to Twitter data, but the author chose to use REST API as it is more useful for this case.

One of the most used REST endpoints is the search API which returns a collection of relevant Tweets matching a specific query. It should be noted that the REST API search service is focused on relevance and not completeness, which means that not all the tweets will be indexed. All interactions with the Twitter API require authentication using the OAuth protocol [10], which provides access to protected API services and server-side resources on behalf of the API owner. For data preparation [11], Twitter API returns tweets in JSON format [12] which is a human-readable data interchange format. Working with JSON tweets requires validation, data cleaning, and data transformation procedures before sorting them in a database. For data cleaning, it is mostly removing unwanted information or redundancy in the raw tweet which can be a group of several tasks that are: (Filtering based on the language "Arabic", Removing usernames, Removing URLs, punctuations, multiple dots, and extra spaces, and Removing words containing non-Arabic characters). Mostly, a tweet in JSON format is composed of several objects which may be more than 70 objects per tweet, some of them are single objects and some are embedded within other objects. Not all the objects will be used but selected objects during different phases for developing and implementing the framework.

Analyzing the Arabic language is challenging due to its complex linguistic structure, also the informal Arabic used in tweets is noisy and poorly structured [13] as in the Arabic region there are more than 25 dialects of Arabic. Text mining is the technique of analyzing mass amounts of text to identify

insights and outcomes of new information and it is purely based on Artificial Intelligence (AI). This technique is widely involved with NLP (Natural Language Processing) which is considered an exciting field that enables computers to analyze human language. Previous research proposed a supervised algorithm that produces a weighted average of word embedding [14]. The purpose of the research is to implement text mining and NLP techniques to investigate NER for Arabic tweets using ML (Machine Learning). Recently DL (Deep Learning) has been strongly implemented in NER systems. Named Entity Recognition (NER) is a sub-task of Information Extraction (IE) that aims to look at and classify named entities presented in unstructured tasks and identify useful information such as person name, location, etc. Named Entity Linking (NEL) is the task of assigning a unique identity to the entity. Python supports NER through the library NLTK. NER and NEL can automatically scan entire articles and reveal organizations, locations, and people's names. Google Map API is used for entity analysis as it provides services related to map information.

We propose an approach that is like [15] in that it handles two binary classification tasks. We evaluate our models to classify Arabic tweets about event detectors and identify the heights performance for the training model's accuracy. Although their approach successfully detects the target messages utilizing complex and skill-required machine learning, the results might be further improved by adopting less time-consuming and labor-intensive approaches using both automated and human data labeling methods. The next part provides a summary of the current methodologies and relevant research on location inference of Twitter data after discussing the methods currently used to identify Twitter events.

The objectives of this study are as follows:

- Collect Arabic text data from the Twitter platform using Twitter API.
- Preprocess the collected data in such a way that it is well visualized and can fit inside the deep learning model using data mining, text mining, rescaling, and reshaping techniques.
- Utilize the deep learning algorithms to build an Arabic location named recognition model.
- Design a named entity link method that links the extracted location entities with their geographical coordinates.
- Optimize and retrain the developed models by using several data mining, data preprocessing, scaling data, and many other data cleaning techniques.
- Evaluate the developed models' performance in terms of classification matrix, f1 scores, precision, recall, and accuracy.
- Evaluate performance in real-time to identify issues and the accuracy of the model.

The contents of this paper are organized as follows. In Section II, we give a brief description of the existing related works. In Section III, we describe the proposed framework. In

Section IV, the Implementation details of the proposed framework are discussed. In Section V, Result and Evaluation of the proposed model is discussed. Finally, the conclusion is shown in Section VI.

II. RELATED WORK

A. Event Detection on Twitter

An event is often thought of as anything that takes place at a certain time and location [16],[17]. A qualitatively significant change in anything might also be referred to as an event. In the context of this study, the word "event" can refer to any condition in the real world that causes an increase in the frequency and quantity of tweets that are likely to include pertinent information about the circumstance [18]. A critical first step in incorporating Twitter as an extra source of information for any application is the identification of the tweets that were generated in reaction to a real-world occurrence. Event detection methods are often divided into two categories: open events and events that are specific to a certain domain (supervised or unsupervised). As a result, the bulk of research done on Twitter event detection may be grouped according to these criteria. According to the kind of event, the method of detection, and the intended use, (Table I) shows a taxonomy of research on Twitter event detection based on event type and approach.

TABLE I. RESEARCH ON TWITTER EVENT DETECTION

Reference	Event Type	Approach	Application
Hagras et al. (2017)[21]	Specific	Supervised	Natural Disaster tweets detection
Ragini et al. (2018) [22]	Specific	Supervised	Crisis Mitigation using Twitter
AL-Smadi et al.(2016)[19]	Open	Unsupervised	General Event Detection
Alabbas et al.(2017) [20]	Specific	Supervised	High-risk floods Detect
Wang et al. (2015) [23]	Open	Unsupervised	General Event Detection
Alomari et al. (2020)[24]	Specific	Unsupervised	Traffic-related event detection
Toujani et al. (2108)[25]	Specific	Unsupervised	Natural Disaster tweets detection
Fu et al. (2020) [26]	Open	Unsupervised	General Event Detection
Rezaei et al. (2022) [27]	Open	semi-Supervised	General Event Detection

Hagras et al. (2017) [21] classified and evaluated tweets related to the Japan Tsunami using the Latent Dircherilet Allocation (LDA) topic analysis approach. Selected 196 tweets for the test set and 6700 tweets for the training set, resulting in 76% accuracy with successful detection. However, this approach may be improved by adding more datasets to speed up processing in real-time and increase accuracy. Emotion analysis and ML algorithms were used in a crisis governance technique that [22] presented. They classified the information depending on its requirements. After using a Support Vector Machine (SVM) to assess the data acquired

from Twitter via human attitudes, both positive and negative. Although the suggested approach makes it easier for emergency crews to identify disastrous situations and take appropriate action immediately, it has some limitations when using social network data for crisis mitigation, specifically the ambiguity in obtaining crisis data from various sources and the absence of the proper criterion. However, these issues may be resolved by collecting data from several sources to properly classify the data and improve precision.

AL-Smadi et al. (2016) [19] describe a knowledge-based approach for fostering event extraction out of Arabic tweets. They used an unsupervised rule-based technique for event extraction. Results show that the approach has an accuracy of, 75.9% for event trigger extraction, 87.5% for event time extraction, and 97.7% for event type identification.

Alabbas et al. (2017) [20] suggested a classification model trained on 3700 Arabic tweets to identify high-risk floods. Several machine learning algorithms were employed, which include k-NN, J48, NNET, SVM, and C5.0. With the training matrix containing the chosen terms and their related values, the classification algorithms were trained. TF-IDF (Term Frequency-Inverse Document Frequency) weights. The outcomes demonstrated that SVM performed with better accuracy.

Toujani et al. (2018) [25] suggested a novel method that uses social networks as the primary source to identify event information after a natural disaster. Then, based on the period of risk, they group people into tiers. Reporters can benefit from this clustering process by streamlining the way they obtain information in urgent situations. Additionally, they applied fuzzy theory techniques to these incidents to enhance clustering performance and get rid of opacity in the data that was gathered.

Alomari et al. (2020) [24] created a lexicon that makes it easier to identify traffic occurrences in Saudi Arabia using Twitter and the big data methodology. For Arabic and Saudi dialect terms, they also applied sentiment analysis based on the lexicon method. To improve the indexing and categorization of nonspecific events [23] provide unsupervised algorithms that create structured lexicon-based event information. Additionally, other research has focused on early event prediction using the Twitter data stream.

Fu et al. (2020) [26] perform an open-domain event text generation task with an entity chain as its skeleton. To build this dataset, a wiki-augmented generator framework containing an encoder, a retriever, and a decoder is proposed. The encoder encodes the entity chain into hidden representations while the decoder decodes from these hidden representations and generates related stories. The retriever is responsible for collecting reliable information to enhance the readability of the generated text.

Rezaei et al. (2022) [27] proposed a semi-supervised framework for the detection of data events on Twitter. Then, they used the Hierarchical Attention Network (HAN) method

to categorize the data events. A virtual backbone was employed so that the stream data could be divided into one or more classes with various grades.

To extract location-named entities from informal texts like those seen on social media sites, many models have been developed [1],[2],[3],[4],[5]. While other languages have gotten comparatively less attention, those models were created to simply apply to the English text. When evaluated in the informal Arabic language, most location-named entity identification models or algorithms underperformed because they were unable to identify the precise pattern of Arabic keywords in the data. Additionally, the retrieved location's geographic coordinates on those systems are not connected to it. To the best of our knowledge, Arabic text recognition models perform poorly when compared to those in English or other languages. This is because any machine learning algorithm requires mathematical parameters to train. Because there are many programming functions for English tweets, we can readily transform them into mathematical form; but, for Arabic, there are no such converters or functions that can quickly transform our dataset into a format that the model can effectively train on.

The globe has been producing data on social media on the terabyte scale, and this unused data might be the key to many future research projects [8]. Obtaining data on behaviors affected by shifting geographies is one promising study area, allowing researchers to make focused, well-informed judgments [1]. These unstructured Arabic text documents are a significant source of such data, and we specifically want to extract geographic information from them [2]. However, most of this data is not provided in an obvious manner and must be retrieved using different NLP techniques [3]. Machine learning methods have traditionally been used to do this [4]. The technique of employing neural networks to learn a task is known as deep learning. Deep learning significantly outperforms all other conventional learning techniques and aims to replicate how the human brain functions. In this area, deep learning has not yet been applied. However, English language research makes up most of these studies. Arabic is one language that has not received enough attention. The few Arabic works that have been created, have problems with generalization. They were completed by concentrating on a tiny, extremely conservative group, leaving a sizable portion unaffected.

The location extraction and linkage from Arabic-language tweets will benefit from the findings of this study. To the best of our knowledge, there is no clear study that has tackled location extraction and linking from Arabic tweets using deep learning approaches, in addition to the scant amount of research on location extraction from Arabic text.

III. FRAMEWORK

Framework design, which describes the framework's design proposed by the author to achieve the aim of this research which is only limited to tweets in the Arabic language.

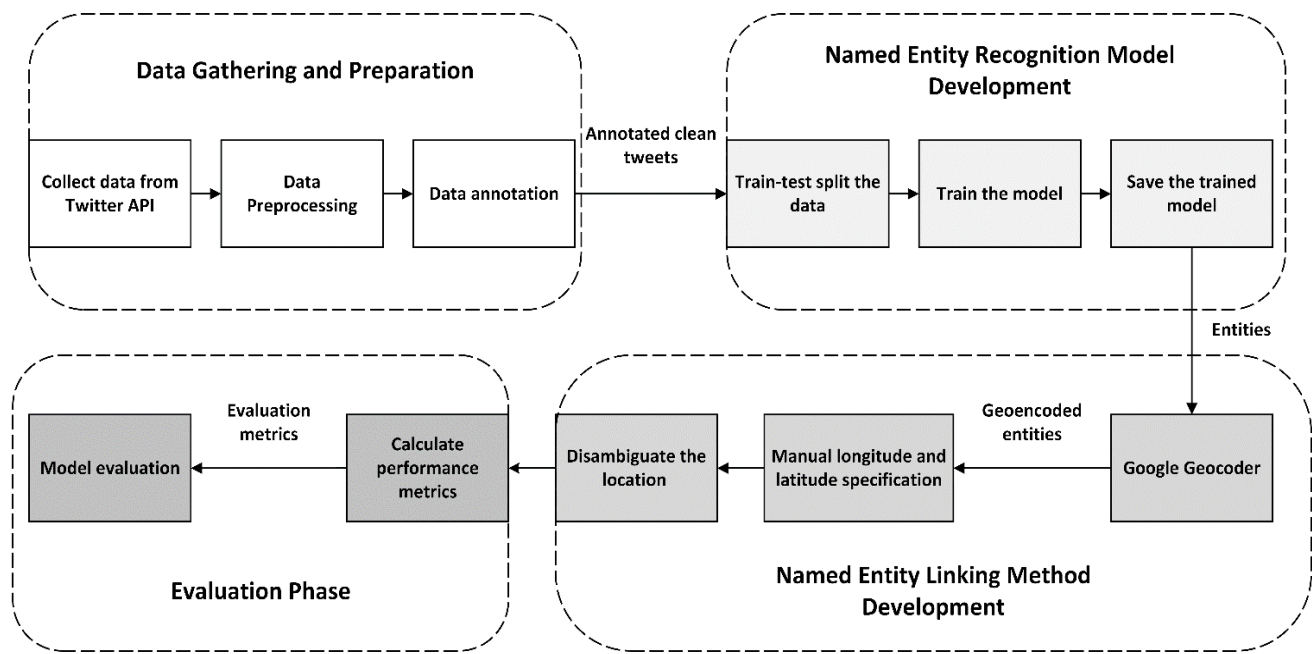

Fig. 1. Framework design.

1) *First part:* Data collection and Preparation which focus on the collection of Twitter data, the pre-processing, and the labeling of the data, which consists of two main components:

- a) The data collection component establishes a persistent connection with the Twitter API and collects public tweets in real time.
- b) The Data Preparation component focuses on the cleaning and pre-processing of the collected tweets.

Data preparation includes a few steps:

- Text Processing: a crucial step as the language used by Twitter is informal. Tweets contain noise that must be removed which may be spelling shortcuts, misspellings, new words, URLs, hashtags, tags, emoticons, or HTML characters.
- Data Annotations: an integral part of the ML model training process, because the NN learns from the pattern that exists in the annotated data and uses such patterns in new unseen data. So, we assign various entity tags to the text data.

2) *Second part:* Location Detection using the NER model which is created by the training set of data obtained in the first part. The NER model analyses the properties of the human Natural Language and the linguistic patterns of the incoming tweet and figures out possible words/phrases that indicate the location. Geocoding service is applied to convert the input location names extracted by the NER to output coordinates and a structured address of the location. The research uses the outputs of the Geo-coding service to hierarchize the location names.

3) *Third part:* Develop a Named Entity Linking method where the tweet's locations are specified and disambiguated.

The location of the non-geotagged tweets can be a challenge in this context, so the Location inference component is designed to predict the location of the tweet in the absence of geotagging. The Location inference component uses NEL to perform the task of mapping words of interest from the tweet text to corresponding unique entities in a target knowledge base such as Wikipedia. The location assigned by the location inference component is the inferred location of a tweet.

4) *Fourth part:* Evaluation Phase in which the results and accuracy level are evaluated using a set of metrics for the assessment of the accuracy and performance of the system. Performance metrics are such as [Recall, precision, and F-measure] to determine the accuracy of the event-relatedness. Also, to evaluate the performance of the location inference component, Mean and Median distance errors are calculated between the inferred and actual locations. The timeliness of the processes done by the prototype is evaluated using several Twitter datasets of different sizes.

IV. IMPLEMENTATION

The system implementation is shown in The implementation architecture, delivers the functionalities of the proposed framework which are:

- 1) Twitter data collection using Twitter REST API which can cope with a large number of tweets and handle errors automatically.
- 2) Data preparation which includes tasks of raw data validation, reduction, annotating, and cleaning.
- 3) Identification of the event-related tweets and inferring their location.
- 4) Presentation of the results in an appropriate data format.

Fig. 2. The implementation architecture.

We followed the Ntair technique for implementing the proposed framework, which is a classic technique for dividing a complex development task into manageable parts (Layered Architecture)[28]. The implementation architecture consists of three layers: Data Layer, the Process Layer, and the Output Layer. The prototype implementation is based on open-source tools using R and Python which support rapid development and fast prototyping [30]. Each section will be explained as shown in Fig. 2, The Implementation Architecture.

A. Data Layer

The data layer performs the tasks of collecting, preparing, and sorting Twitter data. A combination of R and Python packages and libraries were used for the implementation of this layer.

1) *Data collection module*: Using the Twitter API, Arabic tweets of certain keywords related to different events were collected. The Module performs the following procedure:

- Perform API authentication using Twitter OAuth credentials.
- Establish and maintain a persistent connection with the API.
- Infer the approximate location of the event-related tweets from the potential sources of location information embedded within the Twitter data.

Data retrieval on Twitter is done using the web scraping method which aims to obtain information from a website and turn it into a structure that is easy to understand, store and analyze in a database. Data retrieval was done using RStudio with R programming language with the help of the R package “rtweet” which provides different functions to extract data from Twitter REST APIs. The author extracted tweets with Arabic keywords of different events such as (festivals, accidents, tornados, etc.) and stored the tweet data in feather

files which are used to exchange data between Python and R. For the authentication process, The OAuth server generates the OAuth credentials (Consumer Key, Consumer Secret, Access Token and Token Secret) which the user must manually paste into the code fields in the OAuth handler of the rtweet library, as shown in the following The OAuth credentials.

The API Listener writes the raw JSON tweets to a temporary dataset which acts as a data buffer between the data collection module and the data collection module. This data buffer is nothing but a simple text-based JSON file. The collected tweets should be structured in the form of an array by the API Listener where each Twitter object is an element of this array within this file.

```
library(rtweet)

# create token named "twitter_token"
token <- "*****" # From dev.twitter.com
token_secret <- "*****" # From dev.twitter.com

consumerKey <- "*****"
consumerSecret <- "*****"

twitter_token <- create_token(
  consumer_key = consumerKey,
  consumer_secret = consumerSecret,
  access_token = token,
  access_secret = token_secret)
```

Fig. 3. The OAuth credentials.

2) *Data preparation module*: This module which is implemented in python comprises the following steps of validating and cleaning the collected raw tweets:

- Reads the temporary dataset of the collected tweets.
- Handles the JSON validation for each tweet within the dataset.
- Change the annotation file format to fit the SpaCy requirements.
- Performs data cleaning and pre-processing.
- Writes the cleaned tweets to a structured JSON file.

The temporary dataset is loaded into the python environment, then the module should read JSON tweets and check them for JSON schema conformance. For pre-processing the text as shown in Steps of pre-processing a sample tweet, the first step is iterating over the tweets to remove all numbers, English alphabets, and punctuations such as commas (,), period (.), semi-colons (;), colons (:), question marks (?), Arabic question marks, semicolons and so on, to reduce the size of the feature set. Further, removing the hash (#) and underscore (_) symbols from the hashtags. Also, the author removed Arabic diacritic and vowel marks such as Shaddah, which is a diacritic shaped like a small written "w." After that, the text is divided into words (tokens). The tokens are normalized to replace letters that have different forms into the basic shape. Finally, the Stop Words are filtered using the Arabic stop words list in the Natural Language Toolkit (NLTK). The author modified the list to add the missing word and normalize the words before using them.

Furthermore, checking the result of the pre-processing phase before starting the classification. If the remaining number of tokens is equal to zero, the tweet is excluded from the analysis. The following figure shows the steps of pre-processing applied to a sample tweet:

Fig. 4. Steps of pre-processing a sample tweet.

Once the dataset is cleaned, it is stored in a new JSON file that will be later accessed by the Process Layer for conducting the processes associated with the location extraction using NER.

3) *Data annotation*: it is an important part of the ML training process as the NN will be trained from the patterns that exist in the annotated data and tries to identify such patterns for unseen data. Data Annotation is carried out using Label Studio which is an open-source data annotation tool whether locally or on a server using a simple user interface. For NER, we would need to assign various entity tags to the text data we have which are used later by the NN to identify a generalized pattern. The author identified three main entities (Point of interest, City, Region) POI, CTY, REG. Then using word frequency analysis, evaluated each tweet against term classes that are associated with practical locations related to certain events to find the tweets are connected to which location. So, the author considered random location-related tweets which are manually annotated then by applying different entity tags to the existing data to perform NER. The model analyses these collections of tweets with their entity tags to find a generalized pattern. Such a setup is simple for NER tagging, with only the names of tags changed on the customization panel. File imported in the Label Studio is of the supported formats (.csv, .json, .tsv), and after the job is done exporting the annotated data in a format of the same previous supported formats. The time-consuming process of data annotations is made simpler with Label Studio.

B. Process Layer

The core implementation layer deals with tasks of location extraction of the collected tweets.

Model Training:

Data is split into two sets: training and testing sets. The annotated tweets are used for the training set to train the model. Then the model is used to identify the location entities in the testing set. The NER Model development process is carried out using the SpaCy library. The training data is converted in a form of tuples containing text data and a dictionary which is a format supported by SpaCy. The following steps are carried out to train the model:

- 1) Load the model or create an empty model using spaCy blank with the ID of desired language (Arabic in this case).
- 2) Add the new entity label to the entity recognizer using the add_label method.
- 3) Loop over the examples and call the Natural Language Processor (NLP) which steps through the words of the input. Predict each word. Then consult the annotations, to see whether it was right. If it was wrong, it adjusts its weights so that the correct action will score higher next time.
- 4) Save the trained model.
- 5) Test the model to make sure the new entity is recognized correctly.
- 6) Explore the results of the evaluation.

Location Named Entity Linking

Using a Geo-coding service, it takes an input text such as an address or the name of a place and returns a latitude/longitude location on the Earth's surface for that place. The locations are decoded using geocoding APIs offered by Google Places and OpenStreetMap. The geocoded service results in a JSON-formatted list of geocoded addresses representing possible matches, including longitude and latitude coordinate and well-formatted address with all the super regions included. If the extracted location is linked to more than a location, The Linker will disambiguate the locations by estimating the distance between the geospatial location and candidate geospatial locations.

C. Output Layer

This layer uses the structured data of the processed tweets to display the results by generating statistical results and evaluation metrics. Results are output from two main operations:

- 1) Displacement Computations where the displacement between Twitter's entity location points and the coordinates that result from Google Geocoder API, to assess the Geocoding accuracy.
- 2) Generating statistical results: the frequency distributions of displacement values for SpaCy are computed. Then various groupings of SpaCy entities are evaluated to find the entity grouping giving the highest accuracy in predicting.
- 3) Evaluation metrics: Three metrics are commonly used for NER and NEL tasks which are Precision, Recall, and F1.

V. RESULTS AND EVALUATION

A. Data Collection and Preparation

Twitter REST API was used to collect tweets with a specific keyword, where the author conducted the experiment using "accident" as the initial keyword.

Data collection continued up to weeks, during which 11134 unique tweets were collected and stored in different feather files. Then the feather files were concatenated to construct the initial dataset that is processed by the Data preparation module. After the data preparation module, the initial dataset was reduced to 9894 unique tweets after pre-processing and further reduced to 1982 tweets after

annotation. A reference dataset of 320 tweets can be defined as a representation of the correctly classified sample tweets for verifying the model is manually annotated by experts.

B. Evaluation of the NER Model

For measuring the performance, each output word was compared to the truth file and assigned a value of True Positive (TP), False Positive (FP), True Negative (TN), or False Negative (FN). TP, FP, TN, and FN counts for all tweets were added and Precision, recall, and F1 scores were calculated per entity (POI, REG, and CTY as the core entity sets for evaluation). The author only relied on F-score to measure the optimal performance of the results as it combines both precision and recall metrics. The F-measure was able to correctly identify and detect 63% of the location of tweets in a certain Point of interest while on the region and city level, the system was only able to predict 40% and 48% of the location of tweets, respectively, as described in Table II.

TABLE II. RESULTS OF THE NER MODEL

Entity	Precision	Recall	F1
POI	77	54	63%
REG	60	30	40%
CTY	57	41	48%

C. Evaluation of the NEL Model

Second phase in the proposed framework is NEL, this phase aims to extract the geolocation for the extracted entities. Table III represent the evaluation of the NEL model, where:

- 1) The (Label) field represents the corresponding location name label (POI, CTY, REG) assigned to each tweet.
- 2) (Entity), (lat pred) and (lng pred) fields represent the name and the geo-coordinates (latitude and longitude) of the extracted location.
- 3) (lat act) and (lng act) fields correspond to the geotagged coordinates of the tweets that extracted manually (Ground truth).
- 4) The (Distance_km) field represents the distance error (the distance between the actual location and the inferred location of a tweet) which is calculated using the Haversine formula. This field is used as the evaluation metric to measure the accuracy of the proposed solution results. As for the results, in 191 out of 320 tweets with a percentage of (61.3%), the inferred location was at a distance equal to or smaller than 10 km from their actual location. And in 88 tweets (27.5%) the inferred location was located within 10 to 50 km of their actual location. And among the remaining tweets, the locations of 10 tweets (3.1%) were located within 50 to 100 km. While 26 tweets (8.1%) have a distance error greater than 100 km. Fig. 5 below shows the accuracy of the inferred location based on distance error.

TABLE III. RESULTS OF THE NEL MODEL

	Lat act	Lng act	label	entity	Lat pred	Ing pred	Distance km
1	30.04	31.23	['POI', 'CTY']	['القاهرة', 'طريق رئيسي']	30.04	31.23	0.17

Fig. 5. The accuracy of the inferred location.

VI. CONCLUSION AND FUTURE WORK

The framework proposed can assist emergency/event managers to locate necessary warnings and monitor situations. Also, it can provide information on the type and scope of damage that resulted from a certain event. Twitter data collection and preparation is considered one of the foremost contributions of the research. This study proposes a method to process tweets to determine their degree of relatedness to accident events and infer their approximate location. First of all, getting to know the nature and structure of Twitter data together with the identification of the optimum approaches to its collection, storage, and preparation by the emergency response context, by itself, is an essential knowledge area and can be considered as one of the foremost contributions of this research. However, this assertion, along with the possibility of the adoption of the framework in other types of incidents such as bushfires or terrorist attacks, is subject to further research. Another point is that the framework only focused on Arabic tweets. This could be seen as a major drawback in using the framework on a global scale or in countries that speak a language other than Arabic, especially languages that use non-ASCII characters like in our case (e.g., Turkish and Chinese). Therefore, exploring possible solutions to this issue could form a future research topic. The next section outlines several future research directions.

For future research, the manual annotation process is time-consuming and laborious, so an investigation into automation methods is much recommended. Also, the research only considered the textual part of the tweet excluding any images, videos, or links that may likely provide valuable information, so providing visualization of the tweet's content may be suggested for future work. Also, semantic-based solution for accurate assessment of emoticons, acronyms, or slang. As mentioned earlier, extending the applicability of the proposed framework to other commonly spoken languages can improve the performance of the framework. For location accuracy, integration of other sources of information such as remote sensing data, sensor network data, and crowd-sourced mapping repositories can improve the measurement and minimize the error. For Geo-coding, using other sources for location names and geographical databases other than Google Map API such as GeoNames may enhance the applicability of the proposed framework at larger geographic scales.

Abstract—The laborious, and cost-inefficient biochemical methods for identifying thermophilic proteins necessarily require a rapid and accurate method for identifying thermophilic proteins. Recently, machine learning has become a more effective method for identifying specific classes of extremophiles. There is still a need for a low-cost method for identifying thermophilic proteins, despite the fact that studies employing machine learning yielded superior results to conventional methods. Here, we avoid the problem of manually crafted features, which involves experts defining and extracting a set of features using only protein sequences as input for various computational methods. This study classifies thermophilic proteins and their counterparts using only protein sequences in one-hot encoding representation and the bidirectional long short-term memory (BiLSTM) model. The model achieved an accuracy of 92.34 percent, a specificity of 91 percent, and a sensitivity of 93.77 percent, which is superior to other models reported elsewhere that rely on a number of manually crafted features. In addition, the more trustworthy and objective data set and the independent data set for evaluation make this model competitive with other, more accurate models.

Keywords—Thermophilic; classification; one-hot encoding; BiLSTM

I. INTRODUCTION

Extremophiles are microorganisms that have adapted to inhabit ecological niches deemed "extreme" due to unfavorable environmental conditions, such as excessively high or low temperatures, extreme pH values, high salt concentrations, or high pressure. Proteins isolated from extremophiles are biomolecules that possess unusual properties. One exceptional property enables proteins to function under extreme conditions. Researchers use extremophilic proteins in industrial applications since they can resist harsh conditions, which presents new opportunities for biocatalysts and biotransformation [1]–[4]. Thermophiles, extremophiles that thrive at temperatures between 41 and 122 degrees Celsius, with optimal growth temperatures between 60 and 108 degrees Celsius, are among the most studied.

Identifying thermophilic proteins' biochemical and physicochemical properties is critical because this serves as the foundation for designing and engineering proteins and enzymes. However, the biochemical identification method for

thermophilic proteins is time-consuming, labor-intensive, and costly. Therefore, a rapid and accurate method for identifying thermophilic proteins is urgently required.

The increasing availability of data on extremophilic proteins enables computational methods to predict protein classification and identify the key characteristics that define that class [5]. These computational methods provide a more effective means of identifying specific classes of extremophiles than biochemical methods that require wet lab experiments. Many researchers have recently attempted to distinguish thermophilic organisms from their counterparts using machine learning [6]. In general, classifying thermophilic proteins using an approach based on machine learning involves six steps: dataset collection, data pre-processing, feature extraction, feature or dimension reduction, classification, and evaluation. Numerous techniques have been developed for researching and identifying thermophilic proteins. Kumar et al. (2000) identified and categorized thermophilic proteins based on structural differences at room temperature [7], whereas Gromiha et al. (2001) studied the properties of amino acids and the effects of amino acid residues on protein heat resistance [8]. These studies rely on expensive and ineffective biological techniques from the past. In other studies, Zhou et al. (2008) used an amino acid coupling model to identify thermophilic proteins [9]. Zhang et al. (2006) utilized dipeptide composition and amino acid composition to differentiate between mesophilic and thermophilic proteins [10] and achieved an accuracy of 86.6% for five-fold cross-validation. Using neural network-based amino acid composition [11], Gromiha and Suresh (2008) increased the computational complexity of five-fold cross-validation by 89%. Using decision tree methods, Wu et al. classified and identified thermophilic proteins with an accuracy of over 80% [12]. The accuracy of the k-nearest neighbor classifier used by Zuo et al. (2013) to classify thermophilic proteins was 91.02 percent [13].

To classify thermophile proteins and their counterparts, most previous studies have used hand-picked features calculated as input features for various machine learning models. During the feature extraction stage, various features are extracted using various computational methods based on amino acid sequence and transformed into numerical vectors. Protein features have been used in previous studies [6], [11]–

*Corresponding Author.

[19]. Even the most recent study [20], [21] still employs this type of protein representation. However, their scalability is limited because some of these input features are not always available and are computationally expensive to generate. Wu et al. (2009) predicted protein thermostability using protein structure and sequence characteristics, and suggested that although sequence and structural models had slightly higher accuracy, sequence-only models can provide sufficient accuracy for thermostability prediction [12]. Inspired by Wu's claim, we use only protein sequence as input to avoid the problem of obtaining handcrafted features, which requires experts to define and extract a set of features using various computational methods. This study improves accuracy by

using sequence-only, removing all complexity to calculate derived features, and bidirectional long short-term memory (BiLSTM).

II. METHODS

The core structure of the present research consists of the five processes listed below: (1) dataset collecting, (2) feature extraction, (3) classification, and (4) performance evaluation. The framework's flowchart is presented in Fig. 1. One-hot representation is used to encode protein sequence. This representation is input to three distinct classifiers: Multi-layer Perceptron (MLP), Convolutional Neural Network (CNN), and Bidirectional Long Short-Term Memory (BiLSTM).

Fig. 1. Flow chart of a framework for predicting thermophilic proteins

A. Datasets

We utilized Ahmed et al. (2022) thermophilic and mesophilic benchmark dataset [21]. The dataset originated from the Universal Protein Resource (<http://www.uniprot.org>). To provide reliable data, previous studies retained only proteins that had been manually reviewed and excluded proteins with ambiguous residues, sequences that were fragments of other proteins, and proteins inferred from prediction or homology. With the CD-HIT algorithm [22] and a sequence identity threshold of 30%, redundancy and homology bias have been eliminated. There were 1,443 non-thermophilic proteins and 1,367 thermophilic proteins in the final benchmark dataset. The training and testing datasets are identical to those used in the study by Ahmed et al [21].

B. Feature Extraction

Here, instead of describing a protein with physical attributes, we directly encode its amino acid sequence. This approach of vectorizing categorical data is called one-hot encoding. An $L \times n$ matrix encodes a protein sequence of length L , where n is the number of amino acids. Each row of the matrix consists of $(n - 1)$ 0s and a single 1, with the

location of the 1 representing the amino acid residue in the protein at that position.

Using the constructed code dictionary, a 1 letter code is substituted for an integer value for each unaligned amino acid sequence. If the code is not included in the dictionary, the value is replaced by 0 and only the 20 most common amino acids are considered. This phase will transform the 1 letter code sequence data into numerical data. Next, post padding is performed with a maximum sequence length of 1024, either padding with 0 if the entire sequence length is less than 1024 or truncating the sequence to a maximum length of 1024.

C. Classification

We examined several classifiers, including MLP, CNN, and BiLSTM, to find the best model for classifying thermophilic proteins. **MLP** is a feed-forward neural network having input, hidden, and output layers, which are responsible for receiving, processing, and final prediction, respectively. The network is trained using backpropagation with the supervised learning technique. Each trained neuron's output is defined by equation (1), where x_i represents the firing neuron's input values, w_i their weights, f the activation function, and b the neuron's

activation threshold [23], [24]. In the current study, the hidden layer activation function was a rectified linear activation unit (ReLU), while the outer layer activation function was sigmoid. To train the model, input, hidden, and output layers with one neuron, respectively, were used. Table I. shows the hyperparameters in detail.

$$f(\alpha) = f(\sum_{i=1} w_i x_i + b) \quad (1)$$

CNN employs layers with convolving filters applied to local features [25]. The use of convolutional neural networks is the same as that of picture data. The sole difference is that 1D convolutions are applied as opposed to 2D convolutions. The convolution network is made of the following: (1) A Conv1D with 128 units, with the relu activation function and a kernel size of two to extract basic properties, (2) another Conv1D with 128 units with relu activation function, kernel size of two, and l2 regularizer, (3) a dropout layer that randomly drops nodes during training, (4) a MaxPooling1D layer that down-samples the input by taking max over the steps that are constrained to a pool_size in each stride to reduce the spatial size of the representation, (5) another dropout layer, (6) a Dense layer with 250 units for the fully connected layer, and (7) an output layer with the sigmoid activation function because this is a binary problem. Table I. shows the hyperparameters in detail.

LSTMs are excellent at maintaining long-term memory dependencies. The LSTM architecture accomplishes this through the use of input gate, the forget gate, and the output gate [26]. The inputs of unidirectional LSTM, as we can see, are from the past. Hence, it only retains past knowledge. On the other hand, a bidirectional LSTM is able to preserve contextual information from both the past and the future at any time because it run the inputs in two directions, one from the past to the future and one from the future to the past [27]. The first layer of the model is the embedding layer which uses the 256-length vector, and the next layer is the bidirectional LSTM layer which has 256 neurons. These will work as the memory unit of the model, which has a vocab size of 21 representing 20 unique amino acids and one padding character. L2 regularization is added to prevent model over-fitting. After bidirectional LSTM, the dense layer is an output layer with sigmoid function. The hyperparameter used in this study is summarized in Table I.

D. Classification

In order to evaluate the overall model performance, the following parameters were used

$$Sn = \frac{TP}{TP+FN} \quad (2)$$

$$Sp = \frac{TN}{TN+FP} \quad (3)$$

$$Acc = \frac{TP+TN}{TP+FN+FP+TN} \quad (4)$$

$$F1 = 2 \times \frac{Sn \times (\frac{TP}{TP+FP})}{Sn + (\frac{TP}{TP+FP})} \quad (5)$$

where Sn, Sp, Acc, F1 denote sensitivity (or recall), specificity, accuracy, and F1-score. In this study we use the F1-score to make sure that when the accuracy is high, it correctly

predicts both classes. Thermophilic proteins classified as thermophilic are designated as TP (true positive), non-thermophilic proteins labeled as non-thermophilic are TN (true negative), non-thermophilic proteins classed as thermophilic are FP (false positive), and thermophilic proteins regarded as non-thermophilic are FN (false negative).

III. RESULTS AND DISCUSSION

In this study we solely used protein sequences to classify thermophilic proteins. This chain of amino acids was represented using one-hot encoding which is the input for the classifier. Three machine learning techniques, MLP, CNN, and BiLSTM were used to identify thermophilic and non-thermophilic proteins. Hyperparameters tuning was performed to find the optimal model. The best optimized hyperparameters for each model are described in Table I. The result of each model is shown in Table II. The result of each classifier is measured using the following performance metric; accuracy, specificity, recall, and F1-score. The macro average values of specificity, recall, and F1-score are presented in Table II.

TABLE I. BEST HYPERPARAMETER

Hyperparameter	MLP	CNN	BiLSTM
Number of Layer	2	4	3
Number of Neuron	100-1	250-1	256-256-1
Number of Filter	-	128	-
Activation Function	Relu	Relu	Relu
Optimizer	Adam	Adam	Adam
Learning Rate	0.0001	0.001	0.001
Dropout	-	0.6 - 0.8	-

Epoch	250	250	500

TABLE II. PERFORMANCE RESULT

Model	Sn (%)	Sp (%)	Acc (%)	F1(%)
MLP	2.19	97.23	51.06	4.18
CNN	90.10	89.96	90.03	89.76
BiLSTM	93.77	91.00	92.34	92.25

^a Note: Sn: sensitivity (or recall), Sp: specificity, Acc: accuracy, and F1: F1-score

A. Performance Comparison on Different Algorithms

We compared the performance of three machine learning methods: MLP, CNN, and BiLSTM. The same features were used to train and test these methods. Based on the result as shown in Table II, the highest accuracy, sensitivity, specificity, and f-measure were achieved using BiLSTM, at 92.34%, 93.77%, 91.00%, and 92.25% respectively. The MLP, on the other hand, was only capable of achieving an accuracy of 51.06%.

TABLE III. PERFORMANCE OF CNN ON VARIOUS K-MERS

k-mers	Sn (%)	Sp (%)	Acc (%)	F1(%)
1	61.53	53.63	57.47	58.43
2	82.78	89.27	86.12	85.28
3	90.10	89.96	90.03	89.76
4	79.85	94.11	87.18	85.82
5	86.81	89.27	88.07	87.61

^b. Note: Sn: sensitivity (or recall), Sp: specificity, Acc: accuracy, and F1: F1-score

MLP can theoretically approximate any function to any precision. Using the same dataset, MLP architecture in other studies which used protein sequence and several other features as the input could achieve accuracy of 99.26% [21]. However, MLPs were not ideal for processing patterns with sequence. Because we rely on the sequence of amino acids in this study, MLP strives to remember patterns in sequential data to

discover reliance on historical data, which is extremely useful for prediction.

CNN learns to recognize spatial patterns. CNN worked remarkably well, however, when applied to specific NLP issues [28]. When applying CNN to sequential data, the result of each convolution will be triggered when a unique pattern is identified. By altering the size of the kernels and concatenating their outputs, it is possible to identify patterns of numerous sizes, such as 2, 3, or 5 adjacent amino acids (k-mers), which are analogous to the term n-grams. Therefore, CNN can distinguish this k-adjacent amino acid regardless of its position in the sequence. The results of our experiments with various k-mers are summarized in Table III, which reveals that prediction using three consecutive residues (amino acid 3-mers) provides the highest performance with an accuracy of 90.03 percent, a sensitivity of 90.10 percent, a specificity of 89.96 percent, and an f-measure of 89.76 percent.

^d. Support Vector Machine (SVM), Multilayer Perceptron (MLP), Random Forest (RF), Bidirectional Long Short-Term Memory (BiLSTM), K-Nearest Neighbour (KNN), Neural Network (NN), Decision Tree (DT)

Convolutions and pooling processes eliminate information about the local order of amino acids, making it more difficult to implement sequence tagging inside a pure CNN architecture. Additionally, pooling minimizes output dimensionality while maintaining the most essential information. Each filter recognizes a unique characteristic. If this specific feature appears somewhere in the sequence, applying the filter to that region will result in a large value, while applying the filter to other regions will result in a small value. By performing the max operation, we retain information regarding whether or not the feature existed in the sequence, but we lose information regarding where the feature appeared. Although it operates wonderfully, it is incapable of interpreting temporal data. In natural language processing, the resemblance between proteins and sentences explains why CNN performs worse than BiLSTM, which can learn from both past and future data in the sequence.

Among all models, the BiLSTM Model produces the best results. Because it knows what amino acids follow and precede an amino acid in the protein sequence, BiLSTM effectively increases the amount of information available to the network, improving the context available to the algorithm. BiLSTM mines the relationships between contexts in both directions, resulting in a better recognition for classifying thermophilic proteins.

B. Comparison to Other Models

Comparison with previously published methods is required to establish the superiority of the new method. It is widely known that the prediction results would be exaggerated if the suggested technique was trained and evaluated using a benchmark dataset containing a large proportion of homologous sequences. If two protein sequences possess a sequence similarity of greater than 40 percent, they are considered homologous. When a model is trained and evaluated on such a dataset, the vast majority of predictors always attain high levels of accuracy. For instance, previous studies [33] did not eliminate very identical or homologous sequences with 40% sequence identity from their datasets. Other studies only used a 40% cutoff eliminate the homologous sequence [11]. This study's dataset, which uses a 30% cutoff, is therefore judged to be more objective and dependable.

Numerous models have been developed to identify thermophilic proteins [6], [11], [14]–[17], [19], [29], [31]. All of the proposed models were developed using machine learning techniques and assessed using cross-validation. Nevertheless, our model was evaluated using independent data.

While state-of-the-art (SOTA) methods typically use various features derived from amino acid sequences as input to identify thermophilicity, the method(s) presented here use encoded single protein sequences as one-hot encoding, which serve as the only input feature for the prediction. One-hot encodings are sparse, memory inefficient, and high-dimensional by definition. In one-hot encoding, there is no concept of similarity between sequence or structure pieces; they are either identical or dissimilar. In Table IV we summarize the comparison with other models. From the comparison, we can see that using BiLSTM we can still achieve competitive results compared to other models which

use various additional features as input, such as physicochemical properties, amino acid composition, and dipeptide compositions. This model even achieved better accuracy compared to another model from Wu et al. [12] which also consider protein structure in classifying the protein.

Although this study only uses the amino acid sequence without any derived features and combines it with the bidirectional sequential model, we can obtain a competitive classification result. Some other studies that use various handcrafted features provide higher performance. So, including the semantics information in the protein representation might increase the performance. In natural language processing, we can extract features using the Language Model (LM), referred to as embeddings. Instead of manually calculating each feature, LMs offer a potential alternative to this increasingly time-consuming database search as they extract features directly from single protein sequences [36]. Using embedding that has semantic information as input for classification can improve classification performance [37]. Use of embedding to represent proteins for classification as a downstream task can be an exciting topic to explore in the future.

IV. CONCLUSIONS

This research demonstrates that models trained using simply amino acid sequences perform comparably to and frequently exceed models trained using multiple feature representations. Comparing different machine learning algorithms demonstrates that a sequential model with a bidirectional mechanism is applicable to all protein attributes, and that the position of amino acids in the protein sequence has a significant predictive function. This research facilitates the development of predictive models by bypassing many of the challenges associated with generating the biological, chemical, and physical attributes that describe protein sequences.

Comparison of Naive Bayes and SVM Classification in Grid-Search Hyperparameter Tuned and Non-Hyperparameter Tuned Healthcare Stock Market Sentiment Analysis

KaiSiang Chong, Nathar Shah
Faculty of Computing & Informatics
Multimedia University, Cyberjaya, Selangor, Malaysia

Abstract—This paper compares the performance of Naive Bayes and SVM classifiers classification based on sentiment analysis of healthcare companies' stock comments in Bursa Malaysia. Differing from other studies which focus on the performance of the classifier models, this paper focuses on identifying the hyperparameters of the classifier models that are significant for sentiment analysis and the optimization potential of the models. Grid Search technique is used for the hyperparameters tuning process. The performance such as precision, recall, f1-score, and accuracy of Naive Bayes and SVM before and after hyperparameter tuning are compared. The results show that the important hyperparameters for Naive Bayes are alpha and fit_prior, while the important hyperparameters for SVM are C, kernel, and gamma. After performing hyperparameters tuning, SVM gave a better performance with an accuracy of 85.65% than Naive Bayes with an accuracy of 68.70%. It also proves that hyperparameter tuning is able to improve the performance of both models, and SVM has a better optimization potential than Naive Bayes.

Keywords—Machine learning; sentiment analysis; opinion mining, Naive Bayes; SVM Classifier; grid search technique; hyperparameter tuning

I. INTRODUCTION

Sentiment analysis, often known as opinion mining, is a natural language processing (NLP) technique that determines the sentiment behind a body of text. This is a common method for businesses to determine and categorize customer views about a product, service, or idea. Data mining, machine learning (ML), and artificial intelligence (AI) are involved in analyzing the texts and finding out the sentiment.

There are too many ways to perform sentiment analysis by using different machine learning algorithms such as Naive Bayes, Support Vector Machine, K-Nearest Neighbour, and so on. This has made it difficult for the researchers to determine which classifier should be used as the performance of these algorithms is usually dependent on the datasets used. Most studies [7][9][3][6][4], concluded that the Naive Bayes and SVM classifiers outperform all other algorithms in evaluating the sentiment of the text. However, it seems that the performance of Naive Bayes and SVM is very similar. Depending on the datasets used, the performance of the classifiers is affected. In [7] and [9], SVM has a better

performance than Naive Bayes. The dataset used in [7] is Amazon product reviews, and in [9] is Twitter reviews. However, in [3], Naive Bayes has a better performance than SVM, and the dataset used in [3] is about e-sport education. Most importantly, these researches only used default hyperparameters for the classification models, and so far the best performance of the classifier obtained is from [7], which is the SVM with 84% of accuracy. The problem of current research is that most of the papers use the default hyperparameter for the sentiment classification. The results might be good, but there should still be some potential for the models to perform better.

Hence, the purpose of this paper is to compare the performance of Naive Bayes and SVM classifiers based on sentiment analysis of healthcare companies' stock comments, justify which model is best suited for this case, and justify the optimization potential of the models by hyperparameter tuning using the Grid Search approach. The data is collected from the I3investor website and preprocessed by using text preprocessing techniques such as removing stopwords, lemmatization, tokenization, and so on. After that, the preprocessed data will be used to train the Naive Bayes and SVM, and the results will be evaluated. Section II will include some background studies of several similar works, Section III will be the methodology which includes the detailed steps of conducting the research, and Section IV will be the evaluation results of both classifications.

II. BACKGROUND STUDY

Basically, this section of the paper includes the review of several research papers with similar works to ours. According to these research papers, data preprocessing like stopwords removal, stemming, and tokenization are necessary steps before performing the classification. First, the comparison study of Naive Bayes with SVM is reviewed. It appears that the performance of both models is dependent on the datasets used. Second, comes the review of the Naive Bayes classifier and it seems that Naive Bayes outperforms other classifiers. After that, the study about SVM is reviewed, and it shows that the performance of SVM is affected by the dataset used, and using the Grid Search approach for SVM optimization, the performance of SVM can be improved as well.

A. Comparison Study of Naive Bayes and SVM using Different Datasets

Firstly, this section will review the comparative study of Naive Bayes and SVM.

Sanjay Dey et al. [7] conducted a comparison study of two machine learning algorithms for sentiment analysis of Amazon product reviews. Naive Bayes and SVM were used in this paper. The preprocessing steps such as tokenization, removing stopwords, filling missing values, and feature extraction are applied. The result shows that SVM has a slightly better performance with 84 % accuracy than Naive Bayes with 82.875 % accuracy.

Abdul Mohaimin Rahat et al. [9] worked on a research paper to conduct sentiment analysis on the review from Twitter. The dataset collected is preprocessed by stop word removal, hashtag removal, POS tagging, and so on. Two algorithms, which are Naive Bayes and SVM were applied to classify the positive and negative sentiments. As a result, SVM gets a better accuracy of 82.48 % than the Naive Bayes with an accuracy of 76.56 %.

Rian Ardianto et al. [3] performed sentiment analysis toward e-sport education. The data was collected from Twitter. Naive Bayes and SVM are used in this research as a comparative study. Synthetic Minority Over-Sampling Technique (SMOTE) is used in the evaluation of the two algorithms. As a result, Naive Bayes with SMOTE has a better performance with an accuracy of 70.32 % as compared to SVM with SMOTE with an accuracy of 66.92 %.

B. Study on Naive Bayes

Second, this section will review the research on the Naive Bayes classifier.

The research done by Lopamudra Dey et al. [6] focuses on the comparison of two supervised machine learning approaches which are K-Nearest Neighbour and Naive Bayes based on the sentiment analysis of movie reviews as well as hotel reviews. The accuracy, precision, and recall of these models are evaluated. In short, Naive Bayes has a better performance for movie reviews with an accuracy of 82.43 % than K-NN with an accuracy of 69.81 %, while having a similar performance for hotel reviews with an accuracy of 55.09 % as compared to K-NN with an accuracy of 52.14 %. The researchers concluded that Naive Bayes performs better than K-NN in analyzing the movie reviews.

Achmad Bayhaqy et al. [4] focused on comparing three different classification algorithms, which are Decision Tree, K-NN, and Naive Bayes, by the sentiment analysis about the tweets/reviews of E-commerce in Tokopedia and Bukalapak on Twitter. Text preprocessing techniques are applied to the data collected. The comparison of the three algorithms is done with the assistance of Rapidminer. The results show that the accuracy of the Decision Tree is 80%, K-NN is 78%, and Naive Bayes is 77%. The results for precision for Decision Tree is 79.96%, K-NN is 85.67 %, and Naive Bayes is 88.50 %. Although the accuracy of Naive Bayes is 77 % which is the lowest among others, the researchers concluded the Naive Bayes as the most suitable classifiers for use with their

datasets as it has the highest precision of 88.50 % which means it provided more accurate and precise predictions.

C. Study on Support Vector Machine

Lastly, this section will review the research on SVM classification.

Munir Ahmad et al. [1] have chosen to use SVM for the sentiment analysis with WEKA. There are two datasets included which are the tweets about self-driving cars and Apple products, and the data are pre-labeled with the sentiments. In short, the accuracy for the self-driving cars dataset is 59.91 %, and the accuracy for the Apple products dataset is 71.2 %. The outcomes are not very good, demonstrating the dependency of SVM performance on the input dataset. The habits of most Twitter users to use short forms or informal language might be the reason for the difficulty for the SVM to learn successfully.

Besides, using the Grid Search approach for SVM optimization, Munir Ahmad et al. [2] have achieved better results. The precision of SVM is increased from around 70% to 80%. With the Twitter data about the topics of Apple, Google, Microsoft, and Twitter, the potential of SVM optimization is highlighted in this paper.

III. METHODOLOGY

I3investor is a popular stock investment platform for independent stock traders and investors. Every month, the I3investor [5] community creates over 50K comments and posts. In order to be trained by the supervised learning algorithms, the datasets collected from I3investor needed to be preprocessed and labeled. After the preprocessing and labeling, a portion of data is selected from the dataset and is split into train-set and test-set. The words are vectorized by using the TF-IDF vectorizer, and the dataset is used in running both Naive Bayes and SVM classifiers. Moreover, the Grid Search technique is used for hyperparameter tuning to improve the accuracy of both classifiers. The experimental results are then evaluated. Fig. 1 shows the workflow of the methodology. The details of the process will be explained.

A. Data Pre-processing

Every comment may include some words that are neither significant nor beneficial for sentiment analysis. Hence, text preprocessing is a necessary step to obtain a clean dataset, and have better outcomes. The preprocessing steps included:

1) *Removing of URL*: The URL in the comments which basically links users to other websites is meaningless for sentiment analysis and is removed.

2) *Removing of Other Languages*: The data collected will include the comments from Malaysians which means there will be several languages such as Chinese, Malay, and English. Hence, the CLD3 package is used in this case to detect and remove the Chinese and Malay comments, only remain the English comments. Since the classifiers are not trained to assess the sentiment of comments in multiple different languages, the removal of other languages will then have a significant influence on the classification process outcomes.

3) *Removing of Punctuation*: Punctuation has no value for the sentiment analysis and is removed. It is also a step needed for the ease of tokenization.

4) *Removing of Stopwords*: Stop words are function words that have no sentiment yet are regularly used. If these terms are not eliminated, they will have no effect on the analysis's efficiency. These words are known as "noise." For example, frequently used terms are "a," "of," "the," "I," "it," "you," and "and."

5) *Lemmatization*: This stage condenses words into their stem or root forms. For example, "evaluate" and "evaluation", the root of the word "evaluation" is "evaluate", and having both terms in the data increases the algorithm's effort to interpret their sentiment. As a result, lemmatizing the token to its root type is required to minimize the complexity of the comment and reduce processing time, hence enhancing the model's performance.

6) *Lower casing text*: All the text in the datasets is changed to lower case to have a consistent format.

7) *Tokenization*: A method to divide the entire comment into many individual words for convenience of analysis.

words match those in the positive or negative Opinion Lexicon. The number of positive and negative words for each row of data will next be calculated. The score for each row of data will be computed by subtracting the number of negative words from the number of positive words. As a consequence, data with scores more than 0 will be labeled as positive, data with scores less than 0 will be labeled as negative, and data with scores equal to 0 will be labeled as neutral.

C. Feature Extraction using TF-IDF

The term frequency-inverse document frequency (TF-IDF) was used to extract the feature of the dataset. When retrieving information, the TF-IDF technique weights the frequency of a phrase (TF) and the inverse frequency of documents (IDF). Each word or phrase is given a TF and IDF score. The TF and IDF product results of a word, on the other hand, correspond to the phrase's TF-IDF weight. As a result, the TF-IDF score (weight) rises in tandem with the phrase's rarity and vice versa. As a consequence, the TF of a term denotes its frequency, whereas the IDF denotes its importance across the corpus. If a term's content TFIDF weight is high, the content will always show among the top search results, allowing anybody to avoid stopwords while simultaneously finding words with higher search traffic and lower competition.

D. Hyperparameters Tuning using Grid-Search Technique

Hyperparameters are variables whose values influence the learning process and affect the model parameters that a learning algorithm learns. Grid Search is a technique for optimizing hyperparameters. It prepares the machine learning algorithm for every potential combination of hyperparameters. Cross-validation is used to guide the training process, ensuring that the trained model can extract the majority of the patterns from the dataset. The best set of hyperparameter values from Grid Search is then used in the real model. In summary, the optimal hyperparameters are assured, and the model's accuracy can be enhanced.

IV. EXPERIMENTAL RESULT

The research is conducted using the Google Colab environment. A portion of the preprocessed data which consists of 20000 comments is used. There are 6219 positive comments, 6196 negative comments, and 7585 neutral comments.

Grid Search approach is used to find out the best hyperparameters of the models. Both original and tuned versions of Naive Bayes and SVM are trained and tested. The precision, recall, f1-score, and accuracy of each model are evaluated.

Table I shows the hyperparameters setting for Naive Bayes. There are three parameters which are alpha, fit_prior, and class_prior. Parameter alpha refers to the additive smoothing parameter, parameter fit_prior control whether to learn class prior probabilities or not, and parameter class_prior refers to the prior probabilities of the classes. The default hyperparameter for alpha is 1.0, and for fit_prior is 'True.' After performing the Grid Search, it appears that the best hyperparameter for alpha is 1.4, for fit_prior is 'False', and the parameter for class_prior is 'remain unchanged.'

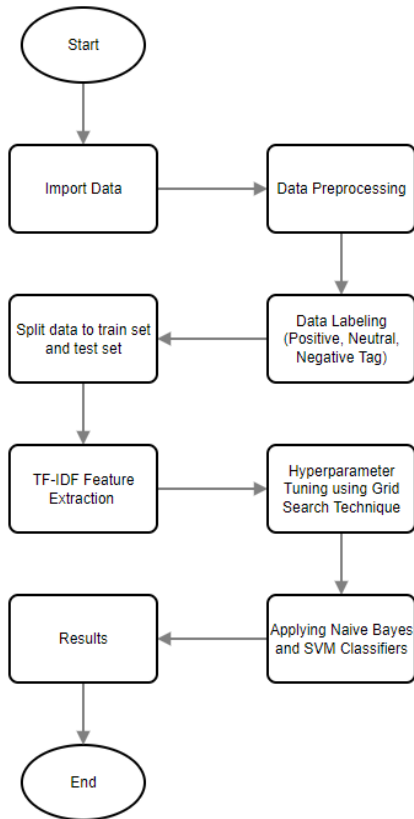

Fig. 1. Methodology workflow.

B. Data Labeling

It is impossible for a human being to manually label the data as the datasets consist of a large number of comments. Hence, the Opinion Lexicon created by Minqing Hu and Bing Liu [8] which contains positive and negative words is being prepared. The preprocessed data is next reviewed to see if the

TABLE I. HYPERPARAMETERS SETTING FOR NAIVE BAYES

Parameters	alpha	fit_prior	class_prior
Default	1.0	True	None
Best	1.4	False	None

TABLE II. HYPERPARAMETERS SETTING FOR SVM

Parameters	C	kernel	gamma
Default	1.0	rbf	scale
Best	7.0	linear	auto

Table II shows the hyperparameters setting for SVM. Basically, SVM has a total of 15 hyperparameters. After performing Grid Search, there are only 3 hyperparameters that have changed which are C from a value of 1.0 to a value of 7.0, the kernel of 'rbf' to kernel of 'linear', and gamma of 'scale' to gamma of 'auto' while the other 12 hyperparameters showing default is the best option to choose. Parameter C refers to the regularization parameter, parameter kernel specified the kernel type to be used, and parameter gamma refers to the coefficient of the kernel. With the other hyperparameters for SVM remaining unchanged, this proves that SVM is already a good model for performing sentiment analysis without tuning the hyperparameter and can usually obtain good performance as in papers [7], [9], [3], and [1].

Precision is a metric used to quantify how many correct positive predictions have been made. It is derived by dividing the number of accurately predicted positive cases by the total number of positive examples predicted. The precision shows the model's accuracy in classifying samples as positive.

Table III shows the comparison of precision for each model before and after hyperparameters tuning. The precision of Naive Bayes has increased from 71.63% to 83.22%, and the precision of SVM has increased from 81.64% to 87.60%. In short, SVM has higher precision than Naive Bayes before and after tuning. Fig. 2 shows the bar chart of precision comparison for Naive Bayes and SVM.

The proportion of valid positive predictions made out of all feasible positive predictions is calculated as recall. The recall metric evaluates the model's ability to detect positive samples. The higher the recall, the more positive samples are discovered.

Table IV shows the comparison of recall for each model before and after hyperparameters tuning. The recall of Naive Bayes has decreased from 79.85% to 75.36%, and the recall of SVM has increased from 86.56% to 88.47%. SVM has a higher recall than Naive Bayes after tuning. Fig. 3 shows the bar chart of recall comparison for Naive Bayes and SVM.

TABLE III. PRECISION COMPARISON FOR NAIVE BAYES AND SVM

Model	Without Tuning	Tuned
Naive Bayes	71.63	83.22
SVM	81.64	87.60

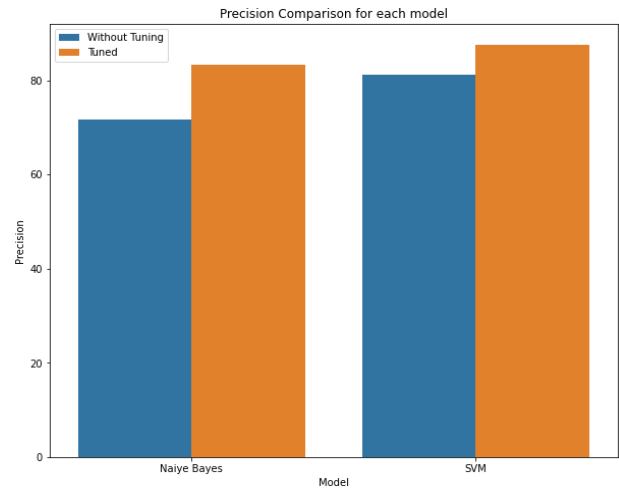

Fig. 2. Bar chart of precision comparison for Naive Bayes and SVM.

TABLE IV. RECALL COMPARISON FOR NAIVE BAYES AND SVM

Model	Without Tuning	Tuned
Naive Bayes	79.85	75.36
SVM	86.56	88.47

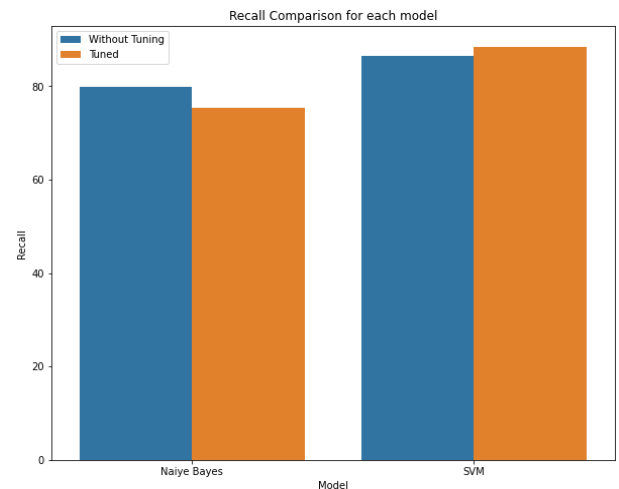

Fig. 3. Bar chart of recall comparison for Naive Bayes and SVM.

The f1-score is a method for combining precision and recall into a single metric that combines both characteristics. We might have good precision with poor recall or vice versa. The f1-score allows you to convey both concerns with a single score.

Table V shows the comparison of f1-score for each model before and after hyperparameters tuning. The f1-score of Naive Bayes has increased from 75.74% to 79.29%, and the f1-score of SVM has increased from 83.90% to 88.04%. SVM has a higher f1-score than Naive Bayes after tuning. Fig. 4 shows the bar chart of the f1-score comparison for Naive Bayes and SVM.

TABLE V. F1-SCORE COMPARISON FOR NAIVE BAYES AND SVM

Model	Without Tuning	Tuned
Naive Bayes	75.74	79.29
SVM	83.90	88.04

Fig. 4. Bar chart of F1-score comparison for Naive Bayes and SVM.

A model's accuracy is a metric that assesses how well it performs in all classes. This is advantageous when all of the classes are equally important. The ratio between the number of right predictions and the total number of predictions is used to evaluate it.

TABLE VI. ACCURACY COMPARISON FOR NAIVE BAYES AND SVM

Model	Without Tuning	Tuned
Naive Bayes	67.65	68.70
SVM	81.73	85.65

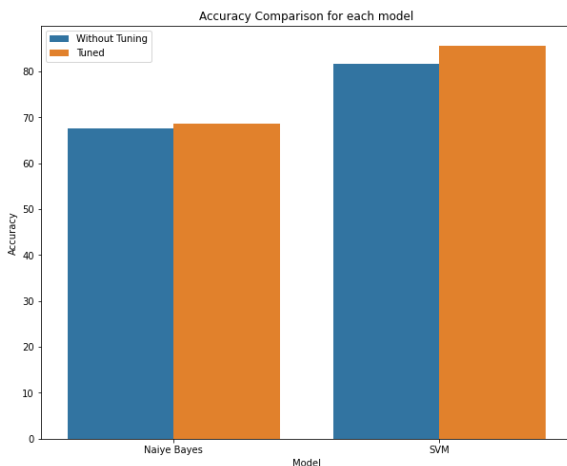

Fig. 5. Bar chart of accuracy comparison for Naive Bayes and SVM.

Table VI shows the comparison of accuracy for each model before and after hyperparameters tuning. The accuracy of Naive Bayes has increased from 67.65% to 68.70%, and the accuracy of SVM has increased from 81.73% to 85.65%.

SVM has higher accuracy than Naive Bayes after tuning. Fig. 5 shows the bar chart of accuracy comparison for Naive Bayes and SVM.

In short, the hyperparameters of Naive Bayes that have a significant effect on sentiment analysis are “alpha” and “fit prior”, while the hyperparameters of SVM that have a significant effect on sentiment analysis are “C”, “kernel”, and “gamma”. SVM has a better performance than Naive Bayes before and after hyperparameters tuning. It appears that SVM has a better potential for optimization with an increase in accuracy of about 4% than the Naive Bayes with an increase in accuracy of about 1%.

V. CONCLUSION

In conclusion, the research has done a comparative study for Naive Bayes and SVM and found out that SVM has a better performance than Naive Bayes based on sentiment analysis of healthcare companies' stock comments. Grid Search approach is used for hyperparameter tuning and is able to identify the hyperparameters of both models that are significant for sentiment analysis. The research is able to prove that hyperparameters tuning can increase the model's accuracy, and SVM has a better potential for optimization as compared to Naive Bayes. There are still many things to be improved in the future such as adding more datasets, using different classifiers, and using different hyperparameter tuning techniques.

Bhubaneswar, India

Abstract—Nowadays, various technological advancements in Intrusion Detection Systems (IDS) detects the malicious attacks and reinstate network security in the cloud platform. Cloud based IDS designed with hybrid elements combining Machine Learning and Computational Intelligence algorithms have been shown to perform better on parameters, such as Detection Rate, Accuracy, and the False Positive Rate. Machine Learning algorithms provide effective techniques for classification and prediction of network attacks, by analyzing existing IDS datasets. The main challenge is selection of appropriate data dimensions to be used for detection of attacks, out of the high number of data dimensions available. For the selected data dimensions, Computational Intelligence Algorithms provide effective techniques for hyper-parameter tuning, by optimizing on reiterative basis. The main challenge is selection of appropriate algorithm which offers optimal performance results. In this research, Hybrid Meta-heuristic approach, which combines a Long Short Term Memory (LSTM) classification model in dimension selection, with the application of Artificial Raindrop Algorithm- Harmony Search Algorithm (ARA-HSA) for hyper-parameter tuning, in order to achieve a high performance IDS in cloud environment. The performance validation of the hybrid LSTM-ARA-HSA algorithm has been carried out using a benchmark IDS data set and the comparative results for this algorithm along with other recent hybrid approaches has been presented.

Keywords—Artificial raindrop algorithm; cloud computing; harmony search algorithm; hybrid meta-heuristic algorithms; hyper-parameter tuning; intrusion detection system; long short term memory classification model

I. INTRODUCTION

The Cloud Computing (CC) platform, which is on-demand network access for several pattern of computing asset, such as servers, applications, networks, and services. Security is the major difficulty for the organizations to accept the cloud enabled solutions. Due to cloud infrastructure (open and fully distributed), which makes it vulnerable to attacks and threats. Thus, it creates incentives for intruders for initiating attack focused devices to permit the data stored in cloud. The threats are confidentiality, availability, and integrity of cloud resources and services. To solve the security challenges, the IDS should be integrated within the cloud environment [1].

Fig. 1. Types of cloud based IDS

There are several kinds of attacks that could probably arise in a network, such as User to Root (U2R), Remote to Local (R2L), and the Denial of Service (DoS) attacks. In U2R attacks, a local user who is the attacker gets unauthorized access to the routing privilege and access control list [2]. In R2L attacks, the attacker is not a local user but remotely forwarded a set of packets to server or computer over the network, to attempt unauthorized access [3]. In DoS attacks, the attacker attempts to stop the standard service in the network by over-whelming the network with high number of request data packets [4].

Machine learning (ML) algorithms offer effective techniques to improve a efficiency and effectiveness of IDS, due to the capability to identify potential attacks through sophisticated classification of network states described by data dimensions, based on comparison with known network states during previous network attacks [5]. Several ML techniques [6], such as Extreme Learning Machine, Random Forest Classifiers, Multi-layer Perceptron Network etc. have been designed and their performance in detecting attacks evaluated [7]. Fig. 1 provides an overview of types of IDS, based on the different ML algorithms adopted.

The main challenges in design of IDS are:

- Selection of appropriate number data dimensions to be used for detection of attacks, out of the high number of data dimensions available
- Hyper-parameter tuning for the selected data dimensions
- Improving performance in classification

The challenge of feature selection is sought to be overcome by adoption of appropriate ML algorithms. The challenge of hyper-parameter tuning is sought to be overcome by adoption of appropriate Computational Intelligence algorithms. The challenge of improved performance is sought to be overcome by adoption of appropriate ML algorithms. The proposed solution therefore, consists of a hybrid approach, in which both ML and Computational Intelligence algorithms incorporated in order to deliver improved performance compared to existing approaches in the literature.

This paper presents a Hybrid Meta-heuristic approach which uses ML techniques- ExtraTrees Feature Selection Method and LSTM classification model- along with Computational Intelligence Algorithms- Artificial Raindrop Algorithm and Harmony Search Algorithm. For feature selection, ExtraTrees (ET) method is used to choose a proper set of data dimensions to be employed for classification [8][9] and prediction [10] of network attacks, out of maximal number of data dimensions available in the standard IDS data set of known attacks from the past. Artificial Raindrop Algorithm (ARA) and Harmony Search Algorithm (HSA) are used for hyper-parameter tuning (i.e. optimizing the parameter values to be used) for the data dimensions selected. Finally, classification is achieved using the LSTM classification model.

To estimate the resulting performance of IDS which uses hybrid combination of LSTM-ARA-HSA approach, the paper presents the results of simulations using the benchmark data set.

In summary, the paper's contributions can be summarized as follows.

- Use an ML technique- ExtraTrees Feature Selection method for selecting optimal set of data dimensions for classification and prediction of network attacks, out of the high number of data dimensions available for analysis.
 - Perform min-max based data normalization to achieve standardization of the different scales for the available data dimensions.
 - Use of ET Feature Selection method for the optimum selection of data dimensions, to enhance the efficiency of IDS.
- Adopt combination of ARA-HSA algorithms for hyper-parameter optimization of the data dimensions selected.
- Perform final classification using the LSTM classification model.

- Design a Hybrid Meta-heuristic approach for IDS using a combination of LSTM-ARA-HSA, as described above.
- Test the performance of Hybrid Meta-heuristic LSTM-ARA-HSA, using simulations on the benchmark IDS data set.

The paper is organized as follows. Section 2 illustrates a brief literature review of some of recent Hybrid Meta-heuristic approaches used by IDS. Section 3 provides an overview of LSTM-ARA-HSA methodologies. Section 4 discusses an overview of the results of testing a performance valuation of proposed hybrid approach. Section 5 lists the key findings and conclusions of this paper.

II. LITERATURE REVIEW

Review of recently developed IDS approaches for cloud environments is described below.

Sethi *et al.* [11] presented a DRL enabled adoptive cloud IDS model that implements fine-grained classification and precise detection of complex and new attacks.

Ji *et al.* [12] introduced a network IDS by integrating asymmetric convolution AE and RF. This method could integrate the benefits of Shallow and Deep Learning.

Singh and Ranga [13] deliberated a robust network driven IDS employing ensemble-based ML method with four classifications, namely voting scheme, RUSBooted, bagged tree, boosted tree, and subspace discriminant. The voting method was integrated with architecture for obtaining the final prediction.

Alkadi *et al.* [14] devised DBF method for offering privacy with blockchain and security-based distributed IDS by the smart contracts of IoT networks. IDS were utilized using BiLSTM-DL technique for managing the consecutive network data, which is computed by the datasets of BoT-IoT and UNSW-NB15.

Zhong *et al.* [15] presented a novel method using features of model. The method would gather features in network layer through tcpdump packet and a application layer through system routine. GRU and Text-CNN approaches are selected since they could process consecutive data as a language system.

Samriya and Kumar [16] proposed a hybridization method for IDS for improving entire security level of cloud computing platforms. Additionally, this technique assists in handling different kinds of security problems i.e., detection of fake identity and data leakage Phishing attacks to retain the security over cloud environment.

Abusitta *et al.* [17] presented an ML based IDS that effectively uses the previous feedback information to improve a capacity for proactive decision making. Especially, presented method was depended by Denoising Autoencoder (DA) that is employed as an element to create DNN method.

III. PROPOSED MODEL

In this research, use of a hybrid meta-heuristic approach-combining Machine Learning techniques, named ExtraTrees Feature Selection method and LSTM classification model with Computational Intelligence Algorithms named Artificial Raindrop Algorithm and Harmony Search Algorithm- is proposed for optimal classification and prediction of network attacks in the cloud environment.

The overall model encompasses the following processes:

- 1) Pre-processing of all available data dimensions in the data-set
- 2) Selection of appropriate data dimensions using ExtraTrees feature selection method
- 3) Hyper-parameter optimization for the selected data dimensions using Artificial Raindrop Algorithm and Harmony Search Algorithm (ARA-HSA)
- 4) Final LSTM based classification by IDS into Attack/ Not an Attack, based on above processes

Fig. 2 illustrates the overall working process of LSTM-ARA-HSA technique for IDS. The detailed working of each of the above processes is elaborated in the succeeding sections.

Fig. 2. Overall process of LSTM-ARA-HSA technique

A. Pre-Processing of All Available Data Dimensions

During this process, Min_max normalization was utilized to standardize the different scales for all the available data dimensions in the benchmark IDS data set. The normalization process transforms the data points with reference to the data range to which they belong, by implementing linear transformation. The value of each data point in a dimension was normalized to a standard range between zero and one, utilizing Min_max normalization as per the following formula [18]:

$$t = \frac{v - \min_d}{\max_d - \min_d} (\text{tran_max}_d - \text{tran_min}_d) + \text{tran_min}_d \quad (1)$$

where t refers to the transformed value of data value v from dimension d , \min_d refers to the existing minimum value for the data range for dimension d , \max_d refers to the existing maximum value for the data range for dimension d , tran_min_d refers to the standardized minimum value (i.e. zero) for the transformed data range for dimension d , and

tran_max_d refers to the standardized maximum value (i.e. one) for the transformed data range for dimension d .

B. Selection of Appropriate Data Dimensions using ExtraTrees Feature Selection Method

ExtraTrees (ET) is ML type technique that aggregates several de-correlated decision trees together in “forest” to output it’s classified results, presented by Geurts et al. [19]. ET is used during this process for the purpose of feature selection, i.e. choosing a sub-set of proper dimensional data from the full set of data dimensions.

Each Decision Tree (DT) in ExtraTrees Forest is created from raw training sample, and every node, every tree is given by random sample of the number of features to select from full set- say “ k ” features from full features-set where every tree must choose optimal feature to divide the data using defined mathematical criteria. Thus, this random feature led to the generation of several de-correlated decision trees. To fulfil the feature selection using process through this forest structure, the defined total minimization in the defined mathematical factors (such as the Gini coefficient) applied to the decision of feature of split is calculated for every feature throughout the forest construction [20].

The benefits of ET model are reduced variance of the DT and computation effectiveness. For each of the available data dimensions, the standardized reduction of the Gini coefficient utilized for splitting the feature decision is estimated. Afterward, the Gini coefficient is ranked in descending order, and the first k features can be chosen. In this way, the number of the sub-set of data dimensions- specified as k in number- can be selected out of the full set of available data dimensions in the benchmark IDS data set.

C. Hyper-Parameter Optimization for the Selected Data Dimensions using Artificial Raindrop Algorithm and Harmony Search Algorithm (ARA-HSA)

For the hyper-parameter optimization or tuning process, a combination of the ARA-HSA algorithms is proposed to be utilized.

The natural occurrence of rainfall served as the inspiration for the ARA, which has been proven to be an effective tool for resolving single-objective optimization issues [21]. The fundamental premise is to model the altitude of the raindrop from where it is initiated to a final state when has minimal altitude and hence has its minimal energy state. The state of minimal altitude is considered to be an optimal state or solution. ARA begins with initiation of the primary population of N raindrops as arbitrarily placed N vapors in the search space, with all vapors having a vapor place determined as follows:

$$\text{Vapor}_i = (x_i^{(1)}, \dots, x_i^{(d)}, \dots, x_i^{(D)}), i = 1, 2, \dots, N. \quad (2)$$

Where N refers to the population size, D refers to the number of dimensions selected for hyper-parameter optimization, and $x_i^{(d)}$ refers to the place of i^{th} vapor from the d^{th} dimension.

Since raindrops are created by constantly absorbing ambient water vapor naturally, the place of each raindrop is determined as follows:

$$Raindrop = \left(\frac{1}{N} \sum_{i=1}^N x_i^{(1)}, \dots, \frac{1}{N} \sum_{i=1}^N x_i^{(d)}, \dots, \frac{1}{N} \sum_{i=1}^N x_i^{(D)} \right) \quad (3)$$

If the effect of external factors is not taken into account, each raindrop falls from its initial altitude in the cloud, to the ground with free-fall due to gravity. This can be modeled as place of each Raindrop being modified to a new place, represented as *New_Raindrop*. Assuming that *Raindrop*^(*d*₁) is the place of a Raindrop from *d*₁th dimension, where *d*₁ (*i* = 1,2,3,4) belongs to the set {1, 2, ..., *D*}, *New_Raindrop*^(*d*₁) is attained by linear combination of *Raindrop*^(*d*₂), *Raindrop*^(*d*₃) and *Raindrop*^(*d*₄), and determined as follows:

$$\begin{cases} New_Raindrop^{(d)} = Raindrop^{(d_2)} + \varphi \cdot (Raindrop^{(d_3)} - Raindrop^{(d_4)}), & \text{if } d = d_1; \\ New_Raindrop^{(d)} = Raindrop^{(d)}, & \text{otherwise.} \end{cases} \quad (4)$$

where φ refers the arbitrary number from the range -1 and 1, $d = 1, 2, \dots, D$. Once the *New_Raindrops* contact the ground, it is split to small raindrops due to speed as well as quality. Afterward, these smaller raindrops (*Small_Raindrop*_{*i*}, *i* = 1, 2, ..., *N*) may move randomly to any direction. For this reason, the place of *Small_Raindrop*_{*i*} is modeled as follows:

$$Small_{Raindrop}_i = New_{Raindrop} + sign(\alpha - 0.5) \cdot \log(\beta) \cdot (New_{Raindrop} - Vapor_k) \quad (5)$$

where *k* refers to the arbitrarily selected index in the set {1, 2, ..., *N*}, α and β refer to two uniformly distributed arbitrary numbers from the range zero to one, and the sign (·) refers to the sign function [22].

During the act of gravity, the movement of *Small_Raindrop*_{*i*} (*i* = 1, 2, ..., *N*) is from higher altitude to lower altitude, and they finally stop at places with minimal altitude (i.e., an optimum solution). The Raindrops Pool (RP) is modeled to track raindrops to the places of minimal altitude as follows:

- 1) RP is initiated randomly to initial places in the search space;
- 2) A better solution for the RP is rationalized at the end of every iteration;
- 3) Once the RP size increases the threshold specified initially, any less optimal solution is deleted from the RP, to maintain the RP's size stable and lower the computation required.

The movement of raindrop *d*_{*i*} for *Small_Raindrop*_{*i*} (*i* = 1, 2, ..., *N*) is modeled as dependent upon linear group of 2 vectors *d*_{*i*}, *d*_{1*i*} and *d*_{2*i*}, where *d*_{*i*}, *d*_{1*i*} and *d*_{2*i*} are explained as:

$$d1_i = sign(F(RP_{k_1}) - F(Small_Raindrop_i)) \cdot (RP_{k_1} - Small_Raindrop) \quad (6)$$

$$d2_i = sign(F(RP_{k_2}) - F(Small_Raindrop_i)) \cdot (RP_{k_2} - Small_Raindrop) \quad (7)$$

$$d_i = \tau_1 \cdot rand1_i \cdot d1_i + \tau_2 \cdot rand2_i \cdot d2_i \quad (8)$$

where *RP*_{*k*₁} and *RP*_{*k*₂} refer to two candidate solutions from RP (*k*₁, *k*₂ ∈ {1, 2, ..., |RP|}), τ_1 and τ_2 refer to two step parameters of *Small_Raindrop*_{*i*} flowing, *rand*_{1*i*} and *rand*_{2*i*} refer to two uniformly distributed arbitrary numbers from the range zero to one, *F* indicates the Fitness Function. Thus the outcome, *New_Small_Raindrop*_{*i*} (*i* = 1, 2, ..., *N*) is determined as:

$$New_Small_Raindrop_i = Small_Raindrop_i + d_i \quad (9)$$

For improving the computational efficiency and convergence rate of ARA, the *N* optimum solutions in *New_Small_Raindrop* ∪ *Vapor* were chosen utilizing sort technique, as the next vapor population. The flowchart of ARA is described in Fig. 3 [22].

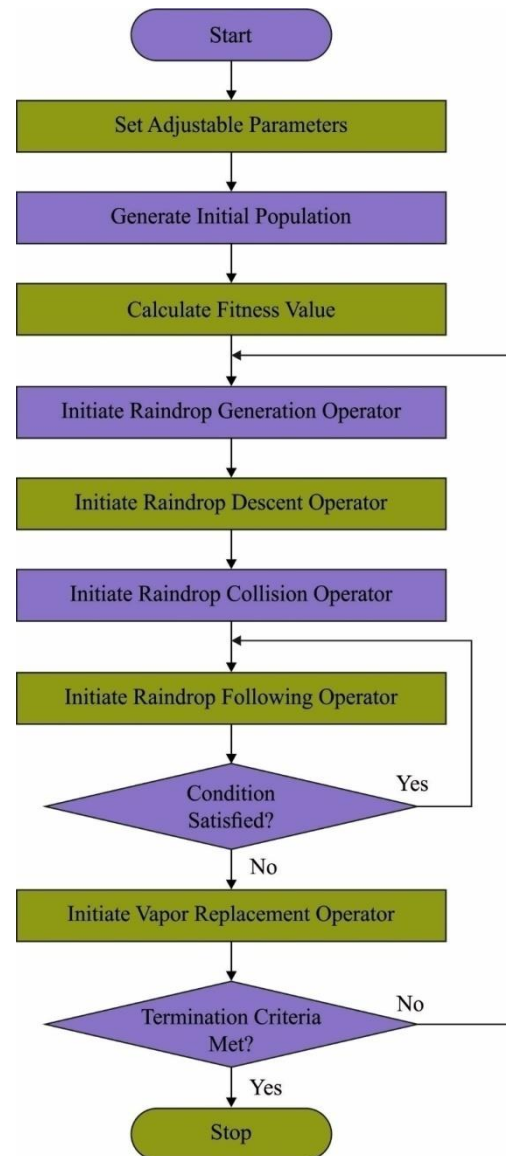

Fig. 3. Flowchart of ARA

The performance of the ARA can be improved by updating every raindrop by the use of the individual model and Harmony Search Algorithm (HAS) based Harmony Search Memory (HM) operator.

HSA attempts several feasible optimal solutions based on use of the HM operator, similar to how multiple musicians attempt to achieve harmony in music based on their collective memory [23]. HSA has been simulated by employing rules of harmony improvisation [24]. It involves the steps as described below.

Step 1. Initializing of HS Memory (HM).

A primary HM has a particular number of arbitrarily created solutions for the optimized solution. For a n dimensional problem, the HM with size of N is modeled as:

$$HM = \begin{bmatrix} x_1^1, x_2^1, \dots, x_n^1 \\ x_1^2, x_2^2, \dots, x_n^2 \\ \vdots \\ x_1^{HMS}, x_2^{HMS}, \dots, x_n^{HMS} \end{bmatrix} \quad (10)$$

where $[x_1^i, x_2^i, \dots, x_n^i]$ ($i = 1, 2, \dots, HMS$) is a solution candidate. Here, the HM was generally fixed between [50, 100].

Step 2. Improving a solution $[x_1', x_2', \dots, x_n']$ in HM.

All the elements in the solution x_j' are attained dependent upon HM Considering Rate (HMCR). Here, the HMCR is determined as the possibility of choosing a module in HM member, and the 1-HMCR is, so, the possibility of creating it arbitrarily. Once x_j' appears into the HM, it can be selected in j^{th} dimension of arbitrary HM members and is mutated based on Pitching Adjust Rate (PAR) that defines the probabilities of the candidate in HM is mutated. Moreover, the improvisation of $[x_1', x_2', \dots, x_n']$ is related to the generation of issues from Genetic Algorithms (GA), and mutation as well as crossover functions. But, while GA generates novel chromosomes utilizing 1 (mutation) or 2 (simple crossover) pre-defined ones, the generation of novel solutions from HSA utilizes every HM member completely.

Step 3. Upgrading the HM. In this step, the Step 2 solution is estimated. Once it creates an optimum fitness which is worse than member from the HM, the existing member will be replaced. Else, the new member is discarded.

Step 4. Repeating Step 2 to Step 3 until a current end circumstance, i.e., a high number of iterations are met. The HSA is an arbitrary search approach and only employs a single search memory for evolving.

In order to optimize the hyper-parameter values for the selected data dimensions, the combination of ARA-HSA is used. The ARA-HSA combination computes a fitness function to accomplish optimization of the hyper-parameters. The value of the fitness function is a positive integer value, which represents the effective outcome of the candidate solution. In case of intrusion detection, the classifier error rate can be treated as the fitness function, as provided in Eq. (11) below. The optimal solutions hold minimum value of error rate and the non-optimal solutions hold maximum value of error rate.

$$fitness(x_i) = Classifier\ Error\ Rate(x_i)$$

$$\frac{\text{number of misclassified instances}}{\text{Total number of instances}} * 100 \quad (11)$$

D. LSTM based Classification

In this final process, the LSTM model can be utilized for the purpose of detecting and classifying the intrusions in cloud environment. LSTM is a kind of Recurring Neural Network (RNN) i.e., used for processing consecutive data and, it addressing a long-term memory problems of vanilla RNN. The LSTM expands the structure of RNN by a gating method and the standalone memory cell that normalizes the data flow in all over the networks. Here, a gating method includes output, input, and forget gates [25]. This gate controls the flow of data over the network to enables which data needed to continue or the period it would persevere afterward sensing it from the memory. The LSTM network is able to discard the insignificant data and preserves critical data. The memory cell provides a recurrent self-connected unit termed Constant Error Carousel (CEC), which offered a state vector to retain long-term dependency. Fig. 4 depicts the infrastructure of LSTM.

Fig. 4. LSTM structure

Then, to differentiate self-contained cell memory from state h_t in LSTM and, it is represented as c_t . The forget gate f_t obtains input x_t and h_{t-1} to define which data requires to be preserved in c_{t-1} . Activation function for gates i_t , o_t and f_t are sigmoid layer whereas all the values are predicted among zero and one in which c_{t-1} provides the data preservation to determine the scale. But the above mentioned procedure is determined by Eqs. (12) to (16):

$$i_t = \sigma(W_{xi}x_t + W_{hi}h_{t-1} + W_{ci} \circ c_{t-1} + b_i) \quad (12)$$

$$f_t = \sigma(W_{xf}x_t + W_{hf}h_{t-1} + W_{cf} \circ c_{t-1} + b_f) \quad (13)$$

$$o_t = \sigma(W_{xo}x_t + W_{ho}h_{t-1} + W_{co} \circ c_t + b_o) \quad (14)$$

$$c_t = f_t \circ c_{t-1} + i_t \circ \phi(W_{xc}x_t + W_{hc}h_{t-1} + b_c) \quad (15)$$

$$h_t = o_t \circ \phi(c_t) \quad (16)$$

Now, $W_{xi}, W_{hi}, W_{ci}, W_{xf}, W_{hf}, W_{cf}, W_{xo}, W_{ho}, W_{co}, W_{xc}$, and W_{hc} indicates weight matrices for the gate and cell memory state, whereas h_{t-1} indicates a preceding hidden state, and c_t denotes a cell state. The bias of the gate is denoted by b_i, b_o, b_f , and b_c whereas 0 indicates an element-wise multiplication process. Likewise, σ displays the logistic sigmoid function and ϕ signifies tangent function.

$$\sigma(x) = \frac{1}{1+e^{-x}} \quad (17)$$

$$\emptyset(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}} \quad (18)$$

IV. EXPERIMENTAL VALIDATION

The experimental validation of the proposed hybrid meta-heuristic approach LSTM-ARA-HSA technique was done by two benchmark data sets; they are NSL-KDD and KDDCup'99 datasets. The NSL-KDD dataset holds 41 features, in which 2 features are symbolic records and other 39 features are numeric record. The data set contains Basic features: 1–9, Content features: 10–22, Traffic features: 23–31, and Host features: 32–41. The results were analyzed along different aspects. Comparative analysis of the proposed model with other recent techniques is also described below.

A. Results Analysis on NSL-KDD Dataset

This section elaborates the intrusion detection results of the proposed LSTM-ARA-HSA on the test NSL-KDD data set.

Fig. 5 showcases the FS result of the proposed model on the test NSL-KDD dataset. The figure displays the set of features elected by the proposed model.

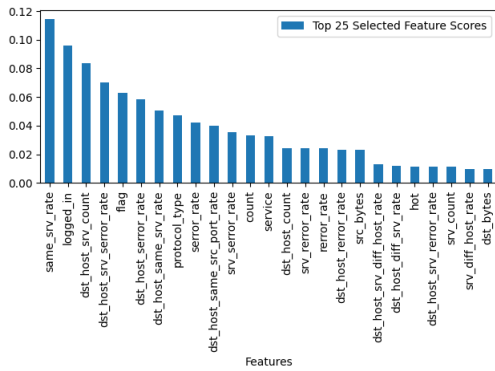

Fig. 5. Selected features and its scores of NSL-KDD dataset

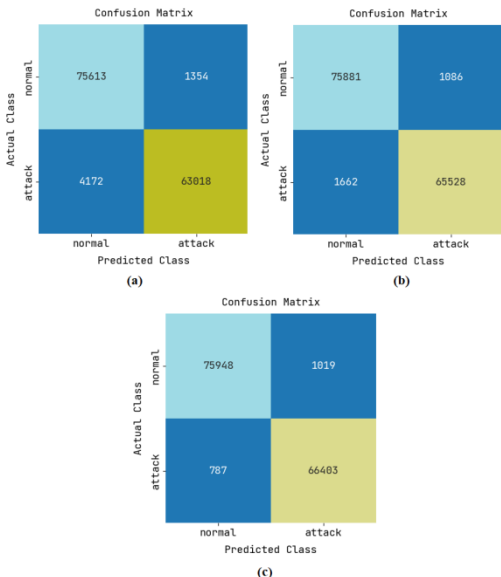

Fig. 6. Confusion matrix of NSL-KDD dataset a) LSTM b) FS+LSTM c) ARA+HS+FS+LSTM

Fig. 6 illustrates the confusion matrix in the proposed model with LSTM and FS+LSTM model. The figure indicates that the LSTM model classified a total of 75613 instances into Normal class and 63018 instances into Attack class. In addition, the FS+LSTM model classified a set of 75881 instances into Normal class and 65528 instances into Attack class. Lastly, the ARA+HS+FS+LSTM model classified a total of 75948 instances into Normal class and 66403 instances into Attack class.

The intrusion detection results of the proposed ARA+HS+FS+LSTM model on the NSL-KDD dataset are offered in Table I. From the table, it is proved that the LSTM model achieved an $accu_y$, $prec_n$, $reca_l$, $F1_{score}$, AUC_{score} of 96.170%, 97.900%, 93.790%, 95.800%, and 96.020% respectively. The FS+LSTM model achieved slightly enhanced outcomes with the $accu_y$, $prec_n$, $reca_l$, $F1_{score}$, AUC_{score} of 98.090%, 98.370%, 97.530%, 97.950%, and 98.060% respectively. Finally, the ARA+HS+FS+LSTM model achieved highest performance with the $accu_y$, $prec_n$, $reca_l$, $F1_{score}$, AUC_{score} of 98.750%, 98.490%, 98.830%, 98.600%, and 98.750% respectively.

The ROC analysis of the ARA+HS+FS+LSTM model with its earlier versions on the test NSL-KDD dataset is shown in Fig. 7. From the figure, it is apparent that LSTM and FS+LSTM models provided reasonable ROC values of 0.9682 and 0.9886. The ARA+HS+FS+LSTM model provided ROC of 0.9875.

TABLE I. RESULT ANALYSIS OF ARA+HS+FS+LSTM TECHNIQUE ON NSL KDD DATASET

Methods	LSTM	FS+LSTM	ARA+HS+FS+LSTM
Accuracy	96.170	98.090	98.750
Precision	97.900	98.370	98.490
Recall	93.790	97.530	98.830
F1-Score	95.800	97.950	98.660
AUC Score	96.020	98.060	98.750

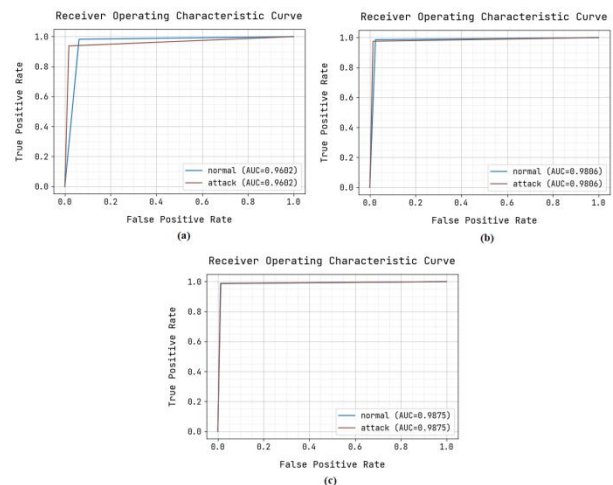

Fig. 7. ROC of NSL-KDD dataset a) LSTM b) FS+LSTM c) ARA+HS+FS+LSTM

A comprehensive comparative result analysis of the ARA+HS+FS+LSTM method with other existing techniques is made in Table II and Fig. 8 [26, 27]. The results indicated that DNN and DT models achieved the least intrusion detection performance. The PCA+DNN and RF models achieved moderately better intrusion detection performance. The XGBoost and Hybrid KPCA-SVM+GA techniques were next in terms of achievement. The Hybrid GA-SVM+PSO technique achieved near optimal outcomes. However, the ARA+HS+FS+LSTM technique achieved the highest performance results compared to other techniques, with the $accu_y$, $prec_y$, $reca_l$, and $F1_{score}$ of 98.75%, 98.49%, 98.83% < and 98.66%, respectively.

TABLE II. COMPARATIVE ANALYSIS OF ARA+HS+FS+LSTM TECHNIQUE WITH EXISTING APPROACHES ON NSL-KDD DATASET

Methods	Accuracy	Precision	Recall	F1-Score
ARA+HS+FS+LSTM	98.75	98.49	98.83	98.66
PCA+DNN	93.80	93.40	91.80	93.70
DNN Model	91.40	89.10	88.20	90.50
Random Forest	93.60	90.00	82.00	94.60
XGBoost	95.50	92.00	98.00	95.55
Decision Tree	92.89	90.20	85.00	94.50
Hybrid GA-SVM+PSO	96.38	94.90	97.77	96.11
Hybrid KPCA-SVM+GA	95.26	94.03	96.39	95.47

B. Results Analysis on KDDCup Dataset

This section elaborates the intrusion detection results of the proposed LSTM-ARA-HSA on the test KDDCUP99 data set.

Fig. 9 depicts the FS results of the proposed technique in test KDDCUP99 dataset. The figure indicates the set of features chosen by the presented method.

Fig. 9. Selected features and its scores of KDDCup99 dataset

Fig. 10. Confusion Matrix of KDDCup 99 dataset a) LSTM b) FS+LSTM c) ARA+HS+FS+LSTM

Fig. 10 demonstrates the confusion matrix of the proposed algorithm with LSTM and FS+LSTM method. The figure showcased that the LSTM model has identified a total of 81289 instances into Normal class and 54397 instances into Attack class. Also, the FS+LSTM model has categorized a set of 83756 instances into normal class and 53804 instances into Attack class. At last, the ARA+HS+FS+LSTM model has classified a total of 85077 instances into Normal class and 54654 instances into attack class.

The intrusion detection outcomes of the proposed ARA+HS+FS+LSTM approach on the KDDCUP99 dataset is indicated in Table III. From the table, it is apparent that the LSTM model achieved $accu_y$, $prec_n$, $reca_l$, $F1_{score}$, AUC_{score} of 93.200%, 89.260%, 94.190%, 91.660%, and 93.370% correspondingly. The FS+LSTM method achieved slightly improved outcomes with $accu_y$, $prec_n$, $reca_l$, $F1_{score}$, AUC_{score} of 94.490%, 92.960%, 93.160%, 93.060%, and 94.260% correspondingly. Finally, the

ARA+HS+FS+LSTM algorithm achieved the highest performance with $accu_y$, $prec_n$, $reca_l$, $F1_{score}$, AUC_{score} of 95.980%, 95.200%, 94.630%, 94.920%, and 95.750%, respectively.

TABLE III. RESULT ANALYSIS OF ARA+HS+FS+LSTM TECHNIQUE ON KDDCUP99 DATASET

Methods	LSTM	FS+LSTM	ARA+HS+FS+LSTM
Accuracy	93.200	94.490	95.980
Precision	89.260	92.960	95.200
Recall	94.190	93.160	94.630
F1-Score	91.660	93.060	94.920
AUC Score	93.370	94.260	95.750

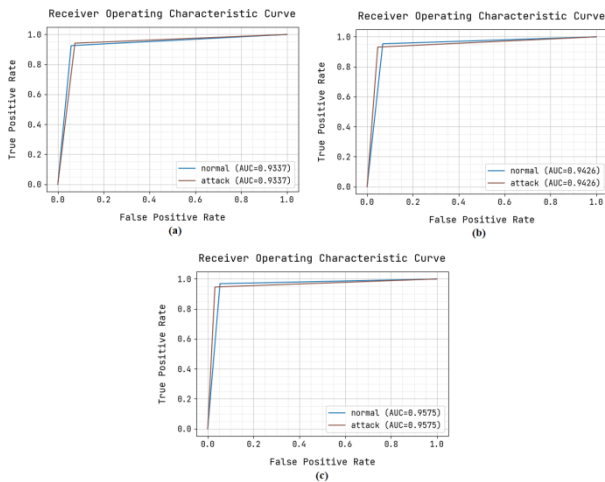

Fig. 11. ROC of KDDCup 99 dataset a) LSTM b) FS+LSTM c) ARA+HS+FS+LSTM

The ROC analysis of the ARA+HS+FS+LSTM technique along with other techniques on the test KDDCUP99 dataset is exhibited in Fig. 11.

From the figure, it is evident that the LSTM and FS+LSTM methods achieved ROC values of 0.9337 and 0.9426. The ARA+HS+FS+LSTM technique achieved ROC of 0.9575.

TABLE IV. COMPARATIVE ANALYSIS OF ARA+HS+FS+LSTM TECHNIQUE WITH OTHER EXISTING METHODS ON KDDCUP99 DATASET

Methods	Accuracy	Precision	Recall	F1-Score
ARA+HS+FS+LSTM	95.98	95.20	94.63	94.92
PCA+DNN	89.80	88.40	89.80	88.20
DNN Model	90.90	89.60	90.90	89.40
Random Forest	93.66	92.46	93.12	94.14
XGBoost	94.06	92.94	93.53	94.50
Decision Tree	93.00	91.28	92.48	92.62
IARADR	94.59	92.90	94.05	94.24
ML-SHNS	93.91	92.68	93.41	94.22

Fig. 12. Comparative analysis of proposed method on KDDCUP99 dataset

A detailed comparative result analysis of the ARA+HS+FS+LSTM method with other existing algorithms is made in Table IV and Fig. 12 [28, 29].

The results indicated that DNN and DT techniques achieved the least intrusion detection performance. The PCA+DNN and RF approaches achieved moderately improved intrusion detection performance. The XGBoost and IARADR techniques were next in terms of achievement. The ML-SHNS approach achieved near optimal outcomes. The ARA+HS+FS+LSTM technique achieved the highest performance results with $accu_y$, $prec_y$, $reca_l$, and $F1_{score}$ of 98.98%, 95.20%, 94.63%, and 94.92% correspondingly.

After evaluating the performance results of the proposed LSTM-ARA-HSA model along with other techniques and approaches, it is apparent that this approach is a feasible hybrid meta-heuristic approach that can be used by cloud-based IDS.

V. CONCLUSION

This paper has proposed a hybrid meta-heuristic approach combining ML techniques of ExtraTrees Feature Selection method and LSTM classification model with the Computational Intelligence Algorithms ARA-HAS, to develop the performance of cloud-based Intrusion Detection Systems and detect network attacks accurately and efficiently. These hybrid methods encompasses different processes such as Pre-processing of data dimensions, ET based feature selection, ARA-HSA based hyperparameter tuning, and LSTM based classification.

The adoption of ARA-HSA enables optimization of hyper-parameters for the dimensions selected using the ET Feature Selection method, in turn enabling more accurate LSTM classification.

The experimental outcome shows that the proposed LSTM-ARA-HSA has better performance than other techniques in terms of accuracy and efficiency. Therefore, this

hybrid approach can be utilized by IDS for detecting and classifying the intrusions in the cloud environment. The objective of the current paper is to only establish that the proposed hybrid approach results in more accurate classification of attacks and the scope is limited to experimental validation using the two main datasets. As a part of future scope of research, the detection efficiency of this hybrid approach can be improved through appropriate design of clustering and outlier detection techniques.

Abstract—Social media users internalise information in a multimodal context. Social media functions as a primary information source for disaster situational awareness encompassing texts, photographs, videos, and other multimodal information widely used in emergency management. Applying ensemble learning to social media sentiment analysis has garnered much scholarly attention, albeit with limited research on rescue and its sub-domain, which is characterised as a major complexity. A multimodal information categorisation model based on hierarchical feature extraction was proposed in this study. The information of multiple modes is first mapped to a unified text vector space in modelling the semantic content at the sentence and multimodal information levels in the multimodal information. Multiple deep learning (DL) models were subsequently applied to model the semantic content at the aforementioned levels. This study offers a BiLSTM-Attention-CNN-XGBOOST ensemble neural network model to acquire extensive multimodal information characteristics. Based on the empirical outcomes, this method precisely extracted multimodal information features with an accuracy exceeding 85% and 95% for Chinese- and English-language datasets, respectively.

Keywords—Natural language processing; social media sentiment analysis; multimodal information processing; ensemble neural network; emergency management

I. INTRODUCTION

Social media platforms involving Weibo, WeChat, Facebook, Instagram, and Twitter have evolved into (1) key real-time information acquisition channels in disaster management and (2) information communication tools in physical and virtual contexts following the advent of the mobile Internet [1-3]. A vast amount of rescue and assistance information is promptly shared on digital platforms. Users post many real-time words, photographs, and videos about casualties, facility damage, and emergency assistance on social media [4]. In disaster management, efficiently identifying complex multimodal information on social media and emergency information has garnered much attention during emergencies. Such multimodal information proves crucial in managing emergencies [5]. Natural language processing (NLP) and computer vision technologies based on machine learning (ML) and DL significantly improved their performance and effect in multimodal data-processing tasks owing to breakthroughs in technologies (artificial intelligence and big

data), which primarily catalysed multimodal information analysis in social media [6]. Research on social media multimodal information analysis in the context of emergencies is a relatively novel study topic that has garnered much scholarly interest and developed a theoretical and methodological system [7]. Current studies on social media multimodal information in emergencies provide theoretical and methodological support for social media multimodal information analysis for emergency management [8].

Before the study model development, specific limitations in using Twitter to monitor situational awareness in a disaster event were identified in multimodalities and social media network types. For example, Twitter users only represented some residents, as not everyone uses Twitter. Generally, some disadvantaged (low-income, low-education, and elderly) groups without the devices or motivation to access social media applications are less inclined to publish or receive disaster-relevant information [9]. Current works only utilised Facebook and Twitter data regarding the perception and humanitarian challenges identified on Twitter. Current research combining images and text to classify social media emergency management information has focused on English datasets and Twitter platforms [10], with less research on cross-social media platforms and cross-language datasets. In addition, the classification accuracy of current research needs to be improved [11].

This study employed data from WeiBo, WeChat, Facebook, and Twitter. The dataset includes English and Chinese. Recent Studies highlight the need for a multimodal and complex information-processing model that gathers, models, and employs feedback information in the social media interaction with users and continually iterates and optimises the information [12]. Such an approach could passively or actively detect errors, implement online learning and dynamic updating mechanisms based on the faults, and construct a set of self-learning frameworks to alleviate information processing issues in emergency management.

The main contribution of this paper is to use the Bi-LSTM-Attention-CNN-XGBOOST ensemble neural network model to resolve the intricate processing of multimodal information in social media. The model uses recurrent neural networks to improve the adaptive and migration capabilities of

the model. Multimodal information obtained from different platforms is first mapped to a unified text vector space to solve the cross-platform cross-language problem. Various DL models are used to model the semantic content at the sentence and multimodal information levels. This model is divided into six layers: (1) Embedding layer: maps words into low-dimensional vectors; (2) BiLSTM layer: generates deeper semantic vector to represent each word with BiLSTM network; (3) Attention layer: achieves the attention weight for all word; (4) Pooling layer: engage k-max pooling to extract the top 'k' words, which are ranked in step 3; (5) CNN layer: input to the CNN network in performing convolutional operations and extracting features through first k-word vectors; (6) X GBOOST layer: the feature vectors extracted by the final CNN are classified by the X GBOOST integrated classifier.

This paper covers six sections. In Section II related work is presented. Section III covers the method while Sections IV and V explain results and discussions, while Section VI concludes the overall contributions and suggested directions for future work

II. RELATED WORK

Given the advancements in mobile internet, social media platforms (WeiBo, WeChat, and Twitter) have gained prominence in real-time information acquisition channels for disaster management and function as information communication tools in physical and virtual worlds. Only 2% of the extracted works directly encompassed the term 'multimodal' in the title or abstract. All the studies were published in the past five years. Notably, social media data on multiple modalities were analysed. A total of 216 articles potentially incorporating the idea of multimodal fusion accounted for 27% of all the documents. The most common publications involved information analysis of text and image modalities.

A study by [13] identified temporal changes in the social media sites extensively utilised for disaster recovery, their usage patterns by catastrophe type, and the geographic areas other studies have emphasised. Empirical outcomes on social media use in multiple disaster recovery aspects, such as (1) financial support and donations, (2) solidarity and social cohesion, (3) infrastructural services and post-disaster reconstruction, (4) socioeconomic and physical well-being, (5) information support, (6) mental health and emotional support, and (7) business and economic activities were also highlighted. Twitter users from Australia and beyond have aided bushfire victims through positive messaging regarding contributions, relief assistance, news updates, and animal welfare. Research by [14] examined how Twitter was utilised to publicise blaze recovery in Australia. Concerns about climate emergency and the perceived lack of political action entailed the primary sources of undesirable attitudes. In [15], researchers proposed fine-tuned BERT for multimodal analysis. While in [16], trustworthy summaries from crisis-related microblogs are predicted.

Modern deep learning methods were recommended by [17] to learn an integrated representation of social media data involving text and picture modalities. Specifically, a multimodal deep learning architecture with a modality-agnostic

common representation was defined with convolutional neural networks. The proposed multimodal architecture outperformed the models developed using a single modality (text or image) based on studies that employed data from actual disasters. The model outperformed the image-only model by approximately 1% in all the informativeness task metrics and 2% in all humanitarian task measurements. Concerns about people's situational awareness during the occurrence of a natural disaster vary based on the stakeholder.

In regarding perception-, humanitarian-, and action-level situational awareness into account, [10] structured a Twitter-based analytic framework for damage estimation: the most prevalent use of Twitter in disaster management. Social media platforms could promptly ascertain damage to save people in danger, determine evacuation routes, and plan countermeasures for potential catastrophes. A study by [18] computed the extent to which volunteering content from one crisis is transferrable to another through language consistency analysis in volunteer- and donation-related social media material across 78 crises. Particular techniques were also provided to offer computational assistance in this emergency support role and establish semi-automated models in classifying social media information on volunteering and donating in the wake of a new crisis. Resultantly, the social media materials associated with volunteering and donations were sufficiently comparable between disasters and disaster types to justify transferring models across the disasters. These models were subsequently assessed with direct resampling procedures.

In comprehending the implications of social media to influence the relief and recovery process, the thematic and emotional nature of Twitter content discussing the 2019–2020 Australian bushfire disaster and its associated wildlife damage was discussed [19]. Thus, the value of social media (and Facebook in particular) has been demonstrated for knowledge sharing, volunteer coordination, fundraising, peer motivation, and accountability. Social media also makes it more challenging to distribute aid and coordinate relief efforts based on disinformation and duplication.

Following [20], past models' categorization of catastrophe signals primarily depends on unimodal techniques. Although specific approaches utilized multimodality to manage data, their accuracy could not be ascertained. A multimodal fusion strategy was developed to identify the relevant catastrophe photos from social media networks and merged the image and text information. The textual characteristics were subsequently elicited from social media with a FastText framework after the visual data were extracted through a deep learning technique. In classifying pertinent catastrophe photographs, a novel data fusion model combining linguistic and visual elements were structured. Well-executed experiments on the Crisis MMD dataset of actual disasters were also conducted.

An efficient DL algorithm was presented in [21] to manipulate multimodal information sources (words and photos) and disseminate helpful information during natural disasters. The programme divided the tweets into seven crucial and actionable groups, including reports of 'hurt or dead individuals' and 'infrastructure damage'. Based on research incorporating a benchmark dataset, integrating text and picture

data from multiple sources proved more successful than employing data from a single source: one of the two in extracting pivotal information in crisis circumstances. Using visual and linguistic inputs, the recommended multimodal architecture in [22] classified damage-related postings using ResNet50 and BiLSTM recurrent neural networks using attention mechanisms. The MTLTS, the first end-to-end method for gathering reliable summaries from a substantial number of tweets on disasters, was introduced to supervise methodology and improve the applicability of solutions to unprecedented situations. This innovative approach involving the extractive document summarization technique summarised tweets on specified events. By concurrently learning the structural properties of information cascades and response stances, the credibility verifier is optimized with advanced components to detect rumours.

Information processing is crucial for large-scale data visualisation, which could be performed through data harmonisation [23] and implies the exact representation as multimodal data. Multimodal information-processing methods are currently categorised into classical and DL methods. Conventional methods primarily include support vector machines (SVM), naïve Bayes (NB), KNN, and LDA [24] topic model algorithms. Deep learning methods have recently undergone rapid development. For example, Mikolov et al. [25] suggested the Word2vec model for word quantisation in 2013, substituting the simple one-hot vectorisation method and resolving data sparsity issues. The CBOW and Skip-gram models in Word2vec were identified to train word vectors. Numerous optimisation methods were recommended for training details to enhance the training speed significantly. An attention mechanism method for deep learning in 2014 to extract essential information [26]. The RNN network-attention mechanism integration outperformed most single models within the image domain.

The author in [27] applied the long short-term memory (LSTM) network to the text classification field in the same year, thus mitigating the lack of contextual information in CNN. The training time is longer for long text datasets as LSTM takes the whole text as input without extracting vital information. A study by [28] suggested a recurrent convolutional neural network structure (RCNN) that connected BiLSTM and the maximum pooling layer. The BiLSTM network captured contextual information while the pooling layer extracted vital features. Hence BiLSTM is fully utilised with the integration of both structures. Extracting contextual information that only retains the pooling layer in the CNN part weakens the CNN's ability to extract features. Noda proposes a model for the multimodal robot in [29] and [30] proposes DeepCEP in 2019 with multimodal information streams and complex, spatial, and temporal dependencies.

The DL method of complex multimodal information based on the neural network has been widely acknowledged for its ability to simulate the cognitive function of the human brain. Regardless, this method (not a mathematical model based on the workings of the human brain) only denotes a formal mathematical description of the neuron structure and signal transmission method. It is also deemed challenging to eliminate the reliance on large-scale training samples. In 2020, Bejan

described the MemoSys system submitted in Task 8 of SemEval 2020 to classify Internet memes sentiments [31]. In 2021, Zahera and colleagues recommended I-AID, a multimodal approach to automatically categorize tweets into multi-label information types [15].

Reference [32] highlighted various multimodal learning challenges and ways to train deep networks to learn features for task management. Cross-modality feature learning was also demonstrated, which allows for better features for a single modality (video) when other modalities (audio and video) are present when the features are being learned. The means to train a classifier with audio-only data to be tested with video-only data and evaluated on a specific task using shared representations between modalities was also denoted. Research by [33] proposed a model and neural network that demonstrated how image-text modelling could mutually learn word representations and image attributes. This methodology provides sentence descriptions for images without templates, structured prediction, or syntax trees in contrast to many other existing techniques.

Essentially, [34] developed and assessed advanced neural network techniques that incorporate input from several modalities to investigate the impact of complex interactions between textual, visual, and metadata on project success prediction. The method requires data gathered from the pre-posting profile to enable pre-posting prediction. Following [35], a multi-label and multimodal framework using text, audio, and visual input modalities was offered to categorise unbalanced data and automatically create static and temporal features using spatiotemporal deep neural networks. A weighted multi-label classifier functioned to manage data using non-uniform distributions.

A revolutionary deep dual recurrent encoder model in [36] was proposed to comprehend speech data fully and concurrently manipulate text data and audio signals. As spoken and musical content constitutes emotional dialogue, this model employed RNNs to encode audio and text sequences information before integrating it to determine the emotion class. Additionally, [37] proposed a deep multimodal attentive fusion (DMAF), a model for image-text sentiment analysis, to manipulate the discriminative features and internal connection between visual and semantic content using a hybrid fusion framework for sentiment analysis. The multimodal information proves crucial in emergency management. In the 'scenario-response' approach, social media provides additional data sources for emergency management. The information content in multiple modalities is interrelated, albeit with contextual differences.

In a text containing events, the content, image, and video details genuinely depict the scenes of the event. Such aspects complement and confirm one another to reflect the development status of real-world events. It is deemed pivotal to abstract, generalize, and integrate the complex social media multi-modal information from different levels and aspects and summarize and extract more accurate and comprehensive information than a single modality for users' holistic and in-depth understanding of real-time emergencies to reduce emergency management ambiguities. Information extraction

from social media is implied as a binary text classification issue with the labels 'relevant' and 'irrelevant' [15]. Nevertheless, effective methods to connect relevant postings to finer-grained classifications remain scarce. Such fine-grained labelling proves useful for crisis responders who need promptly provide catastrophe reactions and update vital information. Mainly, categorizing tweets on disasters with multiple labels facilitates the rapid identification of tweets with helpful information. The model performed optimally when breaking down disaster-related tweets into specific information types.

In research of [12] proposes a multimodal deep-learning framework to identify damage-related information. This framework combines multiple pre-trained unimodal convolutional neural networks that independently extract features from raw text and images, followed by a final classifier that labels posts based on both modalities, ultimately achieving an accuracy of about 92.6% in the English dataset. An approach to classifying thematic social media by integrating visual and textual information through a fused CNN architecture is proposed [38]. Specifically, two CNN architectures are used, targeting visual and textual information of social media posts, respectively. The outputs of the two CNNs, i.e., the features extracted from the social media posts representing visual and textual features, are further connected to form a fused representation. Research in [5] proposed a multimodal approach to identify disaster-related information content from Twitter streams using text and images. The method is based on long and short-term memory and VGG-16 networks, which significantly improve performance. In addition, [39] investigated the extent to which integrating multiple modalities is essential for classifying crisis content. In particular, a multimodal learning pipeline was designed to fuse textual and visual inputs, utilise both, and then classify that content based on a specified task. The average F1 performance in two critical tasks (relevance and humanitarian category classification) was 88.31%. A Python-based data pipeline application, SMDRM, for processing social media data points was proposed in [7].

However, this current work mainly explores the classification of English datasets, and more research needs to be done on Chinese contingency management datasets in social media. Notwithstanding, most multimodal information processing algorithms in social media, which are almost global and static, did not learn from failures and user input in real-time. In research of [40] proposed a multimodal network (MDMN)-based approach for rumour detection, including a text feature extractor, a visual feature extractor, and a fusion classification network, applying a multitask sharing layer, a task-specific converter encoder, and a selection layer to improve the diversity and stability of the text. Domain adaptation involves training adaptive models to extract visual representations. Adaptive models can encode task data better than fine-tuned pre-trained models. Then, experiments with two fusion strategies to fuse multimodal representations of multimodal datasets collected from tweets and microblogs show that the proposed MDMN can outperform the baseline approach. The decision-level fusion strategy achieves more than 92% Recall. In classifying emergency management

information in social media, it is nearly impossible for existing algorithms to imitate the intelligent behaviour of human interaction and lifetime learning. It highlights the need for a multimodal and complex information-processing model that gathers, models, and employs feedback information in the social media interaction with users and continually iterates and optimises the information. Such an approach could passively or actively detect errors, implement online learning and dynamic updating mechanisms based on the faults, and construct a set of self-learning frameworks to alleviate information processing issues in emergency management.

All related literature shows that social media sentiment analysis plays a vital role in the advanced technological world. However, it is also found that the existing DL models contribute a lot. However, no such model developed which cross-platform, cross-lingual, multimodal and used multimodal social media data with high accuracy.

III. METHOD

This study proposed the Bi-LSTM-Attention-CNN-XGBOOST ensemble neural network model (see Fig. 1) to address the complex processing of multimodal information in social media. The model manipulated ensemble learning as presented in Fig. 2. The information of multiple modes was initially mapped to a unified text vector space. Various deep learning models were used to model the semantic content at sentence and multimodal information levels. The MPOD textual data were used for model training and testing. As the name implies multimodality, English- and Chinese-language corpora from different social media platforms were selected for the recommended model. This model is divided into six layers:

1) Embedding layer: the word embedding matrix is regarded as the neural network model parameters and input for the BiLSTM neural network model to encode a sentence.

2) BiLSTM layer: BiLSTM constitutes two independent LSTMs that could summarise information from the forward and backward directions of a sentence. Essentially, the information stemming from both directions could be merged. At each time 't', the forward LSTM computed the hidden vector 'fht' based on the past hidden vector 'fht-1' and the input word embedding 'xt'. The backward LSTM calculated the hidden vector 'bht' based on the opposite (past) hidden vector 'bht-1' and the input word embedding 'xt'. Subsequently, the forward hidden vector 'fht' and backward hidden vector 'bht' were merged into the final hidden vector of the BiLSTM model. In this model, the parameters of two opposing directions proved independent albeit sharing the same word embedding of a sentence to generate a deeper semantic vector and represent each word with the BiLSTM network.

3) Attention layer: the self-attention mechanism functions to extract the more important information by providing them with a higher weight to elevate their significance. This layer primarily aimed to achieve the attention weight for all words and their ranking.

4) Pooling layer: this layer accepts the temporal sequence output by the LSTM layer and performs temporal max-pooling with sole reference to the non-masked portion of the sequence.

The pooling layer converted the entire variable-length hidden vector sequence into a single hidden vector for its output to be fed into the dense layer. The aforementioned layer engages the k-max pooling to extract the top k-words, which are ranked in step 3.

5) CNN layer: CNN layers are added to the front end, followed by the LSTM layers with a dense layer on the output. This layer provides input to the CNN network to perform convolutional operations and extract the key features with first k-word vectors.

6) X GBOOST layer: the XGBoost method enhanced the features extraction mechanism for DL models. This layer generates the feature vectors that are extracted by the final CNN and classified by the XGBOOST integrated classifier.

Fig. 1. The BiLSTM-attention-CNN-XGBOOST structure

Fig. 2. The ensemble learning process [15]

A. Embedding Layer

Word embedding implies the representation method of word vectors in NLP. Although most conventional word vector representation methods utilise one-hot encoding, this method easily results in a high vector dimension. In the proposed study model, the Skip-gram model in Word2vec was utilised in word embedding to pre-train the words.

B. BiLSTM Layer

The LSTM layer utilises BiLSTM for deeper semantic vectors of words. This structure could combine the current word context to prevent future words in RNN from becoming more influential than their previous counterpart.

C. Attention Layer

Videos can be converted into text in the NLP domain. As the basic unit of text implies words, current models are primarily trained and operated on them. The attention mechanism suggested in this study mainly computed the attention of words in a given text. High levels of attention received by the word denoted its pivotal role in the task. Overall, extracting words with high attention could effectively classify multimodal information.

D. K-max Pooling Layer

The pooling layer in the NLP domain is primarily used to extract features and convert multimodal information of different lengths into fixed-length vectors. A common pooling operation denotes the max pooling operation, which retains one of the features. Meanwhile, the multimodal information ‘t’ typically denotes several words or their integration to express the meaning underlying the whole multimodal information. This model adopted k-max pooling, retained the first k-word vectors with larger attention scores, and obtained the combined feature vector ‘y’ of the first ‘k’ words. A larger weight implies higher levels of attention. Based on the outcomes derived from various experiments, the value of ‘k’ implied 8.

E. CNN Layer

This layer adopts the original Text CNN model for feature extraction. The first (network) layer takes the first k-word vectors retrieved by the k-max pooling layer as input. The second (convolution) layer performs convolution on input word vectors with several filters of varying sizes. The third (pooling) layer performs the highest number of pooling operations to create a novel feature vector.

F. XGBoost Layer

The BiLSTM-Attention-CNN-XGBoost ensemble neural network model proposed in this study implied the XGBoost ensemble classifier. If the length of a sentence is ‘n’, word embedding is performed through the pre-trained k-dimensional word vector with each word represented as a k-dimensional vector. Furthermore, the sentence could be converted into an n*k -dimensional data matrix as input. The convolutional layer employs 3*k, 4*k, and 5*k convolution kernels to extract features, pool the extracted features, and fully connect the features extracted by convolution kernels of varying sizes. Lastly, the multimodal information multi-classification processing is completed through the XGBoost classifier. In assuming that a sentence constitutes six words with each word

denoting a four-dimensional word vector, the sentence could be characterised as a 6×4 data matrix as the convolution layer input through 3×4 , 4×4 . The 5×4 convolution kernel performs feature extraction to obtain 4×1 , 3×1 , and 2×1 feature maps. A three-dimensional feature map is derived from maximum pooling while the XGBoost classifier is employed for classification processing.

IV. EXPERIMENT AND RESULTS

Fig. 3. The experiment framework

The experiment was conducted on ubuntu16.04 with Intel(R) Xeon(R) E5-265 as the CPU, 2.4GHz as the frequency, 32GB as the memory size, Python3.0 as the experimental programming language, and Tensorflow1.12.0 as the deep learning framework. The experimental dataset implied the news public opinion corpora in Weibo, Wechat, Twitter, and Facebook. As shown in Fig. 3, this self-collected dataset containing 6,700 text samples, 342 Image samples and 67 sounds samples was referred to as the multilingual public opinion dataset (MPOD). Notably, 70% of the samples were arbitrarily selected as a training set while the remaining 30% were chosen as a test set. The training set was manipulated to train the proposed model and evaluate it with the test set.

In Table I, the overall comparison with existing models implemented on the selected dataset are presented. The performance of the proposed model is more efficient and accurate than all with having 85 to 97%. The NB method performance varies from 78 to 93. Whereas N-gram with TF-IDF have 78-94, as well as charCNN have slightly incremental up to 95. The wordCNN have 95.66% and LSTM have 95.78% and last but not the least RCNN jumps to 96%.

TABLE I. THE COMPARISON OF DIFFERENT METHODS IN MPOD

Method	Chinese language set		English language set	
	WeiBo	WeChat	Twitter	Facebook
NB model	84.12%	78.56%	93.21%	93.02%
Ngrams - TFIDF model	84.78%	78.94%	93.55%	94.67%
charCNN	85.23%	79.04%	93.67%	95.05%
wordCNN	84.97%	79.89%	94.87%	95.66%
LSTM model	85.05%	80.98%	95.67%	95.78%
RCNN	85.24%	81.45%	95.98%	96.02%
The proposed method	87.64%	85.65%	98.34%	97.62%

Fig. 4. The comparison of different methods in MPOD

As shown in Fig. 4, the BiLSTM-Attention-CNN-XGBOOST model proposed in this paper shows better accuracy than NB MODEL, Ngrams-TFIDF model, charCNN, wordCNN, LSTM model, RCNN model, regardless of Chinese or English data, whether from WeiBo, Twitter, Wechat or Facebook. The highest accuracy rate of Chinese language dataset is from WeiBo, reaching 87.64%, and the highest accuracy rate of English language dataset is from Twitter, reaching 98.34%. It can be clearly seen that the accuracy rate in the English data set is significantly higher than that in the Chinese data set by about 10%. In the English data set, Twitter performed better than Facebook, and in the Chinese data set, Weibo performed better than Wechat. Facebook and WeChat are biased towards acquaintance connections, while Twitter and Weibo are biased toward media connections.

V. DISCUSSION

Six multimodal information classification methods were selected in this study to verify and discuss the model superiority. The conventional multimodal information classification method employed the NB and Ngrams-TFIDF models, while the deep learning method utilised the charCNN, wordCNN, LSTM, and RCNN models. Research by [32-37] similarly highlighted the multimodal model utilised in various textual, image and video datasets for different domains. Likewise, [15, 17, 20-22] employed multimodality to develop DL-based models in facilitating disaster management and recovery. Table I depicts the comparison of different classification algorithms and their effects on each model.

This study emphasised three multimodal information categories: (1) natural language, which can be both written and spoken; (2) visual signals that are typically represented by images or videos; (3) sounds that encode auditory and paralinguistic information, such as prosody and vocal expression signal. Following the data analysis in Table I, the classification effect of the study model on the same dataset is better for multimodal information. The two conventional methods, NB and Ngrams-TFIDF, depend on statistics, whereas charCNN, wordCNN, LSTM, and RCNN are classic neural network deep learning algorithms. Owing to the multi-layered nature of deep neural networks, a multimodal representation was constructed with several separate neural layers for each modality, followed by a hidden layer that projected the modalities into the joint space to employ neural networks.

The joint multimodal representation was conveyed through multiple hidden layers or directly used for prediction. In this study, the ensemble learning method served to extract the feature vector or latent semantic information of the multimodal counterpart by (1) studying the language cognitive mechanism of the brain and (2) analysing the relationship between cognitive mechanism and multimodal information computing methods. The four algorithms Bi-LSTM, attention mechanism, CNN, and XGBoost were integrated to extensively derive the advantages underlying each algorithm. For example, l-max pooling could reduce the number of model parameters that facilitates the mitigation of model overfitting issues. The attention mechanism could employ the human visual mechanism for intuitive interpretation, neural network

interpretability, an in-depth understanding of the inner neural network mechanisms, and connect the neural network model structured based on the workings of the human brain. The weight-sharing network structure of CNN implies its mechanism.

The CNN resembles the biological neural network, thus reducing the complexity of the network model and number of weights. For example, XGBoost provides the model with a larger learning space and utilises feedback information for continuous model optimisation. As a result, the model classification accuracy in this study was 2% to 3% higher than that of the general method. This elevation resulted from using the k-max approach in the pooling layer in this study as the 'k' value substantially affected the experiment. Thus, several tests proved necessary to determine the most appropriate parameters and increase the experimental effect at the parameter adjustment stage of test training.

VI. CONCLUSION AND FUTURE WORK

This study proposed a multimodal information classification method based on the hybrid BiLSTM-Attention-CNN-XGBoost neural network to classify multimodal information and maximise the benefits derived from each network model. Based on the experimental outcome, the classification accuracy was considerably improved upon adding the attention mechanism despite consuming much time as the experiment was performed on a single machine. The current study model would be tested on a distributed platform in the future to shorten the classification time. Based on the self-collected dataset called MPOD, the aforementioned hybrid neural network outperformed other models, such as CNN and Bi-LSTM, RCNN and Highways, LDA and SVM, attention mechanism, and GRU network. Further research would emphasise the multiple model fusion impacts on the experimental results with multimodal data.

Design of Human-Computer Interaction Product Interface of Intelligent Service System based on User Experience

Xiaoli Xiong¹, Yongguang Hou^{2*}

College of Education Science, Weinan Normal University, Weinan 714099, China¹

School of Computer Science and Technology, Weinan Normal University, Weinan 714099, China²

Abstract—The current intelligent service platform for human-computer interaction products and services on the user experience is not comprehensive enough, resulting in user satisfaction cannot reach the ideal level. Therefore, a new human-computer interface of intelligent service system based on user experience is designed. Build a user experience based intelligent service system hardware platform, the introduction of the full name of hypertext markup language, so that more personalized design to be met. Design user experience PC terminal and Bluetooth/RS-485 gateway module to achieve two-way signal conversion between Bluetooth and RS-485. Based on ARM processor, the speech recognition of human-computer interaction is completed, the features of collected data are extracted, and the hand gesture recognition is completed. In order to optimize the human-computer interaction effect, Kinect is used to track and identify moving objects, and the 3D interactive image is simulated by fused texture. Experimental results show that the proposed method has a higher probability of receiving data, and the recognition rate of gesture features and recognition accuracy can reach more than 90%.

I. INTRODUCTION

With the rapid improvement of computer's storage capacity and processing speed, the performance of service robot is getting better and better. More and more service robots are applied to all walks of life [1]. In order to make the service robot enter into people's daily life from the laboratory, some key technologies must be broken through, such as path planning, environment representation, control system, human-computer interaction, mechanism design and so on. As an interactive channel between user and robot, the human-computer interaction of intelligent service system is a crucial technology [2]. The human-computer interaction system of a friendly and natural intelligent service system is the key to the success of service robot. The purpose of the human-computer interaction design of intelligent service systems is to make the communication between humans and robots more convenient, more reliable and more in line with human interaction habits, as well as to reduce users' psychological and physical burdens [3].

The most important thing in the human-computer interaction of intelligent service system is how to make the

user complete the task best, rather than how to design the best human-computer interaction of intelligent service system. In applications, the current research direction is no longer the pursuit of function, but "user-centric" design [4-5]. In modern software development, the research and development of human-computer interface of intelligent service system is of great importance. It connects people with computer technology and realizes humanization of computer technology. The human-machine interface of intelligent service system is the most closely related part of application system, so the workload of this part accounts for a large proportion of the whole development work [6-8].

Three core technical modules of intelligent robot: interaction+perception+operation control. Among them, the full name of interaction is human-computer interaction and recognition module. The functions of this module mainly include speech synthesis, speech recognition, image acquisition, image recognition, etc. The technologies related to speech recognition include speech recognition, natural language understanding, natural language generation, speech synthesis and dialogue engine. Image recognition technology includes image processing, analysis, understanding and other different types of technology. But at present, people pay more and more attention to the cross-platform of programs, that is, programs with the same function can run on different system platforms, and keep the same function and interface style, thus enhancing the portability and flexibility of programs. It should be noted that the current intelligent service robot cannot achieve this goal, and the existing technology does not support the robot to be truly customer-centric and truly intelligent and humanized. The innovation of the research is to realize voice recognition and gesture recognition with (Advanced RISC Machines) ARM processor, and realize tracking and recognition of moving images with Kinect technology, thus truly realizing human-computer interaction centered on user experience.

The organizational structure of the paper is as follows. The second part analyzes the current situation of human-computer interaction design of intelligent service robots at home and abroad. The third part designs the human interaction interface of the intelligent service robot with user experience as the center. In the fourth part, the feasibility and reliability of the proposed method are verified by using the comparative design method. The fifth part analyzes the research results and gives a conclusion.

II. RELATED WORK

Robots are high-end emerging technologies that integrate machinery, information, images, materials and other disciplines. Among them, intelligent service robots supported by machine learning, deep learning, artificial intelligence and other technologies have been gradually applied to cleaning, rehabilitation, medical, home services and other fields.

The author in [6] pointed out that the home service robot is a special robot serving human beings, which can replace people to complete home service work, mainly engaged in anti-theft monitoring, security inspection, cleaning, cargo handling, home appliance control, home entertainment, pathological monitoring, children education, alarm clock timing, home statistics, etc. According to the degree of intelligence and the purpose of use, home service robots can be divided into primary small home robots, children's early education robots and human-computer interactive home service robots. The author in [7] pointed out that service robots not only have the characteristics of strong mobility and flexibility, but also can provide a solid hardware foundation for their application in the service industry. They also have the characteristics of convenient mechanical structure, strong human-computer interaction, etc. People can obtain a good user experience in the process of using service robots. The author in [8] proposed a combination of hidden Markov model and Gaussian mixture model to achieve high-precision recognition in the process of dialect interaction. External tools can also be used in the recognition process. This technology has very strong practical value.

The author in [9] tracks interactive targets in real time by improving the efficiency of tracking algorithms. In the case of dialogue analysis, it truly realizes human-computer interaction of intelligent robots by analyzing dialogue video data information. The author in [10] found out how failures occurred and how to solve them in the process of multi-mode voice communication between the interactor and intelligent service robot. Such interdisciplinary work provides opportunities for the communicators and robots to gain new insights into communication problems, so as to provide resources for the mechanisms that can later realize complex human-computer interaction. The author in [11] believed that in the interaction process, the interactor could convey a total of eight positive and negative emotions to the intelligent service robot through touch, and the research results provided a possibility for the follow-up people-centered service. The author in [12] found through experiments that women can communicate emotions for a longer time by using more diversified interaction methods and touching more areas on the robot than male participants. The author in [13] proposed a visual saliency evaluation method of multimedia human-computer interaction interface based on human vision. The adaptive Gaussian filter is used to filter the human-computer interaction interface. The gradient direction of the interface image is converted into the derivative of the horizontal and vertical directions through the Gaussian function to determine the size of the interface gradient direction, and the corrected interactive interface image is obtained. According to different co-occurrence concepts of interface image visual saliency, the influence index of human visual saliency is quantified, and the

spatial position function of interactive interface is obtained. Set the number of direction types and edge points in each image block of the interactive interface, and obtain the texture complexity function of a pixel in each sub image of the interface. The weighting coefficient is given, the interface spatial position function and the texture complexity function of pixels are used as evaluation indexes for weighted output, and the evaluation results of visual saliency of interactive interface are given. The author in [14] analyzes the ergonomic criteria and the aesthetic evaluation criteria of interface layout, establishes four basic principles of interface layout: hierarchy, relevance, simplicity and comfort, and constructs a multi-objective optimization mathematical model of interface element layout according to the principles. Based on this model, an improved genetic algorithm is adopted, a multi-objective optimization method of interface element layout based on genetic algorithm is established. The basic principles of product operation interface layout design are given, and a multi-objective optimization method and process of product operation interface element layout based on genetic algorithm are proposed.

However, the methods mentioned above are not comprehensive enough to consider user experience, leading to the failure of user satisfaction to reach the ideal level. Therefore, a new human-computer interaction product interface of intelligent service system based on user experience is designed. Research and creatively put forward the human-computer interaction key points of the intelligent service robot with user experience as the centre, providing technical support and guarantee for the intelligent robot to develop in the direction of intelligence, interaction and personalization.

III. DESIGN OF HUMAN-COMPUTER INTERACTION PRODUCT INTERFACE OF INTELLIGENT SERVICE SYSTEM BASED ON USER EXPERIENCE

A. Hardware Platform Construction of Intelligent Service System based on User Experience

The introduction of the full name of the Hypertext Markup Language, or HTML, as a way of building and presenting Internet content, will transform the "Web" from a mere tool for presenting content into a full-fledged application platform that will become the standard for a new generation of the Internet. "HTML" 5 adds the ability to interact and present multimedia. Relatively speaking, the user experience has a more specialized level of functionality that allows more personalized design to be satisfied, unlike the H5.

The design of human-machine interface system of intelligent service system based on user experience is shown in Fig. 1.

The framework shown in Fig. 1 is mainly composed of 360PC terminal, gateway module and controller, and the above three parts are briefly introduced respectively. 360 (Program Counter) PC terminal is intended for operation of tablet computers. The gateway module is Bluetooth/RS-485, which is used to integrate Bluetooth and RS-485 chips, so as to achieve the goal of simultaneous Bluetooth wireless communication and RS-485 communication. The controller is

programmable and used in PLC industry. Components 1 and 2 are mainly used to realize information exchange under Bluetooth wireless communication. At the same time, the module and the controller achieve bi-directional data communication through Modbus (Remote Terminal Units) RTU, mainly by shielding the communication interface of the module on the controller. Module and RS-485 signal bidirectional conversion, in order to achieve 360PC and (Programmable logic Controller) PLC information exchange, the need for the data link between the two to be set up.

Fig. 1. System platform framework

1) User Experience PC Side:

The UX PC side, also known as epub360, is a very useful tool for H5 interaction design, and is used on Windows platforms, where designers can design professional-level H5 works online without any programming required. But the epub360 idea is the request specialized level function, it may better achieve the designer to the specialized design request.

a) Professional Animation Control. Epub360 is an H5 design tool, is the only SVG path and deformation animation, and control fine sequence frame animation design tools, it can not only relational control, but also a true sense of the control of the interactive animation, is professional.

b) Professional Interactive settings. It combines dozens of Epub360 provided by the trigger control, can be triggered by gestures, can also shake, related control, personalized interaction design, and can be perfect to meet the designer's needs.

c) Professional Social application. Our country is the first to apply WeChat's JsSDK advanced interface, which can complete the functions of personality nickname, avatar picture, friend circle photo, small video, and easily achieve the H5 design of social interaction class such as friend circle comment, click like.

d) Professional Data application. Some advanced data components, such as parameter variables, database, etc., can complete the H5 design of light game, such as small test, puzzle game, etc., and WebApp level professional application can also realize the visual design in the near future.

i) *Top toolbar*: Add basic and advanced components for the middle section; publish and manipulate the general preview on the left; and operate shortcuts such as save on the right.

ii) *List of pages*: Overview of the entire page; Add or remove pages; adjust the order of the page; manage the page group.

iii) *Canvas*: The main design areas are the safety zone inner frame and the bleeding zone outer frame, which are 640 x 960 px and 740 x 1136 px, respectively.

iv) *Mobile phone adaptation*: The canvas area is specially designed for mobile phone adaptation and consists mainly of an inner and outer frame. Area A is 640 x 960, visible on any phone, and area B is 740 x 1136, and its primary function is to ensure that no white parts are visible on the phone screen.

2) Bluetooth/RS-485 Gateway Module

The role of the module is to carry out Bluetooth and RS-485 two-way signal conversion to achieve the user experience between the PC and PLC can communicate with each other. Gateway module is mainly used for Bluetooth 4.0 and user experience PC in the wireless band, the frequency of 2.4 GHz, and then realizes the operation of Bluetooth 4.0 protocol; Modbus RTU protocol is required through the RS-485 interface to connect with the PLC, the former is wired connection. This module carries on the simultaneous communication between the user experience PC and PLC. The module interprets the data packet sent by the receiving 360 PC terminal, interprets it as the Bluetooth 4.0 protocol, obtains the required and effective data, and then carries out the control instruction or data conversion. If it is necessary for the user to experience the instruction that is to be sent by the PC terminal, it needs to convert it into the Modb protocol, and then transmit it to the PLC, so that the PLC can effectively identify the above instruction. At the same time, the module needs to read, analyze and convert the data sent by PLC and the data collected by PLC according to Modbus RTU protocol, and send the converted data to 360 PC terminal.

B. User Experience

1) Layout Design based on User Sensory Experience

In the process of layout design, we should fully consider the visual flow of the user, follow the left to right and top to bottom order, based on this to highlight the content, so as to attract the user's attention. First, the main menu is set at the top, the left side of the bottom is a secondary menu, the right side is a column link, the middle is the main recommended content, this layout is clearer, but also very convenient to operate, with the advantages and characteristics of symmetrical point of view, so this layout is currently widely used [15-17]. For example, Jing Dong Mall is the way to use screen segmentation for typesetting, to achieve a flexible combination of content, the display of pictures and text to facilitate. At the same time, KnowNet, douban and other websites are also used in this format. Next is the grid multi-column page layout method, this can present more content at the same time in the layout, not only the form is more beautiful, reading is also very convenient, has the very strong maneuverability, quite suits in the online shopping platform foundation demonstration page.

2) Color Design based on the User's Sensory Experience

In the interface design of Internet products, the reasonable combination of colors can give users a very good impression, so as to attract more users to use. In general, the color design of an interface based on user experience needs to consider the following contents: First, the color design needs to have sufficient pertinence, understand the groups that the Internet products face, and understand the habits and emotions of the groups, so as to identify the colors suitable for the products and user experience. For example, if KnowNet is primarily for the sharing of knowledge and experience, then the blue color representing rationality will be used as the primary color of the interface. Secondly, we should have enough comfort in color design, according to the physiology and engineering of human body, according to the physiological characteristics of human vision to choose the color, to reduce fatigue, and improve the comfort of the product.

3) Font Design based on the User's Sensory Experience

In the interface design of Internet products, font plays a key role in information transmission and content description. Whether the design is reasonable or not directly determines the user's reading experience. The font design based on the user experience needs to start from the following aspects: First, for the selection of font, the fonts commonly used in the interface of Internet products include bold type, Song type, round type and calligraphy type. In the selection of font, it is necessary to take into account the user's usual reading habits, but also to combine certain aesthetic habits. In order to make it more convenient for users to find, some content with larger headings will choose bold type, and the remaining text will generally choose bold type or Song type. For example, the major domestic news portal is the application of bold, so that people click and browse. Secondly, the text layout, generally speaking, the interface design of Internet products will involve the font, font size and text color, and so on. It requires designers to make reasonable arrangement of the position of various words, so that they can find the required content more quickly. For example, the use of visual physiology to arrange content in order from high to low purity colors make the user attracted to the color text. Colors can also be used to classify and facilitate user operations [18]. In addition, we can also use word spacing, line spacing and other paragraph settings to highlight the content, so as to greatly simplify the user reading process, shorten the reading time.

C. Speech Recognition based on ARM Processor

Nowadays, there are many kinds of embedded processors, such as MCU, ARM, embedded X86 and so on. The processor is the center of system operation and control, and it tends to adopt RISC instruction set Harvard architecture. ARM (Advanced RISC Machines) is an embedded microprocessor that is also the company's name. In November 1990 ARM was founded in Cambridge, UK. Unlike other semiconductor companies, ARM is an intellectual property (IP) provider, working on intellectual property designs for 16/32-bit RISC microprocessors (reduced instruction set computer, RISC). It does not produce chips by itself, but rather manufactures distinctive chips from partners through the transfer of design proposals. Embedded in full swing today, ARM company has accounted for 75% of the market share. Its microprocessors

and technology have been used in all walks of life, almost all kinds of electronic products microprocessors use ARM technology, such as image, consumer entertainment, automobile, security, industrial control, wireless, and mass storage market. In 2001, almost monopolized the global RISC chip market has become the field of RISC chip standards. ARM's success, on the one hand thanks to its unique mode of operation, on the other hand, an important aspect is its own excellent performance. ARM processor has the following characteristics:

- 1) Low power consumption, small size, low cost, high performance.
- a) Support for ARM (32-bit)/Thumb (16-bit) dual instruction sets, with good compatibility with 8-bit/16-bit devices.
- 2) Using a large number of registers, the instructions are executed faster.
- 3) A variety of addressing methods, that is flexible and efficient.
- 4) Fixed instruction length.

Because this paper is based on embedded ARM system intelligent service system human-computer interaction interface design, not a single application system customization, so here is a general pattern design. As a voice interface of service robot, it is usually used by ordinary users, the language is rich and diverse, and the same meaning may have different ways of expression. Moreover, dynamic keyword importing is used to enlarge the recognition range, which is more helpful to set up multiple expressions and make speech recognition more natural.

Fig. 2 is a design flow chart of a common pattern of human-computer interaction in intelligent service system. Both the speech recognition module and the speech synthesis module are encapsulated as an interface (API) that can be invoked by other applications for voice interaction, and the application performs actions based on the return structure of the speech module (i.e., the recognition results).

Fig. 2. Flow chart of voice interaction

D. Gesture Recognition based on User Experience

Hand gesture recognition is the basis of human-computer interaction in intelligent service system, which enhances the user experience to extract the features of collected data and complete the recognition according to the features to realize the human-computer interaction. Gesture acceleration features usually include frequency-domain features, time-domain features and other domain features [19-22]. The frequency domain features include the frequency domain entropy, FFT coefficient and other features extracted by using wavelet or Fourier transform; the time domain features include signal

amplitude area, statistical maximum value, activity window length, mean value, axis correlation coefficient and standard deviation; the other domain features include the features extracted by using LDA or PCA, etc.

There are $s \times k$ pixels in each gesture motion image, and the values of all pixels are determined by the following formula:

$$\begin{cases} 0 & \text{Point does not pass through the data waveform curve} \\ \sum_{i \in \{1,3\}} 2^i \times 16 & \text{Point does not pass through the data waveform curve} \end{cases} \quad (1)$$

Where, i represents the number of waveform curves passed by the pixel position. The gesture image is obtained according to the gesture acceleration action as a column in matrix $V_{n \times m}$:

$$\begin{bmatrix} x_{1,1} & x_{1,2} & \text{L} & x_{1,k} \\ x_{2,1} & x_{2,2} & \text{L} & x_{2,k} \\ \text{L} & \text{L} & \text{L} & \text{L} \\ x_{s,1} & x_{s,2} & \text{L} & x_{s,k} \end{bmatrix} \rightarrow [x_{1,1} \text{L} x_{s,1} x_{1,2} \text{L} x_{s,2} \text{L} x_{1,k} \text{L} x_{s,k}]^T \quad (2)$$

Transform the data existing in the gesture motion training set to obtain the gesture motion matrix $V_{n \times m}$.

Nonnegative matrix decomposition, which belongs to multivariate data analysis method, uses the product of two low rank nonnegative matrices to replace a nonnegative matrix, and extracts gesture features through nonnegative matrix decomposition method.

The nonnegative matrix algorithm is described by the following formula:

$$V_{n \times m} \approx W_{n \times r} H_{r \times m} \quad (3)$$

In the formula, H represents the weight matrix, W represents the base matrix, V represents the nonnegative matrix, and r represents the rank of the decomposition matrix.

The expression of the optimization objective function is as follows:

$$F = \sum_{i=1}^n \sum_{u=1}^m [V_{iu} \log(WH)_{iu} - (WH)_{iu}] \quad (4)$$

The iterative algorithm decomposes the base matrix W and the weight matrix H , and obtains the weight matrix $H_{r \times m}$ and the weight matrix $W_{n \times r}$ by decomposing the hand gesture action matrix $V_{n \times m}$.

Input the acquired weight matrix and base matrix into the following classifier to realize gesture recognition and complete human-computer interaction of the intelligent service system:

$$h_j(x) = \begin{cases} 1 & p_j g_j(x) < p_j \theta_j \\ 0 & \text{others} \end{cases} \quad (5)$$

In the expression, j represents the feature in the eigenvector; p_j represents the direction of the inequality; $g_j(x)$ represents the eigenvalue of the j rectangle in the sub window to be detected; θ_j represents the threshold of the classifier, the value is 2, $h_j(x)$ represents the classifier.

E. 3D Interactive Image Simulation of Interface based on Fused Texture

When Kinect is used to track and identify moving targets, the problem of target recognition needs to be solved first. However, because Kinect does not have recognition function, it needs to use color histogram for target recognition. At the same time, Kinect cannot directly track human bones. The bone data is acquired by denoising, segmentation and other related technologies on the basis of depth images. Among them, target identification and tracking mainly include virtual target identification and target personnel location tracking, and the specific operation steps are shown in Fig. 3.

In order to obtain better recognition results, the following methods based on image information are mainly used to analyze and research, using Kinect to shoot the color images in the study area, and accurately identify the virtual targets in the study area by color histogram matching results. Among them, color histogram is mainly used to describe the percentage of each color in the whole image. The calculation for color histogram matching is:

$$\begin{cases} d_{\text{corre}}(H_1, H_2) = \frac{\sum_i H_1(i) H_2(i)}{\sqrt{\sum_i H_1^2(i) H_2^2(i)}} \\ H'_k(i) = H_k(i) - \frac{1}{N} \left(\sum_j H_k(j) \right) \end{cases} \quad (6)$$

In the above formula, $d_{\text{corre}}(H_1, H_2)$ represents the matching result; H stands for component; H_1 and H_2 stand for histogram functions; $H_k(i)$ and $H_k(j)$ represent the matching degree of the i and j histogram respectively. $H'_k(i)$ stands for perfect match value; N represents the number of equal components of H .

The corresponding calculation formula of chi-square matching and intersection matching is as follows:

$$\begin{cases} d_{\text{chis}}(H_1, H_2) = \sum_i \frac{(H_1(i) - H_2(i))^2}{H_1(i) + H_2(i)} \\ d_{\text{intersection}} = \min \sum_i H_1(i) H_2(i) \end{cases} \quad (7)$$

Through the formulas (6) and (7), it can be seen that the larger the value of the calculation result of the correlation and

intersection matching algorithm is, the higher the histogram matching degree is, and the perfect matching value is 1; the smaller the value of the calculation result of the chi-square matching algorithm is, the higher the histogram matching degree is, and the value of the perfect matching is 0.

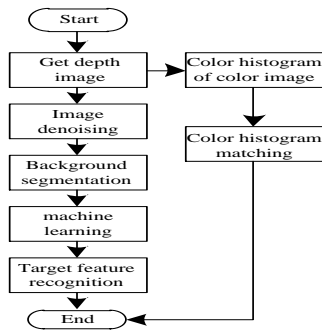

Fig. 3. Flow chart of target identification and tracking

In order to eliminate all the noise in the image, the median filtering method is used to denoise. Among them, the median filter formula is:

$$f(x, y) = \underset{(x,y) \in S_{xy}}{\text{median}} \{g(x, y)\} \quad (8)$$

In the above expression, $f(x, y)$ represents the filtered output value, S_{xy} the number of all pixels in the image, and $g(x, y)$ the gray value of the pixel.

To draw a structure image of a virtual object, it is necessary to first separate the moving object from the depth image. The following methods are mainly used for object detection and background segmentation based on user index numbers. The specific operation process is shown in Fig. 4:

Fig. 4. Operational flow of moving target detection and background segmentation

- 1) Prioritize the use of Kinect to obtain depth images of each research scenario.
- 2) Extracting the depth value and user index number of pixels from the depth image.
- 3) An index number obtained through step (2) marks the moving object.

4) Binary processing shall be used to collect images, and the pixel values in the study area shall be set to 255, and the pixel values of the remaining nodes shall be set to 0, so as to separate the target from the background.

In the early stage of motion recognition, it is necessary to define the starting point and ending point of virtual target motion. Among them, the starting point and the ending point of the moving target are mainly judged by the radius of the palm ball. The radius of the palm ball can be obtained by (Software Development Kit) SDK, and the threshold value is 30mm. When the radius of the center of the hand is higher than the threshold, it indicates that the palm of the target is open, and vice versa, it is closed. If the radius of the palm ball gradually increases from less than 30mm to 30mm, the starting point is indicated, and recognition stops when Leap Motion again captures a threshold of less than 30mm.

The realization of moving target recognition and tracking localization is to recognize each structure accurately in the existing target contour image, and to determine the specific coordinates of the nodes. The above operation process is mainly completed through machine learning technology. Firstly, the sample of decision tree is trained, and then the classification model based on decision tree is obtained. Secondly, the feature value of depth image is classified and evaluated by machine learning. In order to eliminate the influence of external and internal factors on the data noise, the Kalman filtering algorithm is used to eliminate the data's optimal value and measured value iteratively. The Kalman filtering algorithm performs filtering operations on a time-dependent dynamic system, so a discrete control system needs to be added to the algorithm, and the formula is as follows (9):

$$x_{k+1} = F_{k+1}x_k + B_{k+1}u_{k+1} \quad (9)$$

In the above expression, x_{k+1} represents the running state of the system at $k+1$, x_k represents the running state of the system at k , F_{k+1} represents the transformation matrix acting on x_k , B_{k+1} represents the control parameters of the system, the value is 1.5, and u_{k+1} represents the control matrix.

At time $k+1$, the measurements in the system need to meet the following conditions:

$$Z_{k+1} = H_{k+1}x_{k+1} + v_{k+1} \quad (10)$$

In the above formula, H_{k+1} represents the measurement matrix projected into the measurement space by the state at moment x_{k+1} ; v_{k+1} stands for measurement noise.

The state at moment $k+1$ can be deduced by formula (10), and the specific calculation formula is as follows:

In the above expression, $\mathfrak{R}(k+1|k)$ represents the optimal value of the system at time $k+1$, and $x(k|k)$ represents the optimal value of the system at time k .

$$\mathfrak{R}(k+1|k) = \frac{F_{k+1} \cdot \mathfrak{R}(k|k)}{u(k+1)} \quad (11)$$

In the phase of Kalman filter prediction, the LEAP SDK is used to obtain the position and pose information of the next period of time. Given the moment, the central coordinate of the moving object is O , and the following formulae can be obtained in combination with the law of motion:

$$\begin{cases} \mathfrak{S} = v_k t + \frac{a_k t^2}{2} \\ p_{k+1} = \mathfrak{R}(k|k) \cdot \mathfrak{S} \end{cases} \quad (12)$$

In the above formula, v_k represents the running speed of the moving target; a_k represents acceleration; p_{k+1} represents the coordinate position at time t , and \mathfrak{S} represents the motion change law of the virtual target.

Based on the above analysis, the moving target structure information is extracted through the depth image, and all the extracted structure information is fused to track and identify the human-computer interaction target of the intelligent service system.

IV. ANALYSIS OF EXPERIMENTAL RESULTS

In order to verify the overall effectiveness of the design method of the human-computer interaction interface of the intelligent service system, it is necessary to test the design method of the human-computer interaction interface of the intelligent service system under the enhanced user experience. The experimental platform for this test is Division Mockup, and the probability of data received by the host computer is used as a test indicator to test the design method of the human-computer interaction interface, the design method of the human-computer interaction interface based on the evaluation of visual significance and the multi-objective optimization design method of the layout of product operation interface elements. The higher the probability of data received by the host computer is, the better the human-computer interaction effect is. The test results are shown in Fig. 5.

Fig. 5. Test result of probability of receiving data by host

By analyzing the data in Fig. 5, it can be seen that in the process of human-computer interaction, the host receiving data probability of the proposed method is more than 90%, and most of the relevant data can be received to realize human-computer interaction, while the host receiving

probability of the human-computer interface design method based on visual significance evaluation and the multi-objective optimization design method of product operation interface element layout fluctuate around 80% and 70% respectively. The data received by the above two methods is not enough to effectively realize human-computer interaction. Comparing the test results of the above methods, it can be seen that the host receiving data probability of the proposed method in the process of human-computer interaction is high, because the method constructs a data transmission model based on game theory, collects relevant data and information in the process of human-computer interaction, and improves the host receiving data probability.

The proposed method, the human-computer interaction interface design method based on visual saliency evaluation and the multi-objective optimization design method of product operation interface element layout are used to recognize human gestures. The feature recognition rate and recognition accuracy are used as test indicators. The test results are shown in Fig. 6 and Fig. 7, respectively.

Through analyzing the data in Fig. 6 and 7, we can see that the recognition rate and accuracy of the proposed method are high in many experiments, which shows that the proposed method can recognize human gestures accurately and comprehensively. When the method of human gesture recognition based on visual saliency assessment is used, the feature recognition rate and feature recognition accuracy are both low, which indicates that the method of human gesture recognition based on visual saliency assessment is not effective and comprehensive.

Fig. 6. Test results of feature recognition rate

Fig. 7. Test results of feature recognition accuracy

Compared with the test results of the proposed method, the human-computer interaction design method based on visual significance evaluation and the multi-objective optimization design method for product operation interface layout, the proposed method has the best performance in the human-

computer interaction, because the proposed method uses the data transmission model to collect the relevant information of the human-computer interaction, adopts the non-negative matrix decomposition method to extract the features of the gesture information, and inputs the features into the classifier to accurately realize the recognition of the gesture, thus improving the feature recognition rate and the feature recognition accuracy.

In the process of human-computer interaction, user satisfaction is the focus of attention. The overall performance of the method is tested by using user satisfaction as a test index. The test results are shown in Fig. 8.

Fig. 8. User satisfaction test results

Through the analysis of the data in Fig. 8, it can be seen that the user's satisfaction with the proposed method is more than 80% in many iterations, and the user's satisfaction with the human-computer interaction design method based on visual significance evaluation and the multi-objective optimization design method for element layout of product operation interface fluctuate around 40% and 60%, respectively. Through the above analysis, the human-computer interaction effect of the proposed method is better, and the user's satisfaction is the highest, because the proposed method constructs the data transmission model through game theory, and can accurately collect the user's static information and dynamic information in the process of human-computer interaction, and feed the fused dynamic information and static information back to the human-computer interaction system. The human-computer interaction system responds to the acquired data, completes the human-computer interaction process of the intelligent service system, meets the user's needs, and thus improves the user's satisfaction.

Fig. 9(a) and Fig. 9(b) refer to the performance of different human-computer interaction methods in indoor and outdoor environments respectively. It can be seen from the figure that the error of the three human-computer interface optimization methods decreases with the increase of the data size. When the data size reaches about 25, it tends to be stable, while the accuracy shows the opposite change rule. In the indoor environment, the convergence errors of the proposed method, the human-computer interaction interface design method based on visual significance evaluation, and the multi-objective optimization design method of product operation interface element layout are 0.156, 0.278, and 0.415, respectively. The accuracy was 97.58%, 95.21% and 92.24%, respectively. In outdoor environment, the convergence errors of the three methods are 0.217, 0.489 and 0.658, respectively. The accuracy was 96.12%, 93.21% and 91.25%, respectively.

Therefore, the proposed human-computer interaction method has ideal performance in both indoor and outdoor environments.

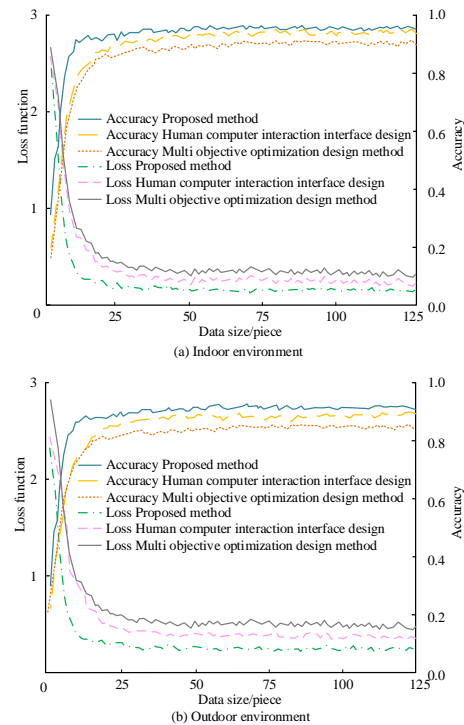

Fig. 9. Performance of different human-computer interaction methods in indoor and outdoor environments

V. DISCUSSION AND CONCLUSION

In order to solve the problems of the current intelligent service platform, such as the low probability of receiving data, the low recognition rate and the low recognition accuracy, a new intelligent service system based on user experience is designed. This introduces the full name of the Hypertext Markup Language and design user experience PC and Bluetooth/RS-485 gateway module. Speech recognition module based on ARM processor is designed to realize human-computer interaction of intelligent service system.

Compared with the human-computer interaction interface design method based on visual significance evaluation and the multi-objective optimization design method of product operation interface element layout, the proposed optimization design method of human interaction interface has higher action recognition accuracy and satisfaction. A large part of tasks completed by computers are completed by human-computer cooperation, which drives the emergence of human-computer interaction systems. However, the traditional human-computer interaction relying on external devices has been difficult to meet the needs of today's society. This has promoted gesture recognition based on machine vision to a certain extent. It is a novel human-computer interaction technology, which has received widespread attention from scholars at home and abroad. Kinect sensor technology is used to realize the tracking and recognition of moving objects. The device includes three functions, namely sensor data flow, bone tracking and advanced audio function. Sensor data stream

mainly refers to accessing low-level streams from depth, color camera sensors and microphone arrays; Bone tracking can mainly track the images of the application driven by the postures of 1-2 people in the field of vision; Advanced audio function, which can process some complex audio sound sources, such as echo, noise and beam forming, and can also integrate with the audio recognition library of Windows to collect infrared data and generate unit images. It can promote Kinect bone tracking to be more robust to users' dynamic gestures in different environments. In complex environments, Kinect uses a separation strategy for human segmentation. Its advantage is that it can build a corresponding segmentation mask for each tracked object and retain the human image. This makes it only necessary to transmit the human body image in the subsequent data stream processing, so as to reduce the amount of calculation of body sensing data.

The advantage of Kalman filter is not that its estimation deviation is small, but that it skillfully integrates observation data and estimation data, conducts closed-loop management of errors, and limits the errors to a certain range. Imagine that if there is no information fusion between the two, and only estimation data, the error will accumulate more and more with time, and the uncertainty will increase with time. For the control of landing on the moon so far and for a long time, It will lead to uncontrollable error when arriving near the moon, and the introduction of observation data will correct the estimated data to prevent the error of estimated data from being too large to be spectral. The estimation data fusion of observation data is equivalent to closed-loop feedback management of the former's estimation. It is undeniable that the Kalman filter still has errors, and its advantage is that it can still maintain stable errors when the time is long, because it relies on an observation data in the information source when making decisions. If you listen to one side, you will be dark; if you listen to both sides, you will be clear. As for whether the error is lower than that of the individual estimated data or the individual observed data, further discussion is needed. At the same time, the color histogram used in the research can directly describe the information features of the target through the analysis of local gradient or edge direction density, greatly reducing the impact of local shape features, not only avoiding the overlap of the original feature vectors to a certain extent during the image formation process, but also preventing the impact of individual movement on the detection results, thus ensuring the accuracy of the collected image. It can be seen from the above analysis that the proposed method has higher probability of receiving data, higher recognition rate and accuracy of gesture features, and higher user satisfaction. The above experimental results show that the proposed method has better performance. However, there are still shortcomings in the research. In the process of data acquisition and subsequent action mapping, the time complexity of the algorithm leads to the jumping phenomenon in the action simulation process. Although the optimized Kalman filter eliminates the discontinuity of the action to a certain extent, when the speed becomes faster, the phenomenon of jamming will still occur.

Age Estimation on Human Face Image Using Support Vector Regression and Texture-Based Features

Jesy S Amelia, Wahyono*

Department of Computer Science and Electronics
Universitas Gadjah Mada, Yogyakarta
Indonesia

Abstract—This paper proposed a framework for estimating human age using facial features. These features exploit facial region information, such as wrinkles on the eye and cheek, which are then represented as a texture-based feature. Our proposed framework has several steps: preprocessing, feature extraction, and age estimation. In this research, three feature extraction methods and their combination are performed, such as Local Binary Pattern (LBP), Local Phrase Quantization (LPQ), and Binarized Statistical Image Feature (BSIF). After extracting the feature, Principle Component Analysis (PCA) was performed to reduce the feature size. Finally, the Support Vector Regression (SVR) method was used to predict age. In evaluation, the estimation error will be based on mean average error (MAE). In the experiment, we utilized the well-known public dataset, face-age.zip, and UTK Face datasets, containing 15,202 facial image data. The data were divided into the training of 12,162 images and the testing of 3,040 images. Our experiments found that combining BSIF and LPQ with PCA achieved the lowest MAE of 9.766 and 9.754. The results show that the texture-based feature could be utilized for estimating the age on facial image.

Keywords—Age estimation; LBP; BSIF; LBQ; MAE; PCA; preprocessing; feature extraction; Support Vector Regression (SVR)

I. INTRODUCTION

The face is a part of the human body that has an important role. Characteristics of the face such as eyes, nose, mouth, eyebrows, and wrinkles or aging provide much information. One of them is age estimation. It is possible to limit that under age to accessing content (related to violence) in the web browser through age estimation. Shopping centers can use age estimation to determine advertising strategies based on the age of visitors and provide recommendations. It can choose the right advertising strategy. It is necessary to have a method used to detect the observer's age. We must have an extensive collection of facial images that will be used in age detection and pay attention to the face, such as wrinkles or aging that will be used in the age detection process to produce better estimation.

Generally, the age estimation process has several steps: preprocessing, feature extraction, and age estimation. The first is preprocessing (resizing and grayscale image) to be uniform. Then, the feature extraction step is to find the unique facial features in the age estimation process. The features were the Binarized Statistical Image Feature (BSIF), Local Binary Pattern (LBP), and Local Phrase Quantization (LPQ) methods and their combination: BSIF + LBP, BSIF + LPQ, and

LBP+LPQ. In addition, Support Vector Regression (SVR) was used in the age estimation stage. SVR is a machine learning algorithm that provides reliable performance in predicting time series data and can classify data that cannot be separated linearly [1].

Several previous studies have been proposed for age estimation, including Ingole et al. [2] and research by Thrukral et al. [3] and analysis by Khunteta, Ajay, et al. [4]. However, these three studies only predict a group of ages (e.g., with categories 25, 35, 45, 55, 65, and 75 years old), not the age. For this reason, in this study, age estimation was conducted not based on age group but on exactly one age estimation value. Furthermore, the texture of the face is one of the essential features in determining age. This study will detect age on the image containing a single face. The age estimation is carried out only at 1-70 years old due to limited data on ages over 70.

Our research aims to find the best feature extraction method based on texture in detecting age with the lowest Mean Absolute Error (MAE) level from the facial images. Several texture-based feature extraction methods obtain good accuracies, such as LBP, BSIF, and LPQ. The BSIF and LPQ methods provide the best results in the age estimation process with an MAE of 3.58 using the MORPH II dataset and an MAE of 9.07 with the same extraction feature method (BSIF+LPQ) using a Subset of LFW [5]. Meanwhile, LBP is one of the best texture description methods for texture classification, face detection, face recognition, gender classification, and age estimation [6]. In addition, LPQ is proven robust for blur images and is considered to show better performance in texture classification, and the combination method gives better performance results [7].

The paper will be divided into several sections. The second section will explain in more detail how the proposed framework has been applied. The third section will discuss the result of the experiment. Then, the fourth section will conclude our work.

II. PROPOSED METHOD

Age estimation is one of the most challenging and crucial issues in utilizing the facial area to produce helpful information. Age estimation can be used in solving scientific problems as well as in subproblems of facial recognition. The prediction of age is formed because the human brain cannot predict age correctly, so it is necessary to have a system that

*Corresponding Author.

can predict age correctly [8]. Many factors can be used in predicting the age of the facial area, including aging, wrinkles on the face, wrinkles in the eye, mouth area, and other features in the facial area. The estimated age itself can be detected using two methods. These methods are classification and regression methods [9]. Age estimation using classification can only estimate based on age range, while age extraction using the regression method can estimate age with exactly one output value of age. It is the difference in age detection using classification and regression methods, as shown in Fig. 1.

Our proposed framework was divided into several significant steps: image preprocessing, feature extraction, and age estimation.

A. Preprocessing

Preprocessing is an initial process that aims to improve an image. It is for eliminating noise in the image. In preprocessing stage, we also uniform the image in color and size [10]. The purpose of this process is to make it easier to perform feature extraction at the next stage and to create an age estimation model. This research has two preprocessing steps: resizing and gray scaling.

1) *Resizing*: Since the dataset contains images with different sizes, the image should be resized to a specific size. The resizing process is used to change the size of the image to either enlarge or reduce size. The resizing function is carried out using the interpolation method. The following is a calculation of the resizing process using the linear interpolation formula:

$$\frac{y-y_0}{x-x_0} = \frac{y_1-y_0}{x_1-x_0} \tag{1}$$

where (x_0, y_0) is two points of initial coordinates, (x_1, y_1) is destination coordinates, and (x, y) is coordinate prediction.

2) *Grayscale*: Grayscale is one of the preprocessing steps to change the image from an RGB image to a gray color (grayscale). RGB is an image with three combination colors: Red, Green, and Blue (RGB). The value of RGB is represented in three dimensions XYZ, consisting of lightness, chroma, and hue. The process aims to convert the value of RGB (24-bit) into grayscale value (8-bit) [11]. A grayscale image is an image that has only one value for each pixel. This value is used to indicate the level of intensity. The three colors in the grayscale process are white, black, and gray. The following is a formula for the grayscale process:

$$W = 0.299R + 0.587G + 0.1140B \tag{2}$$

where W, R, G, and B are grayscale, red, green, and blue values of the image, respectively. Fig. 2 illustrates how the RGB image was converted into a grayscale image.

B. Feature Extraction

Feature extraction is a process used to generate unique feature vectors from facial images that will be used to create age estimation models. This feature extraction stage uses three different texture-based methods, including Local Binary Pattern (LBP), Local Phrase Quantization (LPQ), and

Binarized Statistical Image Features (BSIF), and their combination, BSIF+LBP, BSIF+LPQ, LPQ+LBP.

1) *Local Binary Pattern (LBP)*: LBP gives the best results in various applications, especially for texture classification, segmentation, face detection, face recognition, gender classification, and age estimation [12]. The LBP method is grayscale invariant and can be combined easily with simple contrast by calculating each gray level of each pixel [13]. LBP considered each pixel has a code. It is called Local Binary Pattern code or LBP code. It works by comparing the value of the center image (pixels) with each neighborhood which amounts to 8 pixels, and thresholding of 3x3 neighborhood [14] divided into eight blocks. The following is a simple example of calculation using LBP at 3x3 pixels:

Given a pixel at (x_c, y_c) , the resulting LBP can be expressed in decimal form as follow:

$$LBP = \sum_{p=0}^7 S(H_p - H_c)2^p \tag{3}$$

where H_c is a central pixel, H_p start from $(p = 0, 1, \dots, 7)$, it is neighborhood from H_c , and S is a function of thresholding, which is defined as:

$$S(H_p - H_c) = \begin{cases} 1 & H_p \geq H_c \\ 0 & H_p < H_c \end{cases} \tag{4}$$

After comparing the center image with its neighborhood, the result will be converted into a binary number. As shown in Fig. 3, a binary number generated from pixel 3x3 is 01010100 = 84. The value will be inserted at the center image. Each value of LBP is formed into 256 histograms which will be used as a texture descriptor.

Fig. 1. Age estimation using classification in the left side and regression in the right side.

Fig. 2. Image conversion sample from RGB to Grayscale.

Fig. 3. Example of the basic LBP Operator.

Fig. 4. Circularly symmetric LBP image with different radius.

In addition, LBP has two essential parameters, P and R. P is the total number of neighborhoods, and R is Radius. Radius is measured from the center point distance. There are various kinds of radius in LBP, including 1, 2, 3, etc. Fig. 4 illustrates LBP symmetric sampling with different radius (R) values.

2) *Local Phrase Quantization (LPQ)*: The LPQ descriptor is used in the texture descriptor and classification for blur images [15]. LPQ method is efficiently used to solve the problem of variation expression in the face verification system. LPQ aims to maintain images in local invariant information with various blurring images. Fig. 5 shows the stages of the LPQ. As can be seen in Fig. 5, the $q(x)$ is defined as the following formula:

$$q_j(x) = \begin{cases} 1 & \text{if } q_j \geq 0 \\ 0 & \text{if } q_j < 0 \end{cases} \quad (5)$$

Lastly, the LPQ generates a binary number by combining the pixel values obtained from $\text{Re}\{F \times\}$ and $\text{Im}\{F \times\}$. Fig. 5 received a binary number of 89 for the center image.

3) *Binarized Statistical Image Features (BSIF)*: Inspired by LBP and LPQ, Kannala et al. [16] proposed a new local descriptor called BSIF (binarized Statistical Image features). The basis vectors of a subspace into which local image patches are linearly projected are obtained from images by using Independent Component Analysis (ICA). The coordinates of each pixel are threshold, and thus a binary code is computed. A value represents the local descriptor of the image intensity patterns in the neighborhood of the considered pixel [17]. The following is the formulation of BSIF:

$$S_i = \sum_{v,u} W_i(i, v) * X(u, v) = W_i^T x \quad (6)$$

where X is image with size of $M \times M$, Filter W_i learning from *Independent Component Analysis (ICA)* by maximizing the statistical independence of S_i .

$$b_i(x) = \begin{cases} 1 & S_i \geq 0 \\ 0 & S_i < 0 \end{cases} \quad (7)$$

Fig. 5. Example of the LPQ Operator [10].

where b_i is a binary number obtained from S_i . In all our experiments, the BSIF descriptor has been used with filters of size 9×9 and 8-bit.

C. Principal Component Analysis (PCA)

Principal Component Analysis (PCA) is a statistical method to distinguish patterns and signal processing. PCA reduces dimensional data, feature extraction, and facial recognition [18]. PCA is a powerful method, especially for high-dimensional data. That technique reduces the dimensions of the dataset by extracting the essential components.

D. Age Estimation Using Support Vector Regression (SVR)

Support Vector Regression (SVR) is a supervised learning algorithm to predict discrete values. SVR can solve linear and non-linear problems using kernel functions [19]. The advantage of SVR is that the computational complexity of SVR does not depend on the dimensions of the input space. In addition, SVR has excellent generalization capabilities and high prediction accuracy.

The SVR method is effective for solving problems related to the estimation function. So SVR is the best method for age estimation. SVR is the same as SVM. The idea of SVR is to determine the best fit line. In SVR, the most appropriate fit line is the hyperplane which has the maximum number of points. So, the SVR tries to match the best line within its threshold value. The threshold value is the distance between the hyperplane and the boundary line. So, the regression problem is to determine a function that approximates the mapping from the input domain to real numbers based on the training sample.

E. K-Fold Cross Validation

Cross Validation is a testing method in data mining and machine learning where the dataset will be divided into k parts or folds randomly. Cross Validation is used to evaluate the performance of the algorithm. The data will be separated into two subsets: the learning subset (training) and the validation/evaluation subset [20]. First, the algorithm will be trained using a learning subset, and then the model will be validated using a validation subset. The illustration of the cross-validation scheme is shown in Fig. 6.

Fig. 6. Cross-validation illustration.

III. EXPERIMENTAL RESULT

In this section, we first introduce the databases and the protocol evaluation of our experiments. After that, we will describe experimental setups and their results.

A. Dataset

The facial dataset used in this research was downloaded from face-age.zip [12]. The facial image size is 200×200 pixels with a total of 9,778 RGB face images. In this face-age.zip face image, there are facial images with an age range of 1-110 years, but this research uses face images from 1-70 years of age with the female and male gender. First, a selection process is carried out on the facial image, only selecting a face without glasses and a watermark. In addition, we only utilized images with ages between 1-70 years due to data limitation in the face image dataset from face-age.zip for ages above 70 years. From the face-age.zip dataset with the selection process, we choose a total of 3,040 images for our experiment.

Furthermore, the face image dataset was added using the UTK Face dataset. We then selected 12,162 face images from this dataset. The UTK Face dataset is also obtained from downloading through the same source on the face-age.zip dataset, and the total facial image dataset owned is 15,202 images. Finally, the dataset is divided into training and testing data, where the training data is 12,162 face images, and the testing data is 3,040 facial images (20% of the total facial images) which contain facial images 1-70 years old for training and data testing. Table I shows the selected images used in our experiment.

B. Experiment Scenario

The scenario of the system is divided into two main stages: training and testing. The training stage is applied to find the relationship between one face and another and create a model for age estimation. In contrast, the testing stage is performed to detect the estimated age of the face image. Fig. 7 shows the scenario of the experiment for our proposed framework.

In this research, to produce the best age estimation model, experiments were carried out on feature extraction methods based on texture, such as LBP, LPQ, BSIF, and the combination of these methods, BSIF + LBP, BSIF+LPQ, and LPQ + LBP. From the three extraction methods and the combination, it will be seen which method will produce the lowest MAE level in the age estimation process. In addition, there are several experiments: feature reduction extracted using PCA with values of 40, 50, 60, 70, 80, and 90 features. For age estimation using the SVR method.

Since the estimation output will not be in discrete values, for evaluation purposes, we rounded the estimation output using two strategies. The first strategy is rounding the value up from the detected age. For example, the detected ages 32.5, 17.8, and 23.2 will be 33, 18, and 24. The second strategy is rounding the age value down from the detected age. For example, the detected ages 32.5, 17.8, and 23.2 will be 32, 17, and 23.

C. Evaluation Metrics

To measure the performance of our approach, we adopted Mean Absolute Error (MAE). MAE is a method used to evaluate the performance of age estimation. MAE is the average absolute error between the ground truth age and the predicted one [5]. The age estimation model can be measured by using MAE. The following is the formulation of MAE:

$$MAE = \frac{1}{N} \sum_{i=1}^N |P_i - G_i| \quad (8)$$

where P_i is the estimated age, G_i is the corresponding ground truth, and N is the total number of samples.

TABLE I. THE SAMPLE IMAGES IN THE DATASET

	10 years old	20 years old	30 years old	40 years old
Age				

Fig. 7. General process of the proposed framework.

D. Results and Discussion

1) *Experiment scenario:* In this study, age estimation was carried out with various scenarios of experiments as follows:

a) Resizing the image: 180×180 pixels, 160×160 pixels, 140×140 pixels, and 120×120 pixels.

b) Feature Extraction using different methods and the combination (LBP, LPQ, BSIF, BSIF+LBP, BSIF+LPQ, and LPQ+LBP).

c) LBP Feature extraction using different radius (radius = 1, radius = 2, radius = 3 with same P (total number of neighborhood)).

d) Using the first strategy and second strategies for the age estimation, as explained in section III.B.

e) Comparing MAE from extracted features without PCA and with PCA.

f) Tried several variations of PCA, such as 40,50,60,70,80, and 90 features and compare MAE.

g) Find the optimum parameter of BSIF Filter by ICA.

2) *Evaluation with different images scale and without PCA*: In this paper, experiments were carried out on various image sizes such as 180×180, 160×160, 140×140, and 120×120 with the first strategy and second strategy of age estimation using LBP, LPQ, BSIF, BSIF+LBP, BSIF+LPQ, and LPQ+LBP. Fig. 8 and 9 show the MAE results when applying the proposed framework without using PCA on several image sizes. From these results, it can be concluded that by resizing images to 180×180, 160×160, 140×140 and 120×120 with feature extraction without PCA, the lowest MAE when using the BSIF method with an image size of 180×180 of 10.612 for the first strategy and 10.600 for the second strategy for age estimation. Furthermore, from the results, we could also find that in most scenarios, if the image is resized to a smaller size, the MAE decreases for LBP, LPQ, and BSIF. However, the results are not better compared to the combination of features.

3) *Evaluation of LBP using different radius without PCA*: In this study, experiments were also carried out on the radius of the LBP. Radius tested are 1, 2, and 3 to obtain the best age detection results with the lowest MAE. As shown in Fig. 10 and 11, it is found that the lowest MAE in age detection using LBP radius 3. Therefore, the LBP with a radius of three will be utilized in all experiments.

Fig. 8. Comparison results of different image size without using PCA in the 1st strategy.

Fig. 9. Comparison results of different image size without using PCA in the 2nd strategy.

Fig. 10. Comparison results of LBP radius without using PCA in the 1st strategy.

Fig. 11. Comparison results of LBP radius without using PCA in the 2nd strategy.

4) *Optimal parameter evaluation for LPQ*: Feature extraction on Face recognition uses LPQ with various window sizes: 5, 7, and 9, and the best results were obtained using the LPQ method with window size 7 [10]. For this reason, this study used a window size of 7.

5) *Optimal parameter evaluation for BSIF*: Parameters that can affect the BSIF method are texture filters. Research for Face Recognition using texture filters BSIF with a size of 7×7, 9×9, and 11×11 in 8 bits and the best result using 7×7 [10]. Meanwhile, in the other research, the BSIF descriptor has been used with filters of the size of 13×13 and 8 bits for age estimation [5]. So, we will test texture filters of size 7×7, 9×9, and 13×13 with 8 bits. From Tables II and III, it can be found that BSIF Texture Filter 9×9 8 bits has the lowest average MAE. This texture filter will be used in the entire experiment.

TABLE II. BSIF FILTER COMPARISON WITHOUT PCA IN 1ST STRATEGY

Image Size	MAE Values		
	BSIF 7×7	BSIF 9×9	BSIF 13×13
180×180	10.771	10.612	11.015
160×160	10.997	10.855	10.627
140×140	10.442	10.612	11.269
120×120	10.715	10.749	11.063
Average	10.731	10.707	10.994

TABLE III. BSIF FILTER COMPARISON WITHOUT PCA IN 2ND STRATEGY

Image Size	MAE Values		
	BSIF 7×7	BSIF 9×9	BSIF 13×13
180×180	10.762	10.6	11.004
160×160	10.982	10.877	10.634
140×140	10.402	10.607	11.272
120×120	10.719	10.714	11.07
Average	10.716	10.700	10.995

6) *Evaluation age estimation based on extraction feature:* We use several variations of PCA feature vector sizes, such as 40, 50, 60, 70, 80, and 90, with various image sizes of 180×180, 160×160, 140×140, and 120×120 pixels with optimal parameters from LBP, LPQ, BSIF, and the combination BSIF+LBP, BSIF+LPQ, and LPQ+LBP. However, based on the result of our experiment, we will only display the results at 160×160 pixels because this image size produces the lowest MAE. Tables IV and V show the comparison results of several feature extraction methods for estimating. Based on these tables, it was found that the lowest MAE is generated using BSIF+LPQ with PCA 70. It achieved an MAE value of 9.766 in the first and 9.754 in the second strategies.

7) *Age estimation of public figures:* After obtaining the best model from the previous experiment, we then utilized the model for estimating the age of two public figures: Ralph Fiennes and Indro Warkop. We utilized the BSIF+LPQ model with an image size of 160×160. Due to limited data on these two public figures, the PCA was not performed. Fig. 12 and 13 show the age estimation of these public figures at different ages. Our model achieved MAE of 10.428 and 11.142 at the first and second strategies for Ralph Fiennes. On the other hand, the model achieved an MAE of 12.142 and 13.142 in the first and second strategies for Indra Warkop.

Fig. 12. Estimated age of Ralph Fiennes.

Fig. 13. Estimated age of Indro Warkop.

IV. CONCLUSION

In this research, the age estimation framework using Support Vector Regression (SVR) with texture-based feature extraction has been successfully implemented. The proposed framework can detect the exact age, not based on the age range. Furthermore, a comprehensive experiment has been carried out to determine the optimal model of age estimation, such as the different sizes of the image, utilization of PCA, and applying several feature extractions and their combination. Based on the experiment, we have found several essential findings in constructing of age estimation model. First, image size 160×160 produced the lowest MAE level compared to image size 120×120, 140×140, and 180×180 pixels. Second, utilizing the PCA after feature extraction gains computation time fast and gives the lowest MAE level in age estimation. Third, the optimal parameters for LBP, BSIF, and LPQ are a radius equal to three, a texture filter size of 9×9 8-bits, and a window size set equal to seven. Finally, the optimal model which produces the lowest MAE is the combination of BSIF and LPQ methods with a PCA dimension of 70. The model obtained MAE values of 9.766 and 9.754 for the first and second strategy is 9.754, respectively. However, the model has limitations for estimating the age of facial images from Asian countries since the dataset used for the experiment is mostly from Western countries. Therefore, future research might consider the additional dataset covering various ethnic groups. In addition, we may use another method like ANN or CNN and compare that with this method for age estimation.

Abstract—The practise of recognising unauthorised abnormal actions on computer systems is referred to as intrusion detection. The primary goal of an Intrusion Detection System (IDS) is to identify user behaviours as normal or abnormal based on the data they communicate. Firewalls, data encryption, and authentication techniques were all employed in traditional security systems. Current intrusion scenarios, on the other hand, are very complex and capable of readily breaching the security measures provided by previous protection systems. However, current intrusion scenarios are highly sophisticated and are capable of easily breaking the security mechanisms imposed by the traditional protection systems. Detecting intrusions is a challenging aspect especially in networked environments, as the system designed for such a scenario should be able to handle the huge volume and velocity associated with the domain. This research presents three models, APID (Adaptive Parallelized Intrusion Detection), HBM (Heterogeneous Bagging Model) and MLDN (Multi Layered Deep learning Network) that can be used for fast and efficient detection of intrusions in networked environments. The deep learning model has been constructed using the Keras library. The training data is preprocessed and segregated to fit the processing architecture of neural networks. The network is constructed with multiple layers and the other required parameters for the network are set in accordance with the input data. The trained model is validated using the validation data that has been specifically segregated for this purpose.

Keywords—Intrusion detection system; knowledge discovery and data mining; transmission control protocol; adaptive parallelized intrusion detection; constrained-optimization-based extreme learning machine

I. INTRODUCTION

IDS models can serve a wide range of purposes and requirements when applied in business settings. One of the most popular applications is the method of intrusion detection in personal systems or distributed settings [1]. The design of modern operating systems includes the implementation of technology that detect and prevent intrusions. However, the

handling capabilities of these systems are currently unknown. As a consequence of this, the majority of customers choose to invest in expert intrusion detection solutions for enhanced levels of protection. In addition, there is a considerable need for IDS that may be implemented in clustered systems and used in servers [2, 3]. There are many commercially available intrusion detection systems, some of which include the Bro intrusion detection system, which was developed by VISTAS Labs and the School of Engineering, the Snort intrusion detection system, which is distributed under the GNU licence [4], Network Protocol Analyzer [6], Multi Router Traffic Grapher (MRTG) [7], and a few other options. On the other hand, the computing requirements of the majority of these systems, as well as their accuracy, might be enhanced.

A. Motivation of this Research

This research was motivated by the fact that the majority of currently available intrusion detection systems do not handle the issues listed above as part of their operational process. As a result, there is a need to design an effective intrusion detection system with mechanisms to handle data imbalance and concept drift while simultaneously achieving better accuracy and faster detection of intrusions. This research was carried out to fulfil this need.

B. Objectives

The primary purpose of this work is to create an efficient intrusion detection system that is capable of the identification of intrusion signatures in network data in real time. The secondary goals are as follows:

- To develop a method of intrusion detection that is capable of dealing with the inherent data imbalance that is present within the domain in an efficient manner.
- In order to effectively deal with concept drift, which is an essential component of the domain.

- To incorporate feature reduction in order to lessen the demands placed on the model's computational resources.
- To enable quicker detection of intrusions, parallelization is going to have to be incorporated into the detection process.
- To execute detection of intrusions in real time in order to minimise financial damage as much as possible.

II. LITERATURE SURVEY

One of the essential components of today's continuously networked world is the presence of an intrusion detection system. As a result, there have been a few examination promises made in this area. In this section, we will discuss what are the most recent commitments in the field of intrusion detection. The investigation of the models will be carried out in three important stages. "The primary section discusses the function of AI-based models in identifying intrusions, the subsequent section investigates the significance of component choice in this space, and the concluding section discusses the function of adaptable models in the field of intrusion detection. H. Yang et al. [8] presented a novel and factual model that makes use of Least Square Help Vector Machines (LS-SVM) in order to recognise intrusions. This model divides the data into subgroups that are not consistent with one another. A delegate test will be selected from within this subgroup in order to prepare the model. SVM-based intrusion detection systems are incorporated into another comparative SVM-based model for network intrusion detection models [9]. The most important AI methods have been implemented in a number of the models, and those models also demonstrate intriguing expectations. These models include hereditary and fluffy calculation based models [10], grouping and k-closest neighbour based models [11], IDS utilising Backing Vector Machines (SVM) for preparation [12, 13], and a lot of other similar models. These models additionally rely on signature-based detection of intrusions in order to function well. In most cases, they are made as twofold classifiers, and they are prepared on both typical and irregular marks. Typical marks are the ones that are used. It was determined that the models were computationally incomprehensible, which resulted in significant time requirements. A model of IDS with several layers was suggested [14]. This is a component choice based model, which considers attacks to be layers and selects highlights for each of the layers in order to construct the detection model. It was proposed [15] to use an ongoing-based irregularity detection model for the purpose of network intrusion detection. Keeping up with adaptive mark databases that are not difficult to renew and reproduce under continuous settings is essential to this concept. In addition to this, the model suggests a multi-objective component determination method for the practical selection of attributes that will result in increased levels of precision. An earlier version of this model that deals with the detection of intrusions on systems that have been implanted was proposed [16]. The study [17] presents a proposal for a staggered intrusion detection paradigm that is based on peculiarity detection. A comparable methodology for the detection of peculiarities based on trees was suggested [18]. In order to identify intrusions, this model

relies on a combination of calculations based on the Firefly and Hereditary algorithms. There was a proposal made for a grouping-based intrusion detection approach [19]. The Semi-Directed Multifaceted Grouping Model (SMLC) that was proposed in this work makes use of named data in some capacity for the preparation process, which enables an adjustable detection procedure. Other semi-directed intrusion detection models include a group-based IDS AI- [21], a normal neighbour based model [22], and a semi-regulated model [20].

The models make use of fundamental techniques, which leads to diminished performance when applied to unbalanced data. The author [23] made a suggestion for a model that handled imbalances in the IDS. This is a real-time model that is based on clustering and use the RIPPER algorithm for the detection procedure. The research [24] presented a model with a similar structure that was based on the RIPPER algorithm. The study [25] presented an idea for an intrusion detection model that was based on principal component analysis (PCA). This paradigm is a profiling-based one, and it constructs profiles by making use of the intrusion signatures. Because this model is based on several classifications of classes, it is intended to recognise a wide variety of intrusion signs so that it can provide accurate categorizations. The study [26] presented a proposal that included an in-depth investigation of the classification models that can be utilised for intrusion detection in the most efficient manner.

An efficient methodology for the selection of features has been proposed [27] for use with the KDD CUP 99 dataset. The programme was able to make fairly accurate predictions despite having only six characteristics to work with. In a similar vein, the Flexible Neural Trees model [28] was able to attain an accuracy of 99.19% with just four features. A model for the identification of intrusions that was written in A C# was suggested [29]. Using this method results in the creation of a packet sniffer that has the capacity to effectively gather packets from an interactive TCP session and inspect them. Attackers will frequently engage in packet chaffing whenever they are dealing with models of packet sniffers. Researchers can more easily identify these types of packets with the help of the model, which works by injecting more packets into the network. The study [30] presented a strategy for identifying stepping stone intruders in their research. This model is responsible for carrying out the process of intrusion detection by contrasting the contents of a host's incoming and outgoing traffic packets. When the contents are examined, the model is evaluated to determine whether or not it can serve as a stepping stone. Because of this, it is possible to make a clear distinction between a typical packet and an invasive packet. On the other hand, if the packets are encrypted, this paradigm for detecting intrusions may not be successful. Because of this, inspecting packets cannot be called a model that is 100 percent reliable for spotting invasions. The research [31] presented a model for the identification of intrusions that was very comparable. The stepping stone attack has also been suggested as being detectable by using this concept. In contrast, this model identifies the packet source based on the timestamp, size, and sequence number of the data packets rather than by inspecting the contents of the packets

themselves. Even after they have been encrypted, these parameters are still legible; hence, this model is seen to have superior performance when compared to the model that came before it. Examining the information included within the packet header was also the subject of a suggestion made by [32]. Both [33] and [34] presented an additional method that makes use of the information regarding the packet count in order to identify the stepping stone assault. When it comes to fending off stepping stone attacks, connection chain difficulties are seen as being among the most important components. The author [35] presented a model that determines the stepping stone attack by estimating the length of the connecting chain as a starting point for the calculation. The study [36] presented a model with the aim of precisely determining the connecting chain more of the time. Even while these methods assist cut down on the amount of time needed for training and detection, because they are unable to properly deal with concept drift, they are not ideal for real-time intrusion detection.

III. METHODOLOGY

Detecting an intrusion into a system typically entails searching through a vast repository for intrusion signatures that are particularly sophisticated. For this purpose, a complicated model that recognises these signatures is required. This research provides a neural network model that is based on deep learning and has the capability of performing efficient intrusion detection on network transmission data. The Multi Layered Deep Learning Network that has been suggested is a deep learning network since it is made up of a number of hidden processing layers at various depths across the network. It was discovered that detection through the use of the deep network exhibited effective performances when it came to detecting the intrusion signatures.

A. Multi-Layered Deep Learning Networks (MLDN)

In this paper, a Multi-Layer Deep Learning Network (MLDN) model is presented for the detection of intrusions in a timely and accurate manner. The neural network is one of the primary models that is utilised in the quest to make accurate forecasts. Deep network intrusion detection is capable of identifying a great number of intrinsic patterns, in addition to addressing issues of data imbalance and concept drift. The deep learning architecture that has been proposed for use in intrusion detection is broken down into four distinct stages. These stages are data pre-processing, data separation, network development, and model fitting. Fig. 1 illustrates the suggested model's design, and the corresponding pseudocode may be found below.

Architecture of the Algorithm for the MLDN:

- 1) Input transaction data.
- 2) Perform data pre-processing to eliminate inconsistencies.
- 3) Separate the data into three categories: training, testing, and validation.
- 4) Construct the neural network using the input data as a basis.
 - a) Create Layer and assign activation function.
 - b) Determine Epoch.
 - c) Assign Learning rate.
 - d) Assign Optimizer and Loss function.
 - e) Data Shuffling.
 - f) Create Layer and assign activation function b.
- 5) Get the process of network training off the ground.
- 6) Validate the trained model by using the data from the validation.
- 7) Using the results of the tests, determine the final forecast.

- b) Determine Epoch.
- c) Assign Learning rate.
- d) Assign Optimizer and Loss function.
- e) Data Shuffling.
- f) Create Layer and assign activation function b.
- 5) Get the process of network training off the ground.
- 6) Validate the trained model by using the data from the validation.
- 7) Using the results of the tests, determine the final forecast.

B. Data Collection

The model has been validated through the utilisation of industry-standard benchmark datasets such as NSL-KDD, KDD CUP 99, and Koyoto 2022+ datasets.

C. Data Pre-Processing Phase

In most cases, neural networks are unable to effectively manage all of the different types of data that are incorporated into network data. They are only able to deal with data of the double type, and they require all of the data to fall within the same range in order for it to be relevant to both sets of characteristics. These criteria are dealt with during the pre-processing phase. The procedures that were carried out during the pre-processing phase are illustrated in Fig. 2. Data normalisation follows data imputation. One of the necessary pre-processing steps that must be completed before working with real-time data is known as data normalisation. The operational nature of machine learning models makes it necessary to implement a significant amount of standardisation.

Fig. 1. Proposed MLDN architecture.

Fig. 2. Data pre-processing.

Every machine learning model has the tendency to fit functions to the data that is provided. In most cases, the weights that are applied to an attribute are what decide the level of relevance that the attribute has. The process of fitting the functions has a tendency to become more difficult when the training data comprises values that fall within a wide range of values. If any of the attributes include significant values, this will ultimately result in the actual value being the one to determine the significance of the variable. Because of this, the weights that were assigned are likely to be useless. As a consequence of this, it becomes vital to transform all of the data into comparable ranges so that consistency can be achieved throughout the process of prediction. The three normalising techniques that are employed the most frequently and extensively are the min-max normalisation, the z-score normalisation, and the decimal scaling. The original data range is transformed in a linear fashion with the application of the Min-Max normalisation. This is demonstrated by:

$$x' = \left(\frac{x - \min(A)}{\max(A) - \min(A)} \right) * (D - C) + C \quad (1)$$

where "x" represents the normalised value and "x" represents the actual value of the attribute A. The data will be scaled between the predetermined limits [C, D], which are denoted by the letters C and D. Another method that can be utilised in the normalisation process is known as the Z-score normalisation method. The data are normalised between the intervals of 0 and 1 using this model. This follows logically from the formula.

$$x'_i = \frac{x_i - \bar{A}}{std(A)} \quad (2)$$

where xi' and xi are the normalised and actual values of the attribute A, A is the mean value for the attribute A, and std(A) is given by where xi' and xi are the normalised and actual values of the attribute A.

$$std(A) = \sqrt{\frac{1}{(n-1)} \sum_{i=1}^n (x_i - \bar{A})^2} \quad (3)$$

where "n" refers to the total number of rows or instances contained inside the data. The decimal scaling approach is the simplest one, and it yields results that are dependent on both the current value and the highest value that can be found in the property. This is demonstrated by

$$x' = \frac{x}{10^j} \quad (4)$$

If x' represents the normalised value, x represents the actual value of the attribute A, and j represents the number of digits that make up the highest possible number in the variable A.

For the purpose of normalisation, this study makes use of Min-Max Normalization because it provides the benefit of being able to set both the minimum and the maximum values.

D. Data Segregation Phase

Now that the data have been standardised, the models may be trained using them. On the other hand, it is essential to keep in mind that model validation is a requirement that must be met by any machine learning model. Because of this, the normalised training data is separated into three distinct components: the training data, the testing data, and the validation data. The data is divided in accordance with the proportions 7:2:1. Seventy percent of the total data set is used to sample the training set, twenty percent of the total data set is used to sample the test set, and ten percent of the total data set is used for validation purposes. After the data have been separated, the training data will be utilised in order to construct the trained model.

E. Network Construction Phase

During this phase, a deep neural network model is utilised to facilitate the efficient identification of intrusion signatures derived from the transmission data. In order to construct the neural network, the deep learning library known as Keras was utilised. A neural network, often called an artificial neural network, is a network of neurons that collaborates to perform effective machine learning. Neural networks are also sometimes referred to by its other name, natural neural networks. Neurons, often referred to as perception, are the individual processing pieces that are used to construct neural networks. As can be seen in Fig. 3, a single neuron has numerous inputs coming into it, but it only produces a single output.

Fig. 3. Neuron: A view.

On the other hand, these inputs cannot be independently acted upon. As a consequence of this, the relative significance of each input is reflected in the weights that are assigned to it. Real numbers (w1, w2,...) are the typical notation used to express weights. The output of a neuron is often a weighted aggregate of the neuron's input value and the weights that accompany that value. This is demonstrated by

$$Output = \varphi \sum_{i=1}^n w_i x_i \quad (5)$$

where “the activation function, w and x are the weights and inputs of the neuron”, and the symbol for the activation function. An input layer, one or two processing or hidden layers, and an output layer are the typical layers that make up a neural network. In most cases, the network also contains an output layer. Each layer is made up of multiple neurons, each of which is responsible for processing the information received in that layer and producing the appropriate outputs. Fig. 4 is an illustration that provides a general representation of a neural network.

Fig. 4. A simple neural network.

Every layer in the network operates based on the input that was provided by the layer that came before it, carries out operations as specified by Eq. (5), and then passes along its output to the layer that comes after it. One variety of artificial neural network is known as a deep neural network. This network has several hidden layers within its structure. The technique of running a deep neural network is identical to the process of running an artificial neural network; however, the addition of more layers results in the provision of improved prediction capabilities on vast and difficult situations. They are typically utilised in fields that call for the analysis of massive amounts of complex data that contain a number of properties. Because the field of network intrusion detection entails the processing of massive volumes of data with complicated patterns, a deep neural network would be an effective solution to the issue. Keras is a deep learning package that is open source and based on the programming language Python. It makes it possible to create neural networks. The fact that Keras is a high-level library means that it can simply and efficiently integrate with a number of different low-level systems. This is the primary benefit of using Keras. In its current state, Keras is compatible with TensorFlow, Theano, MXNet, and Microsoft Cognitive Toolkit. Keras is typically combined with low-level base libraries like as TensorFlow and Theano. These are the two most popular low-level base libraries. The fact that Keras was designed from the ground up to be extensible, modulatory, and minimalistic is undoubtedly its most significant selling point. When used with TensorFlow, Graphics Processing Units (GPUs) can also be used in conjunction with Tensor Processing Units (TPUs) for improved and more rapid processing. This is yet another advantage of the Keras framework, which was developed with the facilities to include GPUs from the start.

Both the sequential API and the functional API can be used to construct Keras models. The sequential API is the more traditional method. Models can be built layer by layer using the sequential application programming interface. This type is suitable for the vast majority of the applications that

are now available. Nevertheless, the approach does not perform very well when used to applications that share layers or that have several inputs or outputs. The functional API makes it possible to create networks that are more adaptable and diverse. It enables connections with layers at any level, which in turn makes it possible to create networks with a greater degree of complexity. Image processing, audio and video processing, and natural language processing are just few of the applications that typically make use of them. To construct the network, this work makes use of the sequential Application Programming Interface.

The neural network model is constructed with the help of the sequential application programming interface. An input layer, several hidden layers, and an output layer make up the network. Each of these levels is sandwiched between two other layers. In this particular investigation, the learning rate is 0.3. The rate at which the model must advance in order to become closer and closer to the correct response is known as the learning rate. A slower rate of convergence is indicated by smaller numbers, while a faster rate of convergence is indicated by larger values. Larger values may cause the model to bypass the optimal solution. As a consequence of this, it is necessary to identify the option that offers the highest value taking into account the circumstances. At this time, level 50 has been selected for the period. Epochs are the intervals of time during which the neural network model is provided with training data so that it can acquire new skills. Higher epochs produce better models. On the other hand, extreme care needs to be taken to prevent the model from being overfit. The parameters that were utilised are detailed in Table I.

TABLE I. NEURAL NETWORK PARAMETERS

Parameter	Value
Network Type	Sequential
Batch Size	64
Epochs	50
Learning Rate	0.1
Shuffle	True
Validation Data	Provided
Optimizer	Adam

The data that is being sent to the neural network has been shuffled to ensure that it is not arranged in any particular way before it is sent there. The network will benefit from this in the form of generic training. The validation data has been added to the network in order to ensure accurate prediction and also to prevent the network model from being overly tailored to the data. In order to perform the process of iteratively adjusting the weights of the neural network model depending on the data, an Optimizer algorithm is required to be utilised. The Adam optimizer is utilised right here. The Stochastic Gradient Descent algorithm has been expanded upon in order to create the Adam optimizer. The learning rate determines the level of update that is available. In order to generate adaptable learning rates, the algorithm modifies the levels of the learning rate at increasingly frequent intervals throughout the training process. This helps in better

identifying the best possible solution to the problem. As a result, the Adam optimizer continues to be one of the optimizer algorithms that is utilised the most in neural networks.

The neural network that is suggested will have different layer configurations constructed into it depending on the dataset that is being analysed. It is intended for each of these layers to have a substantial thickness. When all of a layer's nodes are connected to all of the nodes of the layer that follows it, we refer to that layer as dense. This contributes to the construction of a network that broadcasts all of its discoveries to every accessible node on the network.

The input layer is the first layer that is created. The total number of attributes that are included in the training data is typically used to determine how many nodes should be present in the input layer. The model that has been proposed is made up of two discrete levels. Multiple neurons are incorporated into the design of the hidden layers. In this particular experiment, the successive layers each make use of 100 and 50 neurons. One neuron is present in the output layer that comes last. Since the issue that is being worked on is a binary classification issue, it would be sufficient to use a single neuron that was programmed with the output probability.

In addition to these qualities, activation functions are an extremely important factor in determining the effectiveness of the neural network. The activation function of a node in a neural network is what decides what the output of that node will be given the set of inputs for that node. This output is used as an input by the node that is located on the layer below. In most cases, the value that is produced by an activation function falls somewhere in the range of 0 to 1 or -1 to 1.

The activation function that is used is what determines the actual output that is produced. Other activation functions are available, however the sigmoid (Shown in Fig. 5), hyperbolic tangent (tanh), Rectified Linear Units (ReLU), and linear activation functions are the most frequent ones used in neural networks. Other activation functions are also available. In most cases, the sigmoid activation function has the form of the equation below:

$$f(x) = \frac{1}{1+\exp(-x)} \quad (6)$$

Fig. 5. Sigmoid activation function.

The range of the curve, which is S-shaped, is between 0 and 1, and the range of the curve itself is between 0 and 1. The fact that this function's range is [0, 1], which makes optimization more difficult, is the function's primary drawback. Because of its slow convergence, it is particularly well-suited for issues involving binary categorization. It has a problem with the gradient disappearing into nothingness. The activation function of the hyperbolic tangent, abbreviated as tanh, takes the form

$$f(x) = \frac{1-\exp(-2x)}{1+\exp(-2x)} \quad (7)$$

Fig. 6. TanH activation function.

Fig. 7. ReLU activation function.

The ReLU function ranges between 0 and 1 (Fig. 7). It provides six times better convergence compared to TanH. The model is recommended for usage in intermediate layers, as it might lead to dead neurons if the input contains negative values. In the proposed approach the input and hidden layers use ReLU activation function, while the output layer uses linear activation. The S curve can also be seen in this function's plot. On the other hand, the output values are in the range of -1 to 1. This makes it much simpler to perform optimizations. However, this function also has a problem called vanishing gradient, which makes it difficult to evaluate (Fig. 6).

The phenomenon known as the "vanishing gradient problem" typically occurs in models such as neural networks that permit the backpropagation of errors. The fact that errors are typically calculated in the final output layer is the most significant problem. As a result, the layer that comes immediately before the final layer is responsible for handling the faults that have the greatest impact. However, despite the fact that faults are passed on to early layers, each layer is responsible for handling problems and only passes on errors

that are still present to subsequent layers. As a consequence of this, the earliest layers do not typically get a significant amount of influence from the faults. Because of this, the early layers are the ones that take the most time to train. On the other hand, the early layers are the ones in charge of recognising fundamental patterns, which serve as the fundamental constituents of the neural network model. The whole neural networks model converges more slowly as a consequence of this issue. This problem was addressed with the development of the ReLU function. This is the form it takes.

F. Model Fitting Phase

The building of a functional model or architecture is required before the neural network can be created in the phase that came before this one. Fig. 8 depicts the order in which an artificial neural network model is developed and put into operation. The process of model fitting is the activity that actually carries out the training of the network. Before moving on to the next step, the data is first partitioned into two distinct sections: the data section and the labels section. The data part contains the attributes, with the exception of the class attribute; the class attribute is located in the labels section. The data from the training session are input into the neural network model so that it can perform the necessary analysis. The epoch value determines the total number of training iterations that the backpropagation network undergoes before being considered fully trained. The training continues until an error rate that meets the requirements is achieved. The data that needs to be forecasted is sent over this network, and then the conclusions drawn from those predictions are obtained.

Fig. 8. Neural network operational sequence.

IV. RESULTS AND DISCUSSION

Python and the Keras library suite were used to create the MLDN architecture that has been presented. The model has been validated through the utilisation of industry-standard benchmark datasets such as NSL-KDD, KDD CUP 99, and Koyoto 2022+ datasets. The network is constructed with the help of Sequential API, and then the layers that make up the neural network are added. To properly analyse each dataset, a unique network architecture will need to be developed. Tables

II, III, and IV present the structures that were developed for each of the datasets that were utilised.

TABLE II. NEURAL NETWORK CONFIGURATION FOR NSL-KDD

Layer (Type)	Activation Function	Input Dimension	Output Shape	No. of Parameters
Input (Dense)	Linear	41	(None,80)	3360
Processing 1 (Dense)	ReLU	80	(None,100)	8100
Processing 2 (Dense)	ReLU	100	(None,50)	5050
Processing 3 (Dense)	ReLU	50	(None,50)	1530
Output (Dense)	Linear	30	(None,1)	31
Total No. of Parameters				18,071
Trainable Parameters				18,071
Non-trainable Parameters				0

TABLE III. NEURAL NETWORK CONFIGURATION FOR KDD CUP 99

Layer (Type)	Activation Function	Input Dimension	Output Shape	No. of Parameters
Input (Dense)	Linear	38	(None,50)	1950
Processing 1 (Dense)	ReLU	50	(None,250)	12,750
Processing 2 (Dense)	ReLU	250	(None,100)	25,100

Total No. of Parameters				33,291
Trainable Parameters				33,291
Non-trainable Parameters				0

Fig. 9 presents the results of an evaluation of how well the suggested MLDN model performed on the NSL-KDD, KDD CUP 99, and Koyoto 2022+ datasets in terms of their respective ROC charts. The False Positive Rate (FPR) is represented by the x-axis, and the True Positive Rate (TPR) is represented by the y-axis in this graph (TPR). It is anticipated that an effective model will demonstrate high levels of TPR while exhibiting low levels of FPR. After the points have been plotted, the graph demonstrates that the suggested model has ROC curves that are located at the (0, 1) or top-right position. This indicates that the proposed model is effective. Fig. 10 depicts the PR curve, which represents the accuracy and recall levels of the proposed model over all three datasets. An efficient model should display high values on the x-axis for recall and also display high values on the y-axis for precision (y-axis). The graph that represents the PR plot demonstrates that all three datasets have high levels of accuracy and recall, which demonstrates that the suggested model has a high level of prediction performance.

On the NSL-KDD, KDD CUP99, and Koyoto 2022+ datasets, the values that were obtained for a variety of performance measures such as FPR, TPR, Recall, and Precision, among others, are provided in Table V. The MLDN model that was proposed has levels of TPR and Precision that are extremely high, which is an indication of its effectiveness in predicting intrusion signs. In a similar vein, a high TNR level is indicative of the fact that the presented model demonstrates excellent prediction efficiency when it comes to anticipating normal transmission signals. In a similar vein, low FPR and FNR levels of less than one percent imply that the model has exceptionally low levels of incorrect predictions. As a result of this, it is abundantly clear that the MLDN model that was proposed is efficient and offers good performance.

Alterations were made to the settings of the parameters, and a sensitivity analysis was carried out on each of the three datasets in order to determine how the learning rate and the number of epochs affected the results. During the study, multiple parameter pairs were employed, and the accuracy that was acquired for each parameter combination was used during the analysis.

Table VI contains the acquired results for perusal. Within the first five sets, the learning rate is manipulated while the epoch is held constant (P1 to P5). It was possible to see that, as the learning rate was decreased, the performance on all tree datasets tended to decline to some degree, and this tendency increased as the learning rate was decreased further (P1 and P2). The learning rate is decreased, and as a result, the model takes increasingly minute steps in the direction of the best answer. As a result, 50 epochs were insufficient to accomplish the goal of achieving convergence. Taking the example of P11, where the number of epochs is increased, demonstrates that the model was able to reach convergence. When the learning rate is increased, such as in P4 and P5, the results demonstrate a decrease in performance.

TABLE V. PERFORMANCE ANALYSIS OF MLDN

Measures	NSL-KDD	KDD CUP 99	Koyoto 2022+
FPR	0.001934	0.001254	0.005605
TPR	0.991718	0.998519	0.93578
Recall	0.991718	0.998519	0.93578
Precision	0.997917	0.995079	0.953271
TNR	0.998066	0.998746	0.994395
FNR	0.008282	0.001481	0.06422
Accuracy	0.995	0.9987	0.988012
F-Measure	0.994808	0.996796	0.944444
AUC	0.994892	0.998632	0.965087

Fig. 9. ROC curve comparison of MLDN.

Fig. 10. PR curve comparison of MLDN.

TABLE VI. SENSITIVITY ANALYSIS RESULTS

Parameter Set	Learning Rate	Epochs	NSL-KDD	KDD CUP 99	Koyoto 2022
P1	0.1	50	0.94	0.937	0.913
P2	0.3	50	0.97	0.959	0.944
P3	0.5	50	0.995	0.999	0.979
P4	0.7	50	0.991	0.999	0.973
P5	1	50	0.89	0.926	0.851
P6	0.5	10	0.72	0.69	0.583
P7	0.5	25	0.79	0.829	0.811
P8	0.5	70	0.995	0.999	0.979
P9	0.5	100	0.995	0.999	0.979
P10	0.5	200	0.995	0.999	0.979
P11	0.3	200	0.995	0.999	0.978

This is because an increased learning rate results in big steps, and as a consequence, the model has a tendency to miss the ideal convergence point. Epochs are changed while the learning rate remains the same in parameter sets P6 to P10. It is clear from the reduced epochs (P6 and P7) that the model is not being given a long enough period of time to converge. As a result, the highest possible degree of precision is not achieved. The highest levels of precision can be attained when the period is advanced to 50 (P3) and beyond (P8 to P10). It has been noticed that using 50 epochs provides the highest level of accuracy. After reaching this point, increasing the number of epochs will have no effect on the performance because convergence will have already been reached by that point.

It is possible to summarise that the rate of learning plays an essential part in the achievement of successful results. It is vital to locate the best convergence level and the sweet spot that corresponds to it. Any number less than this point necessitates additional time for the model to converge, and any value greater than this point will cause the model to miss the point at which it converges. Epochs represent the number of times that the training data should be iterated through by the model in order to reach convergence. If there are fewer epochs than necessary, the model will not have enough time to converge, and if there are more epochs than necessary, there will be an additional time overhead with no improvement in performance. In addition to that, it will also result in overfitting, which is why it ought to be avoided. Comparisons are made between the HBM model proposed in Part 3 and the APID model proposed in Part 4 in terms of TPR, TNR, Precision, F-Measure, and AUC on the NSL-KDD, KDD CUP 99, and Koyoto 2022+ datasets, which are depicted in Fig. 11 to 19.

A comparison of TPR, TNR, Precision, F-Measure, and AUC on NSL-KDD data demonstrates that the MLDN model exhibits better prediction levels when compared to APID and HBM (Fig. 11 to 13). This is shown by the fact that the MLDN model has a higher AUC.

Fig. 11. Comparison of TPR and TNR of MLDN, HBM and APID on NSL-KDD.

Fig. 12. Comparison of precision and F-Measure of MLDN, HBM and APID on NSL-KDD.

Fig. 13. Comparison of AUC of MLDN of MLDN, HBM and APID on NSL-KDD.

Fig. 14. Comparison of TPR and TNR of MLDN on KDD CUP 99.

Fig. 15. Comparison of precision and F-Measure of MLDN on KDD CUP 99.

Fig. 16. Comparison of AUC of MLDN on KDD CUP 99.

Analysis of performance on KDD CUP 99 dataset shown in Fig. 14 to 16 demonstrate that in comparison to the APID model, the performance of the MLDN model that has been proposed is superior. In contrast to this, the performance levels demonstrate a marginal drop of 0.1% when measured against the HBM model. The levels of reduction are so negligibly very low that they can be ignored as a result.

Fig. 17. Comparison of TPR and TNR of MLDN on Koyoto 2022+.

Fig. 18. Comparison of precision and F-Measure of MLDN on Koyoto 2022+.

Fig. 19. Comparison of AUC of MLDN on Koyoto 2022+.

When compared to the other models, the performance of the proposed MLDN model on the Koyoto 2022+ datasets shows a slight decrease in the performance with respect to certain metrics such as TPR and F-Measure. Even in this case,

the reductions are extremely minimal and, as a result, are insignificant.

Table VII provides a tabular representation of the performance comparisons that were made. The table demonstrates that the overall performance of the proposed models was found to be high and effective, despite the fact that there are slight reductions and elevations in the performance levels of the proposed models.

Table VIII presents a comparison of the amount of time spent training and testing the APID, HBM, and MLDN models. Training is carried out using 70 percent of the records contained in the data, while testing has been carried out using 30 percent of the records across all of the datasets. The HBM model has the most efficiency with regard to its use of time, followed by the APID model and then the MLDN model. Testing requirements for the MLDN model are always less than one second, which is a low requirement that corresponds to a real-time prediction scenario. The training requirements for the MLDN model are quite high. In addition, the little increase in the amount of time needed could be neglected due to the significant boost in terms of performance, which would make the MLDN model the most effective performer when it comes to the detection of intrusions in networks.

The results of a comparative analysis of the proposed MLDN model with the HBM model, the APID model, and models proposed by [5, 6], [7], [8], and [9] are shown in Fig. 20 to 22. This analysis compares the proposed MLDN model with the HBM model and the APID model.

In comparison to other models that are currently available in the literature, the suggested models have a higher level of accuracy in their prediction, as shown in Fig. 20 to 22. The MLDN model produces the best results in terms of performance, followed by the HBM model, which delivers the results with the next best performance. After this comes the APID model, and after that comes the models that already exist in the literature.

TABLE VII. PERFORMANCE COMPARISON OF APID, HBM AND MLDN

Measures	NSL-KDD			KDD CUP 99			KOYOTO 2022+		
	APID	HBM	MLDN	APID	HBM	MLDN	APID	HBM	MLDN
TPR	0.99	0.99	0.99	0.99	1.00	1.00	0.98	0.88	0.94
Precision	0.99	0.99	1.00	0.99	1.00	1.00	0.94	0.88	0.95
TNR	0.97	0.99	1.00	0.97	1.00	1.00	0.99	0.99	0.99
Accuracy	0.99	0.99	1.00	0.99	1.00	1.00	0.99	0.98	0.99
F-Measure	0.99	0.99	0.99	0.99	1.00	1.00	0.96	0.88	0.94
AUC	0.98	0.99	0.99	0.98	1.00	1.00	0.99	0.93	0.97

TABLE VIII. TIME COMPARISON OF APID, HBM AND MLDN

	NSL-KDD		KDD CUP 99		Koyoto 2022	
	Training (sec)	Testing (sec)	Training (sec)	Testing (sec)	Training (sec)	Testing(sec)
MLDN	50	0.259	4	0.316	2	0.279
HBM	2.24	0.21	0.209	0.102	0.107	0.098
APID	2.42	0.302	0.257	0.108	0.0962	0.054

Fig. 20. Comparison of accuracy of MLDN with state-of-the-art models on KDD CUP 99.

Fig. 21. Comparison of accuracy of MLDN with state-of-the-art models on NSL-KDD.

Fig. 22. Comparison of accuracy of MLDN with state-of-the-art models on Koyoto 2022+.

A tabular representation of the findings is presented in Table IX. The best results are highlighted in bold below. It was found that the proposed models performed better than all of the existing models that were researched and used as a point of comparison in the literature. In general, methods are constructed with data as their foundation. When utilised with a wider variety of data, such data-specific models are unable to generate results that are beneficial. This particular illustration could be effectively noticed in models from the literature, where models perform better in certain cases while performing worse in others. Because the models that are provided are generic, it is possible to see that the proposed model performs well regardless of the dataset that is being used. This is because the offered models are general.

TABLE IX. PERFORMANCE COMPARISON WITH STATE-OF-THE-ART MODELS

KDD	
Technique	Accuracy
APID	0.99
HBM	1.00
MLDN	1.00
CANN	0.99
LMDRT-SVM	0.99
LMDRT-SVM2	0.99
NSL-KDD	
Technique	Accuracy
APID	0.99
HBM	0.99
MLDN	1.00
LMDRT-SVM	0.99
LMDRT-SVM2	0.99
TVCPSO-SVM	0.98
TVCPSO-MCLP	0.97
OS-ELM	0.98
Koyoto 2022+	
Technique	Accuracy
APID	0.99
HBM	0.98
MLDN	0.99
OS-ELM	0.96
LMDRT-SVM	0.98
LMDRT-SVM2	0.98

V. CONCLUSION

The initial work provides the Adaptive Parallelized Intrusion Detection (APID) model, which is utilised for finding intrusion signs from data that is sent within a network. This model was developed by the researchers. The transmission data that is later sent to the model is first subjected to pre-processing, and then training bags are produced. The training data bags are then given to the learners at the basic level. The training for every base learner is determined by the training bag that is given to it. The learner that demonstrates the best prediction rates in terms of normal data prediction and in terms of the best overall prediction is determined to be the basic learner.

The final predictions are obtained by utilising heuristic-based combiners, after which the test data are forecasted by using all of the basic learners. After that, the ensemble is retrained based on the false predictions to produce an adaptive model that is capable of changing itself to produce better predictions over the course of time. Despite the fact that the model delivers impressive results, it is not appropriate for use for processing large amounts of data because of the significant computational cost connected with it. In the following

contribution, a Heterogeneous Bagging based Model, or HBM, is presented with the goal of reducing complexity levels. This model features an improved bagging method that makes it possible to detect intrusions both more quickly and more accurately. The training data is divided up into various bags that also overlap with one another. Both the Decision Tree and Random Forest models are utilised here as the foundation learners for the model. The bagging procedure is altered in such a way that each data bag is made available to both models. Each of the bags that are constructed gets its own unique set of several pairs of base learners.

On the basis of these models, predictions are made, and the results of those predictions are combined with the votes from the voting combiner. While this model does a better job of simplifying complex processes, its performance is marginally inferior. A deep learning network-based intrusion detection model, known as the MLDN, is presented as the last contribution. This is done in order to improve efficiency. The Keras library was utilised during the construction of the deep learning model. In order to accommodate the specific processing architecture of neural networks, the training data is preprocessed and partitioned.

The network is built with various layers, and all of the other necessary parameters for the network are configured based on the data that is entered. Validation of the trained model is accomplished by employing the validation data that has been meticulously isolated for the sole purpose of fulfilling this requirement. Standard benchmark datasets, such as KDD CUP99, NSL-KDD, and Koyoto 2022+ datasets, were utilised in the experiments that were carried out. Comparisons were made with previously published models that were already in existence. The analysis was carried out using the existing standard performance metrics for classifiers, which included TPR, FPR, TNR, FNR, Precision, Recall, F-Measure, and Accuracy. According to the findings, the proposed models appear to have superior performance levels when compared to the standard models that are currently in use.

Abstract—The coloring of sketches has a constant market demand in the area of research. The difficulty of the coloring sketch outline is its lack of texture and color. Take footwear design as an example, it is difficult for designers to complete a colorful sketch in a limited time, so an artificial intelligence technology for coloring shoes is required. Though we do not build a new GAN, which is based on pix2pix. We try to integrate the existing model in four ways, including generator, discriminator, loss function and comparison. In this paper, given a set of edges-to-shoes that have 50,025 shoe images, our approach produces an image with vivid shoes images. Unlike the recent research, our approach is not based on a unique adversarial training. We show that shoe sketches can be synthesized from simple lines by a GAN into a high-resolution picture. In particular, we offer a new model to synthesize high-resolution photo-realistic images of shoes, and apply a multi-discriminator to train and distinguish the generated images. Our model enables the shoe designer to benefit from the colorization design.

Keywords—Footwear sketch; generative adversarial network; image to image translation; colorization

I. INTRODUCTION

In the footwear industry, color sketch is a time-consuming step in design period for designers. Creating a concept map of colorful shoes requires a professional color, composition and valid use of shade and texture. This process demands experienced drawing expertise and a good sense of design aesthetics. Even the experts would spend much time coloring the sketches.

In the design process, designer may decrease the needless hours if they overcome the colorization issues. As a result, a standalone coloring system can be a suitable solution for the footwear design industry. With the help of this system, the newcomer can be inspired, while professors save more time on color compositions of product sketches. This idea may totally change the fundamental structure of product development, which do optimize the industrial structure.

However, a lot of challenges remain to achieve this process. At first it is hard for the machine to understand the sketches of footwear which have innumerable drawing styles. As well, footwear sketches have a limited expression. What's more, there is no guidance for a machine to make coloring decisions.

While deep learning in IT vision research is becoming a hot topic, alternative learning-based methods have been developed. For example, Mathias Eitz presented an interactive pattern

recognition system that can identify a human sketch object [1]. Christopher Hesse has operated an online system that can generate cat images from the edges [2]. Although these systems can successfully turn a user sketch into a colorful object, such an application still cannot meet the designer's expectation. In addition, it is hard to shape high-resolution images and images with details and texture. Due to the limitation of an experimental topic, there are still has many opportunities to make progress.

In this article, we propose a method that allows users to enrich their design with hand-made shoes, color based on the Generative Adversarial Networks (GAN). GANs can classify the real or fake images, while forming a model that can minimize the loss. We form our network on an open access edge-to-shoes dataset using a new approach that creates high-resolution images. Different from the previous results with little detail and realistic textures, we explore a new, robust adversarial learning method with multi-scale generator and discriminator framework. This framework can produce a result with better visual quality. In this process, we receive the result with adversarial training rather than any loss by hand-made or pre-trained networks. This method shows that it is possible to improve the addition of perception losses from pre-trained networks. What is more, a multi-discriminator allows a better performance in training and alternative quantitative comparison such as PSNR, SSIM and MSE can have a thorough analysis of the coloring footwear results. Our contributions may be summarized as follows:

- 1) We introduce a new method called local amplifier to synthesize high-resolution photo-realistic images of shoes.
- 2) We consume the discriminator by extending the GAN into a multiple framework while improving the adversarial loss.
- 3) A quantitative comparison using the PSNR, SSIM and MSE is included.

II. RELATED WORK

A. Generative Adversarial Network

In recent years, deep learning has unleashed another wave of artificial intelligence. In particular, in the areas of image recognition, the method based on deep learning [3, 4] has much improved over traditional methods. Their accuracy rate is near to or even greater than that of the manual identification.

The most typical task in unsupervised learning is an image generation [5, 6], and the first image generation model based

*Corresponding Author.

on deep learning is Autoencoder [7]. However, Autoencoder do not have a specific link to measure the error between the reconstructed sample and the real sample. The upgrade model VAE, simply makes the generated images more similar to the database images, instead of learning the generative paradigm for obtaining new images.

A new architecture called the generative adversarial network [8] attempts to resolve this problem. The standard GAN model is made up of two parts, one generator and one discriminator. It no longer updates the generator solely by measuring the similarity between the generated image and the actual image. However, it implements adversarial training through a discriminator, so that the generator can learn then latent picture mode. Meanwhile the distribution is nearer to the distribution of reality.

Today, GAN has become the main model for picture generation [9, 10, 11] and even unsupervised learning. It not only occupies the mainstream in academia, but also has made great achievements in fashion, advertising, audio and video industries, etc.

B. Image-to-Image Translation

The conditional generative adversarial network [12] highlights, automatic Image-to-Image translation, which teaches input mapping to output images has been applied to various tasks. For instance, generating photographs from sketches [13] or attributes, semantic layouts [14]. Concretely, the generative model of Image-to-Image translation has two parameters or variants that are not parametric and distributes with special algorithms. In an Image-to-Image translation task, a generative model can utilize the distribution of the target domain by generating perfect “fake” data which named translated images to derive from the target domain’s distribution [15]. Popular Image-to-Image translation methods include two-domain and multi-domain [16]. First, two-domain can solve problems like computer vision, image processing by using image style transfer in photo editors to benefit from autonomous driving and image colorization [17]. Secondly, multi-domains focus on creating multiple outputs made up different semantic contents or style textures.

In the future, Image-to-Image translation will increase in resolution and generate variable outputs. And the researchers will generalize the Image-to-Image translation methods within the image field to other aspects such as text, language, speech and also multimodal translation tasks.

C. Colorization

Colorization is a computer assisted method of adding color to an image or film [18]. In 1987, Markle invents a colorization process that paints at least one reference frame. It solved the image problem of visual fatigue, by segmenting images into regions and filling in colors.

In the past, coloring was a time-consuming task that required a professional ability to paint. In order to better reduce processing time of sketching as shown in Fig. 1, several interactive technologies have been offered. Levin uses strokes to both indicate the colors of positive pixels and colorized images with optimization where similar pixels have similar

colors [19]. Colorization technologies embrace that image division can be well defined in a different space. Take interactive manga colorization technology as an example, several groups gather in a measurable cluster before colorization. Luan presents an interactive system through color labelling and color mapping for greyscale images, in the absence of complex texture grouping techniques that further improve the system usability [20]. Cheng has a high-quality comprehensive colorization method, but it needs to train on a huge set of reference image data that contains all of the objects [21]. Gupta introduced a sample-based solution to colorize a grey image, adopting a quick cascade feature mapping scheme to voluntarily match matches between reference and target images. While the process still needs to prepare a color example, which is semantically similar to the grey image [22]. In a word, automatic segmentation often failed to identify the complex drawing color, especially the alternative colored selection of different experimental subjects. They have multiple sketch lines and gray image feature. For instance, a difference between fashion and sporty shoes. To solve this problem, we are going to invent more and more techniques of colorization.

Nowadays, we are making advances in colorization. The machine can produce a colorful sketch with little mistakes which is impossible in the previous time presented in Fig. 2. Subversive colorization techniques such as CIC, LTBC, Pix2pix and DC used CNNs appear [23]. Generative coloring designs extend the unconditional image generation to a better vision. These optimization-based methods and learning-based methods have put forward to successfully colorize line sketches or grayscale photos. They can create dramatic color images without any hand-made help.

In the coming years, especially in the field of coloring sketches, increasingly efficient method will be taken. And the object will be a variable that can inspire further investigation in this direction in the generative modeling of the sketch.

Fig. 2. Sketches manual colorization.

III. METHOD

To optimize outputs, we construct a conditional adversarial frame to generate a high-resolution shoe image from line sketches. Apart from generation, we use multi-discriminator variants which increase the difficulty of the generator screening sequence. Initially, a basic model of pix2pix is proven. Second, we explain how to accelerate the image reality and resolution of the picture with a GAN frame design. In addition, the adversarial loss is also considered, which can stabilize the training process.

A. The pix2pix Baseline

Pix2pix method is one of the extensions included in the conditional GAN framework for image-to-image translation [24]. The design framework composed of a generator G and a discriminator D . In our research, the aim of our generator G is to colorize the footwear line sketches to complete concept images, while the discriminator D calculated with the purpose of distinguish real images from the forger. The operation consists of a supervised setting. To sum up, the training dataset is provided as a pair of comparative images $\{(s_i, x_i)\}$, where s_i is a purely footwear shape line sketch and x_i is a corresponding real photo. The purpose of conditional GANs is modeling the assumed distribution of real shoe images by enriching the input line sketches via the underlined minimax operation:

$$\min_G \max_D \mathcal{L}_{GAN}(G, D) \quad (1)$$

And the objection function $\mathcal{L}_{GAN}(G, D)$ is given by:

$$\mathcal{L}_{GAN}(G, D) = \mathbb{E}_{(s, x)} [\log D(s, x)] + \mathbb{E}_s [\log(1 - D(s, G(s)))] \quad (2)$$

The pix2pix method applies U-Net as the generator [25], simultaneously applies fully convolutional patch-base network as discriminator [26]. We put a series of sketches of footwear line and comparative image to the discriminator as our input.

B. Coarse-to-fine Generator

As the resolution of the training images is unstable and the lesser quality, we further improve our pix2pix frame based on the baseline above, the figure presented in Fig. 3. In the beginning, we split the generator into two parts, named G_1 and G_2 . Whereas G_1 is a global network of generators, G_2 has a local network of multipliers. Below is an overview of G_1 and G_2 . The overall generator network's resolution is 256×256 , and the local multiplier network is calculated with an output twice the size of the latter. To integrate a better product image resolution, we can join local excess multiplier networks. For

example, when using G_1 and G_2 as the generator sections, the resolution of the final output image is $G = \{G_1, G_2\}$ is 512×512 . However, the resolution grew when $G = \{G_1, G_2, G_3\}$ is 1024×1024 .

As a vital example of global generator, Johnson et al. [27] constructed a neural network framework for 512×512 image style transfer. The framework is composed of three parts including $G_1^{(F)}$, $G_1^{(R)}$ and $G_1^{(B)}$. $G_1^{(F)}$ represented a convolutional front-end, $G_1^{(R)}$ represented as a set of residual blocks and $G_1^{(B)}$ represented a transposed convolutional back-end. The input of the generator is a 256×256 image, and output of our process operating three parts is an image of 256×256 in resolution.

Apart from global generator, the local enhancer network is composed of three sections as well. And the components, respectively named $G_2^{(F)}$, $G_2^{(R)}$, $G_2^{(B)}$. Firstly, $G_2^{(F)}$ is called a convolutional front-end. Secondly, $G_2^{(R)}$ is called a group of residual blocks, $G_2^{(B)}$ is called a transposed convolutional back-end. We use an input line sketch image to G_2 resolution of which is 512×512 . Comparing to the global generator, the input of residual block $G_2^{(R)}$ is made up of two feature schedules, the output of $G_2^{(F)}$ and the $G_1^{(B)}$. This manipulation assists to synthesize the entire image information from G_1 to G_2 .

In our training course, we operate the global generator before the local enhancer at a certain resolution. After adjusting all the element, the global and local material for shoe line sketches is assembled for image compound. It is obvious that this image generates framework with two-scale is efficient [28]. Other architectures with common usage can be found, such as unconditional GANs or image generator.

C. Multi-scale Discriminators

It's difficult for the GAN discriminator to generate high-resolution images. In order to separate the high-resolution real and forger images, the discriminator should have a comprehensive production program [29]. Aim to accelerate the framework's ability and decrease the overfitting, our process commands an embedded network and larger convolutional kernels. Our memory space usage, which has a high-resolution image generate function should be large enough for training.

As a maintain problem, we address multi-scale discriminators to cope with it in Fig. 4. We apply multiple discriminators which have a definite network framework but operate multiple image scales. It's obvious that a multi-discriminator which approximate $\max D V(D, G)$ can be a good transfer to the generator.

Fig. 3. Two sub-network generators, G_1 for low resolution images, G_2 for high resolution images appending to G_1 input and utilizing the last map from G_1 .

Fig. 4. Multiple discriminators.

To provide a better source for generator, it's necessary to maximize $G(V_i)$. The discriminators are randomly presented, gathering all the optimized V such as the stochastic gradient ascent. $\max_{i \in \{1, N\}} V(D_i, G)$ is the loss of the generator which copes with the problem rendered by the non-convexity of complexes V . In order to minimize the max forces G , we must monitor all of the N discriminators. When we are operating, $\max_{D_i \in D} V(D_i, G)$ doesn't have countless elements, so the above framework is complicated. However, the quantity of the discriminator is still an effective factor.

For example, we construct three discriminators called D_1, D_2, D_3 . In particular, we collect the actual images and compound at high-resolution images by several parts to create a pyramid of image of three scales. All of the three discriminators D_1, D_2, D_3 trained to separate the real and forged at three different scales. To analyze one of the three discriminators, the discriminator that used the roughest scale with the entire field, generating corresponding overall images. Moreover, there is a discriminator with the role of enhancing the finest scale that can produce more specific. This operation allows the calculation to produce higher resolution images that can be an optimized method. By comparing with the previous equation, the multi-scale discriminators equation is:

$$\min_G \max_{D_1, D_2, D_3} \sum_{k=1,2,3} \mathcal{L}_{GAN}(G, D_k) \quad (3)$$

It has been shown that this is a useful method for using multiple GAN discriminators on the same scale. Many researchers have applied the multi-discriminator model to synthesize a better image output [30]. And our purpose is the production of high-resolution images.

D. Improved Adversarial Loss

Our former equation of the objection function LGAN (G, D) has already improved the GAN loss. The steady operation of this loss function helps to produce dramatic results at multiple scales. The process identifies various characteristics of the alternative layers of the discriminators in order to match uncertain representation images. To increase completeness, the following calculation formula is used:

$$\mathcal{L}_{FM}(G, D_k) = \mathbb{E}_{(s,x)} \sum_{i=1}^T \frac{1}{N_i} \left[\left\| D_k^{(i)}(s, x) - D_k^{(i)}(s, G(s)) \right\| \right] \quad (4)$$

where T in the equation means the total quantity of layers and N_i represents the sum of elements in layers. We use the

discriminator related to perceptual loss, and we discuss how to make more progress in operational performance. With the combination of GAN loss and characteristic mismatch loss, the equation is:

$$\min_G \left(\left(\max_{D_1, D_2, D_3} \sum_{k=1,2,3} \mathcal{L}_{GAN}(G, D_k) \right) + \lambda \sum_{k=1,2,3} \mathcal{L}_{FM}(G, D_k) \right) \quad (5)$$

In this equation, λ is the critical point of two terms, explaining that for loss LFM, D_k is a main extractor.

E. Quantitative Comparison Metrics

To better measure the quality of our experiment, we conduct some evaluation on the synthesized images and true label with these metrics below.

Firstly, SSIM is also a famous quality measurement for testing difference between two image samples [31]. Wang developed the SSIM for calculation related to the image quality of the human visual system [32]. The difference of SSIM is its applications of three factors apart from considering the addition of all image error. The luminance comparison function calculates the similarity of two samples' luminance ($\mu_f \mu_g$). The contrast comparison function calculates the closeness of two images' contrast ($\sigma_f \sigma_g$). And the structure comparison function measures the correlation coefficients of image f and image g noting that σ_{fg} is the covariance. The SSIM index positive values are in $[0, 1]$.

The SSIM can be presented as:

$$SSIM(f, g) = l(f, g)c(f, g)s(f, g) \quad (6)$$

Moreover, the $l(f, g)$, $c(f, g)$ and $s(f, g)$ It can be described as follow:

$$l(f, g) = \frac{2m_f m_g + c_1}{m_f^2 + m_g^2 + c_1} \quad (7)$$

$$c(f, g) = \frac{2s_f s_g + c_2}{s_f^2 + s_g^2 + c_2} \quad (8)$$

$$s(f, g) = \frac{s_{fg} + c_3}{s_f s_g + c_3} \quad (9)$$

Secondly, MSE (Mean Square Error) is one of the most popular applications which utilized the integrated sample which measured by square intensity differences of various images pixels [33]. In addition, MSE considers the whole reference metric and the final score are better if it values closed to 0. The equation can be defined as:

$$MSE = \frac{1}{MN} \sum_{n=0}^M \sum_{m=1}^N \left[\hat{g}(n, m) - g(n, m) \right]^2 \quad (10)$$

Lastly, PSNR (Peak signal-to-noise ratio) is a common coherence quality measurement for system operation especially in the video or image sample. It is a simple metric that

researchers utilize the method to evaluate and develop the visual sample quality. Huynh-Thu et al. show that PSNR could be a useful indicator when the content and codec have analogue. However, the situation changed when the different samples mix together [34]. It is said that the higher PSNR value gains a higher visual sample quality, low quality results from image otherness.

Sometimes noisy samples may affect our evaluation results, and studies have shown that PSNR mixed with MSE have the best performance of evaluating the quality of noisy samples. For example, when applying image degradation PSNR value presented between 30-50 dB for 8-bit data or 16-bit data. The equation can be defined as (11) below, peak value (which we denote by *peakval* in the equation below) means the maximum of the image sample data. For an unsigned 8-bit integer data type, the *peakval* is 255.

$$PSNR = 10 \log_{10} (peakval^2 / MSE) \quad (11)$$

IV. EXPERIMENT

A. Datasets

We perform our method on the Edges2shoes data set, which has been obtained from the official Pix2Pix Datasets directory from Pix2Pix Datasets [35]. The total data set is 50,025, one data pair contains an art line and the color image corresponding to the art line. The task is to map the line art to the color picture, such as the colorization task. To form a model with enhanced generalizability, we randomly sampled 49,825 pairs of images from the original dataset as a training set. After completing the model formation process, we need the test set to evaluate quality, so that the remaining 200 data pairs are used as the test set. Fig. 5 shows edge2shoes sample training information:

B. Implement Details

Our model is improved from pix2pix [15], to check the quality of the model generation, we compared with some models in the colorization task. All of these methods are performed using public codes and the Edges2shoes data set for training and testing in the same experimental environment for comparison purposes. We are experimenting on the computer with an RTX 3090 with 24 GB GPU memory and the PyTorch frame. The model parameters are optimized by the Adam optimizer [36], whose hyper-parameters β_1 and β_2 is set to 0.5 and 0.999, respectively. The training periods are 100 to ensure the convergence of model weights can converge.

Our loss model includes multi-scale GAN loss and feature mapping loss and the latter one plays a significant role in making the training process more stable. We carry out a hyper-parameter search on λ in order to obtain the most effective value for the model. We limit the lambda value between 1 and 10 since λ will bring a blurred image. Fig. 6 shows that all the metrics SSIM, MSE, PSNR achieve best at $\lambda = 5$. Consequently, we define $\lambda = 5$ in the training process.

Fig. 5. Samples of edge2shoes in the training set.

Fig. 6. SSIM, MSE, PSNR with different λ selection.

C. Comparison with state-of-the-arts

From the Table I, we can obtain that our ATTGAN method achieved a significant improvement in SSIM with the SOTA models. Regarding the performance of the PSNR metric for image quality measurement, our method may outperform the other models. In terms of MSE, our ATTGAN method can also achieve the lowest score, which shows that the difference between the image generated and the real image is smaller in pixel. The visualization results can be shown in Fig. 7. It is not difficult to see that our model can get different shaded areas according to precise colors. But they also have local details.

D. Ablation Study

We conduct ablation studies on the Edges2shoes data set to find out how the effectiveness of our upgrades are. From Table II, we can see that all assessment measures are improved, proving that all our improvements are effective. Among them, the metric PSNR has the largest optimization effect.

TABLE I. PERFORMANCE WITH DIFFERENT METHODS OF TRANSLATION ON EDGES2SHOES

Method	Evaluation Metrics		
	SSIM	MSE	PSNR
CycleGAN	0.5812	4.7832	16.1214
Pix2Pix	<u>0.7192</u>	<u>3.6011</u>	<u>20.1621</u>
NiceGAN	0.6374	4.5172	17.8964
ATTGAN	0.7881	3.4835	20.8526

TABLE II. PERFORMANCE WITH DIFFERENT COMPONENTS OF TRANSLATION ON EDGE2SHOES DATASET

Components			Evaluation Metrics

✓	✓	✓	20.8526	0.7881	3.4835

V. DISCUSSION

Here, we try to analyze the influence and importance of several aspects in our experiment.

First of all, the results of the experiment prove that in conditional GANs are able to generate high-resolution images of real footwear photos without any manual control or preparation. The combination of perception loss can improve the image generation results [37]. This approach is effective for studies where the aim is to produce high-resolution image results. At the same time, the researcher has benefited from this method in which pre-training for the exam is prohibited.

What’s more, we used multiple discriminators in our GAN network and developed discriminator features exchanging an immersive opponent into effective filters. This GAN network introduces the N-discriminator extension, called Generative Multi-Adversary Networks, which make automatically progress in performance.

Third, the loss matching function fixes the formation where the generator is required to produce image statistics at various scales. This process improves the operational mechanism of the loss function.

Finally, we examine the evaluation measure by PSNR, SSIM, MSE. Treating the pix2pix method as a baseline, we evaluate that ATTGAN has the best performance compared with CycleGAN, Pix2pix and NiceGAN. By three translation methods on Edges2shoes, $\lambda = 5$ in the training procedure gain the best consequence to all. There is no doubt that all measures of evaluation have the highest ratings when it comes to drawing attention, presenting a characteristic and choosing a multi-scale discriminator. While others may have less effort and just below the best.

We believe that the automatic footwear colorization gives designers a chance to minimize the coloring time of the finish drawing line. To implement this automatic colorization footwear design, we are improving the resolution based on an earlier study in another area. At the same time, we make certain multi-discrimination to help the quality of the generation image. We may conclude that the approach for footwear colorization helps to accelerate the effectiveness of the coloring process. However, there are still limitations of the experiment. When the sketch line presented too complex or messy, it would have unavoidable identification errors throughout period. Nevertheless, the color slightly changed which caused by computing constraint.

Fig. 7. Examples of the Edges2shoes colorization by our model.

In the future, designers may have more measures for eliminating colorization time. The development of automatic colorizing solves the problems for selecting color styles and finishing handmade draft. Furthermore, it becomes possible for customers to do DIY based on their individual sketching creation. With the help of artificial intelligence, the distance between manufacturer and consumer brings closeness. It might totally change the current situation of the footwear industry, especially in the post-pandemic era. Consumers may realize their own ideas by interaction media, which even reduce the working-hours of designers. It is no doubt that co-creation of products will be a trend of the times.

VI. CONCLUSION

In this research, we introduce a conditional GAN network for coloring sketches of shoes. The whole process divided into generator and discriminator, which help to perform better for coloring shoes. These methods decrease the difficulties of comparing evaluation measures. The results of our experiments are consistently visual. We believe that our method for coloring shoe sketches can have a good inspiration in the area of research to generate color sketch image samples.

Multi-Exposure Image Fusion based on Window Segmentation and a Laplacian Pyramid for Chip Package Appearance Quality Detection

Fei Hao¹, Jiatong Song², Jiahao Sun³, Yang Fu⁴

Kangni Industrial Technology Research Institute, Nanjing Institute of Technology, Nanjing, China

Abstract—A heterogeneous material image enhancement method based on multi-exposure image fusion is proposed to address the problem of obtaining high-quality images from the single imaging of chips containing two extremely different reflectivity materials. First, a multi-exposure image fusion algorithm based on window segmentation and Laplacian pyramid fusion is proposed. Then, orthogonal experiments are used to optimize the parameters of the imaging system. Next, a method based on information entropy and average gray intensity is utilized to calculate the imaging exposure times of two heterogeneous materials, and two exposure time ranges are obtained that are appropriate for regions with high and low reflectivity. Finally, the subjective and objective experimental evaluations are conducted after the multi-exposure image set has been established. The results show that the fused image has a good visual effect, the information entropy is 6.29, and the average gray intensity is 131.56. In addition, time consumption is reduced by an average of 20.3% compared to the Laplace pyramid strategy. The heterogeneous material enhancement method based on multi-exposure image fusion proposed in this paper is effective and deserving of further research and application.

Keywords—Image fusion; multi-exposure; Laplacian pyramid; window segmentation; chip package

I. INTRODUCTION

Chip defect detection typically includes size measurement, character detection, stain detection and pin defect detection [1]. It is found that because chips in ordinary cameras contain both high reflectivity metal and low reflectivity black plastic, they cannot capture all information through a single image when collecting images [2]. At present, there are devices for directly acquiring high dynamic images [3], but such hardware devices have high cost and few applications, so software algorithm enhancement methods are widely considered instead.

This paper aims to propose a new multi-exposure image fusion method to improve the image quality of an object composed of a variety of materials with very different reflectivity. The main contributions are as follows:

- An image fusion method based on window segmentation and Laplace pyramid was proposed.
- The optimal imaging parameters of the established machine vision system were determined by the orthogonal experiments.

- A strategy for determining the optimal exposure time based on information entropy and average gray intensity was proposed.
- The experimental results show that the image information entropy and average gray intensity of the fused image by our method were 6.29 and 131.56 respectively and the time was averagely reduced by about 1.26 s.

The rest of this paper is organized as follows: the first section is the introduction. The second section reviews the related work in multi-exposure image fusion. The third section describes the image fusion algorithm. In the fourth section, the main factors affecting the imaging quality are determined by orthogonal testing, and the level of the influencing factors is optimized. In the fifth section, through information entropy and average gray intensity, the optimal exposure time for imaging objects with multiple heterogeneous materials is determined. The sixth section discusses the experiment and the analysis of the results. Finally, conclusions are presented.

II. RELATED WORKS

Currently, image quality enhancement algorithms are divided into two categories. One is based on single source image enhancement [4], which primarily use the spatial domain and transform domain to enhance a single image to improve the problems of detail loss and uneven lighting. Common spatial methods include grayscale transformation, histogram equalization, contrast enhancement and other methods [5]. Among them, the histogram equalization method is the most commonly used airspace method. The global histogram equalization map is highly efficient, but the enhanced image will easily lose details. Therefore, Celik [6] adopted the local histogram equalization algorithm based on information entropy to solve the problem of image texture loss. The local histogram equalization map can enhance the local details of the image but lacks global integrity. Wavelet transform [7], discrete wavelet transform [8], stationary wavelet transform [9] and other transform domain methods distinguish the basic information and detailed information of the image and perform multi-exposure image fusion. At present, the transform domain algorithm based on the wavelet transform can achieve the effect of enhancing the image [10]. Such methods can enhance the details while taking into account the global whole but also magnify the noise in the image. Therefore, the final result of the single source image enhancement method experiences

noise and loss of detail, which is typically accepted in the field of natural images but is not suitable for size measurement and defect detection.

The other category is image fusion based on multi-source images. Image fusion refers to obtaining different image sequences of the same scene with imaging sensors and combining the details and complementary information of the image sequence to obtain a rich and comprehensive image [11]. Multi-Exposure Fusion (MEF) is one of the branches derived from image fusion; that is, it fuses multiple images with different exposures in the same scene into a new image, preserving the brightest and darkest details in the scene [12]. From the perspective of image decomposition, multi-exposure image fusion can be divided into pixel-based and image block-based fusion methods. Goshtasby [13] first proposed image block-based fusion and calculated the information entropy to select the best image block for fusion, but there was some distortion in the results. Qin Lyu used nonuniform triangulation to segment images [14]. T Prabhakara Rao performed feature-level image fusion based on contour blocking, improved the distortion and played a crucial role in developing its subsequent feature extraction and detection [15]. Compared with the method of nonuniform division of images, the fusion algorithm speed block based on uniform division of image blocks is more suitable for the application of industrial detection occasions, but it mainly emphasizes the selection of the optimal block of the image sequence, which frequently results in issues with discontinuous images and obvious stitching traces. In contrast, Mertens [16] proposed a pixel-based multi-exposure fusion method, which can make up for the shortcomings of discontinuous images but has a high computational complexity and low efficiency. An extremely critical method in pixel-based image fusion is pyramid decomposition [17], which constructs an image pyramid from the input image, adds a weight matrix, and finally combines the two to obtain the final fusion result. Ashish et al. adopted multiresolution fusion based on a Laplacian pyramid [18], measured by entropy and contrast, which is characterized by seamless fusion and excellent improved details. Zhong Qu and others improved pyramid decomposition and applied it to image fusion, improving the common artifact problem of multi-exposure fusion [19] and retaining more local details. The pyramid algorithm can typically preserve good image edges and textures, but the processing time is generally very long. The fusion method based on image blocks can greatly improve the computational efficiency and remove random noise. Therefore, it is expected that combining the pyramid algorithm with the image block algorithm will allow the fused image to maintain better details and improve the operational efficiency of the algorithm.

The optimal exposure time should be primarily determined according to the material characteristics of a specific object for developing the image fusion methods. The image gradient was employed in the fusion method proposed by Turgut et al. [20]. Image information entropy was adopted by Kataoka et al. as the only indicator to determine the exposure time for image fusion [21]. Camera response curve was uniquely selected and used for exposure fusion by Zhang et al. [22]. Thus it can be seen that the common indicators of exposure fusion include

image gradient, image information entropy and camera response curve, and they were used singly at present. However, these above methods may be invalid and inaccurate for objects with multi-materials. Therefore, this paper will also explore a new multivariate strategy to determine the optimal exposure time for imaging objects with multi-materials.

III. MULTI-EXPOSURE IMAGE FUSION METHOD

A. Image Fusion Algorithm based on Laplacian Pyramid

The source image G_0 undergoes multiple Gaussian fuzzy filtering and downsampling operations and continuously reduces the image size to obtain an image sequence $(G_0, G_1, G_2, \dots, G_N)$. The Gaussian pyramid is obtained by arranging G_0 at the bottom and G_N at the top. The essence of the Gaussian pyramid is the multiscale representation of the image signal, as shown in Formula (1). The Laplacian pyramid is obtained by up sampling and interpolation of the Gaussian pyramid [23], and the image sequence can be represented by $(LP_0, LP_1, LP_2, \dots, LP_N)$, as shown in Formula (2).

$$G_l(i, j) = \sum_{m=-2}^2 \sum_{n=-2}^2 w(m, n) G_{l-1}(2i+m, 2j+n) \quad (1)$$

where $w(m, n)$ is a Gaussian convolution kernel with a fixed size.

$$\begin{cases} LP_l = G_l - G_{l+1}^* & 0 \leq l < N \\ LP_N = G_N & l = N \end{cases} \quad (2)$$

where G_{l+1}^* is calculated according to Formula (3):

$$G_l^* = 4 \sum_{m=-2}^2 \sum_{n=-2}^2 w(m, n) G_l\left(\frac{i+m}{2}, \frac{j+n}{2}\right) \quad (3)$$

For multi-exposure image fusion based on the Laplacian pyramid strategy, each layer of images were first processed in multiple Laplacian pyramids according to the strategy in Formula (4) to obtain the fused Laplacian pyramid image sequence, and then obtain the fused source image according to the method in Formula (5).

$$FLP_l = \sum_{k=1}^H \lambda_k \cdot (LP_l)_k \quad (4)$$

where H is the number of multi-exposure images, $(LP_l)_k$ represents the l -th layer of the Laplacian pyramid decomposition image of the k -th image, λ_k is the weight coefficient corresponding to the k -th image, and FLP_l is the weighted fusion result of the l -th decomposition image of the H multi-exposure image.

$$\begin{cases} FG_N = FLP_N, & 0 \leq l < N \\ FG_l = FLP_l + FG_{l+1}^*, & 0 \leq l < N \end{cases} \quad (5)$$

In the formula, FG_l is the Laplacian pyramid decomposition image of layer l of the fused image, and FG_{l+1}^* is calculated according to Formula (3).

The image fusion based on the Laplacian pyramid strategy comprehensively uses the information of the source image at different spatial frequency levels. Compared with traditional fusion methods, there is no obvious stitching trace, but it also has the problem of long computing times.

B. Multi Exposure Image Fusion Algorithm based on Window Segmentation

Divide the H multiple exposure light source images evenly to obtain an image block with size $m \times n$. The j -th image block in the i -th source image is represented by $A_{i,j}$. Select an appropriate image quality evaluation index to quantize $\{A_{i,j}\}$, and select the optimal image block B_j . As shown in Formula (6), the fused image is finally obtained by "splicing" all the B_j . The basic process of the multi-exposure image fusion algorithm based on window segmentation is shown in Fig.1.

$$B_j = \text{Optimal}(\text{Indicator}(\{A_{i,j}\})) \quad (6)$$

In Formula (6), $i = 1, 2, \dots, H$, $j = 1, 2, \dots, M$, M is the number of image blocks, $\text{Indicator}(\cdot)$ represents the quantitative evaluation function of image quality, and $\text{Optimal}(\cdot)$ represents the optimization function.

Optimizing the exposure quality evaluation index of image blocks and the image block "splicing" algorithm are the core of the multi-exposure image fusion algorithm based on window segmentation. The uniform block-based fusion algorithm has high efficiency, but an inappropriate evaluation index and "splicing" algorithm easily lead to splicing traces. The nonuniform block fusion algorithm has the advantages of obvious edge information and large brightness width, but the efficiency of such methods is usually not high.

Fig. 1. Window segmentation fusion algorithm

C. Image Fusion Algorithm based on Window Segmentation and Laplacian Pyramid

The image fusion algorithm based on window segmentation and Laplacian pyramid combines the characteristics of high efficiency of window segmentation method and less stitching trace of Laplacian pyramid method. Same as window segmentation, first, the H source image is divided into M image blocks of size $m \times n$, and the j -th image block of the i -th source image is expressed as $A_{i,j}$. Then, the appropriate image quality evaluation index was selected to quantize and sort $A_{i,j}$, whose total quantity is M , and select the best N image blocks $B_{k,j}$. Then, the image fusion algorithm based on Laplace pyramid sideratio is adopted, and B_j is obtained by fusing N image blocks $B_{k,j}$. Finally, the fused image is obtained by "splicing" all the B_j . The basic process of the image fusion algorithm based on window segmentation and Laplacian pyramid is shown in Fig. 2.

Fig. 2. Image fusion algorithm based on window segmentation and Laplacian pyramid

For vision systems, exposure time is not the only factor affecting the imaging system. Lighting, camera sensors and lenses are key factors that affect imaging. Therefore, before multi-exposure image fusion, this paper innovatively controls the image acquisition conditions and uses orthogonal experiments to optimize the parameters of the multi-exposure imaging system.

IV. OPTIMAL PARAMETERS SELECTION METHOD FOR IMAGING SYSTEM AND ITS IMPLEMENTATION

A. Machine Vision System

The experiment object of this paper is a semiconductor chip with a size of approximately $4\text{mm} \times 4\text{mm}$. A dual camera image acquisition system consisting of two telecentric lenses was built based on the characteristics of small distortion, as shown in Fig. 3.

Fig. 3. Binocular telecentric vision system

B. Effect Factors of Imaging Quality and Its Levels

There are many factors that affect the image quality during the design of a machine vision system. Among them the ambient light, the artificial light and the camera gain are the three most concerned parameters. It is difficult to control the ambient light to reduce the impact on image quality and thus the dark rooms are typically used to isolate ambient light for image acquisition. The image quality will sharply vary with the light source intensity, light source direction and other illumination conditions. Therefore how to optimize arrangement of artificial lights to ensure the acquisition of high-quality images was studied. In the darkroom, a larger gain may be employed to have more luminous flux to increase the image brightness. However, a larger camera gain may amplify noise and thus reduce the image quality. Accordingly, how to determine the optimal camera gain is also very important. Therefore, in the orthogonal experimental design, the three factors of artificial light source, ambient light and gain must be analyzed to determine their optimal levels to provide stable experimental conditions for multi-exposure fusion research.

TABLE I. EFFECT FACTORS OF IMAGING QUALITY AND THEIR LEVELS

Levels	Factors		
	A	B	C
1	low	4.00	without a dark room
2	medium	5.00	with a dark room
3	high	6.00	/

The above three factors of imaging quality and their levels are tabulated in Table I. Factor A represents the artificial light and has three levels: low, medium and high light intensity of backlights. Factor B represents the gain and has three levels: 4.00 dB, 5.00 dB and 6.00 dB. Factor C represents the ambient light and has two levels: with or without a dark room.

C. Image Quality Evaluation Indicators

An image collected by the machine vision system is an 8-bit single channel gray image. The image quality evaluation indicators include information entropy, average gray intensity, variance and average gradient, which are defined as follows:

1) Information entropy H

$$H = \sum_{i=0}^{255} p_i \log p_i \quad (7)$$

where p_i represents the proportion of pixels whose gray value is i in the image.

2) Average gray intensity U

$$U = \frac{\sum_{i=1}^m \sum_{j=1}^n I(i, j)}{m \times n} \quad (8)$$

where $I(i, j)$ represents the gray intensity at (i, j) in the image. m and n are the size of the image along two coordinate directions.

3) Variance S

$$S = \sqrt{\frac{\sum_{i=1}^m \sum_{j=1}^n (I(i, j) - U)^2}{m \times n}} \quad (9)$$

where $I(i, j)$ represents the gray intensity at (i, j) in the image. m and n are the size of the image along two coordinate directions. U is the average gray intensity of the image.

4) Average gradient G

$$G = \frac{1}{(m-1)(n-1)} \sum_{i=1}^{m-1} \sum_{j=1}^{n-1} \sqrt{\frac{1}{2} \left\{ [I(i+1, j) - I(i, j)]^2 + [I(i, j+1) - I(i, j)]^2 \right\}} \quad (10)$$

where $I(i, j)$ represents the gray intensity at (i, j) in the image. m and n are the size of the image along two coordinate directions.

5) Comprehensive evaluation indicator W

$$W = k \times H \times U \times S \times G \quad (11)$$

where k is a coefficient that is employed to normalize W to be between 0 and 1.

D. Orthogonal Experiments and Results

The orthogonal experimental scheme was established as shown in Table II according to the orthogonal experimental design method.

TABLE II. ORTHOGONAL EXPERIMENTAL SCHEME L6 ($3^2 \times 2$)

Levels	Factors		
	A	B	C
1	1	1	1
2	2	1	2
3	3	2	1
4	1	2	2
5	2	3	1
6	3	3	2

According to the above orthogonal experimental scheme tabulated in Table II, the experiments were carried out with the left camera and the right camera. Six images were collected with the left camera, and the evaluation results of image quality are shown in Table III.

TABLE III. RESULTS OF 6 EXPERIMENTS WITH THE LEFT CAMERA

No.	Factors			Image Quality Evaluation Indicators				
	A	B	C	Information entropy	Average gray intensity	Variance	Average gradient	Comprehensive indicator
1	1	1	1	0.63	242.11	2802.76	0.21	0.908
2	2	1	2	0.61	241.61	3026.27	0.18	0.819
3	3	2	1	0.65	243.29	2431.72	0.23	0.860
4	1	2	2	0.61	241.56	3042.61	0.19	0.840
5	2	3	1	0.65	243.34	2411.14	0.23	0.893
6	3	3	2	0.63	242.62	2703.44	0.20	0.830

The results of orthogonal experiments were calculated by using the comprehensive indicator, whose values are tabulated in Table V. k_i is the sum of comprehensive indicators at the i -th level of factors and \bar{k}_i is the mean value of k_i . r is the range of k_i , and σ is the variance of k_i . The larger the range of a factor is, the more significant the impact of the factor on image quality. The larger the \bar{k}_i of a factor is, the more significant the impact of the level on image quality.

TABLE IV. RESULTS OF 6 EXPERIMENTS WITH THE RIGHT CAMERA

No.	Factors			Image Quality Evaluation Indicators				
	A	B	C	Information entropy	Average gray intensity	Variance	Average gradient	Comprehensive indicator
1	1	1	1	0.7000	241.280	2833.36	0.2400	1.1510
2	2	1	2	0.6600	240.640	3087.94	0.1900	0.9460
3	3	2	1	0.7100	243.070	2244.70	0.2600	1.0170
4	1	2	2	0.6700	240.530	3127.14	0.2000	0.9900
5	2	3	1	0.7100	243.050	2253.85	0.2800	1.0800
6	3	3	2	0.6900	242.260	2522.78	0.2200	0.9170

TABLE V. RESULTS OF ORTHOGONAL EXPERIMENTS BY COMPREHENSIVE EVALUATION INDICATORS

Camera	Factors	Evaluation Indexes							
		k_1	k_2	k_3	\bar{k}_1	\bar{k}_2	\bar{k}_3	r	σ
Left	A	1.748	1.712	1.690	0.8740	0.8560	0.8450	0.0290	0.00043
	B	1.727	1.700	1.723	0.8635	0.8500	0.8615	0.0135	0.00011
	C	2.661	2.489	/	0.8870	0.8300	/	0.0570	0.00162
Right	A	2.141	2.026	1.934	1.0705	1.0130	0.9670	0.1035	0.00538
	B	2.097	2.007	1.997	1.0485	1.0035	0.9985	0.0500	0.00152
	C	3.248	2.853	/	1.0827	0.9510	/	0.1317	0.00867

From Table III, Table IV and Table V, it can be seen that the ambient light has the greatest impact on image quality, camera gain has the smallest impact on image quality and backlight intensity has a moderate impact on image quality, i.e., $C > A > B$. The image quality is the highest when the three influencing factors are set to the first level, i.e., the optimal parameter combination is $C_1A_1B_1$.

V. DETERMINATION OF EXPOSURE PARAMETERS BASED ON INFORMATION ENTROPY AND AVERAGE GRAY INTENSITY

A. Information Entropy-Exposure Time Model for Images of Single Material Object

The exposure time required in imaging is related to the reflectivity of the object surface. Dark areas with low reflectivity require longer exposure times. In contrast, bright areas with higher reflectivity require shorter exposure times. When imaging a single material object or an object with multiple materials but little difference in reflectivity, the relation curve of the information entropy of the acquired image to the exposure time is a downward parabola. The information entropy first increases with increasing exposure time. When the information entropy reaches the maximum value, it will decrease with increasing exposure time, as shown in Fig. 4.

Fig. 4. Theoretical relationship between exposure time and image entropy

According to Fig. 4, when imaging a single material object or an object with multiple materials but little difference in reflectivity, the optimal exposure time can be set to $[t_0 - t_1, t_0 + t_2]$, where the exposure time is t_0 and the information entropy is maximal. t_1 and t_2 are two positive numbers that are smaller than t_0 .

B. Information Entropy-Exposure Time Model for Images of Multi-Material Objects

Different from single material object imaging, a multi-material object imaging has multiple peaks in its information entropy-exposure time curve, as shown in Fig. 5. The above method for determining the optimal exposure time cannot be directly used. Therefore, it is necessary to study the method of determining the optimal exposure time according to the characteristics of the information entropy-exposure time curve.

C. Determination of Optimal Exposure Time based on Information Entropy and Average Gray Intensity

The chip is composed of pins with high reflectivity and plastic packages with low reflectivity. As shown in Fig. 5, two peaks appear when the exposure time is 34200 μs and 500000 μs . If the selected exposure time is less than 34200 μs or more than 500000 μs , it will not be conducive to high-quality imaging of chips made of both materials. Therefore, the best exposure time must be between 34200 μs and 500000 μs .

Fig. 5. Information entropy-exposure time curve of objects with two materials

The length of the above exposure time interval determined according to the information entropy is still relatively large. When collecting the pin image and the plastic package image, there is only one lower limit or upper limit of the exposure time. Therefore, the above interval needs to be further refined to obtain two subsections, which are applicable to collecting the pin image and the plastic package image. For this purpose, the relationship between the rate of the average gray intensity of images and the exposure time was analyzed. Fig. 6 and Fig. 7 show the first-order difference and the second-order difference of the model of image average gray intensity and exposure time, respectively.

Fig. 6. First-order difference of image average gray intensity vs. exposure time

Fig. 7. Second-order difference of image average gray intensity vs. exposure time

Fig. 6 shows that when the exposure time is greater than 34200 μs but less than 95000 μs , the first-order difference in the average gray intensity of the image drops steadily. However, when the exposure time is greater than 95000 μs , it decreases while there is a certain amount of jitter. In Fig. 7, when the exposure time is between 34200 μs and 95000 μs , the second-order difference of image average gray intensity basically shows a horizontal line, although it fluctuates slightly, while when the exposure time is greater than 95000 μs , the second-order difference of image average gray intensity has relatively large fluctuations. With increasing exposure time, low reflectivity targets can be imaged better. When the exposure time is 380000 μs , a peak appears in the first-order difference curve of image average gray intensity vs. exposure time, as shown in Fig. 6. This means that the average gray

intensity of the image has a relatively sharp change at approximately 380000 μs . According to the above analysis, the exposure time intervals for two targets with different materials were determined to be [34000, 95000] and [380000, 500000], respectively. It should be noted that the first exposure time is rounded off appropriately to make calculation more convenient.

Then, the above two exposure time intervals were divided into several segments, and multiple images were accordingly collected and fused. The areas with different materials of chips in the fused image are clear. A camera parameter, defined to be the product of exposure time and gain, was used to reasonably determine the segmentation. According to the optimal gain determined by the orthogonal experiments and the exposure times determined by the peak of the information entropy vs. exposure time curve, the camera parameters for two material targets are 136800 and 2000000, respectively. Compared with imaging objects with high reflectivity materials, the camera parameter should be larger when imaging objects with low reflectivity materials. Accordingly, the segmentation of the interval [34000, 95000] should be much smaller than that of the interval [380000, 500000]. Consequently, the former interval was divided into 20 subintervals, and the latter interval was divided into 10 subintervals. The segmentation of the former interval is 3100 μs and that of the latter interval is 12000 μs .

VI. EXPERIMENTS RESULTS AND DISCUSSION

Thirty multi-exposure images were collected with the machine vision system shown in Fig. 3. During image acquisition, the previously determined optimal exposure parameters were adopted. The proposed multi-exposure image processing algorithm was implemented by using MATLAB@ 2015. An ordinary PC with a 64-bit operating system was used as an image processing system. Some collected images are included in Table VI.

TABLE VI. SOURCE IMAGES WITH DIFFERENT EXPOSURE TIMES

Images	Exposure times (μs)	Descriptions
	45000	The pins can be imaged, but the brightness is slightly dark. The characters are completely invisible.
	85000	The pins are incomplete and the characters are still invisible.
	400000	The pins are missing and the characters are visible.

A. Subjective Evaluation

The information entropy method, window segmentation method and the proposed joint method were employed to fuse the images, and the results are shown in Fig. 8.

Fig. 8. Results of image fusion. (a) image fusion result based on the Laplacian pyramid strategy with $\sigma = 0.1$; (b) image fusion result based on the Laplacian pyramid strategy with $\sigma = 0.2$; (c) image fusion result based on the Laplacian pyramid strategy with $\sigma = 0.3$; (d) image fusion result based on ordinary window segmentation; (e) image fusion result based on the proposed joint method

Fig. 8(a) to 8(c) show the image fusion results based on the Laplacian pyramid strategy. From the perspective of character clarity, the characters on the plastic package in Fig. 8(a) are very vague. The clarity of characters on the plastic package in Fig. 8(b) is obviously improved compared with that of Fig. 8(a). Compared with Fig. 8(a) and Fig. 8(b), the characters on the plastic package in Fig. 8(c) are the clearest. From the perspective of the pin area contrast, the pin area in Fig. 8(b) has the highest contrast. Fig. 8(d) is the result of image fusion based on window segmentation. Although the contrast of the pin area is high and the characters are relatively clear, there is an obvious "fracture" trace in the fused image, which will cause relatively large interference in subsequent image processing and thus may easily cause measurement errors. Fig. 8(e) is the image fusion result based on the proposed joint method. The characters are clear, the pin area contrast is high, the "fracture" trace is significantly eliminated, the details are well protected, and the visual effect is good.

B. Objective Evaluation

The above image fusion results were quantitatively analyzed and compared by using three indices, namely, information entropy, average gray intensity and time consumption. The results are tabulated in Table VII.

According to Table VII, in image fusion based on the Laplacian pyramid strategy, the value of σ will affect the information entropy and average gray intensity of the fused image, while it has little impact on the image fusion efficiency. When $\sigma = 0.1$, the information entropy of the fused image is 6.1473, and the average gray intensity of the fused image is 89.9575. Compared to $\sigma = 0.1$, when $\sigma = 0.2$, the information entropy of the fused image increases by 1.27%, and the average gray intensity of the fused image increases by 33.65%. Compared to $\sigma = 0.1$, when $\sigma = 0.3$, the information entropy of

the fused image increases by 2.12%, and the average gray intensity of the fused image increases by 38.09%.

TABLE VII. OBJECTIVE INDICATORS OF DIFFERENT FUSION RESULTS

Fusion Method	Information Entropy	Average Gray Intensity	Time (s)
Laplace pyramid strategy with $\sigma = 0.1$	6.1473	89.9575	6.246965
Laplace pyramid strategy with $\sigma = 0.2$	6.2252	120.2241	6.245941
Laplace pyramid strategy with $\sigma = 0.3$	6.2778	124.2241	6.220413
Ordinary window segmentation	6.4937	117.4303	5.112153
Proposed method	6.2922	131.5629	4.967878

Image fusion based on window segmentation has the largest information entropy, which is 5.63% higher than the minimum value. However, the average gray intensity of the fused image is not high, ranking fourth (penultimate). The efficiency of the fusion algorithm is improved. Compared with the three image fusion methods based on the Laplacian pyramid strategy, the efficiency of the algorithm is increased by 22.20%, 22.18 % and 21.68%.

Image fusion based on the proposed joint method has higher information entropy, which is better than the three image fusion methods based on the Laplacian pyramid strategy and second to the image fusion method based on window segmentation. The average gray intensity of the fused image is the highest. Compared with the other four methods, the average gray intensity is increased by 46.25%, 9.43%, 5.91% and 12.03%. The fusion algorithm takes the least time. Compared with the image fusion method based on the Laplacian pyramid strategy, it takes approximately 1.3 seconds less. Compared with the image fusion method based on window segmentation, the efficiency of the algorithm is also improved, and this algorithm takes 2.90% less time.

VII. CONCLUSIONS

To address the difficulty of acquiring high-quality images with single imaging for chips made of two materials with extremely different reflectivity, an image enhancement method based on multi-exposure image fusion was proposed in this paper. First, a joint image fusion algorithm based on the Laplacian pyramid and window segmentation was proposed, improving image quality and reducing processing time. Then, the factors that affect the imaging quality their levels were analyzed and the imaging parameters were optimized through orthogonal tests. After that, a method of determining the exposure time based on information entropy and first and second order difference of average gray intensity was studied. Finally, multi-exposure image sets were established, and experiments and subjective and objective evaluations were subsequently performed. The results show that the fused image has a good visual effect, its information entropy was 6.29, and its average gray intensity was 131.56. Furthermore, compared with the Laplace pyramid strategy, the time consumed was averagely reduced by 1.26 s. The fusion algorithm has the advantages of being less time consuming and high efficiency.

It has been demonstrated that the image enhancement method based on multi-exposure image fusion proposed in this paper is effective for an imaging object composed of two materials with great difference in reflectivity. However, obtaining high-quality images is not the ultimate goal, and it is necessary to further verify the effectiveness of the method in a defect detection or size measurement task. Furthermore, the proposal can be further explored and applied to the objects composed of more than two kinds of materials. On the other hand, although the proposed algorithm takes the shortest time in the above experiments, the image fusion process still takes 4.6 s. So the efficiency should be further improved.

ACKNOWLEDGMENT

Image Matting using Neural Networks

Nrupatunga J, Swarnalatha K S

Dept. of Information Science and Engineering
Nitte Meenakshi Institute of Technology, Karnataka, India-560064

Abstract—Image matting, also refers to picture matting in the article, is the task of finding appealing targets in a picture or sequence of pictures i.e., video, and it has been used extensively in many photo and video editing applications. Image composition is the process of extracting an eye-catching subject from a photograph and blending it with a different background. a) Blue/Green screen (curtain) matting, where the backdrop is clear and readily distinct between the foreground (frontal area) and background (foundation) portions. This approach is now the most used type of image matting. b) Natural picture matting, in which these sorts of photos are taken naturally using cameras or cell phones during everyday activities. These are the present known techniques of picture matting. It is difficult to discern the distinction between the frontal area and the foundation at their boundaries. The current framework requires both the RGB and trimap images as inputs for natural picture matting. It is difficult to compute the trimap since additional framework is required to obtain this trimap. This study will introduce the Picture Matting Neural Net (PMNN) framework, which utilizes a single RGB image as an input and creates the alpha matte without any human involvement in between the framework and the user, to overcome the drawbacks of the prior frameworks. The created alpha matte is tested against the alpha matte from the PPM-100 data set, and the PSNR and SSIM measurement index are utilized to compare the two. The framework works well and can be fed with regular pictures taken with cameras or mobile phones without reducing the clarity of the image.

Keywords—Picture matting; RGB picture; Blue/Green screen; foreground; background

I. INTRODUCTION

With the commonness of cell phones [24], image sensors have expanded strongly, and accordingly expanding the quantity of pictures [19] being captured through electronic devices. Hence, to handle this immense measure of visual information into helpful visual data, image processing has formed into a need in the ongoing moment capturing situation. Image processing has many applications and few of them are up-gradation of image, rebuilding of image, and getting relevant information from an image. Picture matting (or Alpha matting) is a sub-space of image processing that can remove the forefront from a picture, as an alpha matte. It has an assortment of utilization [2][3], like segmentation based on colour in an image [28], removal of reflectional lights, picture colorization, deblurring (bokeh effect), fashion e-commerce [14, 29, 30] and denoising to give some examples.

Numerically, picture matting issue can be demonstrated as:

$$I = \alpha F + (1 - \alpha) B$$

where I , F and B signify input picture, frontal area of output and foundation picture separately. α ranges from 0 to 1 which denotes frontal area opacity. 0% opacity of frontal area and 100% opacity of foundation is obtained when $\alpha = 0$ and vice versa when $\alpha = 1$. For every one of the fragmentary estimations of α , these pixels lie in the blended or obscure locales.

In picture matting, most pixels have α esteems either 1 or 0, the essential issue is to gauge the exact α values for pixels in blended locales, obviously to isolate frontal area and foundation locales. Given an information picture I , we need to appraise F , B and α at the same time which is a poorly presented issue. To resolve this issue the most generally utilized technique is a pre-characterized trimap [26] as deduced above. Notwithstanding, for humans it takes more time to get the trimap manually like annotating the edges and will be less precision even if captured through a depth camera or else [17, 18] there arises for another framework for getting a trimap. As a result, a few recent studies [16] have attempted to eliminate model reliance upon this trimap by developing trimap-free techniques.

The proposed PMNN, is a lightweight neural net which disintegrates the representation matting process in three corresponding sub-undertakings and streamlines them at the same time through unambiguous constraints, in order to predict a precise alpha matte from just a single RGB picture. There are two bits of knowledge behind PMNN. In the first place, neural networks are better at learning a bunch of straightforward targets as opposed to a mind boggling one. In this manner, addressing the series matting of sub-targets can accomplish better execution. Secondly, by supervising every sub-target allows different components of the system to know decoupled knowledge, allowing the sub-targets being addressed in one framework.

Due to the removal of the trimap input, the tests suggest that PMNN is more robust in practical scenarios. The technique is attempting to determine whether or not a green screen is required for ongoing picture matting. In rundown, will introduce a neural net framework design called PMNN achieving progressively without trimap representation matting.

II. LITERATURE SURVEY

There are various picture matting approaches [1] (Learning-based matting, propagation-based matting (alpha propagation-based matting), sampling-based matting) have been used to demonstrate the importance of exact alpha matte computation, pixel sample selection, and trimap generation. The interval line based picture matting approach is used to speed up the matte computation. Learning based matting

solutions are becoming more popular among established procedures. To improve Matte precision, propagation based techniques and sampling based strategies can be combined, and learning based matting approaches can be used to modify the matte result.

In [4], the author provides a complete semantic matting in the absence of trimap as supplementary information by combining a data set of coarse annotations [20, 25] as information with fine annotation data. To create a prediction of a mask [21, 27] by a network using hybrid information to gauge the mask of coarse semantics, and then introduce a qualitative unification neural net that can bring together the nature of previous output of coarse mask. To estimate the final alpha matte, a matting refinement neural net takes in the combined mask and information picture. By this it expects to predict the opacity of the per-pixel of the frontal area of human locale which is very difficult and for the most part requires trimap and a lot of excellent annotations on the information. Annotation on such information is work concentrated and requires extraordinary abilities beyond the ordinary use, particularly taking into account the exceptionally point by point hair part of people [13].

By incorporating neural net into the process of learning an alpha matte principal propagation, [5] proposes a deep proliferation based picture matting structure. The deep component extraction module, the propagation of matte module, and the learning affinity [15] module are connected to create the deep learning engineering. By using the training process from end to end, these three components can be separated and streamlined in relation to one another. By learning deep picture depictions tuned to propagation matte, the structure creates a semantic-level sequence of comparability of pixels for proliferation. It consolidates the force of deep learning and matte proliferation. The complex of training was approved by the exploratory outcomes from 243K pictures made in light of two benchmark matting data sets. In order to understand [23] deep picture representation with an adaptation to propagation of alpha matte and create more appealing pairwise propagation compatibility, for the design of a DeepMattePropNet.

Past calculations have terrible showing when a picture has comparable frontal area and foundation tones or textures of complication. The main reasons are due to older methodologies. a) using only features of low-level, b) lack of context from high level. In this [6] study, presents a unique deep neural net-based approach that addresses both of these problems. There are two parts to the deep framework. The first section is a convolutional neural encoder-decoder model that predicts an alpha matte of a picture using a picture and the comparative trimap as information sources. The next section is a small convolutional neural net that enhances the prior network's alpha matte forecasts to see more precise alpha quality and finer borders. Moreover, they've also created a massive scope picture matting data - set, which includes training pictures of 49300 and 1000 test pictures. And evaluated the calculation using a picture matting benchmark, a trial set, and a variety of real-life images. The calculation clearly outperforms previous strategies in the trials.

By thoroughly examining numerous differences between the foreground and background images, Jizhizi Li et al.[31] identified the domain gap issue between composite images and real-world photos. They discover that a properly planned composition route RSSN that seeks to lessen the disparities can result in a superior model with impressive generalization ability. Additionally, they offer a benchmark that includes 10,000 portrait photographs with their manually labelled alpha mattes and 2,000 high-resolution real-world animal images, to be used as a test set for determining how well the matting model generalises to real-world images. To fully utilize the trimap information in the transformer block, GyuTae Park et al. [32] suggest a transformer-based image matting model called MatteFormer. The initial step in our procedure is the introduction of a prior-token, which is a global representation of each trimap region (e.g., foreground, background and unknown). As global priors, these prior-tokens take part in each block's self-attention process. PAST (Prior-Attentive Swin Transformer) blocks, which are used at each stage of the encoder and are based on Swin Transformer blocks but differ in a few ways.

III. DATA COLLECTION

It's interesting that the offer the Photographic Portrait Matting benchmark (PPM-100) includes 100 representative photographs with meticulous annotations and various foundations. In order to modify the example varieties in PPM-100 and assure test variety, need to characterise a few ordering rules. For illustration, (a) if the entire human body has been included; (b) is the picture foundation occluded; (c) if the person is carrying any other items. Since this is more in line with the practical uses, need to respect small items that people hold as part of the closer view. The examples in PPM-100 do have flamboyant postures and more regular foundations, as shown in Fig. 1. In this approach, the PPM-100 standard is a more thorough benchmark.

Fig. 1. The PPM-100 data set.

Fig. 1, has more variation in the frontal areas and unique picture foundations. To display experiments having thin hair [10], including more elements [11], and in the absence of bokeh or in the presence of full-body.

IV. METHODOLOGY

PMNN comprises three branches, which gain disparate sub-targets through unambiguous requirements. A low-goal branch for measuring human semantics is present in PMNN and is controlled by the base truth matte's thumbnail. As a result, a high-goal branch that is familiar with the center around the representation limits is controlled by the progress area ($\alpha \in (0, 1)$) in the base truth matte. In order to predict the final alpha matte, a combination branch (controlled by the full

base truth matte) is introduced toward the end of PMNN. So that it can examine the branches employed to address each sub-objective in the subsections that follow.

Fig. 2. Block diagram of PMNN.

Fig. 2 uses three associated branches, S, D, and C. PMNN predicts human semantics s_p , edge subtleties d_p , and last alpha matte p given an information image I . So that it is easy to simplify PMNN from beginning to end because the disintegrating sub-targets are correlated and help reinforce one another.

1) *Semantic assessment*: The first phase of PMNN is to locate the person information Picture I , much like other existing frame-work techniques. It is essential that to only use an encoder, or the low-goal branch S of PMNN, to extract the high-level meanings, it has two primary benefits. First, since the decoder is no longer used to perform semantic assessment, it will be more effective. Finally, resulting branches and joint streamlining benefit from the high level depiction $S(I)$. As a backbone for S , any CNN [9] [12] can be used. Framework chose the MobileNetV2 [7] technology and [8], a great model created for cell phones, as the S in order to operate with continuous collaboration.

$S(I)$ is through into a convolution layers that is initiated by the sigmoid activation function to bring down the channel count to 1 in order to estimate the s_p coarse semantic mask. And to control s_p using a small portion of the fundamental truth matte α_g . So the block employ loss of L_2 here because s_p should be smooth,

like in:

$$L_s = \frac{1}{2} \| |s_p - G(\alpha_g)| \|_2$$

Where G represents Gaussian blur and also represents the 16x down sampling. It eliminates the fine designs (like hair) that are not fundamental for human semantics.

2) *Detail assessment*: A high-goal branch D that uses I , $S(I)$, and the low-level components of S as information sources surrounds the frontal area representation in the progress. Reusing the low-level spotlights is done in order to reduce the computational burden on D . Additionally, enhancing D in the three following perspectives: (a) Compared to S , D has less convolution layer; (b) The convolution layer in D are chosen with lower channels; (c) Through D , the block doesn't maintain the initial information resolution. In actuality, D has a max channel count of 64 and comprises 12 convolution layer. In the first level, the feature resolution of the map is down-scaled to 1/4 of I , and in the following two levels, it is recovered.

The D outcome results as $D(I, S(I))$, the intricacy between the sub target human semantic $S(I)$ of high level is needed in prior for detail assessment. From $D(I, S(I))$, determine the maximum detail matte d_p and grip it along loss of L_1 , as follows:

$$L_d = m_d \| |d_p - \alpha_g | \|_1$$

where m_d serves as a binary mask for L_d to emphasise the representational boundary. Erosion and dilation on α_g result in the production of m_d . If the pixels are inside the transitional area, its attributes are 1, otherwise they are 0. In actuality, the pixels in the dim area of the trimap are those with $m_d = 1$. Despite the possibility of inaccurate quality in d_p for pixels with $m_d = 0$, it has great accuracy for pixels having $m_d = 1$.

3) *Semantic-detail combination*: A direct CNN module, the combination branch C in PMNN combines semantic and detail. Firstly increase the sample size, to align $S(I)$ from with $D(I, S(I))$. At that point, $S(I)$ and $D(I, S(I))$ is added to estimate alpha matte α_p , which is anticipated by:

$$L_\alpha = \| |\alpha_p - \alpha_g | \|_1 + L_c$$

where L_c is the loss of composition. The background picture ground truth, the frontal area ground truth and the outright difference between the information picture I and the composited picture obtained from α_p are all estimated.

Using the appropriate amounts of L_s , L_d , and L_α PMNN is ready from beginning to end.

$$L = \lambda_s L_s + \lambda_d L_d + \lambda_\alpha L_\alpha$$

where, adjusting the three loss: λ_s , λ_d , and λ_α are hyper parameters. The process of training the hyper parameter is robust. Which lay down $\lambda_s = \lambda_\alpha = 1$ and $\lambda_d = 10$.

V. RESULT

The below Fig. 3 represents the outcome from the framework and the Fig. 4 represents the sample comparison between the generated alpha matte and the dataset alpha matte.

The output of a model is tested using an image similarity measures of PSNR - peak signal-to-noise ratio using the formulas as shown,

$$MSE = \frac{\sum_{M,N} |I_1(m,n) - I_2(m,n)|^2}{M * N}$$

MSE - Mean Square error. The information picture has M row and N column. The following formula is used to determine the PSNR:

$$PSNR = 10 \log_{10} \left(\frac{R^2}{MSE} \right)$$

Fig. 3. Output of the framework consisting of RGB Image, extracted frontal area and alpha matte (From left to right).

Fig. 4. The Comparison result between the generated and PPM alpha matte.

R is the highest pixel value that the image can contain. Notice that to get decibel value logarithm function is used.

SSIM - Structural Similar Index Measure, is based on structures that may be seen in the photograph. In other words, SSIM assesses the perceived variation between two analogous images. Between -1 and 1, the SSIM score denotes complete structural similarity, where 1 being perfect similarity. The distance X - Y across two windows:

$$SSIM(x, y) = \frac{(2\mu_x\mu_y + c_1)(2\sigma_{xy} + c_2)}{(\mu_x^2 + \mu_y^2 + c_1)(\sigma_x^2 + \sigma_y^2 + c_2)}$$

In Fig. 4, the first column displays the alpha matte from the PPM - 100 data - set. The second third column picture displays the PMNN generated output of alpha matte. The PSNR and SSIM calculated values are displayed in the second column for the generated picture along with the standard data set of PPM - 100.

The framework not only performs well with the data set but also outperforms well along with the real picture captured with the cell phones or camera irrespective of the dimension or pixels or size of the picture.

VI. CONCLUSION

A quick, easy, and interesting PMNN is introduced as a result of the framework's aim to avoid the use of a green screen [22]. By relying just on RGB photos as data, the technique permits the forecasting of alpha mattes under changing landscape. The framework operates effectively with the PPM-100 data set, as stated in the result section, and also with captured images, regardless of the file size and dimension of the captured image. The frontal region may now be extracted from the image more easily and without the need for human interaction thanks to the model editing.

PMNN is exhibited to have excellent exhibitions on the meticulously sketched PPM-100 benchmark and various here and now facts. The model's future application must include even more accurate and exact extraction of fine hair and fine details in the image with a move toward zero error. The one significant feature that may be introduced is the user's choice of extraction in the image, similar to how the green/blue screen offers the option for the fine extraction of required frontal area from the device captures. This extraction could be an object in the image, a person with some objects, or a person alone.

Abstract—Steganography is the process of hiding secret data inside other media or cover media. Balancing the requirements for capacity, security, and imperceptibility is the main challenge for any successful steganography system. In text steganography, the data hiding capacity is limited because of the lack of redundant data compared to other digital media, such as images, video, or audio. Other challenges in text steganography are imperceptibility and security. Poor imperceptibility results from the structure of the text file, which is more visually apparent in terms of syntax and grammar than in other media. Low level of security results from the sequential selection of positions for embedding secret data due to insufficient redundant data in a text file. Therefore, an attacker or a third party would notice slight changes in the text file. This paper proposes a new text steganography method that combines cryptography and compression techniques to deal with these issues. This technique is used to conceal secret data to achieve high data hiding capacity in the cover text while maintaining security and imperceptibility. Multilayer encoding and Format-Preserving Encryption (FPE) with Huffman Coding, are applied to secret data before embedding. Invisible Unicode characters are employed to embed secret data into English text files to generate stego files. Results show that the proposed method satisfies capacity and imperceptibility in the cover file by comparing it with previously developed methods.

Keywords—Text steganography; format-preserving encryption; Huffman coding; unicode characters

I. INTRODUCTION

Modern advancements in digital communication are essential to our everyday lives. The utilization of data transfer has substantially expanded because of developments in web-based technologies and the digitization of information. The data transfer includes audio, video, text, and images among individuals and groups, which has become very convenient [1]. However, the allocation of such massive amounts of data over the Internet makes them vulnerable to attacks. Thus, protecting sensitive data has become an important issue requiring immediate solutions. In general, two techniques are used to preserve the security and privacy of sensitive data: cryptography and steganography. One of the most attractive fields for data security is cryptography. This method uses several data encryption techniques to convert sensitive data into ciphertext, which is an incomprehensible format. Another technique for protecting communications during data communication is steganography. Although they have the same

goal, steganography and cryptography use different techniques. Steganography, as compared to cryptography, keeps the original data by concealing it in various medium [2] [3].

Both Greek terms "Stegano" and "Graphy," which make up the name "Steganography," have to do with "Cover Writing". The practice of steganography began centuries ago. For instance, Histiaeus employed steganography to transmit messages by inking (tattooing) on the head of his slave, who would travel after the tattoo had grown enough hair to conceal it. Greeks were famous for transmitting secret messages [4] [5]. Since the text has fewer redundant bits than in other cover media like images, music, and video, inserting hidden data in the cover text is the main challenge in text steganography. Due to the scarcity of redundant bits, any little adjustments made to the cover text will be noticeable. Any steganography system must have three main requirements: capacity, security, and imperceptibility [6] [7]. Steganography highly values the imperceptibility of hiding sensitive data in other media. The hiding process is performed without being noticed by human eyes. The concept of "security" refers to "undetectability", where the concealed data is incapable of being found by statistical methods [8]. A steganography system typically seeks to communicate a significant amount of confidential information using the least-covered media to reduce the risk of being discovered when communicating over an unsecured connection [9].

Let's say there is a need to embed a significant amount of sensitive data in a cover file (which will later be called a stego file). In that instance, altering the cover file is more challenging due to the difficulty in achieving imperceptibility and the possibility of distortion. Therefore, the trade-off between hiding capacity with imperceptibility and hiding capacity with security must be identified [10]. The hiding capacity has an inverse relationship with imperceptibility, which means that when large secret data are hidden within a specific size of cover text, inevitably, the stego file will be distorted. This distortion attracts the intruder's attention, and thus the hidden data is noticeable. In general, Unicode characters are used to embed secret data, which requires modification of the cover file. However, because text media suffer from insufficient locations for hiding secret messages, more text will be needed for embedding. In addition, the selection process of the embedding positions of the secret data is performed sequentially. Sequential patterns of the positions make the algorithm vulnerable to attacks [2]. Moreover, text media is

*Corresponding Author.

naturally bounded in terms of syntax and grammar, making text media more visually apparent in the embedding process.

Several researchers have worked on the relationship between hiding capacity and imperceptibility. Compression techniques are used to reduce the hidden secret data size, simultaneously minimizing the amount of modification in the cover file and increasing the imperceptibility [11], such as work in [12], which compressed the secret message using Huffman coding. Secret messages are also compressed in research found in [13] that combined algorithm with minimum-maximum weight and Huffman coding. Meanwhile, in [14], the secret data are concealed in the forward email IDs platform after compressing it with Huffman coding.

Despite implementing the compression algorithms, there are limitations, especially regarding the compression keys. In steganography, the compressed data will be hidden with the compression information, including the decompression keys, which will be shared separately between authorized participants. However, any third party getting the decompression keys could also obtain the secret data. In other cases, compression also led to low imperceptibility, as found in [15].

In addition, research on hiding capacity and security is being done to provide data protection while maintaining hiding capacity. Work in [16] used the RSA algorithm to provide security by encrypting data with minimum modifications in the presence or characters layout. Another research by [17] employs the Data Encryption Standard (DES), a symmetric encryption key, and combines steganography and cryptography for secure data transfer. However, despite these implemented approaches that improved security, cryptography algorithms also increased the secret data size since encryption generally increases the overall size of the data.

Therefore, any new text steganography technique must consider these issues and propose a method that minimizes the secret message size compatible with the available capacity in the cover text. In addition, changes in the cover text should be minimum since embedding secret data in bulk is more noticeable than in other media. More importantly, the embedding technique used to add layers of security must be in such a way that it does not increase the secret message size.

These issues give the motivation to develop the proposed method described further in Section III, which considers the relationship between hiding capacity and imperceptibility on one hand and hiding capacity and security on the other through the combination of cryptography and compression algorithms. This combination has two objectives. Firstly, is to adjust all steganography requirements simultaneously. Secondly is to preserve the trade-off between high hiding capacity and maintaining the imperceptibility of the stego file.

This paper suggests a new text steganography technique using multilayer encoding with FPE and Huffman Coding, which is applied to secret data that will be embedded using invisible Unicode characters inside the cover text. In addition, this paper explains the nature of the text media and the relationship among factors that must be considered when proposing new techniques for text steganography.

The rest of the paper is organized as follows: Section II presents related works. Concepts in Multilayer encoding with format-preserving encryption (fpe) and Huffman coding illustrated in Section III. Proposed method is illustrated in Section IV. Then, Section V presents the experimental results, followed by the conclusion of the work in Section VI. Lastly, recommendations for future research are presented in Section VII.

II. RELATED WORK

This section analyses related works that share the same fundamental concept as the proposed method. Randomization is a concept that can be used as opposed to the sequential concept. This concept can be seen used in text steganography, as found in [18], which used randomization in selecting the forward emails as a cover text. A randomized index-based word dictionary is used to encrypt the carbon copy field that contains hidden data. A temporary stego key from the public key cryptography generates a system time-based random bitstream and is transmitted separately. This method is considered secure against attacks because noises are excluded from the actual email body content. Moreover, randomizing each word of the index values adds an extra layer of security by inserting an 18-bit key generated using the system time in the "date" column of the forward email format. However, the use of public key cryptography increased secret message size and affected negatively on data hiding capacity.

The author in [19] suggested a set of two letters words based on the Oxford dictionary as indicators to hide the secret data represented through non-printing Unicode characters (UC). The proposed approach maps secret data so that every two bits of secret text with a specific UC generates a UC mapping table that will be shared between the sender and receiver. However, the inserting of secret message after each two letters words leads to increase the changes in a cover text and that minimizes a level of imperceptibility. This work is improved in [20] with the Lempel-Ziv-Welch compression algorithm to minimize the secret data size. The secret data are then represented through non-printing UCs to generate the UC mapping table that will be shared between both sender and receiver. However, the capacity is still low due to mapping representation that used a few bits with non-printing UCs in UC mapping table.

Color coding and LZW compression technique are used by [21] that employed the forward mail as a cover text for the secret data embedding process. The secret data is then compressed by the LZW compression technique and embedded inside the cover text by coloring it based in a color-coding table. However, the capacity is still low due to limitation in mapping representation in color-coding table. Another work that used the Huffman compression can be found in [22] to minimize the secret data. A specific number of characters in an email ID indicates the bits of hidden messages. However, the capacity is still low due to mapping representation that used one bit only in color-coding table.

III. CONCEPTS IN MULTILAYER ENCODING WITH FORMAT-PRESERVING ENCRYPTION (FPE) AND HUFFMAN CODING

The rapid increase in the number of covert activities in communication networks has intensified the need to devise an efficient data-hiding method to protect secret information from malicious attacks. One possible solution to this problem is to combine steganography techniques with encryption and compression techniques. As previously mentioned in Section II, several encryptions and compression techniques have been proposed, each with unique advantages and disadvantages. An encryption and compression technique that can provide a high security and compression ratio while maintaining an acceptable imperceptibility for the output file must be adopted. To this end, the proposed model applies multilayer encoding with (FPE) and Huffman Coding, which seeks to encode by encrypting and compressing the secret message before embedding.

This model consists of encryption and compression techniques (as shown in Fig. 1), which are applied to encrypt and compress the secret message and consequently increase the security ratio and hiding capacity.

Fig. 1. Multilayer encoding with FPE and Huffman coding process

A. Format-Preserving Encryption (FPE)

A novel symmetric encryption method known as FPE is gaining popularity as a solution to previously mentioned problems. This method differs slightly from traditional encryption protocols like AES and DES [23] [24]. It is a rapidly growing cryptography tool that serves the purpose of secrecy in cryptography by ensuring data security. As the name suggests, format-preserving encryption aims to encrypt data without changing its size or format. It involves encrypting data so that the output matches the input's size and format, which offers several advantages over traditional encryption. Feistel structure-based schemes called FF1 and FF3 are used to implement FPE algorithms. The National Institute of Standards and Technology (NIST) advises only two operating modes: FF1 and FF3. A basic block cipher component called BPS-BC is proposed to be used in Cipher Block Chaining (CBC) mode to encrypt messages of any length. FF1, known initially as format-preserving Feistel-based encryption (FFX), was proposed by [25], and FF3, corresponding to the BPS-BC (Brier Peyrin Stern), was proposed by [26]. Fig. 2's non-binary Feistel structure is the foundation for both operating modes. Both FF1 and FF3 can use electronic code book (ECB) mode to encrypt data blocks.

Despite using AES as the underlying block cipher, operating modes may be considered a type of FPE block ciphers. The encryption of data with changeable forms, such as

Primary Account Numbers (PANs) or Social Security Numbers (SSNs) that are not in binary format, is an example of a practical use of FPE [26][27]. FPE can also be used in communication systems when it's crucial to encrypt specific protocols, such as in industry or the military or when encrypting particular image formats [28].

Fig. 2. Generic cipher structure for format preserving encryption: (a) ciphering, (b) deciphering

The present study focuses on the concept of using format-preserving encryption FF1 mode. Data encryption must be considered when developing a conceptual framework because the technique of data encryption leads to an increase in the level of security with maintaining the capacity ratio of stego text files.

B. Compression using Huffman Coding

This section examines the data compression techniques that benefit from current compression techniques related to text files. These techniques can also be combined with steganography to improve the proposed solution. Data compression refers to the process of encoding input data by using a few bits representing the input's original size [29]. In other words, data compression denotes information in a compact format. The data's structure must first be determined to construct such small representations. These data may refer to characters in a text file generated by other processes. Compressed data are only used when both communicating parties are informed of the coding scheme, similar to any other type of communication. Compression is important since it lowers the use of costly resources.

Data compression techniques are highly recommended to increase the hiding capacity in cover files. These techniques, which are popular in computing, require the data transmitted over the Internet to be as compact as possible. Named after the late David Huffman in the 1950s, Huffman coding is a data compression technique that utilizes the greedy algorithm and achieves remarkable savings in capacity (ranging from 20% to 90%).

A variable-length code is employed in Huffman compression coding. Utilizing lower-frequency characters with more extended codes is also preferable in this case. The

encoding process involves assigning a numerical string based on the frequency of characters. The Huffman code algorithm takes a string of symbols and transforms them into a varying-length binary string. Then, a binary tree is generated for decoding the binary strings. Each binary character is assigned with 1 for the right child and 0 for the remaining child routes.

IV. PROPOSED METHOD

This section describes the proposed method. There are four main components: the encoding phase, embedding phase, extracting phase, and decoding phase, as shown in Fig. 3.

Fig. 3. Block diagram of the proposed scheme

A. Encoding Phase

In this phase, a combination of compression and security is achieved by implementing the multilayer encoding with FPE and Huffman Coding for compression, where secret messages are encoded using FPE. This stage is called multilayer encoding because it involves a few layers of encoding, such as from text to binary, then binary to decimal, and finally applying mod 26 to obtain the final encoding. FPE and the multiple encodings provide multilayer security to the secret message before its actual embedding. Multilayer encoding also reduces the size of hidden messages while providing more hiding spaces, as shown in Algorithm 1 of the multilayer encoding with FPE (Fig. 4). Next, Fig. 5 depicts the algorithm

for data compression using Huffman Coding. This algorithm starts by computing the frequency of occurrence of each data (output code from FPE), which is calculated in the input stream. These codes are then arranged from the highest frequency to the lowest.

Algorithm 1: multilayer encoding with FPE

Input: Secret message (M_S), FPE Key (K_p)

Output: EB_i , k_S

Steps:

1. Select K_p
2. For each Char in secret message (M_S)
Convert M_S into Binary.
End For
3. Convert the binary value of M_S into decimal (M_d)
4. Divide M_d with x , $B_i = \frac{M_d}{x}$ // x is random length of the divisor.
5. Encrypt B_i with K_p using FPE.
 $EB_i = Eph(B_i, K_p) \bmod n$
6. Take mod 26 of the Encrypted Block
(B_i) $EB_i = B_i \bmod 26$.
7. Store the remainder bits of mode 26 as the second key, k_S for each block.

Fig. 4. Algorithm 1: multi-layer encoding with FPE

Algorithm 2: Huffman message compression

Input: Output codes from the multilayer encoding with FPE

Output: Compressed secret message (CM)

Steps:

1. Read the output codes
2. Compute the frequency of occurrence of each output code in a list of (output code, frequency).
3. Arrange the list from the highest to the lowest frequency.
4. Calculate summation of the last two frequency numbers.
5. Rearrange the values in descending order based on their frequency numbers.
6. If there is more than one element in the list
Repeat Step 3.
End-If
7. Construct a Huffman tree by assigning the value (0,1) to each pair of branches in the tree.
8. Construct the final table (Huffman coding) that contains the leaf nodes (output codes) and their respective codes according to the Huffman tree.
9. Generate the compressed secret message (CM) by rewriting the output codes using the table in Step 7.

Fig. 5. Algorithm 2: Compression with Huffman coding

In Algorithm 1 (Fig. 4), in line 1, the algorithm selects the value of the FPE key (K_p). The block encoding and encryption processes are shown in lines 2–8. Firstly, each character of the secret message (M_S) is converted into binary. Next, in line 4, a binary string is converted into a decimal string M_d , and M_d is divided into equal blocks with a random length of the divisor (x), shown in line 5. After that, the encryption phase (labelled as Eph) is applied on each block (B_i) with Key (K_p), $EB_i = Eph(B_i, k_p) \bmod 26$ (line 6). In line 7, mod 26 on EB_i is calculated, and finally, the k_S values are determined by collecting the remainder bits of mode 26 for each block (line 8).

The k_S values are used to regenerate encrypted blocks in the extraction process.

In Algorithm 2 (Fig. 5), Huffman coding begins with the input, representing the output codes of the multilayer encoding with the FPE algorithm that need to be compressed. The algorithm then computes the frequency of occurrence of each output code in the input stream. These codes are subsequently arranged from the highest to the lowest frequency. The two codes with the lowest frequencies are treated as children of the node, and the parent node comprises the total frequency of these two child nodes. This node is then inserted back into the list, and the list is rearranged.

The process of applying Multilayer Encoding with FPE and Huffman coding is shown in the following example:

Suppose the Secret message is: "**Universiti Kebangsaan Malaysia**".

1) *Multilayer encoding with FPE:*

Step 1: Select the encryption key "Kp" value for FPE. Assume $K_p=1200$.

Step 2: Convert the secret message into random binary stream blocks. The obtained binary blocks are given below:

```
01010101 01101110 01101001 01110110 01100101 01110010
01110011 01101001 01110100 01101001 00100000 01001011
01100101 01100010 01100001 01101110 01100111 01110011
01100001 01100001 01101110 00100000 01001101 01100001
01101100 01100001 01111001 01110011 01101001 01100001
```

Step 3: Convert each binary block into a decimal stream to obtain the following decimal stream:

```
85110105118101114115105116105327510198971101031
1597971103277971089712111510597
```

Step 4: Convert the decimal stream into random blocks:

```
8511010511 8101114115 1051161053 2751019897
1101031159 7971103277 9710897121 11510597
```

Step 5: Encrypt each decimal block using FPE with $K_p=1200$; the resultant encrypted blocks are given like the following:

```
1909100954 6927975788 1398002705 6714036020
1293204947 2415200591 2308156747 39114904
```

Step 6: Apply mod 26 on each encrypted block, and the remaining bits of each block after applying the mod 26 equation are stored as the second key, K_s .

The results of applying mod 26 on each encrypted block are as follows:

[20 6 21 16 21 11 13 10]

2) *Applying Huffman coding:*

Step1: Read the output codes of multilayer encoding with FPE, which are:

[20, 6, 21, 16, 21, 11, 13, 10].

Step 2: Construct the final table (Huffman coding table) that contains the leaf nodes (output codes), as shown in Table I.

TABLE I. HUFFMAN CODING TABLE

Node	20	6	21	16	21	11	13	10
Codeword	110	1000	11	101	00	010	011	1001

Step 3: Generate the compressed secret message by rewriting the output codes using the table of Huffman coding.

Original secret message: (20, 6, 21, 16, 21, 11, 13, 10)

Compressed secret message: (110, 1000, 11, 101, 00, 010, 011, 1001).

The length of the compressed secret message, as computed using the Huffman algorithm, is 24 bits.

B. *Embedding Phase*

By using the invisible Unicode characters (UC), the embedding process aims to resolve the cover text limitation in data hiding capacity. In the proposed method, the embedding process is performed using eight Unicode characters to embed the secret data. These characters are inserted into spaces between words of the cover text. This phase proposes a text steganography technique using the property of data redundancy in the English text to improve the imperceptibility of hidden information. This method uses eight invisible Unicode characters UC by mapping three bits in each UC, as shown in Table II.

TABLE II. UC MAP FOR HIDING 3 BITS IN EACH CHARACTER

Unicode characters	Abbreviation	Representation
Zero width character	ZWC	000
Zero width joiner	ZWJ	001
Zero width no-joiner	ZWNJ	010
Invisible plus	IP	011
Invisible separator	IS	100
Inhabit Symmetric Swapping	ISS	101
Empty string	''''	110
Left-To-Right Embedding	LRE	111

The algorithm uses UC to hide three secret message bits after each word in the cover text. The first step of Algorithm 3 is to read the cover text and start segmenting text into words. Then, secret messages are converted to binary, which is divided into blocks of three bits. Next, every three bits are checked according to UC mapping, as defined in Table II. Then the alternative Unicode character is inserted after each word of cover text. Fig. 6 shows the Embedding algorithm.

Algorithm 3: Embedding process

Input: cover text, secret message, UC

Output: Stego-text file

Steps:

1. Read the secret message.
 2. Read the cover text file.
 3. Segment cover text to words
 4. Divide the hidden data into blocks of 3 bits each.
 5. For each block in a secret message
 - // there are 8 block options (i.e 000,001,010,100,101,110 and 111) are available to insert UC after each word.
 - Check the state of the first 3 bits of block
 - 5.1 IF 3 bits of block = "000" Insert ZWC after it
Else Read a new word, Repeat Step 5.1.
 - 5.2 IF 3 bits of block = "001" Insert ZWJ after it
Else Read a new word, Repeat Step 5.2.
End IF.
 - 5.3 IF 3 bits of block = "010" Insert ZWNJ after it
Else Read a new word, Repeat Step 5.3.
End IF.
 - 5.4 IF 3 bits of block = "011" Insert IP after it
Else Read a new word, Repeat Step 5.4.
End IF.
 - 5.5 IF 3 bits of block = "100" Insert IS after it
Else Read a new word, Repeat Step 5.5.
End IF.
 - 5.6 IF 3 bits of block = "101" Insert ISS after it
Else Read a new word, Repeat Step 5.6.
End IF.
 - 5.7 IF 3 bits of block = "110" Insert ''' after it
Else Read a new word, Repeat Step 5.7.
End IF.
 - 5.8 IF 3 bits of block = "111" Insert LRE after it
Else Read a new word, Repeat Step 5.8.
End IF.
- End for
6. Return Stego-text file
-

Fig. 6. Algorithm 3: Data embedding

C. Extraction Phase

The extraction phase is the third phase implemented in the proposed method. The stego text file is used as input. The extraction phase aims to extract the hidden data from the stego text file by retrieving each invisible UC. The extraction starts by reading the stego text. Next, the alternative Unicode character after each word is extracted. Then, each UC is mapped as defined in Table II to show the three bits of hidden data. Finally, return the recovered encoded secret message bits for the Decoding phase to reconstruct the secret message. Fig. 7 summarizes the extraction process.

Algorithm 4: Extraction process

Input: Stego-text file

Output: Recovered encoded Secret message

Steps:

1. Read the stego text file.
 2. Set secret data is null
 3. Segment stego text to words.
 4. Read each word and extract the alternative UC.
 5. For each UC
 - 5.1 IF UC = ZWC add to hidden data = "000"
Else Read a new UC, Repeat Step 5.1
End IF.
 - 5.2 IF UC = ZWJ add to hidden data = "001"
Else Read a new UC, Repeat Step 5.2.
End IF.
 - 5.3 IF UC = ZWNJ add to hidden data = "010"
Else Read a new UC, Repeat Step 5.3.
End IF.
 - 5.4 IF UC = IP add to hidden data = "011"
Else Read a new UC, Repeat Step 5.4.
End IF..
 - 5.5 IF UC = IS add to hidden data = "100"
Else Read a new UC, Repeat Step 5.5.
End IF.
 - 5.6 IF UC = ISS add to hidden data = "101"
Else Read a new UC, Repeat Step 5.6.
End IF.
 - 5.7 IF UC = ''' add to hidden data = "110"
Else Read a new UC, Repeat Step 5.7.
End IF.
 - 5.8 IF USC = LRE add to hidden data = "111"
Else Read a new UC, Repeat Step 5.8.
End IF.
- End for
6. Return secret message.
-

Fig. 7. Algorithm 4: Data extraction

D. Decoding Phase

The decoding phase includes two processes, namely: the decompression and deciphering of the secret text. The encoded secret message retrieved in the extraction phase is used as the input, while the retrieved secret message text is produced as the output.

1) *Decoding of Multilayer Encoding with Format-Preserving Encryption and Huffman code:* An encoded secret message retrieved from the extracting phase is decoded using the Huffman coding table to return the indexes. The Huffman coding table is transmitted as a key file. Decoding the retrieved encoded secret message and returning the indexes require rebuilding the Huffman tree based on the Huffman coding table. This process iterates through the binary encoded data.

The process starts traversing from the root until a leaf is found to find the characters that correspond to the current bits. The node on the left of the tree is then approached if the current bit is 0. If the bit is 1, the approach is made to the right node of the tree. When traversing, a leaf node is reached, and its character is displayed. After that, the encoded data is iterated till the end. The significant advantage of Huffman coding is that, although each character is coded with various bits, the receiver will automatically locate the character in order.

In FPE, the encoded data stream is decoded following the same principles applied in the encoding process. The process starts by obtaining the secret message bits from the decompression process with the Huffman code and then applying the decryption process with K_s , which is the key established after applying mode 26 in the multilayer process in the encoding stage. The next step is decrypting the secret message bits from FPE using the K_p key, converting secret bits from decimal to binary to rebuild the characters using ASCII code at the end of this algorithm (Fig. 8).

Algorithm 5: Decoding Multilayer Encoding with Format Preserving Encryption

Input: Encoding data stream , k_s , k_p

Output: Recovered Secret message

Steps:

1. Read Encoding data stream.
2. For each number in stream i.e. (20,6,21,16, 21,11,13,10).
 - get ND using k_s .
 - get NS using , k_p .
- End for
3. For each number in ND stream
 - add number in Temp T
 - IF $T \geq 64$ then
 - Add to DI list (T)
 - T=0
 - Else
 - IF $T = 32$ then
 - Add to DI (T)
 - T=0
 - Endif
- End for
4. For each number in DI list
 - convert to binary
 - retrieve secret message SM
- End for
5. Return secret message.

Fig. 8. Algorithm 5: Data decoding

For example:

The retrieved message: (20,6,21,16, 21,11,13,10)

Step 1: decrypt (20,6,21,16, 21,11,13,10) using k_s which is mod 26 *remainder bits* of each number in encode stage.

The results of decryption will be:

1909100954	6927975788	1398002705
6714036020	1293204947	2415200591
2308156747	39114904	

Step 2: decrypt each block using FPE with K_p ; the resultant decrypted blocks will be:

8511010511	8101114115	1051161053
2751019897	1101031159	7971103277
9710897121	11510597	

Step 3: combine blocks of numbers to accomplish the stream of decimal numbers. The stream will be separated according to original decimal numbers that represented each binary of secret bits:

8511010511810111411510511610532751019897110
10311597971103277971089712111510597.

Step 4: steps to accomplish the separation according to the original of the decimal numbers:

- take two numbers.
- **If** the summation of the two numbers equals 32, then separate
- **else-if** the sum of the two numbers equals or is more than 64, then separate
- **Else** take three numbers and separate

where 32 represents the word space in decimal, which are separate words. This condition identifies the word spaces in the algorithm. At the same time, since each letter in the English language starts with 64 when represented in decimal, and the numbers reflect the secret message letters in decimal, the retrieval numbers must be 64 or more. This condition could be satisfied with two or three numbers from the string while separating the secret message. The output from this stage will be (85 110 105 118 101 114 115 105 116 105 32 75 101 98 97 110 103 115 97 97 110 32 77 97 108 97 121 115 105 97).

Step 5: Convert each decimal number into binary and then retrieve the secret message from the binary. The binary representation will be as follows:

01010101	01101110	01101001	01110110	01100101
01110010	01110011	01101001	01110100	01101001
00100000	01001011	01100101	01100010	01100001
01101110	01100111	01110011	01100001	01100001
01101110	00100000	01001101	01100001	01101100
01100001	01111001	01110011	01101001	01100001

The secret message will be "Universiti Kebangsaan Malaysia".

V. EXPERIMENTAL AND ANALYSIS

In this section, we analyze the experimental results of our proposed method. The performance of the proposed method is measured in terms of capacity and imperceptibility. The hiding capacity is a major crucial parameter for analysis of the text steganography algorithm performance. We used the Jaro-Winkler distance, as used in [20], which is a similarity metric for the cover text and stego cover (1) and (2). The similarity metrics were used to calculate how similar two strings were to one another, with (0) indicating a difference and (1) indicating equal matching or imperceptibility of strings.

$$Jaro_Winkler(S,C) = Jaro_Score + (L * P * (1 - Jaro_Score)) \tag{1}$$

$$Jaro_Score = \frac{1}{3} \left(\frac{m}{Length(s_1)} + \frac{m}{Length(s_2)} + \frac{(m-t)}{m} \right) \quad (2)$$

L is the length of the common prefix at the start of the string up to a maximum of 4, P is the constant scaling factor ($0.1 \geq P \leq 0.25$), m is the number of matched characters, s_1 is the first string, s_2 is the second string, and t is the number of transpositions. As in [18, 21], hiding capacity is defined as the hidden data size relative to the size of the stego cover. Formulation (3) can be used for calculating the hiding capacity.

$$Capacity\ Ratio = \frac{Size\ of\ the\ embedded\ data\ (byte)}{Size\ of\ the\ coverfile\ (byte)} \times 100 \quad (3)$$

The proposed method is applied to the cover file as shown in Fig. 9 and secret messages shown in Fig 10, which are divided into twelve samples to be embedded into the cover file. Table III shows the results of the experiments, which include the secret messages, size secret message (n) and Jaro-Winkler (JW), for the proposed method and the comparison with previous related studies.

“The loss of tree cover as a result of forests being cleared for other land uses such as farming and logging is called deforestation. Deforestation activities affect carbon fluxes in the soil, vegetation, and atmosphere. However, logging can also lead to carbon emissions if the surrounding trees and vegetation are damaged. Deforestation is defined as the destruction of forested land. It is a major problem all over the world. The causes of deforestation vary from place to place. The most common causes, however, are logging, agricultural expansion, wars, and mining. Deforestation has been the cause of many problems facing the world today such as erosions, loss of bio diversity through extinction of plant and animal species, and increased atmospheric carbon dioxide. In this paper, I will present that we can reduce deforestation by moving from physical letter mail to electronic mail. From the ancient era physical letter mail has come, till now it is going on, but, on the other side due to this everyday trees are being cut i.e., deforestation is taking place by the paper industry, hence increasing CO2 emission and global warming. In place of physical letter mail, we can use electronic mail which will definitely do some reduction in deforestation. There are critical effects of deforestation.”

Fig. 9. Cover text (1)

“The importance and size of text data have increased at accelerating pace because the reliance on text based web01234.”

Fig. 10. Secret message (1)

As shown in Table III, the experimental results indicate that the proposed method can be applied to embed the secret message in the cover file. The Jaro-Winkler similarity score is 0.984 which is higher than in the two previous studies.

Next, the performance in capacity is compared with related studies that use the same secret message, as shown in Fig. 11 and the cover file in Fig. 12. Results show that the proposed method also scores higher in hiding capacity results. Table IV compares the hiding capacity of the proposed method with existing techniques. The proposed method achieved 18.4% capacity, which performed better than the other techniques for the same cover text and the secret message. Fig. 13 presents the bar chart comparison of the capacity that is listed in Table IV.

“Behind using a cover text is to hide the presence of secret messages the presence of embedded messages in the resulting stego text cannot be easily discovered by anyone except the intended recipient”

Fig. 11. Secret message (2)

“In the research area of text steganography, algorithms based on font format have advantages of great capacity, good imperceptibility and wide application range. However, little work on steganalysis for such algorithms has been reported in the literature. based on the fact that the statistic features of font format will be changed after using font-format based steganographic algorithms, we present a novel support vector machine-based steganalysis algorithm to detect whether hidden information exists or not. This algorithm can not only effectively detect the existence of hidden information, but also estimate the hidden information length according to variations of font attribute value. As shown by experimental results, the detection accuracy of our algorithm reaches as high as 99.3% when the hidden information length is at least 16” bits.”

Proposed Method	18.4

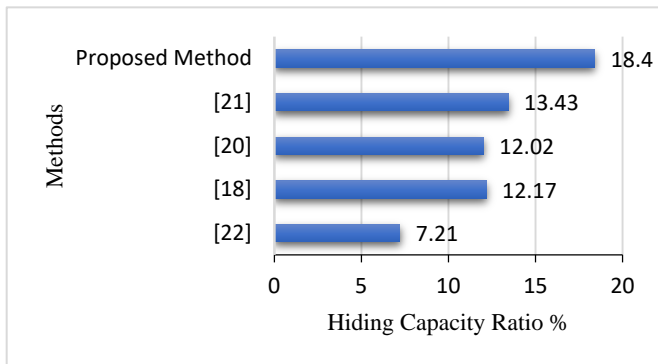

Fig. 13. Capacity of the proposed method compared with related studies

VI. CONCLUSION

This paper proposes a new technique of text steganography using Multilayer encoding with FPE and Huffman coding. The use of UCs shows a significant invisibility due to high imperceptibility after embedding the secret data into the cover text. Each Unicode character represents three bits of data. Before hiding secret data, the proposed scheme minimized the secret data size by applying multilayer encoding and Huffman compression. FPE is applied to secret data to achieve the encryption objective without increasing the size of the secret

data. Results show that the proposed method has demonstrated significant improvement when compared with previous studies.

VII. FUTURE WORK

In future work, enhancement can be made by proposing a new method to solve the sequential pattern in the embedding process by introducing a randomization concept. Therefore, the security level will be increased without using any encryption techniques that require sharing of keys between participants. In addition, increasing the number of bits in UC mapping representation will result in increasing the amount of capacity in cover text.

ACKNOWLEDGMENT

The authors would like to acknowledge Universiti Kebangsaan Malaysia for the Research University Grant with code: TAP-K011439 to support this project.

Abstract—The security of personal identities is a serious challenge in today's digital world, with so many daily transactions requiring secure solutions. The use of biometric characteristics of the person is presented as the reliable solution to solve this problem. Indeed, this solution is effective, but it hides a weak point which lies in the ability to reproduce certain biometric characteristics for fraud. To overcome this weak point, we propose a secure approach for palmprints that relies on the concept of merging multiple features. Indeed, these features will be extracted from multi-spectral images with different spectra, which allow the extraction of information under the skin of the palm for two different spectrums sequentially in two different times (T1, T2) but instantly. The instant fusion of these characteristics will be impossible to replicate. The images used are grayscale. To satisfy a construction of a reliable and secure system, for this kind of patterns (palmprints), we will use the Compound Local Binary Pattern method, since this method adds an additional bit for each P bits coded by LBP corresponding to a neighbor of the local neighborhood, in order to build a robust system. This feature descriptor, it uses both the sign and tilt information of the differences between the central and neighboring gray values. The reliability of the proposed approach has been demonstrated on the Casia Multi-Spectral database. The final experimental results show reliable recognition rates and these recognition rates vary between 99% and 100% for the left and right palms.

Keywords—Biometrics; multispectral palmprint, local features; fusion; compound local binary pattern

I. INTRODUCTION

The uniqueness of personal identity has always been the major concern of individuals in society. This concern is justifiable given the seriousness of the risks. The identity is the entity requested to ensure the majority of critical transactions. Various applications have been proposed to guarantee this uniqueness, however, in this set of applications, biometrics remains the most appropriate solution [1, 2]. A multitude of scientific research has been undertaken in recent decades in this direction. Researchers have proposed a large set of recognition systems with very promising results. A large number of modalities have been investigated and they have shown a distinctive character that ensures the uniqueness of the identity. Among these modalities, we can cite the use of the fingerprint [3], the iris [4], the finger knuckle [5], the voice [6], the hand geometry [7], etc. However, it should be noted that these different biometric mechanisms offer advantages on the one hand and disadvantages on the other. The suitability of a mechanism for all current applications cannot be judged

with certainty. Because of this, scientific researchers have varied their research to try to meet the requirements of different fields. Like all these researchers, the orientation of our work has been guided by constraints. One of the most important constraints that we have taken into consideration relying on the Biometric Zephyr analysis, is intrusion [8]. Indeed, the intrusive nature of the sensors makes the participants uncomfortable during the capture process such as the retina and iris based sensors [9]. This constraint, directed us towards the use of the modalities which reduce the impact of this factor like the descriptors based on the hand. The ease of use and convenience for this kind of descriptors has pushed research in this direction. In the literature, there is a large number of studies that have opted for the use of hand-based modalities and in various fields, such as fingerprints [10, 11], hand geometry [12, 13], finger knuckle print [14, 15] and palmprints [16-18]. Nevertheless, fingerprint-based systems have many challenges that are summed up in the ability of their spoofing easily by third parties [19, 20]. Furthermore, compared to other biometric descriptors, palm prints show low distortion, good stability over time and a highly distinctive character [21, 22]. Unfortunately, palmprint patterns are sensitive to pose orientations, lighting variations, and sensor noise. These factors can lead to misclassification and therefore affect the ability of such systems to recognize users. To overcome these problems, various researches have been done on the extraction mechanisms to improve the relevance of features, which will have a positive impact on the matching of these features. The majority of these researches employed coding-based, statistics-based, subspace-based, and line-based methods.

Coding-based methods are a category widely used in much research on palmprint recognition systems. Various palmprint codes have been generated, among which we cite the fusion code [23], which allows the coding of the phases and the responses of the six Gabor filters. The Robust Line Orientation Code (RLOC) [24], which allows the extraction of palmprint orientation features with a modified finite Radon transform. The feature vector obtained in this technique is used as a competitive code. But, the extracted features have a large size, which leads to a classification over-fitting. The combination of Block Dominant Orientation Code (BDOC) for rough characteristics extraction and Block-based Histogram of Oriented Gradient (BHOG) for fine characteristics extraction [25], Half-Orientation Code (HOC) for palmprint feature extraction, this code employs half Gabor filters [26]. The Double Orientation Code (DOC) of Gabor

filters for feature extraction with a nonlinear classifier [27]. This category can be expensive in computation time and implementation.

Another category that is also used, this category relies on statistics-based approaches; they have shown good performance [28–29]. A multitude of statistical methods have been employed in this category such as variance, standard deviation, energy and histograms of local binary models [30], Zernike and Hu moments [31]. Some transformations have also been used such as the wavelet transform to convert the palmprint image into a small number of wavelet coefficients, and then calculate the variance and the mean of these coefficients to generate the image characteristics [32]. Other methods have been introduced to calculate the statistical characteristics after the extraction phase with certain filters and transforms such as Gaussian derivative filters, Gabor wavelet, and Fourier transform [33]. The use of principal component analysis (PCA) and wavelet transform to extract features from the quaternion matrix, combined with the Euclidean distance classifier for matching process [34].

Approaches based on the concept of subspace also form an important category that intervenes in the construction of recognition systems. This kind of approach has been widely used in scientific research related to palmprint recognition. Among this research, we can cite the use of approaches in the works such as principal component analysis (PCA) [35], independent component analysis (ICA) [36] and linear discriminant analysis (LDA) [37]. In [38], a method to convert palmprint images into a set of feature space, named eigenpalms was proposed to build a palmprint recognition system. For matching, the Euclidean distance classifier was been employed. Researchers in [39] used Two-dimensional vertical and horizontal LDA (2DLDA) to extract Gabor features and then a distance-based adaptive approach to merge the vertical and horizontal features. Other approaches based on multi-spectral images have been deployed; in [40] kernel discriminant analysis (KDA) was used to reduce feature dimensionality and classification was provided by a KNN classifier and in [41], researchers proposed a multi-spectral method based on a digital Shearlet transform. This category can be affected by environmental variables (light and pose rotation).

A last category which is based on the use of lines to recover outlines and lines of palm prints with edge detection methods. Among the studies based on this concept we can cite [42], in which a technique that employs the Sobel edge detector with morphological operations to ensure the feature extraction phase of lines and [43] who used the Sobel mask to calculate the amplitudes of the lines and projected those amplitudes along the x and y axes to produce the discriminant histograms for each class. This last category offers medium performance.

In a brief summary of what preceded, we can identify the following issues: the intrusiveness of the modality, the complexity of many methods employed, the sensitivity of some methods to environmental lighting or rotation of employed modality (in the case of the hand-based modalities)

and finally the possibility of usurping the personal identity by the reproduction of false descriptors.

To overcome these problems, we propose a reliable approach using local features to build a non-intrusive, secure, robust and efficient recognition mechanism, in which, we take into account the optimization of the computational complexity. We will use palmprints to reduce intrusiveness. To reduce the influence of environment lighting, capture conditions and extract relevant features, we will use method of extracting local features Compound Local Binary Pattern (CLBP) [44, 45], which we will evaluate on different block sizes with different classifiers. The classification phase will be based on the use of classifiers that reduce computation time such as distance-based classifiers. We will test three variants of measurements: Jeffrey Divergence, City-Block and Euclidian Distance. We will also pre-process the Casia Multispectral Palmprint database [46], in order to reduce computation time and improve performance.

This paper is organized as follows: Section II describes the proposed approach and the methods used. Section III reports and discuss the experimental results conducted on the Casia Multispectral Palmprint database. Finally, Section IV draws conclusions.

II. PROPOSED APPROACH

The design of the global system went through several stages before arriving at the final system scheme. In the first part, we chose a local extraction method, given the nature of palmprints pattern, which are rich with local information. In addition, this method must be as robust to variations in the lighting of the environment and to rotations. It turns out that the compound local binary pattern method [47] can satisfy these constraints. The objectives of this part can be summarized in two points. In the first point, the goal is trying to demonstrate the reliability of the chosen extraction method.

The second point will concern the classification, which represents a crucial phase to determine the reliability of the systems and their cost in computing time. In this sense and in order to satisfy its needs, experiments will be made with distance-based classifiers, known for their reduced computation time. Several classifiers will be discussed at the beginning, then the choice will be based on the most appropriate with respect to the local extraction method used (ratio optimization: recognition rate and computation time). The concept used for this evaluation is illustrated in Fig. 1.

In the second part, a new gait will be experimented, which aims at the adequacy of the size of the cropping chosen to extract the regions of interest, in order to further improve the reliability and the reduction of the calculation times. During this last point, we will extract the regions of interest with the Principal Based ICP method [48], this cropping will be done with a size of 192x192 pixels; which will generate the first database of ROI images, thereafter, we will proceed to a resizing of the ROI images with the size 128x128 pixels to obtain the second database (Fig. 2). With this approach, it will be discovered that the size 128x128 pixels can offer better results than 192x192 pixels, this can be justified by the fact that if the size of the division block is large and the pattern is

poor in information, then the rate inter-class similarity increases, which will reduce the recognition rate. The consequence of this increase will be a reduction in system performance and an increase in computation times, which we aim to avoid with this approach.

Subsequently, in the experimental part, the relationship between cropping resolution and scoring performance will be demonstrated.

Finally, in the last part, the experimental results and the conclusions obtained in the two previous steps will be used to test the reliability and robustness of the proposed approach. In the proposed approach, the choice will be in favor for a sequential capture of two images at two different times T1 and T2, which follow each other with two different spectrums, in our case we will use the 640 nm spectrum for image 1 and 940 nm for the image (we will explain this choice in the experimental part). These two images will form two different descriptors, in addition, with the 940nm spectrum some veins under the skin will be visible and other characteristics will change. The proposed palmprint multispectral recognition system is shown in Fig. 3.

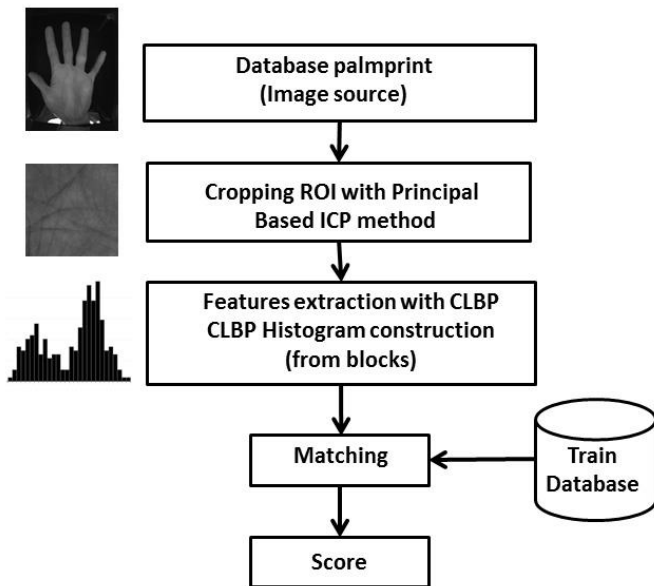

Fig. 1. FKP Recognition System adopted for evaluation.

Fig. 2. Cropping and resizing process for ROI image.

Fig. 3. The proposed multispectral recognition system.

Indeed, this sequential capture in very close times (in ms) will aim; the security of the capture phase against any attempts at fraud or use of false artifacts. Since these fake methods cannot deploy quickly to present two descriptors in a short time (in ms) and therefore, even if descriptor 1 (image1) will be spoofed, descriptor 2 (image2) will not. This will secure the proposed system. This approach will be based on fusion at the score level. The results obtained in this step will be analyzed and compared to the previous step.

A. Features Extraction Process

The construction of recognition mechanisms is generally based on two key factors; the first factor depends on the computation time allocated to satisfy the operation, the second factor depends on the efficiency and the recognition rates. It is also necessary to take into consideration the conditions of the environment which can constitute handicaps for the performance. To avoid this kind of handicaps, local methods robust to rotations and light variations will be introduced (which is the case of this database of palm prints). The feature extraction step will be ensured by a robust variant of Local

Binary Patterns (LBP), this method is called Compound Local Binary Patterns (CLBP) [47]. The LBP method was first introduced by Ojala and Ai [49], this method is effective for feature extraction from images in real environments. The local binary pattern is recognized by a gray scale texture operator characterizing the local spatial structure of the image texture [50]. Given a central pixel in the image, a pattern code is calculated by comparing it to its neighbors. This method is illustrated in Fig. 4. The LBP operator calculates the signs of the differences of the gray levels of P neighbors equidistant with respect to the central pixel, which will be represented with a binary number of P bits (Fig. 4). If a neighbor is not exactly on a pixel position, then the value of that neighbor will be estimated using bilinear interpolation. The histogram of the coded image block obtained with the LBP operator will then be used as a texture descriptor for this block.

Fig. 4. Local binary pattern operator.

The LBP operator takes the form:

$$LBP(x_c, y_c) = \sum_{n=0}^7 2^n S(i_n - i_c) \quad (1)$$

where in this case n runs over the eight neighbors of the central pixel c, i_c and i_n are the gray-level values at c and n. Function S(x) is s defined below,

$$S(x) = \begin{cases} 1 & \text{if } x \geq 0 \\ 0 & \text{if } x < 0 \end{cases} \quad (2)$$

The LBP operator uses a method that employs only the use of the sign of the difference between two gray values, which sometimes leads to a failure to generate binary codes consistent with the texture properties for the local region (Fig. 5). To avoid this handicap, a variant of this operator will be used. This variant assigns a 2P binary code to the central pixel according to the gray values of the local neighborhood comprising P neighbors; this method is Compound Local Binary Pattern (CLBP) [47]. The CLBP operator uses two bits for each neighbor to encode the sign as well as the magnitude information of the difference between the center and the neighboring gray values, unlike the LBP which uses only one bit for each neighbor by representing the sign of the difference between the center and the corresponding neighboring gray values. In this method, the first bit represents the sign of the difference between the center and the corresponding neighboring gray values as the basic LBP encoding. The second bit is used to encode the magnitude of the difference with respect to a threshold value, which is the average magnitude M_{avg} of the difference between the central and neighboring gray values in the local neighborhood of interest. The CLBP operator chooses the value 1 for the second bit if the magnitude of the difference between the center and the corresponding neighbor is greater than the threshold M_{avg} .

Otherwise, it takes the value 0. Thus, the s(x) indicator of equation 2 is replaced by the function below:

$$s(i_p, i_c) = \begin{cases} 00 & i_p - i_c < 0, \quad |i_p - i_c| \leq M_{avg} \\ 01 & i_p - i_c < 0, \quad |i_p - i_c| > M_{avg} \\ 10 & i_p - i_c \geq 0, \quad |i_p - i_c| \leq M_{avg} \\ 11 & \text{otherwise} \end{cases} \quad (3)$$

Fig. 5. Generation of inconsistent binary pattern in LBP.

Fig. 6. Compound local binary pattern operator.

where i_c and i_p are the gray values of the central pixel and the neighbors, and the average magnitude of the difference between i_p and i_c in the local neighborhood is M_{avg} . The mechanism of the CLBP operator is shown in the Fig. 6.

B. Matching Process Phase

The choice of classifiers is crucial for a better performance concerning the proposed approach, to ensure this important phase in all recognition systems, we relied on two important factors. The first factor depends on the resolution of the images used, which is low, classifiers like SVM will be disregard, because are more for high resolutions [51, 52]. The second factor is also important, it depends on the computation time costs, which represents a decisive point for the success of a recognition mechanism; these points will direct our choice towards distance-based classifiers. The consideration of the directives already mentioned, directed the choice towards a set including three classifiers based on the distance, which we will use with the method of extraction employed and see their performances for the generation of the recognition rates. These classifiers are based on Euclidean distance, City-block and Jeffrey Divergence.

The Euclidean distance is the best-known distance metric and used in datasets that represent low-dimensional images, examines the root of the squared differences between the coordinates of a pair of objects. This process is generally known as the Pythagorean Theorem. For the tests, we used this classifier, to calculate the minimum distance between the test image and the train image. The Euclidean distance d is as follows:

$$d(x, y) = \sqrt{\sum_{i=1}^n (x_i - y_i)^2} \quad (4)$$

The Manhattan distance classifier, city-block distance classifier, also called, rectilinear distance, L1 distance, L1 norm, Manhattan length. It represents the distance between points in a city road grid. It examines the absolute differences between the coordinates of a pair of objects as follows:

$$d(x, y) = \sum_{i=1}^n |x_i - y_i| \quad (5)$$

The Jeffrey divergence is a modification of the Kullback-Leibler (KL) divergence, if $P = (p_1, \dots, p_N)$ and $Q = (q_1, \dots, q_N)$ are two discrete distributions, the Jeffrey divergence between P and Q is defined as:

$$D(P, Q) = \sum_i (p_i \log \frac{p_i}{m_i} + q_i \log \frac{q_i}{m_i}) \quad (6)$$

$$\text{Where } m_i = \frac{(p_i + q_i)}{2}$$

III. EXPERIMENTAL RESULT

In this part, an experimental study spread over several stages will be made. The objective of these steps will be articulated on the progressive demonstration of the process reliability for the proposed system. The evaluation of this system will be conducted on the Casia multispectral palmprint database [46]. It should be noted that this database is one of the standards of scientific research in this field.

A. Casia Multispectral Palmprint Database

The construction of the CASIA Multi-Spectral Palmprint database is based on the acquisition of 7200 palmprint images from 100 volunteers. This set of images is shared equally between the palms of the right hand and the left hand (3600 images on each hand). It should be noted that the set of palmar images for each hand is captured in two sessions. The time between the two capture sessions has an interval greater than one month. During a session, each volunteer gives three samples for each hand (a total of six images per user in a single session, so 600 images for 100 volunteers). Each image of a sample is captured with six different electromagnetic spectrums (Fig. 7). The wavelengths used for these captures correspond to the following six spectrums: white light (WL), 460 nm, 630 nm, 700 nm, 850 nm and 940 nm. The captures have been made in such a way that the user has a certain freedom for the pose concerning the angle and the rotation of his hand, the goal is to produce variations of hand postures during the capture session. This procedure will simulate a use that is done in the real world and increase the diversity of samples in the same class, which will present interesting challenges for measuring the performance of a biometric system. It is reminded that the palm images captured are 8-bit grayscale JPEG files.

Generally, the biometric database preparation follows a process that relies on two phases; the first concerns the acquisition of images over different time intervals and the second revolves around preprocessing mechanisms, that can vary depending on the modality nature and the objectives targeted by the research conducted.

A careful examination of the database images reveals two important factors that will direct our preprocessing towards an

extraction of the regions of interest; the first is seen on the capture of hands that will undergo changes (Hand with Corn, Callosity, Induration) due to manual work or intense physical activities in strength sports such as bodybuilding or powerlifting (Fig. 8).

Fig. 7. Casia multispectral palmprint database.

Fig. 8. Images with corn, callosity and induration in casia multispectral palmprint database.

The second factor is noticeable in the images where the pose of the hand for capture is free and not standardized. This hand posing manner (flexion hand) may in some cases present angles with respect to the capture support, which cause the relevant features at the level of the hand palm contour to be inhibited, the same in the case of the poses of the hand which have a concavity (Fig. 9).

Fig. 9. Poses with flexion and concavity in casia multispectral palmprint database.

These two factors may skew experimental results, on the one hand, the change that certain parts of hand palm may undergo, which increases intra-class variations, on the other hand, the absence of relevant features on areas of the hand palm, which may increase the interclass similarities of the histograms with the local methods. To avoid these problems, it

is essential to carry out a pre-processing which aims at extracting the regions of interest ROI. This process of regions of interest extraction will be used to solve the problems of the Casia Multi-spectral Palmprint database images already mentioned. Indeed, the principle aims to adjust the rotation of different angles and the normalization of the scales, then to carry out a cropping on the normalized image central region to extract the relevant characteristics. It is obvious that an ROI extraction method that is based on a good algorithm will be decisive in generating palm prints images with zones, which allow the maximum of distinctive characteristics. This effect will have a significant impact on the performance of the recognition system to be built. The majority of existing methods use algorithms that perform an ROI extraction based on the limit of the palm, or key landmarks between the fingers, or some external factors [53, 54].

Many existing palmprint recognition mechanisms assume that palmprint images are aligned before performing feature extraction and matching. Because of this, they are often affected by residual variations in translation and rotation after the alignment process. To avoid this problem, the Principal Based ICP [48] will be employed, this method uses the linear features to refine the alignment of the image before performing the cropping operation to extract Region of Interest (ROI) images (Fig. 10).

Fig. 10. Casia multi-spectral palmprint ROI database.

B. Evaluation and Analysis of Experimental Results

To approve the recognition mechanism, we opted for an evaluation process divided into three different parts. The first part focuses on the extraction of ROI images with the Principal Based ICP method for a crop of 192x192 pixels and verifying the ability of the chosen classifiers to offer efficient results with the extraction method adopted. In this phase, several detailed experiments for each hand (left and right) will be carried out and which will have as a goal; the determination of the classifiers most adapted to this kind multi-spectral images, this adaptation will obviously be evaluated on two points: the first concerns the recognition rates obtained and the second point concerns the duration of the calculations necessary for the matching process concerning all the classes. In the second part, the resolution adopted for the ROI images will be changed. The resolution will become 128x128 pixels instead of 192x192 pixels. After obtaining the results of this new phase, we will compare them with the previous phase and we will proceed to the analysis of the data to draw conclusions concerning the impact of the resolution of the global image. In the case where the impact of this operation represents positive points in terms of performance and computation time, it will be adopted for the rest of the experiments. Finally, in the last

part, the conclusions obtained in the global approach will be used, the final experimental results of the proposed approach will be examined and the conclusions on the obtained reliability will be drawn.

1) *Multispectral palmprint evaluation:* During this first step, the system will be evaluated. It should be noted that the Casia database presents images in the same class, which represent concavities during the pose and varying angles depending on the capture pose, these factors increase the intra-class variation. For this, an experimental protocol which will respect the real conditions will be used (Fig. 11). The training database will be composed of five images per user and the test database will be composed of a single image per user (as in the real case to ensure the operation in the devices implemented). Therefore, for each volunteer, there are five training samples and one test sample for each spectrum. The proposed approach is based on local techniques. Therefore, the performance of the mechanism will be examined with different sizes of sub-images.

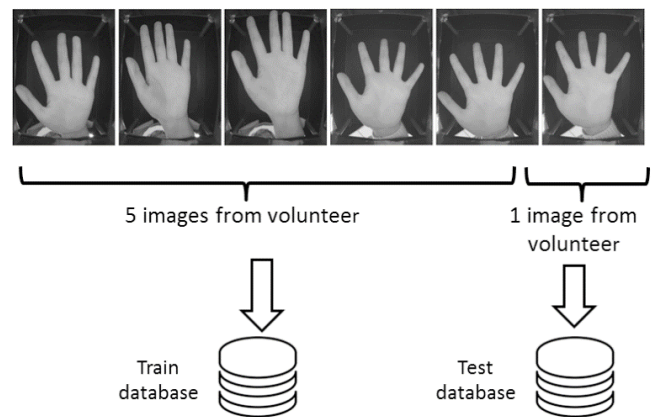

Fig. 11. Protocol used for experiments.

Block subdivision sizes have been classified into three categories: large subdivision, medium subdivision, and small subdivision. The large subdivision is defined by two block sizes: 64x64 and 48x48 pixels, for the medium size: 32x32 and 24x24 pixels, and for the small size: 16x16 and 8x8 pixels. To ensure a better performance of the classification process of the proposed approach, several classifiers based on Euclidean distance, Jeffrey divergence and City-Block was experimented. The recognition rates for each palmprint with the image sub-divisions chosen for the different spectra will be presented later in tables. This comparative evaluation is made in order to show the most adaptive classifiers in our case and the cost in computation time.

a) *Result of experiment with cropping 192x192 resolution:* In this first phase of the experiments, we will use the diagram Fig. 1 with the resolution 192x192 pixels for the images obtained from the cropping made by Principal Based ICP method. This phase aims to evaluate the extraction method, the classifiers used and their impact on Matching Process Time (MPT) with all the spectrums: white light, 460nm, 630nm, 700nm, 850nm and 940nm.

TABLE I. RECOGNITION RATE FOR LEFT PALM - WHITE LIGHT

Table Recognition rate RR for left palm with white light				
Block size	RR/MPT	Euclidian distance	Jeffrey divergence	City-Block
64x64	RR	74%	82%	81%
	MPT	0,079923 s	4,801806 s	0,139913 s
48x48	RR	79%	85%	83%
	MPT	0,085569 s	8,424969 s	0,215667 s
32x32	RR	83%	87%	87%
	MPT	0,143411 s	18,388208 s	0,431222 s
24x24	RR	85%	89%	89%
	MPT	0,224072 s	31,534391 s	0,734840 s
16x16	RR	87%	92%	92%
	MPT	0,414146 s	64,496038 s	1,608370 s
8x8	RR	78%	92%	89%
	MPT	1,774764 s	166,262356 s	6,320234 s

This Table I, clearly shows that the recognition rates (RR) obtained by the classifiers based on the city-block distance and the Jeffery divergence are clearly better than those obtained by the classifier based on the Euclidean distance. The classifiers based on the city-block distance and the Jeffery divergence give the best value of recognition rate 92% for the divisions (sub-images) of 8x8 and 16x16 pixels. We also note that the Matching Process Time MPT increases proportionally to the decrease in the size of the division block. This remark is logical, since the smaller the block size, the more the number of sub-images increases, and consequently the histogram of the image too. It should be noted that despite the similar performance shown by the classifier based on Jeffrey divergence (92%) with the 16x16 pixel block compared to that obtained with city-block (92%), nevertheless, the overall computation time for the set of classes is high (64.496038 s) compared to the city-block distance based classifier (1.608370 s).

We can conclude that even if the rates obtained with Jeffrey diverge and city-block are almost similar, the ratio (recognition rate \ calculation time) remains in favor of city-block. In the following, we are going to join on the same table the recognition rates of the left and right palm prints (resolution 192x192) and no longer record the calculation time, since we already know the behavior of the calculation time with the Table I.

For the right palm (R Palm), Table II shows the same remarks as the left palm (L Palm), the superiority of the classifiers based on the Jeffrey divergence and the City-block, and that the computation time is privileged for the city-block. Note that the value of the high recognition rate is **97%** with Jeffrey divergence for block size 8x8 pixels.

In Table III, the results obtained affirm that the resulting recognition rates with the classifiers based on the Jeffrey

divergence and the City-block are the best. Note that the value of the high recognition rate obtained is 91% with city block for a block of size 8x8 pixels with Left palm and 98% with right palm.

In Table IV, we have the same previous remarks, the superiority of the classifiers based on Jeffrey divergence and the City-block is maintained. Note that the value of the high recognition rate obtained is 88% with Jeffrey divergence for a block of size 24x24 pixels with left palm and 100% with Jeffrey divergence for a block of size 8x8 pixels with right palm. City-block also shows similar results: 99% for a block of size 8x8, 16x16 and 24x24 pixels with right palm, and 87% for a block of size 16x16 and 24x24 pixels with left palm.

16x16	90%	97%	94%	98%	94%	98%
8x8	80%	89%	93%	98%	94%	98%

Finally, for the 940nm spectrum, Table VII again shows the superiority of the classifiers based on the Jeffrey divergence and the City-block. Note that the value of the

higher recognition rate is 94% with Jeffrey and City-block divergence for different block sizes: 8x8, 16x16, 24x24 and 32x32 pixels with left palm. We notice the same thing for the right palm, note that the value of the higher recognition rate is 98% with Jeffrey and City-block divergence for different block sizes: 8x8, 16x16pixels.

In summary, we can draw up the following two tables which summarize the recognition rates obtained for all spectrums.

TABLE VIII. BETTER RECOGNITION RATES FOR LEFT PALM – 192x192 RESOLUTION

Table Recognition rate RR for left palm						
Block size	8x8	16x16	24x24	32x32	48x48	64x64
White light	92%	92%	89%	87%	85%	82%
460 nm	91%	89%	88%	90%	88%	87%
630 nm	86%	87%	88%	86%	85%	84%
700 nm	88%	91%	90%	87%	86%	86%
850 nm	95%	94%	95%	93%	94%	92%
940 nm	94%	94%	94%	94%	93%	89%

TABLE IX. BETTER RECOGNITION RATES FOR RIGHT PALM – 192x192 RESOLUTION

Table Recognition rate RR for left palm						
Block size	8x8	16x16	24x24	32x32	48x48	64x64
White light	97%	96%	95%	92%	89%	81%
460 nm	98%	97%	96%	96%	92%	87%
630 nm	100%	99%	99%	97%	95%	89%
700 nm	97%	95%	95%	96%	91%	85%
850 nm	98%	98%	98%	97%	96%	94%
940 nm	98%	98%	98%	97%	95%	92%

Both Tables VIII and IX show promising recognition rates for the proposed mechanism which vary between 81% and 100%. We also see the superiority of the results obtained with palm prints of the right hand. We can also say that on average the spectrums that give the best results for both hands are the 850nm and 940nm spectra with the exception of the 630nm spectrum for the right hand. It should also be noted that the (recognition rate / global computation time) ratio remains in favor of City-block.

b) *Result of experiment with resizing 128x182 resolution:* Based on the previous conclusions concerning the computation time, and the pattern characteristics of the regions of interest of the palmprints which show clearly visible and large-scale features, we thought that there is a relationship between cropping resolution and the performance of the proposed approach which is based on local methods. This assumption comes from the fact that if we have a high resolution with little relevant information, then we will have division blocks that will be similar between the different classes and therefore a reduction in recognition rates. This is what we will try to dismantle with the following experiments.

In the following we will resize images from 192x192 pixels to 128x128 pixels. The results of previous experiments will guide future experiments towards small and medium-sized blocks, which give reliable recognition rates. The second orientation concerns the choice of 940nm, this choice is due to the fact that the 940nm spectrum shows the veins of the palm which makes the system robust to the temptations of fraud and it has shown good results. The last orientation concerns the 460 nm spectrum, this spectrum best show the characteristics of the pattern and it shows a good performance against white light. The results of these choices will help in the construction of the final mechanism.

At the beginning, we will experiment with white light for left palm, to study the improvement brought with this resize.

TABLE X. RECOGNITION RATE FOR LEFT PALM – WHITE LIGHT

Table Recognition rate RR for left palm – white light				
Block size	RR/MPT	Euclidian distance	Jeffrey divergence	City-Block
32x32	RR	82%	88%	86%
	MPT	0,067901 s	5,478638 s	0,142141 s
24x24	RR	85%	92%	91%
	MPT	0,095663 s	10,647785 s	0,257458 s
16x16	RR	88%	93%	91%
	MPT	0,160716 s	19,651213 s	0,472513 s
8x8	RR	86%	91%	93%
	MPT	0,524071 s	53,258396 s	1,867898 s

The Table X shows a clear reduction in the calculation time compared to the 192x192 resolution, we cite as an example 166.262356 s (8x8 Jeffrey divergence in 192x192) and 6.320234s (8x8 City-block in 192x192) which will be reduced to 53,258396 s (8x8 Jeffrey divergence in 128x128) and 1,867898s (8x8 City-block in 128x128). Similarly the recognition rates have been improved. Note that the value of the high recognition rate is 93% with Jeffrey divergence for block size 16x16 pixels and City-block for block size 8x8 pixels against 92% obtained with Jeffrey divergence for block size 8x8 with 192x192 (cropping resolution) and MPT= 166.262356 s. In the rest of the experiments, we will no longer put the calculation times in the tables; we know very well that it will be significantly reduced.

TABLE XI. RECOGNITION RATES FOR 128x128– WHITE LIGHT

Table Recognition rate RR for left and right palm – white light						
Block size	Euclidian distance		Jeffrey divergence		City-Block	
	L Palm	R Palm	L Palm	R Palm	L Palm	R Palm
32x32	82%	80%	88%	95%	86%	94%
24x24	85%	87%	92%	97%	91%	95%
16x16	88%	98%	93%	98%	91%	98%
8x8	86%	95%	91%	98%	93%	99%

We note in Table XI, the superiority of the Jeffrey divergence and the City-block classifiers, and the value of the

highest recognition rate is 99% City-block for blocks of size 8x8 with right palm and 93% with left palm.

TABLE XII. RECOGNITION RATES FOR 128x128– SPECTRUM 460

Table Recognition rate RR for left and right palm - spectrum 460nm						
Block size	Euclidian distance		Jeffrey divergence		City-Block	
	L Palm	R Palm	L Palm	R Palm	L Palm	R Palm
32x32	85%	93%	92%	99%	92%	99%
24x24	87%	96%	95%	99%	95%	99%
16x16	92%	100%	93%	99%	93%	99%
8x8	89%	89%	93%	100%	95%	100%

The Table XII shows good value rates, the value of the high recognition rate is 95% with Jeffrey divergence and City-block for blocks of size 8x8 pixels and 24x24, similarly, for the right palm we have perfect value rates, the value of the high recognition rate is 100% with Jeffrey divergence and City-block for blocks of size 8x8 pixels.

TABLE XIII. RECOGNITION RATES FOR 128x128– SPECTRUM 940

Table Recognition rate RR for left and right palm - spectrum 940nm						
Block size	Euclidian distance		Jeffrey divergence		City-Block	
	L Palm	R Palm	L Palm	R Palm	L Palm	R Palm
32x32	76%	85%	95%	97%	92%	94%
24x24	86%	91%	94%	98%	95%	96%
16x16	89%	93%	94%	98%	96%	98%
8x8	81%	92%	93%	98%	94%	98%

Table XIII also shows good value rates, the high recognition rate value is 96% City-block for blocks of size 16x16 with the left palm. With regard to the right palm, we have effective value rates; the value of the high recognition rate is 98% with Jeffrey and City-block divergence for blocks of size 8x8 pixels, 16x16 and 24x24 pixels.

The results of the experiments confirmed that resizing the resolution of the crop to 128x128 instead of 192x192 pixels improved the performance of the recognition rates and reduced the calculation time. This is normal, since image databases will have small sizes, this resizing will have a significant impact in the real world for large populations. The blocks that show the best performance are 8x8, 16x16 and 24x24 pixels, which is normal since we are using a local method for feature extraction. Large size subdivisions are not efficient for this kind of methods, henceforth we will only use the 8x8, 16x16 and 24x24 pixel blocks for the remaining experiments.

C. Global Evaluation of Proposed Approach

In this section, we will conduct our experiments to evaluate the proposed approach (Fig. 3). These experiments consist in exploiting the sizes of the blocks, which have shown their performance previously (24x24, 16x16 and 8x8). In this evaluation, we will use the approach with a score-level fusion, with city-block distance and Jeffrey divergence. We will use the Cumulative Matching Characteristics (CMC) curves for

each fusion case to measure the identification accuracy. CMC curves demonstrate the ability of a recognition system to identify a given user in a set of data.

1) Results of fusion left palmprint 460nm and left palmprint 940

a) Results for block size 8x8 pixels: In Fig. 12, we notice that the curves resulting from the fusion of the 460nm + 940nm multi-spectral images with the classifiers with Jeffrey divergence and city-block are clearly higher than the other curves. The recognition rate obtained with the approach equal to 100%, this rate is higher than the best rate obtained for the systems studied with a single spectrum.

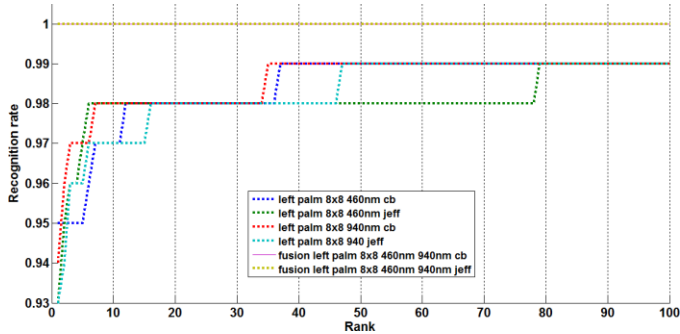

Fig. 12. CMC curve for fusion 460nm+940nm with 8x8 blocks.

b) Results for block size 16x16 pixels: In Fig. 13, we will report the same remark in the case of the block equal to 8x8. The recognition rate obtained with the approach is equal to 99%, this rate is higher than the best rate obtained for the systems studied previously.

Fig. 13. CMC curve for fusion 460nm+940nm with 16x16 blocks.

c) Results for block size 24x24 pixels: In Fig. 14, we notice that the curve resulting from the fusion of the 460nm + 940nm multi-spectral images with the classifier based on city-block is superior to the other curves, but this is not the case of the fusion curve which uses the classifier based on Jeffrey's divergence. The recognition rate obtained with the approach equal to 100% using the classifier based on the city-block distance, this rate is higher than the best rate obtained for the systems studied with a single spectrum.

Fig. 14. CMC curve for fusion 460nm+940nm with 24x24 blocks.

TABLE XIV. RESULTS OF GLOBAL APPROACH FOR LEFT PALM

Recognition rate for left palm – fusion with spectrums 460 and 940		
Block size	Jeffrey divergence	City-Block
24x24	99%	<u>100%</u>
16x16	<u>99%</u>	<u>99%</u>
8x8	100%	<u>100%</u>

The Table XIV summarizes the performance obtained by the global approach used.

2) Results of fusion right palmprint 460nm and right palmprint 940

a) Results for block size 8x8 pixels: In the Fig. 15, we have perfect recognition rates for fusion equal to 100%.

Fig. 15. CMC curve for fusion 460nm+940nm with 8x8 blocks.

b) Results for block size 16x16 pixels: In Fig. 16, we still have perfect recognition rates for fusion equal to 100%, which demonstrates the robustness and efficiency of the proposed approach.

Fig. 16. CMC curve for fusion 460nm+940nm with 16x16 blocks.

c) Results for block size 24x24 pixels: In Fig. 17, we still notice that the curves resulting from the fusion of the 460nm + 940nm multi-spectral images with the classifiers with Jeffrey divergence and city-block are clearly higher than the other curves. The recognition rate obtained with the approach equal to 99%, this rate is higher than the best rate obtained for the systems studied with a single spectrum.

Fig. 17. CMC curve for fusion 460nm+940nm with 24x24 blocks.

TABLE XV. RESULTS OF GLOBAL APPROACH FOR RIGHT PALM

Recognition rate for right palm – fusion with spectrums 460 and 940		
Block size	Jeffrey divergence	City-Block
24x24	99%	<u>99%</u>
16x16	<u>100%</u>	<u>100%</u>
8x8	<u>100%</u>	<u>100%</u>

The Table XV summarizes the performance obtained by the global approach used for right palm.

The results demonstrated by the experiments that we see in the CMC curves, on the Tables XIV and XV and the comparison with others methods in Table XVI, reflect the effectiveness of the approach used to build a reliable and robust recognition system.

TABLE XVI. A COMPARISON OF RECOGNITION RATE OF THE PROPOSED APPROACH AND PREVIOUS METHODS

Method	Recognition rate
EigenPalm (EP) [55]	91,25%
FisherPalm (FP) 55]	92,32%
Gabor-based RCM (GRCM) [55]	96%
Enhanced GRCM (EGRCM) [55]	98%
Image level fusion by PCA [56]	95,17%
Quaternion PCA [56]	98,13%
Quaternion PCA+Quaternion DWT [56]	98,83%
PCA on HOG [57]	98,73%
KPCA on HOG [57]	98,737%
Proposed approach (using 24x24 bloc)	99%
LDA on HOG [57]	99,17%
KLDA on HOG [57]	99,17%
PCA on HOL [57]	99,73%
KPCA on HOL [57]	99,73%
Proposed approach (using 16x16 and 8x8 blocs)	<u>100%</u>

IV. CONCLUSION

In this work, multi-spectral images are used with different spectrums to build a secure system against tampering maneuvers. In this sense, two instances are employed with two spectrums that can be captured at the same time (but sequentially), to be used in a score-based fusion approach. The experimental results were conducted on the casia multispectral database after pre-processing with the Principal Based ICP method, subsequently the cropping used was improved for an optimal construction of the histograms, which made it possible to increase the performance and to reduce the calculation time. Finally, the conclusions drawn were deployed to guide the proposed approach, which clearly showed its effectiveness with rates varying between 99% and 100%. Thus, it is possible to conclude that this approach provides proven reliability and can be used for secure fingerprint recognition systems against fingerprint forgery fraud. This work aims at the possibilities of securing during the "capture" phase, nevertheless this securing will have to affect other aspects such as the base of the images. This perspective will be the subject of future work on securing biometric images with watermarking methods.

Abstract—The creation of this research was born out of interest in creating the art of carved sandstone into Buddha statue found in the area of Phayao Province, which was part of the Lanna Kingdom that prospered during the 19th-23rd Buddhist century. In the area of Phayao province, the sandstone Buddha was created which is an art and valuable artistic feature that has been shown until now. There are five categories of sand stone Phayao Buddha style that are studied and classified which have distinctive characteristics of each Buddha statue. Nowadays, traditional techniques for making Buddha statue are becoming less and less popular as Buddha statue made of sandstone are not as popular as before. Creating a Buddha statue from stone was a difficult and laborious process. Including craftsmen in carving began to decrease in number. In this research, a tool for collecting data on Buddha statue was used photogrammetry to store and process into 3D objects and use processes and techniques for creating 3D work that has been created, and simulating the Buddha statue by using the outstanding features of the Buddha statue collected as the main part in selecting the proportion of the Buddha statue to combine to form a new Buddha statue in 3D format by simulating the Buddha statue by such methods as a prototype to reproduce the appearance of Buddha statue for use in the creation of works of art that are an important part of history. It is also used to study the characteristics of Buddha statue in combination to create the characteristics, and a new way to preserve art by using technology to transfer and preserve these valuable works of art in another way.

Keywords—3D art; 3D artifacts; creation; blending art; reconstruction artifacts

I. INTRODUCTION

Creating Buddha statue data in a Phayao type Buddha statue entails using the exact qualities and structure of each portion of the Buddha statue collected to build a 3D digital file copy of the Buddha statue that references the Buddha statue's true structure. The right structure and proportions of the sandstone Buddha statue are made by the distinguishing qualities developed for imagination and visualization, which are obtained by analyzing the data from the genuine structure and proportions. The depth of Phayao craftsmen's art has condensed the incredible dimensions found in Phayao sandstone Buddha statue from the beginning through the evolution of countless forms into the unique qualities of each

Phayao artisan's work. Beginning with the sandstone Buddha statues discovered in the Phayao an area, the Buddha statues are mixed with characteristics of Buddhist art from other regions of the kingdom and art by other Buddhist artists.

The Buddha statue is rather round and oval, as shown in the art of the Chiang Saen Buddha statue, which was influenced by the U-Thong Buddha statue. The two mouths of the Buddha statue that is frequently seen in the province of Phayao have a tiny and prominent nose; an oval face; a prominent nose; and a mouth with a boundary line. The researcher examined the creation of Buddha statues by artists who make Buddha statues for temples and princes, as well as the development of Buddha statues by local craftsmen in the region, in order to build a Buddha statue. The Buddha statues in this study are a mash-up of many types of art.

The art of sandstone carving in Phayao Buddha statue is not popular with people in today. Because the construction of Buddha statue with sandstone is a difficult process. Due to the factors of the material used to build, the weight of the stone and the procurement of stone. The factors of skilled craftsmen in stone carving are in accordance with the correct characteristics and expertise in production. In addition, the characteristics and guidelines for creating Buddha statue should be inherited and have unique prototypes. The problems and factors mentioned above are the problems that should be using digital tools and technology to assist in the creation of step-by-step and scientific and innovative tools will be used to benefit the art for the preservation and development of these values in next generation.

Instruments of technology and multimedia, such as data-collection science and computers, have been expanded and improved in a variety of ways. All suppliers are also working on new developments to make the systems more cost-effective and accurate, while also reducing current limitations. This is, to the best of our knowledge, the first study to survey various smart shelf innovations and application scenarios. [1] Even human life and activities such as living, consumption, and viewing must be integrally tied to and congruent with the technological environment. As a result, the components of the digital and technical world are astounding. Today, the world and human life are extremely important. These digitization initiatives in the human sciences prompted the cross-

disciplinary discipline of Digital Humanities to investigate computer based semantic analysis and media processing [2] Computer technology has become a new tool for modern artists in terms of art. As a result, animators can devote more energy to creative work rather than the heavy and tedious work of traditional animation [3]. These technological advances have also helped to preserve and promote art and historical understanding. The method of use is the approved recording technique that makes it easier to digitize archeological data. Photogrammetry, which is image-based, creates three-dimensional images by triangulating points (in these case pixels) and using correlation techniques to reconstruct a subject's volume. This method enables us to establish trustworthy digital archives, providing digital reproductions of the shelters and their etched panels [4].

The aim of this research was to simulate the Buddha statue 3D by combining Buddhist art with technology of computer graphic, and 3D creation. In this research will use photogrammetry and the creative process of changing the 3D model to make a 3D model of the Buddha in the style of the ancient Phayao artists. The use of these digital tools and technologies for developing and generating concepts for creating such Buddha statue is another way to develop creative forms of Buddha statues and works. The art of sculpting sandstone Buddha statues today has many problems that can be solved with digital tools. It is also another method that helps to preserve the value of art and culture for further development and dissemination. With this information, art of Buddha statue can be hacked and changed, or they can be developed digitally for research in the future.

II. LITERATURE REVIEW

The main of research use photogrammetry and creative process of changing the 3D model to make a 3D model of the Buddha in the style of the ancient Phayao artists. Each of them has research and creative works to guide and suggest ideas for this research. Using 3D data for reconstruct 3D shapes from point clouds, despite the fact that many point cloud-based 3D reconstruction frameworks have been proposed in recent years, we discovered that the training loss is usually Chamfer Distance (CD), which assigns equal weights to all points within the point clouds. However, for human visual perception, edges and corners are more important than flat points. According to research, the proposed framework can focus on edges/corners and produce more appealing results. The visual-enhanced approach proposed here can also be used to generate high-quality point clouds in a 3D generative model [5].

Complex deep neural networks are required to grasp and disentangle spatial transformation and image data characteristics inherent in training data in order to effectively recreate 3D images which limit the use of data-driven techniques in many practical applications. That using existing geometric information from imaging technology improves the process of unfolding incoming sensor data into 3D space in the context of computed tomography image reconstruction [6].

In the computer vision and graphic design communities, learning to create three-dimensional (3D) point clouds is becoming increasingly popular. Numerous solutions have

been proposed to address the issue of producing 3D point clouds. Because a 3D object can be presented in a variety of formats, such as point cloud, voxel, mesh, and implicit field, these approaches can be classified according to their output format. As a result, manually rebuilding point clouds is the most common method of creating 3D objects. Most techniques start with an encoder that extracts a latent feature from the source images or 3D point cloud, followed by a decoder that maps the latent feature to the ground truth of the 3D point cloud [7].

Visual improvements of 3D point cloud rebuilding from a single perspective is aimed at the construction of 3D Point cloud objects, a type of 3D object creation based on object data collection that is quite common nowadays with numerous types of 3D structure processing and integration procedures involving point cloud., voxel, mesh, and implicit fields. These methods assess processes for extracting 3D structure information from entire 3D objects using point cloud-based processes [7].

The aim of the research was to develop the most effective methodology for virtual 3D reconstruction of damaged archaeological sites, which included construction or building structures, for the sake of cultural heritage conservation. Based on the revised point cloud and excluding affected areas, a surface depicting the terrain shape of the archaeological site prior to mechanical damage was interpolated. Using textured solids and surfaces representing walls, connection channels, and vaults, a rigorous virtual reconstruction of the architectural complex's original condition was carried out using both measured and interpolated surfaces. [8] The goal of this study is to recreate 3D models of ancient buildings that have been severely damaged by using high-quality map data to produce 3D skeletal structures for the preservation of history and culture [8].

In certain circumstances, digital photogrammetry and 3D reconstruction can aid archaeological excavation by reducing time without sacrificing information and even generating unique data, as well as making the site accessible to the public. Using this method, in the research aims to support studies of relative chronology based on the observation of structure textures and the statistical processing of block measurements and presents the results in the case of the St. Maria Veterana complex (Triggiano, southern Italy), a very articulate archaeological site of unknown dating, whose stratification and constructive chronological phases have been very confusing thus far. The statistical analysis of the dimensional dataset revealed indicative correlations between the various rooms of the archaeological site, and thus suggested valuable information on building techniques through comparison with results of lithological and textural observations of areas [9].

The use of photogrammetry technology creates a scalable surveying option that can be deployed faster and at a lower cost than an airplane survey. These rapidly advancing technologies open up exciting new avenues for archaeological inquiry and methodology, with the potential to reach a broader audience by engaging with topics and disciplines outside of archaeology's traditional domains [10].

The technique employed was centered on the use of point cloud 3D modeling to obtain virtual objects of a Roman cornice from the Castulo Archaeological Site (in Spain), followed by the use of those models for material restoration of the losses via 3D printing of the piece for reintegration. The process used focused on using photogrammetric 3D modeling to obtain virtual models of a Roman cornice from the Castulo Archaeological Site (in Spain), followed by the use of those models for material restoration of the losses via 3D printing of the piece for reintegration [11].

Photogrammetry procedures and processes for the digitalization and reconstruction of three-dimensional works in archaeological research and excavations can reduce study time and make knowledge accessible to the public through simulation approaches. The 3D model was created from an archaeological site in Spain using the 3D object modeling method, 3D manipulation of the specimen to generate the updated 3D structure, and 3D printing to validate the modified 3D object data [11].

With a good setup and good quality cameras with a standard lens, photogrammetry-based digitization can be a powerful tool for documenting, conserving, analyzing, and making large swaths of archaeological collections and landscapes available to the public and fellow researchers. Archaeologists and 3D specialists believe that before even taking the object out of the box, one should question their motivations for digitization and ensure the best reproduction quality possible [12].

The use of photogrammetry has aided in the virtual reconstruction of the work for the restitution of the statue, but it has also provided a useful database in 2D and 3D for the documentation of the locations. The combination of these data with historical sources improves the approach for the proposal of a scientific approach useful in restitution work, which is still hypothetical and a topic for debate in the scientific community [13]. In creating a 3D model a method of simulating a similar structure can be used to complete the construction of the object.

In fact, the use of photogrammetry allows for the creation of a detailed virtual model, which has two advantages: on the one hand, it provides valid and, above all, reliable support to historians, archaeologists, and restorers, and on the other, it allows for the dissemination of Cultural Heritage artifacts to a wider audience [14].

III. METHOD

This application, which runs on the Windows 10 operating system, allows the researcher to create and improve 3D objects. The selection of a 3D acquisition method is an important step when designing a digitization plan, and it is highly correlated with requirements such as the purpose of 3D digitization, the final use of 3D models, as well as other aspects of a digitization project such as budget, duration, and available personnel experience [15].

a) *Agisoft metashape* - Photogrammetry Image processing applications and tools. (see Fig. 2)

b) *Autodesk maya 2020* - customization retopology process editing, and improvement tools for 3D models.

This experiment employs both surveys and creative experiments, which are data collection and processing in both the science of producing ancient Buddhist art and the creation and evaluation of multimedia technological tools.

Analysis of the different parts of Phayao Buddha art by looking at and rating the different types of sandstone Buddha statues and picking out the features that make each Buddha statue unique. Fig. 1 explains all the steps involved in the research process.

Fig. 1. Research process

1) Take a picture of the Buddha statue in each body by taking a picture around the Buddha statue. This photo recording uses the recording with the use of recording to obtain a digital image for processing. Photogrammetry is the next step. Data collection of Buddha statues digitally utilizing image processing techniques such as photogrammetry, which is a digital data recording procedure that converts images into 3D images. This will make it easier to get the desired surface proportions and surface attributes for the material.

2) Importing 3D image processing data in the form of photogrammetry. Retopology is the technique of decreasing the features of a 3D model to the lowest resolution possible while maintaining texturing and rendering equivalent to a high resolution actual image. This will make image processing in a computer program easier and faster, as well as enable the workpiece to be used in a wider range of applications, which is a crucial component in making 3D things that users of 3D tools grasp. It is important for 3D tools and applications.

Fig. 2. Photogrammetry processing in agisoft metashape

3) But the workpiece obtained from the above process will have the same result as the real workpiece but with high polygon (high detail), making it difficult to use the 3D workpiece for editing or adjusting. Retopology is the use of the High polygon model to rearrange polygons with fewer polygons to make it easier to In order to create a new Low polygon piece from the original High polygon with the most proportions and appearance equivalent to the original workpiece, the surface treatment technique or Texture UV of the workpiece was also used. The 3D rendering is very close and looks the most similar to High polygon 3D.

4) The Buddha statue s that have been carved into exceptional proportions from the 3D models in each piece can be brought to life by choosing the proportions of the Buddha statue s that have been sketched in a rough outline before joining the Buddha statue s in the next stage.

Analysis of the different parts of Phayao Buddha art by looking at and rating the different types of sandstone Buddha statue s and picking out the features that make each Buddha statue unique. Exploration of alternative means of meaning making in archaeology based on non-linear narratives, three-dimensional perspective, and virtual reconstruction is now possible thanks to 3D visualization and digital archaeological methods. [16]

5) Creating a connection between each statue by using editing software and adjusting 3D pieces by emphasizing the connection to have the least amount of adjustment because it may affect other parts of the Buddha statue and collecting details, such as adjusting and adding texture to the surface for beauty.

By evaluating the structure and proportions of the plinth elements, parts with characteristics that can be connected to each other are used. The parts of the statue will be adjusted to a minimum in order to maintain the original art that has been collected from data as much as possible.

Since then, computer technology has advanced significantly. 3D images created with the right software are truly realistic and look like photographs. They are used for popularization, education, and research. Scientists have recognized the importance of digital 3D imaging as a tool for testing hypotheses and communicating research findings to the public. [17]

IV. ANALYSIS OF PROPORTIONS AND CHARACTERISTICS IN ASSEMBLY AND USE

Characteristics of the Buddha, the Buddha statue that have been selected and used to create this Buddha statue refer to the concept of creating a new 3D Buddha statue while retaining the distinctive characteristics of Buddha statue in the Phayao

art style with a combination of characteristics and widespread beliefs. Therefore, the Buddha statue proportions in the obtained Buddha statue may have different characteristics and feature combinations that are different from those commonly seen in the art of sandstone Buddha statue. But the characteristics of the proportions necessary to take into account the proportions and composition of the sandstone Buddha statue of Phayao are as follows.

- 1) The appearance of the head is oval, round, and flat.
- 2) Curved eyebrows collide into a winged shape.
- 3) Curved and prominent nose shape.
- 4) The curved mouth resembles a bird's wing.
- 5) Hair granules are round or square pyramidal or without hair granules.
- 6) The hair pacifier looks like a lotus flower which comes in both small and large sizes.
- 7) Body parts are plump, with large breasts protruding strongly and prominently. [18]

The above characteristics are a clear feature that will be an indicator of the creation of sandstone Buddha statue in this research process to be creative as the correct characteristics of traditional art.

V. RESULT

Using digital tools and methods to convey or convey the meaning of antiques and to interpret or create new ones. This is a simple and convenient method that can be extended more widely.

A touch-object, in the form of a 3D printed facial reconstruction, extends an otherwise visual experience to the visually-impaired and encourages 'embodied knowledge-making' among all visitors. [19]

The proportions and compositions of the Buddha statue s used to assemble to create a new Buddha statue in 3D are taken from the highlights of sandstone Buddha statue of Phayao that have been recorded, and study with the components shown as follows.

1) A clear base is a type of base that is extensively used in the construction of sandstone Buddha statue in Phayao. Because sandstone Buddha statues are manufactured from a single piece of sandstone, building a sandstone Buddha statue with a clean foundation is the method. Considering the techniques used by sandstone sculptors at the time, flat base styles are classified into three types: flat base, short base, tall base, and tidy hexagon base.

2) The appearance of the Buddha statue 's sitting position is a strong influence from the Chiang Saen Buddha statue , which was influenced by the sandstone Buddha statue while making the first Buddha statue in the Phayao craftsman. The diamond meditation pattern seen in the building of the Buddha statue of Chiang Saen Sing 1st Characteristics of the Buddha statue originated in Chiang Saen Kingdom which is a vast ancient kingdom in the north) and also found in the Sukhothai Kingdom art Buddha statue was used in the fabrication. It has a huge, square foot form and is the same size as the toes.

3) On a wavy crown, the head has a Buddha-shaped mouth at the margin of the mouth. The corners of both sides of the lips are swept up; the eye is bent upward to meet the mouth; and the crown is shaped like a square, comparable to a pyramid.

4) His physique is massive. His arms, influenced by the Chiang Saen Singha, 1st Buddha statue, are huge, plump, aligned, and the same size. Above the tan is a short robe (breast).

A 3D visual used in archaeology to reconstruct cultural heritage objects is a software image that reflects the knowledge gained from an analysis of archaeological excavation sources. Spatial models are built using existing documentation and literature. 3D reconstructions are created by analysing and interpreting photographs taken during excavations. [17] In Fig. 3 creating a Buddha structure by using the structure of the Buddha statue 3D from process of photogrammetry, then selecting the proportions of each part of the statue to be adjusted and corrected using the tools from the 3D program, which uses scaling to be appropriate to be able to connect seamlessly.

Fig. 3. Characteristics of the components of the Buddha statue in each part to bring together

The combination of the proportions of each piece from the 3D creation of the Buddha 3D statue from Fig. 4 in each part that creates a smooth connection and is in accordance with the typical characteristics of creating a Buddha statue carved in the Phayao style.

Fig. 4. 3D Buddha statue created by blending proportions in each art style

VI. DISCUSSION AND CONCLUSION

The result of the development and experimenting is a digital work in the form of a 3D piece of Buddha statue that reveals the qualities of a sandstone Buddha statue carved uniquely because the evidence and art of sandstone sculptures have degraded and cracked significantly due to both eroding material and weather. The application of such strategies or technologies to foster honesty and connect thoughts and tales from the technological process is thus extremely significant

and required in the manufacturing and fabrication of components to assist in the completion and operation of this work. In this sense, the selection of qualities is critical. The Buddha statue and its dimensions should be as similar as feasible so that they can be related to each other. Too much modification in the proportions of the Buddha statue may impact the features of the Buddha statue in other proportions the fullness of the Buddha statue reproduction while applying the creative concept of the Phayao craftsman in each proportion, which is uncommon nowadays. The prospect of extending and developing the concept of Buddhist art or features from simulations, or it can be used to compare simulated Buddha statue in order to estimate the proportions of shattered Buddha statue. The use of proportions that are the overall characteristics of the unique characteristics of the sandstone Buddha statue of the ancient Phayao Buddha art statue used to assemble the Buddha statue is also the researcher's concept that brings out the outstanding features of the Buddha statue of Phayao craftsmen in each era. Assembled into a Buddha statue without finding such a Buddha statue in the creation because the development of the art of creating a Buddha statue in Phayao sandstone stopped developing the guideline, when the Lanna Kingdom and Phayao's prosperity stopped during the decline of the Lanna Empire and the city of Phayao, was abandoned. The science of developing these arts has also stopped developing. This creation is another concept that brings the remaining works of art to be applied and assembled into a new piece without destroying the original prototype. In various movements to assess the probability of previous features, research and simulation, and perfect Buddha statue or antiquities that desire to be examined and postulated in connected and associated sciences diverse works of art in other multimedia domains via the use of simulation technology. In creating a 3D model of Buddha statue, this piece helps guide the construction and production of Buddha statue or is used to create and support the creation of art to occur more conveniently from technological and multi-tools media. It also reduces problems and steps that hinder the creation and production of work pieces. It may be used to compare and evaluate Buddha statue in order to estimate and evaluate Buddha because it will disrupt the connection of the proportions of the simulated Buddha statue. According to the qualities of Buddhist art, the proportions of the presentation may not be comprehensive and attractive. However, in this creative effort, the image utilized has ties to each component of the Buddha statue. The look that was born in this exhibition demonstrates.

Hardware Trojan Detection based on Testability Measures in Gate Level Netlists using Machine Learning

Thejaswini P, Anu H, Aravind H S, D Mahesh Kumar, Syed Asif, Thirumalesh B, Pooja C A, Pavan G R
Department of Electronics and Communication Engineering,
JSS Academy of Technical Education, Bangalore-560060, Karnataka, India

Abstract—Modern integrated circuit design manufacturing involves outsourcing intellectual property to third-party vendors to cut down on overall cost. Since there is a partial surrender of control, these third-party vendors may introduce malicious circuit commonly known as Hardware Trojan into the system in such a way that it goes undetected by the end-users' default security measures. Therefore, to mitigate the threat of functionality change caused by the Trojan, a technique is proposed based on the testability measures in gate level netlists using Machine Learning. The proposed technique detects the presence of Trojan from the gate-level description of nodes using controllability and observability values. Various Machine Learning models are implemented to classify the nodes as Trojan infected and non-infected. The efficiency of linear discriminant analysis obtains an accuracy of 92.85 %, precision of 99.9 %, recall of 80%, and F1 score of 88.8% with a latency of around 0.9 ms.

I. INTRODUCTION

Hardware Trojans are modern-day system attacks that will cause prominent damage to the IC or system in numerous ways. Though the software is considered to be vulnerable, the underlying hardware is generally considered to be safe. However, research has shown that, due to the complex nature of the design, fabrication process, rapid prototype development, and distribution of the final product, new sources of attack are prominent [1]. Speeding up the development cycle and lowering R&D costs is the main goal of most manufacturing companies because the estimated R&D cost is up to \$5 billion. Most companies cannot afford to invest such a huge amount from start to finish. So, companies frequently outsource fabrication to a third-party foundry, buy IP cores from third-party suppliers, and employ EDA tools from third-party vendors. Third-party suppliers can readily enter such a model, and the supply chain is currently deemed vulnerable to assaults like Hardware Trojan insertion, reverse engineering, IP

theft, IC tampering, IC cloning, and IC overproduction, among others. Hardware Trojans are arguably the most concerning of them, and they have attracted a lot of attention. It will eventually change the functionality of the system and the user will be unable to take any action against it [2].

Hardware Trojans can be defined as malicious components introduced during the design, manufacturing, fabrication, testing, or development phase [3]. Once introduced they can be activated anytime, anywhere, and according to the attacker's interest. The activation mechanism divides Hardware Trojan into two groups: always on and triggered. Always-on Trojans are active as soon as the systems or designs are turned on, whereas triggered Trojans require the activation of some form of condition. A Hardware Trojan circuit is generally designed in two parts; a condition-based circuit (trigger) and an operation circuit (payload) which is interconnected via trigger net [4]. The Trojan will be triggered and activated when the predefined criteria is satisfied. The most dangerous part is that they can be inserted anywhere in the circuit, be it processor, IC power grid, IO, and there is no way to immediately know the source of the threat. By the time it is discovered and neutralized it may be too late as it can change the functionality of the circuit. They can also downgrade its performance, leak sensitive information and finally cause a Denial-of-Service attack [3]. Therefore, to find a solution for many such attacks, various researches are being conducted. Amongst them, the logic function test (LFT) is a traditional method [5]. Most of the existing methods of LFT do not effectively activate any potential hidden Trojans. Researchers use side-channel analysis to detect Hardware Trojans by modelling and analysing electromagnetic information generated during chip operation [6]. Traditional side-channel analyses' effect isn't sufficient, according to researchers [7], due to low sensitivity detection rates for big process fluctuations and a small Trojan footprint. Combining principal component analysis and linear discriminant analysis to analyse chip power is effective in evaluating Trojan detection accuracy [8]. Machine learning techniques for malware detection are the most successful state-of-the-art research topic because of their ability to keep up with malware evolution. They concentrate mainly on two areas, one is feature extraction, and the other is dimensionality reduction. Support Vector Machine algorithm seems to be the go-to algorithm for detection in multiple cases [9]. However other advanced algorithms are also being explored to trigger and detect a Trojan. Triggering a Trojan has an impact on the system's

power usage as well as the circuits' delay. This behavior is extensively used to study the power and delay characteristics of hardware Trojans in order to detect them[10].

Even though there is a possibility to detect the Trojan using the different techniques as stated so far, there is still scope for optimization. The contributions made by this paper are as follows:

1) We propose the use of gate-level descriptions of nodes using controllability and observability values to generate a dataset to detect the presence of Hardware Trojan.

2) Machine Learning techniques are used to detect the presence of Trojan.

3) Benchmark circuits-C17, C3540 and C432 are considered to validate our proposed technique.

4) We experimentally prove that our proposed model has an area and power reduction up to 75% and 80% respectively in Trojan free circuits. This performs better in comparison to other state-of-art techniques.

The rest of this paper is organized as follows. Section II and III analyze the related works and motivation. Section IV shows the proposed scheme. The experimental results and discussion are presented in Section V. Section VI shows the conclusion.

II. RELATED WORKS

Various techniques ranging from score-based classification [6] for identifying Hardware-Trojan-free or Hardware-Trojan-infected circuits without using golden model-based approach to deep learning techniques are researched. The side-channel analysis and detection method [11], uses dimensional reduction to detect HTs. This causes the loss of important feature information of Hardware Trojans after the principal component analysis or filtering process. To solve this problem, a Hardware Trojan detection technology is proposed based on Extreme Learning Machine (ELM), which can completely retain important information without any inaccuracies caused by modelling. Results show that detecting the Hardware Trojans only used about 0.15% of resources. The accuracy rate was about 90%.

In terms of router looping, traffic diversion, or core spoofing, a trojan attack corrupts the router packet [9] by changing the destination address. As a solution, SVM is used to increase detection accuracy. According to the estimates, the suggested security solution architecture achieves a 93 percent accuracy for seizure detection applications in 4.8 μ S.

Detection of Trojan using gate-level netlist based on observability and controllability analysis [4] produce sufficient results. When this technique was used on numerous trojans, the findings reveal that even in the worst situation, all Trojans are discovered effectively with zero false positive and negative rates in less than 14 seconds.

Using a specific gate-level netlist that specifies the Trojan nets in full, the review paper [12] covers extracting 51 gate-level Trojan features. The usage of an ensemble-based random forest classifier results in a true positive and true negative rate of 100 percent.

Implementation of SVM using five-dimensional vectors [13] classifies all the nets in an unknown netlist into Trojan affected and normal ones using the Trust-HUB benchmark. Not only SVM but various other machine learning algorithms like Decision Tree, K Nearest Neighbour [14] is applied to identify the Trojan. Further to increase classification accuracies, Hardware Trojans are discretized based on their dominant attributes. The results show that both Machine Learning algorithms when trained on a given dataset perform well. DT and KNN models can accurately predict about 83% of the test data.

In addition, existing deep neural networks security studies are not extensively conducted at these software algorithm levels [15] and the more realistic attacks by third-party vendors are not explored. So, it is successful in demonstrating how an attack is possible. Experiments reveal that the approach can quickly generate and activate a variety of Trojan attacks that can readily overcome existing defenses. This is very important in formulating a solution to the attack.

III. MOTIVATION

The presence of Hardware Trojans (HTs) in circuits causes malfunction on various scales depending on the type of Trojan attack. Amongst the numerous existing state-of-art techniques, the FANCI [16] technique uses a coverage-like approach where it does not require access to any verification stimuli. But the attackers like third-party vendors being aware of this can make the Trojan look benign. The third-party inputs from on-chip IPs can be scrambled to suppress the Trojan triggers. But this would not work for analog triggers. So, the Side-channel techniques can be used to unmask Trojans injected by third parties [17], but this method is unusable until IC is manufactured and inside the supply chain. As a solution, the use of formal proofs enables to development of trusted IPs. However, this assumes that proof is sufficient to rule out injected Trojans and that IP specifications are known. Therefore, there is a need for better-advanced techniques to counter novel malware attacks. One such technique is Machine Learning (ML) [18].

The rise of Machine Learning has profound implications for many industries, including cyber security. ML-based anti-malware tools are generally believed to provide better detection of modern malware attacks and improve scanning methods. Machine Learning algorithms perform better against unforeseen threats as they can be trained to handle unknown potential threats. This is a major advantage over other techniques. They yield more accurate, efficient solutions. As a result, employing ML techniques proves to be beneficial.

IV. METHODOLOGY

The proposed Trojan detection technique is a combinational circuit [19] for avoiding unintended malicious activity is as shown in Fig. 1. Controllability and Observability are the two parameters considered for the detection and classification of Trojan in the given circuit [20].

To implement the proposed methodology, let us consider ISCAS benchmark circuits. These are implemented using Verilog. We have designed a Trojan threat model and applied it to ISCAS benchmark circuits. Then we generate a Gate Level

netlist. Using Python and gate-level netlist, we obtain values of two parameters, Controllability and Observability to detect the presence of Trojan in the circuit. Hence, we create a dataset using these values as input. The model is trained and tested by applying different Machine Learning techniques. The desired output is obtained and verified using functional verification and overhead analysis.

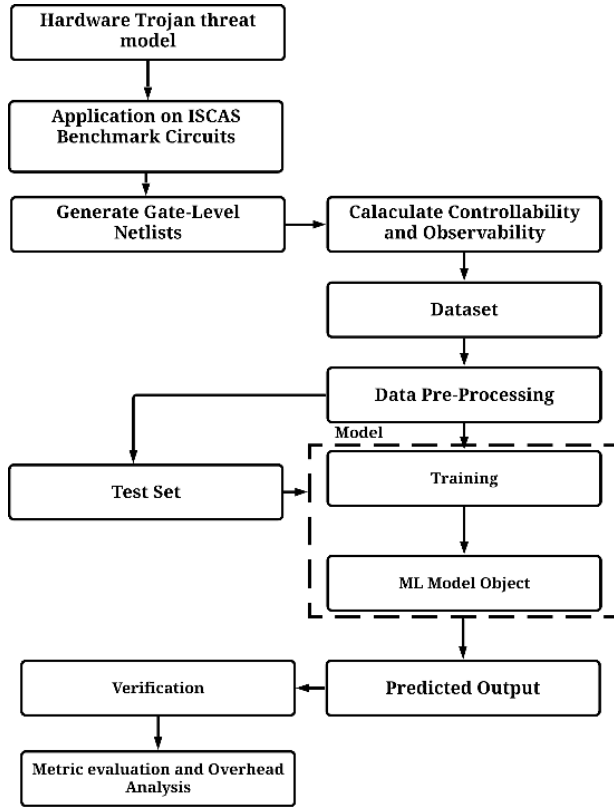

Fig. 1. Block diagram of proposed methodology

A. Design of Trojan Threat Model

A trojan is a unique circuit that performs specific malicious activity [21]. Trojan considered in our proposed work will change the functionality of the circuit. Fig. 2 shows the Trojan threat model designed for our work. Here, 4-bit Linear Feedback Shift Register (LFSR) is used to trigger the Trojan and NOT gate act as payload. One input to the comparator is from LFSR and the other input is a random number generated by the attacker. The output of the comparator is connected to the select line of MUX. If the output of the comparator is one, Trojan is triggered and vice versa.

B. Benchmark Circuit Selection

The proposed method is implemented on a standard ISCAS benchmark circuit [22]. The ISCAS '85 benchmark circuits are combinational circuits that are used by researchers as the basis for performing analysis and comparing results. C17-NAND only circuit, C432-a 27 channel interrupt, and C3540—an 8-bit ALU are the three circuits considered in our work as depicted in Fig. 3, Fig. 4 and Fig. 5.

Fig. 2. Design of trojan threat model

Fig. 3. C17 (NAND circuit)

C. Gate Level Netlist

Gate Level Netlist contains information regarding the logical connectivity of all standard cells and macros [23]. Gate level netlist of C17, C432, and C3540 is generated by synthesizing these circuits using the Cadence tool at 90nm technology. These gate-level netlists are used for calculating observability and controllability values.

D. Controllability and Observability Calculation

The presence of Trojans in the circuits is analyzed by calculating the controllability and observability values.

1) *Controllability analysis*: Nets with poor testability are identified using combinational controllability. The levels of controllability range from 1 to infinity. Because the possibility of detecting such a node is very low, and controlling that particular node is quite difficult, nodes with high controllability (CC) ratings are more susceptible to having a trojan inserted. All signals from primary inputs to primary outputs have their controllability values determined first. The circuit is initially levelled by giving each gate a level value [24]. Each gate's output controllability is then calculated. Controllability (CC) in general is expressed as:

$$CC(i) = \sqrt{CC0(i)^2 + CC1(i)^2} \quad (1)$$

where, CC0(i) is Combinational Controllability 0 and CC1(i) is Combinational Controllability 1

Fig. 4. C432 (27 channel interrupt controller circuit)

Fig. 5. C3540 (8-Bit ALU circuit)

2) *Observability analysis:* Observability is a measure of the ease (or difficulty) with which one can calculate the signal value at any logic node in the circuit by controlling its primary input and observing the primary output [4]. The observability values for all signals from primary outputs towards primary inputs are then calculated. The observability of one input of a AND gate with multiple inputs is given by

$$CO(s) = P(x,y)+1 \quad (2)$$

where, x=output observability and y= CC1 of other inputs. If ‘U’ is a primary output node of a digital circuit, then the combinational observabilities of node I are defined as, $CO(U) = 0$. Table II, Table III, and Table IV reports the controllability and observability values obtained.

E. Machine Learning Algorithms and Data Set Creation

The use of machine learning algorithms aids in the better analysis of various Trojan threats because they are capable of processing massive amounts of data with greater precision. Using Python, dataset is created by evaluating the controllability and observability values received from the chosen benchmark circuits. The more advanced algorithms can be trained to detect any kind of Trojan across various platforms. Hence, we employ various Machine Learning Techniques (MLT) [25] along with our proposed technique to detect the presence of Trojan in the circuits by classifying the nodes as Trojan free and Trojan infected.

V. EXPERIMENTAL RESULTS AND DISCUSSION

A. Functionality Verification

To understand the impact of Trojans on the circuits let us consider C3540, an 8bit ALU. C3540 consists of Mux, shift register, ALU_Core, xor gate, and BCD subtractor. Trojan can be introduced to any block in the circuit. To understand the effect of Trojan, we are introducing Trojan to the BCD adder block in C3540. Let us consider two and five as inputs to this BCD block. When this block is configured as adder, the output is six in the absence of Trojan. When Trojan is activated, the output changes. This can be observed in Fig. 11, where the Trojan activation at 72ns changes the output value from 6D to 83 and remains in the same state as long as Trojan is activated. Once the Trojan is deactivated, output changes to the original value. As the blocks in C3540 are cascaded as seen in Fig. 11, the final output of ALU will also be changed. This clearly demonstrates that, due to the presence of Trojans, functionality of the circuit will change. Similarly, functionality verification of C17 and C432 benchmark circuits are carried out for both the cases, with Trojan and without Trojan. The obtained simulation results are shown in Fig. 6, Fig. 7, Fig. 8, Fig. 9, Fig. 10, and Fig. 11. Thus, this shows how the entire functionality of a circuit or a system change upon Trojan activation.

B. Performance Analysis

Performance analysis of the benchmark circuits-C17, 432 and C3540 using area and power metrics are shown in Table I. The circuits are implemented in Verilog HDL using Cadence Incisive and synthesized in 90nm technology using Cadence

Genus. It can be observed that, area of the circuits without Trojan is less compared to with trojan. It can be noticed that, power consumption of the circuits in the absence of Trojan is less. From Table I, it is evident that Trojan presence can also be determined by performing area and power analysis. This is due to the fact that, any new addition of unwanted components such as Trojan, increases the area and power consumption in a drastic way.

TABLE I. SYNTHESIS REPORT

Bench mark Circuits	Area(μm^2)		Power(μW)	
	With out Trojan	With Troja n	With out Troj an	Wit h Tro jan
C17	16.62	227.07	0.425	6.76
C432	439.002	3279.648	15.205	107.09
C3540	4931.203	5196.118	185.38	194.27

C. Controllability and Observability Calculation

Controllability and Observability are the parameters used for detection of Trojan in the benchmark circuits. Netlist obtained from synthesis of C17, C432 & C3540 is converted into benchmark formats. The benchmark formats are then fed as input to the python code that determines controllability and observability values. The output in the form of a text file is used to create datasets. Combinational controllability is used to identify nets which show difficulty in testability. The controllability values range from 1 to infinity. If 'I' is a primary input node of a digital circuit, then the combinational controllabilities of node 'I' are defined 1 i.e., $CC0(I) = 1$ and $CC1(I) = 1$. Similarly, calculations of combinational controllabilities for various gates are shown in Fig. 12.

An Observability is simply a function of controllability, meaning that it is impossible to observe a given internal node if the circuit is not driven to a given state. The Observability values range from 0 to infinity. If 'U' is a primary output node of a digital circuit, then the combinational observabilities of node 'U' are defined as, $CO(U) = 0$

The formulation of combinational observabilities for various gates are shown in Fig. 13 where,

CC = Combinational Controllability

CO = Combinational Observability

Trojan value 0 = No Trojan detected

Trojan value 1 = Trojan detected

Table II, Table III, and Table IV represent samples of datasets generated using Controllability and Observability values obtained using the calculations for various gates mentioned in Fig. 12 and Fig. 13. The gate-level netlists are converted to benchmark codes that are fed into the python code that performs the calculations to output files with the testability measures.

D. Machine Learning Techniques (MLT)

MLT are used for detection of Trojans in the benchmark circuits. Controllability and Observability values calculated for C17, C432 and C3540 are used as input to create dataset. Upon pre-processing the data, dataset is split into training set and test set. This data set is used on various MLT for classifying the nodes as Trojan free and Trojan infected. Scatter plot shown in Fig. 14, Fig. 15 and Fig. 16 better visualizes the results. C17 circuit is easier to classify as with Trojan and without Trojan but C432 circuit has considerable overlapping and is harder to classify. Thus, non-linear ML models have to be used in order

to separate this nonlinear data. Hence, we propose an MLT model which is a combination of LDA and Naive Bayes. Comparative study of all these MLT along with the proposed model in terms of accuracy, precision, F1 score and Recall is carried out for C17, C432 and C3540 circuits (see Fig. 17 to 22). It is evident from Table V, Table VI and Table VII that our proposed LDA+ Naive Bayes model is best among other MLT with the latency of around 0.9 ms in comparison with the other state-of-art techniques.

VII. CONCLUSION

Considering the various threats to the manufacturing process of an IC/system like functionality change, IC tampering, third party vendor attacks etc, a new Hardware Trojan detection technique using Machine Learning is proposed. Controllability and Observability analysis was performed using Gate Level netlists. Based on the values obtained, the various Machine learning models were able to distinguish the nodes in three of the benchmark circuits used as Trojan free or Trojan infected. Amongst them, our proposed model i.e., LDA + Naïve Bayes performed the best when compared to other state-of-art techniques with an accuracy of 92.85%, precision of 99.9

%, recall of 80% and F1 score 88.8%. The latency of the proposed technique was around 0.9ms. Along with this, the Simulation and Synthesis reports obtained using 90nm technology of Cadence tool also proved that presence of Trojan increasingly affects the system in terms of area and power.

Multi-Objective Optimal Path Planning for Autonomous Robots with Moving Obstacles Avoidance in Dynamic Environments

Kadari Neeraja¹, Dr. G Narsimha²
Research Scholar¹, Associate Professor¹, Professor²
Department of CSE, JNTUH, Hyderabad, India

Abstract—Path planning is vital for robust autonomous robot navigation. Driving in dynamic environments is particularly difficult. The majority of the work is based on the premise that a robot possesses a comprehensive and precise representation of its surroundings prior to its starting. The problem of partially known and dynamic environments has received little attention. This circumstance occurs when an exploratory robot or a robot without a floor plan or terrain map must move to its destination. Existing approaches for dynamic-path-planning design a preliminary path based-on known knowledge of the environment, then adjust locally by replanning the total path as obstacles are discovered by the robot's sensors, thereby sacrificing either optimality or computational efficacy. This paper presents a novel algorithm. A Near-Optimal Multi-Objective Path Planner (NO-MOPP), capable of planning time-efficient, near-optimal, and drivable paths in partially known and dynamic environments. It is an expansion of our earlier research contributions called "A Multi-Objective Hybrid Collision-free Optimal Path Finder (MOHC-OPF) for Autonomous Robots in known static environments" and "A Multi-Objective Hybrid Collision-free Near-Optimal Path Planner (MOHC-NODPP) for Autonomous Robots in Dynamic environments". In the environment, a mix of static and moving dynamic obstacles are present, both of which are expressed by a hybrid, discrete configuration space in an occupancy-grid map. The proposed approach is executed at two distinct levels. Using our earlier method, A Multi-Objective Collision-free Optimal Path Finder (MOHC-OPF), the initial optimal path is found in environment that includes only known stationary obstacles at the Global-path-planning level. On the second level, known as Local Re-planning, this optimal path is continuously refined by online re-planning to account for the movement of obstacles in the environment. The proposed method, A Near-Optimal Multi-Objective Path Planner (NO-MOPP), is used to keep the robot's sub-paths optimum while also avoiding dynamic obstacles. This is done while still obeying the robot's non-holonomic restrictions. The proposed technique is tested in simulation using a collection of standard maps. The simulation findings demonstrate the proposed method's ability to avoid static as well as dynamic obstacles, as well as its capacity to find a near-optimal-path to a goal location in environments that are constantly changing without collision. The optimal-path is determined by taking into account several performance measures, including path length, collision-free path, execution time, and smooth paths. 90% of studies utilizing the proposed method demonstrate that it is more effective than other methods for determining the shortest length and time-efficient smooth drivable paths. The proposed technique reduced average 15%

path length and execution time compared to the existing methods.

Keywords—Autonomous mobile robots; dynamic environment; planning; collision-free; time-efficient paths

I. INTRODUCTION

Path planning for mobile robots, especially when the environment is known, is a well-researched problem [1-8]. However, one issue that arises when putting theory into practice is the fact that incomplete information about the environment is often available. In most cases, it seems unrealistic to expect to have a detailed map with all the obstacles clearly marked. Recent years have seen tremendous progress realized in the realm of path planning in dynamic environments across a wide range of domains. Particularly, mobile robots have found practical use across a wide range of domains. Applications incorporate emergency rescue management in natural disasters [12], planetary exploration [10, 11], inventory control [12], the manufacturing industry [13], etc.

In the 1960s, research began in the arena of path planning for different kinds of robots [1, 2, 12]. The Path-Planning is the procedure of establishing a path-way in an environment that is no-obstacles and that connects a predetermined starting point and an intended ending point [14-15]. The environments in which robots operate can either be static or dynamic. When working in a static known environment, the locations of obstacles remain the same, but when working in a dynamic environment, their positions shift over the course of time. The goal of employing path-planning algorithms is to translate the high-level-specifications which humans execute into low-level-steps [15]. This is accomplished by locating the optimal-path and presenting to the robot in the form of a series of waypoints that it should follow as moving directions.

The dynamic environment comprises moving obstacles, the path-planning algorithm is a necessity not-only to determine the optimal-path but also to observe it. In order to persist responsive to its environments, the approach must know the current position of an obstacle, forecast upcoming paths, and bring up-to-date its path in real-time with sufficient frequency.

In most cases, an autonomous mobile robot is free to follow any one of a number of predetermined routes. The length of the path, the amount of time it takes, and the amount of energy it

takes are all factors that go into determining what constitutes the optimal path. Numerous algorithms were developed to handle the problem of path planning; these algorithms can be categorized as either classical or intelligent. Artificial Potential Field [16], Rapid Exploration of Random Trees (RRT) [15, 17] and its variants RRT*, etc. [15,18], Partitioned Learning Traditional methods, such as D* [20], are utilized to solve dynamic path planning problems. As the search space grows in size, however, these methods become inefficient and get stuck at local maxima. Thus, intelligent optimization techniques like the Genetic Algorithm [21-22], Particle Swarm Optimization [23], Bees algorithm [24] [29] and etc. have been employed to solve path planning difficulties.

Real-time dynamic path planning needs more investigation [30], as stated earlier. This study proposes an A*[3] based Near-Optimal Multi-Objective Path Planner (NO-MOPP) to swiftly identify a near-optimal drivable smooth path in a dynamic environment while taking the kinematic restrictions of the robot into account. The following are some of the contributions made in this work:

1) "A Multi-Objective Hybrid Near-Optimal Dynamic Path Planner (NO-MOPP)" is a new dynamic path planning technique that finds no-collision near-optimal-drivable paths in a dynamic environment with a hybrid environment representation. Since A* ensures both optimality and completeness, the A* algorithm will serve as the foundation for this approach. This algorithm performs comparably to A*.

2) The proposed technique performs on two distinct levels. Initially, using global path planning, the optimal-path is determined in an area with known static-obstacles. The second level, known as Local-replanning, adjusts the optimal path online with the assistance of sensors in order to prevent collisions with dynamically generated immovable and moving obstacles. After that, path tracking is performed, and the path is optimized during path tracking without sacrificing the algorithm's real-time performance.

3) Kinematic constraints, like a robot's orientation, are employed in order to find the most efficient driving smooth paths in ever-changing real-time environments.

4) It finds application in a wide range of different dynamic environments. The percentage of successful attempts is 90%.

5) When compared to RRT and RRT*, our suggested method achieves superior outcomes in dynamic environments in relation to the amount of time required for execution, execution time, and the total length travelled path-length.

The paper is organized as follows. Section II explains related research that is pertinent to the techniques for planning paths. The technique and underlying algorithm for path-planning in the presence of static as well as dynamic obstacles are presented in Section III. Section IV looks at how well the suggested strategy works and gives the results of the experiments. Section V brings the article to a conclusion, which also offers guidelines for future work.

II. RELATED WORK

Past decades have seen many path-planning algorithms. Graph-based techniques include Dijkstra's algorithm [4,24], A* [3], D* [20], and etc. After discretizing the path planning state space into a graph structure, they employ graph search to find a feasible path. A* and Dijkstra's algorithms are suitable for lower-dimension static environments. D* is used for dynamic environments. Optimal Path Planning using Memory Efficient A*. Improved A* Path Planning Method Based on the Grid Map. Sensors [25], Time-Efficient A* Algorithm for Robot Path Planning [26], Safe Path Planning of Mobile Robot Based on Improved A* Algorithm in Complex Terrains [27], Optimal Path Planning using Memory Efficient A*[31] and Fast path planning using modified A* method [32].

The graph-based approach is full and resolution optimal, meaning it finds an optimal-path if a viable path-exists and fails otherwise. The graph-based partition of the state-space yields a massive search space, which makes these graph-based approaches unsuitable for large-scale issues. The recent updates on A*, in research papers like Dynamic-Algorithm for Path-Planning using A* with Distance-Constraint [13] and Improved-Analytic-Expansions in Hybrid A* Path-Planning for Non-Holonomic Robots [9]. They are suffering from high computation time.

Another significant kind of path-planning algorithm is the sampling-based path-planning approach. Instead of discretizing the state space, it generates a graph or tree by randomly selecting points. Sampling-based path planning algorithms beat graph-based ones in large-scale situations. The sampling-based path planning strategy is probabilistically complete, thus when the trials number reaches infinite, the likelihood of discovering a suitable path-way approaches one. Sampling-based planners employ RRT [15,17] and PRM [19] algorithms. The RRT, a single-query path planning method that traverses state space by generating a tree rooted at the start state, is faster than the PRM. Despite finding an initial path in high-dimensional space quickly, RRT has many downsides. RRT's path may not be ideal because it is randomly generated. RRT* [18] advanced RRT. The RRT* takes time and memory to identify the best path. RRT* likewise experiences significant search time variability. Though, these techniques perform poorly and trap in local optima when the search space is big.

Hence, intelligent optimization procedures have been employed in the process of solving path-planning problems. Some examples of these algorithms include the Genetic Algorithm [21-22] [28], Particle Swarm Optimization [23], Simulated Annealing [12], Ant Colony Optimization [8], Bees [29] and etc. Even if these algorithms conquered the difficulties of path planning, they still wouldn't be usable without the partitioning and pre-processing of environment maps. This is because such maps need to be prepared in advance. The accuracy is reduced as a result of discretization and pre-processing, which also results in non-optimal pathways.

III. PROPOSED PATH PLANNING SYSTEM

The purpose of path-planning is to discover a continuous path that will lead a system from its current state to a desired one. Finding a path across a dynamic environment that a non-holonomic robot or vehicle can follow without colliding with any of the environment's obstacles is the goal of dynamic path planning.

1) *Problem formulation:* The path-planning issue's main objective is to identify an optimal-path for an autonomous-robot to proceed from a given beginning-point to a certain goal location in a dynamically changing environment containing static and dynamic stationary as well as moving obstacles by satisfying optimization-criteria. The path-planner's goal is to discover the optimal- or near-optimal-path for a mobile-robot that avoids obstacles in the surroundings.

The environment is denoted as a Grid. The initial step in mobile-robot-path-planning is establishing an environment-model for the mobile-robot's 2-dimensional. As identical square cells, grids are used to represent the mobile-robot's workplace. Each grid-cell is either free (logic 0) or forbidden (logic 1) by an obstacle. There are both static as well as dynamic stationary and moving obstacles in this area.

2) *Optimization criteria:* The proposed path planning system NO-MOPP determines a no-collision smooth path that obeys multi-objective optimization criteria. The criteria is: first one is the Cost objective-function , minimum-cost path for a mobile-robot to move from its start-point to the goal-point, provided that it is a smooth and safe path, i.e., the mobile-robot travels with no collision with obstacles. This measure is specified by Eq. (1) :

$$\text{Cost } f = g + h + \text{SO} + \text{DSO} + \text{DMO} \quad (1)$$

where cost-f is the sum-of-the-costs from the start-node to current-node (g), the estimated-cost (h) to the goal from current-node, the additional-cost for changing the orientation angle, SO is the cost for switching orientation, DSO corresponds to the cost of avoiding dynamic stationary obstacles, and DMO indicates the cost of avoiding dynamic stationary obstacles during local replanning.

The second Criterion is the *Execution time objective* needed for finding a minimum length and safe path. This is given by equation (2):

$$T_{\text{total}} = T_{\text{Global-path-planning}} + T_{\text{local-replanning}} \quad (2)$$

where T_{total} is the time essential for the completion of execution of the path planner, $T_{\text{Global-path-planning}}$ is the time taken by the offline line path planner and $T_{\text{Local-raplanning}}$ is the time needed to update the initial optimal path to skip dynamic stationery obstacles.

The optimal path-planning problem can be stated as:

“Find the lowest cost and least time taking near-optimal smooth path between the start-point and the goal-location, such that the above optimization-criteria Cost function f and Execution time T objective functions given in above equations (1) & (2) are lessened by taking non-holonomic constraints of the robot into account”.

3) *The proposed dynamic path planning system's architecture:* The component structure of the dynamic-path-planning system is depicted in Fig. 1. The system will function efficiently on the two levels. At the first level, global path planning, the optimal route is determined using the information that is currently known about the environment, including the known static obstacles, for instance. After that, the robot will continue along this optimal path. This optimal path is updated online at the second level, which is known as "Local Replanning," in order to skip collisions with-obstacles which are dynamically presented and may be either stationary or dynamic.

Primary components of the dynamic-path-planning system are depicted in Fig. 1. The environment is dynamic and comprises both static and moving obstacles. To represent this ever-changing environment, a binary occupancy grid map is employed. Constraints: Non-holonomic car-like robots or vehicles have kinematic constraints. Optimization criteria: Path smoothness, path length, and the time required to locate a path comprise optimization criteria.

4) *Path-planning:* The path-planning algorithm is the crucial component of a dynamic-path-planning system that addresses a path-planning issue. In this proposed system, there are two levels. A Multi-Objective Optimal Path Finder (MOHC-OPF) is used to obtain a quick initial optimal-path in an environment that includes known static obstacles only in the First level of Global Path Planning. Local-Replanning is the second level of our proposed dynamic path planning approach, a Near-optimal Multi-Objective Path Planner (NO-MOPP), which is employed to avoid dynamic obstacles in dynamically changing environments.

The Architecture of the Proposed Dynamic Path Planning system

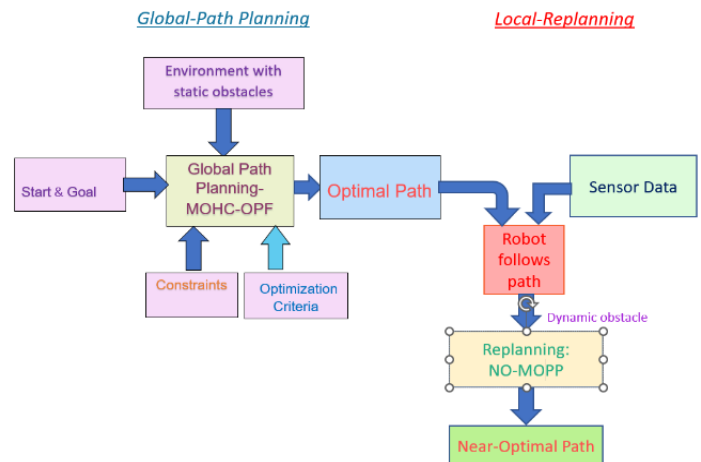

Fig. 1. Block diagram of the dynamic path planning system

A. The Working Principle of NO-MOPP

A novel method called NO-MOPP has been proposed as a way to avoid the limitations of the traditional A* methodology. The kinematics of the car-like robot or vehicle is added to predict the movement of the robot which is dependent on the steering angle in a continuous search space. The proposed

system has a collection of continuous states represented by the coordinates (x_p, y_p, θ) , here (x_p, y_p) represents the location of the robot or vehicle and θ represents its orientation. Non-holonomic robots and vehicles can benefit from this feature since it helps the path planner choose the best successor state for them to follow. One of the five steering actions, maximum-left, left, maximum-right, right, and no-steering, expands the states and leads to an arc of a circle with a minimum turning radius, in accordance with the kinematic restrictions of the simple car-like robot or vehicle. On the basis of these operations, the proposed method, the NO-MOPP algorithm selects the states depicted in Fig. 2.

Fig. 2. NO-MOPP incorporates kinematic constraints with 5 steering angles

B. Multi-Objective Functions for Optimization

As part of this effort, different objectives are analysed and taken into consideration so that the updated path can be optimized.

Cost Function: It calculates the cost of driving from the present-point to a neighboring node. This cost f is the total-cost from the start node to the current node (g), the anticipated-cost from the present node to the goal (h), and the cost for adjusting the orientation angle (SO). Eq. (1) is utilized to calculate this cost.

1) **Path length:** The final path is made up of a series of path segments denoted by the notation $P = \{P_1, P_2, \dots, P_n\}$. The ultimate length of the path is equal to the totality of the lengths of all path segments that connect the Start state to the Goal state via any intervening states. This is illustrated in Fig. 3. To get the length of this final path, Eq. (2) is utilized.

Fig. 3. Path length

$$\text{Path Length} = \sum P_i \text{ where } i=1 \text{ to } n. \quad (3)$$

At each stage, the next state with the lowest possible cost is chosen, and the arcs in the path are optimized to have the minimum turning radius. As a result, it ensures that the final path will be the shortest and most optimal one.

2) **Execution time:** The amount of time required to carry out the method that was proposed for discovering a path and Eq. (2) is used for determining this.

The travelled distance must be sufficient in order to exit the current cell, and the equation that describes this requirement is below (4).

$$l > \sqrt{2} s \quad (4)$$

In this equation, l represents the length of an arc, and s indicates the size of a single cell in the grid map. At each node, the continuous state is rounded off to a discrete state in order to prevent the search graph from becoming an increasingly huge structure. This, in turn, results in a reduction in the amount of search time necessary to locate the ultimate path.

3) **Smooth path:** Kinematic constraints determine the next node in this proposed approach, resulting in minimum turning radius curves. Therefore, the final path produced is smooth.

C. The Heuristic Function

The heuristic function predicts the minimum-cost from any node to the destination on the map. This reduces node exploration. Thus, heuristic function selection directly impacts the performance of path planning approaches. The Euclidean distance is employed as a heuristic function. Equation (5) determines each node's heuristic values.

$$h = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2} \quad (5)$$

D. The Proposed Path Planning Approach

The proposed approach executes the path-planning procedure in a dynamic-environments with both dynamic as well as static obstacles. The method operates on two levels. Global Path Planning 2. Local Redevelopment Replanning. In the first level, the Global-path-planning method is applied to determine the optimal-path through a static obstacle environment. The attained path is provided for the robot to track during the second level. Simultaneously, the algorithm modifies the path in real-time to prevent a collision by means of any new obstacles, to ensure the sub-paths are optimum. Using proposed path-planning system, the path's optimality is preserved. Fig. 1 depicts this process.

1) **The global path planning:** By adhering to kinematic constraints, the MOHC-OPF method, which was the objective of our previous research, is used in Global Path Planning to swiftly construct an optimal path for a given environment containing only static obstacles. The MOHC-OPF algorithm employs Open-list and Closed-list. Comparable to the conventional A*, they keep track of the states while searching. The open list includes the neighbours of states that have been expanded during the search process. The closed list comprises all states for which processing has been finalized. Here is a summary of the MOHC-OPF algorithm.

Input: Occupancy grid map of the environment with static obstacles information, starting position (xstart), target position (xgoal), heading θ , and kinematic constraints of simple car-like robot and $U(x)$ actions set with five forward steering angels.

Output: A mobile robot's optimal path from its starting point to its goal, including path length and execution time.

Step 1: Set Open list and Close list

Step 2: Assign Xstart to the start state,

Step 3: For each of the 5 steering angles, find Xstart 's 5 neighbors. Using a simple car-like robot's kinematic model with a global location of (xg, yg, θ) generated using the equation (6) (LaValle, S.M. Planning Algorithms, 2006. [15]).

$$\begin{aligned} Xg. &= ug \cos \theta \\ Yg. &= ug \sin \theta \\ \varphi &= us / l \tan \theta \\ \rho \min &= l / \tan \varphi_{\max} \quad \text{----- (6)} \end{aligned}$$

Where u is an action set $\{0,1\}$, φ is the steering angle, ρ min is the minimum turning radius and l is the front-rear-axles distance of a simple car.

Step 4: If any of the neighbors is a goal state, then quit.

Step 5: Estimate the cost of each neighbor using the cost function equation (1) if they are not likely to collide.

Step 6: Assign Xstart to a neighbor having the minimum cost function f -value, then execute the related action on the map. Keep the former Xstart and the f values in an open list.

Step 7: Repeat from step 3 until Open-list is empty.

2) *The local replanning:* Global path planning generates the optimal-path in a dynamic-environment with stationary obstacles only. In Local re-planning, the autonomous mobile robot or vehicle takes this optimal path from the starting-point to the target-point in a dynamically changing situation. The robot moves along the course with the aid of surrounding sensors and a scanning procedure. The robot's sensors allow it to survey an area from a 360-degree angle.

The proposed method, NO-MOPP, begins by analysing sensor data to identify any new static or moving dynamic obstacles on the optimal path for tracking. Once an obstacle reaches the robot sensor's exposure range, sensor readings provide all information regarding the robot's movement and location, as well as all obstacles in the surroundings. Using this information, the likelihood of a robot and obstacle collision is evaluated. If there is no collision, the robot will continue along its original path as shown in Fig. 4(a).

However, in the case of a collision, the proposed NO-MOPP technique replans the segment of the path containing a potential collision location. The newly found subpath must be the best and shortest possible. The inventive optimal path was adjusted such that the-robot will track the updated no-collision path. The process of alerting a robot to the presence of new obstacles is known as obstacle detection.

The proposed methodology enables the robot to-move toward the goal though detecting any new obstacles. The following stages are included in this implementation. The measurements of the sensor are recorded. The robot-obstacle distance is then estimated from the robot to the close exterior-surface of the obstacle.

3) *Obstacle detection:* The obstacle's presence is detected when sensors sense the obstacle. The obstacle-robot distance exceeds a certain threshold. The collision check method is invoked when an obstacle is encountered to find that the robot as well as the obstacle will crash.

4) *Collision check:* Even if an obstacle is within the sensor range of the robot, not all detected obstacles will cause a collision. If there is no collision as depicted in Fig. 4(a), the robot will follow the optimal reference path. If there is a collision possibility as depicted in Fig. 4(b) and the distance amid the robot & the obstacle is greater-or-equal to the threshold value, then replanning is performed using the proposed local search method called NO-MOPP; otherwise, the robot will halt and pause for the obstacle to go before continuing along the same path.

The likelihood of a collision is computed based on the robot's location and direction angle in relation to the sensed obstacle. Calculating the time and location of the collision is: If the robot's present location is $P_{r-p1}(x_{r-p1}, y_{r-p1})$ and it is heading toward $P_{r-p2}(x_{r-p2}, y_{r-p2})$, and if the obstacle's present location is $P_{obst1}(x_{obst1}, y_{obst1})$ and its goal is $P_{obst2}(x_{obst2}, y_{obst2})$. The formulas of the robot movement are given by (7).

Calculating robot motion requires the following formula:

$$\begin{aligned} x_{r-p} &= x_{r-p1} + v_{robot} t_r \cos \theta \\ y_{r-p} &= y_{robot1} + v_{robot} t_r \sin \theta \quad (7) \end{aligned}$$

The equation for the movement of the obstacle could be expressed as (8).

$$\begin{aligned} x_{obst1} &= x_{obst1} + v_{obst} t_{obst} \cos \varphi \\ y_{obst1} &= y_{obst1} + v_{obst} t_{obst} \sin \varphi \quad (8) \end{aligned}$$

The collision amid the robot and the moving obstacle occurs when the subsequent Eq. (9) is satisfied.

$$x_{robot} = x_{obst1} \quad (9)$$

$$y_{robot} = y_{obst1}$$

i, e.

$$x_{r1} + v_r t_r \cos \theta = x_{obst1} + v_{obst} t_{obst} \cos \varphi \quad (10)$$

$$y_{r1} + v_r t_r \sin \theta = y_{obst1} + v_{obst} t_{obst} \sin \varphi$$

where θ is orientation and v_{robot} is the robot-velocity, φ and v_{obst} are the orientation and the obstacle-velocity respectively, and t_r and t_{obst} are the current time at which the robot and obstacle are there and they are positive. Then the point of the intersection can be determined by replacing Eq. (7) and (8) with Eq. (9) producing equation (10). In the case of a collision, the robot's sub-path consists of 3 locations. The robot's present location is represented by the first point, $X_{present}(x_1, y_1)$, the collision points by $X_{colisn}(x_c, y_c)$, and the next point in its path

by $X_{new_next}(x_n, y_n)$. If there is a collision, the obstacle will be on this sub-path. For this reason, a modified local search is proposed, NO-MOPP, for replanning in order to locate an alternate collision-free sub-path. When both of the below circumstances are true Local replanning is done by invoking the proposed method NO-MOPP. The first circumstance is when a new obstacle enters the robot sensor's coverage range. Second, when a collision detection judgment is made favourably. In this local search, NO-MOPP looks for the next neighbour with minimum cost value calculated using Eq. (1) in the Global path planning from its neighbor's list, named Open list. The computational cost is less because the next node is selected from the open list which is readily available. Therefore, the replanning has no impact on the time efficiency of the proposed technique. Once again, the new neighboring point is checked for collisions; if there are none, a minimal turning radius path segment is constructed. This is repeated until the goal is found.

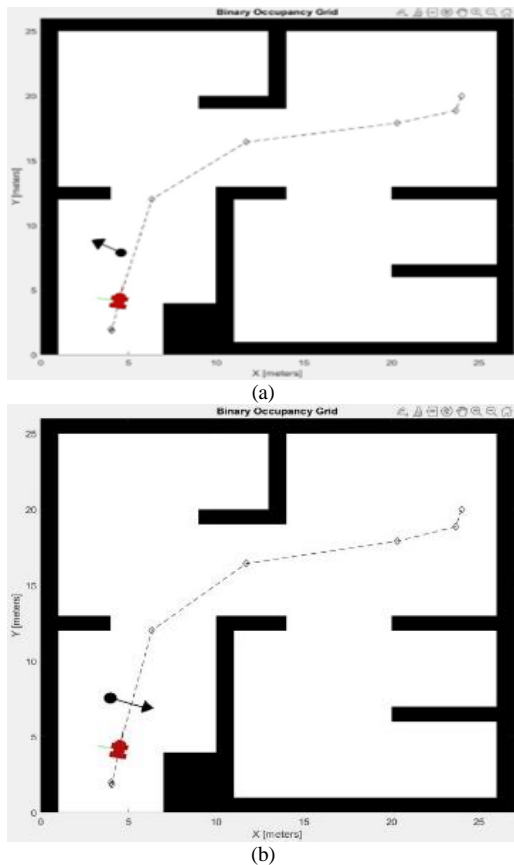

Fig. 4. (a) No collision Case (b) Collision case

The shortest path is guaranteed by a Minimum turning radius path segment. The near-optimal sub-path is returned by the proposed method NO-MOPP. The robot is instructed to pursue this new branch of the course. Because the Global-path-planning of the proposed dynamic path-planning system previously computed the costs of five neighbors corresponding to each steering angle for each location on the global optimum path, the cost computing in the proposed method NO-MOPP is no longer required. There is therefore no computational overhead. The time needed for this is likewise quite short

because there are just five neighbour points with regard to five steering angles while looking forward and only those points for which the arc length is greater than the cell size Eq. (4) So, search time is also reduced. Therefore, the method has no consequence on the efficiency of time. The following Algorithm 2 summarizes the pseudo-code of the proposed dynamic path planning algorithm NO-MOPP:

Algorithm 2: NO_MOPP

Input: Start, Goal, Closed-list and Open-list

Output: The near-optimal-path for an autonomous mobile-robot from the given initial point to the goal-position in Path length and Execution time.

Algorithm NO_MOPP (Open_List, Closed_List, X_{start} , X_{goal})

```
1.  $X_{next}=X_{start}$

```

IV. EXPERIMENTAL RESULTS

Using MATLAB 2021a on Windows 10 64bit-with an Intel-core i5 NVIDIA G5-CPU, the performance of the proposed method, a novel Near-Optimal Multi-Objective Path Planner (NO-MOPP), was evaluated. For testing, sensor views from -45° to +45°, -90° to +90°, and -180° to +180° were captured. In ninety percent of the studies, it was discovered that the dynamic obstacles were successfully avoided. On a variety of dynamic maps, all simulations were executed with varying starting and ending points. Path-Length-Mean and Average-Execution-Time between the provided start and goal locations on the map are the performance metrics considered when evaluating the effectiveness of our proposed system. The execution time and length of the near-optimal-path was recorded.

1) *Case-study-1: Complex Map:* A more complex dynamic environment is considered; the environment is a complex maze with both static and dynamic obstacles that are stationary and moving. The proposed method was executed one hundred times in order to determine its average execution time. Fig. 5(a), (b) and (c) depicts a nearly optimal path generated by NO-MOPP for this complex environment on two levels known as Global path planning and Local-replanning paths and how robot (arrow) avoiding dynamic stationery(purple color) and moving obstacle(green color). In ninety percent of experiments, it successfully avoids dynamic obstacles.

Fig. 5. (a) & (b): No collision and collision avoidance with a moving dynamic obstacle (green color) using NO-MOPP. (c) Collision avoidance with dynamic moving (green color) and stationary obstacles (purple color) using NO-MOPP

The findings for the Complex map's Path Length Mean and Average-Execution-Time are given in below Table I.

TABLE I. TYPE RESULTS FOR COMPLEX MAP

	Offline path planning	After Local-replanning
Path length_mean in meters	64.5589	67.8374
Execution time in secs	0.457936	1.986376
Direct_Path_Length in meters	51.856	51.856

2) *Case-study-2: Package pickup in Warehouse scenario:* A package pickup in a warehouse dynamic-environment contains static and dynamic moving and stationary obstacles. Fig. 6(a), (b), and (c) illustrate, NO-MOPP devised a path that was close to optimal for avoiding static (purple color) and moving (green color) obstacles on the way to the package pickup site. In 90% of the experiments, the proposed strategy was effectively avoided.

The Path length mean and execution time outcomes for the Package Pickup scenario are summarized in Table II.

Fig. 6. (a) & (b): No collision, collision avoided with a moving dynamic obstacle (green color) using NO-MOPP. (c) The collision was avoided with the moving dynamic obstacle (green color), and stationary obstacle (purple color) using NO-MOPP

TABLE II. RESULTS FOR PACKAGE PICKUP IN A WAREHOUSE SCENARIO

	Global path planning	After Local-replanning
Path length_mean in meters	73.5541	91.5263
Execution time in secs	0.4951	2.953216
Direct_Path_Length in meters	62.1488	62.1488

Performance Evaluation: In the preceding two case studies, we describe the efficacy of the proposed method NO-MOPP and comparability it to the current techniques RRT and RRT*. In this section, we compare NO-MOPP to RRT and RRT*. The proposed method NO-MOPP has been rigorously examined. The comparison of performance is summarised here. In comparison to RRT and RRT*, the path length supplied by the Proposed Method NO-MOPP was superior. The execution time of No-MOPP is considerably shorter.

1) *Case Study-1:* Complex Dynamic map: Table III provides a visual representation of the results of a performance evaluation that compares the proposed technique NO-MOPP to the existing methods RRT and RRT* when applied to a complex dynamic map. The figures provide abundant evidence that the proposed technique is successful even when the level of map complexity increases.

TABLE III. PERFORMANCE EFFICIENCY COMPARISON IN A COMPLEX MAP

Planner/performance metric	Path length Mean in meters	Avg_Execution Time in secs
RRT	110.873295	4.136285
RRT Star	105.567284	4.513792
Proposed method NO-MOPP	67.8374	1.986376

As is evident from the Fig. 7 below, the proposed method NO-MOPP performed better than the existing methods RRT and RRT* after being run through 100 iterations. The blue line that depicts its performance shows that the proposed method developed the shortest length paths in contrast to other existing approaches in the Complex Dynamic Map. This is proved by the fact that the method created the shortest length paths in each iteration.

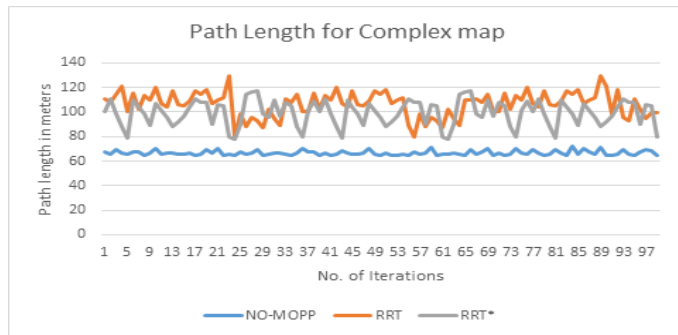

Fig. 7. Path length comparison in complex map

The Fig. 8 displays the efficiency and efficacy of the execution time. The proposed method NO-MOPP is represented by a blue line in virtually all 100 iterations of the Complex Dynamic Map. This method generates paths that require significantly less time consuming compared to the existing techniques RRT and RRT*.

Fig. 8. Execution time comparison in complex map

2) *Case Study-2:* Dynamic map for Package Pickup: The RRT and RRT* approaches, as well as the proposed approach, were evaluated using the Warehouse scenario as a point of comparison. Table IV presents a comparison of various performance metrics for further consideration. Examining how the proposed solution comes up in path length as well as execution time in comparison to the other available options. The proposed method is carried out fairly well when applied to this difficult warehouse map.

TABLE IV. PERFORMANCE EFFICIENCY COMPARISON IN A COMPLEX MAP IN WAREHOUSE

Planner/performance metric	Path length Mean in meters	Avg_Execution Time in secs
RRT	170.8753	4.596832
RRT Star	150.3547	4.975649
Proposed method NO-MOPP	91.5263	2.953216

The Fig. 9 indicates how the performance of the recommended method NO-MOPP compares to that of the existing methods RRT and RRT* in 100. When compared to the other existing methods in the Warehouse dynamic map, the proposed method NO-MOPP consistently created paths that were the shortest in length. This can be seen from the blue line that depicts the performance of the proposed methodology.

Fig. 9. Performance metric path length comparison in warehouse map

The results of a comparison between the efficiency of our method NO-MOPP and the existing techniques RRT and RRT* can be found in the following Fig. 10, which can be found below. The strategy that was suggested consistently produced the least time-consuming paths when compared to other approaches that were already being used for the dynamic map of the Warehouse.

Fig. 10. Performance metric execution time comparison in warehouse map

V. CONCLUSION AND FUTURE WORK

In this paper, A Near-Optimal Multi-Objective Path Planner (NO-MOPP) is used to determine the optimal path for mobile autonomous robots operating in dynamic environments. While complying with the robot's kinematic constraints, the robot is able to follow the determined path and avoid new obstacles. Detection of obstacles is dependent on the coverage area of the sensors of a robot and an assessment of the likelihood of a collision. Collision avoidance is achieved through re-planning if the collision check method indicates a collision with a newly introduced dynamic obstacle. Consequently, the development of smooth, drivable paths, which are required for realistic scenarios, is ensured. On average, smoother, collision-free, near-optimal paths may be discovered 90% of the time. NO-MOPP accomplishes Multiple Objective Optimization, which includes Path length, Execution Time, Cost function, and Path Smoothing. Based on the preceding experiments, it is obvious that applying the proposed technique reduced average 15% path length and execution time compared to the existing methods RRT and RRT*. Compared to these existing methods, the proposed method has exhibited superior performance efficiency in complex settings.

Future studies may extend the NO-MOPP method to dynamic situations with higher dimensions for real-time autonomous robots and autonomous vehicles.

Eye-Vision Net: Cataract Detection and Classification in Retinal and Slit Lamp Images using Deep Network

Binju Saju^{1*}, Rajesh R²

Research Scholar¹, Associate Professor²

Department of Computer Science, Christ (Deemed to be University), Bengaluru, Karnataka 560029, India

Abstract—In the modern world, cataracts are the predominant cause of blindness. Early treatment and detection can reduce the number of cataract patients and prevent surgery. However, cataract grade classification is necessary to control risk and avoid blindness. Previously, various studies focused on developing a system to detect cataract type and grade. However, the existing works on cataract detection does not provide optimal results because of high detection error, lack of learning ability, computational complexity issues, etc. Therefore, the proposed work aims to develop an effective deep learning techniques for detecting and classifying cataracts from the given input samples. Here, the cataract detection and classification are performed using two phases. In order to provide an accurate cataract detection, the proposed study introduced Deep Optimized Convolutional Recurrent Network Improved Aquila Optimization (Deep OCRN_IAO) model in phase I. Here, both retinal and slit lamp images are utilized for cataract detection. Then, the performance of these two image datasets are analysed, and the best one is chosen for cataract type and grade classification. By analysing the performance, the slit lamp images attain higher results. Therefore, phase II uses slit lamp images and detects the type and grade of cataracts through the proposed Batch Equivalence ResNet-101 (BE_ResNet101) model. The proposed classification model is highly efficient to classify the type and grades of cataracts. The experimental setup is done using MATLAB software, and the datasets used for simulation purposes are DRIMDB (Diabetic Retinopathy Images Database) and real-time slit lamp images. The proposed type and grade detection model has an accuracy of 98.87%, specificity of 99.66%, the sensitivity of 98.28%, Youden index of 95.04%, Kappa of 97.83%, and F1-score is 95.68%. The obtained results and comparative analysis proves that the proposed model is highly suitable for cataract detection and classification.

Keywords—Cataract detection; grade classification; CRNN; dense CNN; Aquila optimization; BE-ResNet101

I. INTRODUCTION

The eyes are the major organs that offer a clear vision to humans and living organisms. A cataract is a severe eye disorder that affects the original vision of the eyes and produces vision distortion. A cataract is the major cause of vision impairment or blindness worldwide [1-2]. Vision or Visual Impairment (VI) in humans refers to the inability to perceive clear vision. A global survey by the WHO (World Health Organization) estimated that among 285 million people, 39 million are blind, and the remaining are reported to other VIs [3]. Some of the retinal disorders are Cataract, DR (Diabetic Retinopathy), Glaucoma, AMD (Aged Macular

Degeneration), RP (Retinitis Pigmentosa), [4-5] etc. Cataracts are the leading cause of vision loss in aged and younger individuals [6-7]. The risk factors related to cataracts are people over 40 years, uncontrolled diabetes, steroid usage, family history, trauma in the eye, UV (Ultra-Violet) light exposure, [8] etc.

Early cataract diagnosis can control global vision loss. Based on the location and development, the cataract is divided into different types, namely NC (nuclear cataract), CC (cortical cataract), and PSC (posterior subcapsular cataract) [9]. The severity of the cataract can be identified with the grading procedure. Eye diseases are often diagnosed using several methods such as slit-lamp images [10], VA (visual acuity) examination [11], digital photography [12], retinal images [13] and ultrasonic images [14-15]. Ophthalmologist utilizes retinal and Slit-lamp images to detect the presence and absence of cataracts [16-17]. In ophthalmology, the screening and detection of cataracts have produced robust outcomes with deep learning (DL) models [18-20]. DL offers significant advantages by using several HL (Hidden Layer) sequences to extract useful image features. Moreover, in the medical field, DL learns the image features effectively and automatically. The advent of computer infrastructure has contributed to the faster adoption of DL due to its high level of feature extraction, processing of huge amounts of data and accurate classification.

Motivation: The eyes are the sensory organs that view the elegance of our surrounding environment. In recent years, the research organization are focussed on developing a robust cataract detection and classification methodology to assist affected people. From the recent studies, it is observed that deep learning techniques are attaining great attention for cataract detection. By using different types of datasets, the deep learning approaches gain better results in detecting and classifying cataract diseases. Many existing studies exhibit that using slit-lamp images produces high performance because of reduced cost, easy of maintain, flexibility etc. The neural network based feature extraction techniques can detect the features automatically. Also, such kind of feature extraction methods directly enhances the classification accuracy. Thus, it motivates the author to establish a deep learning based method for cataract detection and grade classification using slit lamp images. The major contribution of proposed work is given as,

- To develop an effective cataract detection and classification in retinal and slit-lamp images by

*Corresponding Author

proposing a new Deep Optimized Convolutional Recurrent Network (Deep OCRN).

- To reduce the detection error rate, the presented loss in the proposed Deep OCRN model is minimized by updating the weight parameters through Improved Aquila Optimization (IAO) algorithm.
- To extract the required features and to effectively identify the cataract type by proposing Dense CNN.
- To develop Batch Equivalence ResNet-101 method for classifying the grades of cataracts.
- To evaluate the performance of the proposed DL model by comparing it with other state-of-art classifiers.

The rest of this paper is structured as follows: Section II discussed recent existing studies on cataract detection, and Section III presents the proposed cataract detection classification model grade classification model. Section IV represents the results and discussion of the proposed study, and Section V deals with the overall conclusion and future scope for further research.

II. RELATED WORKS

Some recent research studies which are carried out on cataract detection and classification are listed as,

Pratap and Priyanka [21] presented a computer-aided robust cataract diagnosis using DNN (Deep Neural Network) in retinal fundus images. This diagnosis model involves CFE (Combined Feature Extraction) using dual fine-tuned independent DCNNs (Deep Convolutional Neural Networks). Moreover, multi-class SVM (Support Vector Machine) classifiers were trained on the noise levels from 0–25. The developed model obtained higher accuracy of (93.49%). However, the performance is affected due to noise problems.

Akil et al. [22] introduced the deep learning based CNN model for detecting retinal abnormalities in retinal fundus images. The ensemble learning based DR (Diabetic retinopathy) detection attained 97.7% accuracy and, with the grading achieved 98.5% accuracy. The main drawbacks were caused due to the limited number of training images and the lack of earlier screening.

Hu et al. [23] developed a unified automated NC (Nuclear Cataract) grading in slit-lamp smartphone images. The DL YOLOv3 model was used to localize the ocular lens nuclear region. Moreover, the combination of ShuffleNet and SVM was used in grading cataract severity by measuring the gray conjugate features of the core region. The overall performance obtained was accuracy (93.5%), F1 (92.3%), AUC (0.9198), and Kappa (95.4%). The drawbacks were high computational complexity and convergence loss.

Liu et al. [24] presented the diagnosis framework based on the localization of paediatric cataracts in slit-lamp images using deep feature modelling of CNN. The classification was completed with the combination of SVM and Softmax classifier. The overall classification accuracy was 97.07%. The Performance is not as much effective due to an inappropriate extraction of features.

Zhang et al. [25] developed automatic detection and grading of cataracts using DCNN (Deep Convolutional Neural Network). This DL framework DCNN was used to automatically examine cataracts by visualizing the feature maps with empirical higher-order semantic meaning at the pool5 layer. The overall accuracy performance obtained with cataract detection was (93.52%), and the grading of cataracts was (86.69%). The major limitation was classification and grading were analysed only on the fundus retinal images.

Problem statement: Earlier and accurate diagnosis of cataracts is more essential to limit the risk categories and prevent blindness. In existing, different techniques are developed to afford accurate cataract detection. However, they face several challenges while detecting cataracts from the given input samples. The detection accuracy of existing methods are reduced due to an enhanced computational complexity problem and large number of parameters in the detection models. By concerning this, the proposed study optimally selects the needed parameters using an effective algorithm. In addition, to make effective detection, extraction and selection of optimal features are more important. But, the existing detection techniques cannot extract the relevant features because of reduced efficiency. So, that the existing methods are not as suitable for detecting cataracts from the provided inputs. Also, many of the existing studies prefer retinal images for detecting cataracts and only few of them uses slit lamp images. To fulfil this gap, the proposed study used both retinal and slit lamp images for detecting cataracts. Moreover, robust DL models are utilized in the proposed study to learn appropriate features and make the system to attain higher detection accuracy with reduced complexity.

III. PROPOSED METHODOLOGY

The proposed detection and classification of cataract images involves two phases. In phase 1, the detection of cataracts using both retinal and slit-lamp images are performed. Initially, image acquisition is enabled for collecting retinal and slit-lamp images from the DRIMDB data source and real-time slit lamp images. Next, pre-processing is enabled to refine the quality of images, which involves image resizing, color conversion, removal of uneven illumination, quality selection and image enhancement. Here, score based image quality selection is performed using Hybrid NIQE-PIQE, and image enhancement is processed with Improved Mean Adjustment (IMA). To reduce the complexity and processing time, the proposed study extracts different features like shape, wavelet and texture. The relevant shape features are initially extracted through Pyramidal HOG (Histogram Oriented Gradient). Then, wavelet features are extracted using Haar Wavelet Transform (HWT) and the texture features are extracted using GLCM (Gray Level Co-occurrence Matrix). In order to reduce the high feature dimensionality, selecting an optimal feature set is essential. Thus, Relief Neighbourhood Component Analysis (RNCA) approach is proposed. Finally, the cataract detection is performed using Deep Optimized Convolutional Recurrent Network_Improved Aquila Optimization (Deep OCRN_IAO). Here, the loss in the network is optimized using Improved Aquila Optimization (IAO) and through this learning ability is increased. Moreover, the detection performance can be compared with other DL

models to validate the proposed performance. Fig. 1 represents the proposed methodology of the proposed work in both phases.

Fig. 1. Block diagram of proposed methodology

In phase 2, the slit-lamp cataract type and stage classification are done. Initially, image resizing and green channel color conversion are performed to enhance the image quality. Next, feature extraction and type classification can be performed using the Dense Convolutional Neural Network (Dense CNN) based deep learning framework. Finally, the classification of stages or grading as mild, moderate and severe can be attained using Batch Equivalence ResNet-101 (BE_ResNet101).

A. Image Acquisition

Image acquisition is the initial step for cataract detection, where various images are collected from different sources. The proposed work collects the retinal and slit-lamp images from popular datasets like DRIMDB and real-time slit lamp images. Fig. 2 shows some of the input images acquired from the dataset.

Fig. 2. Original input images

B. Pre-processing

Pre-processing an image is a significant step because it affords better classification results. The proposed pre-processing stage aims to refine the image quality to obtain effective performance. The images are pre-processed by,

- Image resizing
- Color conversion
- Uneven illumination removal
- Image enhancement
- Quality selection

In the proposed work, the high resolution images of the varied pixel are resized into 224*224 pixels for easy processing. The proposed work used green channel conversion in the pre-processing stage. Due to the presented uneven illumination and the available reflection of the eyes, the accurate classification of the different grades of cataracts is more difficult. Thus, the uneven illumination is removed in the pre-processing stage to enhance the performance of grade classification.

Image enhancement using Improved Mean Adjustment (IMA): Image quality enhancement plays a vital role in each algorithm. The poor quality of images lead to performance degradation of a specific classifier. Therefore, it is necessary to enhance the image quality during the phase of training and testing. This method is performed to elevate the image contrast. Here, the original input image I^O is utilized to generate the enhanced I^E image. The original image is split into 3×3 blocks of non-overlapping, and for each block mean is calculated. The highest mean value is mentioned as μ_{max} and the lowest mean is indicated as μ_{min} . When the variations among μ_{max} and μ_{min} is small, then it is represented that the image contains a poor contrast. Hence, it can be enhanced by,

$$I^E(k, l) = T(I^O(k, l)) \quad (1)$$

$$\text{Where, } T(f) = \frac{f \times s}{\mu_{max} - \mu_{min}} - \frac{\mu_{min} \times s}{\mu_{max} - \mu_{min}} \quad (2)$$

Here, the gray scale value at $I^o(k,l)$ is mentioned as f and the maximum gray scale value in the given image is represented as S .

Quality selection using hybrid NIQE-PIQE: The module of image quality selection is performed to filter out the improved quality of images for cataract diagnosis. The proposed work selects the image quality through the NIQE-PIQE model [21]. In NIQE-PIQE, the score value is evaluated for each image in which a low score is considered the best quality of image and the high score of images is assumed to be the worst quality. By [26] and [27], the higher values of NIQE-PIQE for the best image quality are observed to be five and 50 correspondingly. NIQE-PIQE is evaluated on the presented dataset, and the quality selection is performed based on the threshold. Fig. 3 shows the pre-processed images in the proposed study.

Fig. 3. Pre-processed images (a) Resized image (b) Output image of color conversion (c) Enhanced image

C. Feature Extraction

When the pre-processed images are directly subjected to the classification stage, the system faces several problems in diagnosing cataract disease and also it degrades the performance. Thus, extracting suitable features is essential to attain optimal detection results. The features that are extracted by the proposed feature extraction stage are described as,

1) Extraction of shape feature through pyramidal HOG: Pyramidal HOG is utilized for the object retrieval process and is highly suitable for extracting shape features from the input samples. In existing several methods are used to extract the shape features but they are not as much effective. The proposed method separates a localized and tracked region into several cells at varying pyramid levels. Depending on the direction of the image gradient, the pyramidal HOG is termed an image descriptor. The gradient direction $\theta(a,b)$ and gradient magnitude $m(a,b)$ is evaluated in each cell on every pixel. It is mentioned as,

$$m = \sqrt{g_a(a,b)^2 + g_b(a,b)^2} \quad (3)$$

$$\theta = \arctan \frac{g_a(a,b)}{g_b(a,b)} \quad (4)$$

Where, $g_a(a,b)$ and $g_b(a,b)$ are indicated by the image gradients with the directions a and b correspondingly. The histogram vector is computed based on the direction and size values in all the cells. A large feature vector is generated by concatenating the histogram vectors of cells together, and the

last feature vector is the outcome of the pyramidal HOG approach.

2) Extraction of wavelet features through Haar Wavelet Transform (HWT): The Haar transform is one of the simplest methods in wavelet transforms. This HWT method cross multiplies a function over the Haar wavelet with several stretches and shifts. In various existing studies, the wavelet transform is used in the pre-processed retinal image to contrast with the background and blood vessels. Still, they face some troubles while extracting wavelet features. Thus, the proposed study uses a robust HWT to extract the wavelet features in which the retinal images are dissolved into three levels: reduced contrast vessels, the background, and the vessel mentioning the background. Then, it crosses over the sum and continues to present the upcoming scale. The HWT is expressed in the form of a matrix.

$$B = HIH^T \quad (5)$$

Where, I states the images of $M \times M$ matrix, H mentions the Haar transformation of $M \times M$ matrix and B denotes the transform of $M \times M$ matrix that involves the Haar basis functions. Thus, the wavelet features are extracted via HWT.

3) Text feature extraction through GLCM (gray Level co-occurrence Matrix): The texture features correspond to the image spatial organization of pixel values. The proposed model prefers the GLCM method to attain text-based features. Because GLCM is one of the powerful method to extract texture based features. The GLCM approach acquires the specific relationship among two pixels spaced by a certain distance in an image. The GLCM techniques contain several features, where the proposed work extracts the statistical features like Angular Second Moment (ASM), correlation, contrast, entropy (ENT_y), energy (ENE_y), homogeneity (HOM_y), inverse difference moment (IDM) and variance (VAR).

The proposed feature extraction methods extract numerous features, which has the chance to enhance the computational complexity. Thus, to minimize the computational complexity, selecting an optimal feature set is essential.

D. Relief Neighbourhood Component Analysis (RNCA) based Feature Selection

The feature selection process reduces the high data dimensionality by choosing the most effective features. In the proposed cataract detection system, RNCA is utilized for feature selection. This method can make optimal feature predictions through feature weights. The aim of this stage is to diminish the computational complexity, and also it helps to boost the classification accuracy. The proposed RNCA is one of the multi-level feature selection approaches which incorporates both ReliefF and NCA algorithms. The mentioned NCA [28] is a feature selection and dimensionality minimization method and is mainly utilized in varied classification studies. The NCA utilizes training data with varied class labels when selecting the projection that will better isolate classes in the prescribed region. The objective function used in the NCA method is expressed as,

$$\Gamma(w) = \frac{1}{m} \sum_{i=1}^m Q_i - \psi \sum_{r=1}^q w_r^2 \quad (6)$$

Where, ψ represents the regularization parameter, feature weight is indicated as w_r , total amount of images are given as m , the probability score of the image i is mentioned as Q_i , q signifies dimensionality. When the parameter ψ is randomly selected, each of the feature weights can acquire values that are nearer to 0. The ReliefF approach is a method which can generate an accurate prediction of features. With the aid of feature weights, the features are estimated. Initially, the feature weights are set as zero then it randomly chooses the images from the input at every step. After that, the nearest k images from a similar class and the nearest from a varied class are identified. Then, weights are updated for each feature, and the feature that does not reach the particular condition is ignored from the input. The formulation of the ReliefF approach is represented as,

$$\omega(z^b) = \omega(z^b) - \frac{\sum_{j=1}^k \text{diff}(F, C_i, Y_j)}{nzk} + \sum_{d \neq \text{class}(C_i)} \left[\frac{Q(D)}{1 - Q(\text{class}(C_i))} z \sum_{j=1}^k \frac{\text{diff}(F, C_i, N_j)}{nzk} \right] \quad (7)$$

Where, z^b mentions the b^{th} feature, the feature set is represented as F , C_i and Y_j indicates the feature set instances and the user chosen parameter is signified as n and k . By this, the optimal set of features is selected using the proposed RNCA, and the selected reduced feature sets are subjected to the Deep OCRN_IAO model for cataract detection. By generating low dimensionality features, the process becomes smooth and reduces computational time.

E. Cataract Detection using Deep OCRN_IAO

This stage detects the cataract from the input images using a hybrid mechanism. Recently, recurrent neural network gained more attention for detecting diseases. In existing, several deep learning models are used to detect cataracts. But they cannot achieve higher detection accuracy due to the reduced learning capability. In order to obtain better detection results, the proposed work hybridizes the convolutional recurrent neural network (CRNN) with IAO algorithm. The major module of CRNN is the recurrent convolutional layer (RCL). The parameter setting of CRNN is given as, total number of epochs-10, maximum iteration-500, iteration per epoch-50 and learning rate-0.001. The RCL units develop against discrete time steps. For a unit placed at (i, j) on P^{th} feature map in RCL, its input is represented as,

$$x_{ijp}(t) = (\omega_p^h)^T v^{(i,j)}(t) + (\omega_p^\beta) z^{(t-1)} + b_p \quad (8)$$

Where, $v^{(i,j)}(t)$ indicate the feed forward input and the recurrent input is mentioned as $z^{(t-1)}$, ω_p^h signifies as feed forward weights, ω_p^β mentions the recurrent weights and bias

is represented as b_p . The initial term in equation (19) is utilized in conventional CNN, and the second term represents the recurrent connections. The activity of this unit is mentioned as the function of its input and is given as,

$$z_{ijp}(t) = g(r(x_{ijp}(t))) \quad (9)$$

Where, r specifies the rectified linear activation function. The function of local response normalization is represented as g.

$$r(x_{ijp}(t)) = \max(x_{ijp}(t), 0) \quad (10)$$

$$g(r_{ijp}(t)) = \frac{r_{ijp}(t)}{\left(1 + \frac{\alpha}{M} \sum_{p'=\max(0, p-M/2)}^{\min(p, p+M/2)} (r_{ijp'})^2 \right)^\eta} \quad (11)$$

Where, P mentions the overall feature maps in the present layer. It is observed that in equation (23), the sum process over M feature maps at a similar region (i, j) , the constant that maintains the normalization's amplitude is mentioned as α and η . The exploding state is avoided by using local response normalization. The dynamic characteristics of RCL are described in equations (20) and (21). The CRNN holds a stack of RCLs with max pooling layers. The initial layer is the feed-forward convolutional layer without the connections of recurrent layers. This convolutional layer generates an activation map and transforms all the pixel values into a single value. The second layer is the max pooling layer in which the feature dimensionality is reduced and minimizes the number of parameters to learn. The third is stacked with recurrent layers, and the next layer is fully connected. In the fully connected layer, each input from one layer is linked to each activation function of the upcoming layer. Finally, the cataract is detected in the softmax layer, which is given as,

$$o_p = \frac{\exp(\omega_p^T z)}{\sum_p \exp(\omega_p^T z)} \quad (p = 1, 2, \dots, D) \quad (12)$$

Where, o_p represents the predicted probability from the P^{th} category and feature vector created by max pooling layer is represented as z . However, the available loss function influences the detection performance of CRNN. Thus, the loss function is minimized by updating the weight parameters using the IAO approach. The available loss function is described as,

$$L_F = \frac{1}{T} \sum_{i=1}^T (a_i - k_i)^2 \quad (13)$$

Where, T represents the total number of iterations, the actual value is signified as a_i and k_i mentions the predicted value. Cataracts in the retinal images are detected based on the objective function and are expressed as,

$$\text{Objective function} = \text{Min}[L_F] \quad (14)$$

The proposed IAO method aims to minimize the loss function through weight parameter update. This is one of the population based approaches and is motivated by the hunting behaviour of Aquila. In order to update the weight parameters, Aquila algorithm used the below formulation.

$$L_1(h+1) = L_{best}(h) \times \gamma(P) + L_r(h) + (x - y) \times rand \quad (15)$$

Where, $L_1(h+1)$ represents the upcoming iteration of the solution h , P mentions the position of the feature, levy flight distribution function is denoted as $\gamma(P)$ and $L_r(h)$ represents the random solution. To enhance the efficiency of Aquila algorithm, weight strategy is introduced.

Weight strategy: According to the maximum iteration, the feature's distribution scope is compressed, generating the search space as small. The weight factor is applied to enhance the different characteristics of features and recover the optimization algorithm from the local optima. This is represented as,

$$\varpi_j = \exp(n \text{ iter}_j / n \text{ iter}_{\max} - 1) \quad (16)$$

Where, ϖ_j denotes the weight at j^{th} iteration, the maximum iteration number is specified as $n \text{ iter}_{\max}$ and the current iteration number is signified as $n \text{ iter}_j$ where, $n \text{ iter}_j \leq n \text{ iter}_{\max}$. In this, the objective function is evaluated for each iteration, and the attained result from every iteration is compared. By analysing the best objective function, the optimal solution is obtained. Therefore, the proposed Deep OCRN_IAO model identifies the cataract from the given dataset image. However, determining the grade and severity of the cataract is highly important to cure the disease. Thus, the proposed work used the cataract type classification and grade categorization in phase 2 using effective deep learning techniques.

F. Cataract Type and Grade Classification using Slit Lamp Images through Dense CNN+BE_ResNet101 Model

The automatic detection of grading and type is challenging for several existing studies. Thus, the proposed work focussed on developing an automatic cataract grade and type classification with the support of deep learning techniques. Here, the Dense CNN is developed to detect the type of cataracts and BE-ResNet101 is performed to classify the cataract grades. The hyperparameters of the proposed type and grade detection model is described as, maximum number of epochs-10, maximum iteration-500, iteration per epoch-50 and learning rate-0.001.

1) *Pre-processing of slit lamp images:* Initially, the slit lamp images are pre-processed to enhance the classification performance. The pre-processing steps that carried out on slit lamp images are,

- Resizing of slit lamp images
- Green channel color conversion

After pre-processing the input images, the image quality is enhanced and fed to the Dense CNN method for feature extraction and cataract type categorization.

2) *Feature extraction and detection of cataract type using dense CNN:* The proposed work is done on feature extraction from the pre-processed images to minimize the classification error. For this purpose, Dense CNN is preferred in this study for feature extraction. Because CNN has the ability to extract features automatically, it helps to produce higher classification results. After feature extraction, the Dense CNN model's final layer classifies the cataract type from the provided slit lamp images. The proposed approach contains a set of dense layers that evaluate each input's weight average and is transmitted to the activation function. The input layer is the initial layer of CNN, where the images from the dataset are set as input. Next, the convolutional layer is the second layer designed by various convolutional kernels. The parameters in the convolutional layer are optimized via a back propagation approach. The major intention of this layer is to extract the most needed features from the slit lamp image, which helps to maintain the complexity. Next, a max-pooling layer is presented which generates feature mapping, and it reduces the feature dimensionality. The information from the pooling layer is passed into the set of dense layers. Here, the neurons of the layer are linked to each neuron of its previous layer. The CNN functionality mainly confides in the activation function, a systematic layer. It is noted that the rate of training can prevent over-fitting problems.

$$h(z) K \max(z; 0) \quad (17)$$

The functionality of the convolutional layer is described as follows,

$$z_p^l = h\left(\sum_{i \in Np} z_i^{l-1} * K_{ip}^{l-1} + b_p^l\right) \quad (18)$$

Where, p mentions feature mapping, Np represents input mapping, K_{ip} is denoted as filter and bias of feature mapping is specified as b_p . The training process of the network is accelerated using the activation layer, and batch normalization is performed among the activation function and convolutional layer. The cross entropy is analysed in the output layer and is defined as,

$$Loss_{class} = -\sum_{i=1}^m 1\{f = i\} \log \frac{e^{xi}}{\sum_{l=1}^f e^{xi}} \quad (19)$$

Where, q is denoted as the number of classes, X_i is the final layer and f represents the information of each feature from the input image. During the process of CNN training, the feature extraction is performed, and also it diminishes the

cross entropy loss and reconstruction error. In the training process, each kernel is trained to acquire cataract types from the input source. The confidence value is enhanced and fine-tuned by minimizing the cross entropy loss function. Thus, the proposed Dense CNN classifies the types of cataracts precisely.

3) *Grade or stage classification of cataracts using BE_ResNet101 framework:* The proposed study used the BE-ResNet101 approach for cataract grade categorization. The fundamental ResNet is also a type of CNN model, and the structure of ResNet was inspired by the traditional VGG-19 method. The proposed BE-ResNet101 detects the grade by avoiding the issues of attaining information from unbalanced instances. The presented batch equivalence in ResNet101 helps to improve the cataract grade detection results. Also, the proposed model helps to reduce the degradation issue. The basicResNet-101 is a residual network that contains 101 layers and is the advanced version of the ResNet-50 model. The layers available in the ResNet contain a similar amount of filters for a similar size of output feature map. The amount of filter is twice if the feature map's size is minimized to reduce the time complexity. In the ResNet model, down sampling is directly performed by convolving layers with two strides. This ResNet structure ends with a pooling layer and a fully connected layer with a softmax layer. The objective of distributive layers is to avoid the vanishing gradients issues through reutilizing activation from the previous layer till the closest layer of the current layer has learned its weights.

Fig. 4. ResNet-101 structure

The ResNet-101 involves a total of 104 convolutional layers. It contains layers of 33 blocks, and 29 of such blocks utilize the output of the preceding block. It is shown above as remainder connections, and such remainders are used as the initial operand of the addition operator used at the end of all blocks to get the input of the coming blocks. The rested four blocks acquire the output of the preceding block and utilize it in a convolutional layer with 1x1 of filter size and one stride, followed by a batch normalization layer. This layer enables the normalization process, and the attained outcome is transmitted to the addition operator at the output of the block. The structure of ResNet is illustrated in Fig. 4.

Batch equivalence: In the proposed experimental data, the number of images graded from 3.0 to 4.0 is considered the highest. When a mini-batch is designed randomly, the grading model obtains the information from unbalanced occurrences and becomes biased. This issue is solved by applying a strategy of batch balancing. Here, the batch is separated in to

five varied groups like [1, 2], [2, 3], [3, 4], [4, 5] and [5, 6]. A similar number of occurrences are randomly chosen during the construction of a mini-batch, i.e., 25 from all the groups and generate the batch fully balanced. Thus, the proposed BE_ResNet101 model classifies and detects the grade of cataracts effectively. Fig. 5 illustrates the cataract grade classified images from the proposed Dense CNN+BE_ResNet101 model.

Fig. 5. Classified images

IV. RESULTS AND DISCUSSIONS

This section presents the simulation results of the proposed cataract detection and classification system with clear analysis. The experimental setup was executed through MATLAB software.

A. Dataset Description

The input images utilized in this work are chosen from two different datasets like DRIMDB (Diabetic Retinopathy Images Database) <https://academic.oup.com/doi/10.1093/eye/eyaa001> and real time slit lamp images. The DRIMDB dataset is utilized in several retinal image analysis studies. In this dataset, a total of 216 consecutive images are taken in the proposed experimental analysis. The real-time slit lamp images are collected from various hospitals containing five types of cataracts: cortical, hyper mature, mature, nuclear and posterior.

B. Performance Metrics

The performance metrics are utilized to evaluate the efficacy of the proposed model. The metrics utilized in the proposed study are expressed below.

$$Accuracy: A_y = \frac{Tp + Tn}{Tp + Tn + Fp + Fn} \quad (20)$$

$$Sensitivity: S_y = \frac{Tp}{Tp + Fn} \quad (21)$$

$$Specificity: Sp_y = \frac{Tn}{Tn + Fp} \quad (22)$$

$$Youden\ Index = S_y + Sp_y - 1 = TPR - FPR \quad (23)$$

$$F_1 - score = 2 \times \frac{Pr\ ecision \times Sensitivity}{Pr\ ecision + Sensitivity} \quad (24)$$

$$Kappa = \frac{P_{observed} - P_{chance}}{1 - P_{chance}} \quad (25)$$

C. Performance Analysis of Proposed Classification

The performance of the proposed BE_ResNet101 model is analysed by measuring the performance metrics and comparing the attained results with some other approaches. The confusion matrix of the proposed classification is shown in Fig. 6.

True Class	Cortical Cataract	41	2			1
	Hyper mature		26		1	1
	Mature		1	67	1	1
	Nuclear		1		31	1
	Posterior subcapsular		1	1	2	85
		Cortical Cataract	Hyper mature	Mature	Nuclear	Posterior subcapsular
		Predicted Class				

Fig. 6. Confusion matrix of proposed Dense CNN+BE_ResNet101 classification model

The above confusion matrix reveals the efficiency of the proposed model also, it mentions the prediction ability. At each testing phase, different cataract types are detected. During classification, only few classes are misclassified as others. Thus, the confusion matrix exhibits that the proposed model provides accurate classification. Fig. 7 shows the obtained accuracy and loss during training and testing.

Fig. 7. Accuracy and loss graph of proposed Dense CNN+BB_ResNet101model

The accuracy and loss are measured at each iteration by varying the number of epochs. By analysing the results, it is clear that the accuracy and loss is well maintained in the proposed model. This proves that the proposed classifier is powerful for cataract type and grade classification. The results obtained from phase I by using retinal and slit lamp images are shown in Table I.

TABLE I. PERFORMANCE ANALYSIS IN PHASE I USING RETINAL AND SLIT LAMP IMAGES

Datasets	Accur acy (%)	Sensiti vity (%)	Specifi city (%)	Precisi on (%)	FI sco re (%)	Youd en Index (%)	Kap pa (%)
(DRIM DB) Retinal images	92.36	94.58	96.57	91.06	91.47	89.65	89.32
Slit lamp images	94.67	96.68	98.29	93.03	93.81	91.23	90.28

In order to determine the strength of datasets, the performance metrics are evaluated, and the obtained results reveals that the slit lamp images obtain a better outcome than retinal images from the DRIMDB dataset. Thus, slit lamp images are preferred in phase II to detect the type and grade of the cataract. The accuracy measure comparison is illustrated in Fig. 8.

Fig. 8. Accuracy performance comparison

The above analysis clearly shows that, the accuracy of the proposed classifier is enhanced because of the higher efficiency. Besides that, the proposed BE-ResNet101 model diminishes the training error and also it avoids the vanishing gradient issue. But, the existing approaches generates higher classification errors and leads to low accuracy. The accuracy of proposed model is 98.87%, ResNet-101 is 87.6%, GoogleNet is 83.53% and UDFA is 93.48%. The comparative analysis of proposed and existing works in terms of sensitivity is shown in Fig. 9.

Fig. 9. Sensitivity performance comparison

The above analysis shows that the proposed Dense CNN +BE_ResNet101 model obtains enhanced sensitivity to existing approaches. The average value of sensitivity attained from the proposed model is 98.28%, ResNet101 is 80.39%, GoogleNet is 75%, and UDFA is 89.2%. The specificity comparison analysis is illustrated in Fig. 10.

Fig. 10. Specificity performance comparison

The existing approaches face several issues when detecting cataracts from the given image. Thus, the previous studies are unable to provide improved specificity results. The average specificity value attained from the proposed Dense CNN+BE_ResNet101 model is 99.66%, ResNet 101 is 97.1%, UDFA is 97.37% and GoogleNet is 99.5%. The F1-score comparison is depicted in Fig. 11.

Fig. 11. F1 score performance comparison

The average F1-score of proposed classifier is 95.68%, UDFA is 92.3%, and ResNet101 is 88.2% and GoogleNet 85.71%. Compared with other approaches, the F1score of the proposed classifier is superior. This states that the developed Dense CNN+BE ResNet101 is more suitable for detecting cataract type and grade. The comparative analysis of the kappa coefficient is shown in Fig. 12.

Fig. 12. Kappa performance comparison

The comparison analysis using the kappa measure shows that the proposed techniques are more potent than the others. The average kappa value obtains from the proposed Dense CNN+BE-ResNet101 is 97.83%, UDFA is 95.4%, ResNet101 is 90.5% and GoogleNet is 89.2%. The Youden index comparison of proposed and existing techniques is shown in Fig. 13.

Fig. 13. Performance comparison in terms of Youden index

The average Youden index attained from the proposed model is 95.04, UDFA is 84.6%, ResNet101 is 77.5%, and GoogleNet is 75%. Compared with others, the proposed method is the highly enlarged range in the Youden index. The comparison of the ROC curve and AUC values of different techniques is illustrated in Fig. 14.

Fig. 14. ROC curve and AUC values of proposed and existing approaches

The ROC curve comparison represents that the proposed model is better than the other techniques. Analysing the ROC curve, the obtained AUC values are superior in the proposed cataract grade detection model. By analysing the proposed work with different approaches, the proposed model obtains improved outcomes in terms of accuracy, sensitivity, specificity, Youden index, Kappa and F1 score.

V. CONCLUSION

This research presents cataract detection and classification using deep learning approaches through retinal and slit lamp images. Here, the proposed work is carried out in two phases. In the first phase, the cataract is identified, and in the second phase, the type and grade of the cataract is categorized. In phase I, the images are gathered from DRIMDB and slit lamp images. By using these two varied dataset images, the cataract is detected through proposed Deep OCRN_IAO model. The experimental results prove that the slit lamp images are obtained improved performance than the retinal images.

Thus, in phase II, the slit lamp images are preferred for cataract type and grade classification. In the proposed work, the type of cataract is detected using Dense CNN model, where the convolutional layer of CNN reduces the feature dimensionality. Depending on the outcome of convolutional layer, the dense layer categorizes the features. Because of the presence of a dense layer, the CNN network accurately detects the type of cataracts. Also, the proposed BE-ResNet101 model detects the grade of cataracts by reducing the degradation issue. This model classifies the grades as mild, severe and moderate. Therefore, the system obtains enhanced results than the existing ones. The experimental results show that the proposed Dense CNN+BE-ResNet101 model attains good performance results in an accuracy of 98.87%, sensitivity 98.28%, specificity 99.66%, kappa coefficient 97.83%, F1 score 95.68% and Youden index 95.04%. In future studies, the proposed work will be applied to different biomedical images and detect their performance and effectiveness through various datasets.

Fast Comprehensive Secret Sharing using Naive Image Compression

Heri Prasetyo¹, Kukuh Caezaocta Prayuda²

Department of Informatics, Universitas Sebelas Maret (UNS), Surakarta, Indonesia

Abstract—This paper presents a simple method for performing (k,n) -Secret Sharing (SS) with fast computation. It aims to reduce the computational time of the former scheme in the shadow generation process. The former scheme performs SS with the polynomial function computation by involving the color palette. The color palette transforms noisy-like shadow image into more meaningful appearance. However, this scheme requires a high computational burden on this transformation process. The proposed method exploits naive image compression to decrease the required bit for representing a secret and cover image. It effectively avoids the color palette usage previously used by the former scheme. The proposed method produces a set of shadow images with a cover image-like appearance. In addition, the secret and cover image can be reconstructed by gathering at least k shadow images. As documented in the Experimental Results section, the proposed method yields a promising result in the (k,n) -SS with reduced computational time compared to that of the former scheme.

Keywords—Comprehensive; image compression; naïve; polynomial; secret sharing

I. INTRODUCTION

Several methods have been proposed for secure secret image communication. The SS is the most popular approach to securely send one or multiple images from the sender to other parties, i.e. called as receiver or participant. The first work in the SS can be traced back to the classical paper [1]. It introduces a SS concept under (k,n) -SS thresholded setting. In this method, a secret method is converted into n shadow images and then transferred to the n participants. The recovery process aims to reconstruct a secret image by collecting k or more shadow images to achieve a correct or lossless result. If the number of collected shadow images is less than k , the recovered secret image is lossy, or nothing is obtained. An improvement of SS method is Visual Cryptography (VC) [2] which performs SS into a grayscale image. This improvement leads the direction for further development of SS methods. On the other hand, the Chinese Remainder Theorem (CRT)-based SS [3] also gain popularity because of its wider application ability. However, the CRT-based SS has a slight limitation in the secret image recovery process. The recovered image is lossy compared to that the original image. While the other methods use a binary set basis [4-5], modular arithmetics [6], general access structure [7], bitwise Boolean operation [8-9], adaptive weight priority [10], etc., to generate a set of shadow images.

In another ways, several techniques have also been developed for the multiple secret sharing [11-14]. Most methods exploit the exclusive-OR operation and CRT

computation to generate a set of shadow images. The method in [11] involves a simple image encryption, while scheme in [12] utilizes the generalized chaotic image scrambling. The methods in [13] and [14] use the hyperchaotic image scrambling and improved beta chaotic image encryption, respectively, to yield a set of shadow images. However, all technique produces the noise-like shadow.

The SS and its variants effectively secure secret image communication. But, a set of shadow images generated by these methods are in a noise-like appearance. A malicious attacker can easily recognize these shadow images as a secure image containing some confidential information. This attacker may collect several shadow images to obtain a fake or counterfeit secret image. This situation is unacceptable in secret image communication. Thus, the friendly SS tries to solve this problem by converting each shadow image into a more friendly appearance or cover image-like. An attacker now cannot perceive the noise-like shadow image. The method in [15] is an example of a friendly SS approach. It utilizes the CRT and bitwise Boolean operation to generate a set of shadow images. The methods in [16] and [17] perform thresholded SS and progressive SS, respectively, with the meaningful shadow images. Meanwhile, the method [18] generates a set of meaningful shadow images under the multiple secret sharing framework.

Several method have been reported in literature in order to convert the noise-like shadow image into more friendly or meaningful appearance such as in [15-19]. The method in [19] performs the comprehensive visual SS. A secret image is converted into a set of shadow images with a friendly or cover image-like appearance. This scheme employs the polynomial function computation and color palette in the shadow image generation stage. It can be categorized as (k,n) -SS. This method effectively produces a set of shadow images in the cover-like appearance. The secret and cover images can be recovered from at least k collected shadow images. However, this method requires a very high computational burden in the shadow image generation since it needs to compare the similarity over four bits as mentioned in [19]. It becomes inferior for the practical implementation of SS required fast computation. The method offers a solution to transform the noise-like shadow to be more meaningful.

Thus, this paper offers a solution to reduce the computational time of [19] using naive image compression. This naive compression or image companding scheme effectively overcomes the former scheme limitation. The proposed work give a significant contribution on reducing the computational time of [19] in the comprehensive secret sharing

task. It replaces the color palette usage with a simple image compression technique. It introduces a new concept for converting the noise-like shadow image into more friendly appearance with noise compression (companding) which can be further utilized for future works, i.e. friendly secret sharing, comprehensive secret sharing, image watermarking [20], etc.

II. FORMER SCHEME OF COMPREHENSIVE SECRET SHARING

This section introduces the former scheme [19] for performing secret sharing. It can be regarded as (k, n) -SS, with $k < n$, since it converts a secret image into n shadow images, while it requires at least k shadow images to obtain a recovered secret image. The method in [19] generates a set of shadow images in which their appearance is maintained as similar as possible to the targeted cover images. It employs a set of cover images in shadow image generation. The secret image can be recovered by using at least k shadow images. In addition, the cover image can also be reconstructed using after obtaining the recovered secret image. This aforementioned method employs the color palette to generate a set of shadow images and to recover secret and cover images.

The detail of the former method [19] can be explained as follow. Let I be a secret image, and $\{C_1, C_2, \dots, C_n\}$ be a set of cover images. This method forces to change I into a set of shadow images $\{S_1, S_2, \dots, S_n\}$. The appearance of shadow image should be as similar as possible to the cover image, i.e. $S_i \approx C_i$ for $i = 1, 2, \dots, n$. The method in [19] firstly extracts four bits of each cover image C_i as follow:

$$C_i = \langle c_1, c_2, \dots, c_4 \rangle \quad (1)$$

where c_1, c_2, \dots, c_4 denotes four extracted bits of C_i , with c_1 is the most significant bit. These four bits are acquired by using a color palette [19]. Yet, The secret image is regarded as a_0 , i.e. $a_0 = I$. Subsequently, the polynomial function computation is applied to perform (k, n) -SS as follows:

$$f(x) = a_0 + a_1x + a_2x^2 + \dots + a_{k-1}x^{k-1} \pmod{P} \quad (2)$$

where $f(x)$ is the polynomial function order k , for $x = 1, 2, \dots, n$. The value of P is a prime number. It is typically set as $P = 257$ in the 8-bits image representation. While the value of a_i is a random number generated in the range $a_i \sim [0, P)$, for $i = 1, 2, \dots, k - 1$. The temporary shadow image T_i can be obtained by changing the value of x in (2) with the index of shadow image, i.e. $i = 1, 2, \dots, n$. The computation of T_i can be conducted as follow:

$$T_i = f(i) \quad (3)$$

for $i = 1, 2, \dots, n$. From this process, one obtains a set of temporary shadow images $\{T_1, T_2, \dots, T_n\}$.

Until this process, the appearance of each shadow image T_i is in noise-like form. The appearance of T_i should be exchanged to be more resemble as C_i . An additional step is needed to perform this process. The temporary shadow image T_i should be converted from decimal into 8-bits representation. This binary number extraction process is given as:

$$T_i = \langle t_1, t_2, \dots, t_8 \rangle \quad (4)$$

where t_i is the i -th bit, for $i = 1, 2, \dots, 8$, with t_1 is the most significant bit. The proposed method simply compares the four significant bits of T_i with the four significant bits of C_i . If there are all identical, T_i is then regarded as the shadow image S_i . Specifically, if $c_i = t_i$ for $i = 1, 2, \dots, 4$, this process is performed:

$$S_i = T_i \quad (5)$$

where S_i denotes the i -th shadow image, for $i = 1, 2, \dots, n$. Otherwise, the proposed method needs to recompute (2), i.e. the computation of polynomial function is executed again until the four significant bits are identical to that of the four significant bits of cover image. This process produces a set of shadow images $\{S_1, S_2, \dots, S_n\}$. Now, each shadow image S_i is visually similar to the cover image C_i .

The Lagrange interpolation is utilized to extract a secret image. Herein, the receiver simply collects at least k shadow images in the recovery process to obtain a lossless secret image. One gets a recovered secret image \tilde{I} after applying the Lagrange interpolation. To reconstruct the cover image, the receiver needs to extract four significant bits of each S_i . Then, the inverse process of color palette computation [19] is performed to yield C_i , for $i = 1, 2, \dots, n$, by considering four significant bits of S_i . This process produces a set of recovered cover images as $\{C_1, C_2, \dots, C_n\}$. The former scheme performs well in the (k, n) under the comprehensive SS setting.

Even though the former method effectively generates a set of shadow images with a cover-like appearance. However, the computation of similarity matching over four significant bits, i.e. $c_i = t_i$ for $i = 1, 2, \dots, 4$, need a high computational burden. The method should recalculate $f(x)$ if the four bits are not identical. It will be inconvenient if a fast computation response is required to generate a set of shadow images from a secret image.

III. PROPOSED METHOD

The proposed method offers a simple solution for the limitation of former scheme [19]. It tries to reduce the computational burden of similarity matching for four significant bits. The proposed method avoids this similarity matching to further reduce the computational time. Herein, simple naive image compression is exploited in the shadow image generation and secret image recovery. Sender and receiver do not use the color palette in this SS process. The proposed method is further explained in this section as follows.

A. Shadow Image Generation

As mentioned before, the proposed method converts a secret image I into a set of shadow images. This method involves a set of cover images as $\{C_1, C_2, \dots, C_n\}$. Let r and q be the required bit for compressing the secret and cover images, respectively. The value should satisfy $r + q = 8$, for an 8-bits representation of an image. These two values should be kept for both sender and receiver in the SS process. The proposed method performs naive image compression or image companding process utilizing two specific quantizer values. These two quantizer values can be computed as follows:

$$Q_s = 2^{8-r} \quad (6)$$

$$Q_c = 2^{8-q} \quad (7)$$

where Q_s is the quantizer value for the secret image, and Q_c is the quantizer for cover image. Subsequently, the compression processes for secret image I and cover image C_i are performed as follows:

$$\hat{I} = \left\lfloor \frac{I}{Q_s} \right\rfloor \quad (8)$$

$$\hat{C}_i = \left\lfloor \frac{C_i}{Q_c} \right\rfloor \quad (9)$$

where \hat{I} is a compressed secret image, and \hat{C}_i is the i -th compressed cover image. The symbol $\lfloor \cdot \rfloor$ represents the floor operator. From these computations, the lengths of \hat{I} and \hat{C}_i are now with r and q -bits, respectively. The compressed secret image \hat{I} can be converted into binary form as follow:

$$\hat{I} = \langle \hat{l}_1, \hat{l}_2, \dots, \hat{l}_r \rangle \quad (10)$$

where \hat{l}_i is the i -th bit of \hat{I} , for $i = 1, 2, \dots, r$. While \hat{l}_1 is the most significant bit. The binary conversion of compressed cover image \hat{C}_i is given as:

$$\hat{C}_i = \langle \hat{c}_{i1}, \hat{c}_{i2}, \dots, \hat{c}_{iq} \rangle \quad (11)$$

where \hat{c}_{ij} is the j -th bit of \hat{C}_i , for $j = 1, 2, \dots, q$. The most significant bit is represented with \hat{c}_{i1} . These binary numbers are used in shadow image generation.

Subsequently, the polynomial function is computed with $P = 2^r$. Herein, the value of P is a non-primary number. In our proposed method, the value of P depends on the required bit of secret image, i.e. r . Similar to the former scheme [19], the proposed method also considers $a_0 = I$. It also generates a set of random numbers in a specific range, i.e. $a_i \sim [0, P)$ for $i = 1, 2, \dots, k - 1$. The polynomial function for the SS can be calculated as follow:

$$f(x) = a_0 + a_1x + a_2x^2 + \dots + a_{k-1}x^{k-1} \pmod{P} \quad (12)$$

This computation is for $x = 1, 2, \dots, n$. It should be noted that $f(x)$ is in r -bits representations, i.e. the length of $f(x)$ is r under the binary form. The temporary shadow image is then obtained by replacing x with the index of shadow image, i.e. $x = i$. This process is formally defined as follows:

$$T_i = f(i) \quad (13)$$

for $i = 1, 2, \dots, n$. Each temporary shadow image is also in r -bits representation, i.e. $T_i = \langle t_{i1}, t_{i2}, \dots, t_{ir} \rangle$. The proposed method performs bit concatenation between all bits in T_i with all bits in \hat{C}_i . Then, the final shadow image is obtained as follows:

$$S_i = [\hat{c}_{i1}, \hat{c}_{i2}, \dots, \hat{c}_{iq}, t_{i1}, t_{i2}, \dots, t_{ir}] \quad (14)$$

where S_i is the i -th shadow image, for $i = 1, 2, \dots, n$. The symbol $[\cdot]$ denotes the bit concatenation operator. Herein, the length of S_i is 8-bits. After converting the binary number into the decimal representation of each S_i , one can gain a set of shadow images $\{S_1, S_2, \dots, S_n\}$. The sender sends these shadow images to the receiver via a communication channel.

B. Secret Image Recovery

In the secret image recovery process, the receiver tries to produce a set image and recovered cover image by collecting several shadow images $\{S_1, S_2, \dots, S_K\}$, while $k \leq K \leq n$ to obtain a perfect reconstruction process. The receiver firstly converts each shadow image into binary representation as follows:

$$S_i = [\hat{c}_{i1}, \hat{c}_{i2}, \dots, \hat{c}_{iq}, t_{i1}, t_{i2}, \dots, t_{ir}] \quad (15)$$

for $i = 1, 2, \dots, K$. Where K denotes the number of collected shadow images. The r least significant bits are extracted from (15) to generate a temporary shadow image. This binary number is then converted into decimal number as follows:

$$T_i = \text{Dec}(t_{i1}, t_{i2}, \dots, t_{ir}) \quad (16)$$

for $i = 1, 2, \dots, K$. While $\text{Dec}(\cdot)$ denotes the operator from binary to decimal number conversion. The Lagrange interpolation as used in [19] is then applied to all T_i to yield I^* , where I^* denotes a temporary secret image. This temporary secret image is still in low dynamic range, i.e. it is still in r -bits representation. The final secret image is then produced using the following process:

$$\tilde{I} = Q_r \times I^* \quad (17)$$

where \tilde{I} represents a recovered secret image. In the proposed comprehensive (k, n) -SS, the cover image can be recovered from the shadow image. The receiver extracts q -bits from (15) to recover the cover image. The process of cover image recovery is given as follows:

$$\tilde{C}_i = Q_c \times \text{Dec}(\hat{c}_{i1}, \hat{c}_{i2}, \dots, \hat{c}_{iq}) \quad (18)$$

where \tilde{C}_i denotes the i -th recovered cover image, for $i = 1, 2, \dots, n$. Both sender and receiver need Q_s and Q_c in the secret image recovery and cover image reconstruction process. The receiver only keeps the values of r and q for computing Q_s and Q_c . Using this simple approach, the proposed method overcomes the limitation of the former scheme [19] in the high computational burden.

IV. EXPERIMENTAL RESULTS

Several experiments have been conducted to investigate the proposed method performance. All experiments are then reported in this section. This section firstly shows the experimental results under the visual inspection, i.e. the correction of the proposed method is only observed under human investigation. Subsequently, it delivers the performance comparisons under the objective quality assessment. In our experiments, all images are of size 512×512 . All images are in color format. The histogram is given at the bottom left of each image.

A. Visual Observation

This subsection reports the proposed method performance for dealing with $(3,4)$ -SS and $(2,3)$ -SS. This experiment only overlooks the generated shadow images and recovered secret image with the visual investigation. Herein, one secret image is involved, and several cover images are used in the experiment. Fig. 1(a) depicts a secret image used in the experiment. This image is in original I , while Fig. 1(b) is the compressed version

\hat{I} with $r = 4$. A set of original cover images is shown in Fig. 2, while the compressed version of all cover images are given in Fig. 3. Herein, the required bit for the cover image is set as $q = 4$.

Fig. 1. Secret image used as experiment: (a) original image I , and (b) compressed version \hat{I}

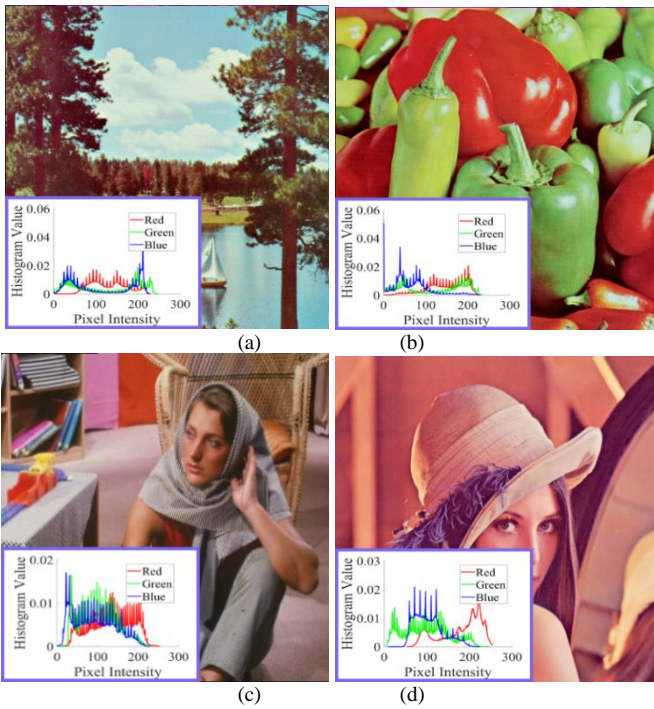

Fig. 2. A set of cover images: (a) C_1 , (b) C_2 , (c) C_3 , and (d) C_4

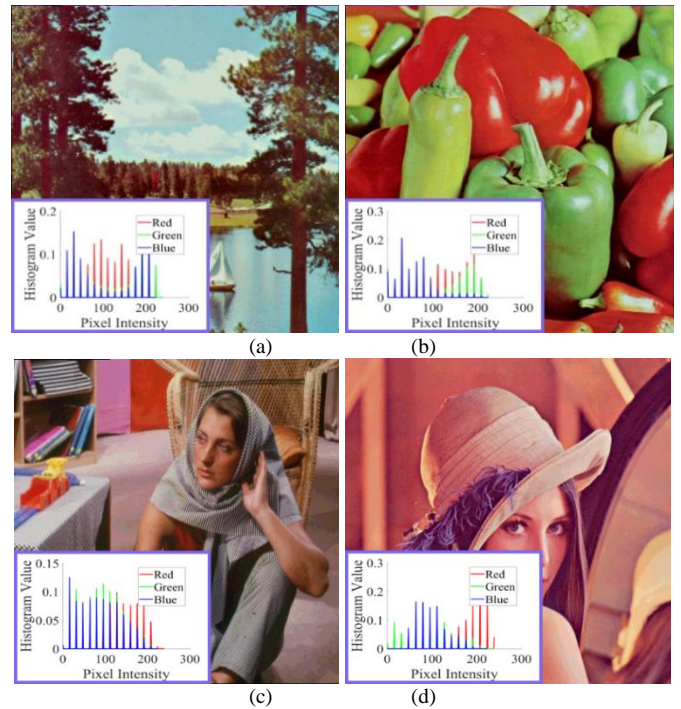

Fig. 3. A set of compressed cover images: (a) \hat{C}_1 , (b) \hat{C}_2 , (c) \hat{C}_3 , and (d) \hat{C}_4

This section firstly considers the proposed method performance under (3,4)-SS setting. Fig. 4 is a set of shadow images obtained from our scheme. As shown in this figure, the content of each shadow image is almost similar to that of the original cover image. Thus, the proposed method effectively performs the comprehensive secret sharing with (3,4)-SS approach. Recovered secret images are obtained by performing the secret image recovery process involving several shared images. Fig. 5 delivers the recovered secret image \tilde{I} while two or more shared images are used in the recovery process. The proposed method yields correct results for (3,4)-SS. The secret image can be losslessly recovered while at least three shadow images are used in the recovery process. In addition, a set of cover images can be recovered after extracting the secret image. Fig. 6 reports the result of recovered secret image. Herein, all shadow images are employed for performing the cover image recovery. As demonstrated in this figure, the proposed method is able to recover the cover image with an identical result compared to the compressed version of cover image.

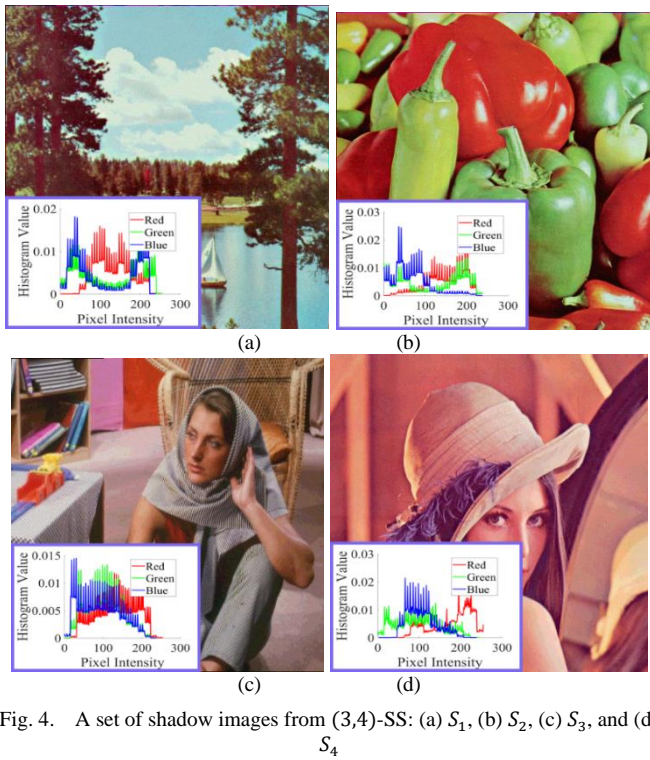

Fig. 4. A set of shadow images from (3,4)-SS: (a) S_1 , (b) S_2 , (c) S_3 , and (d) S_4

Fig. 6. Recovered cover images from (3,4)-SS: (a) \tilde{C}_1 , (b) \tilde{C}_2 , (c) \tilde{C}_3 , and (d) \tilde{C}_4

Fig. 5. Recovered secret image \tilde{I} from (3,4)-SS by involving several shared images: (a) $\{S_1, S_2\}$, (b) $\{S_1, S_2, S_3\}$, (c) $\{S_2, S_3, S_4\}$, and (d) $\{S_1, S_2, S_3, S_4\}$.

An additional experiment is also executed further to examine the correctness of proposed method under visual investigation. This experiment inspects the proposed method under (2,3)-SS setting. A secret image and three cover images are from Fig. 1(a) and Fig. 3(a-c), respectively. It also utilizes $r = q = 4$. The proposed method yields a set of shadow images as delivered in Fig. 7. Again, the proposed method performs well in converting the secret image into a set of shadow images whose appearance is similar to that of the cover image. Fig. 8 exhibits the visual result of the recovered secret image \tilde{I} while one or more shared images are involved during the recovery process. The recovered secret image is lossless, while at least two shadow images are used. Thus, the proposed method is correct for performing the (2,3)-SS. A set of recovered cover images can also be obtained using all shadow images during the recovery process. Fig. 9 shows a set of recovered cover images. All of these images are identical to that of the compressed cover image. It can be concluded that the proposed method gives promising results for (k, n) -SS with the comprehensive scenario. In addition, the proposed is a strong candidate while implementing the comprehensive secret sharing compared to the other scheme. It avoids the computation burden as used in [19]. It also requires a simple step for conducting the comprehensive secret sharing.

Fig. 7. A set of shadow images generated by (2,3)-SS: (a) S_1 , (b) S_2 , and (c) S_3

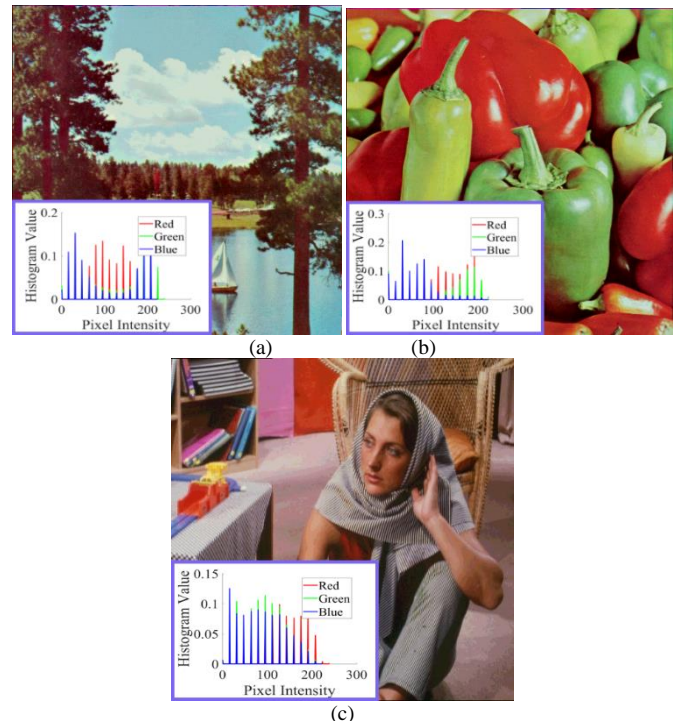

Fig. 9. A set of recovered cover images from (2,3)-SS: (a) \tilde{C}_1 , (b) \tilde{C}_2 , and (c) \tilde{C}_3

Fig. 8. The visual of \tilde{I} from (2,3)-SS when shared images are used in the recovery process: (a) $\{S_2\}$, (b) $\{S_1, S_2\}$, (c) $\{S_2, S_3\}$, and (d) $\{S_2, S_3, S_1\}$

B. Objective Comparisons

This subsection summarizes the proposed method performance under the objective image quality assessment. This experiment only examines the proposed method under (3,4)-SS setting. It observes the performance by investigating the effect of required bit for secret image r . It means that the cover image is compressed with various q with $q = 8 - r$. All shadow images are involved during the secret image recovery process. The similarity between the shadow image and the original cover is measured with Peak-Signal-to-Noise Ratio (PSNR). It computes the average PSNR scores over all four shadow images. The similarity between the recovered cover image and the original version is also observed under the average PSNR score. This calculation is also for the recovered and original secret images. A higher value of average PSNR indicates better performance. Fig. 10 displays the performance comparisons with the average PSNR value over various $r = \{2,3, \dots, 6\}$. The quality of shadow image and recovered cover image is decreased while applying higher r . But, the quality of a recovered secret image is increased by using a higher value r . The proposed method yields the best performance with $r = q = 4$, as confirmed in Fig. 10.

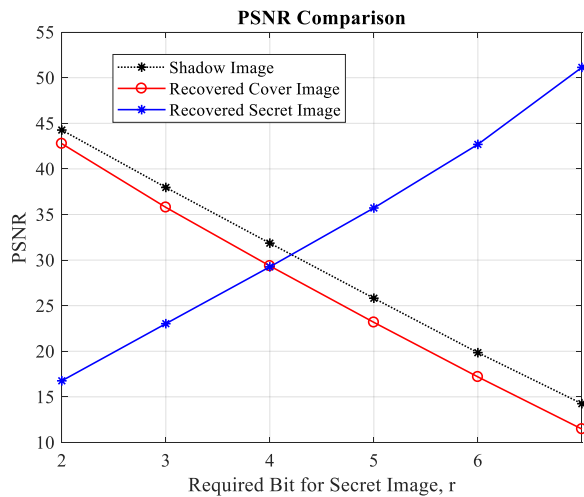

Fig. 10. Performance comparisons in terms of average PSNR value

The evaluations are also observed for the proposed method performance in terms of Structural Similarity Index Metric (SSIM). Herein, this experiment also considers the quality of shadow image, recovered cover image, and recovered secret image. A higher value of SSIM also implies better performance. Fig. 11 demonstrates the proposed method performance under the average SSIM score evaluation over various r , i.e. $r = \{2,3, \dots, 6\}$. The quality of shadow image and recovered cover image is reduced while applying a higher of r . However, the quality of recovered secret image is increased with higher r . The proposed method yields the best performance by setting $r = 4$ as demonstrated in Fig. 11. The proposed method effectively (k, n)-SS setting.

Fig. 11. Performance evaluations in terms of average SSIM score over various required bit for secret image

V. CONCLUSIONS

A simple solution for reducing the computational time for the former (k, n)-SS has been presented in this paper. The proposed method utilizes naive image compression to replace the color palette usage. This image compression is a straightforward approach to reduce the required bit of secret and cover image. The proposed method effectively produces a

set of shadow images with a friendly appearance. In addition, it can recover the secret and cover images. For future works, the security level of the proposed method can be improved by involving image encryption or hashing functions. It can also be extended for secret video communication. The proposed method can also be applied to multiple secret sharing.

Menoufia University, Egypt

Abstract—Modern organizations of all sizes emphasize safeguarding sensitive consumer information. Regardless of the limits given by the degrees they choose to pursue, people are nevertheless required to possess data management skills. In addition, determine if the data should be centralized or decentralized to meet the objective of enhancing accessibility. In addition, you will need to be able to monitor who has access to your data and regulate who has access to your data.

Keywords—Big data; blockchain; internet of things; data security; healthcare; data processing cost; IOMCT; climate change and global warming

I. INTRODUCTION

This article focuses on the Internet of Things (IoT) and massive datasets to investigate the use of blockchain technology, specifically to enhance the overall quality of the healthcare system. The fast growth of the internet of things is inextricably related to the rapid growth of the information technology sector (IT). A Model (Internet Of Medical Thing) IOMCT was created to address these issues since it was difficult to get the necessary insurance approvals and there was a difficulty with the dispersion of information. This concept was created to solve the challenges associated with getting the requisite insurance approvals. In addition, there is a reduced likelihood that sensitive information and data may be stolen by unauthorized individuals as a direct result of being exposed.

The findings of this research indicate that the technique we have developed will contribute to the safeguarding of patients' personal information. In addition, it will improve people's awareness of the connection between paper use and global warming. Therefore, it is fair to assume that individuals would choose the paperless technique, which will contribute to the conservation of natural resources.

It should not come as a surprise that healthcare is a top priority in countries with low per capita income since it has direct effects on the health and longevity of the people. It has the potential to considerably benefit society as a whole by reducing the occurrence of a broad range of illnesses and ailments that are harmful to one's health as shown in Fig. 1. This study should be continued since its potential benefits to society as a whole are substantial. In light of this, it is glaringly evident that recent advances in technological capabilities and ongoing research and development have been crucial to the advancement of the medical sector [1].

In the not-too-distant future [19], it is anticipated that the Internet of Things will become a formidable mechanism for the production of counterfeit wristbands, smart cards, and watches. Using a blockchain ledger in this capacity, data such as a patient's heart rate, blood pressure, and blood sugar levels may be recorded automatically and exactly.

Advanced Technologies including the IoT, Blockchain, and Big Data, can assist doctors and medical sectors in the early diagnosis of various diseases.

As a direct consequence of technological improvements, our lives have grown simpler, more accurate, and more reliable. By the time you conclude this essay, you will understand how to simplify the patient care procedure at any medical institution. The Internet of Things employs a broad range of technologies, including sensors, the cloud, wireless technology, and security, to name a few [10]. Paper organization. Section II explains the essential problems and illustrates the objectives of the paper. Section III explains the literature reviews of the previous researchers. Section IV explains the research methodology. Section V explains the Healthcare proposed model (IOMCT). Section VI explains the proposed Blockchain Algorithms. Section VII illustrates the results of the research. And finally, Section VIII clarifies the conclusions and recommendations of this paper.

Fig. 1. Conceptual model of IoT in healthcare [1].

II. PROBLEM DEFINITION AND OBJECTIVE

In the HealthCare era, the patient always feels that he wastes a lot of time to form registration or even if wants just a simple consultation. So, he must move through the whole

*Corresponding Author.

hospital procedure, and waste time in waiting. On the other side, for people who face problems with heart pulse rates, sugar rate or blood pressure continuous monitoring and observation are. They don't have a solution except to go to the doctor and wait till they take only consultation, or they can only send an email or message to the doctor and then wait till he answers. In another situation, people don't need their data to be exposed to all hospitals. As he can see the patient history from before. So, according to that patient cannot own and control or secure his data from exposure. In addition, people who work in sensitive positions, and face some health problems, don't have the luxury to save their information. So, in this paper, we will go through all these problems and propose effective solutions.

III. LITERATURE REVIEW

Jalel Ktari and his coworkers came up with the concept of developing a heterogeneous embedded platform to facilitate the construction of electronic health records (EHRs) with multiple inputs. This platform can collect data from a variety of sensors that are interconnected via the internet of things. Utilizing Ethereum's permissioned network, this method encrypts data not once, but twice, thereby enhancing the security of the data [17]. To complete this task, the PoW consensus technique will be utilized. We decided on this course of action to protect the privacy of our patients. This information must be protected from both unauthorized access and prying eyes [3].

Tian-Fu Lee, et al. proposed a mechanism for preserving medical information that considers the entire process of data from data generation through transmission by wearable devices to mobile devices and then to a medical Center server [4]. In a presentation, Gautam Srivastava et al. discussed both the advantages and practical challenges associated with using blockchain-based security solutions for the Internet of Things-based remote patient monitoring. In addition, it assesses the relative benefits and drawbacks of a variety of cryptographic algorithms that might be useful for Internet of Things deployment. In this study, we provide a paradigm for securely transporting data over networks and storing data in the cloud using low-overhead cryptographic techniques, such as the ARX encryption scheme [5].

Partha Pratim Ray and colleagues [6] suggested the use of an IoBHealth data-flow architecture for storing, retrieving, and managing electronic medical information. IoBHealth combines blockchain technology with the Internet of Things. The purpose of this presentation by K. Azbeg and colleagues is to classify the Internet of Things and blockchain technology applications in the medical industry. Six distinct medical service applications were examined, along with a study of the problems that may occur when trying to use Blockchain technology in IoT-based healthcare systems [7]. In a newly published research, Manal Al-rawashdeh and her colleagues categorized the characteristics that influence IoT adoption as follows: personal considerations, technical considerations, security issues, health concerns, and environmental aspects [8].

The authors undertake a literature study on the issue of healthcare IoT application adoption between 2015 and 2021. The purpose of this study was to compile prior studies on the acceptability and deployment of Internet of Things (IoT)

technologies in smart healthcare. The research painstakingly explored, obtained, evaluated, and synthesized the relevant material for the study [9].

A. Decentralization

We need a decentralized system in order to avoid many-to-one traffic flows, as well as ensuring that the system is both resilient and scalable. It's possible that using a decentralized approach would reduce the amount of time that passes between blocks of information in Blockchain [13]. An overlay scattered network is used in our approach to the problem.

B. Healthcare Providers and Patients

Patients or insurance companies might hire healthcare professionals to carry out diagnostic procedures or to provide therapy initiatives. When they get a network alert, medical practitioners are able to begin treating patients immediately after receiving the notification [13]. Patients have complete authority over the individuals who are granted access to their medical information and are free to revoke consent at any time [5]. This covers the companies that supply their insurance and healthcare services.

C. Smart Contracts

Any agreement that is made via an Internet of Things device has the potential to be converted into a "smart contract" and put into effect when certain criteria are satisfied [18]. Take into consideration the fact that we determined the highest and lowest values of blood pressure for each of our patients. If the smart contract receives a blood pressure measurement from a wearable device that is outside of the normal range, it will send an alarm to the appropriate individual or healthcare professional and save the abnormal data in the cloud. This will allow the provider to see the data in real time. The contemporary world has given rise to a wider variety of potential uses for RFID technology. This technology has seen widespread use for the automation of industrial processes as a direct result of the complicated manufacture of consumer goods such as motor cars, home appliances, and other products (refrigerators and washing machines) [11]. The Vatican Library, which possesses more than two million books, uses a technology called radio frequency identification (RFID) to speed up inventory and book searches, automate book distribution, and assist in the prevention of theft. Over seven hundred of the major libraries in the world have either already accepted this technology or are in the process of adopting it [2, 3].

RFID chips are being embedded into all newly issued passports by a growing number of countries throughout the globe. These travel papers are referred to as biometric e-passports, and they include a chip that has the same information as the printed pages of the passport. The healthcare industry is "establishing a foothold" for this technology [14]. A woman and her baby might be connected at the hospital via the use of an RFID bracelet. In traditional hospitals, they are often used to keep track of patients who need continuing medical attention by following their movements throughout the facility. The unique usage of the idea of a wireless sensor network [4] that is used to monitor and change physical things is shown by connecting the tracker to the heart rate monitor. The connection

between these devices and GPS trackers, mobile phones, social networking platforms, cloud servers, and big data analytics tools is now essential to the functioning of the Internet of Things (IoT) [12].

IV. PROPOSED METHODOLOGY

This research and its methodology, suggest new research methods, newly apply, and interpret the existing methods, also it complements scientific theories, concepts, and models with new data and newly interprets this data, presents new empirical data obtained through the application of the existing and new research methods, and independently collected, processed, and analyzed by the researcher [20].

Methodology of this research contains:

- 1) Data collection.
- 2) Data preparation.
- 3) Data analysis.
- 4) Data processing Costs.
- 5) Data Acquisition.

A. Data Collection

Data should be collected from multiple resources, like public and private sectors hospitals and clinics, most of the data could be collected from the ministry of health.

B. Data Preparation

Data should be classified according to each major and specialty in the health industry, like, Cardiology, Dermatology, Chest, ENT, gastroenterology, Nephrology, Orthopedics, and Ophthalmology. In the end, each patient should have like a folder that contains all his history in every specialty.

C. Data Analysis

It was taken from various perspectives through various technologies: The blockchain is a decentralized, auditable, and reliable ledger for storing and transferring data. It is a database that tracks the activity of the various users it serves in its most fundamental form. Utilizing this decentralized database should not put you in danger. Users are supplied with the option to independently check the chain's validity via distributed data storage and verification. [3] Blockchain technology will help in saving all information for one patient in a block taking its hash function as a reference to another block, to build up a chain of blocks that configure a blockchain. Internet of Thing (IoT), which help in collecting data from cloud sources or databases that have the patient information got from sensors applied in bracelets, watches, and electronic cards. Big Data it's a concept of how to save structured and unstructured data combined from all sources that contain all information needed, through its techniques.

D. Data Processing Costs

Another key challenge that modern healthcare organizations have to overcome is the high cost of gathering and distributing patient data. The vast majority of time is used by sharing the patient's medical history to other facilities. It is both time-consuming and expensive to compile a patient's complete medical history from the several, non-computerized hospital record systems that are available [15]. It is possible

that the administrative expenses generated by present healthcare systems for third parties will be reduced if blockchain technology is used. In addition to this, it enables flexible data access to the patient's medical record. The patient's medical record is compiled and kept up to date using information from a range of sources, such as personal wearables, mobile devices, and patient records. It is possible that blockchain technology may reduce the operational costs of healthcare providers since it would consolidate patient data in a single location.

The process of getting useful data from extensive databases is referred to as information extraction [4]. The strategy is dependent on the manner in which the information is gathered [5]. "Having access to the data is fantastic, but it serves no use if we are unable to turn it into something of value." Because of this, it is the most important component of big data, since it is the area in which the majority of businesses invest their money and resources in order to gain knowledge and make money [16].

E. Data Acquisition

The majority of data-collecting systems take analogue wave patterns and convert them into digital values so that they can be processed more easily. A data collection system is comprised of a variety of components all working together to form the whole. Sensors are devices that collect data from the real world and convert it into a format that computers and other electronic devices can interpret. Signal conditioning circuitry that transforms analogue sensor data into a format that can be successfully digitized. Following conditioning, sensor signals are transmitted to an analogue-to-digital converter, which receives the digitized data. Through data acquisition, we can close the circle of integrating the internet of things with blockchain and big data. The majority of the time, software applications used for data collection are managed by programs written in one of several general-purpose programming languages. [2].

V. HEALTHCARE PROPOSED MODEL IOMCT

Proposed Model Phase 1

A. Internet of Medical Card Thing (IOMCT) Phase 1

The IOMCT model represents the cycle of patient data collection.

Phase one as shown in Fig. 2 talks about two paths for data collection:

When the IoT that is represented in the patient bracelet detect the patient's heart pulse, Sugar Rate, and pressure Rate. Then add this information to the patient Block through the cloud storage. So that it will update the patient history, which will be automatically added to the patient card when uploading the updated information through the cloud storage. Data collection is formed in the hospital when the patient presents the card to the reception desk. It only needs just one tap to check the patient's data.

B. Internet of Medical Card Thing (IOMCT) Phase 2

Phase two as shown in Fig. 3 talks about the rest of entire procedure that represented in validating the patient data in couple of steps.

Fig. 2. IOMCT model Phase 1.

Fig. 3. IOMCT model Phase 2.

First step, with the insurance company whether for hospitals, clinics, or pharmacies and save validations results to the patient history that will be added directly to the patient Block through cloud storage to update the patient Card information.

Second step, when patient visit any of the hospitals, clinics or pharmacies, this visit will be updated in the patient block and added to the patient card so that data will be automatically maintained and updated whenever any new visit happen.

VI. HEALTHCARE PROPOSED BLOCKCHAIN ALGORITHMS

The Tables I and II show the IOMCT model algorithm phase 1 and phase 2 that present the Blockchain creation and the hash creation.

TABLE I. IOMCT ALGORITHM PHASE 1

Algorithm 1: Blockchain Creation

Input: hashlib, json, Time

Output: new blockchain

Procedure:

-Step1: Create essentially chain object. x = essential block. chain
Y = Current transaction z = nodes.

```
X []
x.y = []
x.z = set []
```

-Step2: Create new Block for the created chain in step1.
x. new block (p.hash= 1, proof=100) where
p.hash = previous block hash =
SHA1

-Step3: Generate hash for blocks.

Define hash (block):

```
Block_string = json.dumps (block.
```

```
Sort_key=true). encode ()
```

Where json used for sorting

&exchanging data &

Generate SHA256 value.

```
Return hashlib. sha256
```

```
(block_string).hexdigest().
```

Where hashlib is a module for hashing messages.

-Step4: Create new block in the created blockchain
Define new_block (x, proof, p.hash = Name):

Where

```
Block = {'index' = len(x.chain)+1,
```

```
'timestamp' = time(),
```

```
'transactions': x.y,
```

```
'proof' = proof,
```

```
'p.hash': p.hash or x.hash
```

```
(x [-1]),
```

```
}
x.y = [] x.append
```

```
(block)
```

```
return block
```

where x.y [] for resting the current

list of transaction

-Step5: Create last block

Define last_block (x):

Where last_block (x) return the last block in the

```
chain(x)
```

```
return x [-1]
```

End procedure

TABLE II. IOMCT ALGORITHM PHASE 2

Algorithm 2: Blockchain Creation

Input: hashlib, json, Time, x [essential block.chain], y [current transaction]

Output: add new transactions to blocks & validate their data

Procedure:

-Step1: Define new transactions statement Define N_T (x, sender, recipient, amount):

```
x.y.append({"sender": sender,  
"recipient": recipient, "data": amount,})
```

Return int (x.last_block['index']) +1 Where N_T = new_transaction

-Step2: Define proof of work statement.

Define proof_of_work (x, last_proof): Proof = 0

While x. validate_proof (last_proof, proof) is false:

Proof += 1 Return proof

Where pr is containing 4 zeroes & pr is the previous pr

-Step3: validate proof

Define validate_proof (last_proof, proof): Guess= pr {last_proof} {proof}

.encode()

Guess_hash = hashlib.sha256 (Guess).hexdigest()

Return Guess_hash [:4] == "0000"

Where validate_proof shows if

hash (last_proof, proof) contains 4 zeroes or not?

End procedure

VII. RESULTS

Results in this paper were taken from two stages:

1) Development Stage: that presents code written using the python tool.

2) Interface designed application stage, with the aid of a designed card handles all information about a certain patient that will hold the card: this design is connected with the code forming the results shown below.

- First Stage: Development Stage: The code below will initiate the new blockchain node and create a new globally unique identifier as shown in Fig. 4.

```
app = Flask(__name__)  
  
node_identifier = str(uuid4()).replace('-', '')  
  
blockchain = Blockchain()
```

Fig. 4. Unique identifier.

The blockchain class object definition by initiating:

- New chain array.
- Current transactions array.
- New Node creation.
- New block creation and setting the hash method and proof (success) as shown in Fig. 5.

```
class Blockchain(object):  
    """ Main Blockchain class """  
    def __init__(self):  
        self.chain = []  
        self.current_transactions = []  
        self.nodes = set()  
  
        self.new_block(previous_hash=1, proof=100)
```

Fig. 5. New block creation.

The code below shown in Fig. 6 describes the new block by setting the index, timestamp, current transaction, proof, and previous hash. According to the code above shown in Fig. 5, the previous hash is passed with the value one. However, if it is passed by none the value will be set according to hashing value done in the previous chain block value.

```
def new_block(self, proof, previous_hash=None):  
  
    block = {  
        'index': len(self.chain)+1,  
        'timestamp': time(),  
        'transactions': self.current_transactions,  
        'proof': proof,  
        'previous_hash': previous_hash or self.hash(self.chain[-1]),  
    }
```

Fig. 6. Hashing value.

```
@staticmethod  
def hash(block):  
  
    block_string = json.dumps(block, sort_keys=True).encode()  
    return hashlib.sha256(block_string).hexdigest()
```

Fig. 7. Code value.

The code shown above in Fig. 7 was developed to hash the block using the SHA256 protocol. After setting the block, we will empty the current transaction array. Then, adding the new block to the current node as shown in Fig. 8.

```
self.current_transactions = []  
self.chain.append(block)  
return block
```

Fig. 8. Chain protocol.

The code shown in Fig. 9 and Fig. 10 is for new transaction creation in the blockchain and setting the transaction values. However, before submitting the transaction received, we will check if the required values are passed or not (sender, recipient, and amount).

```
def new_transaction(self, sender, recipient, amount):  
  
self.current_transactions.append({  
    "sender":sender,  
    "recipient":recipient,  
    "data":amount,  
})  
return int(self.last_block['index'])+1
```

Fig. 9. New transaction creation with setting values.

```
@app.route('/transaction/new', methods=['GET'])  
def new_transaction():  
  
    values = request.get_json()  
    required = ['sender', 'recipient', 'amount']  
  
    if not all(k in values for k in required):  
        return 'Missing values.', 400  
  
    index = blockchain.new_transaction(  
        sender = values['sender'],  
        recipient = values['recipient'],  
        amount = values['amount']  
    )  
  
    response = {  
        'message': f'Transaction will be added to the Block {index}',  
    }  
    return jsonify(response), 200
```

Fig. 10. Registration nodes.

Registering new nodes by getting the JSON object and then searching for node values as shown in Fig. 11. The code checks if there are no nodes. So, it will give an error. Otherwise, iterating on nodes and adding them to the current block.

```
@app.route('/nodes/register', methods=['POST'])  
def register_nodes():  
    values = request.get_json()  
  
    print('values',values)  
    nodes = values.get('nodes')  
    if nodes is None:  
        return "Error: Please supply a valid list of nodes", 400  
  
    for node in nodes: blockchain.register_node(node)  
  
    response = {  
        'message': "New nodes have been added",  
        'all_nodes': list(blockchain.nodes),  
    }  
  
    return jsonify(response), 201
```

Fig. 11. New nodes.

The new node addition will be done by calling the below code shown in Fig. 12.

```
def register_node(self, address):  
  
    parsed_url = urlparse(address)  
    self.nodes.add(parsed_url.netloc)
```

Fig. 12. Additional new nodes.

Fig. 13 shows how to find the whole chain in the current blockchain by passing the chain value along with the length of the chain.

```
@app.route('/chain', methods=['GET'])  
def full_chain():  
    response = {  
        'chain': blockchain.chain,  
        'length': len(blockchain.chain),  
    }  
    return jsonify(response), 200
```

Fig. 13. Whole chain value.

Now in Fig. 14 shown below, it finds the latest block in the chain.

```
@property  
def last_block(self):  
  
    return self.chain[-1]
```

Fig. 14. Latest block.

The below code as shown in Fig. 15 validates if the proof is like the previous proof containing the same structure with leading four zeros in both.

```
def proof_of_work(self, last_proof):  
  
    proof = 0  
    while self.validate_proof(last_proof, proof) is False:  
        proof += 1  
    return proof
```

Fig. 15. Mining block.

Before mining the block, some inputs need to be validated like the below code shown in Fig. 16 to validate the proof by encoding the last proof values using SHA256 protocol and then validating if the proof does contain four leading zeroes or not.

```
@staticmethod  
def validate_proof(last_proof, proof):  
  
    guess = f'{last_proof}{proof}'.encode()  
    guess_hash = hashlib.sha256(guess).hexdigest()  
    return guess_hash[:4] == "0000"
```

Fig. 16. Input validation.

After submitting the transaction, the next step is mining as shown in Fig. 17. So, the code below will be used to mine the newly submitted block through the following:

- 1) Running the proof of work.
 - 2) Submitting new transaction.
 - 3) Rewarding the mining server for finding the proof by one coin.
 - 4) Hashing the block.
 - 5) Adding the new block.
- Second Stage: Interface designed application stage

As mentioned in this paper, the data of health records will be distributed and secured through the blockchain, however, we need to show the data using different channels like mobile, tablets or other devices that will be used by medical authorities or doctors. We believe that this data should be managed dynamically and completely by the patient to show only the piece of information required. This will be achieved through a health record card that will be owned by the patient and s/he can control this data through a health record administration app.

The health record will be shown to the doctors, and authorities by tapping the card on an NFC reader that could be mobile, tablet or handheld that has NFC embedded to show the health record as shown in Fig. 18.

The health record will be shown on the device according to a piece of information selected through the medical record administration app as shown in Fig. 19.

```
@app.route('/mine', methods=['GET'])  
def mine():  
  
    last_block = blockchain.last_block  
    last_proof = last_block['proof']  
    proof = blockchain.proof_of_work(last_proof)  
  
    blockchain.new_transaction(  
        sender=0,  
        recipient=node_identifier,  
        amount=1,  
    )  
  
    previous_hash = blockchain.hash(last_block)  
    block = blockchain.new_block(proof, previous_hash)  
  
    response = {  
        'message': "Forged new block.",  
        'index': block['index'],  
        'transactions': block['transactions'],  
        'proof': block['proof'],  
        'previous_hash': block['previous_hash'],  
    }  
    return jsonify(response, 200)
```

Fig. 17. Mining step.

Fig. 18. Patients' health card.

Fig. 19. Patient record.

Fig. 20. Segmentation.

The patient can edit his medical profile to select which information is to be shown once the card tapped on the device (ex: ENT) as shown in Fig. 20.

Fig. 21. Profile.

Now, the information that will be shown on the card is what is selected through the administration app. So, the ENT medical record information will be shown, and authorities/doctors can click on it to show the data as shown in Fig. 21.

The document shown in the Fig. 22 mentioned above is the last medication taken by the patient and now the doctor can take a decision accordingly. All this information and documents are synced through the patient block in the ministry of health block chain with all security measures taken benefiting from encryption and distributing data across all servers.

Fig. 22. Documentation.

VIII. CONCLUSIONS AND RECOMMENDATIONS

Even though blockchain is still thought of as a concept that is in its infancy, a significant amount of study has been carried out on the topic. There are still research holes that need to be filled, even though there has been some development in our understanding of how these things might be used in Hyperledger. The course of this investigation led to the discovery of a potential loophole in the data security that is in place between the participants. The vast majority of the work done in the field thus far has been devoted to investigating a wide variety of subjects, including the transmission of sensitive data, the veracity of distributed systems, various ideas and types of blockchains, blockchain capabilities, and distributed ledger technology.

In addition to above loophole, the policies that should be implemented should be integrated pragmatically to support data compliance with code of ethics in using the online data. A unified health policy based on multidisciplinary partnership is critical to safeguard online data and promote public trust.

During this long journey, there's a lot of other pillars that will need to be studied like the migration and integration between medical authorities in addition to the cost of ownership and return of investment.

Relying on this paper, a real case is under study now in Abu Dhabi for facilitating to the UAE citizens who are getting some treatments abroad and how they can manage their health record to show the piece of information required from the authorities abroad to avoid sharing the medical history over emails with doctors or through physical documents.

The approach proposed through this paper is serious trail that approaching to connect all stakeholders in one platform taking into consideration the data security and integrity.

Adding to this, there are some benefits will be achieved

- Better healthcare service quality.
- Better patient experience.
- Holistic connected care
- Unified patient medical record.
- Increasing the efficiency of services provided.

ACKNOWLEDGMENT

The research reported in this paper has been created through combined efforts. Thanks, are due to Dr Hatem Abdelkader and Kardania [21] team for their valuable comments and feedback and contribution on the early drafts and ideas for assisting with preliminary queries on the Trove database used to implement the practical part shown.

Abstract—The subject of oral healthcare is a crucial research field with significant technological development. This research examines the field of oral health care known as dentistry, a branch of medicine concerned with the anatomy, development, and disorders of the teeth. Good oral health is essential for speaking, smiling, testing, touching, digesting food, swallowing, and many other aspects, such as expressing a variety of emotions through facial expressions. Comfort in doing all these activities contributes to a person's self-confidence. For diagnosing multiple oral diseases at a time panoramic radiograph is used. Oral healthcare experts are important to appropriately detect and classify disorders. This automated approach was developed to eliminate the overhead of experts and the time required for diagnosis. This research is based on a self-created dataset of 500 images representing six distinct diseases in 46 possible combinations. Tooth wear, periapical, periodontitis, tooth decay, missing tooth, and impacted tooth are all examples of diseases. This system is developed using the concept of transfer learning with the use of a different pre-trained network such as “ResNet50V2”, “ResNet101V2”, “MobileNetV3Large”, “MobileNetV3Small”, “MobileNet”, “EfficientNetB0”, “EfficientNetB1”, and “EfficientNetB2” with XGBoost and to get the final prediction The images in the dataset were divided into 80% training and 20% images for testing. To assess the performance of this system, various measuring metrics are used. Experiments revealed that the proposed model detected Tooth wear, periapical, periodontitis, tooth decay, missing tooth, and impacted tooth with an accuracy of 91.8%, 92.2%, 92.4%, 93.2%, 91.6%, and 90.8%, respectively.

Keywords—Panoramic radiograph; dentistry; deep learning; ensemble classifier; multi-disease classification and prediction; oral diseases; weighted ensemble module; XGBoost

I. INTRODUCTION

According to the WHO survey, the population of seniors aged 65 and more has surpassed 150 million, and the population of patients with chronic conditions has surpassed 400 million. Due to the increase in periodontal diseases in the 35-44 age group, the percentage of infection is higher in the 65-74 age group. Additionally, proper oral health is essential for maintaining a healthy heart and digestive system. Aging and mouth problems have a long history of interdependence; a lack of attention to oral health might predispose older individuals to other health conditions, such as malnutrition, heart-related issues, Digestion related problems, etc. [2] This has increased the demand for automated medical and healthcare solutions that are secure and of superior quality.

Which must be useful for the early detection and classification of the present disorders of an individual. To perform diagnosis of present tooth-related diseases in the mouth, Currently, dental radiography plays a crucial role in diagnosing the condition of oral health. Due to its accurate confirmation of clinical findings, dental panoramic radiography (DPR) images are attracting a rising amount of attention in the diagnostic process. Typically, three types of dental X-ray radiographs are used for diagnosis in dental imaging. Dental radiographs consist of bitewing, periapical, and panoramic types. Bitewing focuses mostly on the coronal half of teeth, periapical encompasses the apical region of teeth, and panoramic X-ray scans consider the entire upper and lower jaw, including teeth and supporting bones. For disease localization diagnosis, periapical radiography is suggested. But when the disease is widespread, panoramic X-rays are used to obtain a thorough perspective for diagnosis and therapy planning. They are easily standardizable and reproducible.

Fig. 1. Different types of dental radiography

Due to the unspecified quality of x-ray images, varying tooth sizes, and other factors, numerous challenges are associated with automatically separating teeth from dental radiograph images. Fig. 1 depicts the three main types of x-ray images of teeth: bitewing, periapical, and panoramic teeth. The dentist manually clarifies radiographs by identifying each tooth and the corresponding issue. But if the x-ray radiography is unclear, it can lead to misinterpretation during analysis [1]. Conventionally, a dentist uses dental radiographs and a clinical evaluation of the patient to make a diagnosis, based on the available infrastructure and expertise. These numerous methods encourage researchers to use and build new machine learning, deep learning, and dental image comprehension techniques more effectively [2][3]. This approach will help to classify multiple oral diseases automatically.

Image processing is currently the most prominent field in digital healthcare applications; it is also utilized well in the medical environment to analyze illness more precisely [4]. As

a result of these developments, medical image processing has become prevalent in both medical and health sectors in analyzing diseases with precise sensitivity and measurement [5]. Similarly, medical image processing is applied to dental information to identify and classify disease types and severity [6]. To identify dental problems, all factors must be considered [7]; this is the predominant trend in the detection of dental diseases. The kind and severity of the condition differed between patients [8] due to inconsistencies in the data. Several mathematical models have been created to predict, identify, assess, and monitor the early oral health of teeth [9]. However, the issues are not addressed because of the complexity of the images [10]. Furthermore, dental images differ depending on the patient's genes and body condition. Predicting dental disease is thus a difficult task. Furthermore, a mathematical model has carried out the different cavity analysis processes practically. The cavity severity analysis procedure has varied depending on the patient's body and tooth conditions [11]. Finally, the current tooth diseases and their causes were identified. Nonetheless, those model features are insufficient for real-time data. Because actual time tooth X-ray data contains whiter spaces, and some tooth X-rays have tooth clips [12] disease identification becomes more difficult. Furthermore, those types of images have required more additional features to identify the affected tooth [13]. As a result, those approaches failed to identify the diseased tooth. Furthermore, a standard filtering process was used to remove the noisy features in the trained data, which increased the cost of the resource [29]. Furthermore, when the dataset images were complex, the filtering results were poor. In other domain concepts, deep learning is used to efficiently estimate remote heart rates and to classify breast lesions in mammography using a conventional neural network, which helped us understand the running complexity of different machine intelligence techniques [14]. These issues prompted the current study to develop optimized deep networks with filtering parameters to obtain more precise disease classification results [17].

The current article has descended into a new solution for maximizing disease classification by utilizing the different pre-trained deep learning models. The proposed study has a step-down in the multi-disease classification model, which is defined as multiple parameters in the proposed framework being upgraded to classify multi-disease features. The following section goes over the specifics and importance of detecting tooth wear, tooth decay(cavity), impacted tooth, missing tooth, periapical, and periodontitis at an early stage. The image of a patient suffering from tooth wear is shown in Fig. 2.

A. The Necessity of Detecting Tooth Wear in Dentistry

Teeth have specific anatomy consisting of several cusps and fissures to serve the function of chewing food like a mortar and pestle where the approximating cusps work as a pestle and fissures work as mortar crushing the food coming in between. If these anatomical landmarks are worn-out due to wear, this crushing mechanism gets disturbed and food slips from between the teeth causing a decrease in chewing efficiency ultimately leading to nutritional deficiency and decreased quality of life. Hence teeth wear if diagnosed early can be

treated conservatively and a patient can be counseled to prevent further damage. Dental wear has several types which include dental attrition, erosion, abrasion, and abreaction. Dental attrition, abrasion, and erosion are commonly found in the Indian population. All these have specific patterns and causative factors following which they can be diagnosed.

Fig. 2. Tooth wear (erosive)

All these wear patterns can cause irreparable harm to a tooth's structure without creating any noticeable pain in the early stages. When wear and tear reached a severe stage, treatment can be quite costly for the patient. It is possible to avoid getting them by getting checked for them early and making some changes to one's way of living. [15]

B. The Necessity of Detecting Periodontitis

The following section describes the details of gingivitis, periodontitis, and the process of diagnosing these diseases using radiographs and clinical examination. Gingivitis is an inflammatory disease limited to gums adjoining the teeth in which the primary signs are redness and bleeding from the gums along with their swelling. Whereas periodontitis is when the inflammation of the gums extends to the adjoining tooth-supporting bone it is derived as periodontitis. Primary signs of periodontitis are loss of tooth-supporting bone and tooth mobility. Methods are different to diagnose periodontitis and Gingivitis as gingivitis can be diagnosed with the help of clinical examination, observing for the signs and symptoms of the disease. Like red, swollen, and bleeding gums. Periodontitis can be diagnosed with the help of clinical and radiographic examinations. Clinically Doctors can measure the loss of supporting bone with the help of a periodontal probe measuring the sulcus depth, and radio graphically the amount of horizontal and vertical bone loss can be identified to gauge the severity and prognosis of periodontitis. The reason for not considering Gingivitis in this implementation is as it is an early stage that can be diagnosed only on clinical examination and here in our research, we had considered OPGs as a sturdy base which is the most preferred diagnostic tool to diagnose periodontitis. By considering all mentioned parameters early diagnosis is needed to prevent the further loss of teeth-supporting tissues and plan for the repair. Fig. 3 represents an image with periapical and periodontitis.

Fig. 3. Periodontitis and periapical

C. The Necessity of Detecting Tooth Caries (Dental Cavity)

Dental caries is a disease that can be diagnosed easily on clinical and radiographic examination. Treatment of decayed teeth depends upon the extent of decay which can be viewed only radiographically. Orthopantomograms are used to diagnose caries between the teeth and over the teeth and Intraoral periapical radiographs and bitewing radiographs are the specific radiographs to detect the extent of the decay. A representation of a tooth with a cavity is shown in Fig. 4.

Fig. 4. Tooth caries/dental cavity

D. The Necessity of Detecting Periapical

periapical infections can only be diagnosed radiographically as clinical symptoms often appear in the delayed stage. In OPG the extent and the size of the periapical lesion can be exactly gauged. It is shown in Fig. 2 and Fig. 7.

E. The Necessity of Identification of Missing Teeth

Often one or more missing teeth do make complex changes in patients' quality of life. One missing tooth can lead to decay and periodontal disease to seven teeth as the teeth approximating the edentulous space and opposing arch teeth drift from their natural definite position. These all changes can be diagnosed only through an OPG. Fig. 5 shows missing teeth. it is observed that two teeth are missing and the last is affected by decay.

Fig. 5. Missing tooth

F. The Necessity of Identification of Impacted Tooth

Impacted wisdom teeth or any other tooth can't be seen clinically. OPG gives the exact two-dimensional view of the impacted tooth. A representation of an Impacted tooth is shown in Fig. 6

Fig. 6. Impacted tooth

Fig. 7. Wear, decay periapical, and impact

This research work is conceived as a collaborative effort between technical expertise and a dentistry stream in an area of significant interest to the medical community. Literature review reveals that extensive research on tooth extraction or diagnostic purposes used in cybercrimes such as estimation of age, identification of a person based on tooth anatomy, etc, but regrettably, there has been very little work combining the oral health care and engineering fields for continuous engineering and clinical problem-solving. This research began with an emphasis on the various stages of oral illnesses [16]. Such as tooth wear, periapical, periodontitis, tooth decay, tooth loss, and tooth fractures, impacted tooth.

The remaining sections are organized as follows. Section II offers a concise assessment of pertinent literature. It discusses the current state of the art in the use of image processing, machine learning, and deep learning techniques in the domain of dentistry. Understanding different types of radiographs and their importance in evaluating models is discussed using various methods and networks. Section III describes the data collection, radiograph selection, and disease identification processes. The importance of various diseases that can be identified using panoramic radiographs has already been discussed in the introduction section. This section focuses on dataset labeling as well as expert validation of labels. Section IV elaborates on the concept of transfer learning with XGBoost and ensemble learning concerning medical image processing. The proposed methodology is illustrated in Section V, which is followed by the results and discussion and future scope sections.

II. RELATED WORKS

A comparative analysis of the deep learning model for dental segmentation in panoramic radiographs is reported in [18]. The comparison is made between U-Net, DCU-Net, Double U-Net, and NanoNet. On the 1500-image dataset provided by Silva and Olivia. There is also a teeth mask available for this. Their system is designed to identify 32 teeth, fillings, braces, and dental implants. Data enhancement is achieved through random rotation and horizontal inversion. Using a dataset with data augmentation and segmentation without data augmentation based on the segmentation model, the experiment results are shown. The outcome is then compared to the current state of the art.

In this biomedical study [19], the U-Net approach to apical lesion segmentation on panoramic radiographs is discussed. The objective of this study was to extract apical lesions from 470 dental panoramic radiographs. This dataset included 380 images for training, 43 for validation, and 47 for testing. 1140 images were generated after augmentation was applied at the second stage of implementation. For augmentation, horizontal

and vertical flips are used. Cropping (pre-processing) is used after augmentation to divide images into four parts: upper right, upper left, lower right, and lower left with size=1000x530. They then multiplied 1140 by 4 for the training group. This dataset is not available to the public.

For apical lesion segmentation from panoramic radiographs, [20] adopts a deep learning technique. There were a total of 1691 images utilized for segmentation. For the training set, all radiographs were manually tagged in red using a polygon labeling tool to construct lesions' contours. The name of the software is "deep stack." The image's original resolution of 1976x976 was reduced to 960x480. Various augmentation techniques, including flip, blur, shift, scale, rotation, sharpness, emboss, contrast, brightness, grid distortion, and elastic transform, are utilized to increase the dataset via online augmentation. Utilizing a pre-trained U-Net CNN for pre-processing and training.

In [21]: Work on a multimodal panoramic x-ray dataset for diagnostic system benchmarking was presented. There are a total of one thousand photos about the labeling of anomalies and teeth. This study was carried out on five levels: anatomical location, peripheral characteristics, radiodensity, surrounding structure effects, and anomaly category. Using eye tracking and a think-aloud methodology, this is the first-time radiologist skill has been captured. This study includes a publicly accessible dataset as well as benchmark performance analyses for a variety of cutting-edge devices. In addition, picture enhancement and image segmentation are carried out. The maxillomandibular region of interest is delineated using x-ray images, gaze maps, and multimodal audio text files. A thousand radiographs and a ground truth mask make up the dataset. 15% is utilized for validation, whereas 85% is used for training. Adam was trained on GPUs with 32 GB of RAM that was NVIDIA Tesla V100 devices. However, in terms of image quality, CLAHE outperforms well with AME Score=24.32 and Log AME=0.3702. Ground truth images were used for segmentation, and the results were compared using UNET, UNET++, PSPNet, DeepLabV3, and DeepLabV3+. VGG19, ResNet18, and ResNet 50 were used to train each of the given networks. The module learning rate is 1×10^{-3} , the weight decay is 1×10^{-4} , the epoch is 150, and the batch size is 16. Pixel accuracy, intersection over union, and dice coefficient are all evaluated. To achieve the desired result, CNN for periodontal bone loss and Squeeze Net for implant fixtures were used. To detect and classify periodontal bone loss, a hybrid framework with Mask RCNN and ResNet101 was used. For intraoral radiographs covering caries, a back propagation neural network is used.

Work on dental caries is being conducted by [c]concepts.]s (cavity). Utilizing a multi-input deep convolutional neural network ensemble known as MI DCNNE, they were able to obtain accurate results and overcome negative perceptions of panoramic radiography. This system is based on computer-based intelligent vision systems supported by techniques for machine learning and image processing. This new approach accepts both raw periapical images and an improved version of them as inputs. In total, 340 photos were considered for this study. The model has a 99.13% accuracy rate when diagnosing dental caries from periapical pictures.

The primary goal of this work [25] is to extract the area of interest (ROI). Because of background noise, the original image may contain useless information. We occasionally come across images that are of poor quality. Because of this, separation is critical. U-Net was used in three phases to accomplish this: one feature encoder, corresponding decoder, and multipath feature extractor.

The author of [26] proposed an automatic teeth recognition model based on residual network-based faster R-CNN techniques. This model is implemented in two stages. The results obtained in step one, i.e., using R-CNN, are refined further using candidate optimization techniques. These improvements improve the results by about 1%. Ten-fold cross-validation is used in this system to test the model's feasibility and robustness. This model is used to describe the various tooth categories in a panoramic radiograph.

The implementation in [27] is based on the use of u-net architecture to perform panoramic radiograph segmentation. They used CNN to achieve accurate panorama image segmentation. With a 94% accuracy and a 94% dice score. The performance of the u-net is compared with various segmentation techniques in this work. This fuzzy c-means (FCM) is developed using a hybrid of FCM and a neutrophilic approach to segment the jaw and lesion present in the jaw using a panoramic radiogram. This paper investigates the comparison of global thresholding, fuzzy c-means, watershed, canny edge detection algorithms, and the U-NET model. When compared to the other techniques, n-net performed the best. Ivison lab provided the dataset for this study.

In [28], researchers offered an innovative approach to segmenting and classifying data. They have covered 15 various disorders including healthy teeth, missing teeth, dental restoration implants, fixed prostheses, mobile prostheses, etc. To depict all 15 diseases, a total of 2,000 images are made. All these images were taken at separate dental clinics. A convolutional neural network (CNN) was trained to perform semantic segmentation on images from the dataset, and many techniques were employed to enhance the annotated data. Images are segmented and then binarized with multiple thresholds. The detection of teeth is a two-stage algorithmic process. When discrepancies are uncovered during semantic segmentation, refinement techniques are employed to rectify the situation. In this study, the Nobel approach to teeth detection and dental problem classification using deep learning and image processing was introduced.

The paper [22] compares ten different segmentation methods for use with dental imaging. The offered solutions were evaluated and classified using five different metrics: accuracy, specificity, precision, recall, and F1-score. Because of the shattered bones in the buccal cavity, not one of the ten segmentation methods tried was successful in isolating the teeth.

With the help of a mask region-based convolution neural network, the authors of [23] suggested a method for instance segmentation of teeth in panoramic photos. In the wake of Resnet-101-driven feature extraction, a feature pyramid network (FPN) is built with predetermined anchors and extracted regions of interest.

Each region's proposal network consists of the FPN and its anchors (RPN). The regions of interest are then repositioned so that they are all the same size. Additionally, the bounding box coordinates are used to classify each feature as either a tooth or a background and to pinpoint its exact location. Finally, a bounding box is formed around the tooth once it has been segmented.

DeNTNet, described in [24], is a deep neural transfer network trained to identify panoramic dental radiographic evidence of periodontal bone loss (PBL). During detection, several convolutional neural networks are trained. A segmentation network is then trained to extract teeth from the ROI, and a second network is trained to predict areas of periodontal bone loss. Using the encoder portion of the lesion

segmentation network as a pre-trained model, a classification network is constructed to predict the presence of PBL in each tooth.

Table I provides a complete overview of the various datasets available, the work done in dental image processing, and the disorders linked with it. It has been observed that work is being done in various disciplines of dentistry employing artificial intelligence techniques. To begin, a private dataset is produced and not made public. Another observation is that most systems are designed to segment teeth. Furthermore, the minimum one and maximum four diseases covered for classification and detection are one. One method is used, in which 14 diseases are investigated, but just the highlighting of diseases is done, rather than classification or detection.

TABLE I. ANALYSIS OF AN AVAILABLE DATASET AND METHODOLOGY USED

Papers	Variable detected	Total Images	Publicly available	Labeled Teeth	Labeled abnormalities	Methodology Used
[36]	Teeth	100	No	Yes	No	CNN
[37]	Teeth	100	No	Yes	No	CNN
[38]	Teeth	1500	Yes	Yes	No	Mask R-CNN
[39]	Teeth	1352	No	Yes	No	CNN
[40]	Endodontic	85	No	No	Yes	CNN

[43]	Teeth	1000	No	Yes	No	Deep Learning and Image Processing Techniques
Own Dataset	Teeth	500	No	No	Yes	Transfer Learning and XGBoost

III. DATASET DESCRIPTION

Researching any specific domain data availability is the primary step, but in the field of dental informatics dataset availability is a major concern. After analyzing all the related work in Dental Image Processing (DIP), we discovered that obtaining a suitable dataset for the early stages of research is challenging. As a result, we collaborated with many dental healthcare sections to acquire data. Rather than waiting for new patients for each ailment, we chose to screen panoramic dental X-rays from electronic medical records to collect data efficiently. There is no ethical issue because these images do not contain any personally identifiable information. The dataset consists of images and a questionnaire, which was supplementary at the initial level of research. Collecting symptoms and images for every patient is a time-consuming task so we focused on a collection of radiographs. Principally there are many types of radiographs available in dental radiography, such as Bitewing X-ray, Periapical X-ray, Occlusion X-ray, Panoramic X-ray, Cephalometric Projection, and Cone Beam X-ray. Among these categories, Panoramic OPG (Orthopantomogram) is considered as is two-dimensional radiograph that covers maximum all diseases with complete coverage. Dental radiographic images in OPG format were collected.

A. Panoramic (OPG) X-Ray and its Benefits

The maxillary and mandibular teeth, as well as the surrounding periodontium and certain anatomical landmarks like the maxillary sinus and the temporomandibular joints, are all visible on an OPG, a two-dimensional radiograph. Oral disorders such as periapical abscess, cysts, osteitis, and various tumors and cysts of mandibular and maxillary origin can be diagnosed using OPG X-ray. OPG is useful for determining how much bone has been lost due to periodontal disease and how severe it is. OPG X-ray is useful for diagnosing a wide variety of dental conditions, including cavities, root fractures, and periodontal inflammation. OPG X-rays can help identify and evaluate dental cusp fracture and enamel deterioration, but their two-dimensional nature has its limitations.

The data was collected from Government Dental College and several private dental clinics and laboratories in Nagpur and cities across India. Here image collection work is focused on the wear of the tooth to find erosion, attrition, and abrasion of the tooth and other oral diseases, including impacted tooth, periapical lesion, fractured tooth, missing teeth, etc.,

B. Process of Collecting, Preparing and Labeling the Data

This section describes the process of collecting, preparing, and labeling the dataset. The main contribution while

collecting images and preparing the dataset are expressed with the help of the diagram given below:

- a) From 2019 to 2021, we collected approximately 2,000 OPG radiographs from multiple sources.
- b) All images were then checked for contrast and illumination quality.
- c) Images of poor quality and nonrelevant, such as images with prostheses, multiple caps, braces, etc were removed from the dataset.
- d) Diseases that can be seen through OPG are identified and discussed with clinicians.
- e) OPG radiographs can be used to diagnose diseases such as caries, periodontitis, periapical infection, impacted teeth, tooth wear, bone fracture, missing teeth, and anatomy of the maxillary sinus and temporomandibular joint.
- f) Following disease identification, images are labeled with the assistance of various dental experts (such as Oral and Maxillofacial Radiologists, Prosthodontists, Oral and Maxillofacial Surgeons, Periodontics, and endodontists.).
- g) Image labeling is done in two ways: radiograph with multiple diseases and radiograph with a single disease.
- h) After the image sorting process, it is discovered that the approximate probability of receiving a relevant radiograph is 50/500. Finally, we can filter 500 useful radiographs from available images.
- i) Before developing any module, various pre-processing steps are performed to create the extension of the data set, In this automatic cropping of the image is done to extract the relevant portion by using an automatic cropping algorithm.
- j) Our dataset is cross-validated and tested with the help of three different domain experts to make it more consistent, reliable, authentic, and useful.
- k) The final label matrix is generated for different six diseases if the disease is present in that image so marked as 1 otherwise 0 which is shown in Table II: Labelled dataset. For example, in image id 92 wear, decay, missing, and impacted tooth diseases are present.

TABLE II. SAMPLE LABELLED DATASET

Image Id	Wear	Decay	Peri-Apical	Periodontitis	Missing	Impacted
1	0	1	0	0	0	0
92	1	1	0	0	1	1
104	1	0	0	0	0	1
238	1	1	0	0	1	0
347	1	1	1	0	0	0
457	1	0	1	1	0	0

To check the validity and authentication of dataset creation complete supplementary material is available. The panoramic dental images were obtained from a variety of sources, including dental laboratories. The image properties due to

different acquisition systems vary in terms of contrast and brightness. The pre-processing challenge was to adjust the contrast and illumination levels of all the collected images so that subsequent stages produced the same set of features corresponding to each class or group. We gathered images that were prone to six major issues: dental decay, dental wear, periapical, periodontitis, missing teeth, impacts, and a combination of all six diseases. An experienced medical practitioner in the respective field. While creating the LABEL matrix great care was taken to avoid any false labeling in the LABEL matrix. Images with low contrast and illumination were discarded after being manually sorted one by one. Duplicated images were identified using image comparison and separate codes. Finally, 500 images were taken for this research project, while the remaining unclear images were discarded. Fig. 8 shows the analysis of the total number of images available in the dataset.

Fig. 8. Analysis of images available in the dataset

IV. TRANSFER LEARNING, XGBOOST, AND ENSEMBLE APPROACH

A. Transfer Learning

Deep feature extraction (DFE) and Transfer learning (TL) are two of the most effective alternatives to employing a small number of images as training samples. When a small sample size of images is present. TL refers to the process of applying previously taught models to unexpected challenges. TL is not a distinct classification of Machine learning algorithms; rather, it is a technique that can be used to create a new Machine learning model. The model will be able to use the knowledge and skills acquired from earlier training in new scenarios. In a manner like the preceding task, data will need to be organized based on the type of data. A further application of TL is the extraction of deep feature data.

Rather than manually modifying the activation layers of the CNN, it is possible to extract feature vectors by utilizing pre-trained CNN models. The deeper layers, which are activated by the activation of the lower-level layers, include the picture classification-critical higher-level features.

Transfer Learning is a technique in which we reuse a previously trained model as the foundation for a new model on a new challenge. In this case, a model trained on one task is repurposed for another. Transfer learning tries to improve target learners' performance on the target domain by

transferring knowledge from distinct but related source domains. ResNet50V2, ResNet101V2, 'MobileNetV3Large', 'MobileNetV3Small', 'MobileNet', 'EfficientNetB0', 'EfficientNetB1', and 'EfficientNetB2' are examples of pre-trained networks. [33].

ResNet50V2 [34] is a changed version of ResNet50. It does better on the ImageNet dataset than ResNet50 and ResNet101. ResNet-101 is a 101-layer convolutional neural network.

MobileNetV3 [35] is a convolutional neural network that is tuned to mobile phone CPUs using a combination of hardware-aware network architecture search (NAS) and the NetAdapt algorithm. It was then improved by making new architectural advances.

EfficientNet-B0 is a convolutional neural network that has been trained on more than a million images from the ImageNet database [30]. The network can divide images into 1000 different kinds of objects, like a keyboard, mouse, pencil, and many animals.

B. XGBoost

Extreme Gradient Boosting, which is what XGBoost stands for, is a distributed gradient-boosted decision tree (GBDT) machine learning library that can be used on a large scale. It is the best machine learning library for regression, classification, and ranking problems, and it has parallel tree boosting. It's like Random Forest in that it builds a group of decision trees, but instead of training the models at the same time, XGBoost trains them one at a time. Each new decision tree learns from the mistakes made by the one before it. Boosting is the process of training models one after the other. A gradient in XGBoost stands for a type of boosting that uses weak learners. Weak learners are simple models that only do better than random chance. The algorithm starts with a weak learner at the

beginning. Each new model tries to fix the mistakes that the previous decision tree made. This keeps happening until there are no more ways to make the model better. The result is a strong learner model. [31]

C. Ensemble Modeling

Ensemble modeling is a way to predict what will happen based on several different base models. The goal of using a group of models is to reduce the prediction's generalization error. When the ensemble approach is used, the prediction error goes down if the base models are different and can be used on their own. The method tries to figure out what will happen by asking a variety of individuals. Even though the ensemble model is made up of several base models, it works like a single model. [32]

D. Weighted Average or Weighted Sum Ensemble

Weighted average or weighted sum ensemble is a type of machine learning that uses a group of models to make a prediction. The contribution of each model is weighted according to how good it is. The voting ensemble has something to do with the weighted average ensemble. In this method, we didn't tune it; instead, we used the weights that were already there. In other words, a weight tells how much the input affects the output. Biases, which are always the same, are an extra input for the next layer that will always be 1[33][34].

V. PROPOSED METHODOLOGY

We have created a database of 500 images of panoramic radiographs which are explained in section III. Dataset is divided into a training set and a testing set. The training set goes to eight different pre-trained models.

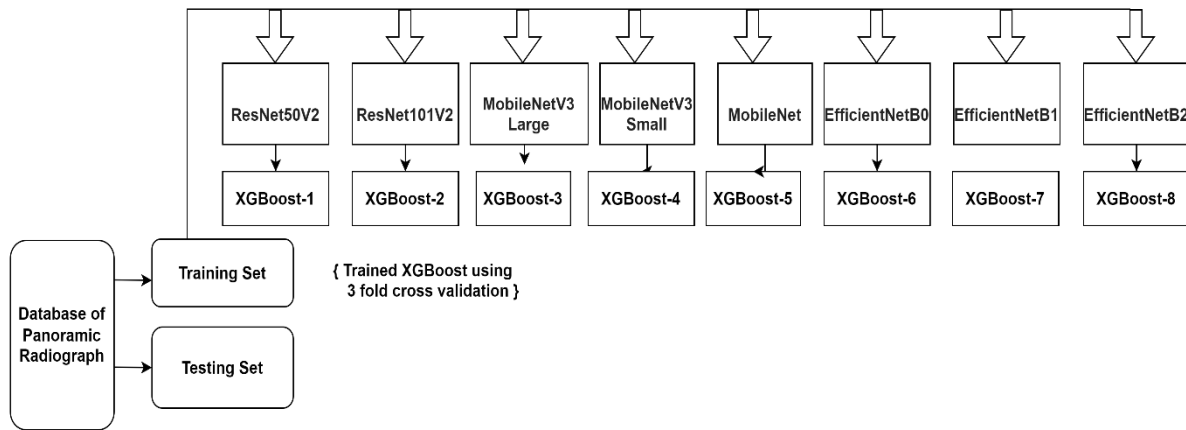

Fig. 9. Proposed methodology (training phase)

Different pre-trained models used for this phase are 'ResNet50V2', 'ResNet101V2', 'MobileNetV3Large', 'MobileNetV3Small', 'MobileNet', 'EfficientNetB0', 'EfficientNetB1', and 'EfficientNetB2'. Out of 500 samples 80% samples used for training. The detailed process of the training and evaluation phase is given in Fig. 9 and Fig. 10. While training we used 3-fold cross-validation. Cross-validation is a technique for testing models that involves

training them on distinct subsets of the available input data and then testing them on the other. Dataset D is divided into three identically sized subsets. The process of fitting and evaluating the model is done three times, and each time a different subset is used as a training sample. At last, in the testing phase given in Fig. 10, we get eight tuned XGBoost. pre-trained networks are used to extract the features and then extracted features are given as input to the XGBoost model for training.

In comparison to other gradient-boosting approaches, XGBoost is nearly ten times faster and has a strong predictive power. Additionally, it contains a range of regularizations that minimize overfitting and enhance overall performance. These eight trained XGBoost will generate eight different classifier

prediction outputs. To get the final prediction weighted ensemble module which is an extension of a model averaging ensemble where the contribution of each member to the final prediction is weighted by the performance of the model.

Fig. 10. Proposed methodology (evaluation phase)

VI. RESULTS AND DISCUSSION

The developed methodology employing transfer learning is processed using Python; the predicted model's success rate is evaluated utilizing existing mechanisms in terms of accuracy, sensitivity, F-measure, precision, and recall. In this approach, 500 X-ray dental images are utilized by considering 80% for training and 20% for testing. The proposed system can classify multiple diseases which cover six different categories with 46 possible combinations. the dataset covers all types of images like one image with one disease and one image with multiple diseases. For example, this system can identify images where only wear or decay is present, apart from this it is also able to identify and classify images where different diseases are present such as wear, and decay as shown in image id.347. Thus, to prove the sustainability of the proposed work ablation study is performed which is expressed in Tables III, IV, V, and VI by considering different 8 pre-trained networks. Table III shows the performance of the model by considering seven different networks with 91% accuracy. Similarly, Table IV shows the performance of the classification of six different diseases by considering six different networks with 90% accuracy on average.

A. Precision

Precision is the proportion of precise teeth affected region computed using Eqn. (1).

$$P = \frac{T_p}{T_p + F_p} \tag{1}$$

Fig. 11 shows the evaluation of precision for different diseases. it is observed that the precision of wear, decay, periapical, periodontitis, missing tooth, and impacted tooth is 79%, 85%, 73%, 82%, 84%, and 78% respectively.

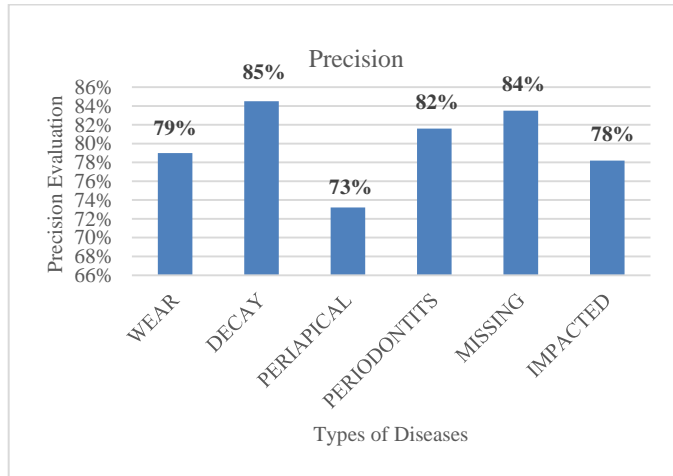

Fig. 11. Comparison of precision for different diseases

B. Recall

It expresses the proportion of predictions that have been correctly diagnosed as expected outcomes and is calculated using Eqn. (2).

$$R = \frac{T_p}{T_p + F_n} \tag{2}$$

It is observed from Fig. 12 that the Recall value for wear, decay, periapical, periodontitis, missing tooth, and impacted tooth is 95%, 93%, 86%, 93%, 91%, and 94% respectively.

Fig. 12. Comparison of recall for different diseases

C. F-measure

F1-score is measured using Eqn. (3).

$$F1 - score = 2 \left(\frac{P * R}{P + R} \right) \tag{3}$$

As per statistics shown in Fig. 13, it is observed that the F1-score for the detection of wear, decay, periapical, periodontitis, missing tooth, and impacted tooth is 86%, 88%, 79%, 87%, 87%, and 86% respectively.

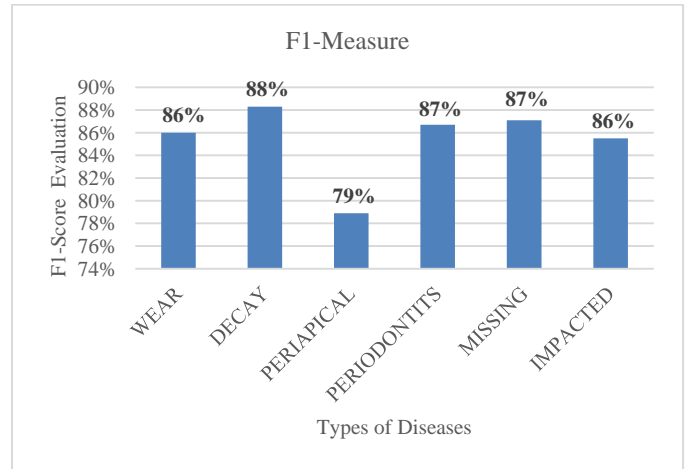

Fig. 13. Comparison of F1-measure for different diseases

D. Specificity

A recall is the probability of a negative diagnosis such as the patient being free from that disease. It is measured using eq. (4).

$$S = \frac{T_n}{(T_n + F_p)} \tag{4}$$

As per the statistical data presented in Fig. 14 specificity for all the diseases covering wear, decay, periapical, periodontitis, missing, and impacted teeth are found to be 90%, 92%, 94%, 93%, 92%, and 89% respectively.

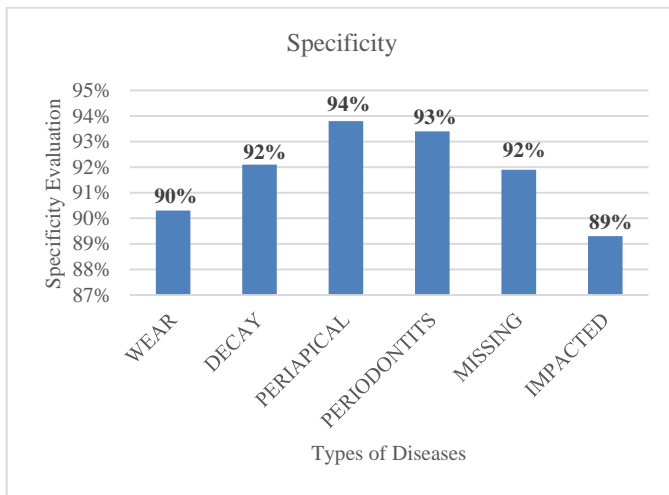

Fig. 14. Comparison of specificity for different diseases

E. Accuracy

Accuracy to the entire observations that are expressed in Eqn. (5),

$$A = \frac{T_p + T_n}{T_p + T_n + F_p + F_n} \quad (5)$$

As per statistics shown in Fig. 15, it is examined that accuracy for classification of wear, decay, periapical, periodontitis, missing tooth, and impacted tooth is 92%, 92%, 93%, 92%, and 91% respectively.

Fig. 15. Comparison of accuracy for different diseases

VII. CONCLUSION AND FUTURE WORK

This system is implemented using the idea of transfer learning and different pre-trained networks, such as 'ResNet50V2', 'ResNet101V2', 'MobileNetV3Large', 'MobileNetV3Small', 'MobileNet', 'EfficientNetB0', 'EfficientNetB1', and 'EfficientNetB2', with XGBoost. To get the final prediction, a weighted ensemble module is used. Additionally, the developed technique has achieved better outcomes in terms of accuracy, precision, F-measure, recall, and sensitivity. Thus, it achieved 92-93% of accuracy in classifying multiple dental diseases including tooth wear, periapical, periodontitis, tooth decay, missing tooth, and

impacted tooth. This approach is implemented on new diseases and compared the measuring parameters against different diseases. For some measuring parameters, values are less compared which can be improved in future work by using the extension of this dataset. In this present study, the given model is tested by classifying six diseases and their 46 possible combinations. This system can identify one disease present in an image as well as a combination of multiple diseases present in one image. The proposed method performs better in terms of accuracy and different measuring parameters than current state-of-the-art methods and has a variety of uses in computer-assisted multiple tooth disease identification and classification.

ACKNOWLEDGMENT

This work is supported by the following dental clinics for data collection, understanding, annotation, authentication, and validation of images.

- a) Government dental college, Nagpur.
- b) Dr. Jayaswal's clinic of Dentistry and Geriatric oral health care center, Nagpur, India.

Cairo, Egypt

Abstract—Speech enhancement is the process of improving the quality of audio relative to target speaker while suppressing other sounds. It can be used in many applications as speech recognition, mobile phone, hearing aids and also enhancing audio files resulted from separation models. In this paper, a convolutional neural network (CNN) architecture is proposed to improve the quality of target's speaker resulted from speech separation models without having any prior information about the background sounds. The proposed model consists of three main phases: Pre-Processing phase, Autoencoder phase and Retrieving Audio phase. The pre-processing phase converts audio to short time Fourier transform (STFT) domain. Autoencoder phase consists of two main modules: dilated multi-Activation encoder and dilated multi-Activation decoder. Dilated multi-Activation encoder module has a six blocks with different dilation factors and each block consists of three CNN layers where each layer has different activation function then the encoder's blocks are arranged in reverse order to construct dilated multi-activation decoder. Audio retrieving phase is used to reconstruct audio depending on feature resulted from second phase. Audio files resulted from separation models are used to build our datasets that consist of 31250 files. The proposed dilated multi-activation autoencoder improved separated audios Segmental Signal-to-Noise Ratio (SNRseg) with 33.9%, Short-time objective intelligibility (STOI) with 1.3% and reduced bark spectral distortion (BSD) with 97%.

Keywords—Speech de-noising; speech enhancement; speech separation; short time Fourier transform (STFT); autoencoder; dilated Convolution neural network; multi-activation functions, convolution neural network (CNN); bidirectional long short memory (BLSTM)

I. INTRODUCTION

The field of machine learning proposed different architectures in complex and difficult problems that were unattainable in the field of speech processing. Speech separation and enhancement are considered two of the most important problems in signal processing where machine learning field achieves better performance on dealing with them. Speech enhancement is used as a step of removing or reducing background noise to enhance the main signal of the target speaker. In the current days, researchers do a lot of effort to have a very high quality speech that relative to the target speaker.

In the field of speech analysis, speech enhancement [1] focus on having high quality sound of the target speaker by suppressing other sounds except sound of the target one [2]

while speech separation [3] is considered the process of separating mixed sounds.

The main objective of speech enhancement and separation is extracting signals of interest parts from an audio according to critical rules that can be done by post production software that depends currently on deep learning field. Speech enhancement is considered the main stone of many applications as teleconferencing systems, speech recognition [4,5], hearing aids [6-8], speaker recognition [9,10] and also can be used to enhance the resulted signals from speech separation systems.

Speech understanding in noisy environments is still one of the major challenges as we need very high quality audio files with large datasets and different types of noises to train the enhancement models and this will need very high quality resources. To face the previous challenge, we built a dataset with 31250 audio files resulted from separation model that trained on a subset samples from The Oxford-BBC LRS2 Dataset.

Recently, deep learning made a great improvement in the speech enhancement field by using different structures over signal processing methods that based on supervised enhancement techniques.

The main contribution of the proposed model is implementing speech enhancement structures to improve the speech quality of the target's speaker resulted from separation models by analyzing input speech in multiple levels. The proposed model plays an important role in the digital speech signal processing according to the type of degradation and background sounds in the speech signal of the target speaker.

In this paper, we proposed a new approach for speech enhancement which achieved an interesting performance comparing against old methods. It improves the quality of speech resulted from separation model. It consists of three main phases: Pre-Processing phase, AutoEncoder phase and Retrieving Audio phase. It considers low quality audios resulted from separation models as an input and complex ratio mask relative to cleared audio as output. The dilation convolutional neural network is considered as the main stone of our proposed model as it has ability to expand the covered areas of the input audio without needing to apply pooling that maybe cause missing some information. Dilated convolutional network mainly uses dilation factor to control the size of the covered area. It also could analysis input signal to suppress background sounds without increasing kernel parameters.

The rest of this paper is organized in the following order. Section II introduces the related work; Section III introduces the proposed structures and defines the main mechanism of speech enhancement in details. Section IV describes the dataset, network parameters and demonstrates the performance of our network. Finally, we conclude the idea of the proposed model in Section V.

II. RELATED WORK

Neural Networks is considered one of the most common machine learning algorithms. It has been improved over time and also outperforms other algorithms and methods in speed and accuracy. There are different types of neural network as convolutional neural network (CNN) [11,12], RNN (Recurrent Neural Networks) [13], Autoencoders [14], LSTM (Long short Tern Memory) [15,16] and also WaveNet that depends on dilated convolution network [17].

Emad el al. [11] proposed multi-resolution convolution neural network that support them in separating audio files from mixed sounds. They proved that concatenating sets of convolution network with different filters could improve the performance of separation compared with deep neural network (DNN) and fully convolution neural network.

Jen-Cheng el al.[12] proposed audio visual model for speech enhancement using CNN that complete its process by analyzing visual and audio stream which processed using separated CNN models then fed into AUDIO-VISUAL Autoencoder model. Their model could outperform speech enhancement models that use audio-only and existing audio-visual enhancement models.

Jinuk el al. [13] proposed model to separate audio sounds of two speakers. They used CNN followed by LSTM and recurrent neural network (RNN) then a fully connected layer is applied on the concatenation of forward LSTM-RNN and backward LSTM-RNN. They achieved better signal-distortion-ratio (SDR) and signal interference ratio (SIR) compared with deep clustering method that used in sound separation.

Yi Luo and Nima Mesgarani [15] proposed time-domain audio separation model to obtain target speaker sound with acceptable performance. Their proposed autoencoder is able to outperform LSTM that analyze log power magnitude spectrogram to complete the process of separation.

Jitong Chena and DeLiang Wang [16] proposed speech separation model based on LSTM that suitable to temporal dynamics of speech. They used Short-time objective intelligibility (STOI) to measure the performance of their model which outperformed DNN model as LSTM could capture long term context of input speech and has low latency in completing speech separation process.

Aaron et al. [17] proposed dilated CNN model called wavenet that captures the main characteristics of multiple speakers. their model has been trained on thousands of samples. They trained wavenet on different datasets as text to speech and music datasets. It could generate musical fragment that very near to realistic and has very high quality. In WaveNet, a set of dilated convolution layers are stacked together to generate a very large receptive fields with a few

layers. Recently, wavenets are used in time domain. It can be used in songs separation from background noise and enhancing speech quality.

Dario et al. [18] proposed speech de-noising technique that able to improve speech signals quality with background-noise. Their proposed model depends on dilated convolution. Their proposed model used different dilation factor in each layer changes in the following order 1, 2, ..., 256, 512. Their pattern is repeated three times. Their model has capability to de-noise an entire audio file in one-shot. They generated their datasets from two sources: speech data from the Voice Bank corpus and environmental sounds from Diverse Environments Multichannel Acoustic Noise Database (DEMAND). Their Perceptual tests proved that their model's outperform the Wiener filtering results. They proved that their system able to learn multi-scale hierarchical representations from raw audio instead of magnitude spectrograms.

Yi Luo and Nima Mesgarani [19] proposed Time-domain Audio Separation Network (TasNet). Mainly, their network structure used in speech separation and also can be used in speech enhancement. It consists of four processes: a preprocessing normalization, an encoder to retrieve the mixture weight, a separation and a decoder to construct waveform. The first process in their network is used to predict the weights that relative to each source in the mixture weight. The weight detection is defined as masks that predict the contribution of each speaker in the mixture weight as T-F masks that are used in short time Fourier transform (STFT) models. In the Separation Network, a deep LSTM network is used to estimate the source masks. They used WSJ0-2mix dataset to evaluate their system on two-speaker speech separation problem. The mixtures relative to their dataset are generated randomly speakers from Wall Street Journal (WSJ0) dataset. Their proposed TasNet system could outperforms systems that use a T-F representation as an input to complete the process of learning. Comparing with STFT system, their experiments proved that the TasNet system was six times faster and could achieve very high quality speech separation performance and also it can be used in speech enhancement.

Craig Macartney and Tillman Weyde [20] proposed speech enhancement model that used Wave-U-Net architecture for speech enhancement. Their experiments proved that the Wave-U-Net could improve several metrics as Perceptual Evaluation of Speech Quality (PESQ), the rating of background distortion (CBAK), the rating of speech distortion (CSIG), segmental signal-to-noise ratio (SSNR) and the predicting rating overall quality (COVL) over the state-of-the-art. They showed that reducing number of hidden layers is more suitable for speech enhancement.

Yong Xu et al. [21] proposed a speech enhancement regression model depending on deep neural networks (DNNs) that consists of multiple-dense layers. Their proposed model could achieve better performance in case of different objective measures. They held a subjective evaluation measure to check the quality of DNN model with 10 listeners, about 76.35% of the listener prefer using DNN results to complete the process of enhancement.

Andreas Jansson et al. [22] proposed a novel architecture of the U-Net architecture that used to complete the source separation task. They benefit from skip connections paths in building encoder-decoders of u-net. They held quantitative evaluation and subjective assessment to evaluate the performance of their model. Their experiments proved that their proposed architecture able to achieves state-of-the-art performance.

III. PROPOSED MODEL

In this paper, we proposed a model based on dilation convolution neural network that able to analysis and discover local pattern of the target speaker in STFT. The main objective of the proposed model is suppressing other human's sounds except target speakers. It mainly enhances the quality of speech resulted from separation models [23].

Fig. 1 depicts the structure of the proposed model. It consists of three main phases: Pre-Processing phase, Autoencoder phase and Retrieving Audio phase. It takes low quality audios resulted from separation models as an input and scaled complex ratio mask of the cleared audios with same size of the input using (1,2) as output.

$$Mask_{(t,f)} = \frac{Target\ sound_{(t,f)}}{Mixed\ Sound_{(t,f)}} \quad (1)$$

$$Scaled\ Mask_{(t,f)} = 10 \frac{1-e^{-0.1*Mask}}{1+e^{-0.1*Mask}} \quad (2)$$

where, t and f are considered as indexes of time and frequency.

In the Pre-Processing phase, audio files are converted to STFT to generate 304X256X2 real and imaginary numbers that taken as an input to the Autoencoder phase and saved as numbers to make the process of training faster.

Autoencoder phase consists of two modules, Dilated MultiActivation Encoder and Dilated MultiActivation decoder as in Fig. 2. Dilated MultiActivation Encoder module consists

of six blocks with different dilation factors and filters to analysis and track relation between audio patterns. Encoder module able to cover more information from patterns depending on dilation factor without pooling which reduces the size of the matrix that are taken as input to the next convolution layer, this will cause missing some audio features and maybe has bad effect on the model performance. Each block consists of three layers, first one is CNN with dilation factor that different in each block to expand the covered area of the input features, second one takes the resulted features from the first layer as an input then apply CNN with the same dilation factor, number of filters of the first layer and uses activation function called activation 1 and finally, the third layer takes the resulted features of first layer as input then applies CNN with activation function named activation 2 where the filter size in second and third layers is s3*s4 as in Fig. 3. Each block has different activations, RELU and element wise multiplication of resulted data from nonlinear output of activation1 and activation2 as experiments results [18] proved that the non-linearity activation work better than RELU activation in dealing with audio signals. Finally, the element wise multiplication of the second and third layers is taken as input to the next block. In the Dilated MultiActivation decoder, the six blocks of the encoder are reversed to build the decoder module. There are different number of filters in each block with kernel size s1*s2 starting with reduction factor changes according to this range [N1, N2, N3, N4, N5, N6] and dilation factor changes according to the following range [D1, D2, D3, D4, D5, D6]. We used dilated convolutional layer in our proposed model as it could expand the covered area in the input audio without pooling. We controlled the covered area in the input by changing the value of the dilation factor. Dilated autoencoder support us in dealing with speech and discover relation between background sounds and target sounds without needing to increase kernel parameters or reducing size of the input features.

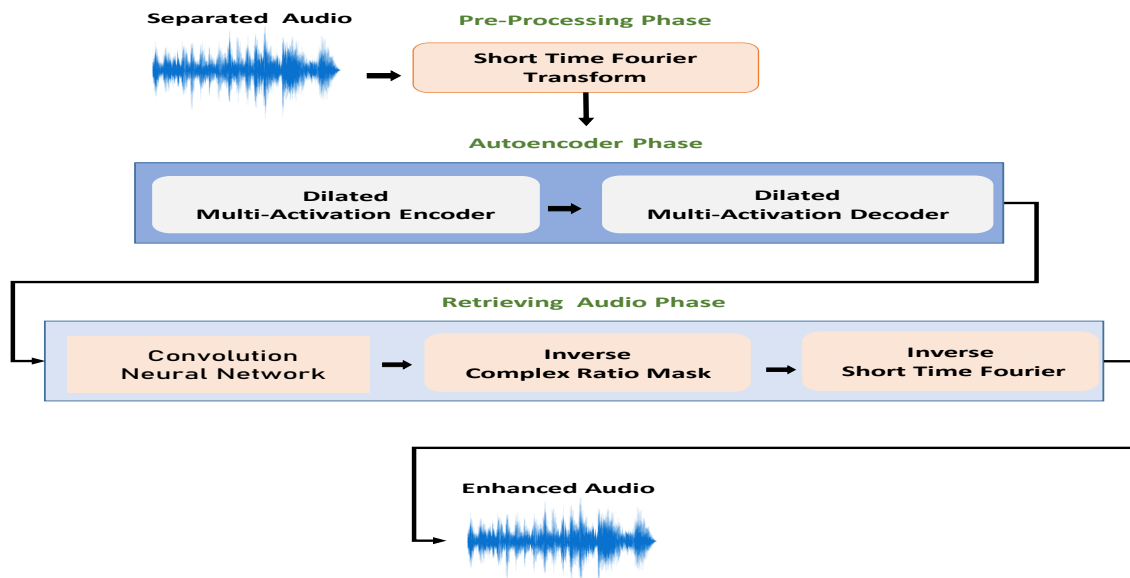

Fig. 1. The proposed model of speech enhancement

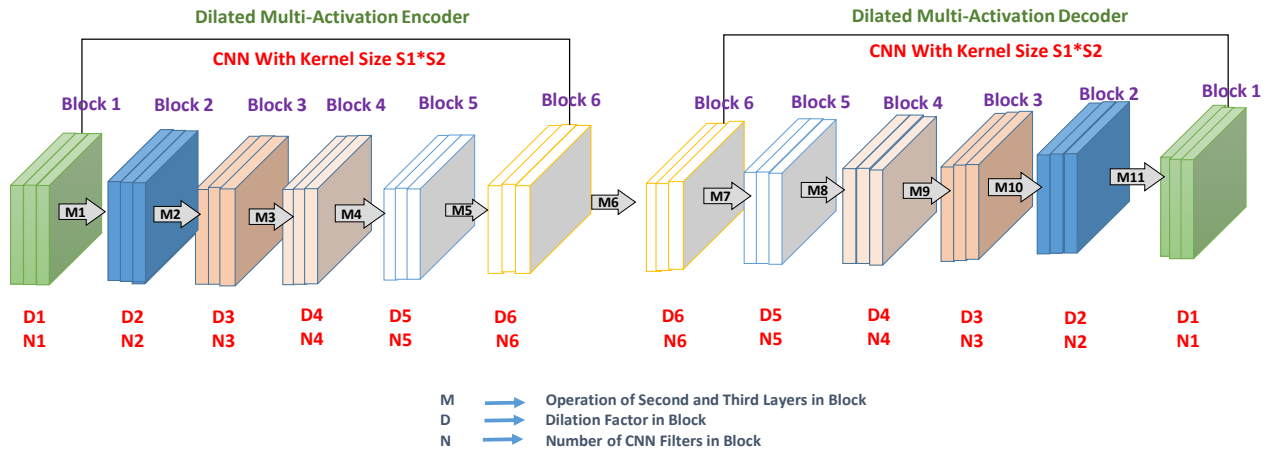

Fig. 2. Dilated multi-activation autoencoder

Fig. 3. Second and third layers of autoencoder's blocks

In the retrieving audio phase, CNN layer is applied on the resulted features from decoder, then inverse complex ratio mask is calculated on the resulted features from CNN [13] after rescaling it by using (3) and finally inverse short time Fourier transform (ISTFT) is used to retrieve the enhanced version of separated audios.

$$S(\text{Resulted Mask}) = \frac{1}{0.1} \log\left(\frac{10 - \text{Resulted Mask}}{10 + \text{Resulted Mask}}\right) \quad (3)$$

where, S is the scaled complex ratio mask.

IV. EXPERIMENTS AND RESULTS

We introduce a small-scale audio dataset containing speech audio with no interfering background signals taking from separated audio of our previous work [23]. The audio segments have length between 3 and 10 seconds. The enhanced audio dataset which is used to train our network contains 31250 audio files resulted from separation process [23] that are splitted into 28126 for training and 3124 for testing. Fig. 4 shows Mixed signal of two speakers in time domain and corresponding spectrogram and amplitude spectrum. It also shows magnitude spectrum and spectrogram of speaker 1's sound and speaker 2's sound before mixing them.

Fig. 4. Original signal in time domain, spectrogram and magnitude spectrum [mixed signal, speaker 1 and speaker2]

We implemented Dilated MultiActivation AutoEncoder in keras. In case of training, we use a batch size of 2 samples and Adam optimizer for 14062 batches with a learning rate 1×10^{-5} . Tables I and II indicate Hyper-parameters that used to complete the process of training. The nonlinearity activation function is a combination of Tanh and Sigmoid. The number of filters in the retrieving phase is two. Number of filters in the autoencoder's blocks starting from 256 to 4 with decreasing factor equal half and dilation factor starting from 64 to 1 with decreasing factor half. We used STFT as a pre-processing phase on the input audio where STFT is calculated using a Hann window with length 25ms, hop length of 10ms, and FFT size of 512.

TABLE I. TRAINING HYPER-PARAMETERS OF DILATED MULTIACTIVATIO AUTOENCODER MODEL

	Value
Learning Rate	1×10^{-5}
Optimizer	Adam
S1*S2	15*15
S3*S4	3*3
Activation 1	Tanh
Activation 2	Sigmoid
CNN Filters of Retrieving audio phase	Number of filters[2]

TABLE II. TRAINING HYPER-PARAMETERS OF MULTI-ACTIVATION ENCODER AND DECODER BLOCKS

	Number of Filters	Dilation Factor
Block 1	N1 =256	D1=64
Block 2	N2 =128	D2=32
Block 3	N3 =64	D3=16
Block 4	N4 =32	D4=4
Block 5	N5 =8	D5=2
Block 6	N6 =4	D6 =1

The proposed model takes STFT of separated audios resulted from separation model [23] as input and its output is enhanced version of the target speaker by removing background sounds of other speakers. Fig. 5 shows spectrograms and spectrums of two speaker resulted from separation model [23] before enhancement process where the separation models take mixed signal as input and generated separated sound relative to each speaker by using facial embedding of each speaker as a guide to complete the separation.

To test the performance of our model, we held four experiments, three from literature papers and the last one depending on our proposed model. All experiments use the same dataset resulted from the audio separation models.

In the first experiment, advanced version from DNN [21] is trained to reduce background sounds. It consists of a pipeline of dense layers [24]. The pipeline consists of three dense layers followed by dropout and the previous architecture is repeated two times. Fig. 6 indicates the magnitude spectrum and spectrogram of the enhanced audio after taking the low quality speeches resulted from separation models as input.

In the second experiment, we train u-net [22] to suppress background sounds. Firstly, three convolution layers with filters [128,128,1] is applied on the STFT values to prepare U-net input [25]. It is considered as deep convolutional autoencoder with skip connection between encoder and decoder parts. They adopted their network to de-noise voices and we used the same architecture to enhance audio signal resulted from separation model. After training, u-net could have better spectrogram and magnitude spectrum comparing with results of separation model as in Fig. 7. In the third experiment, we trained Wavenet [18] architecture to enhance speech of the target speaker. Fig. 8 shows the enhanced magnitude spectrum and spectrogram of the target speakers after applying wavenet architecture on separated audio it has better results comparing with DNN as it depends mainly on dilated convolutional neural network. In the last experiment, our proposed multi-activation AutoEncoder is trained to complete the process of enhancement, Fig. 9 shows the enhanced magnitude spectrum and spectrogram resulted from our proposed model that is very near to original spectrogram and magnitude spectrum.

Fig. 5. Speech separation of two speakers [spectrogram and spectrum]

Fig. 6. Speech enhancement using DNN [spectrogram and spectrum]

Fig. 7. Speech enhancement using U-net [spectrogram and spectrum]

Fig. 8. Speech enhancement using wavenet [spectrogram and spectrum]

Fig. 9. Speech enhancement using autoencoder [spectrogram and spectrum]

Fig. 5-9 show that the proposed model has best spectrum and spectrogram compared with all experiments that is very near to the original version as it is mainly depends on dilated convolution with different dilation factor in each block to analysis input signal in different level and it does not use pooling in its architecture so there is no missing information during the training process

Fig. 10 illustrates the average testing loss during the process of learning. It is clear that dilated multi-activation Autoencoder experiment has best testing loss comparing with DNN, U-NET and Wavenet.

DNN has loss equal to 0.0991 after the second epoch, U-net [experiment 2]. has loss equal to 0.099 that is very near to DNN Wavenet [experiment 3] has loss equal to 0.095 that less than DNN and U-NET. Dilated multi-activation autoencoder has the minimum loss compared with DNN, U-NET and Wavenet that equal to 0.89.

The number of trainable parameters relative to each experiments is summarized in Fig. 11. It is cleared that the dilated autoencoder has an acceptable number of parameters that very near to Wavenet, u-net and less than DNN. Although DNN consists of high number of dense layers and has very high parameters, it has low performance comparing with our proposed model. Wavenet has the minimum number of parameters but its performance is lower than our proposed model.

Fig. 10. Average testing loss of enhancement models

Fig. 11. Trainable parameters of enhancement models

To evaluate objective performance of the proposed model, supporter Python Speech Enhancement Performance Measures (Quality and Intelligibility) project [26] is used. Four speech objective evaluation metrics are calculated to measure speech quality [Segmental Sign al-to-Noise Ratio (SNRseg), PESQ, bark spectral distortion (BSD) and STOI].

Table III and Fig. 12 and 13 indicated that the proposed autoencoder outperform most of enhancement models in SNRseg, STOI and BSD.

It improved SNRseg of separation audio with 33.9%, STOI with 1.3% and reduced BSD with 97%, it is cleared that our proposed model has the best SNRseg, STOI and BSD comparing with audio resulted from separation and other enhancing models. Table III proved that audio files resulted from separation models has high noise and also high distortion comparing with enhanced version resulted from our proposed model that trained on 31250 audio files divided into 28126 for training and 3124 for testing.

TABLE III. OBJECTIVE EVALUATION MEASURE OF SPEECH ENHANCEMENT MODELS

Model/Measure	SNRseg	Stoi	Pesq	BSD
Separation model[23]	3.63	0.80	2.17	4,329.90
U-net[22]	2.87	0.80	2.17	218.90
DNN [21]	2.81	0.80	2.13	231.69
WaveNet[18]	2.71	0.80	2.15	212.62
Dilated AutoEncoder	4.86	0.81	1.95	128.89

Fig. 12. Bark spectral distortion

V. CONCLUSION

We proposed dilated multi-activation autoencoder to enhance the performance of audio sounds resulted from separation models. It consists of two main modules, dilated multi-Activation encoder and dilated multi-Activation decoder where dilated multi-Activation encoder module has six convolutional neural network blocks with activation functions and different dilation factors. To build the structure of the decoder, the six blocks of the encoder are arranged in reverse order. Dataset consist of 31250 files splitted into training and testing sets where training set consists of 28126 files and testing set consists of 3124. The proposed model improved SNRseg of separated audios with 33.9%, STOI with 1.3% and reduced BSD with 97%. In the future, we will try to improve the performance of the proposed model by adding face embedding features relative to target speaker.

Abstract—Brain Strokes are considered one of the deadliest brain diseases due to their sudden occurrence, so predicting their occurrence and treating the factors may reduce their risk. This paper aimed to propose a brain stroke prediction model using machine learning classifiers and a stacking ensemble classifier. The smote technique was employed for data balancing, and the standardization technique was for data scaling. The classifiers' best parameters were chosen using the hyperparameter tuning technique. The proposed stacking prediction model was created by combining Random Forest (RF), K-Nearest Neighbors (KNN), Logistic Regression (LR), Support Vector Machine (SVM), and Naive Bayes (NB) as base classifiers, and meta learner was chosen to be Random Forest. The performance of the proposed stacking model has been evaluated using Accuracy, Precision, Recall, and F1 score. In addition, the Matthews Correlation Coefficient (MCC) has been also used for more reliable evaluation when having an unbalanced dataset, which is the case in most medical datasets. The results demonstrate that the proposed stacking model outperforms the standalone classifiers by achieving an accuracy of 97% and an MCC value of 94%.

Keywords—Stroke disease; prediction model; ensemble methods; stacking classifier

I. INTRODUCTION

Stroke is considered one of the riskiest and deadliest diseases affecting humans, as it suddenly strikes the brain. This occurs when the blood flow to the brain is interrupted. Consequently, the brain's ability to receive oxygen and nutrients is compromised, which results in brain cell death within minutes [1]. It is the second leading cause of death globally after ischemic heart disease, as reported by the World Health Organization (WHO) [2]. Ischemic and hemorrhagic strokes are the two primary types. Ischemic stroke happens when a blockage decreases or interrupts blood flow to brain cells, killing the cells within minutes and leading to death. In contrast, Hemorrhagic stroke occurs when weak blood vessels are severely damaged as a result of hypertension, high cholesterol, and other risk factors [3]. Strokes are caused by a variety of risk factors, including medical factors such as high blood pressure, heart disease, diabetes, high cholesterol, and atrial fibrillation, as well as bad habit factors such as smoking, obesity, unhealthy foods, and lack of physical inactivity. The word "FAST" can be used to recognize the main stroke symptoms [4]. The abbreviated FAST stands for four words. F stands for facial laughter perception that they cannot smile or that their mouth or eyes have closed. A refers to the individual with a stroke who might not be capable of raising both arms

and maintaining them up. S stands for speech that the person is unable to speak or hard to understand. T is the time at which the patient needs to visit the hospital right away.

The early prediction of brain stroke occurrence to deal with their risk factors is considered a lifesaving matter. Machine learning and AI techniques can be used to determine the likelihood of a stroke occurring in light of their significant advances in predicting different diseases. Different classification algorithms have been used for predicting strokes with reasonable results [5] [6] [7]. The ensemble method is widely used in medical applications due to its accuracy in predicting different diseases [8] [9] [10]. These methods integrate the prediction outcomes of various classification models to enhance the overall performance. They fall into three main categories: Bagging, Boosting, and Stacking. In bagging, several base classification models are sequentially trained, and then use the majority voting to integrate the prediction outcomes [11]. Whereas, in boosting, several base models are trained sequentially to correct the previous models' errors sequentially [12]. In stacking, the classification task is completed in two stages: the first involves training multiple base models on the entire dataset, and the second involves using a meta-learner classifier to train on the first layer's prediction results to provide the final prediction [13]. The base models in bagging and stacking must be homogenous, but in stacking it could be heterogeneous. Rather than relying solely on the output of a single model, these techniques guarantee the delivery of more accurate and trustworthy results from multiple models [14] [15]. Few studies have used ensemble methods for developing brain stroke prediction models, despite the value of using a stacking ensemble classifier to build predictive models with trustworthy outcomes in a variety of fields, including medical and natural phenomena [16] [17] [18].

The main contribution of this paper is to propose a stroke prediction model using a stacking classifier with multiple base model classifiers to enhance the prediction process. Level one classifiers in the stacking model are the Random Forest, K-Nearest Neighbors, Logistic Regression, Support Vector Machine, and Naive Bayes. In level two, the random forest classifier serves as a meta-learner, combining the prediction results of level one to provide the final prediction. To fulfill this aim, the following tasks have been completed:

1) As with most medical datasets, the used dataset is unbalanced. To balance the dataset, this study conducted the SMOTE technique [19].

- 2) The standard scalar technique has been used to put the data values on the same scale.
- 3) The model has been constructed using cross-validation with $cv = 10$.
- 4) Hyperparameter tuning was employed on the base classifiers to pick the best parameters for each classifier.
- 5) In addition to the classical evaluation metrics, the MCC (Matthews Correlation Coefficient) value [20] has been used to evaluate the proposed model as it is more realistic for unbalanced datasets.

This paper is structured as follows: Section II provides the literature reviews that have been done on using machine learning classifiers to generate a stroke prediction model. Section III describes the methodology and proposed model used to construct the prediction process. Section IV offers insights into the assessment of the study's findings. Section V displays the discussion of the study. Finally, Section VI reports the conclusion of the work and aspects of future works.

II. LITERATURE SURVEY

A. Building Stroke Prediction Model by using Classification Algorithms

Most works in the area of brain stroke prediction, using machine learning techniques, are building their models based on standalone classifiers.

Singh and Choudhary [21] built a neural network model for stroke prediction. They used a dataset from the cardiovascular health study (CHS). They applied the Principal Component Analysis (PCA) to minimize the dimensionality of the features and then the decision tree algorithm to choose the most relevant features. The number of instances they have used to build the predictive model is small enough to ensure the accuracy of the results.

Nwosu et al. [22] presented a prediction model for brain strokes by using various machine-learning classifiers. The prediction model was built by using three classifiers Neural network (multi-layer perception), Decision tree, and Random Forest. They achieved 75% accuracy when using the neural network classifier. The main purpose of any medical prediction model is to increase the model's accuracy, but in this study, their results are not sufficient to be trustworthy.

Almadani and Alshammari [23] proposed a stroke prediction model using J48, Jrip, and neural networks (multilayer recognition). The model was built using datasets from the data management department of King Abdulaziz Medical City, Saudi Arabia. Comparing the accuracy of the algorithms, they found that the J84 algorithm achieved a higher accuracy prediction of about 95.25% using principal component analysis (PCA).

Jeena and Kumar [24] developed a stroke prediction model that predicts the probability of developing a stroke based on various risk factors. Model age, atrial fibrillation, gait symptoms, visual impairment, etc. Predictive models were created using support vector machine classification with various kernel functions such as linear, quadratic, RBF, and polynomial. The most accurate function was the linear kernel

function, which achieved 91% accuracy. The main drawback here is that the database size is not large enough to make the prediction results more reliable and consists of 350 cases. However, this study did not consider the unbalancing in the stroke dataset, resulting in inaccurate results.

Mahesh and Srikanth [25] wanted to develop a stroke prediction model using decision trees, naive Bayes, and artificial neural network classification algorithms for machine learning. Their study highlights the impact of modifiable and non-modifiable risk factors for stroke. The data set has some risk factors, such as high blood pressure, smoking, and other factors. They utilize the AUC (area under the curve) and ROC (receiver operating characteristics) to measure the total performance of predictive models. The higher the AUC result, the better the prognosis. Their results show that the three algorithms provide acceptable accuracy in the prediction process. A web application was used as the user interface to provide stroke risk alerts. The AUC_ROC score alone cannot be considered a measure of a predictive model.

Sailasya and Kumari [26] trained their prediction model for stroke using Logistic regression, Decision tree, Random Forest, K-nearest neighbors, Support vector machine, and Nave Bayes, six machine learning classifiers. They used a dataset containing risk factors for strokes. They also developed an HTML page as a user interface to get the values of stroke parameters from the user and provide him with the prediction result. They evaluated the overall performance by using the F1 score, accuracy, precision, and recall. The outcome demonstrates that the Nave Bayes classifier has achieved the highest accuracy of 82% compared with the other used classifiers. The achieved accuracy is not accurate enough to predict such a critical medical condition.

Sudha et al. [27] used three machine learning algorithms: decision trees, naive Bayes, and neural networks to build a stroke prediction model. They used a series of data consisting of the patient's troops. The dimensional reduction process is done using a PCA. The decision tree algorithm achieved the highest accuracy of 94%.

Tazin et al. [28] implemented a stroke prediction model using the machine learning techniques of the decision tree, random forest, logistic regression, and voting classifier. The prediction model was built using a stroke dataset that included risk factors. They evaluated the classifiers by using the confusion matrix. The random forest classifier has the highest accuracy of 96% among all classifiers.

Cheon et al. [29] performed a study to decide the ability to predict patients with strokes and the ability of death. They constructed their prediction model using data from the Korean Centers for Disease Control and Prevention (KCDC). Deep neural networks were utilized in the model's construction. They reduced the dataset dimension by using PCA (principal component analysis). They evaluated their model by the confusion matrix. Their area under the curve (AUC) was at its highest, at about 83.5%.

I) Monteiro et al. [30] built a model to predict stroke functional diagnosis. A dataset consisting of 541 patients was used. Popular algorithms such as logistic regression, decision

tree, support vector machine, random forest, and XGBoost were used to construct the prediction model. The area under the curve (AUC), which is greater than 90%, was used to assess the final performance of the models.

Amini et al. [31] conducted decision tree and k-nearest neighbors' classifiers in their stroke prediction model. A stroke dataset with various risk factors was used in their study. The evaluation step reveals that the decision tree algorithm outperformed the KNN algorithm in terms of accuracy, achieving a score of 95.42%.

Ali et al. [32] extended their prediction model of strokes by using distributed machine learning algorithms with the aid of a popular platform in big data called Apache Spark. The prediction model was built using a Decision Tree, Support Vector Machine, Random Forest, and Logistic Regression classifiers. A healthcare stroke dataset was used in their work. They evaluated the model's performance using accuracy, precision, recall, and the f1-measure. Out of all classifiers, Random Forest has achieved the highest accuracy of 90%.

Islam et al. [33] executed a cloud-based mobile application that helps provide the user with a warning about the probability of having a stroke. Building a prediction model using classifiers from machine learning, such as Logistic Regression, Decision Tree, K-Nearest Neighbors, and Random Forest, is the fundamental principle on which the web application is based. A dataset consisting of stroke risk factors was used. They evaluated their classifiers by using accuracy, precision, and f1-score. The highest accuracy of 96% was attained by random forest across all performance metrics.

Akter et al. [34] proposed a stroke prediction model with acceptable accuracy. Popular machine learning algorithms like Random Forest, Support Vector Machine, and Decision Tree were developed using their model. The confusion matrix was used to evaluate their prediction model, and the results show that the Random Forest classifier had the highest accuracy (95.30%).

My main criticism of the above works is that the evaluation process is based on traditional measures that do not consider that the datasets are unbalanced by nature (like most medical datasets). Furthermore, few research works have been proposed in the area of stroke prediction using ensemble classifiers.

B. Stroke Prediction Model by using Ensemble Classifiers

Govindarajan et al. [35] used homogenous ensemble classifiers and conventional machine learning algorithms to create their prediction model, including artificial neural networks, Support Vector Machines, boosting, bagging, and random forests. Their work has been done on 507 stroke patients. They evaluated their work using accuracy, precision, recall, sensitivity, specificity, and standard deviation. The neural network classifier has achieved the highest accuracy of 95.3.

Rado et al. [36] built an ensemble model using the homogeneous ensemble method Random Forest (Bagging), Adaptive Boosting, and the heterogeneous ensemble method Stacking and compared their results. They evaluated the model's performance by using accuracy, Mean Squared Error

(MSE), precision, and F-measure and compared it with standalone classifiers. Their results show that the ensemble classifiers have attained better accuracy than standalone classifiers. With an accuracy of 87.58%, the stacking classifier is the most accurate.

III. PROPOSED MODEL

The proposed ensemble model for predicting whether an individual will have a brain stroke or not is based on many risk factors such as age, gender, heart disease, marital condition, and other factors. The model uses multiple algorithms as shown in Fig. 1. The dataset called Stroke Prediction Dataset has been used [37]. The dataset was firstly loaded, and then data preprocessing techniques were applied such as Simple Imputer for handling null values, Label Encoder for converting categorical values into numerical values, standardization technique for making data on the same scale, and SMOTE technique for making data more effective to build the model. Following that, machine learning algorithms such as K nearest neighbors, Gaussian naive Bayes, Logistic Regression, Support Vector Machine, and Random Forest were used after tuning them by using the hyperparameter tuning concept to find the best hyperparameters for each algorithm. These algorithms are the base learners in level one for building the stacking model. The Random Forest was then employed as a meta-learner in level two of the stacking model, which generate the final prediction by using the predictions from the base learners in level one as input. Finally, the proposed prediction model was evaluated by measuring the accuracy, precision, recall, F1 score, and MCC (Matthews Correlation Coefficient) for realistic evaluation.

Fig. 1. Stroke prediction model.

A. Stroke Dataset

The prediction model was built by using a stroke prediction dataset from Kaggle that has been presented in Fig. 2. This dataset consists of 5110 rows and 12 columns. The features include ID, gender, age, hypertension, heart disease, ever married, work type, residence type, avg. glucose level, BMI, and smoking status as shown in Table I. The target column is stroke. The identifier column was deleted during the experiment because it does not give any information, it is just the number of the patient.

B. Data Preprocessing

1) *Handling missing values:* There is an important step before building the predictive model, data preprocessing should be done in which any noise removed, duplication, or incomplete information and handle any missing data. These issues may lead the model to produce incorrect results or affect the overall model quality. In this stroke dataset, there are no duplicated rows. But there are 201 missing values in the BMI column as shown in Fig. 3. Those missing values were filled by using the data column's mean.

2) *Converting categorical values into numerical values:* The next step was to convert categorical values into numerical ones. The dataset consists of five features with type strings; namely gender, ever married, work type, residence type, and smoking status. The label encoding technique has been employed to convert those features into numerical values.

3) *Data scaling:* After that, the Standardization technique was used to make the data values in the same range because the input data values fall in different scales. The Standard Scalar function was applied which makes the data values between zero and one, and it is also working with the standard deviation and the data point mean.

4) *Handling imbalanced dataset:* Class imbalance of datasets is a communal problem in machine learning. Imbalance data can affect the accuracy of machine learning models negatively. This problem occurs when the target class has observations not equal in distribution. That is, there is a high number of instances for a one-class label but an exceptionally small number of observations for the other class exists. In the dataset, the target class of stroke is imbalanced

because class "0" which is the number of occurrences of patients who do not have a stroke exceeds class "1" which is the number of patients who have a stroke. As shown in Fig. 4, the total number of instances for classes "0" and "1" is 4861 (about 4.9%) and 249 (about 95.1%), respectively.

To manage this issue, Synthetic Minority Oversampling Technique (SMOTE) which is an oversampling technique is applied. Oversampling requires increasing the number of instances in the minority class by duplicating the records of the minority class to make the instances in the minority class equal to the instances in the majority class. SMOTE technique is a modified version of oversampling in which it is not just duplicating the records in the minority class because it will not add any latest information, it uses the concept of k nearest neighbor to randomly select the neighbor instances and create a synthetic instance. It easily works by selecting examples that are close to the feature space, drawing a line between the examples in the feature space, and drawing a new sample at a point along that line. After applying it, the dataset became balanced with the number of instances of 0 equals 1 in the target class as shown in Fig. 5.

TABLE I. DATASET ATTRIBUTES AND THEIR DESCRIPTION

Attribute Number	Attribute Name	Description
1	id	A unique identifier number for the patient
2	gender	Refers to the gender of the patient
3	age	The age of the patient
4	hypertension	refers to if the patient suffering from hypertension or not
5	heart_disease	refers to whether the patient is suffering from any heart disease or not
6	ever_married	refers to if the patient is married or not
7	work_type	refers to the different types of work
8	Residence_type	refers to the type of the patient's residence
9	avg_glucose_level	refers to the level of blood sugar
10	bmi	refers to the body mass index of the patient
11	smoking_status	refers to the patient's smoking status
12	stroke	refers to if the patient had a stroke or not

id	gender	age	hypertension	heart_disease	ever_married	work_type	Residence_type	avg_glucose_level	bmi	smoking_status	stroke
9046	Male	67	0	1	Yes	Private	Urban	228.69	36.6	formerly smoked	1
51676	Female	61	0	0	Yes	Self-employed	Rural	202.21	N/A	never smoked	1

C. Hyperparameter Tuning

Hyperparameter tuning is the process of finding the optimal hyperparameters for the classifier. It tests several combinations of the parameter values and finds the optimal values that maximize the accuracy of the prediction model. In that work, the grid search technique was used to find the best parameters for using classifiers as presented in Table II.

D. Building Stacking Model

1) *Base classifiers for the stacking model:* After the step of data preprocessing and hyperparameter tuning, the stacking model was started to build for stroke prediction. The first step is to train multiple heterogeneous algorithms on the dataset, this step is called stacking level one. The second step is to build a meta-model that helps in combining the base learners' predictions with the final prediction. Five popular machine learning classification algorithms were trained on the dataset at level one, which was as follows:

- K-nearest neighbors

- Random Forest
- Gaussian Naïve Bayes
- Logistic Regression
- Support Vector Machine

a) *K nearest neighbors:* K-nearest neighbors are the most commonly used algorithm for both classification and regression problems in machine learning. It is also known as KNN or K-NN. The basic idea of KNN is to group data points falling in near to each other in the same class. It classifies the new data point based on a similarity measure. It uses Euclidean distance to determine the nearest neighbor class to a data point that needs to be classified.

b) *Random Forest:* Random Forest is the most commonly used algorithm for classification and regression problems in machine learning based on Bagging ensemble learning. In ensemble learning, it combines the results of the prediction of multiple base classifiers to build one robustness model with higher performance. A random forest consists of several decision trees that were trained individually on a random data sample and subset features. Decision trees produce several results, and these results are combined using the majority voting in the case of the classification problem and the mean average in the case of the regression problem to produce the final result. The greater number of trees in the random forest leads to the highest prediction performance. This algorithm prevents the issue of overfitting and enhances the model's accuracy.

c) *Gaussian Naïve Bayes:* This classification algorithm employs the Bayes theorem. It assumes that all the input features or attributes are independent of each other. Bayes' theorem finds the probability of an occurrence of an event given the probability of another event that has already occurred before.

$$P(A|B) = \frac{P(B|A)P(A)}{P(B)}$$

TABLE II. HYPERPARAMETER TUNING FOR BASE CLASSIFIERS

	Best Parameter values with grid search cv	Best score by selecting the best parameters
K-Nearest neighbors	neighbors=1 weights='uniform'	0.947
Random Forest	n_estimators= 2000 max_depth= 50 criterion=entropy bootstrap= False random_state=1	0.966
Gaussian Naïve Bayes	var_smoothing= 0.0533	0.776
Logistic Regression	C=0.00294 max_iter=100 penalty=L1 solver=saga	0.792
Support Vector Machine	C=1000 Kernel=rbf Degree=1	0.928

d) *Logistic Regression*: Logistic regression is an effective algorithm for binary classification problems. It uses some independent features to predict a categorical or discrete dependent variable, such as 0 or 1, male or female, yes or no, and so on. It uses the Sigmoid function that gives the probability values between 0 and 1 instead of giving the output values 0 and 1 by mapping the predicted values to probabilities.

e) *Support Vector Machine*: The main concept of SVM is to create the best fit line or decision boundary that can split the classes, so it can easily classify the new data point in the correct class in the future. The best fit line or decision boundary is called a hyperplane.

2) *Stacking meta learner*: Stacking is one of the most efficient machine-learning techniques. It is a widely used ensemble technique because it improves the model performance and solves complex problems. It is used to combine the predictions from multiple models by using a meta-model. In stacking, the dataset is divided into two sets, the first one is the training set and the second one is the test set. This training set is divided into a training set that is trained by heterogeneous base learners to create the first-level models and a validation set that is used by the models to make the predictions of level one, which are used as new features for the second-level meta-learner. This meta-learner is trained on this new training data, which consists of the first-level predictions, and uses the test set to make the final prediction. The major point is to construct a meta-model that is trained with the first-level outcomes. This step helps in providing an accurate final prediction. Fig. 6 shows the sequence of the stacking model. The base model classifiers were K-nearest neighbor, Random Forest, Gaussian Naive Bayes, Logistic Regression, and Support Vector Machine. In the second level, the Random Forest has been chosen to be the meta learner which has been trained on the outputs of the base learners, as it is the most suitable algorithm for providing an accurate result. It has the best accuracy of 96% compared to other stand-alone classifiers.

3) *K-Fold Cross-Validation*: While building the model, the k-fold cross-validation is conducted to divide the dataset into K collections with equal sizes, Where K represents an integer number. Those collections are called folds. Making iterations equal to the number of folds. At each iteration:

- Take k-1 folds for training and k-fold for validating.
- Changing the folds of training and validating.
- Calculate the accuracy of each iteration.
- Take the average of all accuracies.

It usually gives more accurate results for the model as it trains the model multiple times by changing the training and testing data slot at each iteration. Fig. 7 is an example of cross-validation with five folds.

Fig. 6. Sequence of stacking model.

Fig. 7. Example of cross-validation with k=5.

E. Final Prediction

The Random Forest classifier has been used in the second level of the stacking model, which is a meta-learner that combines the results of the first level. This learner trained on those results and provided the final prediction result.

F. Model Evaluation

The prediction model was evaluated by using various evaluation metrics such as accuracy, precision, recall, f1-score, and MCC (Matthews Correlation Coefficient). This paper considered the MCC value for the classifiers because it is an effective measure for binary classification and unbalanced datasets, as in the used stroke dataset. It calculates the correlation between the actual and the predicted values. If that correlation value is higher, that means that the prediction is better. It considered all the confusion matrix values. When the value of MCC is close to one then it means that the model well predicted the actual and the predicted values.

$$\text{Accuracy} = \frac{TP}{TP+TN+FB+FN}$$

$$\text{Precision} = \frac{TP}{TP+FP}$$

$$\text{Recall} = TP / (TP + FN)$$

$$\text{F1-score} = 2(\text{recall} * \text{precision}) / (\text{recall} + \text{precision})$$

$$MCC = \frac{TP * TN - FP * FN}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}}$$

True Positive (TP) Predicted Positive and they are Positive

True Negative (TN) Predicted Negative and they are Negative

False Positive (FP) Predicted Positive but they are Negative

False Negative (FN) Predicted Negative but they are Positive

Positive here means that patient has a stroke (1) and negative means that the patient does not have a stroke (0).

IV. RESULTS

After building the prediction model, the classification algorithms were compared with the accuracy, precision, recall, f1 score, and MCC measures as shown in Table III and Fig. 8:

- All features were used.
- SMOTE was applied to balance the data.
- Standard scalar was applied to make the data values on the same scale.

- Cross-validation was used to build the prediction model with cv=10.
- Hyperparameter Tuning was applied to the base classifiers to choose the optimal parameters for each classifier as shown in Table II.
- Hyperparameter Tuning is the process of choosing the best parameters for the classifier to increase the classifier's performance.
- Built the stacking model with KNN, RF, NB, LR, and SVC in level one and RF as meta learner in level two.
- Model evaluation was done by using accuracy, precision, recall, f1 score, and MCC measures.

TABLE III. COMPARISON BETWEEN THE ALGORITHMS WITH HYPERPARAMETER TUNING

	Accuracy	Precision	Recall	F1 Score	MCC
KNN	0.95	0.91	0.99	0.95	0.89
Random Forest	0.96	0.99	0.97	0.96	0.92
Naïve Bayes	0.78	0.79	0.83	0.78	0.55
Logistic Regression	0.79	0.79	0.85	0.80	0.58
SVC	0.93	0.94	0.98	0.94	0.87
Stacking	0.97	0.99	0.97	0.97	0.94

Fig. 8. Comparison between the base classifiers and the stacking model.

From III, the stacking algorithm has achieved the highest accuracy compared with the other standalone classifiers as it achieved the highest accuracy about 97%, and this result shows the efficiency of the ensemble methods. It also achieved the highest MCC value of 94% which means that the stacking model provides an accurate prediction as it well predicts the actual and the predicted values.

Table IV shows the difference between using SMOTE technique to balance the data and without it in comparison with the model accuracy.

Fig. 9. Stacking confusion matrix.

TABLE IV. ALGORITHMS ACCURACY BETWEEN USING SMOTE AND WITHOUT USING SMOTE

	Accuracy without SMOTE	Accuracy with SMOTE
K-NN	0.91	0.95
Random Forest	0.95	0.96
Gaussian Naïve Bayes	0.87	0.78
Logistic Regression	0.95	0.79
Support Vector Machine	0.95	0.94
Stacking	0.95	0.97

V. DISCUSSION

Over an effort to enhance a brain stroke prediction model a combination of classification algorithms and the stacking ensemble classifier was used to create the prediction model. The outcomes of this research supported the advantages of employing the ensemble method when establishing predictive models.

The prediction model procedures have included the following steps: data preprocessing, in which dataset issues are addressed using various techniques such as column's average for filling in missing values, Label Encoder to convert categorical features into numerical features, Data Scaling to align the data values, and Smote technique to balance this medical dataset. Then, to improve the accuracy of each classifier, hyperparameter tuning was used to determine the most appropriate hyperparameter. The stacking model's level one consists of the Random Forest, K-Nearest Neighbors, Logistic Regression, Support Vector Machine, and Naive Bayes while level two is mainly composed of the Random Forest classifier, which serves as a meta-learner by combining the level one prediction results to generate the final prediction.

Comparing the proposed stacking prediction model with other standalone classifiers, it demonstrated higher classification performance as shown in Table III and Fig. 9. It obtained the best accuracy result of approximately 97%, demonstrating the efficiency of the ensemble methods. As well, it achieved the maximum MCC value of 94%.

VI. CONCLUSION AND FUTURE WORK

This paper intended to demonstrate a stacking ensemble classifier-based prediction of brain stroke disease. Traditional classifiers served as the stacking model's base models. To enhance the final prediction result, the output of those classifiers was combined using the stacking meta-learner.

According to the experimental findings, using a stacking ensemble classifier can significantly increase prediction accuracy as it achieved about 97% and give the highest MCC measure of about 94%, which ensures that the prediction is correct. It also demonstrated that the MCC value is more trustworthy than the conventional measures in the evaluation of the two-class confusion matrix. Using some risk factors, this model aids in accurately predicting whether someone will suffer a brain stroke or not. The future scope of this study will include using other combinations of the base model classifiers in the stacking model. As well, it may extend to utilizing other effective attributes for building the prediction model or employing deep learning algorithms.

Information Systems Department-Faculty of Computers and Artificial Intelligence, Beni-Suef University, Egypt^{1,2}
Information Systems Department-Faculty of Computers and Artificial Intelligence, Helwan University, Egypt³

Abstract—Women's cancers, signified by breast adenocarcinoma and non-small-cell lung cancers, are a significant threat to women's health. Across the globe, the leading cause of death for women is a group of tumors referred to as "female-oriented cancers". The most recent researches in the classification of molecular tumors is the analysis of women's cancers using RNA-Seq data for precision cancer diagnoses. Furthermore, discovering the different genes' patterns behaviors will lead to predict the cancer-specific biomarkers to early diagnosis and detection of cancer-specific in women. An overfit model will be resulted due to the high-dimensional data of RNA-Seq from a small samples of data. In this work, we propose a filter-based selection approach for a deep learning-based classification model. In addition, hybrid classification models have been proposed to be compared with the new modified deep learning model. The Experiments' analysis showed that the proposed filter-based selection approach for a deep learning-based classification model performed better than the other hybrid models in terms of performance evaluation metrics, with an accuracy of 96.7% for RNA-Seq breast adenocarcinoma data and 95.5% for RNA-Seq non-small-cell lung cancer data.

Keywords—Women's cancers; RNA-Seq; deep learning; molecular tumor; hybrid classification models

I. INTRODUCTION

Today, cancer is the number two mortality globally and the number one mortality in both developed and developing nations. Twenty million new cases of cancer are diagnosed each year, and ten million people die from it. Women account for nine million of these cases and 4.4 million deaths globally each year [1]. According to the World Health Organization, breast cancer will be the most prevalent and deadly cancer in women in 2020, accounting for more than two million new cases and 684,996 deaths annually. Lung cancer is the third most frequent type of cancer in women overall, with roughly 607, 465 deaths and 770, 828 cases every year [1].

Determining the presence of cancer, making a primary diagnosis, and identifying new, more effective treatment options could all aid in reducing mortality and morbidity rates. Genetics, individual lifestyle, body shape, age, menopause status, family history, smoking, and history of exposure to carcinogens or viruses, hormone therapy, chemicals, and other airborne particles are all associated with the occurrence and frequency of women's cancers [2]. One of the most crucial methods to investigate genetic correlations in medical

investigations is transcriptomics by next-generation RNA sequencing (RNA-seq). Large data sets generated by NGS technologies offer a thorough perspective of the human genome [3]. Numerous molecular structures are adopted by nucleic acids, and these designs are crucial for the storage, processing, and transmission of genetic information [4]. DNA molecules are translated to mRNA for the synthesis of proteins. Proteins are the primary factors in the most fundamental cellular processes. The process via which a fragment of DNA is read and then transformed into an addiction to a protein has excessive awareness in several therapeutic analyses in addition to biological ones [5]. The significant aim of cancer disease research is to recognize the genes that cause normal cells to mutate into cancer [6].

Researchers now have access to an unprecedented amount of tumor genomic and transcriptome data thanks to developments in next-generation sequencing methods. A molecule that is reliably tested and assessed as a marker of healthy biological processes, harmful biological processes, or pharmacologic reactions to therapeutic intervention is referred to as a biomarker [7]. Next-generation sequencing (NGS) technologies are used by RNA-Seq. As a crucial tool, RNA sequencing has been used in many aspects of cancer research and therapy, including the identification of biomarkers and the characterization of cancer heterogeneity and evolution, drug resistance, the cancer immune microenvironment, and immunotherapy, among others [8].

It is critical to develop biomarkers for disease progression and potential therapy response, as this will enable personalized care, enhance clinical outcomes, and accomplish the objective of precision oncology [9]. This kind of technology is gathering data from cells and tissues about variations in gene expression [10]. Depending on whether targeted-exome or whole-exome sequencing is utilized, the potential of RNA sequencing resides in the ability to combine the twin characteristics of discovery and quantification in a single high-throughput sequencing, allowing for the simultaneous investigation of thousands of genes [11]. Finding the set of genes that are associated with and highly expressed in many types of tumor cells is one of the difficult issues in the field of cancer classification [12]. Massive gene data sets with few samples are frequently used to represent gene expression data [13]. The large number of ambiguous and redundant features in gene data has been highlighted as adding to the classifiers' complexity challenges.

There are two significant problems with the RNA-Seq gene expression datasets [13]. Due to the high dimensionality of the RNA-Seq datasets, the datasets are extremely complicated and noisy [14]. In these datasets, only a small number of samples were gathered, even though each sample measures the levels of expression of countless thousands of genes [14]. As a result, the learning model will be overfit due to the dimensionality problem and the problems with such a large dataset. Using gene expression analysis, researchers may categorise malignancies, forecast clinical outcomes, and identify biomarkers connected to the disease. The current main hurdle in the cancer diagnosis problem is thought to be the differentiation of normal from malignant tissues, as well as the selection of the few informative genes [15].

In this work proposed RNA-Seq gene expression classification models that are optimised for deep learning and combined with PDA, SVMRadial, GaussprPoly, NB, RF, NN, and the Gmboost Method. The NCBI GEO accessions GSE19804 and GSE70947 were used to download the RNA-Seq gene expression profiles. And extensive packages that make RNA-Seq analysis possible when using Bioconductor and R programming. It has five modules: feature mapper, preprocessing gene expression, dimension transformer, feature selector, deep learning approach, machine predictors with hyper-parameters, and prediction biomarkers with performance evaluation including accuracy, sensitivity, specificity, precision, the F1 score, and the area under the curve (AUC) score.

The contribution of this work can be summarized as follows:

- Using supervised learning and a deep learning algorithm known as a feedforward neural network with hyper-parameters for model optimization,
- For the selection approach, we introduce filter-based selection for dimensionality reduction methods for selection informative genes by applying the FCBF algorithm.
- To determine the dependencies of genes and identify the optimal subset of genes, the enhanced gene selector and feed-forward neural network classifier combined the statistical results of pertinent genes using the symmetrical uncertainty (SU) assessment.
- We adopted further classification. A model that achieves robust classification with little CPU consumption while maintaining accuracy under test conditions is based on hybrid learning models with feedforward neural networks.

The rest of this paper is organized as follows. Section II discussed some of related works, Section III discussed the materials and methods used in this work, and Section IV illustrates the proposed approach, while Section V discusses our results. Finally, Section VI provides conclusion.

II. RELATED WORK

Different related works have been proposed in the era of detection and the diagnosis of human cancer, and in this

section reviews the most recent studies on the use of deep learning and machine learning in the field of malignant tumor gene expression data. Studies on biomarker gene documentation will also be tested. Researchers will be able to evaluate and appraise their suggested analytical methodologies using data on cancer gene expression from the resources they have identified.

Zhang et al. [16], proposed a SVM classifiers based on various features selection to forecast lymphatic metastasis in a range of malignancies. Such classifiers were applied to identify differentially expressed signatures in lymph node metastatic and non-metastatic cancer groups. These SVM classifiers were found to be successful, with an overall accuracy of 81.25% on various profiles with light biomarker sets (seven biomarkers on average). They also contrasted these SVM classifiers with two other benchmark classifiers based on comparable profiles (Random Forest, KNN, and K-Nearest Neighbor, RF).

Han et al. [17], argue that Rao's score statistic is arithmetically appropriate to associate several mechanisms through a typical set of weight factors to yield a biased universal indicator. Next, the weightiness slash statistics measure the purposeful influences of various alteration categories on the target population. Finding cancer-associated genes with mutations that cause the cancer phenotype during cancer genome sequencing is a significant issue for this paper.

Simsek et al. [18], proposed the machine learning classification model for the classification of leukemia subtypes using the gene expression data set from 72 patient records and 7129 gene regions. In the research, machine learning classification techniques such as support vector machines (SVM), linear discriminant analysis (LD), ensemble classifiers (EC), and K-nearest neighbor (KNN) were used. It is evident from experience that the SVM model outperforms the other algorithms despite the fact that the collective test data and collective training data were shared and combined to create a fresh training dataset. Results show that these machine learning models can be helpful in determining the leukemia subtype.

Das et al.'s [19], grouping and classification approach by gene-gene similarity matrix is permeated by the suggested study. The feature selection strategy in this attempt is SVM-RFE. Based on the gene-gene similarity matrix, specific traits are further clustered into several groupings. These pairwise correlation-based clusters use reduction into a smaller set of features for further processing by the neural network, which is required to categorise the various types of cancer.

Yin et al. [20], The CNN-Cox model, which combines a unique CNN framework with prognosis-related feature selection cascaded W_x and has the advantage of fewer computing requests while using light training parameters, has been established as a short and effective survival analysis model. The Cancer Genome Atlas cohort's seven cancer type datasets, including those for head and neck squamous cell carcinoma, bladder carcinoma, brain low-grade glioma, kidney renal cell carcinoma, skin cutaneous melanoma, lung squamous cell carcinoma, and lung adenocarcinoma (LUAD), show that the CNN-Cox model achieved reliable higher C-index values and better survival prediction performance. They demonstrated the use of protein-protein interaction network analysis to

identify potential prognostic genes and further investigated the biological roles of 13 core genes, whose high expression is significantly associated with poor survival in LUAD patients.

Houssein et al. [21], proposed an algorithm to choose the most relevant and instructive genes from cancer microarray datasets. The first goal of this study is to select the most predictive genes, and the second goal is to extract the most accurate gene expression datasets with the least amount of difficulty. The most informative genes are chosen from a tiny, filtered dataset that is collected from the IG feature subset evaluator after filtering out irrelevant and noisy genes and getting their relationships from the datasets using the BMO method with the SVM classifier. To calculate this suggested model's efficiency, four benchmark microarray datasets—namely, Leukemia1, Leukemia2, Lymphoma, and SRBCT—were used.

Vaiyapuri et al. [22], proposed a new Red Fox optimizer for deep learning-supported microarray gene expression classification (RFODL-MGEC). The current RFODL-MGEC model aims to improve classification performance by selecting appropriate features. The RFODL-MGEC model employs a novel feature selection technique based on the red fox optimizer (RFO) with the goal of creating an ideal subset of characteristics. A bidirectional cascaded deep neural network (BCDNN) created for data classification is also part of the RFODL-MGEC model.

Shen et al. [23], report that DCGN, a deep learning method, has been proposed for cancer multi-classification tasks; this model is recommended since it can handle high-dimensional sparse gene expression data better than previous models that have been put out. The DCGN performs well on all five of the examined datasets when it comes to classification evaluation factors like accuracy and precision, especially on the BLCA-TCGA and BLCA-CIT datasets.

Rezaee et al. [24], proposed a hybrid method that assigns rank to the five key genes in the microarray data based on soft ensemble and stacking auto-encoders. The least number of genes needed for final classification was found by combining the three soft wrapper techniques with classification using the k-NN algorithm.

At the conclusion of this section, In this work, we are interested in diseases that affect women, and therefore we strive to provide the latest technologies that help in the early detection of these diseases in order to speed up the treatment process and help doctors take accurate measurements and develop medicines suitable for each disease as Targeted therapies are determined according to the biomarkers for

women's carcinoma that were discovered through powerful learning models suitable to deal with high-dimension RNA-Seq gene expression with hyper-parameters to optimizing the model, so this model in our study gave the best results with performance evaluation of classification models on test datasets for women's cancer.

III. MATERIALS AND METHODS BACKGROUND

A. Women's Cancers RNA-Seq Gene Expression Datasets

Biotechnology National Center Information is a key resource for multi-omics research, including genetic data, and it facilitates the advancement of science and health by making biomedical and genomic information accessible. For example, genome, transcriptome, epigenetic, and proteome information are applied to methodology issues in bioinformatics. Fresh genetic structures (i.e., RNA, DNA, ChIP sequence, whole exome sequencing, protein chips, and amino acid structures) are among the most abundant public raw data in omics and are easily accessible via the following group sequencing tools. The RNA-Seq gene expression profiles used in our investigation were downloaded from the Gene Expression Omnibus (GEO) database, a free public database that included various genes (<https://www.ncbi.nlm.nih.gov/geo/>). Under the accession numbers GSE19804 and GSE70947, the dataset was downloaded. The explanation for each kind of tumor is given in Table I.

B. Methods and Materials

In this section, we examine the various methodologies used for the proposed model.

1) *Feature mapping*: For each row in the gene expression dataset, feature mapping translates the Entrez Gene id to the gene symbol and gene name before using the merging procedure to connect those annotations [25].

2) *Preprocessing*: Combinations of normalization-transformation and the imputation method. Normalization is a crucial step in the interpretation of RNA-Seq data since normalization- transformation combinations are regulated by preprocessing. To enable samples to be evaluated on the same scale, systematic deviations must be identified and corrected [26]. These systematic changes may result from both within-sample variations such as gene length and sequence composition as well as between-sample variations such as library size (sequencing depth) and the presence of majority fragments. Additionally, for data compatibility, transformations are used. In order to handle missing values in gene expression, imputation is utilized.

TABLE I. WOMEN'S CANCERS RNA-SEQ GENE EXPRESSION DATASETS

Accession number	Dataset name	Number of features (genes)	Number of samples	Summary
GSE19804	non-small-cell lung cancer (NSCLC)	54,675 features	120 samples	Even though smoking is the main risk factor for lung cancer, in Taiwan, just 7% of female lung cancer patients had ever smoked, a significantly lower percentage than among Caucasian females. This study provides a thorough examination of the molecular profile of female lung cancer in Taiwan that is not caused by smoking.
GSE70947	breast adenocarcinoma	62,976 features	296 samples	Through accelerating angiogenesis and tissue remodeling in the tumor microenvironment, chronic inflammation aids in the growth and invasion of breast tumors. The intricate interaction between estrogen, which promotes the growth of 70% of breast cancers, and inflammation.

3) *The dimension transformer.* After the RNA-Seq reads have been mapped to a reference genome or transcriptome, the number of reads mapped to the reference genome can be tallied to determine the abundance of the transcripts. For the approaches to be used, it is crucial that the count values be raw sequencing read counts [27].

4) *Feature selector:* The high dimensionality of the dataset is one of the main issues with machine learning [24]. The weighting features reduce processing time and redundant data, boosting algorithm performance because the analysis of several features uses a lot of memory and results in overfitting [20]. The method of eliminating all unnecessary and irrelevant genes while also identifying the most informative genes [28]. Finding the group of genes that are associated and highly expressed in many types of tumor cells is one of the other difficult issues in the field of cancer categorization [29]. Gene expression data is frequently characterized by an enormous amount of gene data and a small number of samples. It has become clear that the abundance of confusing and duplicated features restricted in the gene data adds to the classifiers' difficulty. To improve the accuracy of predictive models, this research proposed FCBF filter-based dimensionality reduction approach as a selection method. Gene prioritization, often known as the finding of biomarkers, is another name for the feature selection method.

5) *Supervised methods:* The cross-validation concept: A method for minimizing bias in the estimation of prediction accuracy is cross-validation [6]. When a classification system is over fitted to a certain dataset, bias might result because the algorithm learns the classification "by heart" but struggles to generalize it to new, untested samples. In a nutshell, the dataset is deterministically divided into a number of training and test sets for cross-validation [18]. Each training set is used to build the model, which is then tested on the test set. Over these fits, the accuracy metrics are averaged. N fits are used in leave-one-out cross-validation, with N training sets of size N-1 and N test sets of size 1. As a result, we employed 10-fold cross-validation to define training control in this study's two

data sets, splitting the data randomly into a test set (30% of the dataset) and a train set (70% of the dataset).

a) *Learning models:* Classification and regression are two examples of supervised learning tasks that attempt to anticipate the intended output based on the input data [30]. For instance, a classification algorithm trained on a dataset of correctly classified genes using supervised learning will learn to recognize diseases. In this study, supervised machine learning algorithms with tuning parameters for the gene expression of women's tumors were incorporated in seven learning models to predict biomarkers.

- Neural Network (NN).
- Support Vector Machines with Radial Basis Function Kernel (SVMRadial).
- Penalized Discriminant Analysis (PDA).
- Naive Bayes (NB).
- Random Forest (RF).
- Gaussian Process with Polynomial Kernel (GaussprPoly).
- Boosted Generalized Linear Model (Glmboost).

b) *Feedforward neural network algorithm (FNN):* An input, multi-hidden, and output hierarchy shape is the Multilayer Perceptron Architecture's most noticeable feature at first glance (Fig. 1). If input data is provided, the output result is computed directly along the subsequent layers of a multilayer perceptron. This type of neural network operating process is referred to as feedforward [31]. A number is obtained as the current output of each neuron in the middle-hidden layer by multiplying the vector-format output results from the previous layer by a weight vector plus a bias value in the current layer, then feeding the biased weighted sum into a nonlinear function (such as a sigmoid, hyperbolic tangent, or rectified linear unit (ReLU), etc.). The feature layer is a new numeric vector made up of enormous neuron outputs in the same hidden layer.

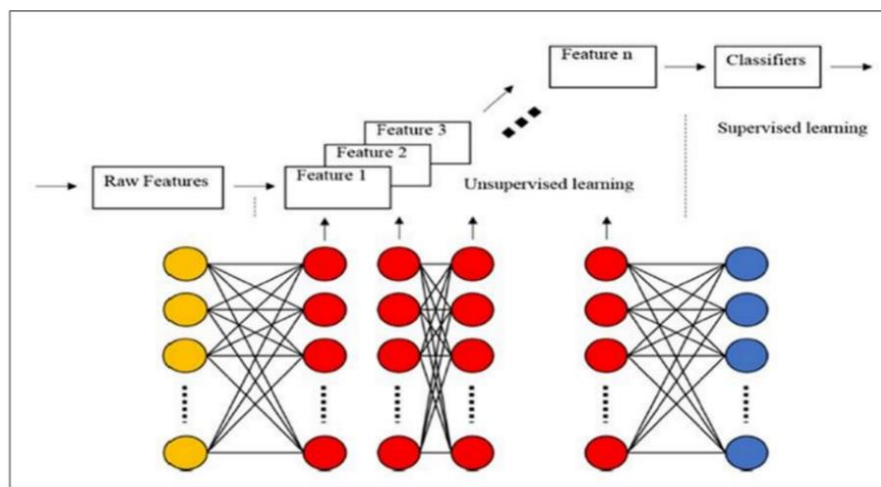

Fig. 1. Multilayer perceptrons architecture.

Evaluation Metrics for Classification Models on test dataset: Several metrics are used to evaluate machine learning approaches. The optimal models are designated using these metrics [30]. To systematically determine the detection effect, the metrics are often used concurrently in our proposed approach as follows:

- Accuracy: A test's accuracy is determined by how well it can distinguish between cancer and healthy instances. Accuracy = $TP+TN/TP+TN+FP+FN$.
- Sensitivity: A test's sensitivity is how well it can identify cancer instances (true positive rate). Sensitivity = $TP / TP + FN$.
- Specificity: A test's specificity is how well it can identify healthy instances (false positive rate). Specificity = $TN / TN + FP$.
- Precision is the ratio of the number of true positive findings to the number of positive results the classifier anticipated. Precision equals $TP / TP + FP$.
- The F1 score is a direct reflection of the model's performance and is used to evaluate test accuracy. The F1 score can vary from 0 to 1, and the objective is to reach as near to 1 as possible.
- Receiver operating characteristic curve (ROC) / area under curve (AUC) score: The performance of the classification model at every threshold is shown graphically by the ROC curve. The entire region below the ROC curve in two dimensions is known as the AUC. Sensitivity and specificity, two crucial parameters, are produced by this curve.

IV. PROPOSED APPROACH

As shown in Fig 2, we employed the RNA-Seq features as the inputs for deep learning-based classification together with other well-known techniques such as PDA, SVMRadial, GaussprPoly, NB, RF, and glmboost to predict biomarkers for women's malignancies.

A. Proposed Approach for Women's Cancers Classification

1) *Feature mapper module*: By using an organism-level package (an "org" package) that employs a central gene identification (such as the Entrez Gene id) and provides mappings between this identifier and other types of identifiers, annotations can be provided in packages curated by Bioconductor (e.g., GenBank or Uniprot accession number, etc.). The number of reads mapped to the reference genome can be tallied to determine the abundance of the transcripts once the RNASeq reads have been mapped to a reference genome or transcriptome. For the approaches to be used, it is crucial that the count values be raw sequencing read counts.

2) *A preprocessing module*: The normalization-transformation combinations are controlled by using transformations for data compatibility for two reasons: Making non-numeric features into numeric features. Since a string cannot be multiplied using a matrix, it must be converted to a representation that is practically numerical. Resizing inputs to a consistent size. For instance, feed-forward neural networks require input data to be a constant size since they have a certain number of input nodes.

Fig. 2. The pipeline of RNA-Seq female cancer data-based machine learning and deep learning workflow development

NAs in this data collection are another problem. That's typical. I'll explain. Without showing log transformations, the expression data have a very wide range, with several outliers in the higher range. However, as log-transformation frequently produces data with negative infinity (-Inf) values or NAs, which are brought on by all the 0-values in the data since $\log_2(0) = -\text{Inf}$, this frequently creates a new issue. As a result, set their NAS value to zero.

Methods used for normalization and transformation: deseq-rlog available in MLSeq package in R programming: Deseq median ratio approach is used for normalization. The normalized data is transformed using a regularized logarithmic formula.

z-Score Normalization (zero-mean Normalization)

3) *FCBF-PCA Feature selector module*: subsequently applied PCA using the FCBF-reduced datasets. While feature selection shrinks the dataset by deleting useless characteristics, dimensionality reduction uses feature extraction to reshape and simplify the data. Use Bioconductor's FCBF (Fast Correlation Based Filter for Feature Selection) to filter highly correlated genes. A multivariate gene selection technique called a fast correlation-based filter (FCBF) begins with a complete collection of characteristics (genes). It determines the optimum subset by calculating the dependencies of the genes using the symmetrical uncertainty (SU) measurement. An effective computer approach called FCBF is used to discriminate between redundant and irrelevant features.

It assesses each property individually, finds the main correlations, and heuristically eliminates superfluous features. When there are no features, it stops due to an internal halting requirement. Implementing FCBF for GSE70947 and GSE19804 datasets seems like 0.1 as a threshold that is reasonable for this both two datasets. After running FCBF for GSE70947, we went from 62976 features to now a lean set of twenty-four features/genes. As can see, EZH2.1 has the strongest correlation to the target class with an SU value of 0.41, and then comes COL10A1.1 with an SU value of 0.40, and so on. As demonstrated, Table II shows the best informative genes and FCBF for GSE19804, we went from 54,675 features to now a lean set of seventy-nine features/genes. As can see, COL10A1 has the strongest correlation to the target class with an SU value of 0.72, and then comes PROM2 with an SU value of 0.68, and so on. As demonstrated, Table III shows the best informative genes

Subsequently, run the FCBF algorithm using a heat map plot to illustrate the gene correlation of the 79 genes for GSE19804 gene expression: Observing the heat map in Fig. 3, we can see the genes are not either positively or negatively correlated with each other as they appear in a lighter color (blue = negative correlation, red = positive correlation). However, there are some that are quite correlated with each other. However, they are quite correlated with each other. For example, HBM, LOC101927069, and PITPNM2.1 are fairly correlated with each other, and H2AFV, KIAA0101, and COL11A1 are quite correlated as well. As shown in Fig. 4,

gene correlation of the 24 genes for GSE70947 gene expression includes EZH2.1, COL10A1.1, and LOC100132724, as well as SDPR, LincRNA.chr2.120459730.120511405_R, and KCNA4.1.

4) *Deep learning for classification module*: The H2O package serves as the foundation for the deep learning technique, and it uses multi-layer neural networks that have been trained using stochastic gradient descent search to forecast the results of diagnoses. To achieve the best classification outcomes for the neural network setup, H2O enables users to conduct hyper parameter grid searches on several deep learning models. Rectifier or Tanh are often the activation functions.

A single hidden layer site (100 or 200 neurons), two discrete layer locations (10, 20 or 50 neurons each), three discrete layers with 30 neurons each, and four discrete layers with 25 neurons each are predefined for assortments. The feed-in dropout ratio options are available in steps of 0.1 from 0 to 0.9.

Typically, there are zero or two total training samples per iteration, where 0 represents one epoch and 2 represents two. The H2O package chooses the automatic value with caution. The maximum number of epochs (iterations) to run the entire dataset is set at 500. Momentum starts out at a value of 0 or 0.5. (Default zero, without hyper-parameter grid search.)

TABLE II. LIST OF SOME OF THE BEST INFORMATIVE GENES FOR GSE70947

gene symbol	SU values
EZH2.1	0.4083618
COL10A1.1	0.4042125
LOC100132724	0.3069758

Fig. 3. Heat map for GSE19804 gene expression.

Fig. 4. Heat map for GSE70947 gene expression.

The momentum quickens the iterations for a quicker concourse or dampens the oscillation to achieve the optimal spot. 0.5 Or 0.99 is the adaptive learning rate decay factor (). (Default 0.99, devoid of hyper-parameter grid search) while simultaneously doing quantile regression, the quantile rate (quantile alpha rate in H2O) is set between 0 and 1. Contrary to linear regression, which tests the answer variable's provisional mean, quantile regression tests the provisional quantile. Between 0 and 1 is set as the threshold between quadratic and

linear loss (Huber alpha rate in H2O) (default 0.9). In order to make it easier to search on entire combinations of the hyper-parameters, the "random discrete" technique is abandoned.

The most extreme number of models for each run is set at 100 as part of the automatic ML training. If the misclassification values do not increase by 0.01 after five iterations, the training phases come to an end. Score duty cycle, which refers to how frequently validation metrics are

computed, is set to 0.025 H2O, which means that no more than 2.5% of the total training time will be spent to create the validation measurements.

Following grid search, the final hyper-parameters for the DL model are listed as follows for the Women's Cancers RNA-Seq dataset: "Rectifier" activation function, four hidden layers with 25 neurons each, insert dropout ratio zero, defaulting training samples each iteration per H2O (value of -2), epoch rate of 430.9, momentum beginning value zero, value of 0.99, quantile regression rate one, and a Huber -value of zero.

Additionally, additional hyper-parameters with an L1 regularization rate of 2.5e-5 and an L2 regularization rate of 2.6e-5 are included. Along with the eleven existing machine learning algorithms that were previously used in H2O for classification, these new DL algorithms are PDA, SVMRadial, GaussprPoly, NB, RF, NN, and glmboost. Based on the data and the size of the sample, to prevent overfitting, N-fold cross-validation with a default N of 10 is feasible. With training data that has been cross-validated 10 times.

To obtain average metrics, we randomly repeated this process ten times. As module number six is illustrated in section VI, bar graphs are used to inform classification metrics such as accuracy, F1 score, area under the curve (AUC) score, precision, sensitivity (SEN), and specificity (SPEC).

V. EXPERIMENT RESULTS AND EVALUATION METRICS WITH TEST DATASET

The proposed architecture was developed using R studio with Bioconductor, with dependencies on the following packages: h2o, dplyr, tidyr, GEOquery, ggplot2, FCBF, pheatmap, devtools, ggbiplot, factoextra, ROCR, limma, psych, caret, foreach, DESeq2, MLSeq, affy, genefilter, hgu133a.db,

AnnotationDbi, org, M3C, matrixTests, impute, and gbm The implementation was carried out on a computer server with a core CPU (Intel(R) Xeon(R) CPU E5-2680 v3 @ 2.50 GHz, 32 GB RAM) and 64-bit operating system, but it may also work on less powerful machines.

The results indicate that the feedforward neural network algorithm is statistically superior in the metric when compared to other algorithms, with an area under the curve score of 0.982 for RNA-Seq breast adenocarcinoma data and 0.980 for RNA-Seq NSCLC cancer data. Whole evaluation metrics are applied to test datasets, as discussed in Table IV.

So, all evaluation metrics achieved higher rates in breast adenocarcinoma data than in NSCLC cancer data, as plotted in Fig 5. By utilizing a feedforward neural network, this suggested model can assist in the early detection and diagnosis of malignancies in women and, consequently, aid in the formulation of preliminary treatment methods to improve survival. Finally, NSCLC and breast adenocarcinoma cancer may be affected by the top ten possible hub-gene biomarker discoveries.

Biomarkers of lung cancer identified by RNA-non-small-cell sequencing as stated in table V, the top seven choices for differentially expressed genes were found to be shared by all methods. All algorithms found COL10A1 as a common factor, indicating that this gene may be important in NSCLC.

As stated in Table V, the top seven choices for differentially expressed genes were found to be shared by all methods. All algorithms found COL10A1 as a common factor, indicating that this gene may be important in NSCLC. As stated in Table VI, the top four choices for differentially expressed genes were found to be shared by all methods.

Evaluation Metrics on test dataset for GSE19804

Fig. 5. Evaluation metrics for GSE70947.

TABLE IV. PERFORMANCE EVALUATION OF CLASSIFICATION MODELS ON TEST DATASET

Women's cancers RNA-Seq gene expression Classification using Deep learning with a hybrid Model with Tuning Parameters for Non-Small-Cell Lung Cancer

TABLE V. THE BIOMARKERS FOR NON-SMALL-CELL LUNG CANCER RNA-SEQ

SYMBOL	GENE name
COL10A1	Collagen Type X Alpha 1 Chain
SH3GL3.1	SH3 Domain Containing GRB2 Like 3, Endophilin A3
GOLM1.1	golgi membrane protein 1
RTKN2	rhotekin 2
EFNA4	ephrin A4
FUT2	fucosyltransferase 2
CLIC5.4	chloride intracellular channel 5

TABLE VI. THE BIOMARKERS FOR BREAST ADENOCARCINOMA RNA-SEQ

SYMBOL	GENE name
EZH2.1	enhancer of zeste 2 polycomb repressive complex 2 subunit
COL10A1.1	collagen type X alpha 1 chain
COL1A1.1	collagen type I alpha 1 chain
CDH1.4	cadherin 1

VI. CONCLUSION

Women's cancers are a group of illnesses exhibiting abnormal cell proliferation that have the potential to attack or spread to various body areas. Due to improvements in efficiency and accuracy, RNA-Seq has previously greatly increased the analysis of human genetics and helped to better understand the nature of cancer disorders. In order to classify two different types of cancer, non-small-cell lung cancer and breast adenocarcinoma, this paper introduced an intelligent

framework based on a feedforward neural network with an optimization model and applied other integrated learning models suitable for gene expression data for women's cancers. The five modules that made up the suggested strategy were: A core gene identification (such as the Entrez Gene id) is used in the first module, "Feature mapping," which applies an organism-level package (an "org" package) and which contains mappings between this identifier and other types of identifiers (e.g., GenBank or Uniport accession number, etc.). Preprocessing is covered in the second module. The deseq-rlog approach and z-score Normalization and transformation are

two techniques used for normalization and transformation. The dimension transformer is the third module. After the RNA-Seq reads have been mapped to a reference genome or transcriptome, the number of reads mapped to the reference genome can be tallied to determine the abundance of the transcripts. For the approaches to be used, it is crucial that the count values be raw sequencing read counts.

The feature selector module, is the fourth module. The fast correlation-based filter (FCBF) was chosen as the method for feature selection in this framework. A deep learning technique, machine predictors with hyper-parameters, and prediction biomarkers with hyper-parameters comprise the final module. Accuracy, sensitivity, specificity, precision, the F1 score, and the area under the curve (AUC) score are among the performance evaluation metrics. Given that the results show that the feedforward neural network approach has an area under the curve score of 0.982 for RNA-Seq breast adenocarcinoma data and 0.980 for RNA-Seq NSCLC cancer data, it is statistically considerably superior to other algorithms in the measure.

Transfer Learning for Closed Domain Question Answering in COVID-19

Nur Rachmawati, Evi Yulianti

Faculty of Computer Science, Universitas Indonesia, Depok, Indonesia

Abstract—COVID-19 has been a popular issue around 2019 until today. Recently, there has been a lot of research being conducted to utilize a big amount of data discussing about COVID-19. In this work, we conduct a closed domain question answering (CDQA) task in COVID-19 using transfer learning technique. The transfer learning technique is adopted because a large benchmark for question answering about COVID-19 is still unavailable. Therefore, rich knowledge learned from a large benchmark of open domain QA are utilized using transfer learning to improve the performance of our CDQA system. We use retriever-reader framework for our CDQA system, and propose to use Sequential Dependence Model (SDM) as our retriever component to enhance the effectiveness of the system. Our result shows that the use of SDM retriever can improve the F-1 score of the state-of-the-art baseline CDQA system using BM25 and TF-IDF+cosine similarity retriever by 3,26% and 32,62%, respectively. The optimal parameter settings for our CDQA system are found to be as follows: using 20 top-ranked documents as the retriever's output, five sentences as the passage length, and BERT-Large-Uncased model as the reader. In this optimal parameter setting, SDM retriever can improve the F-1 score of the state-of-the-art baseline CDQA system using BM25 by 5,06 % and TF-IDF+cosine similarity retriever by 24,94 %. Our last experiment then confirms the merit of using transfer learning, since our best-performing model (double fine-tune SQuAD and COVID-QA) is shown to gain eight times higher accuracy than the baseline method without using transfer learning. Further fine-tuning the transfer learning model using closed domain dataset (COVID-QA) can increase the accuracy of the transfer learning model that only fine-tuning with SQuAD by 27, 26%.

Keywords—COVID-19; closed domain question answering; sequential dependence model; transfer learning; BERT

I. INTRODUCTION

Corona virus disease 2019, known as COVID-19, has been a popular topic in recent period, from 2019 until today. COVID-19 can cause severe respiratory disease in humans [1]. This disease initially came from Wuhan city in China, and was detected for the first time on December 29, 2019 [2]–[4].

In this COVID-19 pandemic, obtaining information about COVID-19 is really necessary. A specific question answering (QA) system on COVID-19, referred to as closed domain question answering (CDQA) system, is beneficial to provide direct answers to many questions that may arise related with COVID-19 issue. This system will be useful for health practitioners as well as public in general to have deeper knowledge on COVID-19. This motivates us to implement a

question answering system on specific COVID-19 topic in this study.

To build an effective CDQA system in COVID-19 using state-of-the-art deep learning approach, a large benchmark consisting of pairs of questions and answers together with a huge collection of documents about COVID-19 issue, is needed. A previous research has built CORD-19 dataset which includes a collection of one million articles about COVID-19 [5]. However, a large number of pairs of questions and answers about COVID-19 from that data are still unavailable to train a deep learning-based QA model. A previous work has paid some attention to this matter and put some effort to build 2019 question-answer pairs in COVID-QA dataset [6]. This number, however, is still relatively low to learn a deep learning-based QA model from scratch.

To tackle the above problem, we adopt transfer learning technique to build more effective CDQA system in COVID-19. Transfer learning is commonly used to make use of knowledge extracted from high-resource data to solve the task on the low-resource data. It becomes our intuition to use transfer learning for our case of low resource COVID-19 QA benchmark. Transfer learning approach enables us to exploit rich knowledge learned from an available large benchmark of open domain QA system, i.e., SQuAD dataset [7] to extract answers about COVID-9 topic from low-resource closed domain COVID-19 dataset, i.e., CORD-19 [5].

Some research has used transfer learning method to build CDQA system [8] [9]. Alzubi et al. [8] and Yang et al. [9] both implemented CDQA system using dual architecture (retriever-reader system) and transfer learning principle. Here, retriever component will find subset of relevant documents, and reader component trained on high-resource data will find the span of text from those documents as the answer to the given question. In this work, we aim to improve the accuracy of CDQA system of Alzubi et al. [8] and Yang et al. [9] by enhancing the retriever component of CDQA system. By improving the accuracy of retriever, it will result in the increasing the accuracy of the reader in extracting answers. While Alzubi et al. [8] and Yang et al. [9] used TF-IDF vectorizer with cosine similarity, and BM25, respectively, as their retriever, we propose to use Sequential Dependence Model [10] as the retriever component in the CDQA system. Here, the retriever model of Alzubi et al. [8] and Yang et al. [9] will be changed to the CDQA systems. Our intuition in using SDM is because it optimizes the scoring functions of documents by modelling question term dependencies, which therefore can capture different variations of question terms in the documents. While many previous work has demonstrated the effectiveness of this

model for an ad-hoc retrieval [10]–[12], to the best of our knowledge, none of previous studies have investigated the use of SDM for QA system, more specifically dual architecture CDQA system. This becomes a research gap that is fulfilled by this work.

In this paper, there is some following research question (RQ) that has been investigated:

RQ1: Does the use of SDM as retriever in the retriever-reader architecture improve the performance of state-of-the-art transfer-learning-based CDQA systems in COVID-19 using TF-IDF+cosine and BM25 retriever?

RQ2: What are the effects of tuning some parameters (top n retrieved documents, passage length, and reader variations) on the accuracy of CDQA system in COVID-19? What are the optimal parameter settings for our system?

RQ3: To what extent the use of transfer learning technique using SDM as retriever in reader-retriever architecture can improve the CDQA system in COVID-19 that does not use transfer learning technique?

Our contribution in this work are as follows: (1) we propose to use Sequential Dependence Model as retriever in retriever-reader architecture of CDQA system in COVID-19; (2) we conduct empirical evaluation on the effectiveness of our proposed method compared to the state-of-the-art CDQA method used by Alzubi et al. [6] and Yang et al. [9]; we also perform evaluation to show the merit of using transfer learning technique by comparing our method with the method that does not use transfer learning.

The rest of this paper is organized as follows. Section II describes about the related works. Section III explains our research methodology such as the dual architecture of our CDQA system, dataset, and baseline methods. Section IV and V presents our experiment details and results. Section VI discusses about the limitation and the challenges of this work. Finally, Section VII concludes this study and answers all research questions outlined above.

II. RELATED WORK

A. Closed Domain Question Answering (CDQA)

Question Answering is a system that is used to answer the question given by users. The input to the system is a question and a list of documents. The system tries to find the answer by finding the start/end positions where the answer is located within the text. Question answering can be divided into two parts: closed domain and open domain. Closed domain question answering (CDQA) is a question answering system that has ability in answering questions regarding the specific domain by exploiting mainly domain-specific knowledge [8]. An example of this closed domain question answering is COBERT implemented by Alzubi et al. [8]. They used a specific domain of COVID-19 when building such CDQA system. Meanwhile, open domain question answering is a question answering system that has an ability to answer questions about any domains and rely on general ontology and world knowledge [10]. In open domain question answering, they often use Wikipedia as the unique knowledge source when looking for answers [13]. An example of this open domain

question answering is DrQa [13]. In this paper, our work focus is on building CDQA system in COVID-19 domain.

B. Machine Reading Task for Question Answering

Machine reading task for question answering has been accelerated in recent years. This technique is about how machines can read and learn from articles that have been given to the QA system. Some dataset has been built for this machine reading text such as SQuAD [7], WikiQA [14], CoQA [15], QACNN [16], etc.

Some previous researches have paid attention about this topic. DrQA has been built for open domain question answering using a retriever-reader architecture. The retriever is a module using bigram hashing and TF-IDF matching that will retrieve relevant articles from Wikipedia. Then, the reader is RNN model that detects answer spans from the relevant documents. In general, DrQA pipeline combines bigram hashing with TF-IDF matching retriever and bidirectional RNN paragraph reader [13].

Some recent methods have utilized BERT for question answering, as a result of the effectiveness of BERT that has been shown in various text processing tasks in previous work [17], [18]. Alzubi et al. [8] proposed COBERT, COVID-19 Question Answering System Using BERT. The system uses a retriever-reader architecture and COVID-19 dataset [5] as the input. They used TF-IDF vectorizer with cosine similarity, implemented using scikit-learn [19] tool, to get the top N most relevant documents. These documents are then split into passages to be inputted into the reader. The reader used BERT model that was fine-tuned with SQuAD dataset [7] to identify the answer spans based on the final score. These answers were then ranked based on this score.

Yang et al. [9] proposed end-to-end open domain question answering with BERTserini, a combining BERT with Anserini toolkit. With the Wikipedia article and SQuAD dataset [7] as the input, BERTserini tried to use dual architecture (retriever-reader). In retriever, they used Anserini IR toolkit with BM25 [20]. The retriever will retrieve a set of documents and produce a set of text segments (passages) to be inputted into the reader. They used BERT reader that has been fine-tuned with SQuAD dataset [7] to identify the answer span. The system was shown to outperform the DrQA system [13]. Nogueira et al. [21] also adopted BM25 and BERT model to perform passage / answer retrieval.

Semnani et al. [22] proposed Mindstone, a domain-specific question answering system using Wikipedia and Snowflake text corpora. In the Mindstone pipeline, there are three components: retriever, ranker, and reader. In retriever, they used Anserini based on Lucene version 8.0, and Okapi BM25. Then, Neural RM3 (Relevance based language models) is used as ranker to expand the query and re-rank the documents based on the new score given by the ranker. For reader, they used BERT-base model to rank the retrieved answers. The system outperformed the BERTserini system in terms of EM (Exact Match) dan F1-scores.

In this paper, we use retriever-reader architecture in machine reading task for question answering, similar to Alzubi et al. [8] and Yang et al. [9]. However, we use different

retriever using Sequential Dependence Model (SDM) to improve the performance of CDQA system.

C. Transfer Learning

Transfer learning is a method using machine learning / deep learning that is commonly used to improve the performance on low-resource tasks. Transfer learning describes the learning schemes when information in source task is used to achieve some improvement in target task performance [23].

Some previous researches on question answering system used this method. Akdemir et al. [24] proposed transfer learning for Biomedical Question Answering. They used this method because available datasets in biomedical question answering are limited. Therefore, with transfer learning schema, they want to transfer information learned in high-resource tasks which is a similar domain with the source task, into a low-resource target task. They hope by applying transfer learning can improve the performance on their question answering system. Other research that used transfer learning method is Syed et al. [25]. They used transfer learning by using SQuAD dataset [7] to fine-tune the question answering system. Alzubi et al. [8] also used transfer learning method to build closed domain question answering system in COVID-19. They used transfer learning because available dataset in COVID-19 question answering is still limited. In this paper, transfer learning method will be used too. It is the same approach with Alzubi et al. [8] and Yang et al. by utilizing SQuAD [7] dataset to fine-tune the reader component of our CDQA system. However, we propose to replace the retriever component of Alzubi et al. and Yang et al. with SDM (Sequential Dependence Model) that has been shown to achieve satisfactory results in previous work on document ranking [10]–[12].

III. METHODOLOGY

A. System Architecture

In this work, we use dual architecture (retriever-reader) of question answering system similar to Alzubi et al. [8] and Yang et al. [9]. The difference is that the architecture does not use TF-IDF vectorizer or BM25 as retriever. We implement SDM (Sequential Dependence Model) as retriever using PyTerrier tool [26]. Fig. 1 illustrates the architecture of our system. Initially, the collection of COVID-19 articles, COVID-19, are preprocessed, and then indexed using PyTerrier. The retriever is implemented using SDM and the reader is implemented using BERT model that was fine-tuned using SQuAD dataset. The flow of the process in our system is as follows: Given a question input, the SDM retriever will retrieve a top-N relevant documents that further will be split into passages. These passages will be inputted into the reader that will extract the answers from the passages and rank them to generate the ranked list of answers.

1) *Retriever system*: Sequential dependence model (SDM) was proposed by Metzler et al. [10] to optimize the document scoring function by including proximity in the query based on the occurrences of single terms, ordered phrases, and unordered phrases. The SDM method has an assumption that all pairs of sequential terms extracted from the query are dependent [27]. It assumes that the occurrences of adjacent query terms are related.

$$score_{SDM}(Q, D) = \lambda_T \sum_{q_i, q_{i+1}}^{|Q|-1} f_T(q, D) + \lambda_O \sum_{i=1}^{|Q|-1} f_O(q_i, q_i + 1, D) + \lambda_U \sum_{i=1}^{|Q|-1} f_U(q_i, q_i + 1, D) \quad (1)$$

Fig. 1. Architecture System.

The SDM scoring function is described in Eq 1. Given a query Q, the function will calculate the SDM score for each document D in the collection. There are three types of features in SDM: single term features which are standard unigram language model features (fT), exact ordered phrase features which are words appearing in sequence (fO), and unordered window features which require words to be close together, but not necessarily in an exact sequence order (fU) [28]. fT, fO, fU are term frequency for the respective features, and λT , λO , λU are weight of the respective features.

System will rank documents in the collection based on the result of SDM scoring function, and top-n documents will be retrieved. We further split each of these documents into passages and choose eight sentences as the passage length, following the setting used by Alzubi et al. [8].

2) *Reader system*: The reader system receives a set of passages from top-n documents retrieved by the retriever system. There are three model used as the reader. They are BERT-base-uncased, BERT-large uncased, and BERT-large-word-whole-masking.

- **BERT-base-uncased**: BERT-base-uncased is variation of BERT, a transformers model pretrained on a large corpus of English language [29], using base and uncased version. Uncased means that it does not make any difference between lowercase and uppercase.
- **BERT-large-uncased**: BERT-large-uncased is another variant from BERT using large and uncased version. This model was pretrained using higher number of parameters and attention heads than base version of BERT model as a result of using a higher number of encoder layers. BERT-base has 12 encoder layers and 768 hidden layers with 12 attention heads and 110 million parameters. On the other hand, BERT-large has 24 encoder layers and 1024 hidden layers with 16 attention heads with 340 million parameters [11].

The architecture of the single encoder from BERT can be seen from Fig. 2. We can see that the architecture of single encoder consist of input embedding, positional encoding, and N block encoder. In input encoding, word will be converted into vector with some steps: tokenization, numericalization and word embedding generation. After converting into vector, the next part is positional encoding. In this part, it will add positional information. Then, the data will go through N encoder blocks in iterative process. This process will capturing more complex relationships between words in the input sequence.

- **BERT-large-uncased-whole-word-masking**: BERT-large-uncased-whole-word-masking is another BERT version which was pretrained using new technique, called as ‘whole word masking’ [29]. In this technique, all tokens that are associated with a word will be masked only at once. Meanwhile, for the overall masking rate will remain the same.

The reader component in our CDQA system is each of the BERT model above that is fine-tuned with SQuAD version 1.1 [7]. The CDQA tool is used to fine-tuned the reader. To fine-tune the reader, every document passage will be paired with the query and be transformed into BERT format. Then, the reader will be calculated start logit score and end logit score from every word based model. The logit score itself is the logarithm of the odds from $p/(1-p)$ where p is the probability. Then, the start index is determined based on the start logit value and end index based on end logit value. Once found, predictions are taken based on the start index and end index.

Predictions are taken with several criteria: predictions cannot exceed the maximum answer length, the start index cannot exceed the end index, and some other criteria. Then reader will determine the probability value of each prediction by calculating the softmax function. After that, the results are issued in the form of a tuple by giving three best answer and the order of the answers based on final score. Final score is calculated from retriever score and reader average of start and end logits.

B. Dataset

Table I summarizes all dataset used in this work. In general, there are three datasets utilized in our experiment: SquAD (Stanford Question Answering Dataset) version 1.1, CORD-19 (COVID-19 Open Resource Dataset), and COVID-QA (Question Answering Dataset for COVID-19).

Fig. 2. Architecture from Single Encoder.

TABLE I. STATISTIC DATASET

Dataset	Total Documents	Total Question-Answer Pairs	Topic
SQuAD v.1.1	442	87.599	Open domain
CORD-19	368.618	-	COVID-19 (closed domain)
COVID-QA	147 scientific articles in CORD-19.	2.019	COVID-19 (closed domain)

In order to do transfer learning in our CDQA system, we use SQuAD dataset version 1.1. (SQuAD) as an auxiliary resource. SQuAD will be fine-tune to our reader system in BERT model. SQuAD itself is a reading comprehension dataset. This dataset consists of questions that have been posed by crowd workers from Wikipedia articles. The answer of every question in this dataset can be as a segment of text / span from the corresponding reading passage. This dataset contains over 100.000 question-answer pairs on over 500 articles [7]. This dataset split into training set, development set, and test set. But in this work, we just use training set to fine-tune the reader. So, the squad dataset that we use is 87.599 question-answer pairs on 442 articles. This dataset can be downloaded from <https://raw.githubusercontent.com/rajpurkar/SQuAD-explorer/master/dataset/train-v1.1.json>.

CORD-19 dataset use as input in this work. CORD-19 will be indexed by our retriever in order to produce document ranking for every given question to our CDQA system. This dataset is a collection of articles/academic paper in COVID-19, SARS-CoV-2, and related coronaviruses. This dataset was collected by the Semantic Scholar team at the Allen Institute for AI. This dataset consists of over 1,000,000 scholarly articles [5]. But in this research we use 368.618 document that contain the fulltext. This dataset can be downloaded from <https://huggingface.co/datasets/cord19>.

For evaluation part, COVID-QA dataset [6] will be used because it contains question-answer pairs from the CORD-19 dataset [5] that can provide ground truth answers for the questions. All of COVID-QA dataset will be used to evaluate our CDQA system with the baseline. We also use this dataset to evaluate the effectiveness of transfer learning by split this dataset into 70% for fine-tuning and 30% for evaluation. COVID-QA dataset itself consist of 2.019 question-answer pairs. This dataset annotated by volunteer biomedical experts. They selected 147 scientific articles that mostly correlated with COVID-19 from dataset CORD-19 when building this dataset [6]. This dataset can be download in <https://github.com/deepset-ai/COVID-QA>.

C. Baselines

Three baselines will be used to test the effectiveness of our CDQA system:

- COBERT (TF-IDF+Cosine+BERT) [8]: COBERT [8] is a closed domain question answering that uses TF-IDF Vectorizer with cosine similarity as retriever in order to get top N documents that are related to query.
- BM25+BERT [9]: This baseline uses BM25[9] [20] as retriever to retrieve top N documents that are related to query.
- DLM+BERT: This baseline use Dirichlet Language Model [30], [31] as Retriever to retrieve top n documents that are related to query.

All the above baselines using retriever-reader architecture of CDQA system. They all use BERT model that are finetuned using SQuAD dataset. They only differ in terms of the method used in the retriever component. After the top N documents are split into passages (with the size of passages is eight sentence),

the reader then predict / extract answers from the passages and rank them as the results.

IV. EXPERIMENT

A. Pre-processing

In the indexing process using PyTerrier, we do some pre-processing in CORD-19 dataset, such as: removing some punctuation, removing stopwords, and lowercasing the text. Then the next process is replacing multiple space into a single space.

B. Hardware

In this work, Google Colab Pro + is used as the machine. This machine use 1 GPU with Tesla T4 type running on CUDA 11.2. Because of technical issue, when doing evaluation part, we move to DGX-1, machine from Tokopedia AI Centre, Universitas Indonesia. It uses 1 GPU with Tesla V100.

C. Finetuning Process

The next process is fine-tuning the reader component based on pretrained language model BERT. Here, BERT-base-uncased, BERT Large Uncased, and BERT-large-uncased-word-whole-masking models are fine-tuned on open domain QA dataset, i.e., SQuAD dataset version 1.1. The hyperparameter that is used to finetune the reader can be seen in Table II.

TABLE II. HYPERPARAMETER TO FINE-TUNE READER

Hyperparameter	Rincian
Training_batch_size	4
Learning_rate	3e-5
Num_train_epoch	1
Optimizer	adamw
Max_seq_length	384
Max_query_length	64
Gradient_acumulation_step	3
Doc_stride	128

The resulting models are then used to extract and rank answers in closed domain dataset about COVID-19, i.e., CORD-19. By conducting this process, the transfer learning approach is applied by utilizing knowledge learned from large open domain QA dataset to solve the closed domain QA task.

D. Evaluation Metric

In evaluation part, there are two metrics that will be used. They are exact match and F1-score. Exact Match (EM) measures if a resulting answer is exactly similar to the ground truth answer. The score will be 1 if the predicted answer similar with ground truth. Otherwise, the score will be 0.

F1 score is more general metric, that combine together the precision and recall scores. Precision is the ratio that is calculated by the number of the shared words to the total number of words in the prediction. While recall is the ratio that is calculated by the number of shared words to the total number of words in the ground truth. To calculate F1-score, we use the Eq. below (2).

$$F_1 = \frac{2}{\text{recall}^{-1} + \text{precision}^{-1}} = 2x \frac{\text{precision} \cdot \text{recall}}{\text{precision} + \text{recall}} \quad (2)$$

V. RESULT

A. The Effectiveness of SDM as Retriever in Transfer-Learning-based CDQA System

In the evaluation part, we compare our system with three transfer-learning-based CDQA systems that use retriever-reader architecture as baselines. They are TF-IDF+Cosine+BERT that has been proposed by Alzubi et al. [8], BM25+BERT that has been proposed by Yang et al. [9], and DLM+BERT. Table III shows the comparison of the EM and F1-scores of our method against all baseline methods. The models presented in the table using top 10 document as the retriever output and eight sentences as the passage length.

Our result in Table III show that the use of SDM retriever can improve the F-1 score of the state-of-the-art baseline CDQA system using DLM, BM25 and TF-IDF+Cosine similarity retriever by 3,26% , 3,26% and 32,62%, respectively. Besides, there is improving in EM score when using SDM retriever. SDM retriever can improve EM by 63,06 % for TF-IDF+Cosine similarity, 2,96% for DLM and BM25. From the result, it turns out that our CDQA system using SDM retriever outperforms all baseline methods. It related with how SDM work. SDM uses various query representations by rewriting each input query in close proximity so that results will be more accurate.

We also explore the answer from two question from all retriever randomly based on Table III in Table IV.

Table IV shows us that one of three answers from SDM retriever and BM25 retriever close to the ground truth both of two questions. Because of that, their F-1 score and EM become one. While, DLM gets the third position, because DLM gets wrong in all answer in first question but true in next question because one of the answer is close to ground truth. While TF-IDF+Cosine similarity gets the bad result in both of two question because EM Score and F1-score is 0. This cases show us that our SDM retriever is better than TF-IDF+Cosine similarity practically.

B. The Effect of Tuning the Top N Retrieved Documents, Passage Length, and Reader Variations on the Effectiveness of CDQA System

Table III shows us that SDM becomes the best model among others. Because of that, we try to explore some variation analysis in SDM retriever.

1) *Top n document variation:* We vary SDM retriever with reader bert based uncased with retriever setting: top five document, top 10 and top 20 document.

Table V shows us that if SDM-BERT-base-uncased sets in top 10 document, it will improve the Top5-SDM-BERT-base-uncased by 10,73% in EM and 3,53% in F-1 score. Then, changing top n document into 20 document can improve Top 5-SDM-BERT-base-uncased by 21,46% in EM and 9,55% in F-1 score. In conclude, setting parameter into top 20 document will make CDQA system become the best result among others.

TABLE III. EVALUATION ON TOP 10 DOCUMENT IN COVID-QA.

Model	EM (%)	F1 Score (%)
Top10-TF-IDF+Cosine-BERT-based-uncased	5.35	17.66
Top10-DLM-BERT-base-uncased	8.42	22.68
Top10-BM25-BERT-base-uncased	8.42	22.68
Top10-SDM-BERT-base-uncased (ours)	8.67	23.42

TABLE IV. EVALUATION IN TWO QUESTIONS IN TOP 10 DOCUMENT IN COVID-QA

No.	Question			
1.	Question	What is the most common species of Human Coronavirus among adults?		
	Answer (Ground Truth)	HCoV-OC43		
	Method	3 Answer	EM	F1-score
	Top10-TF-IDF+Cosine-BERT-base-uncased	<ul style="list-style-type: none"> • bats, • obesity • Measles 	0	0
	Top10-DLM-BERT-base-uncased	<ul style="list-style-type: none"> • Bats • bats • Rotaviruses 	0	0
	Top10-BM25-BERT-base-uncased	<ul style="list-style-type: none"> • Rhinovirus • HCoV-OC43 • HCoV-229E 	1	1
2.	Question	What is a natural reservoir of coronavirus?		
	Answer (Ground Truth)	Bats		
	Method	3 Answer	EM	F1 score
	Top10-TF-IDF+Cosine-Bert Based Uncased	<ul style="list-style-type: none"> • Host Cell Receptor GRP78 • largemouth bass Micropterus salmoides • These reservoirs are located in east Texas 	0	0
	Top10-DLM-Bert Based Uncased	<ul style="list-style-type: none"> • bats • sooty mangabeys • Wild rodents 	1	1
	Top10-BM25-Bert Based Uncased	<ul style="list-style-type: none"> • bats • sooty mangabeys • Chinese horseshoe bats are considered to be the natural reservoirs of SARS-CoV. MERS-CoV 	1	1
Top10-SDM-Bert Based Uncased (ours)	<ul style="list-style-type: none"> • bats • SARS-CoV • one or more of them may serve as the natural reservoir of SARS-CoV and/or its progenitor virus 	1	1	

TABLE V. EVALUATION ON TOP N DOCUMENT VARIATION IN COVID-QA

Model	EM (%)	F1 Score (%)
Top5-SDM-BERT-base-uncased	7,83	22,62
Top10-SDM-BERT-base-uncased	8,67	23,42
Top20-SDM-BERT-base-uncased	9,51	24,78

2) *Passage length variation:* In Table III, IV and V, we set passage length to eight sentence in every passage based on Alzubi et al. [8] that used eight sentence too. Then, we think about making a deep analysis with some variation of passage length.

Table VI shows us that our CDQA system will get the bad result if the passage length sets under five sentence: one sentence (7,92 for EM and 21,10 for F1-score), three sentence (8,77 for EM and 23,40 for F1-score). It also get the bad result if the passage length sets upper five sentence: eight sentence (8,67 for EM and 23,42 for F1-score), 10 sentence (7,63 for EM and 22,16 for F1-score). So, we can see from Table V that the best passage length is five sentence with 8,77 EM and 23,45 F1-score.

3) *Reader variation:* We also vary the reader with some models. They are BERT base uncased, BERT large uncased, and BERT large uncased word whole masking in Table VII.

Table VII shows us that the reader with BERT large uncased gets the best result among others. It improves BERT based uncased by 9,68% in EM and 2% in F-1 score. It also improves BERT large uncased whole word masking by 5,55% in EM and 1,01% in F-1 score.

From the above variation, we conclude that the optimal parameters in our CDQA system is retriever with Sequential Dependence Model that uses the top 20 document when retrieved, having passage length five sentence, and having BERT Large Uncased for the reader. Because of that, we try to set all the retriever methods with the optimal parameter in Table VIII.

Table VIII shows us that by optimal parameter in all of the retrievers (top 20 documents as the retriever results, five sentences as the passage length, and BERT-large as the reader model) our CDQA system outperform the baselines by 37,28% in EM and 24,94% in F-1 score for TF-IDF+Cosine similarity retriever, 5,59% in EM and 4,67% in F-1 score for DLM retriever, and 5,59% in EM and 5,06% in F-1 score for BM25 retriever.

Our CDQA system with SDM retriever with the optimal parameter achieves 10,20 for EM and 24,90 for F1-score. This value is better than SDM retriever in another parameter setting before in Table III, V, VI, and VII.

C. Transfer Learning Versus Non-transfer Learning

We also think that what is the effect of using transfer learning, with the reader retriever (SDM) method for building closed domain question answering, compared to non-transfer learning method. To answer this, we do some work. Different with experiment in Table II, III, V, VI, VII, and VIII that use all COVID-QA for evaluation part. In this experiment, COVID-QA will be split into 70% for fine-tuning and 30% for evaluation. In this experiment, the configuration in the model with the optimal parameter in our closed domain question answering from Table VIII (Top20-SDM-BERT Large Uncased-5 Sentence) will be used. We compare how if the CDQA system use a transfer learning method where the question answering system is fine-tuned with another dataset, such as SQuAD. Then, how if the CDQA system is fine-tuned

again with COVID-QA after fine-tuning with SQuAD, and how if the CDQA system is fine-tuned without transfer learning method, that is fine-tuned to COVID-QA only. Table IX will show some experiments about comparing the CDQA system between transfer learning and non-transfer learning.

TABLE VI. EVALUATION ON PASSAGE LENGTH VARIATION IN COVID-QA

Model	EM (%)	F1 Score (%)
Top10-SDM-BERT-base-uncased-1 sentence	7,92	21,10
Top10-SDM-BERT-base-uncased-3 sentence	8,77	23,40
Top10-SDM-BERT-base-uncased-5 sentence	8,77	23,45
Top10-SDM-BERT-base-uncased-8 sentence	8,67	23,42
Top10-SDM-BERT-base-uncased-10 sentence	7,63	22,16

TABLE VII. EVALUATION ON READER VARIATION IN COVID-QA

Model	EM (%)	F1 Score (%)
Top10-SDM-BERT-base-uncased	8,67	23,42
Top10-SDM-BERT Large Uncased Word Whole Masking	9,01	23,65
Top10-SDM-BERT Large Uncased	9,51	23,89

TABLE VIII. EVALUATION ON THE OPTIMAL PARAMETER IN COVID-QA

Model	EM (%)	F1 Score (%)
Top20-TF-IDF+Cosine-BERT Large Uncased-5Sentence	7,43	19,93
Top20-DLM-BERT Large Uncased-5Sentence	9,66	23,79
Top20-BM25-BERT Large Uncased-5Sentence	9,66	23,70
Top20-SDM-BERT Large Uncased-5Sentence	10,20	24,90

TABLE IX. EVALUATION ON TRANSFER LEARNING AND NON-TRANSFER LEARNING METHOD IN 30% COVID-QA

Model	EM (%)	F1 Score (%)
Top 20-SDM-BERT Large Uncased-5 Sentence-Fine-tuned to CovidQA (Non-transfer learning)	0,0	3,20
Top 20-SDM-BERT Large Uncased-5 Sentence-Fine-tuned to SQuAD (transfer learning)	6,44	23,29
Top 20-SDM-BERT Large Uncased-5 Sentence-Double Fine-tuned(SQuAD+COVID-QA) (transfer learning fine-tuned to COVID-QA)	10,07	29,64

Table IX shows us that models that use transfer learning are better than models that use non-transfer learning method. Models that use transfer learning try to mitigate question answering system that has low resource question-answering dataset by transferring information from auxiliary dataset to improve their performance. It is especially useful for low-resource tasks such as our closed domain question answering in COVID-19. Models that use non-transfer learning, where the reader is fine-tuned to COVID-QA, achieve bad results. It gets 0.0 in EM and 3,20 in F1-score. It looks like this model becomes underfitting because the question-answer pair dataset

in COVID-QA train is too small. All of us know that SQuAD has 87599 question-answer pairs, while COVID-QA has only 2019 question-answer pair. Then for fine-tuning, 1413 question-answer pair has been used. The amount of the dataset makes the model unable to learn. If COVID-QA dataset as big as SQuAD may be the model will be better.

Because there is no dataset question-answer pair in COVID-19, our work tries to use transfer learning method. Table IX shows two model that use transfer learning. First is a model that reader is fine-tuned to SQuAD only. The second is a model that reader is fine-tuned to SQuAD and fine-tuned again with COVID-QA. We do the double fine-tuned based on Yang et al. [32]. They said that fine-tuning again question answering system will make improvement to the model.

Table IX shows us that our system that use transfer learning (fine-tune to SQuAD) improves the effectiveness of non-transfer learning method with six times higher accuracy than the baseline method without using transfer learning. Further fine-tuning again the reader model that has fine-tuned before with SQuAD into closed domain dataset (COVID-QA) can increase the accuracy of the model by 27,26 % in F-1 score and improve F-1 score of non-transfer learning method with eight times higher. From this result, we can say that transfer learning method will get better result than non-transfer learning when resource of dataset question-answer pair itself is small.

VI. DISCUSSION

Our experimental results show that transfer learning can give a significant improvement to the CDQA system that does not use transfer learning. The transfer learning model gains eight times higher accuracy than the method without using transfer learning. When the model is further fine-tuned with close domain dataset CDQA, the accuracy increased by 27,26%. This accuracy can further increase when a bigger CDQA dataset is available for fine-tuning. Therefore, creating a bigger CDQA dataset will become a research challenge in this case.

This research also has some limitation in terms of the variation of parameters explored in the experiment. For example, for the number of documents retrieved by retriever, we only experimented until 20 documents retrieved for each question. Then, for the length of passages, we only experimented until 10-sentences length for each passage. This restriction is related with the availability of GPU computing resource that is limited, while our model in general requires high computing resource. From this reason, we limit the variation of parameters in our experiment when fine-tuning the reader component. When a higher GPU is available, it may worth experimenting with more parameter values in our system. We can investigate, for example, whether retrieving more than 20 documents may further increase the performance of CDQA system.

VII. CONCLUSION

This paper explores the use of transfer learning technique to build close-domain question answering (CDQA) system in COVID-19. We propose to use Sequential Dependence Model (SDM) as retriever in the retriever-reader architecture to improve the accuracy of CDQA system. Our experimental

results show that the use of SDM as retriever leads to significant performance of the CDQA system. Our model using SDM as the retriever and BERT-base that was fine-tuned on SQuAD benchmark as the reader can outperform F-1 score of the state-of-the-art baseline by 3,26% for BM25, 3,26% for DLM and 32, 62% for TF-IDF+Cosine similarity.

The hyperparameter tuning on top n documents, passage length, and reader variations are shown to affect the performance of our CDQA model. We found that the best parameter is achieved by using top 20 documents as the retriever results, five sentences as the passage length, and BERT-large as the reader model. Our CDQA system using this parameter setting results in the best-performing model that achieves higher outperforming in F-1 score to the state-of-the-art baseline by 24,94% for TF-IDF+Cosine similarity retriever, 4,67% for DLM retriever, and 5,06% for BM25 retriever.

Our results also confirm the merit of using transfer learning to build CDQA system in a condition where a large benchmark for CDQA is unavailable. Our CDQA system using transfer learning technique (i.e., using SDM retriever and BERT-large reader that was fine-tuned on SQuAD benchmark) is significantly more effective than the method that does not use transfer learning. Our best-performing model (double fine-tuning SQuAD and COVID-QA) is shown to gain eight times higher accuracy than the baseline method without using transfer learning. Further fine-tuning the transfer learning model using closed domain dataset can increase the accuracy of the transfer learning model that only fine-tuning with SQuAD by 27,26%.

VIII. FUTURE WORK

For future works, we consider developing closed domain question answering with Dense Passage Retrieval to get better result than this work. We also want to modify how if all documents have split into passages before sending it to the retriever.

ACKNOWLEDGMENT

This research was funded by the Directorate of Research and Development, Universitas Indonesia, under Hibah PUTI Pascasarjana 2022 (Grant No: NKB-03/UN2.RST/HKP.05.00/2022).

Abstract—This paper proposed ovarian cancer detection in the ovarian image using joint feature extraction and an efficient Net model. The noise of the input image is filtered by using Improved NLM (Improved Non-Local Means) filtering. The deep features are extracted using Deep CNN_RSO (Deep Convolutional Neural Network Rat Swarm Optimization), and the low-level texture features are extracted using ILBP (Interpolated Local Binary Pattern or Interpolated LBP). To improve the feature extraction and reduce the error, use a cascading technique for the feature extraction. RSO also helps to efficiently optimize the DCNN features from the images. Finally, the extracted image is classified using the Efficient Net classifier, which performs a global average summary and classification of ovarian cancer (normal and abnormal). The system's performance is implemented on the Cancer Genome Atlas Ovarian Cancer (TCGA-OV) dataset. The system's performance, like sensitivity, specificity, accuracy and error rates, shows better with respect to other techniques.

Keywords—Ovarian cancer; deep convolutional neural network rat swarm optimization; CT image; joint feature; efficient net; improved non-local means; interpolated local binary pattern

I. INTRODUCTION

Ovarian cancer (OC) a disease that affects women's ovaries, is difficult to diagnose early, and has a high fatality rate [1]. OC has the highest mortality rate and is the leading cause of gynaecological deaths. There are two primary forms of invasive ovarian cancer, often referred to as Type-I and Type-II tumours [2]. Low-grade endometrial carcinomas, Low-grade serous carcinomas, clear-cell carcinomas, mucinous carcinomas, and malignant Brenner (transitional) tumours are examples of early-stage, nonaggressive type-I malignancies [3] [4]. Seventy-five percent of epithelial ovarian malignancies are type II tumours, which include high-grade serous carcinomas, high-grade endometriosis carcinomas, undifferentiated carcinomas, and malignant mixed mesodermal tumours. CT scans are routinely used to diagnose ovarian tumours, detect metastases, determine the stage of ovarian cancer, monitor patients following surgery, and evaluate the success of treatment [5].

Some ovarian epithelial tumours do not seem to be malignant when examined in the lab, and they are referred to as borderline epithelial ovarian cancer. Screening tests and exams identify diseases in people with no symptoms, such as cancer [6]. The abdomen and pelvis CT scan is the first-line imaging modality for ovarian cancer staging, therapy options selection and disease response assessment. The imaging

surrogate for surgical-pathological FIGO staging is the staging CT, which gives disease distribution and load. This is mostly due to late detection, although OC often recurs after treatment. The remarkable difference in cure between patients with close illness and those with distant disease (15% vs. 25%) eloquently illustrates the need for a non-invasive but feasible diagnostic applicable to a large population expected to be afflicted by OC in its early stages [7].

Regardless of the fact that OC is only the 6th most frequent female cancer in Singapore, it is still a leading cause of gynaecological cancer mortality. As a result, the risk of cancer increases throughout life [8], leading to some complications, such as the inability of women with OC to have children and a problem after menopause. Therefore, to overcome these problems for women, accurate identification, solid cancer analyses [9], and the treatment procedure need all be improved. Despite all of these efforts, early detection of OC continues as a critical concern [10, 11]. With the use of proteomic analysis in serum, there has been continuing study to detect new cancer indicators. The cause or causative factor for OC is unknown, making early detection of ovarian cancer difficult [12].

The link between OC diagnosis and survival led to thinking and efforts to improve the outcomes obtained at the early recognition phases. This information is used to make better informed decisions while saving money [13, 14]. There are five reasons why a big data strategy can help cancer detection. Pathologists also noticed and examined the numerous gene articulations in this specific OC as well as the amounts of gene articulating in distinct neurotic phases and situations [15], as part of the same inquiry. Both organic and statistical computing may be used to characterize gene articulations for such relationships [16], especially in dynamic conditions when the tumour progresses from the quantitative processing of OC tissue [17, 18]. Different X-ray absorption coefficients in the human body indicate tissue properties in CT scans. CT provides the advantages of quick scan time and accurate localization [19].

The number of lesions and the simplicity with which they may be imaged are more important than the expense of the imaging technique. Radiation is a type of energy that may injure the human body. The resolution of CT scans is very important [20]. According to the statistics and machine learning part, various classification approaches were utilized in the cancer classification process, although it has certain non-trivial job problems. The knowledge about gene

*Corresponding Author.

articulation is unlike anything else that these approaches have ever dealt with. The supervised learning method uses the training set of categorized data to create a classifier that can be used to classify new data.

1) *Motivation*: The recognition of CT images is difficult to identify using segmentation or clustering. It may have a greater impact on the FAR and FRR rate at the moment of identification from the knowledge base. Existing systems have a functioning accuracy level of 90 to 95. It may be improved so that the system classifies more precisely and efficiently. Previous techniques were unable to classify the cancer stage. The assessment of the patient's stage aids in the more efficient treatment of the patient. The presented issues of the system motivated to development of a new methodology known as joint feature extraction with an efficient net classifier for ovarian cancer detection.

2) *Contribution*

- To improve the feature extraction of the CT image, Joint feature extraction is introduced based on the fusion of high-level (deep) and low-level (shallow) features are introduced for performing better image feature extraction.
- The deep features are extracted using Deep CNN_RSO, and the low-level texture features are extracted using ILBP. Both techniques are used to reduce the error rate in feature extraction.
- The efficient Net classifier is used to categorize the ovarian CT image by minimizing the greatest number of features in the data without sacrificing its original properties and decreasing the processing time and memory space.

The structure of the paper: Section II gives the related works of ovarian cancer detection in the CT images, the proposed methodology describes in Section III, Section IV explains about the result and discussion, and Section V concludes the paper.

II. RELATED WORK

Lu et al. [21] presented a technology based on learned and created a non-invasive reduction in the quantity of the main ovarian tumour. Despite best efforts, the five-year survival rate for epithelial ovarian cancer (EOC) is around 35–40 per cent, underlining the use of classification markers for tailored treatment. Here, extracted 657 quantifiable statistical characteristics from the data in this section. 364 EOC patients' pre-operative CT scans at their initial presentation. The "Radiomic Prognostic Vector" is made up of four descriptions (RPV). RPV has a high level of accuracy when it comes to identifying people. The 5% of people with a median survival rate of fewer than two years improves dramatically. Based on well-established prognostic methodologies and has been tested in two separate multi-centre cohorts. In addition, two separate datasets were analyzed genetically, proteomic and transcriptomic. The activation of the stromal phenotype and DNA damage response mechanisms are included.

Lago et al. [22] proposed the Sentinel lymph node technique for the early detection of ovarian cancer (SENTOV). Ovarian cancer in an early stage may be the optimal disease setting for lymph node monitoring. Nonetheless, it appears that the documented experience is limited. The purpose of this study was to evaluate the feasibility and safety of sentinel lymph node biopsy in patients with clinical stages I and II ovarian cancer. Twenty patients in total are being monitored. Sentinel lymph nodes were seen in 14/15 individuals. (93%) pelvic region and each of the twenty para-aortic regions (100%). Due to this, five individuals did not receive an utero-ovarian injection when the average time between injection and beginning of symptoms was reached. The resection of sentinel lymph nodes required 53–15 minutes (range; the average number of sentinel lymphocytes recovered was 30–80). There were 2, 21.50 lymph nodes in the pelvic region (range: 0–5).

Wang et al. [23] suggested non-invasive recurrence forecasting models in HGSOc that aggregate prognostic characteristics from pre-operative computed tomography (CT) images utilising a unique deep learning (DL) technique. Equipment and procedures include 245 HGSOc patients from two hospitals, including a feature-learning cohort (n = 102) and two independent validation cohorts (n = 49 and n = 45). To capture the prognostic biomarkers (DL feature) of HGSOc, 8917 CT images from the feature learning cohort were used to train a unique DL network. A DL-CPH model including the DL feature and Cox proportional hazard (Cox-PH) analysis was created to predict patient recurrence risk and three-year recurrence probabilities.

Castellani et al. [24] developed a standard pre-surgical staging for the identification of ovarian cancer. The most important prognostic factor in ovarian cancer is the stage of the disease at the time of diagnosis. The current staging system (FIGO classification) is based on clinical and histological results. Despite the fact that the clinical stage is the standard method in ovarian cancer, the first patient care relies on an imaging-based which was before staging evaluation to detect disease that is unrespectable or difficult to resect. Radiologists must know the advantages and disadvantages of the many imaging techniques available. For effective staging and treatment planning, a clear understanding of the path of disease dissemination and review regions is essential. CT scans of the chest, abdomen, and pelvis are the current standard of care for pre-surgical staging. This enables a quick assessment of the disease's severity and is cost-effective.

Funston et al. [25] described CA125, an excellent screening test for ovarian cancer in primary care, particularly for women under the age of 50. To avoid diagnostic delays, patients with increased CA125 values should be evaluated for non-ovarian malignancies, especially if ovarian cancer has been ruled out. Our findings allow physicians and patients to predict the risk of ovarian cancer and other malignancies at any CA125 level and age, which can be used to guide individual decisions about the need for additional testing or referral.

Nougaret et al. [26] proposed radio genomics and radionics computational ways to measure tumour heterogeneity to investigate the entire tumour heterogeneity rather than a single biopsy sample. Cancer heterogeneity has been identified at the genetic and histological stages of ovarian cancer and has been linked to poor health outcomes. In advanced ovarian cancer with peritoneal carcinomatosis, traditional magnetic resonance or computed tomography imaging methods do not allow for intra- or inter-tumor heterogeneity. Feature extraction, which involves extracting various variables from pictures and is an element of radionics', has subsequently been suggested to assess progressed ovarian tumour heterogeneity. This brief overview covers the fundamentals of radionics, how to do texture analysis, and how to apply it to ovarian cancer imaging.

Forstner et al. [27] propose a Standardization of imaging techniques for ovarian cancer detection. Early detection is the only way to achieve a high cure rate in females with ovarian cancer. Despite rapidly evolving biomarkers, there is still no viable technique for early detection. Ovarian cancer has a low prevalence, a low specificity, and a high sensitivity. False positive percentages have been one of the screening programmes' drawbacks. Transvaginal sonography and magnetic resonance imaging (MRI) are useful methods for identifying ovarian masses in the hands of professionals. Efforts to standardize procedure and analysis are now underway and are expected to continue. Improve clinical diagnostic capabilities and the usage of cancer risk prediction algorithms. Radiogenomics and Radiomics could provide a plethora of extra information in the diagnosis and treatment of ovarian cancer.

These studies about ovarian cancer detection in CT images show that many issues exist in the detection of ovarian cancer in the CT image, such as increased noise in feature extraction, classification error, low specificity and low sensitivity. To improve the method's performance and reduce the error, here propose a new methodology named ovarian cancer detection in CT image by joint feature extraction and Efficient Net classifier.

III. PROPOSED METHODOLOGY

Ovarian cancer is a type of cancer that affects the ovaries. The cells can enter and harm healthy biological tissue and grow rapidly. Most techniques failed to identify cancer in the CT image due to the error and noise in the output image. Here, the proposed ovarian cancer detection by joint feature extraction and efficient net classifier. In this case, the pre-processing technique is initially done by using Improved NLM filtering to remove unwanted noise in the image. Next, Joint feature extraction is done based on the fusion of high-level and low-level features. Here, the deep features are extracted using Deep CNN_RSO and the low-level texture features are extracted using ILBP. Both the features are cascaded to obtain joint feature extraction for performing ovarian image classification. Finally, the Efficient Net classifier performs a global average pooling and classification of normal and abnormal images. Thus, the suggested Efficient Net classifier can lower the maximum number of data features without altering their original properties and cut processing time and

memory space. The performance of the presented approach will be examined with recent existing approaches in terms of performance metrics to prove the performance efficiency. The architecture of the proposed method is shown in Fig. 1.

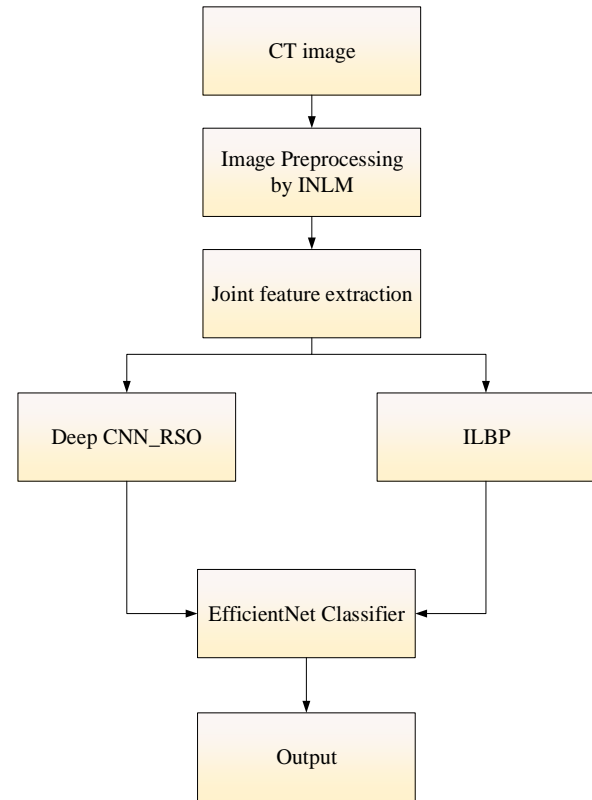

Fig. 1. Architecture of the proposed system.

A. Pre-processing

Image pre-processing is the preparation of images prior to their use in model training and inference. This covers orienting, resizing, and colour adjustments of the CT image. After collecting the CT images of ovarian cancer, upload the dataset picture and transform the RGB image into a grayscale image. Here pre-processing is done by using Improved Non-Local Means (INLM). According to the NLM, the weights are produced under the Gaussian noise assumptions that are used to quantify the closeness between a core area patch in a searching window and nearby patches. Only pixel data is used to construct the weights for the NLM, which quantifies the closeness between a centre area patch and its nearby patches. The variance is used to calculate the neighbourhood similarity measure. This similarity metric does not completely consider the structural data of the picture whenever the noise levels are too high in the case of NLM. There are errors generated in the case of noise in the CT images, so an improved NLM is used for the smooth region to achieve a better effect in the image, to provide good protection for the edge and the adaptive selection of the Gaussian weighting coefficients. The algorithm for INLM is shown below.

$$S = \frac{1}{\sqrt{3P}} \sum_{p=0}^{p=1} \|f_k(x, y) - g_k\|_{f_k(x, y) \in Patchwindow} \quad (1)$$

$$w(u, v) = \exp\left(-\frac{\sum_{p \in P} \|f_k(x+p, y+p) - f_k(x_0+p, y_0+p)\|_2^2}{h^2}\right) \quad (2)$$

$$w(x, y, x_0, y_0) = \exp\left(-\frac{\sum_{p \in P} \|f_k(x+p, y+p) - f_k(x_0+p, y_0+p)\|_2^2}{h}\right) \quad (3)$$

$$w_i(x, y, x_0, y_0) w_{21}(x, y, x_0, y_0)$$

$$g_k(x, y) = \frac{\sum_{u, v \in N} f_k(x+u, y+v) w(u, v)}{\sum_{u, v \in N} w(u, v)} \quad (4)$$

S Shows the general expression for the INLM algorithm, w represents the weight of the CT image and $g_k(x, y)$ shows the grey level representation of the image. The detailed algorithm of the INLM is shown below.

B. Joint Feature Extraction

Fusion of high-level (deep) and low-level (shallow) features is used to do joint feature extraction. Here, Deep CNN RSO is used to extract the deep features, whereas ILBP is employed to extract the low-level texture features. Both the features are cascaded to obtain joint feature extraction for performing ovarian image classification. The architecture of joint feature extraction is shown in Fig. 2.

1) *Deep CNN_RSO for deep feature extraction:* The high level (deep) features of the ovarian images are extracted by using the CNN (Convolutional neural network). The extracted features are then optimized using the Rat Swarm Optimization (RSO). Fig. 3 shows the DCNN's architecture. In this work, the DCNN consists of five convolutional layers: three max pooling layers and two complete reconnect layers. The activation function of each layer was a Rectified Linear Unit (ReLU). Three max pooling layers with a size of 3*3 pixels and a stride of 2 were employed to reduce the input image size of the subsequent convolutional layer. At the end of the DCNN, two fully linked layers containing a significant number of neurons were applied. The network extracts the deep features, is then optimized.

a) *Rat Swarm Optimization:* Rats are enormous, medium-sized rodents with long, variable-length tails. Black and brown rats are the two most common species of rats [28]. Male rats are referred to as bucks, while female rats are referred to as does. Rats are naturally smart social beings. They indulge in grooming and jumping, chasing, tumbling, and punching. Rats are territorial and inhabit colonies composed of both males and females. Rats are noted for their aggressive behaviour, which has been known to kill other creatures. This aggressive behaviour is the fundamental motivation for performing this action when pursuing and combating prey. The mathematical expression for determining the optimization value of the deep features of ovarian cancer from a CT picture using RSO is provided below.

The feature of the CT image can be found by,

$$\vec{F} = A \cdot \vec{F}_i(x) + C \cdot (\vec{F}_r(x) - \vec{F}_i(x)) \quad (5)$$

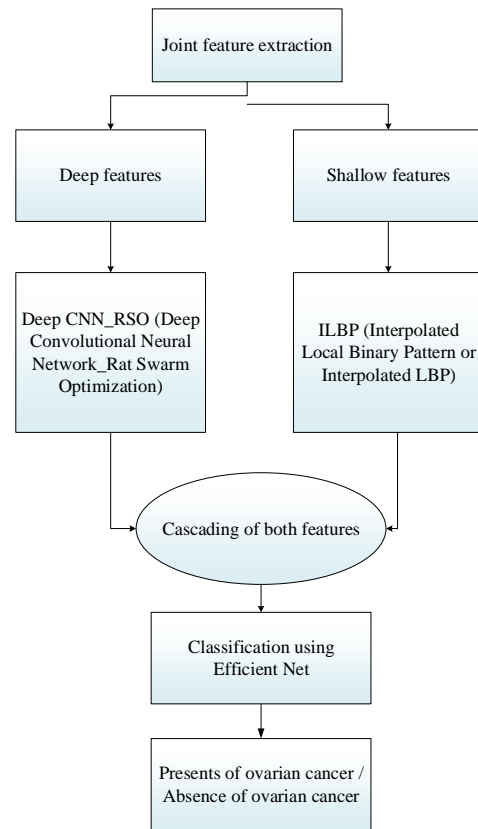

Fig. 2. Joint feature extraction.

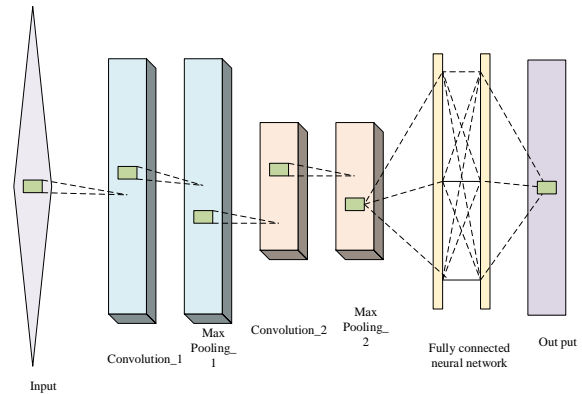

Fig. 3. DCNN's architecture.

Where \vec{F} shows the deep features, $\vec{F}_i(x)$ represents the features present in the CT image, $\vec{F}_r(x)$ shows the best optimal feature, A and C shows the parameters. They can be calculated as,

$$A = R - x \times \left(\frac{R}{M_{itr}}\right) \quad (6)$$

$$x = 0, 1, 2, \dots, M_{itr} \quad (7)$$

$$C = 2 \cdot rand() \quad (8)$$

R is the random number between the $[1, 5]$ and $[0, 2]$

The updated features can be obtained by,

$$\vec{F}_{deep} = \left| \vec{F}_r(x) - \vec{F} \right| \quad (9)$$

Here by using the Deep CNN_RSO the deep features of the CT images are extracted. Then, need to extract the shallow feature for that purpose ILBP is used.

2) *Interpolated Local Binary Pattern (ILBP) for shallow feature extraction:* LBP compares the grey levels of the centre pixel to the grey values of the eight neighbouring pixels in a 3x3 window and generates 1 or 0 to identify a pixel in the picture. It generates an eight-bit binary image as a result of the difference between grey values, with each grey value being split by its corresponding weight. Finally, these values are added together to produce a decimal value used to designate the centre pixel. Like LBP, the proposed ILBP characterizes each pixel depending on its neighbours. The only variable is that these pixels are chosen in a circular pattern and are evenly spaced in the center pixel to be labeled

Consider the position of the sampling point (X_n, Y_n) is represented as

$$x_n = x_c + R \times \cos\left(\frac{2\pi n}{N}\right), y_n = y_c - R \times \sin\left(\frac{2\pi n}{N}\right) \quad (10)$$

(x_c, y_c) Represents the pixel centre and $N(1 \leq n \leq N)$ shows the surrounding pixel number. N, R Represents the changing values of the CT image. The Generation of the circulation pattern is depicted in Fig. 4. Each phase of the circulation pattern is depicted in Fig. 4(a), (b), (c), and (d).

The grey value point $g(x, y)$ can be estimated as,

$$g(x, y) = g(0, 0)(1-x)(1-y) + g(1, 0)x(1-y) + g(0, 1)(1-x)y + g(1, 1)xy \quad (11)$$

The weight of each pixel is given as

$$P(x, y) = w_1P_1 + w_2P_2 + w_3P_3 + w_4P_4 \quad (12)$$

$$w_1 = (1-x)(1-y) \quad (13)$$

$$w_2 = x(1-y) \quad (14)$$

$$w_3 = y(1-x) \quad (15)$$

$$w_4 = xy \quad (16)$$

Interpolated LBP can be found by

$$\vec{F}_{shallow} = \sum_{n=0}^{N-1} f(I_n - I_c)2^n \quad (17)$$

Fig. 4. Generation of circulation pattern.

$\vec{F}_{shallow}$ Represents the feature extracted by LBP, I_n and I_c Shows the grey value of the neighbouring pixel.

a) *Joint feature:* The low-level textural characteristics can characterise the edges, direction, and intensity distribution, while the high-level features retrieved from the medical CT picture can indicate the visual characteristics of the lesion's location. CNN RSO gives deep characteristics, whilst the ILBP provides shallow ones. Both CNN_RSO and ILBP output features are cascaded to form feature extraction output. The joint feature gives a better feature extraction output. The joint feature can be obtained by normalizing both the deep and shallow features. The deep feature of the picture is the network's output, and the deep feature's dimension is 1024. ILBP is utilised as the image's texture for the shallow texture feature. The ILBP element is 59 inches in length. The high and low level fusion features of an image are generated by normalising and cascading the two features.

$$\vec{F}_{shallow} = \frac{\vec{F}_{shallow} - \vec{F}_{shallow}^{\min}}{\vec{F}_{shallow}^{\max} - \vec{F}_{shallow}^{\min}} \quad (18)$$

$$\vec{F}_{deep} = \frac{\vec{F}_{deep} - \vec{F}_{deep}^{\min}}{\vec{F}_{deep}^{\max} - \vec{F}_{deep}^{\min}} \quad (19)$$

$$\vec{F}_{eff} = \left\{ \vec{F}_{deep}, \vec{F}_{shallow} \right\} \quad (20)$$

\vec{F}_{eff} represents the joint feature extraction of the deep and shallow features of the ovarian cancer images, $\vec{F}_{shallow}$

Represents the feature extracted by ILBP and \vec{F}_{deep}

Represents the deep feature extractions.

C. Efficient Net for Classification of CT Images

The classification of the image is used to calculate the neighbourhood similarity metric. This similarity metric does not completely include the structural data of the picture whenever the noise levels are too high. The classifier follows the classification process. Here uses a classifier named Efficient Net classifier. The output of the Efficient Net is given by the global averaged features of the CT image of the ovary. On the image Net, the Efficient Net classification model delivers state-of-the-art performance. The proposed classification of the CT image follows two stages: pre-trained and training stages. The pre-trained stage frees the image weights with respect to the network. The CT image is fully retained in the second stage with an efficient net classifier.

The Efficient Net family of CNN models is based on a revolutionary scaling method. It utilizes a simple compound coefficient that is quite effective. Efficient Net scales each dimension uniformly using a predefined set of scaling factors, unlike previous approaches that scale network parameters such as breadth, depth, and resolution. In practice, increasing subjectivity improves the model's performance, but balancing all network features under available resources considerably improves overall performance. Efficient Net is considerably more compact than other variants with the same Image Net accuracy.

This research applies the Efficient Net CNN model to provide an efficient approach. This form of Efficient Net was chosen because it strikes a reasonable balance between processing resources and precision. These strategies can likewise be used to more resilient variations. Mobile inverted bottleneck convolution (MBConv) is a fundamental component of the Efficient Net model family. The Mobile Net models inspired the development of MBConv. One of the key concepts is the use of depth-wise separable convolutions, which mix depth-wise and point-wise convolution layers in succession. Fig. 5 depicts an efficient architecture for Net classifiers.

Fig. 5. Architecture of Efficient Net classifier.

The success of the previously proposed strategy for model scaling is strongly dependent on the baseline network. Searches automatically for a CNN model that maximises accuracy and efficiency (in FLOPS). The fundamental network is referred to as Efficient Net, and its essential layout is depicted in Fig. 5. The first thing to observe is that this baseline model is composed of recurring MBConv1, MBConv3, and MBConv6 blocks. These are the various sorts of MB Conv blocks. The second observation is that the number of channels per block has expanded or increased (through a bigger number of filters). The final observation relates to the inverted residual connections that exist between the thin layers of the model. Given the CT scans detection of ovarian cancer, the Efficient Net classifier output is displayed.

IV. SIMULATION RESULTS

The ovarian cancer detection in the CT image using joint feature extraction and the Efficient Net model is presented using the PYTHON platform with the TCGA-OV dataset. Here the method is analyzed using sensitivity, specificity,

accuracy, root mean square error (RMSE) and mean absolute percentage error (MAPE). Also, the ROC curve is obtained for the performance analysis of the system. For the classification of the features, an Efficient Net model is used. This model is analyzed by comparing the classification result using Le Net, Alex net, Google Net and VGG Net using the TCGA-OV dataset.

A. Dataset Description

1) TCGA-OV: TCIA provided a public database of abdominal CT scans used in this study: The Ovarian Cancer (TCGA-OV) dataset from the Cancer Genome Atlas. A group of researchers created the dataset. The Cancer Genome Atlas is a project examining the relationship between cancer characteristics and genetics by supplying clinical photographs. Clinical, genetic, and pathological data are stored in Genomic in TCGA-OV. TCIA stores radiological data, while the Data Commons Data Portal stores data. The TCGA-OV database contains 143 abdominal contrast-enhanced CT images and has two instances. The pelvis was outside the CT scan range, hence it was excluded from this study. The 141 remaining occurrences were included in the current investigation. The 141 samples were randomly divided into 71 training cases.

B. Performance Analysis

Here the performance of the system analyzes with respect to sensitivity, specificity, Accuracy, RMSE and MAPE. Sensitivity is the capacity to sense or respond to simulation. The equation for the sensitivity of the classifier is given as

$$\text{Sensitivity} = \frac{TP}{TP + FN} \quad (21)$$

Specificity is defined as the condition of being specific in any method. Specificity of the classifier is represented as,

$$\text{Specificity} = \frac{TN}{TN + FP} \quad (22)$$

The system's accuracy is defined as the state of being accurate in a process. The accuracy of the classifier system is given as

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \quad (23)$$

The RMS value is the root mean square value, and the RMSE is the process's root mean square error.

$$RMSE = 1 - \sqrt{\frac{\sum_{i=1}^m (T_i - P_i)^2}{N}} \quad (24)$$

The MAPE can find it as

$$MAPE = 1 - \left(\frac{\sum_{i=1}^m (T_i - P_i)^2}{N} \right) \times 100 \quad (25)$$

Where TP = True Positive, TN = True Negative, FP = False Positive, FN = False Negative, $i = 0,1,2,\dots,m$, $m = \text{max value}$.

The result obtained by each of the performance metrics is shown below. Fig. 6 shows the sensitivity of the proposed Efficient Net model with respect to other models. Here the graph shows that the sensitivity of the proposed system is 98.8% when using Le Net is 97.5%, Alex Net is 97.4%, Google Net is 97.2%, and VGG Net is 97%. Through this, the sensitivity of the proposed system is higher than that of the other classification methods.

Fig. 7 shows the specificity of the proposed method with respect to the Efficient Net. The figure shows that the specificity of the proposed method is 99.8%, the specificity of the classification method by using Le Net is 98.8%, using Alex Net is 98.6%, using Google Net is 98.4% and using VGG Net is 98.3%. Through this, the specificity of the proposed method using Efficient Net is better than that of the other classification methods.

Fig. 6. Sensitivity of the proposed method.

Fig. 7. Specificity of the proposed method.

Fig. 8. Accuracy of the proposed method.

Fig. 8 shows how well the proposed method works in comparison to the Efficient Net. The graph shows that the proposed method is 99.8% accurate, the classification method is 99.5% accurate when using Le Net, 99.3% accurate when using Alex Net, 99.2% accurate when using Google Net, and 99% accurate when using VGG Net. Through this, the accuracy of the proposed method using Efficient Net is better than that of the other classification methods.

Fig. 9 shows how the proposed method compares to the Efficient Net in terms of the RMSE. The graph shows that the proposed method has an RMSE of 0.01%, the classification method using Le Net has an RMSE of 0.05%, Alex Net has an RMSE of 0.07%, Google Net has an RMSE of 0.09%, and VGG Net has an RMSE of 0.096%. Because of this, the RMSE of the proposed method using Efficient Net is better than that of the other classification methods.

Fig. 9. RMSE of the proposed method.

Fig. 10. MAPE of the proposed method.

Fig. 11. ROC of the proposed method.

Fig. 10 demonstrates the MAPE of the suggested technique relative to the Efficient Net. The graph reveals that the MAPE of the suggested technique is 1.23 percent, while the MAPE of the classification method utilising Le Net is 2.5 percent, Alex Net is 2.7 percent, Google Net is 3.5 percent, and VGG Net is 4.33 percent. Consequently, the MAPE of the suggested method utilising Efficient Net is superior to that of the other categorization techniques. Fig. 11 illustrates the ROC of the proposed Efficient Net approach versus the Le Net, Alex Net, Google Net, and VGG Net. The curve demonstrates that the suggested Efficient Net model outperforms the alternatives.

V. CONCLUSION

This paper proposes ovarian cancer detection in CT images by joint feature extraction and an Efficient Net classifier. Here, the deep features are extracted using Deep CNN_RSO (Deep Convolutional Neural Network Rat Swarm Optimization) and the low-level texture features are extracted using ILBP (Interpolated Local Binary Pattern or Interpolated LBP). The cascaded feature extraction is used for the

classification of the image. Also, the optimization gives better results to integrating with DCNN. The classification result shows better performance with minimum noise in the extracted images. The joint feature reduces the noise and improves the feature extraction efficiency. Finally, Efficient Net performs global average pooling and classification of ovarian cancer. By using the Efficient Net classifier, the sensitivity, specificity, accuracy, RMSE, and MAPE can be improved to 98.8%, 99.2%, 99.8%, 0.01% and 1.23%. The system's performance is compared using Le Net, Alex Net, Google Net and VGG Net using the TCGA-OV dataset. The outcome indicates that the performance of the proposed system is superior. Future work can improve the classifier's ability to classify tiny cysts in CT images.

Department of Mangement, Universitas Tarumanagara, Jakarta, Indonesia⁴

Abstract—The integration of the internet of things in the information system application service web platform implemented in the supply chain has given rise to new formats and models, which are important manifestations of industry transformation and improvement. In the context of implementing long-term rural development plans, deep integration of the application of information technology and rural revitalization will act as a trigger that drives productivity and the development of other village business industries. The purpose of this research is to build a web service management model that can be used to manage and help optimize IoT-based salt farming production. The model built consists of software and hardware architectures and interconnections between tools. This research is divided into three stages: the first stage is to identify the data sources needed for big data needs, the second stage is to build a big data microservices model and the IoT model, the third stage is to integrate IoT data with the big data microservices model that has been built. The results of this study are in the form of an IoT device that can be run with big data micro services. The resulting IoT device can be used to automate water distribution based on the salinity value measured using a sensor.

Keywords—Web service; big data; salt; IoT

I. INTRODUCTION

Big data and the Internet of things (IoT) are part of the components of the Industrial Revolution 4.0. Growing rapidly and affecting all fields, including business, technology, health, education, agriculture and increasing benefits for many other fields. IoT is contributing to the growth of large amounts of data, and high speeds, which are characteristics of big data, as described by Gartner.

Indonesia is a country that has more ocean area, so of course it is a country that can produce its own salt and even export it to other countries. In fact, Indonesia has succeeded in producing abundant salt in 2012-2015, with a surplus of up to 2.9 million tons. However, the problem occurred in early 2017 that domestic salt production decreased, so we had to rely on imports for industrial salt needs [1].

Salt is a food ingredient that is consumed by all groups which is obtained through the process of crystallization of seawater or brine from sea salt or by the mining process of rock salt [2]. The influencing factor is that salt production in Indonesia has decreased because it still uses traditional salt processing methods such as dependence on sunlight and less use of the latest technology.

The Internet of Things (IoT) describes the ubiquitous connection between common objects and the Internet. IoT works by deploying thousands of smart devices in a living or industrial environment. This device collects information from the surrounding environment, performs desired processing activities on the data obtained and transmits the processed data via a secure and reliable communication channel. Recent advances in software, hardware and communication systems have significantly improved human lifestyles in terms of time, energy and cost savings [3, 4].

Digital farming is one of the key technologies that has gained support through different research initiatives in the last decade. A fundamental digital farm setup consists of a central management platform, a human-computer interface and a dedicated IoT module, which monitors the animals, their behavior and facilities [5]. All of these building blocks are connected into a common platform, using a communications network that, today, is often based on an IoT architecture combined with cloud- or edge-based functionality. A smart atmosphere is, in the digital farming scenario, a more sophisticated concept, which enables information processing from big data, combined with the current context and conditions, and adequate adaptation according to prior knowledge or decisions generated from machine learning algorithms [6].

This research is in line with the demands of industry 4.0 which is characterized by increased manufacturing digitization with four driving factors: 1) increased data volume, computing power, and connectivity; 2) the emergence of business analysis, capabilities, and intelligence; 3) the occurrence of new forms of interaction between humans and machines; and 4) improvement of digital transfer instructions to the physical world. The uniqueness and advantage of this program is that it integrates the application of Internet of Things (IoT) technology. The purpose of the proposed program is to increase salt production, both in quantity and quality through the application of IoT-based information technology.

Web service is an application of a collection of data (database), software (software) or part of software that can be accessed remotely by various devices with a certain intermediary. The use of web services is able to overcome interoperability problems and integrate different systems. In general, web services can be identified by using a URL like just a normal web (eg: www.webname.com). However, what distinguishes web services from the web in general is the interaction provided by web services [7].

This research resulted in an IoT design that can measure salt salinity, temperature and humidity. The salt salinity measure is then used to open the faucet and automatically circulate water for the next production process. The data generated by the sensors is then combined with other data related to the supply chain of salt commodities using big data architectures and application microservices.

II. BIG DATA

The term Big Data is often used to describe a variety of different concepts, from the collection and processing of large amounts of data to the various techniques used to process data [8] (Favaretto, 2020). The use of this term is often popularly used in various fields such as: health [9], geography [10], psychology [11], and social life [12]. The term Big Data has been used since the 1990s as technical and marketing jargon by silicon graphics. The use of this term in academia began to emerge in the 2000s on the topic of computer science [13] and statistics/econometrics [14]. Then, in subsequent years, as it develops, the use of big data is increasingly used, especially in conducting data analysis [15].

Weiss and Indurkha [14] stated that a very large data set and compiled in a centralized data warehouse allows analysis using more complex techniques to analyze more comprehensive data. In theory, big data is able to provide more comprehensive conclusions. However, in practice, there are various problems that arise.

There are various definitions of big data. However, basically, big data has three attributes known as 3Vs, namely volume (large amount), velocity (fast processing), and variety (various data) [16]. Then, along with the larger amount of data, big data attributes are growing with additional attributes to the three previous attributes, such as: veracity, value and variability. Even with various definitions, big data is a large amount of data that comes from various sources [8].

One application of big data technology is in enterprise systems. For example, big data can be applied to manufacturing systems. Big data can help predict manufacturing equipment failures. Potential problems can be found by analyzing structured data (year, equipment make, and model) and unstructured data (log entries, sensor data, error messages, engine temperature, and other factors). With this data, manufacturers can maximize parts and equipment uptime and implement maintenance costs more effectively.

In the village there are several applications of big data in rural areas. For example, big data can be used to automate agriculture. Agricultural automation uses various tools connected to the internet/ internet of things (IoT). The use of various kinds of sensors and tools certainly produces various kinds of data that need to be controlled to automate agriculture [17].

III. METHODOLOGY

The stages of program implementation can be divided into several parts, namely:

1) *Requirements gathering and analysis:* Requirements Gathering and Analysis or mapping and analysis to get needs is the initial stage of the prototype model. In this stage the system requirements are defined in detail. In the process, developers and users provide feedback to each other. At this stage the required data sources are also identified, namely:

- Internal Data, The majority of internal data will come from database systems Gadingsari Village. This data includes production data, stock data, company financial data, as well as data from various instruments contained in village business units.
- External Data, this data includes raw material prices, selling prices, weather predictions, and input from related departments. There are various data sources that can be used to support the business units that are owned. These data can be collected from various sources and then analyzed which can produce conclusions that can help village businesses. These data are generated at different times. For example: weather data can be retrieved 7 days in advance while raw material data is sometimes available 1 month later. Of course this time difference can provide imperfect comparisons between data. Data types are also different. The average external data is unstructured, where the data does not have a fixed structure.

2) *Design model:* The second stage is to build a microservices model and an IoT model. Creating a micro service model design that will provide a brief description of the applications contained in the web service management system that you want to create. IoT model design: namely the IoT model that will be implemented in optimizing salt production. The IoT model will then be run using the proposed web service.

3) *Integration:* Design of Microservice System Integration and IoT technology in Web Service management.

IV. RESULT AND DISCUSSION

At the initial stage of the design is to build a microservices model and an IoT model, at this stage it is necessary to design a microservices model which will provide a brief description of the applications contained in the web service management system that you want to create. The Webservice Model Design created can be seen in Fig. 1.

Fig. 1. Salt production webservice model design

A. Application Program Construction

Program construction is a codification process, namely building application programs based on designs that have been made at the application design stage. There are several stages in this activity, namely:

1) The first stage, the application program is to build a data ingestion application, to integrate data from various sources using the Application Programming Interface or API, as shown in Fig. 2. In this section, big data processing is carried out using several layers, such as the data visualization layer, analytical storage, analytical engine, data processing layer.

Fig. 2. Big data server architecture design

2) The second stage provides micro service services for users or business actors. At this stage, program construction is carried out to build application services. The target to be achieved is the availability of application services that can be connected to the IoT system for monitoring the salt production process, as shown in Fig. 3.

Fig. 3. Big data architecture microservice design

B. IoT Model Design

The conceptual design of the IoT model that will be implemented in optimizing salt production can be seen in Fig. 4, and the IoT design can be seen in Fig 5. The IoT model will then be run using the proposed web service. The picture shows the ESP32, which is a low-cost, low-power system on a chip (SoC) series with dual-mode Wi-Fi and Bluetooth capability! The ESP32 family includes the ESP32-D0WDQ6 (and ESP32-D0WD), ESP32-D2WD, ESP32-S0WD, and ESP32-PICO-D4 system-in-package (SiP) chips. At its heart is a dual-core or single-core Tensilica Xtensa LX6 microprocessor with a clock speed of up to 240 MHz. The ESP32 is highly integrated with a built-in antenna switch, RF balun, power amplifier, low noise receiver amplifier, filter and power management module. Engineered for mobile devices, wearable electronics, and IoT applications, the ESP32 achieves extremely low power consumption through power-saving features including smooth resolution clock gating, multiple power modes, and dynamic power scaling.

Fig. 4. Conceptual design diagram of the IoT model

Some of the functions of the IoT model design with web services are as follows:

1) The controller is an IoT tool that will automatically control the valve based on sensor conditions. All automation occurs at the controller level to save traffic going out through the modem

2) The controller will be connected to the web service via the tcp protocol. It should be noted that the controller can first connect to the local server or go directly to the web service.

3) The service data will be received. This service also allows the system to send messages to IoT devices.
4) Finally, the management system allows the use of data to and from IoT devices. The system for will also simplify the management of IoT devices

Fig. 5. IoT design

DHT22, shown in Fig. 6, is a digital relative humidity and temperature sensor. The DHT22 sensor uses a capacitor and thermistor to measure the surrounding air and output a signal on the data pin. DHT22 is claimed to have good reading quality, judged by the fast response of the data acquisition process and its minimalist size, and the price is relatively cheap when compared to a thermohygrometer [18].

Fig. 6. DHT22: Temperature and humidity module

Furthermore, the program is run based on program construction using the Python programming language as shown in Fig. 7.

```
from machine import Pin, ADC
import network
import dht
import ujson
import time
from umqtt.simple import MQTTClient

# VOID
# Register All Pin
sensor = dht.DHT22(Pin(12))
pmeter = ADC(Pin(13))
pmeter.atten(ADC.ATTN_11DB) # Set Analog to 3.3V
relay = Pin(15, Pin.OUT)

# Parameter to control Relay
relay_state = 0

# MQTT

# MQTT Server Parameters
MQTT_CLIENT_ID = "device1"
MQTT_BROKER = "localhost"
```

```
MQTT_TOPIC = "iot/device/1"

print("Connecting to WiFi", end="")
sta_if = network.WLAN(network.STA_IF)
sta_if.active(True)
sta_if.connect('Wokwi-GUEST', '')
while not sta_if.isconnected():
    print(".", end="")
    time.sleep(0.1)
print(" Connected!")

print("Connecting to MQTT server... ", end="")
client = MQTTClient(MQTT_CLIENT_ID, MQTT_BROKER,
port=1883)
client.connect()

print("Connected!")

# LOOP
while True:

# Pasive Sensor
print("Measuring Data....")
sensor.measure()
message = {
    "temp": sensor.temperature(),
    "humidity": sensor.humidity(),
    "pmeter": pmeter.read(),
}
# Some Logic Sensor
relay_state = 0
if(message["pmeter"] >= 1000):
    print("ook")
    relay_state = 1

# Active Sensor
relay.value(relay_state)
message["relay"] = relay_state

print(ujson.dumps(message))

print("Reporting to MQTT topic {}: {}".format(MQTT_TOPIC,
message))
client.publish(MQTT_TOPIC, message)

# Looping
time.sleep(3)

Fig. 7. IoT program construction

Furthermore, the design of the IoT model that has been built with the Python program is run using a server with web service management (Fig. 8).

Fig. 8. Running IoT program design with web service management

The program that is run shows the results that the system design is in accordance with the expected goals. Each module of connected devices, such as temperature sensors, humidity, wifi servers can communicate with each other and provide information in the form of the desired report. This proves that the designed web service management model is running as expected.

V. CONCLUSION

The web service model with IoT has been successfully built and can be run with the Web Service management model. The web service is run using a Public IP server, making it easier to run additional applications. Application programs run well with time optimization, as expected. The test results show that the sensor valve can function automatically based on the water level measurement sensor.

Abstract—In the modern day, protecting data against tampering is a significant task. One of the most common forms of information display has been digital photographs. Images may be exploited in a variety of contexts, including the military, security applications, intelligence areas, legal evidence, social media, and journalism. Digital picture forgeries involve altering the original images with strange patterns, which result in variability in the image's characteristics. Among the most challenging forms of image forgeries to identify is Copy Move Forgery (CMF). It occurs by copying a portion or piece of the picture and then inserting it again, but in a different place. When the actual content is unavailable, techniques for detecting fake content have been utilised in image security. This study presents a novel method for Copy Move Forgery Recognition (CMFR), which is mostly based on deep learning (DL) and hybrid optimization. The hybrid Grey Wolf Optimization and African Buffalo Optimization (GWO-ABO) using Convolution Neural Network (CNN) technique i.e., GWO-ABO-CNN is the foundation of the suggested model. The developed model extracts the features of images by convolution layers, and pooling layers; hereafter, the features are matched and detect CMF. The MICC-F220, SATs-130, and MICC-F600 datasets were three publicly accessible datasets to which this methodology has been implemented. To assess the model's efficacy, the outcomes of implementing the GWO-ABO-CNN model were contrasted with those of other approaches.

Keywords—Copy move forgery; convolutional neural network; image authentication; deep learning; tampered images

I. INTRODUCTION

Today's technological images play a crucial role in a broad range of fields. They are used in a variety of uses in the fields of broadcasting, journalism, medicine, and the army, to name a very few. The computerised image can be seen as a notable resource of information in today's advanced globe due to the advancement in the technology of sophisticated picture, such as sensors, coding, and Computers, as well as the widespread usage of the internet [1]. In addition, advanced image forgery refers to the intentional manipulation of a digitized image in

order to change the conceptual interpretation of the contextual perspective contained within. Also, with availability of cutting-edge information structures editing tools like Photoshop, it becomes quite simple to create sophisticated fakes from one or more images. The reliability of photographs plays a crucial role in a variety of fields, such as measurement analysis, criminal probe, surveillance systems, organisational learning, medical imaging, and media broadcasting. Creating phony pictures is a specialty with a lengthy tradition. But in the current technology age, it showed out to be very simple to change the facts talked to by an image without any obvious consequences.

One of the most widely popular techniques for altering digital photographs is copy-move. One of two factors can explain why there are copy regions in an image: first, the proximity of two particles or objects that are identical in size, form, and colouring; one of them may be a copy of the other one. Second, the appearance of duplicate regions in the results is caused by the proximity of a reasonably massive area with one colour and similar in features, such as foundational principles sky, splitter, etc. Copy-move forgeries is created by copying and pasting a region or sector from one spot in an image to some other spot inside the same picture in order to modify or hide one or more objects and create a false vision. Moreover, copy-move forgeries identification is known to be successful when using key point-based analysis. There were some changes made to the image during copy-move forgeries. Moreover, to implement quality impersonating forgeries, techniques including turning, cropping, lightening, reduction, and force and contribute are used. Nowadays, even a non-expert may easily produce convincing forgeries in digital images because of modern digital imaging and robust image manipulation tools. Huge different forgeries have been created in recent decades as a result of digital manipulation, which involves incorporating or removing certain parts from the image. Thus, checking the materials of digital photos or discovering fraudulent areas would be immediately helpful, for example, when images are used as evidence at trial.

Evidently, there is no one single, efficient option to the challenge of detecting digital forgery [2].

Two kinds of techniques and block-based approaches—can be used to recognize the presence of a copy-move in a visual. The fundamental area of assessment consists of examining the decentness of images and identifying signs of modification without the requirement to use image files. Structurally complex transform, resilient to disturbance and geometrical modifications are only a few samples of the main aspects that feature-based techniques for copy-move verification retrieve from copied images. Block-based copy-move identification, in comparison, analyses the properties of each block in the frequency response by splitting the copied images into matching or non-matching blocks [3]. LBP uses the features retrieved from the frames of gray-level image data to pinpoint the fake portions in visuals. Moreover, with SURF, local picture features that are resistant to noisy and geometrical changes are quickly extracted. In terms of how the two methods replace a specific image location with some other picture, copy move manufacture is very similar to picture patching. For instance, copy move forgery uses a portion of the original base picture as its origin instead of using an external image. The comparable image served as both the origin and the endpoint for the modified image. Hereafter, parts of the initial image are duplicated, moved to the perfect location, and then merged in a duplicated move fraud. Typically, this is used to conceal particular nuances or to replicate specific areas of an image [4]. Moreover, to minimise the impression of irregularities between the initial and delayed region, some additional preparation, such as center separation and hiding, is often linked along the edge of the modified region.

Furthermore, the judgement regarding the validity of the data is subsequently made by evaluating the outcomes of several strategies. In single-image forgeries, the copy-move approach is used to substitute a section of the original picture with a section that was previously eliminated. Forgers employ certain comment on these thread modifications on the duplicated portions, including spin, scalability, and reflections, as well as mouldings and mixing, to make forgeries are easier to conceal. The addition of content for one image that comes from another image or photos is called forgeries using various pictures [5]. In addition, there are two distinct streams of computerized photo fraud detection. They are passive tactics and dynamic approaches. Images are extremely simple to change in the technological environment utilising well-known image manipulation software applications like Adobe Illustrator and Gimp, which results in an astounding number of phoney images entering in every day over the Web.

Identification of Digital image forgery is an important research area; however, it seems to be a significant problem. Finding proof of a fake is done by looking for unique characteristics, and traits. The actual image's analytical, architectural, or physiological qualities must be homogeneous for the detection techniques to work, but manipulated images lack this homogeneity. Digital image counterfeiting comes in a variety of forms, including picture merging, image reshaping, image editing, image re-sampling, and copy-move forgeries [6]. Several modified over time in a variety of domains,

including target detection, ML, and computation imagery, were successfully solved using the DL method. As a result, it can be useful in developing patching forgery investigative techniques.

Among the most successful and effective techniques applied in a variety of applications for image processing during the past ten years is the Artificial Neural Network. In addition, Convolutional Neural Network (CNN) is commonly employed for Copy-Move Forgery Detection in recent years. However, CNN method implemented on challenging datasets has attained less accuracy and high testing time in CMF recognition [7]. To address this issue, the current work proposes an effective hybrid optimization with CNN for recognizing CMFD from digital images, which can achieve great result at a very cheap computational effort. CMFD's objective is to identify areas that are comparable to certain other areas of the image. Architectural or post-processing procedures are typically performed upon altered areas during the tampering procedure to make the forgeries realistic and undetectable. The key piece of evidence in CMFD is the strong resemblance between the modified areas and the origin. Here, the GWO-ABO with CNN technique serves as the framework's main tenet.

The rest of the section is organized as follows: Section II describes the recent literatures related to CMF detection, Section III explains the materials and methods in which the dataset and proposed methodology are detailed, Section IV describes the result and discussion, and Section V concludes the paper.

II. RELATED WORKS

Although there are many other styles of digital picture scams, it can be quite difficult to spot copy-move forgeries. In order to identify copy-move fraud, the study utilized a new robust approach which is based on the Speeded up Robust Feature descriptor, Approximate Nearest Neighbour for feature representation, and Simple Linear Iterative Clustering for categorising the actual image into large pixel blocks. The portions that are in dispute are identified by swapping out paired key frames for comparable large pixel blocks, followed by the merging of adjacent blocks based on similar LCF [8]. On a variety of samples, including MICCF220, MICCF600, MICCF2000, and CoMoFoD, the paper measured a time complexity of 3.84 secs with 91.95% positioning accuracy. However, because the process takes longer than the alternative way, it cannot be used in the present circumstances.

The author in [9] utilised robust feature enhancement acceleration, and the SVM is used to recognise the particular object. There were some changes made to the image during copy-move forgeries. To create effective portrayal forgery, techniques including rotating, magnification, lightening, reduction, and force and contribute are used in this paper. The dominant features from the source images are chosen in this case by the SURF extracting features. The SVM classifies these input photos using detection and recognition in order to retrieve the paired local features. Here, the outcomes demonstrate that forging images are taken from a collection of test images. When there is additional uncertainty in the data set, SVM doesn't really function very well.

The paper [10] used a reliable technique for identifying Copy-Move forgeries in digital photographs. The procedure begins by removing an image's SIFT characteristics, which are resistant to modifications in lighting, spin, scale, etc. Characteristics are then compared to one another in order to check for any potential picture forgeries due to the resemblance between the inserted region and the duplicate data region. The utilised system works well with various post-image analysis methods and is resistant to complex image analysis because of the high robustness of SIFT features extracted. However, to increase the robustness over inadequate SNR and small-size tampering regions, more research is still required.

The paper [11] utilized a technique for spotting fake parts in digital photographs. The steps in this procedure are as follows: (1) transform the colour image into gray, (2) break the image representation into overlaying blocks of pixels, (3) use DCT to identify and extract feature, (4) aggregate blocks using the K-means approach, and (5) use radix order to correlate features. Here the method was applied to four different photos and on the foundation of the experimental work. Diverse methods, such as DCT and DWT, are typically utilized to extract the characteristics from the digital photos in unrelated domains, such as feature recognition and image fraud prevention.

A reliable copy-move picture fraud prevention method used Gaussian-Hermite Moments in the paper. The method separates the image as an input into overlaying, fixed-size chunks, and then extracts the GHM values for every chunks. GHM is a powerful tool that may be used to recover picture characteristics that are rotation-, translation-, and scale-invariant. Through lexicographically ordering all the characteristics', related chunks are matched. The outcomes of the experiments demonstrate how precisely the suggested technique can find the duplicate forged portions in a forged image [12]. Here, the used technique performs better than previous relevant strategies, according to experimental findings, both at the image and pixel levels. However, the method can necessitate additional time, rendering it inappropriate for the next presentation.

The outcome of applying the lighting estimation technique reveals that the method is only marginally improved by excluding specific observations, such as geometry depending on shadowing and upgrade and improve characteristics on selected input images [13]. The technique to identify image modifications is approved by the publication in consideration of the abnormal illumination. By calculating surfaces and lighting data from the centre points, the counterfeit in images is identified. The process produces acceptable results for many source images. Here, the procedure is not just restricted to human faces and the identification of image regions with the same brightness. It can be used for photographs with any kind of item included in the scene. However, the method needed to be improved in order to estimate sections with the same brightness and to automatically choose spots.

The method developed in this work is a reliable one for spotting digital picture forgeries and is sufficiently robust to withstand attempts at image alteration. The very first process

in the work is to generate the Rgb values into YCbCr space. Next, the Hilbert-Huang Transform includes are obtained from the chrominance-red element Cr. Finally, three distinct classification techniques, KNN, SVM and ANN—have been evaluated and contrasted for the task of classifying images as accurate or fake. Structural-Similarity is used to measure the precision of copy - move and to validate the findings. The suggested technique may identify pixels in the context of several images post-processing assaults, according to the findings of the robustness assessment; nevertheless, these cyber-attacks gradually degrade it [14]. However, since these techniques necessitate a large amount of storage for the training examples, the procedure might be slowed significantly.

The paper [15] employed a blind verification approach based on bundle segmentation and visual scrambling to discover repeated sections for copy-move forgeries. DCT is employed to find the DCT coefficient matrices for each level sufficient source image in suspected images. The visual hashing characteristic matrices and matrices are treated in a systematic manner. Additionally, to increase analysis is an essential part; a package grouping technique is utilized in place of conventional textual order techniques in this work. The perceptive hashing vectors in every package and its neighbouring packages, comparable chunks can be distinguished. A computerisation that builds a feature representation to describe an image block using perceptive hash characters can withstand certain common attacks like adding white Gaussian noise and GB. Additionally, the suggested approach is vulnerable to some sophisticated assaults such sector manipulation and scalability. However, it is more expensive than other ways, consequently not everyone can benefit from it.

One of the most prevalent popular forms of digital image forgeries, merging, was identified using a technology in the study [16]. Here, the VGG-16 CNNs are the foundation of the algorithm. The network architecture is used to receive visual features as information and determines whether an update is authentic or fake. During the learning phase, the work chooses portions on the edges of the inserted splice and from the original image portions. The potential for using the strategy when the JPEG technique repeatedly compresses deformed photos over a small range. As compared to other techniques, the reported findings show great generalization ability for a set of photos with intentional imperfections. However, Dynamic graphic images cannot be handled by the JPEG image standard, and stacked images are not supported.

The forensic evidence of analyser sensors was addressed in the paper using a ML-based method. Numerous diagnostic approaches, including digital image authenticating, related to Google, and security mechanisms, are crucial for digital image assessment because of the rising accessibility and effectiveness of image altering applications. In this work [17], a CNN-based method for identifying scanner framework has been used. The test results demonstrated that originating scanner authentication may be done with extreme precision. A system, which brings together the advantages of ResNet and GoogleNet while still being compact. A dependability map that shows the altered areas in a digital image is also generated

by the article. However, a deeper network has a significant downside in that it typically takes weeks to train, rendering it unworkable in practical systems.

In the paper [18], two methods for recognizing image combining are supported. Both techniques are used to retrieve input image features by using overlapped chunks. The first method is used to extract LBP or LTP components based on the image's chrominance's gray-levels, while the other approach retrieves ELTP characteristics from the luminance site's fast Fourier transformation. These methodologies' outcomes have been summarized in a favourable manner. By reaching an accurateness of 88.62% on data compression from the CASIAv1.0 collection, the FFT-ELTP approach works reasonably well. However, all of the strategies that are being discussed entail intricate modifications like the DCT and FFT, which makes the technique more difficult. It may be possible to eliminate the requirement for such sophisticated activities with the effort in a similar approach. An additional subject for investigation in the investigation is the distribution of the forgeries in the photograph.

The paper [19] utilized, a key point-based image evidence collection procedure based on the Helmert conversion and super pixel recognition technique has been suggested. The method seeks to gather forensic data while detecting copy-move forgery photos. The activities or tasks make up the suggested approach's process. First, use a SIFT approach to

identify the key details and related attributes. The resemblance between key points will then be determined based on the descriptors to produce matched pairings. In order to determine the precise counterfeit zones, the Helmert conversion to group the matched pairs according to geographical distances and geometry restrictions. In respect to province approaches, the experimental outcomes from evaluating multiple samples show that the suggested approach achieves excellent highly precise rates. However, the used method is not resistant to symmetrical, recurrent, and smoother processes for regional manipulation.

III. MATERIALS AND METHODS

A. Dataset Description

The most difficult or well-known databases in the evaluation of CMF recognition methods are MICC-F220 [20], SATs-130 [21], and MICC-F600 [22]. Table I provides detailed information of various assessment datasets. The MICC-F600 database challenged attacks have been organised into four tiers with various forgery attacks. The MICC-F600 and MICC-F220 databases had been used to effectively test the presented technique. While the SATs-130 database has only 96 images, which is too little and collide with DL method's nature. Large databases are required for the training phase of DL methods in order to accurately extract feature maps and construct system behaviour.

TABLE I. DATASET SPECIFICATION

Sl. no	Database	Image Composition			Tampered region size	Images size (Pixels)
		Total	Forged	Original		
1	MICC-F600	600	152	448	The size of the forged region changes from image-to-image.	800×532 to 3888×2592
2	SATs-130	96	48	48	The size of the forged area changes from image-to-image.	1024×683 to 3264×2448
3	MICC-F220	220	110	110	1.2% of the entire image seems to be the forged area.	722×480 to 800×600

B. Proposed Methodology

The suggested model has four steps, and Fig. 1 depicts the proposed method's workflow. Pre-processing seems to be the initial step. Two things are being accomplished by this technique. The first objective is to uniformly scale all of the input images, and the second objective is to transform the images into tensors. The extraction of features seems to be the second stage. To retrieve the features from the raw images, this step is obtained. Feature matching seems to be the third stage, which is obtained to demonstrate the presence of forgeries. The final stage is post processing. First, potential erroneous matches are removed at this stage. The CMF in digital images is afterwards identified.

1) *Pre-processing by GWO-ABO*: GWO appears to be a bionic optimization method. It mimics the cooperative, well delineated working relationships found in grey wolf hunting behaviour. Grey wolves often live in packs of five to twelve people and have a rigid, dominant hierarchy based on wolf leadership skills. The three phases of the GW pack's predatory process: hunting, encircling, and attacking. The most prominent wolf in the pack, also known as wolf, typically

served as its leader. The GWO terminology for the second and third tiers of leadership wolves is wolf and wolf, respectively. These second- and third-ranking auxiliary wolves aid the main wolf in making hunting decisions. All other following wolves are classified as wolves, and they pursue and engage in combat with the prey alongside these powerful wolves.

For hunting, the enclosing of prey approach is used. For iteration i , the mathematical framework for this method is shown in below Eqns. (1) and (2).

$$\vec{F} = |\vec{Y} \times \vec{Q}_p(i) - \vec{Q}(i)| \quad (1)$$

$$\vec{Q}(i + 1) = \vec{Q}_p(i) - \vec{D} \cdot \vec{F} \quad (2)$$

Here, \vec{D} and \vec{Y} are coefficient vectors, which is described as $\vec{D} = 2\vec{d} \cdot \vec{v}_1 - \vec{d}$ and $\vec{Y} = 2 \cdot \vec{v}_2$. Where, the random vectors $\vec{v}_1, \vec{v}_2 \in (0,1)$ and $\vec{d} = d_1(1 - i/maxi)$, linearly decreases from d_1 to zero; d_1 value was set as 2 in actual GWO. Moreover, $maxi$ represents maximum number of iterations. The GWO's hunting process has been headed by three finest solutions i.e., α , β and γ wolves. Thus, these 3 leading solution's positions have been saved in the pack and the remaining ω wolves update their positions predicated on them.

This position updating technique's mathematical model is represented in Eq. (3).

$$\vec{Q}(i+1) = (\vec{Q}_1 + \vec{Q}_2 + \vec{Q}_3) / 3 \quad (3)$$

Where, $\vec{Q}_1, \vec{Q}_2,$ and \vec{Q}_3 is computed by Eqn. (4)

$$\begin{aligned} \vec{Q}_1 &= \vec{Q}_\alpha(i) - \vec{D}_1 \cdot \vec{F}_\alpha \\ \vec{Q}_2 &= \vec{Q}_\beta(i) - \vec{D}_1 \cdot \vec{F}_\beta \\ \vec{Q}_3 &= \vec{Q}_\gamma(i) - \vec{D}_1 \cdot \vec{F}_\gamma \end{aligned} \quad (4)$$

Here, $\vec{F}_\alpha, \vec{F}_\beta,$ and \vec{F}_γ are computed by Eqn. (5)

$$\begin{aligned} \vec{F}_\alpha &= |\vec{Y}_1 \times \vec{Q}_\alpha(i) - \vec{Q}| \\ \vec{F}_\beta &= |\vec{Y}_2 \times \vec{Q}_\beta(i) - \vec{Q}| \\ \vec{F}_\gamma &= |\vec{Y}_3 \times \vec{Q}_\gamma(i) - \vec{Q}| \end{aligned} \quad (5)$$

Fig. 1. Presented methods workflow

African buffalos' three principal characteristics are extensive memory capacity, cooperative cum communicative ability in both good and bad times, and extreme intellect gives origin to a democratic character. There are two sounds: 'maaa' and 'waaa', which are indicated by P_k and S_k , respectively. The buffalo's movement is determined by Eq. (6).

$$P_k + 1 = P_k + V_1(\vec{Q}(i+1) - S_k) + V_2(d_u \cdot k - S_k) \quad (6)$$

Here, the input image is denoted as S_k , P_k is the image size, k represents the iteration, the learning factors are represented as V_1 and V_2 , the wolf's best fitness is represented as $\vec{Q}(i+1)$ and $d_u \cdot k$ is buffalo's best in each iteration. The image \rightarrow tensors process is done by Eq. (7).

$$S_k + 1 = (S_k + P_k) / \pm 0.5 \quad (7)$$

2) *Feature extraction*: Three convolutional layers, typically preceded by a pooling layer, make up the suggested feature extraction method. A max pooling layer comes after a convolutional layer that combines 32 filters in total. In complement to the ultimate combo of a convolutional layer with 128 filters and the final max pooling layer, a convolutional layer with 64 filters as well as a max pooling layer are also used. A feature map, which reflects the input image, has been produced by this process. The layers in extracting features from input images are shown in Fig. 2.

Fig. 2. Layers in feature extraction

The convolutional and pooling layer sequencing creates a feature vector out of the feature map. The CNN structure is shown in Fig. 3. The input for the following step is this feature vector.

a) *Convolutional layer*: A series of 2D digital filters make up the extracting features layer known as the convolutional layer. A convolution layer was used to minimise the data variables and extract the important features. The convolution layer includes scale invariance, interpretation invariance, and rotation invariance. Both the over-fitting problem is lessened and the generalisation idea is added to the fundamental framework. Eq. (8) illustrates the input of the convolutional layer like a collection of GWO-ABO pre-processed images.

$$h_k^l = f(\sum_{j \in Y_k} h_k^{m-1} * R_{ki}^l + Y_k^m) \quad (8)$$

Here, h_k is the given map cluster; R_{kj}^m is the convolution kernel, which has been employed for joining

Pre-processed image

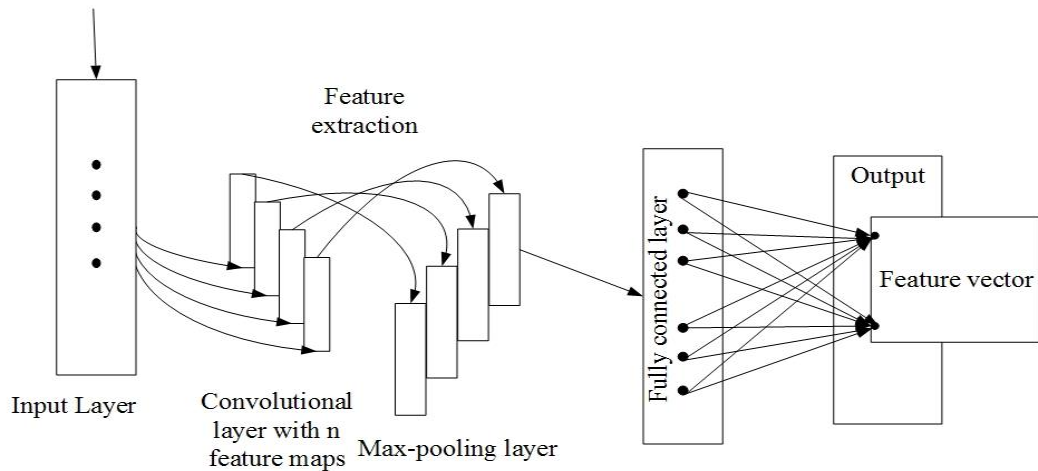

Fig. 3. CNN structure

the i^{th} input feature map with k^{th} output feature map; Y_k^m defines the consistent bias to the i^{th} input feature map, the activation function is denoted as f .

$$\delta_k^m = \delta_k^{m+1} C_k^{m+1} \times (s^m) = \beta_k^{m+1} up(\delta_k^{m+1}) \times (s^m) \quad (9)$$

Here, $m + 1$ describes the pooling layer; the convolution kernel is denoted as C . The error function's partial derivatives convolution kernel and cost is described in Eq. (10) and (11)

$$\partial G / \partial R_{ki}^m = \sum_{v,n} (\delta_k^m) v, n (A_k^{m-1}) v, n \quad (10)$$

$$\partial G / \partial Y_k^m = \sum_{v,n} (\delta_k^m) v, n \quad (11)$$

Where, $(A_k^{m-1})v, n$ is h_k^{m-1} patch for every convolution and $B_{kj}^m(v, n)$ is the patch centre. Lower random weights are used to initialize these filter's values. Then, during the training phase, these weights' values have been modified. The characteristics from the input images should be extracted by the filters that have been used. A feature map with an input image's filtered copies depth is produced by this procedure. A pixel's updated value (P_n) is equal to the sum of its former surrounding pixels' (p) values multiplied by the filtration elements (g) that have been used. The calculation is shown in Eq (12).

$$P_n = \sum_{j \in w} P_j \times g_j \quad (12)$$

b) *Pooling layer*: The convolutional layer's feature map's dimensions are reduced using the pooling layer, a form of feature reduction technique. Windows are created using the split input feature map. Every window is divided into its highest value from its contained values by the max pooling method. In contrast, the mean pooling divides the windows into the average value of the window's contained values. The suggested approach has implemented the max pooling layers.

3) *Feature matching*: To detect forgeries after obtaining the feature matrix, relevance searching has been carried out. In order to expedite the matching process, the feature matrix has been first lexicographically processed for this reason. Following that, the Euclidean distance used to compare vector similarities is provided. By using the provided Eq. (13) to contrast the vectors distances with a predefined threshold δ , the matching vectors have been identified.

$$f_k^i = (f_1, f_2, \dots, f_{10}), \sqrt{\sum_{k=1}^{10} (f_i - f_j)^2} \leq \delta \quad (13)$$

Where, $\delta = 1.5$. The Euclidean distance between the matched blocks is used to check similarities in the following stage of matching; it must be larger than threshold β to prevent false matches.

4) *Post processing*: First, potential erroneous matches have been removed in this stage. The shift vector between identical blocks has been computed for this reason. Shift vectors have been produced from the suspect pairs' top left coordinates. Additionally, it is assessed whether the quantity of blocks with the similar shift vector surpasses a predefined threshold value ($\gamma = 32$). If this criterion is met, it is demonstrated that CMF has finished handling the relevant blocks. The CMF on digital photos is finally discovered.

IV. RESULTS AND DISCUSSION

The assessment of the suggested algorithm's findings was reported in the results section. A comparative study with earlier methods working with CMF recognition was conducted after findings listing and discussion. A computer system running Windows 10 with an Intel Core i7 8th generation CPU, 4 GB of GPU hardware supporting CUDA, processor-64-bit, and RAM 8 GB was utilised to construct the suggested method. In addition to Keras and TensorFlow, Python 3.5 software tools were used to implement the suggested method's backend toolkits.

A. Evaluation Metrics

The major metrics for evaluating the DL model's detection performance are: F-measure, TPR, accuracy, FNR, FPR, TNR, and TT. These metrics were employed for evaluating the presented GWO-ABO-CNN models performance in CMF recognition.

True negative (T_n) represents the number of real images that were really identified as real images. False negative (F_n) refers to the number of altered images that were mistakenly identified as real images. True positive (T_p) represents the number of manipulated images that were accurately identified

and false positive (F_p) represents the number of real images that were mistakenly identified as altered images.

1) *Accuracy*: Accuracy has been referred to as the percentage of correctly detected image pixels. Absolute pixel precision is another phrase for this. Despite being the most fundamental performance indicator, anytime there is a class disagreement, it may lead to erroneous image detection findings. When one recognised category outperforms another, there is a category disparity. In this scenario, the dominant class's superior accuracy will outweigh the other group's poorer accuracy, leading to biased findings. If there has been no group discrepancy, the accuracy measure was advised for evaluating detection results using images.

Accuracy is described in Eq. (14),

$$Accuracy = \frac{T_p + T_n}{T_p + F_p + T_n + F_n} \quad (14)$$

2) *True positive rate (TPR)*: TPR, or the proportion of images which have been accurately identified as CMF, relates to the capacity to positively detect an instance of forgery. Moreover, sensitivity is described as the proportions of predicted forgery among those images are real.

TPR is described in Eqn. (15),

$$TPR = \frac{T_p}{T_p + F_n} \quad (15)$$

3) *True negative rate (TNR)*: The chance that an image which does not have any forgery will have a negative test outcome is known as TNR, and it is the proportion of forgery which is appropriately detected as CMF. Moreover, specificity is described as the proportions of predicted negative outcomes among those images are tested as original.

TNR is described in Eq. (16),

$$TNR = \frac{T_n}{T_n + F_p} \quad (16)$$

4) *False positive rate (FPR)*: The FPR is determined by dividing the total quantity of forgery images by the number of forgery images that were mistakenly classified as original images (false positives).

TNR is described in Eqn. (17),

$$FPR = \frac{F_p}{T_n + F_p} \quad (17)$$

5) *False negative rate (FNR)*: The likelihood that a true positive would be overlooked by the sample is measured by the FNR, also known as the miss rate. The FNR seems to be the percentage of positive test results that result in failed tests. The FNR has been computed as the difference between the number of altered images that were incorrectly identified as true images and the total number of altered images that were incorrectly identified as altered images as well as the number

of altered images that were correctly identified as altered images.

FNR is described in Eq. (18),

$$FNR = \frac{F_n}{T_p} + F_n \quad (18)$$

6) *F-measure*: The effectiveness of the procedures is demonstrated through a pixel-based assessment that involves determining whether or not each individual pixel is false. The proposed as well as considered approaches are evaluated in terms of performance using the F-measure. Its improved performance in identifying the CMF in digital images is shown by a higher F-measure outcome.

F-measure is described in Eq. (19),

$$F - measure = 2 \times \frac{T_p}{2 \times (F_p + F_n + T_p)} \quad (19)$$

7) *Testing time (TT)*: Testing Time (TT) has been further employed to assess the presented model and compare it to other models. TT seems to be the average amount of time required to evaluate the images for the specified number of runs (k). Additionally, as this step has only been completed offline once, Learning Time has been not taken into account.

B. Results

The research introduced a novel DL (CNN) method for the procedure of detecting image forgery. The suggested model combines a CNN model with a hybrid optimization of GWO and ABO. The suggested DL model has been tested using the MICC-F600, MICC-F220, and SATs-130 databases, among other datasets. The goal of the computational experiments has always been to develop the best model possible in terms of complexity and TT. Moreover, the suggested method had been tested using the k-fold cross-validation method. This framework starts with a learning phase that will be repeated (k) times to get a diversity of the images being looked at and provide accurate estimation by thoroughly looking through the datasets. The dataset is further divided into (k) groups (folds) with almost the similar dimension in this approach.

The suggested model employed (k-1) the residual categories for testing and the classes for training. For both testing and training there are (k) iterations. The suggested approach made advantage of a method for 5-fold cross-validation. Accordingly, for each of the five rounds, 30% of the dataset's images were utilised for testing while the remaining 70% were randomly chosen for training. Each iteration will employ a different 30% of the images instead of the previous 30% of images for assessment.

TABLE II. PRESENTED MODEL PERFORMANCE @ 25 EPOCHS

Metrics	Datasets		
	MICC-F600	SATs-130	MICC-F220
Accuracy (%)	95	92	97
TPR (%)	90.4	84	100
F-measure (%)	93.98	88.79	91.55
FNR (%)	28.5	6.7	0
TT (sec)	1.23	5.02	1.24
TNR (%)	85.19	77.5	98.2
FPR (%)	5.7	10.4	10.8

Five trials at training epochs of 25, 75, 50, and 100 make up the test. At each epoch, the TPR, FNR, F-measure, TNR, FPR, and accuracy are recorded. In the computational experiments, a recording of the TT has been also taken into account. The simulation outcomes for every epoch for all databases are presented in Tables II to V.

TABLE III. PRESENTED MODEL PERFORMANCE @ 50 EPOCHS

Metrics	Datasets		
	MICC-F600	SATs-130	MICC-F220
Accuracy (%)	97.33	93.04	91.45
TPR (%)	97.5	93.97	100
F-measure (%)	93.4	88	82
FNR (%)	34.4	1.6	0
TT (sec)	1.31	4.25	1.25
TNR (%)	87	93	97
FPR (%)	10.1	5.6	4.3

It is evident that the implementation of the suggested model grows as the number of epoch's increases. Additionally, how the suggested technique is implemented varies from one database to another. Therefore, the suggested model cannot be implemented due to two limits. The first constraint seems to be the number of training epochs, and the other is the databases construction, based on which the suggested model has been used.

TABLE IV. PRESENTED MODEL PERFORMANCE @ 75 EPOCHS

Metrics	Datasets		
	MICC-F600	SATs-130	MICC-F220
Accuracy (%)	94.4	97.8	98.7
TPR (%)	100	97.5	100
F-measure (%)	98.2	98.2	99.05
FNR (%)	9.7	0	0
TT (sec)	1.23	4.14	1.27
TNR (%)	97.6	96.25	98.54
FPR (%)	1.7	5.4	3.2

The effectiveness metric variable findings for the various four databases at epochs 25, 50, 75, and 100 are shown in Tables II, III, IV, and V, correspondingly. The findings shown in the tables show that after 100 epochs, F-measure, TPR, accuracy, and TNR increase by over 100%. In contrast, FNR and FPR decreased almost to zero at the same time that the number of epochs reached 100. Additionally, as the number of epochs increased, the TT decreased to a minimum.

TABLE V. PRESENTED MODEL PERFORMANCE @ 100 EPOCHS

Metrics	Datasets		
	MICC-F600	SATs-130	MICC-F220
Accuracy (%)	98.2	100	100
TPR (%)	98.6	99	100
F-measure (%)	99.9	100	100
FNR (%)	2.2	0	0
TT (sec)	1.24	1.32	1.132
TNR (%)	100	98.05	100
FPR (%)	1.04	2.84	0

It is clear from the previous findings that the number of training components has a significant impact on the performance of the entire model. Additionally, it is noted that 100 epochs yield the greatest results. The suggested model included a number of identifiers that might affect the results in terms of accuracy, F-measure, or TT. These variables include the volume of data utilized for training (which is connected to the utilized databases dimension), the volume of data employed as inputs to the network, the volume of hidden prototype layers, and the volume of the chosen epochs. The Identifiers for how much data are employed for training, how much data is employed as input, and how much data is employed for the network's hidden layers all remain constant. The number of the chosen epochs seems to be the only identifier left that might affect testing time.

TABLE VI. PRESENTED MODEL'S OPTIMAL PERFORMANCE

Datasets	Metrics		
	Accuracy (%)	F-measure (%)	TT (sec)
MICC-F600	98.2	99.9	1.24
SATs-130	100	100	1.32
MICC-F220	100	100	1.132

It was discovered that the number of epochs chosen has a significant effect on how long the method takes to reach the optimal state feature map. The method can obtain the best

performance by taking the time necessary to produce the appropriate feature map. The optimum feature map would be retrieved by choosing a precise number of epochs. Along with the number of epochs, interpolation will occur. In addition, the model will perform worse if fewer epochs than the chosen number are used, also failed to obtain the optimal feature map. As a result, if the other identifiers have been kept constant, the number of chosen epochs affects the TT. The optimal performance of proposed model in CMF detection on different databases is shown in Table VI.

Fig. 4. Different dataset's optimal accuracy and F-measure of detection

The best accuracy and F-measure representation for each database is shown in Fig. 4. According to the simulation findings, the suggested algorithm is a valid and practical method for CMF detection. Moreover, the presented model's MICC-F220 dataset's accuracy was compared with other existing models like Speeded Up-Robust Feature (SURF) [8], Spatial features-based Image CMF detection (IC-MFDs) [23], CNN [24], and Convolutional Long-Short Term Memory (ConvLSTM) [25].

TABLE VII. MICC-F220 DATABASE ACCURACY COMPARISON

Method	Accuracy (%)
SURF	91.95
IC-MFDs	98.44
CNN	100
ConvLSTM	100
Presented (GWO-ABO-CNN)	100

The MICC-F220 dataset accuracy comparison of different models is shown in Table VII and Fig. 5. The comparison outcome indicated that the CMF detection performed by CNN model has attained 100% accuracy.

Fig. 5. Comparison of accuracy

The accuracy attained by the model SURF was 91.95%, IC-MFDs was 98.44%, CNN was 100%, ConvLSTM was 100%, and the presented GWO-ABO-CNN was 100%. The models with higher accuracy are reliable for CMF detection. The main problem in the CMF recognition is less accuracy on challenging database. From the current research results, it is evident that the presented GWO-ABO-CNN method detects CMF in challenging datasets like SATs130, MICC-F220, and MICC-F600 with 100% accuracy. Thus, the presented method is reliable for CMF recognition in digital images.

V. CONCLUSION

This research presents a deep learning system for CMF detection predicated on hybrid optimization GWO-ABO with CNN (GWO-ABO-CNN). The main goal of this study is to construct and enhance the DL classification framework for identifying real and forged classes in alleged digital image forgeries. The suggested approach anticipates creating a new paradigm that will offer improved performance, demand less testing time, and incur little computational expense. Four layers—pre-processing, feature extraction, feature matching, and post-processing (detection)—are addressed in the creation of the proposed forgery detection method. GWO-ABO has been used to unify the picture size and turn the images into tensors in the pre-processing layer. The suggested method is predicated on a novel invention that builds a serial series of convolutional layers and a pooling layer to speed up the detection process in the feature extraction layer. Several challenging datasets, including the SATs130, MICC-F220, and MICC-F600 datasets, have been employed in the evaluation process. The test findings revealed that 100 training epochs had produced the best accuracy.

Abstract—Recently, the number of different kinds of events on social media platforms show a tremendous increase in each second. Hence, event detection holds a very important role in the current scenario. However, event detection is challenging in information technology (IT). Several machine learning-based approaches are established for the event detection process, but it generates a high error and makes various information loss, affecting the system's performance. Thus, the proposed work introduces a new detection strategy based on a deep learning architecture. In this, both text and image data are utilized for event detection. The different procedures for image and text databases are pre-processing, extraction and classification. The text data is pre-processed using four methods: lower case filter, tokenization, stemming, and stop word filter. An adaptive median filter (AMF) is utilized for pre-processing the image data. After the pre-processing stage, feature extraction is performed for text and image-based data in which most useful features are extracted. Finally, the varied events are detected and classified using the proposed Deep Compressed Convolutional Neural Network (DCCNN). The entire work is implemented using the PYTHON platform. The efficiency of the proposed model is measured by evaluating the performance metrics such as accuracy, recall, precision and F-measure. The simulation validation exhibits that the proposed classification method attains an improved accuracy of 97.1%, obtained precision is about 95.06%, recall value is 91.69%, and f-measure is 93.35%. The efficacy of the proposed deep learning method is proved by comparing the attained results with various state-of-the-art techniques.

Keywords—Event detection; erosion; dilation; deep learning; deep compressed convolutional neural network; hashing; median filter

I. INTRODUCTION

In digital societies, the demand to express oneself and communicate with others is becoming more prominent. In many sectors of smart societies, this is being accomplished through digital platforms such as social media, which have increasingly become easy and inexpensive sensors compared to physical sensors [1-3]. The term “big data” is used to demonstrate the trend of data explosion. Many research and surveys try to describe what big data means. Each work put forward a variety of viewpoints in terms of background, opportunities, applications, and challenges. Digital data, created by many digital devices, rises at breakneck speed [4-6]. The McKinsey Global Institute (MGI) offered a detailed analysis of big data in terms of three various parameters such as innovation, competition and productivity. Different ML techniques show better results in big data processing

applications from the last decades. Also, the ML approaches provide improved detection results in road traffic applications [7] as the size and number of data generated increase daily, handling these data using traditional learning methods is very difficult.

Data generated by social media users is massive in volume, rapidly expanding, diverse in nature, and variable quality. These are the most important elements that define big data. Because of its immense popularity, the subject of event detection has recently drawn the attention of researchers. The big data age has arrived due to the abundance of data in virtually every area of our society [8-10]. It is a hot topic that affects many facets of our lives. Twitter has been used as a valuable data source in various situations [11, 12]. There has been a growing body of research on using Twitter as a sensor for traffic monitoring, flow forecasting, congestion prediction, and incident detection in recent years. These techniques have a lot of promise in this field. Event recognition from unstructured, quickly developing tweets is a difficult task from data mining. Many existing works developed different approaches for twitter-based event detection [13-15]. The volume, pace, variety, and authenticity of Twitter data are all hallmarks of big data. As a result, managing and analyzing Twitter data for event detection is a huge difficulty. Deep learning uses a vast amount of data to learn how features behave during training and predicts the class of data that has never been seen before. The proposed approach will be processed on both text and image datasets to analyze and improve the performance.

Event detection is a significant area in fundamental language processing that mainly focuses on automatic event prediction [16]. Generally, events are the particular actions performed in a certain period. The events are mainly represented in varied lengths of expressions from the collections of text documents. The certain event detection is based on the features, and the particular data are extracted from the text [17]. The detection and classification of events in texts and images play an important role in several applications. An effective event detection helps to analyze which event has occurred. Various techniques have been developed for event classification in the past few years. Some of the classification approaches are failed to classify the exact events because of the high computational complexity. Mainly, most traditional approaches are not suitable for high data dimensionality. Also, the classification performance model is affected due to the large over fitting issue.

*Corresponding Author.

Moreover, the existing works are troubled to process two different data types like image or text. Hence, event detection with text and image data is difficult in image processing. Thus, an effective methodology for accurate event detection and classification in image processing is necessary. Nowadays, deep learning approaches play a significant role in event classification and also it is highly appropriate for big data applications [18-20]. For this reason, the proposed work concentrates on deep learning techniques for event detection and classification using text and image-based data.

A. Motivation

Event detection using big data plays a very important role in a wide variety of applications. Many researchers use a wide variety of strategies to detect big data events. This work introduces a new deep learning-based technique for the efficient detection and classification of events. The prevalence of big data creates several challenges for the usual feature selection task. Scalability and stability are two issues in feature selection for big data analytics. A minimum amount of work can be done to detect events using Twitter. Big data techniques are critical since they allow for the system's scalability in data analytics and control.

DL can improve the accuracy and efficiency of the event detection process, which would be extremely beneficial. Unsupervised feature learning approaches and deep learning have been widely deployed for image and text applications. These strategies have shown a lot of promise in these domains for autonomously expressing the feature space using unlabelled data to improve the accuracy of subsequent classification tasks.

B. Contribution

The main contributions of the work are summarized below.

- To achieve an efficient event detection process using a compressed deep learning architecture, named deep compressed convolutional neural network.
- To implement the event detection approach for both image and text data, also improvise the overall performance.
- To utilize efficient text and image data pre-processing approaches to get accurate results for the event detection process using big data.
- To evaluate the performance of the event detection using statistical measures such as accuracy, recall and f1-score, and compare it with the existing performance.

C. Organization

The concept is briefly explained in Section I. Some of the recent related work is explained in the Section II. The proposed event detection approach is elaborated in Section III. The implementation results and the dataset description are provided in Section IV. Finally, the conclusion and future scope are provided in Section V.

II. RELATED WORKS

Some of the existing works carried out on event detection using different approaches are discussed below.

Cherichi et al. [21] developed a real-time event detection methodology using big data analytics in microblogs. In this existing work, a new metric is developed to enhance the outcome of microblogs searches. Here, the system is processed by executing five modules: lexical analysis, morphological analysis, syntactic analysis, extraction and interpretation module. Initially, the tweets are pre-processed by performing tokenization, splitting the sentence and normalization. After the completion of the pre-processing stage, feature extraction is enabled. The feature extraction is performed with the assists of Natural Language Processing (NLP) by integrating the author's relevance, content relevance, and the relevance of the tweet. Finally, the event information is interpreted in the last stage. The established technique depends upon the framework of temporal marker classes and the contextual searching approach. A knowledge management system is constructed for measuring the developed approach. This existing work cannot obtain better results because of the high correlation between event information in tweets.

Yadav et al. [22] developed signal energy transformations for analyzing various events in real-time. A synchrophasor data is utilized for detecting multiple events in power systems. The events are detected using the Teager-Kaiser energy operator (TKEO) approach. The mentioned technique is also responsible for temporal localization. This approach is invulnerable to large amplitude oscillation in the data, and it provides the extent of time resolution. The events are classified by introducing an energy similarity measure (ESM) to differentiate the events with improved accuracy performance. This developed model categorizes different events with unequal severity and reduced time gaps. For real time, this approach utilizes only 10 samples of data windows. Hence, this technique is appropriate for sensing the events in power systems with better reliability. But, it faces increased computational complexity, which can disrupt the system's entire performance.

Wang et al. [23] established an extended R-FCN model for event detection based on audio. The developed framework involves two phases for event prediction. Initially, the convolutional kernels in the time axis are slide to identify the presence of audio events. Then, the proposals which feasibly involves audio events are produced by utilizing region proposal networks (RPN). In the next phase, the domain: frequency and time are combined with categorizing the proposals, and the boundaries are refined. This developed approach utilizes spectrogram features from the audio signals as the input. This existing work uses ResNet50, ResNet101 and enhanced ResNet50 methods to make real-time outcomes. This approach helps to make the system process easier. The accurate position of the audio event is detected at first, and it cannot consider the event class of audio in the initial phase. Therefore, it generates a binary classification issue. Thus, the process is turned into the second phase in which the proposal is classified, and the boundaries are refined. The developed

approach is better for event detection, but it is computationally expensive.

Zhang et al. [24] suggested a deep learning-based approach for detecting events with images and text from social media. This existing study develops an approach named collective action events from social media (CASM). The main intention of this model is to detect the collective action events utilizing the data from social media. Both image and text data are used for the event detection process. For processing the image data, a convolutional neural network (CNN) is utilized, and for text data, a recurrent neural network (RNN) with long short-term memory (LSTM) is used. This study uses a two-stage classification model for social media posts event prediction. The developed CASM is executed on Chinese social media data and detects numerous action events from 2010 to 2017. This deep learning approach provides better classification results in event detection for image and text-based data.

Chen et al. [25] developed a semi-supervised deep learning approaches for traffic event detection using multi-modal data. For traffic event detection, the suggested work uses big data applications. The input data is encoded into numerical vector forms using feature learning components in multi-modal data. The multiples of data are processed simultaneously in a neural network and combine the features of each varied form of input data. The experimental results represent that the suggested technique is not suited for different classes of events. Also, this approach takes high learning time in the training process.

Alomari *et al.* [26] introduced a new approach for road event detection. This paper also put forward a new and efficient big data tool named Iktishaf. It is developed with the help of Apache Spark to detect events related to traffic data. This existing study develops several classifiers using three ML technologies to detect eight different kinds of events. The classifiers were tested against a variety of criteria and other sources. Text pre-processing, event detection, and feature space are all improved with Iktishaf Stemmer. The pre-processing phase minimizes the grammatical errors and mistakes in an Arabic dialect text. Also, this stage diminishes the noises and typos in the input data. Tokenizer and normalizer are performed to improve the data quality in the initial stage. The features are extracted from the pre-processed data using the term frequency-inverse document frequency (TF-IDF). In the end, the event is classified by using the tweets filtering component (TFC). This study faces reduced accuracy, scalability, functionality, and data management issues. Thus, developing an effective technique for event detection is important for obtaining better outcomes.

A. Research Gap Analysis

As surveying several existing works, event detection in image processing is critical for various techniques. Many of the previous works are not applicable for multi-modal applications in big data. In some cases, the traditional approaches fail to perform in large data dimensionality and make the system performance a minimum. The popularity of

big data creates several challenges for the usual feature selection task. Scalability and stability are two issues in feature selection for big data analytics. A minimum amount of work can be done to detect events using Twitter. The techniques for detecting events must be exact. The retrieved data must be accurate in order to make better decisions. But many of the existing systems provide less accuracy for event detection procedures. Another limitation of the existing methods is difficulty in the run time and computational complexity. Also, these works utilized only one type of data. The previous techniques did not provide better results for event detection using text and image data. The effective event detection technique has not yet been developed to support multiple input data. So it is better to use multiple types of data to show the method's efficiency. Big data techniques are critical since they allow for the system's scalability in data analytics and administration. Numerous works use big data to detect events. However, several of the studies focused solely on text data. As a result, this research considers both image and text data.

III. PROPOSED METHODOLOGY

Event detection using big data holds a very important role in several applications. This work introduces event detection by the Deep compressed Convolutional Neural network (DCCNN). Here, utilizing both text and image data for processing the event detection approach. Different stages include pre-processing, feature extraction, and classification in-text data processing. The workflow of the proposed approach is shown in Fig. 1.

The different pre-processing steps are tokenization, lower case filter, stop word filter and stemming. Then, feature extraction is done. For the text analysis to be perfect, feature extraction needs to be done, making the process easier. It helps to accurately deduct the data from the vast dataset without losing important information. The speed of the processing technique is increased due to the feature extraction stage. Here this process is achieved with the help of glove and feature hashing approaches. Finally, the classification of text data is carried out with the help of DCCNN. Next is image data processing. Initially, the image data is forwarded for the pre-processing stage to remove noise and other redundant information.

An adaptive median filter is used for noise removal. Then, morphological operations such as erosion and dilation are applied for removing redundant data from the image. Then, it is sent to the DCCNN. The proposed DCCNN can perform extraction, selection and classification of image data. This technique is proposed to learn hierarchical features of data from an entire feature extraction technique. This combination makes DCNN input feature reduction (selection) with complexity reduction. While applying compression on DCNN will lead to feature reduction. In this way, the architecture reduction is achieved. This results in lower latency, as well as learning time, becomes faster.

Fig. 1. Workflow of the proposed methodology.

B. Text Data Processing

1) *Pre-processing*: The initial step considered here is the pre-processing. The data usually contains the presence of noise, redundant data and some other irregularities. Hence it should be pre-processed before extraction. The collected data contains several redundant information as well as noise. Here, four well-known text data pre-processing approaches are utilized: tokenization, lower case filter, stop word filter and stemming. Applying the tokenization procedure, a sentence or a paragraph can be split into smaller units. The stemming process can be applied to effectively reduce words into their stem by chopping off the ends of words and often by removing derivational affixes. Stop words usually indicates the words like ‘a’ ‘an’ ‘the’ ‘in’ etc. and are removed in the pre-processing stage.

2) *Feature extraction*: The feature extraction (FE) process aims to remove the redundant information from the text data. Here, it is accomplished with the help of glove and feature hashing approaches.

The glove is the method used to represent the words in their vector form. The words are mapped into space to find their vector representation. In this technique, the distance between words is related to semantic similarity. The glove can be explained by considering a matrix of word-word co-occurrence counts(Y). The entries (Y_{ji}) of the matrix tabulate how many times a word i occurred in the context of the word

j . The number of words that appear in a context j is denoted by Y_j and is given by the following expression.

$$Y_j = \sum_l Y_{jl} \quad (1)$$

The probability of word i which appears in the context of the word j is given by,

$$P_{ji} = P(i / j) = Y_{ji} / Y_j \quad (2)$$

Feature hashing (Fh) is considered the simplest technique for FE purposes, and it is also termed a hashing trick. The reduced feature space can be accomplished by simply applying a hashing function in this approach. A second hash function is used here to indicate the sign of the feature set obtained, and it can also be possible to remove the collision of feature vectors. The hashing function applied for FE is shown below.

$$\vec{F}_i^{(l)} = \sum_{F \in A_i; h(F=i)} \chi(F^l) \sum_{i=1}^{n^{(l)}F^l} x_i^{(k,A)} \quad (3)$$

Where $\vec{F}_j^{(l)}$ indicates the reduced feature vector, and the l^{th} word is represented using F^l . The context of l^{th} word is

indicated using A_l . The hashing function is represented using h and the second hashing function is χ . The parameter $n(l)F^l$ is the number of times a word appears. The weighting of the word A based on the word l is represented as $x_i^{(k,A)}$.

C. Image Data Pre-processing

1) *Pre-processing*: Usually, the image data consist of different irrelevant information along with noises. Hence it needs to be pre-processed to achieve better classification results. In previous studies, several techniques are used to pre-process image data in the event detection mechanism. The proposed work is accomplished with the help of an adaptive median filter (AMF). The AMF approach removes the noise or other redundant information from the image dataset. AMF is considered a very efficient filter for noise elimination as well as it preserves the edges of the image. The AMF mainly works on two stages. In the first stage, AMF identifies the median value for the kernel. In the second stage, AMF checks whether the current pixel is noised or not. If noise is detected, each pixel's value is replaced with the median values of its neighbourhood, as stated in the equation below.

$$Q(x, y) = \text{median } p(i, j) : (i, j) \in \alpha \quad (4)$$

Where (x, y) represents the image's location, and its surrounding neighbourhood points are denoted using α .

2) *Extraction*: The feature extraction stage is an important stage in which the most discriminative information is extracted. This stage aids to improve the classification accuracy of the proposed model. In the proposed work, the image features are extracted with the help of a technique named erosion and dilation. These erosion and dilation are the two basic morphological operators that aim to extract relevant attributes from the image database. It can be achieved by probing the image with another set, known as structuring element (SE) or kernel. This operator provides varied outcomes when executed to binary or gray-scale images. In an image, the dilation process includes pixels to the boundaries of objects, while erosion eliminates the pixels on the boundaries of objects. The number of pixels included or eliminated from the image object is based on the element's shape and size utilized to process the image. Each pixel of an image is minimized by performing the process of erosion. The erosion operators acquire a pair of data as the input, and the SE mentions the accurate effect of the erosion performance on the input pre-processed image. Generally, the dilation process is applied to fill the gaps in the most important pixels, which is useful for classification. The erosion process is utilized to ignore the unessential features of pixels in an image. The extraction of erosion and dilation related features will enhance

the classifier's performance. Let $Er_B(A)$ denotes an erosion of set A by the element B , and the expression is given below.

$$Er_B(A) = \{A|B_A \subseteq A\} \quad (5)$$

The dual operator of erosion is termed dilation. The dilation operation can be indicated as $Di_B(A)$, which is caused by the element B on the set A .

$$Di_B(A) = \{A|B_A \cap A \neq \emptyset\} \quad (6)$$

In this process, the features are extracted using morphological operations with the aid of erosion and dilation. This erosion and dilation based features are fed to the input of the classification stage.

D. Classification

The events are classified with the help of a deep learning architecture termed as deep compressed convolutional neural network (DCCNN). DCCNN can process both image and text data. The architecture of DCCNN is illustrated in the following Fig. 2.

Fig. 2 represents the architecture of the proposed DCCNN. The basic CNN method is considered to be efficient neural network architecture, and it utilizes the spatial properties of the input. In the training process, the input image features are passed throughout the DCCNN structure, and then the weights are updated in the backpropagation. The architecture contains different layers such as the input, convolutional, pooling, compression, and output layers. In the input layer, the image-based features are subjected as the input, and it transfers the input data to the convolutional layers. The convolutional layers can extract different kinds of features from the input images. Moreover, the convolutional layers extract features' large dimensionality from the images. This high dimensionality of features is minimized in the pooling layer. Then, it again transferred to convolutional and pooling layers. In the proposed work, the compression layer is included in the deep CNN technique in order to compress both the features of image and text data. In the compression layer, the features from text data are given as the input. This compression layer provides a compressed output, and it helps to improve the classification accuracy. During the process of training, the image and text-based data are updated. The initial layer of the proposed DCCNN architecture is the convolutional layer, and it contains filters to extract the input features. Initially, the image data is applied at the convolution layer of DCCNN. Hence the applied image data is further extracted with the help of this convolution layer. Let $l = (l_0, l_1, \dots, l_{n-1}) \in R^n$ be an input vector having n components. The convolutional layer gives an output, $m = (m_0, m_1, \dots, m_{n-1}) \in R^n$:

$$m_i = \sum_{j \in N_i} s_j l_j \quad (7)$$

Fig. 2. Architecture of DCCNN.

Where weight is represented using s_j , and N_i represents indices in the local receptive field at l_i . The weight s_j is said to have a constant input of 1. Hence, each output m_i is a weighted sum of neighbours $\sum_{j \in N_i} s_j l_j$ plus constant. Equation (8) is the convolution of l_i using the filtering kernel s_j , and rewriting this equation using convolutional operator $*$ gives,

$$m = l * s, \quad (8)$$

Where, $s = (s_0, s_1, \dots, s_{c-1}) \in \mathcal{R}^c$. The convolutional layers use different weight parameters to process input data, and the resulted output is a concatenated vector. Then it is passed to the next layer (i.e., pooling layer). The pooling layer can select the suitable features from the image dataset. Hence this layer can also be termed the feature selection layer of DCCNN. It can have the ability to generate in variance to small transformations, and it divides the disjointed regions having a size of $S * S$. If the input feature size is applied to the pooling layer is $P * P$, and the following expression gives the resulting output.

$$E_{pooling} = \frac{P}{S} \quad (9)$$

After the pooling/feature selection layer, the compression layer is placed. It is the most important layer in this architecture. The selected image features from the pooling layer are passed to the compression layer, and the processed text features are applied directly to the compression layer. This layer can combine the text and image features related to

different events and compress the size of features. The useful features of the compression layer can reduce the computational complexity of the proposed event detection process. This layer forwarded the compressed output to the output layer. This layer usually comprises of softmax classifier. The following equation represents the output of the softmax classifier.

$$S_i = \frac{e^{l_k}}{\sum_{j=1}^m e^{y_j}}, k=1, \dots, m \quad y = y_1, \dots, y_m \quad (10)$$

Where S_i indicate the outcome of the softmax classifier.

l_k denotes the factor of the input vector l , and m indicates the total number of neurons present in the output layer. This layer is responsible for suitably classifying the events. The output contains both image and text data of the same event. The classification stage of the proposed work is depicted in Fig. 3.

The event detection is achieved with the help of image and text data. The proposed model attains the training accuracy of 80% and obtains the testing accuracy of 20%. The data is forwarded for pre-processing and extraction. Further processing and selection are accomplished with the help of the DCCNN network. It is considered one of the best neural networks for the classification process. Here the convolution layer is utilized for extraction, and the selection is made with the help of the pooling layer. Here a new compression layer is introduced to achieve the efficient result and reduce complexity. The text data is applied directly to the compression layer. Finally, the softmax layer obtains the result, containing a single event's compressed and combined output.

Fig. 3. Classification stage of the proposed method.

IV. RESULT AND DISCUSSION

The proposed DCCNN network is evaluated based on image and text data, and it is implemented with the help of the PYTHON platform. Here seven text data and one image data are utilized. The image data is created using the images available on the Internet. The dataset explanation and the evaluation metrics computation are explained in the following sections.

A. Dataset Description

The proposed methodology uses five text databases and one image database. The image dataset is created by using the images available on the Internet. Various kinds of images are available on the Internet, and the images suitable for event detection are collected for the proposed event detection process. The proposed work collects the Internet images related to the environment, transport, geospatial, water and education. In that, education dataset belongs to 22 images, and the environment consists of 76 images, geospatial have 100 images, transport has 250 images, and water contains 300 images. Among these, 80% of data is used for training and 20% for testing. The text data for the event detection process is attained from the data.world dataset. This dataset contains 127708 different datasets for varied applications like transportation, environment, statistics, atmosphere etc. This dataset has obtained great attention for event prediction in different fields in the past few years. The proposed work gathers the text data from education, transportation, water, geospatial and environment using data.world dataset. The data from both text and image datasets are employed to experiment with event detection in the proposed study. The text data is explained in Table I.

B. Evaluation Metrics

The overall performances of the proposed technique are assessed with the help of various parameters such as accuracy, precision, recall and F-measure. Accuracy is the value close to the true value given by the following expression.

$$Acc = \frac{Tr_p + Tr_n}{Tr_p + Tr_n + Fa_p + Fa_n} \quad (11)$$

Precision is an important parameter, and it represents the ratio between numbers of positive samples to the total samples. It is computed using the following expression.

$$precision = \frac{Tr_p}{Tr_p + Fa_n} \quad (12)$$

Recall indicates the ratio between positively classified positive samples and the total number of positive samples can be computed using the following expression.

$$recall = \frac{Tr_p}{Tr_p + Fa_n} \quad (13)$$

F-Measure generates a single score that accounts for both accuracy and recall concerns in a single number. The expression is given below.

$$F\ measure = 2 \times \left[\frac{precision \times recall}{precision + recall} \right] \quad (14)$$

These equations Tr_n and Tr_p indicates the number of true negative and true positive values. The parameters Fa_n and Fa_p represent the false negative and false positive values.

TABLE I. TEXT DATASET DESCRIPTION

Name of text dataset	Details
Education – (https://data.world/cityofchicago/performance-metrics-city-colleges-of-chicago-course-s):	This is based on the records obtained in the college of Chicago university and describes the course’s success rate
Transportation – (https://data.world/buffalony/y93c-u65y):	This dataset comprises the details about the traffic count data.
Environment – (https://data.world/dublin-city):	The annual traffic counts conducted at 33 locations across the city cordon created by the Royal and Grand Canals from 2008 to 2012 at 15-minute intervals
Geospatial – (https://data.world/dcopendata/03fcb333c5a3441ab9823116b4359c4a-4):	It includes 311 Service Requests in the last 30 days for illegal dumping on public property.
Water – (https://data.world/city-of-ny/bkxf-xfky):	The data tables summarize the turbidity values, coliform, fluoride and chlorine found at sides in distribution.

C. Evaluation Results

The proposed approach is analyzed on four performance parameters: accuracy, precision, recall, and f measure. The overall performance of the proposed approach is explained in the following Table II.

Table II indicates the entire evaluation result of the proposed DCCNN based event detection approach. As Table II indicates, the proposed approach is assessed on four statistical measurements: accuracy, precision, recall, and f-measure. Accuracy value generally refers to the obtained value being close to the true value. The obtained classification accuracy of the proposed work is 97.41%. Improved accuracy in the classification approach exhibits that the proposed approach is highly effective for the event detection process. The proposed DCCNN approach attains the precision value of 95.06%, recall is 91.69%, and the obtained F1-score is 93.35, respectively. The simulation results prove that the proposed model is highly applicable for event detection mechanisms. The class-wise comparison of different performances is indicated by the following Table III.

Table III shows the class-wise comparison of the proposed approach. The proposed approach is assessed based on five different events: education, transportation, environment, geospatial, and water. According to the experimental results, the education database has obtained higher accuracy of 99.35%. The proposed framework attains the accuracy for transportation, environment, geospatial, and water are 96.77%, 98.70%, 98.06% and 94.19%, respectively. Compared with other events, an achieved precision performance of the DCCNN approach is minimum for the education database. The transportation database obtains 97.87% of improved precision value. The precision values obtained for education, water, geospatial and environment are 83.33%, 91.80%, 90.47%, and 95.00%. The education database attains 100% of recall performance, and similarly, the environmental and geospatial database obtains the same recall performance of 95%. Using the transportation and water database, the DCCNN methods obtain the recall value of 92.5% and 93.335%, respectively. The environmental database achieves 95% of the F1 score value, and the attained f1-score of education, transportation, geospatial and water databases is 90.90%, 94.845, 92.685 and 92.56%. The graphical representation of the accuracy comparison is shown in Fig. 4.

Fig. 4 is used to illustrate the accuracy performance of the proposed technique, along with a comparison of the existing approach. In Fig. 4, the horizontal axis denotes different existing approaches along with the proposed approach, and the vertical axis indicates the performance results, expressed in percentage. The existing methods used for the comparative analysis are Simple CNN, ResNet50, and DNN. The simple CNN approach is the deep learning approach; the existing CNN approach also improves event detection outcomes. But it faces over fitting problem, and also it suffers from a class imbalance issue, which affects the overall performance. The training process of the ResNet model is not as much better. Also, the DNN model is highly complex to perform event detection in big data. In order to avoid such issues, the proposed work uses the DCCNN model for perfect event detection. The accuracy obtained for the proposed approach is 97.41%. Simple CNN is better than ResNet50 and DNN for accuracy in the existing methods.

TABLE II. OVERALL PERFORMANCE

Sl. no.	Parameter	Accuracy (%)
1	Accuracy	97.41
2	Precision	91.69
3	Recall	95.06
4	F1-score	93.35

Fig. 4. Accuracy performance comparison.

TABLE III. PERFORMANCE OF DIFFERENT EVENTS

Parameters (%)	Events				
	Education	Transportation	Environment	Geospatial	Water
Accuracy	99.35	96.77	98.70	98.06	94.19
Precision	83.33	97.87	95.00	90.47	91.80
Recall	100	92.00	95.00	95.00	93.33
F1 score	90.90	94.84	95.00	92.68	92.56

Fig. 5. Precision performance comparison.

Fig. 5 represents the performance comparison in terms of precision. The precision value obtained for the proposed DCCNN based event detection methodology is 91.69%. The Simple CNN approach has a nearly close value to the proposed method in the comparison results. The DNN approach shows the least performance than other methods indicated in Fig. 5. The following Fig. 6 indicates the recall performance comparison.

Fig. 6 illustrates the recall performance comparison of the proposed DCCNN approach with the existing three approaches. The DCCNN method has a recall value of about 95.06%. All other three methods have almost similar performance, among that, Simple CNN shows better performance, and DNN shows the least performance. The following Fig. 7 indicates the f1-score performance comparison.

The performance comparison in terms of f1-score is illustrated in Fig. 7. The corresponding result for the proposed technique is 93.35%. It indicates that the proposed approach is better than all other existing methods. In short, the overall comparison result shows that the proposed approach is better for the event detection process. The graphical representation of class wise performance comparison is shown in Fig. 8.

Fig. 8 represents the performance comparison of different events such as education, environment, geospatial, transport and water. The accuracy of education, transportation, geospatial, environment, and water databases is 99.35%, 96.77%, 98.70%, 98.06% and 94.19%, respectively. It means that this education event showed better performance in terms of accuracy. The precision value for the corresponding events are 83.33%, 97.87%, 95%, 90.47% and 91.80% respectively. Likewise the recall values are 100%, 92%, 95%, 95.5% and 93.33% respectively. The f1-score is also better and the values are 90.90%, 94.84%, 95%, 92.68% and 92.56% respectively. The overall results show that the proposed DCCNN based

event detection approach is better than other methods. Table IV represent the overall performance comparison of the proposed approach with previously existing techniques.

The proposed event detection model is compared with previous techniques like simple CNN, ResNet50, DNN. These existing approaches involve drawbacks like over fitting issues, imbalance classification, computational complexity, high processing time etc. Also, many of the conventional approaches are difficult to process in different modalities of data. The proposed work introduces the DCCNN model for event detection and classification by considering these issues in the existing works. This approach provides enhanced event classification results regarding the accuracy, recall, precision and F-measure. The above table reveals that the proposed DCCNN approach is highly effective than the state-of-the-art techniques.

Fig. 6. Recall performance comparison.

Fig. 7. F1-score performance comparison.

Fig. 8. Performance comparison of different events (a) education (b) environment (c) geospatial (d) transport (e) water.

TABLE IV. OVERALL PERFORMANCE COMPARISON OF PROPOSED CLASSIFICATION APPROACH WITH EXISTING APPROACHES

Methods	Accuracy (%)	Recall (%)	Precision (%)	F-measure (%)
Simple CNN	95.87	91.53	86.32	88.85
ResNet50	92.77	80.93	76.31	78.55
DNN	89.67	71.06	68.97	70
Proposed DCCNN	97.41	95.06	91.69	93.35

V. CONCLUSION AND FUTURE SCOPE

Event detection is considered a very important procedure in various fields. Due to its diverse application, much research work exists in this field. Most event detection strategies utilize only one particular type of data (i.e. text or image). Many of the previous traditional approaches are not appropriate for multi-modal input data for event detection. Hence this work put forward a new event detection procedure with text and image data. The proposed event detection framework involves pre-processing, feature extraction and classification. These stages are performed for the input data from the image and text dataset. For pre-processing, the text input data, approaches like tokenization, stop word filter and lower case filter are utilized. Similarly, the image-based input data is pre-processed by using the AMF method. Then, the essential features that smoothen the classification process are extracted in the feature extraction stage. The events from the text and image dataset are classified using the DCCNN model in the last stage. The proposed work is implemented with the help of the PYTHON platform. The evaluation parameters considered are accuracy, precision, recall and f1-score, and the corresponding values obtained are 97.41%, 95.06%/ 91.69%, and 93.35%, respectively. The results show that the proposed approach performs well. In future, we will extend the work with more datasets and improvise the overall performance. Also, the computational complexity of the system will be evaluated, and more parameters to evaluate the system's performance will be included. Moreover, hybrid optimization algorithms will be introduced to enhance the efficacy of the classification approach.

Estimation of Transmission Rate and Recovery Rate of SIR Pandemic Model Using Kalman Filter

Wahyu Sukestyastama Putra*, Afrig Aminuddin, Ibnu Hadi Purwanto, Rakhma Shafrida Kurnia, Ika Asti Astuti

Faculty of Computer Science, Universitas Amikom, Yogyakarta, Sleman, Indonesia

Abstract—COVID-19 is a global pandemic that significantly impacts all aspects. The number of victims who died makes this disease so terrible. Various policies continue to be pursued to reduce the spread and impact of COVID-19. The spread of a disease can be modeled in differential equation modeling. This differential equation modeling is known as the SIR Model. A differential equation can be expressed in a state-space model. The state-space model is a model that is widely used to design a modern control system. This research carried out the transmission rate and recovery rate estimates in the SIR pandemic model. Estimation of the transmission rate and recovery rate in this study poses a challenge to the value of the number of people confirmed as infected. The experimental result shows that the transmission and recovery rates can be estimated using the data for the infected and recovered persons. Estimates of infected and recovered people were conducted using the Kalman Filter.

Keywords—Kalman filter; pandemic; SIR model

I. INTRODUCTION

COVID-19 is a global pandemic disease that is currently challenging for various countries worldwide. The current effort is to prevent an explosion of infected cases, considering the limited medical facilities available. This condition will be more difficult if not controlled because the growth in cases of infection is exponential [1]. The spread of a disease can be modeled in differential equation modeling. This differential equation modeling is known as the SIR Model. A differential equation can be expressed in a state-space model. The state-space model is a model that is widely used to design a modern control system. Modeling the distribution of COVID-19 to the SIR state-space model is interesting because this model can control the spread of measured diseases. The advantage of controlling using state-space modeling is that the model supports MIMO (Multiple Input and Multiple Output) cases. Two essential parameters must be known in the SIR model: transmission and recovery rate.

Transmission and recovery rates are the points to observe a process of controlling a disease outbreak in this model. The system model can be divided into input, output, and process. In this study, the input in the model is a suspect person (a person who is likely to be infected). Meanwhile, state-space modeling is carried out in the process stage with the state of the infected person and recovered person. At the same time, the output is an active case of an infected person. The output becomes a dynamic system because it adds a migration factor to the control system model.

According to previous research, the SIR model is used to predict and control a pandemic [2]–[9]. However, the pandemic SIR model has a problem because the transmission rate and recovery rate in the SIR model are constant [10]–[16]. Using these constants in predicting the number of infected and recovered is unsuitable for a condition that does not restrict population movement [17]–[22]. In this study, the authors are interested in identifying the transmission and recovery rates of the SIR model in real time. The updated results of the transmission rate and recovery rate values are then used to predict the number of states in the SIR model. State estimation needs to be done because detection bias of infected people can occur in a pandemic control.

Kalman filter is an algorithm that can be used to estimate the state of the SIR model. The Kalman filter is a two-step process that involves prediction and measurement updates. In the prediction step, the Kalman filter uses the current state of the system and the system's dynamics to predict the state at the next time step. In the measurement update step, the Kalman filter uses the predicted state and the new measurement to compute a more accurate estimate of the system's state.

The rest of this paper is organized as follows. Section II presents the related works of the SIR model implementation in various pandemics. Section III describes the proposed methods used in this study. Section IV presents the result and discussion. Finally, Section V concludes this study.

II. RELATED WORKS

Research on SIR models was conducted in 2010, and an H1N1 disease distribution model was designed using the SIR Model [2]. G. Yang [3] also carried out the control design using the SIR model. Based on these two studies, it can be concluded that the pandemic can be modeled into a control system. Research related to control systems using the SIR Model continues to grow. H. Weiss [4] formulated several policy examples to prevent the spread of disease based on the SIR model. W. Chen [5] modeled the Ebola distribution model using the SIR Model. Using the SIR model, W. Huang and G. Provan [6] designed several forecasting filters. The use of the SIR model to form state space was carried out in [7] and [8] forecasted the spread of influenza using the SIR state-space model approach.

Meanwhile, related to the COVID-19 pandemic, Chen et al. [10] added an undetectable infected person factor to the SIR model for the COVID-19 disease. The model uses two types of infected people: detachable infected persons, people with symptoms, and Asymptomatic infected persons. The SIR

*Corresponding Author.

equation turns into a matrix with the order of 3×3 . The dataset was taken from the National Health Commission of the People's Republic of China (NHC) daily Outbreak Notification. The experimental result showed that the method could predict infected and recovered persons with an error of 3%.

G. Fabricius and A. Maltz [11] have identified the threshold for disease spread in the SIR model with local and global contacts. The study modeled a SIR model into the Stochastic and deterministic models. The research built space detection parameters in a region to avoid the exponential spread of disease. In comparison, [12] and [13] carried out mathematical modeling of the transmission and control of COVID-19. The method used in [12] is the stochastic transmission method, while in [13], the logistic equation is used to describe and interpret the SIR epidemic model. This study indicates that research [12] made early predictions of locations with the potential to transmit disease based on data models that had occurred in Wuhan. Whereas [13] shows that identifying the transmission rate in the SIR model can be done using the logistics equation model.

C. Tsay et al. [14] use the SEAIR model. The SEAIR model is a modification of the SEIR (Susceptible-Exposed-Infected-Recovered) model. The research built an optimal control for the model by using the parameters of social distancing, quarantining, rate of testing, recovery rate, death rate, and initial exposure. In comparison, [18] used a modified generalized Lotka-Volterra (gLV) model. It developed a control for the model using immigration, infection, recovery, dead, and control parameters. At the same time, the form of the augmented model is to add a birth factor. While the state in the model used is estimated using the Extended Kalman Filter method. In comparison, [17] uses the SEIQR (Susceptible-Exposed-Infected- Quarantine-Recovered) model. It used a fixed control parameter on the migration parameter (M). The main finding of this study was that researchers were able to develop a mathematical model that could be used to observe the dynamics of COVID-19.

A. Abuhasel et al. [19] use the SIR model to predict cases of the spread of COVID-19 in the Kingdom of Saudi Arabia (KSA). At the same time, the ARIMA model is used to predict prevalence cases. The data used in this research is daily case data in Saudi Arabia (KSA). The results show that the SIR model can predict the development of infection cases and shows that the policies taken by the government are appropriate. At the same time, the ARIMA model shows that this model is an estimation model with current and past data with a high correlation and showed a small error. In comparison, [20] used the SIR model to predict the distribution of disease in a community. This prediction helps determine what anticipation needs to be done to control the spread of COVID-19. The data used in this study are data from various countries such as China, South Korea, India, Australia, the USA, and Italy.

III. PROPOSED METHOD

The SIR Pandemic model is simple. The model consists of S (susceptible person), I (Infected person), and R (recovered person). A susceptible person is a person who has the potential to be infected with the disease. Meanwhile, infected people are

people who have been infected with the disease. The rate of change from susceptible persons to infected persons is known as the transmission rate. Meanwhile, the rate of change from an infected person to a recovered person is called the recovery rate. In this study, an estimate of the transmission rate and recovery rate of the COVID-19 epidemic was carried out. The dataset used in this study is the confirmation data for COVID-19 based on the public database.

To estimate the transmission rate and recovery rate, the SIR epidemic model is first carried out in the form of a differential equation which is written as follows,

$$\frac{dS(t)}{dt} = \frac{-\beta(t)S(t)X(t)}{n}, \quad (1)$$

$$\frac{dX(t)}{dt} = \frac{\beta(t)S(t)X(t)}{n} - \gamma(t)X(t) \quad (2)$$

$$\frac{dR(t)}{dt} = \gamma(t)X(t) \quad (3)$$

where $\frac{dS(t)}{dt}$ is the rate of change of susceptible persons, $\frac{dX(t)}{dt}$ is the rate of change of confirmed infected persons, and $\frac{dR(t)}{dt}$ is the rate of change of people recovering from infection. A susceptible person is a person who has the potential to be infected.

The differential equation (1) to (3) is then changed to the form of the differential equation into:

$$S(t + 1) - S(t) = \frac{-\beta(t)S(t)X(t)}{n} \quad (4)$$

$$X(t + 1) - X(t) = \frac{\beta(t)S(t)X(t)}{n} - \gamma(t)X(t) \quad (5)$$

$$R(t + 1) - R(t) = \gamma(t)X(t). \quad (6)$$

where n is the known population in an area. The differential equation (4) to (6) is then converted into the state-space model equation with the assumption that $n = S(t)$ becomes:

$$\begin{bmatrix} S(t + 1) \\ X(t + 1) \\ R(t + 1) \end{bmatrix} = \begin{bmatrix} 1 & -\beta & 0 \\ 0 & 1 + \beta - \gamma & 0 \\ 0 & \gamma & 1 \end{bmatrix} \begin{bmatrix} S(t) \\ X(t) \\ R(t) \end{bmatrix} \quad (7)$$

with:

$S(t)$ = Susceptible person.

$X(t)$ = Infected person.

$R(t)$ = Recovered person.

$\beta(t)$ = Transmission rate

$\gamma(t)$ = Recovery rate

In (7), the infected persons and the recovered person do not depend on the state of susceptible person. Thus (7) can be converted into:

$$\begin{bmatrix} X(t + 1) \\ R(t + 1) \end{bmatrix} = \begin{bmatrix} 1 + \beta - \gamma & 0 \\ \gamma & 1 \end{bmatrix} \begin{bmatrix} X(t) \\ R(t) \end{bmatrix} \quad (8)$$

with the output equation:

$$y = \begin{bmatrix} 1 & -1 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} X(t) \\ R(t) \end{bmatrix} \quad (9)$$

Estimates of $X(t)$ (infected person) and $R(t)$ (recovered person) were performed using the Kalman Filter method. The steps of the Kalman filter algorithm are presented in Fig. 1.

Fig. 1. The flow diagram of the proposed method.

Step 1: Initialization Process

- 1) Initialization of $X_{k-1}(t)$ and $R_{k-1}(t)$
- 2) Initialization of $\beta(t)$ using:

$$\beta(t) = \frac{(X(t)-X(t-1))+(R(t)-R(t-1))}{X(t-1)} \quad (10)$$

- 3) Initialization of $\gamma(t)$ using:

$$\gamma(t) = \frac{R(t)-R(t-1)}{X(t-1)} \quad (11)$$

- 4) Initialization of covariance matrices

Step 2: Prediction Process

- 1) State prediction using:

$$\begin{bmatrix} \hat{X}_k(t) \\ \hat{R}_k(t) \end{bmatrix} = \begin{bmatrix} 1 + \beta(t) - \gamma(t) & 0 \\ \gamma(t) & 1 \end{bmatrix} \begin{bmatrix} X_{k-1}(t) \\ R_{k-1}(t) \end{bmatrix} \quad (12)$$

- 2) Covariance prediction using:

$$\hat{P}_k(t) = AP_{k-1}(t)A^T + Q, \quad (13)$$

with Q is a covariance noise and A is transition matrices written as:

$$A = \begin{bmatrix} 1 + \beta(t) - \gamma(t) & 0 \\ \gamma(t) & 1 \end{bmatrix} \quad (14)$$

Step 3: Correction Process

- 1) Calculate Kalman Gain using:

$$K_k = \frac{\hat{P}_k(t)H^T}{H\hat{P}_k(t)H^T + R} \quad (15)$$

which R is measurement noise, and H represents measurement matrices written as:

$$H = \begin{bmatrix} 1 & -1 \\ 0 & 1 \end{bmatrix} \quad (16)$$

- 2) State Correction using:

$$\begin{bmatrix} X_k(t) \\ R_k(t) \end{bmatrix} = \begin{bmatrix} \hat{X}_k(t) \\ \hat{R}_k(t) \end{bmatrix} + K_k(z_k - \begin{bmatrix} 1 & -1 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \hat{X}_k(t) \\ \hat{R}_k(t) \end{bmatrix}) \quad (17)$$

which z_k is the measurement data

- 3) Covariance correction using:

$$P_k = (I - K_k \begin{bmatrix} 1 & -1 \\ 0 & 1 \end{bmatrix})\hat{P}_k(t). \quad (18)$$

Step 4: Parameter Update

- 1) Transmission rate $\beta(t)$ update using:

$$\beta(t) = \frac{(X_k(t)-X_k(t-1))+(R_k(t)-R_k(t-1))}{X_k(t-1)} \quad (19)$$

- 2) Recovery rate $\gamma(t)$ update using:

$$\gamma(t) = \frac{R_k(t)-R_k(t-1)}{X_k(t-1)} \quad (20)$$

Step 5: Go to Step 2

IV. EXPERIMENTAL RESULTS

Estimating the number of infected and recovered people is a topic to do because early detection of COVID-19 infection is less massive. This detection is increasingly difficult with the community's attitude, who still think that being infected with COVID-19 is a bad thing that has the impact of being excluded by the community. Awareness of the dangers of COVID-19 has not been good because it was found that people had not implemented health protocols in an orderly manner. With both conditions, matters are complicated because the movement of people who ignore health protocols increases the potential for infection and becomes an infection agent for others. This condition is amplified by the lack of mass testing for COVID-19 and undetectable infected person in the early pandemic.

In this study, the transmission rate and recovery rate are estimated using the SIR pandemic model. The estimation of the transmission rate and recovery rate in this study poses a challenge to the value of the number of people confirmed as infected. The number of people confirmed as infected is essential in determining the value of the transmission and recovery rate. An estimate of the number of infected people and the number of people recovered was carried out to overcome this problem. Estimation is done using the Kalman Filter.

The results of estimating the infected and recovered person using the Kalman Filter are depicted in Fig. 2 and Fig. 3. The estimation results show that the estimates and the confirmed data have the same trend. An error covariance matrix tuning in the estimation algorithm is performed to obtain the slightest difference between the estimated recovered person and the confirmed recovered person. The difference between the estimate and the confirmed recovered person is used as a reference.

The difference between the estimates and the confirmed recovered person is then used to determine the estimation error of the proposed algorithm. The recovered person estimation error is depicted in Fig. 4. Fig. 4 shows that a fairly large estimation error occurs in the first 15 days of the estimation. This error occurs because of the low number of cases of confirmed recovered, so the percentage of estimation error is large. After the 20th day, the estimated error of the recovered person is decreased to less than 5%.

The error of the recovered person is then used as the basis for determining the estimated error of the infected person. Given the estimated error value, an upper and lower limit of the estimate can be made. This limit is then used as the basis for the validation of the data for the confirmed infected person. If the data for the confirmed infected person are within the estimated range, then the data has good validity. However, the data has dubious validity if it is outside the estimated range. The estimated range of the infected person is depicted in Fig. 5. In Fig. 5, the lower limit of the estimate is depicted using the yellow line, and the blue line represents the upper limit of the estimate. Meanwhile, the confirmed infected person is depicted using the orange line. From the comparative data between the confirmed infected person and the estimated range of the infected person in Fig. 5, it can be seen that the position of the confirmed infected person is not always within the estimation

range. Thus there are several data of confirmed infected persons who are in doubt.

Fig. 2. The confirmed and estimation of the recovered person.

Fig. 3. The confirmed and estimation of the infected person.

Fig. 4. The error estimation of the recovered person.

Fig. 5. The confirmed and estimated range of the infected person.

Fig. 6 shows data for confirmed infected persons outside the estimated limits. In Fig. 6, it can be seen that for the estimated day 0 to day 100, the confirmed infected person is still within the estimated limit, and if it exceeds the estimated limit, it only has a slight difference, namely a maximum of 2. However, after the 100th day, the confirmed infected person is almost always outside the estimated range. So the number of confirmed infected persons has questionable validity. On the other hand, the estimated recovered person has a reasonably good estimation error. Thus the transmission rate and recovery rate are predicted using estimated data.

Estimated infected people and estimated recovered people are used to estimate the transition rate and recovery rate. The results of the transmission rate estimation are depicted in Fig. 7. Fig. 7 shows that the transmission rate values from day 0 to day 40 experience convergence characterized by decreasing oscillations. After convergence, the transmission rate oscillates with a value above zero. This value indicates that the transmission process is still occurring. Meanwhile, the transmission rate is said to stop if the transmission rate is zero.

Fig. 6. The confirmed infected person outside the range.

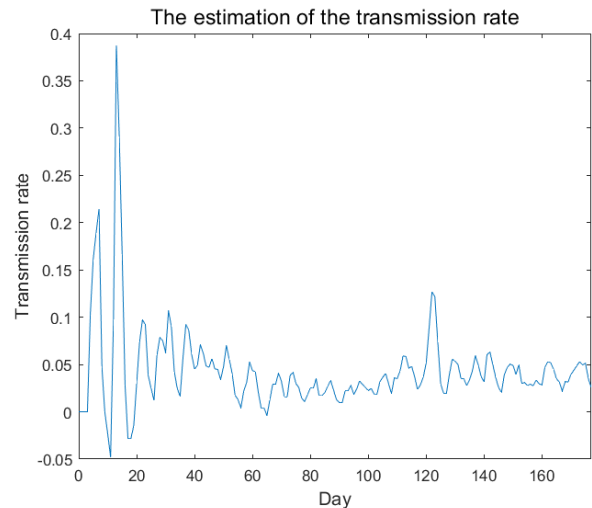

Fig. 7. The estimation of the transmission rate.

The results of the recovery rate estimation are depicted in Fig. 8. Fig. 8 shows that the recovery rate values from day 0 to day 40 experience a convergence like what happened to the transmission rate marked by reduced estimation oscillations. After convergence, the recovery rate also experiences an oscillation like what happens in the transmission rate. However, the oscillation amplitude at the recovery rate is smaller than at the transmission rate. The recovery rate of the oscillation value is also above zero. It means that the recovery process of an infected person is also in progress.

Fig. 8. The estimation of the recovery rate.

V. CONCLUSIONS

The research shows that the transmission rate and recovery rate can be estimated using the estimated data for the infected and recovered persons. Estimates of infected and recovered people are carried out using the Kalman Filter. Estimates of the infected and recovered people are carried out to address the data of the confirmed infected persons whose validity is doubtful. In further research, developing a more comprehensive pandemic model is necessary. In pandemic

modeling, SIR has not included factors for the asymptomatic infected person. Thus, research on developing pandemic models needs to be carried out.

Abstract—Most real-world datasets contaminated by quality issues have a severe effect on the analysis results. Duplication is one of the main quality issues that hinder these results. Different studies have tackled the duplication issue from different perspectives. However, revealing the sensitivity of supervised and unsupervised learning models under the existence of different types of duplicates, deterministic and probabilistic, is not broadly addressed. Furthermore, a simple metric is used to estimate the ratio of both types of duplicates regardless of the probability by which the record is considered duplicate. In this paper, the sensitivity of five classifiers and four clustering algorithms toward deterministic and probabilistic duplicates with different ratios (0% - 15%) is tracked. Five evaluation metrics are used to accurately track the changes in the sensitivity of each learning model, MCC, F1-Score, Accuracy, Average Silhouette Coefficient, and DUNN Index. Also, a metric to measure the ratio of probabilistic duplicates within a dataset is introduced. The results revealed the effectiveness of the proposed metric that reflects the ratio of probabilistic duplicates within the dataset. All learning models, classification, and clustering models are differently sensitive to the existence of duplicates. RF and Kmeans are positively affected by the existence of duplicates which means that their performance increase as the percentage of duplicates increases. Furthermore, the rest of classifiers and clustering algorithms are sensitive toward duplicates existence, especially within high percentage that negatively affect their performance.

Keywords—Deduplication; deterministic duplicates; probabilistic duplicates; supervised learning models; unsupervised learning models; evaluation metrics

I. INTRODUCTION

Data quality has been an active research area that affects different domains. Many data quality dimensions have been addressed through the literature[1]–[5], Data Duplication has been considered as one of the most intriguing dimensions. Data duplication is defined as multiple representation of the same real world object or a measure of undesirable duplicates within a certain field, record or dataset[6]. The duplication can be found in two different types, the Deterministic and the Probabilistic duplications[7], [8]. The Deterministic (exact) duplication, where two records or more are identical and Probabilistic (near/fuzzy) duplication, where multiple records are nonidentical and refer to the same real world entity[9], [10].

Duplicates can occur due to two main causes. The intra source duplicates, and the inter source duplicates[11]. The

intra source duplicates occurs when a single data object can be entered many times into the same database. Whereas the duplicates that appear while merging multiple data source are called inter source duplicates[11]. The process of removing the intra source duplicates is called deduplication[12] which is the main scope of this paper. Whereas removing duplicates from inter source duplicates is called Record Linkage[13].

Data quality dimensions are assessed to evaluate by how much the data is qualified for a task at hand. Dimensions are measured either objectively or subjectively. Subjective measurements are based on consumers' opinions like questionnaires, and surveys. Whereas Objective measurements are used to give a simple ratio between the undesirable outcomes and the total[14]. For example, to calculate the percentage of duplicates in the dataset, the following equation can be used (number of duplicate records/Total number of records). This simple metric can be perfectly used within exact duplicates, however, in the case of near duplicates the probability of these duplicate records should be considered to reflect the true percentage of duplicates within a dataset.

The research effort in duplication area is diverse. However, little work has focused on clarifying the effect of both data duplicate types on the analysis results. In the domain of android malware [15], has addressed the sensitivity of the supervised and unsupervised learning models due to the existence of near duplicates. Thus, in this paper an initiative is taken to clarify the effect of both types of duplicates on classification and clustering learning models.

This paper investigates the impact of the deterministic and the probabilistic duplicates on the results of descriptive (clustering task), and predictive (classification task) data analytics. Five classification models namely, Decision Tree (DT), Support Vector Machine (SVM), Naïve Bayes (NB), Linear Discriminant Analysis (LDA) and Random Forest (RF) are used to clarify the effect of the deterministic duplicates with different ratios. The sensitivity of the five classifiers has been evaluated using three evaluation metrics, Accuracy[16], Matthews Correlation Coefficient (MCC)[17] and F1-Score[18]. While the impact of probabilistic duplicates is investigated through four clustering algorithms namely, The Partition Around Medoids (PAM), Clustering for Large Application (CLARA), K-means and Density-Based Spatial Clustering of Applications with Noise (DBSCAN). Furthermore, two evaluation indices namely the Average Silhouette Coefficient (ASC)[19] and DUNN Index (DI)[20]

are used to track the sensitivity of the four clustering algorithms.

Since that the simple metric doesn't consider the probability of the near duplicates, thus a metric is introduced to estimate the true percentage of near duplicates within a dataset.

The remainder of this paper is organized as follows, Section II, reviews the state of the art and presents the related studies. Where the used clustering evaluation indices are described in Section III. The experimental framework and results are discussed in Section IV. Section V concluded the paper.

II. RELATED WORK

The field of duplication and its treatment methods is immense in the literature. It is addressed from different perspectives and domains, started from an overview of the duplication and techniques[21]–[23], improving the detection techniques[24], [25], evaluating the impact of the duplicates[26], and proposing new frameworks[27], [28] and methods[29], [30] to effectively enhance the detection process. However, little research addresses the impact of duplicates on the analysis results. Some studies are presented below.

In [15], they examined the effect of duplication on the supervised and unsupervised learning in the domain of android malware detection. From their perspective, duplication in this domain means that data samples (e.g., the APK, the DEX code, etc.) appear many times within a corpus. They declared that duplication has limited impact on the supervised classification model, however, it has a significant effect on the unsupervised clustering model.

In [31], two of the benchmark datasets are cleaned from near duplicate images. Deep leaning models are tested against the datasets before and after removing near duplicates. The results revealed a decrease in the classification accuracy by 9% to 14% which means that the duplicates' existence can give more inflated results.

Furthermore in[32], the author examined the impact of code duplication while evaluating machine learning models. He declared that code duplication has a negative effect on the machine learning models' performance which sometimes inflated by 100%. So, he recommended removing any exact or near duplicates to have more reliable and accurate results.

In the image processing field[33], the near images between training and test sets are removed to improve the quality of machine learning results. Four classifiers, RF, DT, SGD, and perceptron classifiers are used, and their performance is recorded. There is a slight decrease in the accuracy of four classifiers after removing near images which means that duplicates can give deceptive performance.

The authors[10], introduced a new technique to detect the near duplicates. Their technique doesn't depend on columns to detect duplicates, but on the metadata that describes the datasets. Their experiments declared around 95% accuracy rate.

While [34] propose a new record linkage deduplication framework through six steps that detects and visualizes duplicates in the datasets.

Within another study[35] the natural language preprocessing and machine learning are used to detect the duplicates with 90% for area under the curve.

The probabilistic duplicates detection approaches, such as similarity-based derivation, and decision-based derivation, are presented in[36]. To effectively detect duplicates they examine the adaptation of search space reduction, like using Blocking and Sorted Neighborhood methods which effectively reduces the record pair comparisons.

A new duplication detection framework is proposed[37]. It depends on metric functional dependencies (MFDs) to enhance the detection accuracy. Their experimental results on three real datasets show an improvement of 25% and 34% in precision and recall respectively.

Most of the studies have focused on introducing the duplicates detection techniques and reducing the search space of the records comparison. However, few studies investigated the effect of duplicates on the analytical results. Most of them tackled the problem of probabilistic (near) duplicates[38]–[43] due to its complexity than the exact ones[44].

III. CLUSTERING EVALUATION INDICES

A. Average Silhouette Coefficient

Average Silhouette Coefficient is a measure of the separation distance between clusters, (1). It is a graphical display of how well each data point is clustered. The silhouette coefficient ranges from -1 to +1, higher values that are closer to 1, indicate more coherent clusters[45].

$$s = \frac{b-a}{\max\{a,b\}} \quad (1)$$

Where (a) is the mean of the intra-cluster distance, the average dissimilarity of data points in the same cluster. And (b) is the mean value of the nearest-cluster distance, the cluster with the smallest average dissimilarity.

B. DUNN Index

The Dunn Index quantifies the ratio between the smallest distance between cases in different clusters and the largest distance within a cluster, (2). A high DI means better clustering since observations in each cluster are closer together, while clusters themselves are further away from each other[46].

$$D = \min_{i=1,\dots,k} \left\{ \min_{j=i+1,\dots,k} \left[\frac{d(C_i, C_j)}{\max_{l=1,\dots,k} \text{diam}(C_l)} \right] \right\} \quad (2)$$

Where k is the number of clusters, C_i is the i th cluster, $d(C_i, C_j)$ is the distance between cluster C_i and C_j , and $\text{diam}(C_i, C_j)$ is the diameter between the two clusters[46].

IV. EXPERIMENTAL DESIGN

The main target is clarifying the effect of the presence and absence of duplication on data analytics. The two types of

duplication are investigated, the deterministic and the probabilistic duplication. The effect of the deterministic duplicates is examined through five different classifiers: DT and RF follow decision tree manner, SVM follows linear algorithms that separates between classes with a hyperplane, NB works using Probabilistic technique, and LDA works on discriminating between classes by maximizing distance and minimizing scale between them. The five classifiers are tested against a dataset with different ratios of deterministic duplicates (5%, 10% and 15%). For more accurate tracking of the changes in the performance of each classifier, three evaluation metrics are used, Accuracy, F1-Score and MCC.

Due to the lack of the labelled benchmark datasets within probabilistic duplicates, unsupervised learning is applicable in this case. The sensitivity of four clustering algorithms toward probabilistic duplicates is evaluated through different ratios of probabilistic duplicates (Zero, 3.06% and 5.54%). The PAM, CLARA and K-means are partitioning based clustering. Where DBSCAN is a density-based clustering. The performance of the four clustering algorithms is validated using Average Silhouette Coefficient and DUNN Index. The full description of the used datasets, experimental steps, and results are presented below.

A. Datasets

For a classification task, a synthetic dataset obtained from UCI Machine Learning Repository [47] is used. Whereas two benchmark datasets[48] are used in clustering task. Table I shows more description about these datasets.

TABLE I. DESCRIPTION OF THE DATASETS

Dataset Name	Size	Features	Data Type	Dataset Type
Dry Beans	13,611	17	Numeric	Synthetic
DBLP	2616	5	Mixed	Benchmark
ACM	2294	5	Mixed	Benchmark

B. Experimental Design

A total of 84 experiments were conducted to measure the effect of different types of duplicates on the results of descriptive and predictive data analytics. The detailed experimental steps are presented below.

1) *Experimental steps for deterministic duplicates:* The sensitivity of five classifiers toward the presence and absence of deterministic duplicates is investigated through 60 experiments, divided into four groups. Group 1, zero duplicates, where the classifiers are tested against the original dataset to report the baseline performance. Group 2, the 5% duplicates, where 5% of the deterministic duplicates are inserted into the original dataset then the sensitivity of the classifiers are measured using the three-evaluation metrics, Accuracy, F1-Score and MCC. Group 3, the 10% duplicates, and Group 4, the 15% duplicates, follow the same structure as Group 2 except that the percentage of the deterministic duplicates is changed before testing the sensitivity of the classifiers toward the duplicates. The 60 experiments, 15 for each Group (5 classifiers x 1 dataset x 3 evaluation metrics),

are conducted to clearly report the changes of each classifier's performance. The upper part of Fig. 1 shows a general description of the four groups of experiments.

2) *Experimental steps for probabilistic duplicates:* In this section the sensitivity of four clustering algorithms toward the presence and absence of probabilistic duplicates is measured through 24 experiments. The experimental steps have been divided into 3 groups, 8 experiments in each group (4 clustering algorithms x 1 dataset x 2 evaluation indices). Group A, the DBLP dataset has been integrated with ACM dataset to be one dataset with 0% of probabilistic duplicates. The four clustering algorithms are tested against the integrated dataset and have been evaluated using the Average Silhouette Coefficient and DUNN Index. In Group B, the percentage of the duplicates increased to 3.06%, then the sensitivity of the four clustering algorithms was tested and evaluated. In Group C, the ratio of probabilistic duplicates increased to 5.54%. Then the performance of the four clustering algorithms is measured and reported using the evaluation indices. In the three groups of experiments, Group A, B, and C, the percentage of near duplicates is measured using our proposed metric. The lower part of Fig.1 represents a general description of the three groups of experiments.

Fig. 1. Framework of all duplication experiments.

C. Experimental Results

The experimental results are addressed in two sections, the first section includes the results of the effect of deterministic duplicates on predictive analytics. Whereas the second section interprets the effect of probabilistic duplicates on descriptive analytics.

1) *Results of deterministic duplicates effect:* This section takes place into four subsections, the first subsection presents the baseline performance. The three other subsections show the experimental results of Group 2, 3 and 4 when having different ratios of deterministic duplicates.

a) *The Zero Duplicates Experiment:* The five classifiers are tested against the original dataset (zero duplicates) and their performance is reported and evaluated using three evaluation metrics as shown in Table II. The best classifier performance is recorded for RF followed by SVM, DT, LDA and NB respectively when evaluated by MCC, Accuracy and F1-Score measures.

b) *The 5% Duplicates Experiment:* In this group of experiments, 5% of deterministic duplicates are added to the original dataset. This duplicate percentage is measured using the simple equation, (3), that measures the ratio of duplicates.

$$Duplication = \frac{\text{Total Number of Duplicate Rows}}{\text{Total Number of Rows}} \quad (3)$$

The sensitivity of the five classifiers toward these duplicates is tested and recorded by the evaluation metrics. It is obviously clear that the performance of the five classifiers increased across all evaluation metrics compared with the baseline performance, Table III. 5% of duplicates positively affected the classifiers, which means that the five classifiers are positively sensitive to the existence of deterministic duplicates in this case. Higher performance means higher sensitivity. In this case, SVM reported higher sensitivity across all metrics, then comes RF, followed by DT and LDA. Whereas NB has the lowest sensitivity compared to other classifiers.

However, the performance of the five classifiers increased, this performance doesn't reflect the reality, true performance as in Table II, thus it can't be trusted or even used in making decisions.

c) *The 10% Duplicates Experiment:* Following the same steps in Group 2 experiment, the original dataset is contaminated by 10% of deterministic duplicates calculated by the same Eq., (3). As shown in Table IV, the performance of the five classifiers is still increasing after adding the 10% of duplicates compared with their performances in the previous two Groups of experiments, Table (II and III). The results declared that the five classifiers are still positively sensitive to the presence of deterministic duplicates. Furthermore, the performance of the five classifiers is still unreliable and can't be trusted. SVM and RF reported higher positive sensitivity in this case. NB has the lowest positive sensitivity, where DT and LDA have middle sensitivity toward 10% of exact duplicates.

d) *The 15% Duplicates Experiment:* The sensitivity of the five classifiers is measured and evaluated after adding 15% of deterministic duplicates into the original dataset. Table V shows that the performance of all classifiers except RF drastically decreased under the baseline performance. This indicates that DT, SVM, NB, and LDA are negatively sensitive to the existence of deterministic duplicates with large percentages more than 10%. However, the performance of RF is still increasing through the three-evaluation metrics (MCC, F1-Score, and Accuracy) compared with its performance across all previous experiments. In the case of negative sensitivity, NB has the highest sensitivity, then DT and SVM. Whereas LDA has the lowest negative sensitivity in this case.

Following are some observations after executing the four Groups of experiments:

- The performance of the RF classifier is positively affected by the presence of deterministic duplicates under small and large ratios, Fig. 2(a).

- As shown in Fig. 2(b), (c), (d), and (e), the DT, SVM, LDA and NB are positively sensitive to deterministic duplicates with certain percentages of duplicates ranging from 5% to 10%.
- However, they are negatively sensitive when having deterministic duplicates of more than 10%, Fig. 2(b), (c), (d), and (e).
- In general, the presence of deterministic duplicates limited to 10% has a positive effect on a classification task. As this percentage increases the effect of the deterministic duplicates differs based on the classifier used.
- Neither the positive nor the negative classifiers' sensitivity are good results. The classifiers in both cases are giving deceptive performance that doesn't reflect the reality. Hence, any decision taken based on a dataset contaminated by deterministic duplicates with any ratio is a completely wrong decision which can have negative implications on any business.

TABLE II. THE BASELINE PERFORMANCE

Dataset	Metrics	DT	SVM	NB	LDA	RF
Dry Beans	MCC	89.51%	91.00%	87.45%	87.86%	90.72%
	F1-Score	91.30%	92.50%	89.50%	89.70%	92.30%
	Acc.	91.31%	92.53%	89.54%	89.72%	92.31%

TABLE III. THE SENSITIVITY OF THE CLASSIFIERS WITH 5% OF DETERMINISTIC DUPLICATES

Fig. 2. Performance of the five classifiers with different ratios of deterministic duplicates.

2) *Results of probabilistic duplicates effect:* The experimental results on the effect of probabilistic duplicates are presented into three subsections. In the three subsections, the performance of the clustering algorithms with different ratios of probabilistic duplicates ranged from 0% to 5.54% is reported and evaluated using the Average Silhouette Coefficient and DUNN Index, both distance functions, Manhattan, and Euclidean functions, are used to calculate DUNN Index.

a) *Group A Experiments:* In this experimental group, the ACM and DBLP datasets are merged to have one cleaned integrated dataset. Then the four clustering algorithms are applied, and their quality is measured. Table VI shows the baseline performance of all clustering algorithms with zero duplicates. Generally, the performance of all clustering models is low, this is due to the dimensionality reduction problem. As stated in the literature [49]–[51], reducing the dimensions of the dataset improves the clustering results, however this is not the scope of this paper but showing the effect of near duplicates on the performance of the clustering models within different ratios.

TABLE VI. THE SENSITIVITY OF THE CLUSTERING ALGORITHM WITHOUT PROBABILISTIC DUPLICATES

Evaluation Indices	PAM	CLARA	Kmeans	DBSCAN
DUNN- Manhattan	0.018	0.017	0.016	0.096
DUNN- Euclidean	0.029	0.026	0.021	0.149
AVG.silhouette Coefficient	0.2	0.26	0.159	0.076

Fig. 3. Performance of the four clustering algorithms with zero probabilistic duplicates.

The evaluation done by DUNN index using the two distance functions shows that DBSCAN has the higher performance, followed by PAM then, CLARA whereas Kmeans reported the lowest performance. However, this is not the case when evaluating the quality of the four algorithms with Average Silhouette Coefficient. CLARA reported highest value, followed by PAM then Kmeans whereas DBSCAN has the lowest performance in this case. The baseline performance of the four clustering algorithms is depicted in Fig. 3.

The clusters created using DBSCAN and CLARA are clearly depicted, Fig. 3(a) and (b). Whereas the clusters created by PAM and Kmeans, as shown in Fig. 3(c) and (d), overlapped, and cannot be detected clearly.

b) *Group B Experiments:* In this group of experiments, the integrated dataset is contaminated by 3.06% of probabilistic duplicates. The following example is given to explain how this percentage is calculated.

A dataset is given with the following:

Total Number of Records = 2,667 Unique Records = 2,388

Duplicate Records = 279 Probabilistic Match

The Data Uniqueness of the given dataset using the old metric is:

$$Uniqueness = \frac{\text{Total Unique Rows}}{\text{Total Number of Records}} = \frac{2388}{2667} = 0.895$$

So, the data duplication will be:

$$\begin{aligned}
 \text{Duplication} &= 1 - \text{Uniqueness} \\
 &= 1 - \frac{\text{Total Unique Rows}}{\text{Total Rows}} \\
 &= \frac{\text{Total Number of Duplicate Rows}}{\text{Total Number of Rows}} \\
 &= 1 - 0.895 = 0.105 = 10.5\%
 \end{aligned}$$

However, the total number of duplicate records in the above equation refers to the deterministic duplicates and it does not consider the probability or the similarity by which the record is considered duplicates. To consider the probabilistic duplicate records, a new metric is proposed.

$$\text{Data Duplication} = \frac{1}{N} \sum_{i=1}^N P_i \quad (4)$$

Where N is the total number of records, i is the record number, and Pi is the probability that I record has a duplicate. So, if the i record is unique then Pi = 0, if it has a deterministic duplicate, Pi = 1, and if it is probably duplicate, then Pi is the similarity measure between this record and its linkage.

$$\text{Data Duplication} = (0.2 * 162 + 0.4 * 105 + 0.6 * 12) / 2667 = 81.6 / 2667 = 0.0306.$$

This means that the uniqueness of the integrated dataset = (1-0.0306) = 0.969.

Thus the 10.5% of duplicates measured using old metric doesn't reflect the similarity of the probabilistic records, whereas the proposed metric considers the probability of probabilistic duplicates while measuring, thus the true percentage of near duplicates in this case is 3.06%.

Fig. 4. shows different effects of near duplicates on clustering algorithms as the ratio of duplicates increased. Generally, DBSCAN is a robust algorithm as its performance doesn't change from its baseline. Whereas Kmeans is positively affected by such increased ratio. PAM and CLARA give different performances depending on the evaluation indices used. A detailed description of the sensitivity for each clustering algorithm is presented in Table VII.

The following observations can be derived from this group of experiment:

- DBSCAN has robust performance when evaluated by DUNN index. While it is negatively affected by the increase of the duplicates when Average Silhouette Coefficient used, which means that its performance degraded from its baseline performance. It decreased by 0.022%.
- The performance of Kmeans is increased by around 0.006% when evaluated by DUNN index. Kmeans has a positive sensitivity in this case. But this is not the case while using Average Silhouette Coefficient, Kmeans is negatively affected by near duplicates, its performance decreased by 0.012%.
- PAM shows different sensitivity, robust and negatively affected by near duplicates, within DUNN index using both distances Manhattan and Euclidean respectively.

Also, Average Silhouette Coefficient shows negative sensitivity for PAM.

- CLARA has different sensitivity, positive, robust, and negative sensitivity, when evaluated by Manhattan, Euclidean, and Average Silhouette Coefficient respectively.

c) Group C Experiments: The ratio of probabilistic duplicates increased to 5.54% within the integrated dataset using the new metric, (4) within the given dataset:

$$\text{Total Number of Records} = 2,947 \text{ Unique Records} = 2,389$$

$$\text{Duplicate Records} = 558 \text{ Probabilistic Match}$$

$$\text{Thus, Data Duplication} = (0.2 * 324 + 0.4 * 210 + 0.6 * 24) / 2,947 = 163.2 / 2,947 = 0.0554$$

The four clustering algorithms are tested against the integrated dataset and their sensitivity is assessed using the evaluation indices. In Fig. 5, it is obviously clear that the performance of the four clustering algorithms except Kmeans is low. This means that the clustering algorithm, CLARA, PAM, and DBSCAN are negatively affected by the new ratio of probabilistic duplicates, Fig. 5(a), (b), and (d). However, Kmeans is positively affected by such increase in the duplicate's ratio, Fig. 5(c).

TABLE VII. THE SENSITIVITY OF THE CLUSTERING ALGORITHM WITH 3.06% OF PROBABILISTIC DUPLICATES

Evaluation Indices	PAM	CLARA	Kmeans	DBSCAN
DUNN- Manhattan	0.018	0.022	0.021	0.096
DUNN- Euclidean	0.023	0.026	0.028	0.149
AVG.silhouette Coefficient	0.19	0.2	0.147	0.054

Fig. 4. Performance of the four clustering algorithms with 3.06% of probabilistic duplicates.

Fig. 5. Performance of the four clustering algorithms with 5.54% of probabilistic duplicates.

TABLE VIII. THE SENSITIVITY OF THE CLUSTERING ALGORITHM WITH 5.54% OF PROBABILISTIC DUPLICATES

Evaluation Indices	PAM	CLARA	Kmeans	DBSCAN
DUNN- Manhattan	0.011	0.012	0.023	0.045
DUNN- Euclidean	0.018	0.017	0.035	0.073
AVG. silhouette Coefficient	0.2	0.21	0.196	0.008

Based on the quantitative results presented in Table VIII, we can conclude that DBSCAN is highly sensitive toward a high ratio of duplicates, PAM came in the second rank of sensitivity, whereas CLARA has the lowest sensitivity compared with other algorithms. In this case the performance of Kmeans increases as ratio of probabilistic duplicates increased too. Thus, Kmeans is the only algorithm that has a positive sensitivity toward near duplicates.

Fig. 6 and Fig. 7 show the sensitivity observation of the four clustering algorithms after conducting all groups of Experiments, Group A (zero duplicates), Group B (3.06% duplicates), and Group C (5.54% duplicates).

1) Sensitivity measured by DUNN index

a) PAM Algorithm has a negative sensitivity toward the existence of probabilistic duplicates which means that its performance decreases as the percentage of the duplicates increases Fig. 6(a).

b) Fig. 6(b) shows that CLARA has a negative sensitivity only in the case of a high percentage of

probabilistic duplicates, 5.54%. The performance of CLARA remains the same or slightly increases (by 0.005%) when the percentage of duplicates increased from zero to 3.06%.

c) DBSCAN has the same performance as CLARA, its performance is negatively affected by high ratios of the probabilistic duplicates, Fig. 6(c). Its performance remains the same when having zero and 3.06% of these duplicates.

d) On the other flip of the coin, comes Kmeans. Kmeans has a positive sensitivity to the existence of probabilistic duplicates with different ratios. Fig. 6(d) shows that the performance of Kmeans increases as the ratio of probabilistic duplicates increases too.

2) Sensitivity measured by average silhouette coefficient

a) As depicted in Fig. 7(a), the performance of PAM algorithm decreased from its baseline when 3.06% of duplicates were inserted into the dataset. Then it started to increase again as a larger ratio of probabilistic duplicates inserted. This indicates that PAM has no clear performance.

b) CLARA is a negatively sensitive clustering algorithm to the presence of near duplicates, Fig. 7(b). Its performance decreases when probabilistic duplicates exist. However, the performance of CLARA during different ratios of duplicates (3.06% and 5.54%) is almost the same, only 0.01% difference.

c) In Fig. 7(c), the performance of DBSCAN algorithm is negatively affected by the existence of probabilistic duplicates. The performance of DBSCAN clearly decreased when the ratio of the duplicates increased. Thus, we can conclude that DBSCAN is the highly sensitive algorithm toward probabilistic duplicates.

d) Fig. 7(d) declared that generally Kmeans is considered as a positively sensitive algorithm. Compared with the baseline, its performance increased (by 0.037%) as high ratios of probabilistic duplicates increased too.

Neither the positive nor the negative sensitivity of the clustering models toward probabilistic duplicates is good performance. The same as concluded from deterministic experiments, any decision taken in these cases will cause severe harm to any business either financially wise or management wise.

The experimental results agreed with what mentioned in different studies [15], [31]–[33], that the existence of both types of duplicates is somehow has an effect either positive or negative on the performance of the learning models.

Based on the quantitative results for each experiment, the existence of duplicates has a significant effect on the performance of supervised learning models, whereas it has a moderate impact on the performance of unsupervised learning models, which is the opposite of what mentioned in [15]. Fig. 8 shows the sensitivity of the learning models toward duplicates.

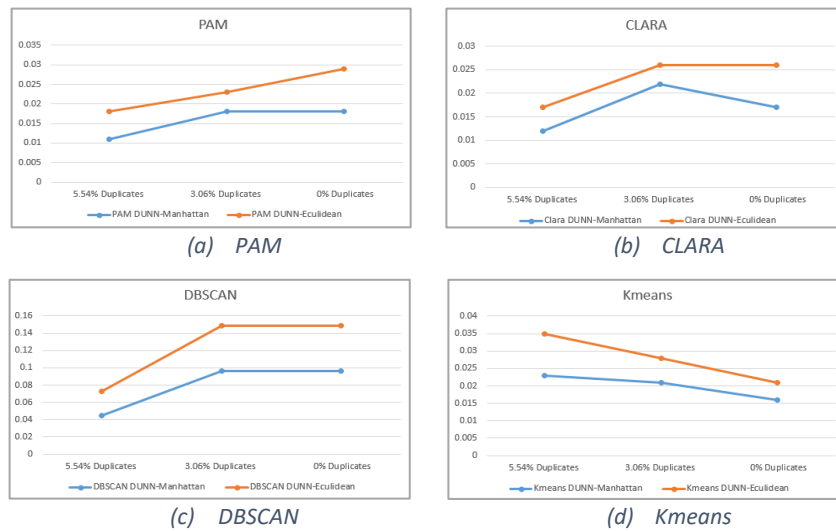

Fig. 6. The sensitivity of the four clustering algorithms using DUNN index.

Fig. 7. The sensitivity of the four clustering algorithms using average silhouette coefficient.

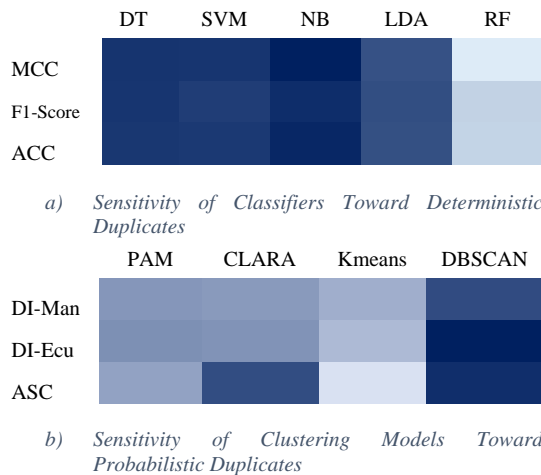

Fig. 8. The sensitivity of all learning models toward different types of duplicates.

In Fig. 8. the Dunn index using Manhattan function is referred to as (DI-Man), whereas Dunn index using Euclidean function as (DI-Ecu). The Average silhouette Coefficient is referred to as (ASC). Furthermore, the accuracy is shortened in (ACC).

The difference in the average performance from the baseline performance is calculated and depicted in Fig. 8. It is clearly noted that DT, SVM, NB, and LDA are highly sensitive toward the existence of deterministic duplicates. Whereas RF is positively sensitive in this case. Thus, generally deterministic duplicates have a severe influence on most of the classifiers.

However, most of the clustering models are moderately sensitive toward the existence of probabilistic duplicates. Only DBSCAN is extremely sensitive toward near duplicates. Thus, the existence of probabilistic duplicate has a moderate influence on the unsupervised learning models.

The existence of both types of duplicates can cause significant harm to the analysis results and then the whole business. Thus, it is highly recommended to remove any duplicates from the dataset before putting it through the processing phase.

V. CONCLUSION

Cleaning the data from quality issues like missing values, inconsistencies, duplication, etc. is an essential step if accurate decision is needed. Thus, in this paper the sensitivity of supervised (DT, SVM, RF, NB, and LDA) and unsupervised (DBSCAN, Kmeans, CLARA, and PAM) learning models toward the existence of two types of duplicates, probabilistic and deterministic, with different ratios (0%-15%) is investigated. The results of these models are validated using five evaluation metrics, MCC, F1-Score, Accuracy, Average Silhouette Coefficient, and DUNN Index. Three datasets are used through 84 experiments. The experimental results can be concluded as follows. First, both types of duplicates have an influence on the sensitivity of the learning models, which differs based on the learning model itself. Second, small percentages of deterministic duplicates have a positive impact on the five classifiers. This declares that the performance of five classifiers increased when exact duplicates exist with small ratios. Third, RF is the only algorithm that has a positive sensitivity toward exact duplicates with ratios more than 10%, whereas negative sensitivity is reported for the rest of classifiers under high ratio of exact duplicates. Fourth, Kmeans clustering algorithm has a positive sensitivity when having near duplicates with either small or large ratios. Fifth, generally the rest of clustering algorithms are negatively sensitive toward near duplicates especially with high percentages. Sixth, the proposed duplicate metric proved its effectiveness in measuring the true percentage of near duplicates within a dataset.

Abstract—Due to the wealth of data available from different radiographic images, detecting dental caries has traditionally been a difficult undertaking. Numerous techniques have been developed to enhance image quality for quicker caries detection. For the investigation of medical images, deep learning has emerged as the preferred methodology. This study provides a thorough examination of the application of deep learning to object detection, segmentation, and classification. It also examines the literature on deep learning-based segmentation and identification techniques for dental images. To identify dental caries, several techniques have been used to date. However, these techniques are inefficient, inaccurate, and unable to handle a sizable amount of datasets. There is a need for a way that can get around these issues since the prior methods failed to do so. In the domains of medicine and radiology, deep convolutional neural networks (CNN) have produced amazing results in predicting and diagnosing diseases. This new field of healthcare research is developing quickly. The current study's objective was to assess the effectiveness of deep CNN algorithms for dental caries detection and diagnosis on radiographic images. The Convolutional Neural Network (CNN) method, which is based on artificial intelligence, is used in this study to introduce hybrid optimal deep learning, which offers superior performance.

Keywords—Dental caries; deep learning; convolutional neural network

I. INTRODUCTION

Detecting dental caries was an exciting task due to the information gleaned from various radiographic images [1]. One of the most frequent chronic illnesses worldwide is dental caries. Especially large, obvious cavities on afflicted teeth respond well to such treatment methods. The effectiveness of conventional approaches has been hindered by the complicated visual features of dental caries images, which include concealed or difficult-to-access lesions [2]. The majority of common caries detection techniques focus on visual examination of the teeth, which also seems to be effective for both big, clearly apparent carious lesions and those that are only faintly visible but may be seen in hand

mirrors. Dental radiography is used to find lesions that are hard to see or that are otherwise concealed from view [3]. The adoption of new instruments is advantageous since early diagnosis of dental caries lesions is a key therapeutic factor. The area of health care with the biggest growth is dentistry treatments.

By doing this, the danger, therapy, and identification of oral disorders are reduced [4]. Bitewing radiographs are frequently used by dentists to help them find tooth cavities. They concentrate on both the radiological data and the medical background of their patients. Detecting dental caries is a difficult process, and even skilled dentists may fail to spot carious lesions on bite-wing radiographs [5]. Dental caries detection methods have also typically used visual-tactile methods [6]. Visual-tactile techniques have poor sensitivity, particularly when applied to the surfaces of the proximal posterior teeth. Although radiographic techniques entail the utilization of ionizing radiation, they have a high sensitivity [7]. It might be challenging to detect cavities in certain teeth early on. Numerous carious lesions are discovered at a later stage [8]. The great majority of its screenings, however, are based on data analysis, even though dental radiography is often recognized as one of the most accurate screening methods for finding dental caries. Additionally, there is little research on identifying and diagnosing dental caries [9]. The effectiveness of deep learning techniques for spotting dental cavities in bite-wing radiographs. Blob identification on bite-wing radiographs helps us specify where and how to look for dental caries.

Blob detection is a statistical method for identifying particular regions in radiographic or digital images. Blobs are areas that stand out greatly from their surroundings. Blobs are also areas that contrast with their environment in brightness or darkness. Since their locations are derivative functions, blob detectors fall within the category of variable approaches. Blobs include data about different areas of interest that may be utilized in subsequent image processing with an increase in popularity in the processing of medical imaging [9]. Dentists

frequently employ biting radiography to help identify tooth cavities. But this is a challenging procedure. Dentists use their clinical knowledge and the people's clinical background to validate their radiographic caries results. Even seasoned dentists tend to overlook cavities. Dental caries is brought on by an inflammation of the calcified tissue on the teeth. Through early discovery and treatment, they are easily preventable [10].

Effective and prompt treatment may result from the development of a reliable framework for the identification and categorization of dental caries [11]. Cavities are one of the most prevalent illnesses of the mouth that impact individuals of all ages, from infants to elders. It is a condition that weakens the structure of the teeth. Caries is mostly brought on by bacteria that turn the glucose and carbohydrate in food into acid. Because this acid melts and damages the minerals in the enamel, it causes significant damage to the tooth. Dental caries is a chronic condition that most patients experience a delayed onset of. It may impact the dentine tissue, which lies underneath the cementum and enamel on the root, as well as the enamel and cementum's exterior coverings. Infant and toddler caries is the term used to describe cavities in young children's primary teeth [12].

Dental hard tissues undergo periodic demineralization and remineralization as a result of the multifactorial, dynamic, biofilm-mediated illness known as dental caries. Including both permanent and primary teeth, caries can develop at any age and harm the tooth crown as well as the exposed root portions over time. Caries' start and development are impacted by the imbalance of protective and pathogenic factors. The categorization of individuals and groups into carious lesions risks identified is supported by the interplay of these variables, allowing for a more individualized approach to management [13]. Dental caries is a treatable, unequally distributed illness that imposes high costs on both the economy and the quality of life. The worldwide drop in cavities over the past several decades is attributed to the regular utilization of toothpaste. To find caries, experienced testers often conduct a thorough visual examination of clean teeth. Even though they are still frequently utilized, pointed dental probes offer little additional diagnostic value and can harm some teeth.

The detection and treatment of dental caries are changing [14]. Dentists presently use optical, tactical, and radiological data to identify somewhat severe alterations in the oral hard tissues. Instead of treating the illness itself, the clinical therapy of dental caries has focused on treating its symptoms by implanting solutions. Utilizing cutting-edge equipment, dentists would be able to identify developing dental caries before the clinically noticeable white spot. Dental caries is a continuing phenomenon that can be stopped at any stage—from the beginning to the end. When chemicals from bacterial respiration spread into enamel and dentine and break down the mineral, a dental cavity develops as a fungal illness. As a consequence of the bacteria's metabolism of fructose and glucose, organic acids are created [15].

But it has been known for more than a generation that bacteria digest meals produce acids that dissolve tooth minerals and cause dental disease. Dental caries is a

contagious bacterial condition mostly brought on by the germs mentioned above feasting on the carbohydrates that people put in their mouths. In the dentistry industry, detecting dental caries is still referred to as the finding of demineralized areas, particularly cavities. Instead of responding medically before cavitation occurs and while the nutrition loss mechanism is still repairable, or at the very least may be implicated, the practising dentist “fixes” cavities by drilling and filling. Dental caries is not the actual disease; rather, it is symptomatic of an existing and past illness. As a result, it is crucial to document the beginning phase of parasite infection or the phases of lesion growth that are not cavitated. [16].

The key contributions of this study are:

- Initially, radiographic images from a large number of patients are collected, and the datasets are analyzed in the framework.
- Moreover, the collected images contain noise, which is filtered using the Wiener filter.
- The filtered images are subjected to segmentation, in which an enhanced Bat Whale optimization model has been used.
- The GLCM is used in the feature extraction to extract the features, and the Convolutional Neural Network is used for classification.
- The BWO-CNN model continues to perform best in terms of accuracy and provides independent advice to the medical professional in the classification of dental images.

The remainder of the essay is divided into the following sections. In Section 2, a summary of prior research on dental caries is provided. Section 3 discusses the proposed classification and framework. Section 4 presents the findings and a discussion of both the proposed and current approaches. The article comes to a close in Section 5 with a few more observations.

II. RELATED WORKS

Some of the literature related to dental carries are summarized as follows:

Deep learning for earlier dental caries identification in bitewing radiographs was proposed by Shinae Lee [17]. In this work, they evaluated whether a convolutional neural network model for caries identification on bitewing radiographs employing a U-shaped deep CNN may enhance physicians' effectiveness. The study conformed with all applicable standards of ethics. 304 bitewing radiographs altogether were utilized to train the convolutional neural network model, and 50 radiographs were employed to assess its efficacy. On the entire test dataset, the convolutional neural network model performed pretty accurately in terms of accuracy, recall, and F1-score, with scores of 63.29%, 65.02%, and 64.14 % respectively. The overall classification performance of all three physicians improved significantly when utilizing the convolutional neural network model findings as the data source to identify caries, as seen by an enhanced sensitivity ratio. Thus, physicians may benefit from

using the deep learning model to effectively identify dental caries. Despite matter how much the diagnostics performance of the CNN model is improved, there will inevitably be some false-positive mistakes.

Perna Singh and Priti Sehgal employed the optimal CNN-LSTM for the categorization and preparation of the G.V. Black dental caries [18]. A common health issue for many individuals worldwide is dental caries, a type of oral illness. Inflammation of the calcified tissue of the teeth leads to dental caries. Early detection and treatment make it simple to avoid and cure them. One approach that is well-liked around the globe is the G.V. Black Categorization for dental caries. Depending on the location of caries, it divides the condition into six classifications. To identify and diagnose dental caries on periapical dental images, a novel deep convolution layer network using an LSTM model is proposed in this research. This study's primary goal is to identify dental cavities and categorize them according to the G.V. Black Classification. Deep convolutional neural networks receive pre-processed periapical dental images as input. The Dragonfly optimization technique was used to optimize the suggested algorithm, which provided an accuracy of 96%. Examining and contrasting the suggested model with current state-of-the-art deep learning models is done through experiments. The suggested ideal CNN-LSTM model exhibits the best efficiency and aids in the categorization of dental images as a recommendation for the medical specialist.

The Logit-Based Artificial Bee Colony Optimization Approach was utilized by M. Sornam and M. Prabhakaran to classify dental caries using a back propagation neural network [19]. Caries, a bacterial infection that may cause oral discomfort, is a problem that can greatly reduce people's capacity to carry out their daily activities. Dental practitioners are working hard to discover a suitable strategy to minimize the miscategorization of dental caries phases and probable incorrect diagnoses. Utilizing dental X-ray images as the numerical input produced through a GLCM, a texture feature extraction process, this method is used to strengthen the back-propagation algorithm for an appropriate training and testing process, thus further achieving the best categorization accuracy. But the obtained accuracy is not higher when compared to the other optimization techniques.

For teledentistry, Devesh Saini et al. [20] presented a convolutional neural network for the identification of dental cavities. The primary cause of tooth loss is dental caries, a bacterial illness that progresses over time. This happens as a result of bad dental hygiene, which also causes several dental illnesses. This study attempts to identify dental cavities utilizing digital colour images at a preliminary phase, allowing for simple and efficient treatments. On a categorical collection with caries-containing and non-caries-containing images, training, validation, and testing have been done. Vgg16, Vgg19, Inception v3, and Resnet50 models are

employed to attain classification performance, with Inception v3 achieving the greatest efficiency among them with training and validation accuracy of 99.89% and 98.95%, respectively, with the least loss when comparing to Vgg16 CNN models.

Hongbing Yu et al. [21] proposed a new method for Dental Caries Identification on the Child's First Permanent Molar. Recent studies have revealed a significant incidence and prevalence of caries in children's teeth, particularly in the first permanent molar, which might be very harmful to their overall health. Luckily, early identification and prevention can lessen treatment complexity and safeguard kids' dental health. To develop a new method for completely automated identification of dental caries on a child's first permanent molar, they present a unique caries identification and evaluation (UCDA) architecture in this research. The presented UCDA system primarily consists of a backbone that is started with ResNet-FPN and two simultaneous task-specific subnetworks for area reduction and area categorization. These subnetworks were motivated by an effective in-network featured pyramid and anchor boxes.

Shashikant Patil et al. [22] proposed an algorithm for the detection of dental caries employing an adaptable neural network architecture. AI approaches have a long-lasting effect on biomedicine and provide broadly recognized results. The study's only goal is to examine the effectiveness of combining the Adaptive Dragonfly algorithm, Neural Network classifier, feature extraction, and categorization of dental images for accurately detecting caries. The suggested caries classification method in this case is made to accurately identify dental cavities. The two key stages of this technique are feature extraction and categorization. To assess performance, the 120 entire picture database is divided into three sets at random. Additionally, this classification of the test scenarios helps to guarantee speed improvement. Comparing the proposed MPCA-ADA model to other existing features allows for the model's performance to be assessed. The potential effectiveness of IP and NN algorithms for the identification and treatment of dental caries is emphasized in the study effort.

III. PROPOSED BWO-BASED CNN

The radiographic images of dental caries are first gathered. The images are then used for training and testing purposes. Images from dental caries radiography go through a pre-processing stage where the wiener filter is employed to eliminate the extra noise. In this work, dental cavities are detected early on using a combined bat and whale optimization technique. Dental caries and their severity are categorized using the proposed BWO-CNN approach. To operate enormous datasets and obtain a greater accuracy value, a convolutional neural network is used. Fig. 1 represents the various stages of the detection of dental caries.

Fig. 1. Proposed BWO-CNN model.

A. Data Collection

This experiment employed data from about 10,000 datasets, including radiographic images of dental cavities. 50 per cent of the images from this set are utilized as training data and 50 per cent are used as testing data. Accordingly, 5000 radiographic images of dental caries are used as training data and 5000 radiographic images of dental caries are used as testing data.

B. Pre-processing

To detect dental caries, pre-processing is the initial step. It is employed to fill in dataset gaps and remove irrelevant data. The radiography images are impacted by independent and abnormal noises, which reduces the sample image analysis rate. The speckle noises, which can be induced by both internal and external sources, have a significant negative impact on radiography images. To minimize the noise in dental caries radiography images, the developed Wiener filter is used. The Wiener filter is a linear filter used to conceal visual noise. The BWO-CNN model for identifying dental caries, therefore, makes advantage of the noise-reduced images. Given the Wiener function,

$$w(a, b) = \sigma^2 [m - p(a, b)] \quad (1)$$

Here σ^2 is the Gaussian noise variance, a and b are the dimensions of the pixel, and m is the feature of noise.

C. Segmentation using BWO

In radiography images, the segmentation procedure is primarily utilized to isolate the afflicted area. The effectiveness of the segmentation process is necessary for the execution of image processing. Image segmentation is frequently used to identify where dental cavities are present as well as any limitations posed by curves and lines in the images. Image segmentation divides the images into sets of pixels and labels the pixels in the samples. The primary

objective of image segmentation in medical image processing is to identify dental cavities and produce sufficient data for further identification. Here, an upgraded and optimized Bat and whale algorithm are used to complete the image segmentation.

D. Bat Optimization algorithm

The echolocation of microbats was used to develop a metaheuristic bat algorithm. Bats typically utilize echolocation to find food. The bats typically emit brief pulses, but when they come upon food, both the pulse rate and frequency rise. The precision of the location is improved and the echolocation time is reduced due to the increase in frequencies. Each individual in the bat algorithm has a fixed position $u_i(n)$ and velocity $v_i(n)$ in the search space, which are upgraded as the number of iterations rises. The new positions $u_i(n)$ and the velocities $v_i(n)$ can be calculated as follows:

$$u_i(n+1) = u_i(n) + v_i(n) \quad (2)$$

$$v_i(n+1) = v_i(n) + (u_i(n) - q(t)) \cdot f_i \quad (3)$$

$$f_i = f_{\min} + (f_{\max} - f_{\min}) \cdot \beta \quad (4)$$

Where $[0, 1]$ is the range of the random vector, which has a similar distribution. $f_{\min} = 0$, $f_{\max} = 1$, and $q(t)$ represents the current global optimal solution.

1) *Whale optimization algorithm*: The whale optimization algorithm was inspired by humpback whales' use of bubble nets for hunting. The humpback whales will randomly locate their prey, begin to envelop it in a spiral-shaped bubble, and then swim up toward the surface. Two steps make up the whale Optimization algorithm. The prey is randomly hunted in the first phase, and then spiral bubble nets are used to enclose and attack the prey in the second phase. To find its prey, the whale must be in the best possible posture. The equation shown below can achieve this:

$$\vec{Y}(i+1) = \vec{Y}^*(i) - \vec{A} \cdot \vec{B} \quad (5)$$

$$\vec{B} = |\vec{C} \cdot \vec{Y}^*(i) - \vec{Y}(i)| \quad (6)$$

$$\vec{D} = 2 \cdot \vec{z} \cdot \vec{r} - \vec{z} \quad (7)$$

$$\vec{C} = 2 \cdot \vec{r} \quad (8)$$

The ideal whale posture is represented by $\vec{Y}^*(i)$. The search agent's current location is given by the variables $\vec{Y}(i+1)$ and \vec{B} (the range between the whale and its target). The coefficients are \vec{C} and \vec{D} . The value of z decreases from 2 to 0, reaching 0 at the end of the iteration. A random variable, \vec{r} , has a value between 0 and 1.

2) *Bat-Whale Optimization algorithm*: To reliably identify dental caries, the traits of both whales and bats are merged and optimized. The whale's fitness is indicated in eq. (9)

$$y_i(n+1) = y_i(n) + v_i(n) - \vec{D} \cdot \vec{B} \quad (9)$$

Algorithm: BWO-CNN mechanism

Input: Radiographic images of dental caries

Output: Detection of regions with dental caries

Load input images

Train the input images P_i in the system,
where $i = 1$ to n

Pre-processing of images

Let $J(i)$ be the input image from the dataset

$$w(a, b) = \sigma^2 [m - p(a, b)] \quad // \text{Wiener filter}$$

Segmenting the affected part // Bat
and Whale Optimization

Initially, the affected part is detected using Eqn. (2)

If (initial region is met)

Update the fitness of Bat and Whale to find the next affected region using Eqn. (9)

Else

Find the initial location

Repeat until the stopping condition is reached // until
all the affected region is identified

End if

Return

Feature extraction using GLCM

Classification of dental caries //CNN Classifier

E. Feature Extraction

Inexperienced data are transformed into numerical traits called features that can be used to save the information in the original data set. Each patient perceives images differently; these traits are derived from the total number of images captured. The image's dimensions are enhanced during testing, however, to identify dental cavities, the image's dimensions must be decreased. The processing of feature extraction helps to resolve this issue. In feature extraction, GLCM is used. Correlation, energy, homogeneity, contrast, entropy, and other second-order image attributes are examined to eliminate the probabilistic texture feature.

1) *Energy*: Squares with frequently higher grayscale values and unpredictable concentration values in images are summed to create energy. In Eq. (10), the energy of the input data is determined.

$$E = \sum_x \sum_y \{N(x, y)\}^2 \quad (10)$$

Where the squares in the image with grey levels are labelled as (x, y) , and the images are denoted as N .

2) *Contrast*: The local contrast of an image is measured using features, and it is projected to be low when the mean concentration is even. The complete grayscale information of the main image is then projected, as per Eq. (11),

$$C = \sum_{a=0}^{I_y} a^2 \left\{ \sum_{x=1}^{I_x} \sum_{y=1}^{I_y} M(x, y) \right\} \quad (11)$$

(x, y) represents the square of an image's grayscale, N represents the images, and I stands for the images' grayscale.

3) *Correlation*: Using the correlation characteristics shown in Eq. (12) the numerical connections between the variables and the proportional dependency of grey levels on pixels.

$$C_o = \frac{\sum_x \sum_y (x, y)N(x, y) - \mu_u \mu_v}{\sigma_u \sigma_v} \quad (12)$$

The values of the mean and standard deviation in the images are represented as rows and columns by the letters μ_u , μ_v , σ_u , and σ_v .

4) *Entropy*: Entropy is referred to in Eqn. (13), the anticipated high value of the range of grey levels being randomly generated sticks out.

$$En = - \sum_x \sum_y N(x, y) \log(N(x, y)) \quad (13)$$

F. Classification using Convolutional Neural Network (CNN)

To identify dental caries, CNN classifiers are used. It effectively evaluates the radiography images and extracts the necessary characteristics. Four layers are present in convolutional neural network classifiers: the convolutional layer, the max pooling layer, the fully connected layer, and the softmax layer. The CNN ranges the intensity values of the image pixel before the training phase. CNN is the model that trains the quickest. The input radiography image ought to be the same size. Each image in the training set has an equation that is presented in Eq. (14).

$$p(a, b) = \frac{\sigma(a, b) - \mu}{\sigma} \quad (14)$$

1) *Convolutional layer*: A convolution layer was used to decrease the image of factors and extract the important features. The convolution layer includes rotation invariance,

scaling partially invariant, and interpretation invariance. Both the over-fitting problem is lessened and the generalization idea is added to the fundamental framework. The convolutional layer collects a variety of images to analyze how complicated each one is. It is related to the qualities we seek in the given image. It is written as an eqn. (15).

$$f_i^m = x(\sum_{j \in M_i} f_j^{m-1} * p_{ji}^m + x_i^m) \quad (15)$$

M_i – It stands for an input choice. The output has been specified as an additive bias b. When the sum of maps a and b across map i the kernel is applied to map i.

2) *Max pooling layer*: In order to reduce fitting and the size of the neurons used in the downsampling layer, this layer is used. The pooling layer reduces the rate of calculation, the size of the feature map, the training time, and regulates overfitting. Overfitting is calculated using an equation and is defined as 50% on test data and 100% on the training dataset.

$$x_{mab} = \max_{(s,t) \in f_{mst}} \quad (16)$$

Map, f_{mst} is the component at (s, t) in the pooling region pst, and it represents the immediate area.

3) *Fully connected layer*: In the field of classifying images, a Fully Connected Layer has been applied. The FC layers are placed after the Convolutional layers. The FC layer makes it easier to map a picture between the input and output. Fully linked layers make up the network's upper tiers. The output of the max pooling layer serves as the input for the fully connected layer.

4) *Softmax layer*: The Softmax layer converts the values into a normalized ratio distribution. The output is provided to the classifier as an input. The dental caries structure is implemented in the Softmax layer and the Softmax classifier is the standard contribution classifier. It is depicted in Eq. (17).

$$\sigma(\vec{X})_n = \frac{e^{x_n}}{\sum_{i=1}^n e^{x_i}} \quad (17)$$

The whole process for detecting dental caries is shown in Fig. 2. The loading of input images starts the flowchart. The next step after loading the images is to train the loaded images. The Wiener filter is used during pre-processing to get rid of any unwanted noises from each image. The segmentation method uses the images that have had the noise removed. The segmentation process uses the suggested BWO-CNN. Using Eq. (2), the impacted region's position is initially determined. If the first region is met, use equation (9) to locate the subsequently impacted region; otherwise, return to the previous step and repeat the calculation of equation (2) until the initial region is fulfilled. Repeat Eq. (9) after identifying the subsequently impacted region until the stopping condition is satisfied. The process moves on to feature extraction if the halting condition is satisfied. GLCM is used for feature extraction. Following that, a Convolutional Neural Network is used to classify dental caries.

Fig. 2. Flow diagram of the BWO-CNN model.

IV. RESULTS AND DISCUSSION

The existing methods consume a large time for processing and they cannot process a large number of data sets. More precise accuracy cannot be achieved with the existing methods. The employed BWO-CNN method overcame these limitations. The proposed strategy has been tested utilizing dental caries radiography datasets. The combined innovative bat and whale optimization-based convolutional neural network is employed to identify dental caries. Performance metrics are used to evaluate how well the given approach is presented.

A. Accuracy

Measured by accuracy, the system model's performance across all classes is evaluated. In general, it is the idea that all observations will be correctly predicted. In Eq. (18), accuracy is expressed.

$$Accuracy = \frac{T_{Pos} + T_{Neg}}{T_{Pos} + T_{Neg} + F_{Pos} + F_{Neg}} \quad (18)$$

B. Precision

The number of correct positive assessments that deviate from the overall positive evaluations is used to measure precision. By using an Eq. (19), you can compute the precise identification of dental caries,

$$P = \frac{T_{Pos}}{T_{Pos} + F_{Pos}} \quad (19)$$

C. Recall

The relationship between the number of genuine positives correctly labelled as positives and the overall number of positive samples is known as the recall. It describes the proportion of predictions that were correct in the Eq. (20) based detection of dental caries,

$$R = \frac{T_{Pos}}{T_{Pos} + F_{Neg}} \quad (20)$$

D. F1-Score

The F1-Score calculation is the combination of recall and precision. The F1-Score shown in Eq. (21) is calculated using precision and recall.

$$F1 - score = \frac{2 \times precision \times recall}{precision + recall} \quad (21)$$

Table I shows that the training accuracy of CNN and BWO-CNN is 99.2% and 99.55% respectively. The testing accuracy of CNN and BWO-CNN is 97.3% and 98.6% respectively. It is represented in Fig. 3.

TABLE I. PERFORMANCE EVALUATION BASED ON BWO-CNN

	CNN (%)	BWO-CNN (%)
Training accuracy	99.2	99.5
Testing accuracy	97.3	98.6

Fig. 3. Evaluation of testing and training accuracy.

TABLE II. ACCURACY COMPARISON OF VARIOUS METHODS

Method	Accuracy (%)
U-shaped deep CNN	63.29
CNN-LSTM	96
CNN	98.95
BWO-CNN	99.12

Fig. 4. Comparison of accuracy.

The projected technique Combined novel Bat and Whale Optimization-based Convolutional Neural Network achieves higher accuracy when compared to the existing dental caries detecting methods such as U-shapes CNN, CNN-LSTM, CNN, and BWO-CNN which are tabularized in Table II. Fig. 4 represents the Comparison of accuracy between BWO-CNN and other methods.

The projected technique Combined novel Bat and Whale Optimization-based Convolutional Neural Network achieves higher recall when compared to the existing dental caries detecting method like U-shaped CNN and BWO-CNN which are tabularized in Table III. Fig. 5 represents the Comparison of recall between BWO-CNN and U-shaped CNN.

TABLE III. COMPARISON OF RECALL

Method	Recall (%)
U-shaped deep CNN	65.02
BWO-CNN	92

Fig. 5. Comparison of recall.

TABLE IV. COMPARISON OF F1-SCORE

Method	F1-score (%)
U-shaped deep CNN	64.14
BWO-CNN	91

The proposed technique Combined novel Bat and Whale Optimization-based Convolutional Neural Network achieves a higher F1-score when compared to the existing dental caries detecting method like U-shaped CNN and BWO-CNN which are tabularized in Table IV. Fig. 6 represents the Comparison of recall between BWO-CNN and U-shaped CNN.

V. CONCLUSION

Although image processing in medical technology is expanding quickly nowadays, there are some situations where the complexity of the images makes it challenging to classify and identify diseases. The suggested approach is utilized to categorize, find, and segment the diseased or damaged portion. It focuses mostly on finding dental cavities. Individuals' information is first provided through radiographic images of patients with various types of dental caries, which are gathered. The unwanted effects or noise in the radiography images are then eliminated during the pre-processing step using a wiener filter. GLCM was used for feature extraction. Additionally, the damaged part is segmented using the suggested BWO-CNN method, and dental caries is classified using a CNN. Using BWO-CNN, high categorization and accuracy are also attained. The prediction accuracy of this model was 99.12% as a consequence. Even though the proposed method is effective, the performance can be increased by introducing LSTM. Therefore, in the future, a lot of research is being focused on creating a lightweight CNN-LSTM model that can shorten training time and is resistant to weight initiation effects.

FDeep: A Fog-based Intrusion Detection System for Smart Home using Deep Learning

Tahani Gazdar

Cyber Security Department-CCSE
University of Jeddah, Jeddah, Saudi Arabia

Abstract—Smart Home is an application of the Internet of Things (IoT) that connects smart appliances and the Internet. The emergence of Smart Home has caused many security and privacy risks that can lead to fatal damages to the user and his property. Unfortunately, Intrusion detection systems designed for conventional networks have shown their inefficiency when deployed in Smart Home environments for many reasons that rely basically on the resources-constrained devices and their inherent intermittent connectivity. So, an intrusion detection system designed for IoT and particularly Smart Home is mandatory. On the other hand, Deep learning shows its potential in enhancing the performance of Intrusion Detection Systems. According to recent studies, Deep learning-based intrusion detection systems are deployed either on the devices or in the Cloud. However, Deep learning models are greedy in terms of resources which makes it challenging to deploy them on Smart Home devices. Besides, in the IoT architecture, the IoT layer is far from the Cloud layer which may cause additional latency and jitter. To overcome these challenges, a new intrusion detection system for Smart Home deployed in the Fog Layer is proposed, it is called FDeep. FDeep will inspect the traffic using a Deep Learning model. To select the most accurate model, three Deep Learning models are trained using an IoT dataset named TON/IOT, also the proposed models are compared to an existing one. The obtained results show that the long short-term memory model combined with the convolutional neural networks outperforms the other three models. It has the best detection accuracy compared to other Deep Learning models.

Keywords—Fog computing; smart home; deep learning; IDS; classification

I. INTRODUCTION

The IoT environment is a system of smart devices that are interconnected and enabled with sensing and data transmitting capabilities [1]. IoT technology is used in Smart Home to enhance safety and convenience. Nevertheless, providing privacy and security in Smart Home environments is the key challenge facing their deployment. Many attacks threaten a Smart Home and may expose the data or properties to risks. One of the popular attacks is Denial of Service (DoS) on client-server applications. Eavesdropping is another common attack where an attacker intercepts data packets flowing in the network.

An intrusion detection system (IDS) analyzes the data packets to detect potential intrusion, and then generates alerts in case of any suspicious behaviour [2]. Particularly, anomaly-based IDSs are characterized by their efficiency in detecting zero-day and new attacks. This kind of IDS is based on

Machine learning (ML) models that can automatically learn from experience and analyze patterns based on collected data. Deep Learning (DL) is a subcategory of ML, it can understand patterns using many layers of processing however it needs a large amount of data [3][4]. This represents one of the main challenges facing deploying IDS based on DL in IoT, in addition to the limited computation capabilities of the IoT devices. More important, most IDSs proposed in the literature are deployed on IoT devices which is not practical. DL models cannot run efficiently on resources constrained IoT devices because of the huge amount of data to analyze in addition to the complexity of DL models that needs high computation resources [2]. Further, many approaches implement the DL models in the Cloud, however, a centralized intrusion detection approach is not adequate for IoT because of their large scale and the caused latency. A distributed approach would be more appropriate. Besides, the efficiency of DL models degrades over time, so they need to be re-trained regularly with new data to enhance the detection capabilities mainly for zero-day and unknown attacks [5]. Most approaches re-train the models either on the Cloud or on desktops, then replace the old model with the new one. In these approaches, a huge amount of data packets is required. In the context of IoT and particularly Smart Home, the collected data may contain sensitive data related to the end user which may violate his privacy. Thus, an efficient, distributed, and accurate IDS for Smart Home is required to provide strong intrusion detection capabilities [2].

In this paper, new Fog-based IDS architecture dedicated to Smart Home named FDeep is proposed. The objective is to leverage Fog computing in IoT to provide a distributed, efficient, and high computation capacity IDS for Smart Home. An IoT application particularly a Smart Home consists of three main layers: the Edge layer and the Cloud layer and a Network layer. The Edge layer consists of a set of Smart devices responsible for sensing their environment, collecting data, and transmitting it through a Network layer to the Cloud Layer. This data is processed and analyzed in the Cloud layer to provide a wide range of applications and services to the end user. The two layers communicate with each other through gateways and routers. Generally, the Edge layer is too far from the Cloud layer, which might cause additional latency and jitter and requires high bandwidth consumption. Here, the paradigm of Fog computing comes to overcome this limitation by extending the Cloud and making it closer to the user. Fog computing provides computing, networking, and storage services to the Edge and Cloud layers in a distributed environment [6]. Unlike many approaches where DL models are implemented either in the Cloud or the Edge layers, in

FDeep the proposed DL model will be implemented in the Fog layer which represents the glue between the Cloud and Edge Layers. Besides, to maintain the DL model and avoid its degradation in terms of detection, periodic training of the DL model will be triggered using the data newly collected from the real network in the Fog layer.

The key contributions of the paper are summarized as follows:

- In FDeep, the DL model will be implemented in the Fog layer to guarantee low latency and reduce bandwidth consumption in addition to a fast inspection and detection of the attacks occurring in the IoT layer.
- An accurate DL model aiming to classify the attacks into seven types is proposed.
- An IoT dataset is used to train our models and select the most accurate one to be deployed in FDeep.
- The DL model to be deployed in FDeep will be periodically re-trained and updated to avoid its degradation. To do so, the data packets are collected from the IoT layer of the real network and fed to the model to re-train it.

The remainder of the paper is structured as follows. In Section II, the most recent approaches interested in DL-based IDS for IoT and its applications are discussed. Section III presents the architecture of FDeep in detail. In Section IV, the used dataset is described. In Section V, the experiments set up are presented and the obtained results are analyzed. Section VI concludes the paper and presents future work.

II. RELATED WORK

DL-based Intrusion detection systems are widely adopted to inspect network traffic and detect intrusion and misbehaviour [2][7]. In [8], a DDoS detection system based on Deep Learning DL is proposed. The authors evaluated the performance of several DL approaches with ML techniques for DDoS attack detection. The obtained results point out the potential of Deep Learning in enhancing the accuracy of detection of DDoS attacks. A behavioural model is proposed in [9] to detect malicious traffic generated by compromised IoT devices using Autoencoder (AE). It is a kind of Deep Learning that learns unsupervised data. AEs are widely used in IoT security. In their study, AEs were used to extract features derived from cyber systems. In [10] a Deep Learning based intrusion detection system for IoT has been proposed. The authors used an SMO model to enhance the convergence time and feature extraction. Besides, they used the SDPN classifier to distinguish benign traffic from malicious one. The authors pretend that their model can handle datasets with redundant values and uncertain or missing data. However, the proposed model detects a few attacks: DoS, U2R, probe, and R2L. Unfortunately, all the above-discussed approaches don't mention how to implement the proposed DL models.

The authors proposed in [5] an attack detection system for IoT based on Deep Learning. They have implemented the proposed framework on Fog nodes. The authors have adopted an LSTM model to analyze and inspect the data packets

collected from IoT devices to detect potential attacks. The maintenance of the model is performed in the Cloud layer to update the DL model and avoid its degradation in terms of detection capabilities. The limitation of the proposed architecture is the fact that the administrator must regularly check the accuracy of the model and maintain it manually. Additionally, the authors used dataset KDD CUP 99 which is not an IoT-specific dataset. However, according to [2], a model trained for a specific network or application may not be efficient for another network or application. In IoT, it is even recommended to design each kind of device with its own DL/ML model given the diversity of their sensing capabilities [2]. In [11], an LSTM model has been used to detect attacks in Fog-to-Things Communications. They proposed a distributed framework to detect attacks. However, their approach detects only attacks on Fog nodes and disregards the risk from IoT devices.

In [12], the authors proposed an intrusion detection model to detect attacks in a Fog computing environment. They have integrated CNN with LSTM to obtain an integrated and more accurate model. The limitation of this approach is the use of NSL-KDD which is not an IoT dataset. According to [13], many research studies are interested in intrusion detection systems for Fog-based IoT applications, however, these approaches detect only intrusions in Fog nodes. In [14], the authors proposed an IDS based on Ensemble learning for Fog-to-things environments. To enhance anomaly detection accuracy, the authors combine many classifiers to build two levels of classifications. The first layer detects the potential anomalies while the second layer classifies the detected anomalies. Similarly, DL models for attack detection in Fog-assisted IoT are proposed in [15] and [16]. Again, a non-IoT-specific dataset is used. Consequently, the accuracy of the model may be negatively affected once it is deployed in Fog-to-things environments.

To overcome the limitations of the above-discussed models we propose in this paper to implement the DL model in the Fog layer. Additionally, an IoT-specific dataset called TON/IIoT is used, it contains records collected from real IoT devices, and also it contains records about seven attacks.

III. PROPOSED IDS ARCHITECTURE

A. Fog Computing and IoT

Recently, Cloud computing is the most popular computing paradigm. However, the spreading of IoT creates several challenges for Cloud computing. Particularly, most IoT applications require low latency which is not easily provided by Cloud computing since it has a centralized architecture that ill-suits the huge scale and the distribution of IoT. Moreover, the huge scale of IoT that relies basically on the high number of Smart devices increases the amount of data generated in the network. Sending this high amount of data to the Cloud will certainly need a high network bandwidth in addition to privacy concerns. Data generated in edge devices should be processed locally as most as possible. However, edge devices are usually resource-constrained devices unable to perform complex tasks and run complex protocols and models. Moreover, the intermittent connectivity due to the geographical distribution of edge devices makes them unable to benefit from

uninterruptible Cloud services. Thus, an intermediate layer between the Cloud and the IoT devices is unavoidable [6].

Fig. 1. 3-tier fog architecture.

Fog computing comes to bridge this gap and provide distributed networking, storage, control, and computing capabilities between the Edge Layer and the Cloud layer [6]. Typically, the Fog layer is connected to the edge layer, which means that it is closer to the user than the Cloud layer. It is characterized by its flexibility to provide computation services to a large scale of end users in its proximity. Hence, it fosters decreasing the latency and accelerating decision-making. As depicted in Fig. 1, Fog computing has three-tier architecture: IoT layer, Fog layer, and Cloud Layer.

The lower layer is the IoT layer which is composed of the IoT devices such as smart vehicles smartphones, sensors, Cameras, smart appliances, etc. These IoT devices are heterogeneous in terms of computing capabilities, vendors, firmware, etc. They are geographically distributed, and their role is to collect data like temperature, fire, images, etc, and send them to the upper layer. The Fog layer consists of many Fog nodes responsible for providing computing, storage, and control services to the Cloud layer and IoT layer. A Fog node may be a router, a virtualized Fog server, or a simple data centre. Typically, the data is routed from the IoT layer to the Fog layer using smart gateways. The Cloud layer is the upper layer that consists of many servers characterized by their high storage and computational capabilities.

B. FDeep Architecture

As depicted in Fig. 2, the architecture of FDeep consists of 3 layers: IoT layer, Fog layer, and Cloud Layer. In the following, the role of each layer and the communications between them are detailed.

1) *Data collection*: All packets exchanged between the Smart devices in the IoT layer or to/from the Fog Layer pass through gateways. A network sniffer such as sflow or tcpdump, is deployed on these gateways to capture all network traffic, and the output will be saved in .pcap files. Then, the records are preprocessed to extract the useful features

(timestamp, protocol, IP addresses, etc) and create CSV files containing pertinent data that will be inspected in the Fog layer to detect potential intrusions in the Smart Home. These data will be also used to re-train the DL model to improve its detection capabilities.

2) *Data analysis and intrusion detection*: The objective of FDeep is to detect potential intrusions in a Smart Home environment. To this end, a DL model is used to catch attacks and classify them. Three DL algorithms will be trained later and the best one in terms of detection accuracy will be deployed in FDeep.

In the current paper, the aim is to leverage Fog computing to build an efficient IDS by deploying the DL model on the Fog layer, doing so has many benefits. First, Fog computing is usually close to the user which reduces the latency and makes it best suited the real-time applications in IoT contexts. This feature is interesting in our context because rapid intrusion detection is required. The data will be processed close to the smart devices from which it is originating, no need to transmit it to the Cloud which reduces bandwidth consumption. Secondly, the OpenFog Security Group¹ has defined two main security goals of Fog computing. The first goal is the intrinsic security of Fog computing in terms of responsiveness, availability, fault tolerance, and trust. Fog computing can provide security services for the IoT layer since most of them are resources constrained such as identity verification, and endpoint protection.

In the current study, the aim is to use a DL classifier to detect and classify intrusion in a Smart Home based on data received from the IoT layer, and since most IoT devices have limited resources, it seems interesting to implement the DL model in the Fog layer instead. It will provide a scalable, distributed and high computation environment for FDeep.

3) *Updating the DL model*: Generally speaking, DL models degrade over time because new applications may be deployed, and attacks may emanate. That is why maintaining the DL model is mandatory [5]. Hence, periodic training of the DL model will be triggered in the Fog Layer using the traffic newly captured from the IoT layer. Doing so has two main benefits, first, it will reduce the load on the Cloud layer in terms of computation, and also reduce the latency of transmitting the collected data from the IoT Layer to the Cloud. Secondly, it will make the model customized to the set of edge devices under the control of the Fog nodes. The edge devices deployed in the IoT layer may have different sensing capabilities and are vulnerable to different attacks, so it is interesting to have a DL model trained on the data received from the target devices [2].

The different models obtained in the Fog layer may be later shared with the Cloud layer to create a more generic model in a way similar to Federated Learning [17].

Fig. 2. FDeep architecture.

C. DL Model

To select the best DL model to deploy in FDeep, the performances of three DL algorithms are compared in terms of accuracy, precision, recall, and F1 score.

1) *LSTM*: Long Short-Term Memory Network (LSTM) is capable of learning order dependence in sequence prediction problems. It has feedback connections, that make it can process the entire sequence of data [18]. The state of an LSTM model is maintained over time by a memory cell named 'cell state'. This characteristic of LSTM makes it very suitable for environments where data should be processed sequentially like network traffic analysis, particularly, IoT systems. In intrusion detection, the major feature of LSTM is its ability to differentiate between benign and malicious traffic by only inspecting a small number of network data packets which makes it efficient for real-time analysis of the traffic [7].

2) *CNN*: CNN (Convolutional neural network) is among the most commonly used deep learning algorithm. The advantage of CNN is its ability to handle large datasets also its computational efficiency. CNN is also known for its efficiency in feature extraction. CNN consists of an input layer, a hidden layer, and an output layer. The hidden layer consists of many convolution layers, pooling layers, and a fully connected layer. First, the convolution layer extracts the features or information from the data using filters. The pooling layer is responsible for parameter reduction. Unlike conventional feature extraction algorithms, CNN can

automatically learn the best features. Afterwards, the convolution maps are combined to form a unique vector known as CNN code [2]. Then, the classification layer receives the CNN code from the preceding levels and merges its characteristics to categorize the data [2].

3) *CNN-LSTM*: CNN-LSTM is a hybrid model that combines CNN and LSTM [19]. It is initially designed for visual time series predictions and textual generation from image sequences. In this model, the CNN is the features extractor, then the output is fed to LSTM which is the classifier. CNN-LSTM has been used also for intrusion detection [5].

IV. DATASET

A new IoT dataset named TON/IOT [20] is used. It is a recent dataset that consists of data collected from a real testbed of IoT devices like a Thermostat, smart fridge, weather sensor, motion light, etc. The dataset consists of many CSV files, each file corresponds to one device, and it contains data, features, and attacks that rely on the sensing capabilities of that device. The CSV files contain records that correspond either to benign or malicious traffic. The malicious records correspond to the following attacks: backdoor, DoS, DDoS, jamming, ransomware, scanning, password, XSS, cracking, injection, and man-in-the-middle [20]. In the current study, the results for only two devices are shown: the weather sensor and the Thermostat. Table I represents the set of features in the CSV file of the Thermostat.

TABLE I. FEATURES IN THE THERMOSTAT CSV FILE

Feature	Description
Ts	Timestamp of sensor reading data
Date	Date of logging sensor's telemetry data
Time	Time of logging sensor's telemetry data
current_temperature	Current Temperature reading of a Thermostat sensor
thermostat_status	Status of a Thermostat sensor is either on or off
label	Identify normal and attack records, where '0' indicates normal and '1' indicates attacks
Type	A tag with normal or attack sub-classes, such as DoS, DDoS and backdoor attacks

The CSV file of the Thermostat contains 52774 where 17774 correspond to malicious traffic and the rest represent normal traffic. Similarly, the CSV file of the IoT Weather Sensor contains 54260 records whereas 19260 records correspond to attacks. The distribution of records among classes is shown in Fig. 3.

Fig. 3. Records distribution per attack [2].

V. EXPERIMENTS AND RESULTS

A. Experiments Set up

Google Colaboratory platform is used in all the experiments since it provides a panoply of Python libraries that support Deep Learning. The dataset is split into a training set that contains 75% of the total records, and 25% of the records are used in testing. DL models are implemented using Keras libraries. Softmax is used activation function since it is a multiclass classification problem and Adam is an optimizer to compute individual learning rates and enhance the accuracy of the models. The batch size is equal to 256, the total epochs number is equal to 300, and the LSTM output is equal to 100.

Since the attacks are classified into seven classes (attacks), we have opted for Categorical Cross Entropy as a loss function. The loss function is a way to evaluate to which extent the algorithm is modelling the dataset [21]. In the Categorical Cross Entropy, one category value encoded in binary is assigned to the output label. If it is in integer form, the 'keras.utils.to_categorical' method is used to convert it into categorical encoding using.

B. Results Analysis

We have used the accuracy, precision, recall, and F1-score to evaluate the performance of the DL models[2]. The accuracy is the ratio of correctly classified inputs to the total number of inputs:

$$\text{Accuracy} = \frac{\# \text{ correctly classified input}}{\# \text{ of inputs}} \quad (1)$$

The precision is the ratio of correctly predicted positive observations to the total number of positive observations. It is computed as follows:

$$\text{Precision} = \frac{\# \text{ True Positives}}{\# \text{ True Positives} + \# \text{ False Positives}} \quad (2)$$

Recall evaluates the proportion of malicious input correctly identified. Its mathematical equation is as follows:

$$\text{Recall} = \frac{\# \text{ True Positives}}{\# \text{ True Positives} + \# \text{ False Negatives}} \quad (3)$$

F1 score shows if the model has correctly classified malicious input while minimizing false positives and false negatives rates:

$$F1 = 2 * \frac{\text{Precision} * \text{Recall}}{\text{Precision} + \text{Recall}} \quad (4)$$

Fig. 4 and 5 represent the accuracy of LSTM, CNN, CNN-LSTM, and the LSTM model proposed in [19] for the IoT Weather sensor and the Thermostat. CNN-LSTM achieves the highest accuracy for both devices. It is about 98% for the IoT weather sensor and 75% for the Thermostat. The difference in performance between the devices is due to the unbalanced dataset for the Thermostat. Besides, as depicted in Fig. 4 and 5, the LSTM model proposed in [20] has the lowest accuracy among all models, it is about 85% for the IoT weather sensor and about 67% for the Thermostat. The accuracy of CNN-LSTM is close to LSTM which is about 97% for the IoT weather sensor.

Fig. 4. Average accuracy-thermostat.

Fig. 5. Average accuracy-IoT weather sensor.

Fig. 6 and 7 plot the loss values for CNN-LSTM for the Thermostat and the IoT weather sensor respectively as a function of the epochs. The loss function is used to compute the distance between the current outputs of the algorithm (training) and the expected output (testing). As shown in Fig. 6 and 7, as the training progresses, the value of the loss continuously decreases.

Fig. 7 shows that the loss decreases inversely to the epochs for the IoT weather sensor; it stabilizes and reaches a minimum of 0.05 after the first 100 epochs. Similarly, in Fig. 8 and 9, the accuracies of CNN-LSTM in the training and testing are compared for the Thermostat and IoT weather sensor respectively as a function of the epochs. As depicted in Fig. 8 and 9, the accuracies of the model in training and testing are close for both devices. It increases as the number of epochs increases to achieve the best accuracy at 300.

Fig. 6. CNN-LSTM loss values-thermostat.

Fig. 7. CNN-LSTM loss values-IoT weather sensor.

Fig. 8. Accuracy performance CNN-LSTM-thermostat.

Fig. 9. Accuracy performance CNN-LSTM-IoT weather sensor.

Tables II and III show the values of accuracy, precision, recall and F1 score of the different DL models in multi-class classification for the Thermostat and the IoT weather sensor, respectively. Additionally, the performance of the proposed models is compared to the performance of the LSTM model proposed in [20] for the Thermostat and the IoT weather sensor. The results show that CNN-LSTM outperforms all the other DL models for both devices. It reaches the highest accuracy of 76.19% for the Thermostat and 98% for the IoT weather sensor. Additionally, the LSTM model proposed in [20] has the worst performance compared to other DL models.

TABLE II. PERFORMANCE OF DIFFERENT MODELS- IOT WEATHER SENSOR

	Accuracy (%)	Precision (%)	F1-score (%)	Recall (%)
LSTM[20]	82	82	80	81
LSTM	96.69	96.87	96.69	96.52
CNN	94.25	94.67	94.24	93.82
CNN-LSTM	98.02	98.02	98	97.97

TABLE III. PERFORMANCE OF THE DIFFERENT MODELS FOR IOT WEATHER SENSOR IN MULTICLASSIFICATION

	LSTM			CNN			CNN-LSTM		
	Precision (%)	Recall (%)	F1 score (%)	Precision (%)	Recall (%)	F1 score (%)	Precision (%)	Recall (%)	F1 score (%)
Backdoor	94	93	94	94	76	84	94	76	84
DDoS	92	88	90	78	90	83	78	90	83
Injection	94	95	94	96	89	92	96	89	92
Normal	100	100	100	100	100	100	100	100	100
Password	88	93	91	85	85	85	85	85	85
Ransomware	92	89	91	75	91	82	75	91	82
Scanning	99	96	98	99	96	97	99	96	97
XSS	87	88	87	89	77	83	89	77	83

It is also obvious from Tables II and III that CNN-LSTM has the best performance in terms of precision, F1-score and recall for both devices. Particularly, the performance of CNN-LSTM for the IoT weather sensor is better than the Thermostat. The outperformance of CNN-LSTM is due to the proven efficiency of LSTM in the classification in addition to the effective feature extraction performed by CNN.

For multi-class classification, every CSV file of a device has seven attacks in addition to the normal or 'benign class'. Only the performance of the IoT Weather Sensor is presented in detail for multi-class classification because of space limitations. Table IV shows the precision, recall, and F1 score for each DL model.

As depicted in Table IV, CNN-LSTM outperforms LSTM in terms of overall performance for 5 classes (among 8), however, the performance of CNN-LSTM is close to that of CNN. The unbalance of the dataset has a negative impact also on the performance of all DL models.

TABLE IV. PERFORMANCE OF DIFFERENT MODELS - THE THERMOSTAT

	Accuracy (%)	Precision (%)	F1-score (%)	Recall (%)
LSTM [20]	66	45	54	67
LSTM	76	100	79.4	66.28
CNN	75.63	100	79.31	66.17
CNN-LSTM	76.19	100	79.31	66.17

VI. CONCLUSION

In this paper, a new distributed IDS system based on Fog-computing to detect intrusions in a Smart Home is proposed. The architecture consists of three layers: IoT layer, Fog layer, and Cloud layer. The IDS detects the intrusion by inspecting

the traffic collected from the IoT devices in the IoT layer. A DL model implemented in the Fog layer has been used to inspect the data packets. The implementation of the DL model in the Fog layer provides a high computation environment for the IDS, reduced latency, and avoids implementing the DL model in the end-user devices. To maintain and update the DL model, the model is re-trained periodically in the Fog layer using the data collected from the IoT layer. Many experiments have been conducted to evaluate the performance of many DL models to select the appropriate and efficient one to be implemented in the IDS. In the training, an IoT dataset named TON/IoT is used, it contains the data collected from a real testbed composed of many IoT devices. The results show that CNN-LSTM has the best performance in terms of accuracy, precision, recall, and F1-score compared to other DL models and the model proposed in [20]. In future work, the performance of the architecture in terms of response time and robustness will be evaluated.

A Novel Approach to Cashew Nut Detection in Packaging and Quality Inspection Lines

Van-Hung Pham, Ngoc-Khoat Nguyen*, Van-Minh Pham

Faculty of Electrical Engineering, Hanoi University of Industry, Hanoi, Vietnam^{1,3}

Faculty of Control and Automation, Electric Power University, Hanoi, Vietnam²

Abstract—YOLO standing for *You Only Look Once* is one of the most famous algorithms in computer vision used for detecting objects in a real-time environment. The newest version of this algorithm, namely YOLO with the seventh version or YOLOv7, is proposed in the present study for cashew nut detection (good, broken and not peeled) in packaging and quality inspection lines. Furthermore, this algorithm using an efficient convolutional neural network (CNN) to be able to successfully detect and identify unsatisfactory cashew nuts, such as chipped or burnt cashews. In order to deal with the quality inspection process, a new dataset called CASHEW dataset has been built at first by collecting cashew images in environments with different brightness and camera angles to ensure the model's effectiveness. The quality inspection of cashew nuts is tested with a huge number of YOLOv7 models and their effectiveness will also be evaluated. The experimental results show that all models are able to obtain high accuracy. Among them, the YOLOv7-tiny model employs the least number of parameters, i.e. 6.2M but has many output parameters with higher accuracy than that of some other YOLO models. As a result, the proposed approach should clearly be one of the most feasible solutions for the cashew's quality inspection.

Keywords—Cashew; CNN; cashew detection; YOLOv7; computer vision

I. INTRODUCTION

It is undeniable cashews (*anacardium occidentale*) are among the most widely consumed nuts globally, owing to their nutritional value. As of 2016, the world's cashew nut production reached 4.89 million tons, with Vietnam being the leading producer [1]. Cashews are high in protein and polyunsaturated fats, high in carbohydrates and fats, and contain abundant calcium, iron, and phosphorus [2]. Often, they are served as snacks or incorporated into confectioneries or food preparations to increase their value and are generally consumed in raw, roasted, salted or flavoured forms. Consequently, cashews provide various health benefits, such as cancer prevention, cardiovascular protection, nerve protection, antioxidant action, and vitamin content [1].

The cashew nut processing process includes many stages such as roasting, shell cracking and removal, peeling of kernel skin, grading, and packaging [3]. The main issue affecting product cost in the cashew nut processing industry is the yield and quality of cashew nuts after processing. Therefore, many automation technologies have been applied in the cashew nut production process. However, cashew nuts are often graded by vibrators, removing unsatisfactory particles, followed by a manual inspection and hand-picking. In general, skilled

workers grade cashews based on their size, shape, and color. Such a manual inspection method is time-consuming, tedious, laborious and less productive.

Therefore, several studies have applied a computer vision approach to assist people with classification, defect detection, quality inspection, and grading of fruits [4-9], vegetables [10-12], grains [13-15], and other food products [16, 17]. For example, Cervantes-Jilaja et al. [13] proposed a computer vision-based method to detect and identify visual defects in chestnuts using external features such as shape, color, size, and texture. In [18], the authors used invertible neural networks to locate and segment damaged soybean seeds in a fast and effective manner. Several review papers on the classification and quality evaluation of fruits and vegetables based on a computer vision approach can be found in [12, 19].

This paper aims to propose a novel algorithm for detecting and classifying cashew nuts. A practical system is also built to verify the studied method in steads of using a manual system. The main contributions of this study focus on:

- 1) Proposing a new algorithm based on an efficient convolutional neural network (CNN) to detect and recognize unsatisfactory cashew nuts, i.e. chipped or burnt cashew ones.
- 2) Designing a simulation model representing practical packaging and inspection lines systems consists of conveyor and camera (see Fig. 1). This model is employed to construct a dataset of cashew images.
- 3) Using the newest and best version of YOLO (v7-tiny) to effectively train the models and evaluate quality of these models.

The rest of this paper is organized as follows. First, Section II presents a number of related works which motivate this study. Then, Section III presents the materials and methods for cashew nut detection and recognition. Next, Section IV shows the evaluation results, while the last section provides the study's conclusions and future work.

II. RELATED WORKS

There have been some computer vision-based studies regarding the identification and grading of cashew nuts in the literature. The simplest methods of classifying cashew kernels are based on their color or texture and a single layer neural network [20, 21]. Aran et al. [22] extended this work by testing external features like color, texture, shape and size. In addition, they analyzed the impact of some image preprocessing methods on cashew nut classification. Finally, they evaluated

*Corresponding author: Ngoc-Khoat Nguyen

several classifiers in terms of accuracy and performance. The results show that Back Propagation Neural Network (BPNN) was the most optimal among the classifiers. However, these studies will not be able to classify splits, which occur when kernels split lengthwise naturally. In [23], a novel machine vision method for classifying whole and split cashews (split-up and split-down) is proposed using object shadow combined with surface grayscale-intensity profile.

In addition, methods based on convolutional neural networks (CNNs) are also applied to classify cashew nuts. For instance, Shivaranjani et al. [15] introduced CashNet-15: an optimized cashew nut grading system based on deep CNN and data augmentation. However, this method can only classify wholes and others (scorched whole, splits, butts, pieces). In [24], four deep CNNs combined with image processing were used to classify cashew kernels into five categories based on their adulteration with butts and pieces. Therefore, the above studies demonstrate the effectiveness of machine vision in the classification and grading of cashew nuts. To the best of our knowledge, no study has been conducted on the cashew detection problem, i.e. being able to identify the location and type of cashews (good, broken, and shelled) as they move along the packaging and product inspection lines. Solving this problem can help remove bad nuts (broken or shelled) before packaging and automate product quality inspection.

In recent years, CNN-based object detection has made significant progress and applied to many practical problems. There are two main approaches. The first is a two-stage target detection method such as Faster Region-based CNN (Faster R-CNN) [25], which identifies proposed regions first and then classify them by region. The other method employs a single neural network to detect the type and location of objects simultaneously in an image, such as Single shot multi-box detector (SSD) [26] and YOLO [27-30]. Due to its much faster execution speed than Faster R-CNN, the YOLO model is continuously improved in both speed and accuracy of detection, with many versions such as YOLOv1, YOLOv2, YOLOv3, YOLOv4, YOLOv5 [27-30] and YOLOv7 [31]. Several studies have been conducted using Faster R-CNN [14, 32, 33] or YOLO [34-38] to detect fruits.

However, these approaches have not been applied to the cashew detection problem. This paper proposes an algorithm based on a convolutional neural network (CNN) to detect and identify unsatisfactory cashew nuts, such as chipped or burnt cashews. First, we construct a dataset containing cashew images obtained from cameras mounted on packaging and inspection lines, and then we label the images. Then, we use the YOLOv7 (version 7) to train the model on this dataset. Finally, we conduct a quantitative evaluation of the proposed model's effectiveness on the test dataset and a qualitative assessment from the videos obtained by cameras mounted on the cashew packing line.

III. MATERIALS AND METHODS

A. YOLOv7

YOLO (You Only Look Once) is a well-known CNN architecture used for general object detection problems because it balances quality requirements and speed. This architecture not only detects the presence of an object but also determines the object's position in an image. YOLO has three official versions YOLOv1, YOLOv2, and YOLOv3. Then there are many improved versions e.g. YOLOv4, YOLOv5, YOLOX [39], YOLOR [40], and the latest is YOLOv7. The newest version, YOLOv7, significantly enhanced speed and accuracy over previous versions. Therefore, in this paper, we choose this version for cashew detection.

YOLOv7 has applied several improvements to increase speed and accuracy. The computational block in the YOLOv7 backbone is called E-ELAN, which stands for Extended Efficient Layer Aggregation Network. Through the E-ELAN architecture of YOLOv7, the network can continuously improve its learning ability by using "expand, shuffle, merge cardinality" without losing its gradient path.

Model scaling allows the generation of models that meet the requirements of different applications by adjusting key attributes. It is possible to optimize a model by scaling it in terms of width (number of channels), depth (number of stages), and resolution (input image size). With traditional concatenation-based architectures (for example, ResNet or PlainNet), scaling factors cannot be analyzed independently and must be analyzed together. Model depth scaling, for example, causes a change in the ratio between the input and output channel of a transition layer, resulting in a decrease in hardware usage. As a result, YOLOv7 introduces a compound model scaling method for concatenation-based models. Compound scaling maintains the model's properties at its design level and thus maintains its optimal structure. Scaling compound models involves two steps: scaling the depth factor of a computational block requires a change in its output channel, and width factor scaling requires a similar change in its transition layer.

RepConv achieves excellent performance in VGG architectures but is significantly less accurate when applied directly to ResNets and DenseNets. YOLOv7 implements re-parameterized convolution using RepConv without identity connection (RepConvN). Re-parameterized convolution avoids an identity connection when replacing residual or concatenation convolution with a re-parameterized one.

A YOLO architecture contains a backbone, a neck, and a head. The head responsible for the final output is called the lead head, and the head used to assist training in the middle layers is named the auxiliary head. In addition, and to enhance the deep network training, a Label Assigner mechanism was

introduced that considers network prediction results together with the ground truth and then assigns soft labels. Compared to traditional label assignment that uses ground truth as a basis for generating hard labels based on given rules, reliable soft labels utilize calculation and optimization methods that also consider the quality and distribution of prediction outputs along with the ground truth.

B. Dataset

To collect the dataset, we built a simulation model for the actual packaging and quality inspection lines, as shown in Fig. 1.

Fig. 1. Cashew nut identification system model

A surveillance camera is securely mounted on a rack and viewed at right angles to the conveyor belt. The camera is connected to a computer via a USB port to capture images of cashews moving on the conveyor. To ensure the robustness of the model in practical applications, we changed the light intensity of the laboratory to collect images of cashew nuts at different brightness levels (strong, normal, and weak). Furthermore, the cashews are placed on the conveyor with varying rotation angles and distances from the camera's position. In this study, we only consider three types of cashew nuts that need to be detected and classified: broken cashews, unshelled cashews, and good cashews (not broken and peeled), as shown in Fig. 2.

Fig. 2. Types of cashews to detect and classify: good cashews (left), broken cashews (middle) and not peeled cashews (right)

After collecting the images, the next step is to annotate them manually using the graphical image annotation tool LabelImg [41]. The annotation classes include 0-good, 1-broken, and 2-Not peeled. As a result, a new dataset named CASHEW dataset was constructed. It contains 312 images and 5115 instances, of which 80% (248 images) were selected

randomly as the training dataset, 10% (32 images) as the validation dataset, and the remaining 10% (32 images) as the test dataset. The test dataset was only used to evaluate the model performance after the training, as shown in Table I.

TABLE I. NUMBER OF ANNOTATED IMAGES FOR EACH CASHEW TYPE

CASHEW dataset	Good	Broken	Not peeled	Number of images
Train	1387	1569	1163	248
Test	316	139	89	32
Val	154	164	134	32

C. Metrics for Performance Evaluation

To evaluate the effectiveness of a model on the test dataset, we use the following metrics: precision (P), recall (R), average precision (AP), and mean average precision (mAP). Before defining these metrics, we need to define an intersection over union (IoU). The IoU is defined as the percentage overlap between the ground truth (G) and detection boxes (D) and is calculated as:

$$IoU = \frac{Intersection}{Union} = \frac{G \cap D}{G \cup D} \quad (1)$$

Fig. 3. Examples of intersection and union. ground truth (green) and detection (red)

An example describing the intersection and union with ground truth (green) and detection (red) is shown in Fig. 3. For quantifying accuracy, confusion matrix criteria are calculated, such as True Positive (TP), False Positive (FP), True Negative (TN), and False Negative (FN). TP should have the same ground truth class as detection, and its IoU should be greater than 50%. In contrast, if the detection belongs to the same class as the ground truth and its IoU is less than 50%, it is considered FP. If a ground truth box exists, but the model does not make any detection, this situation is categorized as FN. Lastly, there is no ground truth or detection for the background, so it is classified as TN.

Precision refers to the percentage of correct positive predictions among all detections, while Recall represents the percentage of true positives among all ground truths, as shown in (2) and (3).

$$P = \frac{TP}{TP + FP} = \frac{TP}{\text{All detection}} \quad (2)$$

$$R = \frac{TP}{TP + FN} = \frac{TP}{\text{All ground truths}} \quad (3)$$

The average precision (AP) is the area under the Precision multiplies Recall curve for each class. This can be calculated using (4). After this, the mean average precision (mAP), presenting the overall performance of the model in the detection of possible classes, could be estimated by calculating the mean of all classes' AP.

$$AP = \sum_{i=1}^n p(i) \cdot \Delta r(i) \quad (4)$$

Where n indicates the total number of detections, i refers to the rank of detection in the list of sorted detections, $p(i)$ represents the precision of the sub-list from the first to the i th detection, and $r(i)$ represents the change in Recall from $(i - 1)$ th to i th detection.

IV. RESULTS AND DISCUSSIONS

A. Dataset Training of YOLOv7

We next conduct the training on the Google Collab Pro platform with the dataset described above. YOLOv7 is trained on the Pytorch platform. First, we select the desired model and edit the configuration file to match the requirements. Next, based on the Train and Val datasets, use pre-trained weights to conduct training process. The number of layers to be classified is 3, including 0-good, 1-broken, and 2-Not peeled. The stochastic gradient descent (SGD) was adopted with an initial learning rate of 0.001. The hyper-parameters used in training the YOLO models are shown in Table II.

TABLE II. HYPER-PARAMETERS USED IN TRAINING YOLOV7 MODELS

Models	Initial Learning Rate	Momentum	Decay	Batch Size
YOLOv7-tiny	0.01	0.937	0.0005	16
YOLOv7	0.01	0.937	0.0005	8
YOLOv7X, W6, E6	0.01	0.937	0.0005	4
YOLOv7D6, E6E	0.01	0.937	0.0005	2

B. Results of Evaluation

Some results of detecting cashews while moving on a conveyor belt with the YOLOv7 model are shown in Fig. 4. It is found that, due to the reflection of light, the accurate detection of cashew nuts is good, chipped or left peeled easily confused. We have tested the performance of the proposed model under different ambient light conditions. The results in Fig. 4 show the same case with three other lighting conditions (strong, normal, and weak). YOLOv7 model could still detect cashews, whether they were unshelled or broken, even though

the particles were traveling at less than 0.6 cm/s on the conveyor.

Fig. 4. Results of the YOLOv7 model for detecting cashew nuts as they move on a conveyor at a speed of 0.6 cm/s. The algorithm can accurately detect not_peeled (green), broken (blue), and good seeds (red)

Next, we perform a quantitative evaluation of the model's effectiveness on the test dataset. The evaluation results are given in Table III below. The YOLOv7tiny, YOLOv7, and YOLOv7X models with 6.2M, 36.9M, and 35.7M parameters, respectively, were trained with an input image of size 640 × 640. YOLOv7tiny model has the least number of parameters but has higher F1-score, Precision, Recall, and mAP values than YOLOv7. Even YOLOv7tiny has higher F1-score and Recall parameters than YOLOv7X.

The YOLOv7W6, YOLOv7E6, YOLOv7D6, and YOLOv7E6E models had 70.4M, 97.2M, 154.7M, 151.7M, respectively, and were all trained with 1280×1280 input images. Model YOLOv7D6 has the highest number of parameters, 154.7M; however, many parameters, like Precision and mAP, have the smallest value (blue) among all models.

Comparing all seven models shows that YOLOv7W6 has the largest Recall and mAP values, while YOLOv7E6E model has the largest Precision and F1-score values. On the other hand, we also find that the YOLOv7tiny model with the least number of parameters can be installed on low-profile embedded computers but can still achieve high evaluation indicators. Therefore, the YOLOv7tiny model can be applied to detect and identify actual cashew nuts.

When considering the influence of the ambient light intensity, we found that the light intensity can affect the model's detection results. In Fig. 5, the YOLOv7E6E model incorrectly detected one case (highlighted in yellow), while the YOLOv7tiny model with much fewer parameters correctly detected all the cases.

(a) Detection result of YOLOv7E6E (b) Detection result of YOLOv7tiny
Fig. 5. Comparing YOLOv7tiny and YOLOv7E6E cashew detection results in weak light conditions

TABLE IV. ENT RESULTS ON THE TEST DATASET

Model	#Param	Image size	F1-score	Precision	Recall	AP			mAP
						Good	Not peeled	Broken	
YOLOv7tiny	6.2M	640	0.88	0.88	0.88	0.952	0.942	0.824	0.906
YOLOv7	36.9M	640	0.86	0.862	0.856	0.934	0.938	0.827	0.900
YOLOv7X	71.3M	640	0.84	0.881	0.801	0.960	0.949	0.814	0.908
YOLOv7W6	70.4M	1280	0.89	0.873	0.903	0.950	0.960	0.822	0.911
YOLOv7E6	97.2M	1280	0.87	0.875	0.866	0.940	0.905	0.864	0.904
YOLOv7D6	154.7M	1280	0.86	0.856	0.869	0.835	0.958	0.790	0.895
YOLOv7E6E	151.7M	1280	0.90	0.903	0.888	0.951	0.949	0.827	0.909

V. CONCLUSIONS AND FUTURE WORK

This study has presented an algorithm to detect and identify good, broken, or missing cashews in the packaging line and check product quality. The CASHEW dataset was developed to test the model's effectiveness by collecting cashew images in different lighting conditions and camera angles. The YOLOv7 convolutional neural network model with many different versions was employed. The evaluation results revealed that the model can recognize cashew nuts with an average accuracy (mAP) of about 90%. Besides, the YOLOv7tiny model has the least number of parameters (6.2M) but has many parameters with higher accuracy than that of some other YOLO ones. In this paper, we have only applied the YOLOv7 model without any improvement. Therefore, it is possible to improve the YOLOv7 model, test and compare it with some other neural network models, and integrate the proposed algorithm on embedded systems with low configurations for the actual cashew packaging and quality inspection lines.

Improvement Classification Approach in Tomato Leaf Disease using Modified Visual Geometry Group (VGG)-InceptionV3

Jiraporn Thomkaew, Sarun Intakosum

Automation Innovation Intelligence and Data Science Research Unit-Department of Computer Science-
School of Science, King Mongkut's Institute of Technology, Ladkrabang, Bangkok, Thailand

Abstract—This paper presents a new method for optimizing tomato leaf disease classification using Modified Visual Geometry Group (VGG)-InceptionV3. Improved performance of VGG-16 model as a base model with InceptionV3 block reduced the number of convolution layers of VGG-16 from 16 to 10 layers, and added an InceptionV3 block that was improved by adding convolution layer from 3 to 4 layers to increase the accuracy of tomato leaf disease classification and reduce the number of parameters and computation time of the model. The experiments were performed on tomato leaves from the PlantVillage dataset of 10 classes, consisting of nine classes of diseased leaves and one class of healthy leaves. The results showed that the proposed method was able to reduce the number of parameters and computation time with and accuracy of tomato leaf disease classification was 99.27%. Additionally, the proposed approach was compared with state-of-the-art Convolutional Neural Network (CNN) models such as VGG16, InceptionV3, DenseNet121, MobileNetV2, and ResNet50. Comparative results showed that the proposed method had the highest accuracy in the tomato leaf disease classification and required a smaller number of parameters and computational time.

Keywords—Modified VGG-InceptionV3; InceptionV3; VGG-16; tomato leaf disease classification

I. INTRODUCTION

The rapidly changing climate will have a detrimental effect on agricultural crops. If farmers do not deal with such impacts in time, the result could be widespread damage, causing the production to not meet the standards and market demands. Therefore, there are many researchers from various fields of knowledge trying to develop new research and technology to help solve problems for farmers to be able to recognize and solve plant diseases quickly and accurately. One of the popular technologies for plant disease identification is image processing. Computer image classification is becoming increasingly popular and applied to a wide variety of applications. Developing a computer that can see images like humans and training computers to learn images, be able to analyze and recognize images, and be able to classify images like humans. Computer image processing can be applied to machine learning to allow computers to process large numbers of images accurately and quickly. Detecting and identifying plant diseases requires computer-aided image classification because machine learning can classify images accurately and quickly.

Computer vision is a part of Artificial Intelligence technology that seeks to train computer algorithms to automatically analyze, classify and detect images using neural networks and deep learning. It can detect and recognize images in both still images, video images, as well as real-time images. Computer vision technology is widely used in current research such as medical imaging diagnosis [1], [2], [3], [4] sign language classification [5] facial emotion recognition [6], and includes the detection and identification of various plant diseases such as the identification of corn leaf disease [7], pepper bell [8], rice diseases [9], mango leaf disease [10] etc. In addition, research on real-time plant disease detection and identification [11], [12], [13] was developed by developing a model that can be used on resource-constrained mobile devices. It can be used more easily and conveniently to including the development to use on mobile devices and work without an internet connection [14]. Currently developing or improving the model of the Convolutional Neural Network (CNN) focuses on reducing the number of parameters and computational costs of the model. Because the previous CNN model was a large, multi-layered deep network, and the huge number of parameters used for computation also required a lot of machine resources, it was not suitable for use on mobile devices with resource constraints. A lightweight Convolutional Neural Network is a small CNN model developed to support deployment on mobile or resource-constrained devices. Lightweight CNN reduces the number of model layers and the number of compute parameters of the model to reduce computation time but to still have better performance. Describe lightweight CNN models [15] such as MobileNet, MobileNetV2, SqueezeNet, ShuffleNet, and PeleeNet. These models use a smaller number of parameters and computation time and can perform faster while providing cost-effectiveness. The accuracy is still high compared to the base and state-of-the-art CNN model.

A lightweight CNN model is presented in this paper. The aim is to optimize tomato leaf disease classification with lightweight models that can reduce the number of model parameters and reduce computational time for the model to be deployed on mobile devices. However, the accuracy of disease classification was still high. We present Modified VGG-InceptionV3. By using the base model of VGG-16 from the original VGG-16 which has a total of 16 layers and approximately 138.4 million parameters. This is considered a large network, so it takes a long time to process and requires a

lot of computing costs, in this work the number of layers has been reduced from 16 to 10 layers and the InceptionV3 block has been improved by adding a convolution layer for getting the input image from 3 to 4 convolution layers to make the model wider and faster in parallel, which can reduce the number of parameters and computation time and resizing the convolution filter size from 3×3 to 1×3 and 3×1 , then add an modified InceptionV3 block to the VGG model. The proposed model was implemented for the disease classification of tomato leaves from the PlantVillage dataset of 10 classes for nine classes of diseased leaves and one class of healthy leaves. The proposed method used 1,767,652 parameters and compared the accuracy of tomato leaf disease classification and compared the results with state-of-the-art CNN models such as VGG16, InceptionV3, DenseNet121, MobileNetV2, and ResNet50. The proposed method uses the least parameters but had the highest accuracy.

The remainder of this paper is as follows: "Related Work" is presented in the second part, "Proposed Methods" is presented in the third part, presents the, "Results and Discussion" is presented in the fourth part, and the "Conclusion" is presented in the fifth part.

II. RELATED WORK

This section presents articles related to tomato leaf disease classification using the CNN model and various improvements to CNN models. The research without the CNN model for disease classification of tomato leaves required manual extraction of tomato leaf features [16] such as color features, shape features, texture features, etc. But using the CNN model, the image features are extracted automatically.

Zhou and Zhou et al. [17] presents a hybrid deep learning model for tomato leaf disease identification by improving residual dense network to Restructure Deep Residual Dense Network. The develop model would combines deep residual networks and dense networks. Original residual dense blocks extract image features through dense-connected convolution layers, where RDBs are directly connected to all subsequent layers, where input images are aggregated into Res-Dense-Block (RDB) batch normalized and are then added after convolution in the RDB. A LeakyReLU activity function was added. Then, in the residual layer, concatenate tensor combines an improved RDB block with the input layer. Experiments were performed on a tomato leaf dataset from the AI CHALLENGER dataset of 13,185 images. The results showed that the proposed method was 95% accurate in tomato leaf disease classification and had the highest accuracy compared to other CNN models such as Deep CNN, ResNet50, and DenseNet121 with 93.21%, 88.49%, 91.96% accurate, respectively.

Djmelis - Tsajio and Thierry et al. [18] presents an automated method for the detection and identification of tomato leaf disease using a neural network. The model of the proposed method uses transfer learning from ResNet101 and ResNet152 models to extract the features of tomato leaf images. The disease of tomato leaves was then classified by Multi-Layer Perceptron (MLP). Transfer learning from pre-trained ResNet101 and ResNet152 models to achieve shape features, color features, and other features. Features are

separated into multiple levels, giving different feature vector sizes. ResNet101 and ResNet152 were then adjusted and combined image features based on the variance and mean deviation of features, mean of two features, and concatenation of two features. Then, use the MLP to classify the features vector that is assigned several 400 neurons in the hidden layer and 10 in the output layer. The results showed that the classification from the features vector with the combination of features from ResNet101 and ResNet152 models had an accuracy of 98.3% with the highest accuracy being 98.9%.

Thangaraj and Anandamurugan et al. [19] presented a model to identify tomato leaf disease using a Modified-Xception model deep neural network. The proposed method uses transfer learning for transfer learning weights and parameters. The process of the model is divided into two parts: feature extraction and classification. The feature extraction process consists of convolution layers and pooling layers using the Rectified linear unit (ReLU) activation function, using max-pooling to reduce the size of the feature map obtained from the convolution layers. The classification process uses Global Average Pooling (GAP) instead of the fully connected layer in the original networks. GAP calculates the mean value of each feature map and sends it to the output layer. In the output layer, use the Softmax function for tomato leaf disease classification. After replacing the output layer with GAP, fine-tuning was used to update the weights obtained from training the model with the tomato leaf dataset. The model training process was compared using various optimizers such as Adaptive Moment Estimation (Adam), Stochastic Gradient Descent (SGD), and Root-Mean-Square Propagation (RMSprop), and experiment with tomato leaf datasets from the PlantVillage dataset. The results showed that using Adam and RMSprop optimizers had better accuracy than SGD optimizer. The Adam optimizer had the highest accuracy of 99.55%, followed by RMSprop of 99.01%, SGD of 81.77%, respectively.

Kaur and Harnal et al. [20] presented a Modified InceptionResNet-V2 (MIR-V2) model to identify tomato leaf disease. Improved from the basic model, the InceptionResNet-V2 (IR-V2) model, which is a collaboration of InceptionV1 and ResNetV2, is used to transfer learning from the InceptionResNet-V2 model to increase the accuracy of tomato leaf disease identification and improve the model with four different InceptionResNet-V2 types. Changing the internal Maxpool layer of InceptionResNet-V2 as follows: 1) 3 - Max pool layer InceptionResNet - V2 (3MPL - IR - V2), 2) 3 - Max pool layer with skip connection (3MPL - SC), 3) 2 - Max pool - layer InceptionResNet - V2 (2MPL - IR - V2) and 4) 2 - Max pool layer with skip connection (2MPL - SC). Then, experiment with the tomato leaf dataset and determine the accuracy of the modified MIR-V2 model and basic IR-V2 to obtain the highest accuracy in disease identification of tomato leaves. The results showed that the 2MPL-SC modification of the Maxpool layer of InceptionResNet-V2 with the highest accuracy was 98.92% compared to the remaining three improvements.

Moussafir and Chaibi et al. [21] presents a model to optimize tomato leaf disease identification using a CNN model in combination with a genetic algorithm. In the first step,

tomato leaf disease identification results were compared from the 10 classes PlantVillage dataset. Experiment with CNN models such as VGG16, ResNet50, EfcientNetB0, EfcientNetB1, EfcientNetB2, EfcientNetB3, and EfcientNetB4 using transfer learning and fine-tuning techniques. Two of the models with the highest accuracy in tomato leaf disease classification were obtained. The two most accurate models are then adapted to the genetic algorithm. The genetic algorithm selects the weights generated during the CNN learning process to create a new weight matrix and then considers it the weighted average. The CNN model for disease identification of tomato leaves showed that the two most accurate models, ResNet50 and EfcientNetB0, had 96.6% and 95.6% accuracy. When a genetic algorithm was used to create a new weight matrix from the ResNet50 and EfcientNetB0 models, the accuracy of tomato leaf disease identification was increased to 98.1%.

Thakur and Sheorey et al. [22] presents a model for the identification of plant disease with leaf imagery. Convolutional Neural Network named 'VGG-ICNN'. The presented model is a collaboration of VGG-16 and GoogleNet InceptionV7 block models, aiming to reduce the size of the network while maintaining high data classification performance. The proposed model consists of two convolutions (Conv) layers using filter size 64, followed by a max-pooling layer, followed by two convolutions (Conv) layers using filter size 128, and followed by the max-pooling layer like the base model of VGG-16. Three Inceptionv7 blocks were then added to the end of the VGG-16 max-pooling layer. The InceptionV7 block uses a filter size of 1024. The Global Average Pooling (GAP) layer is used instead of the flattening layer to reduce the number of parameters for model training followed by a fully connected layer using the SoftMax activation function for data classification. The proposed model can reduce the number of parameters to approximately six million parameters, which is comparable to lightweight CNN models. The model was evaluated by experimenting with five datasets, including small datasets and large datasets: PlantVillage dataset, Embrapa dataset, Apple dataset, Maize dataset, and Rice dataset. The results showed that the proposed method when experimented with all five datasets, the PlantVillage dataset had the highest accuracy of 99.16%, followed by the Rice dataset, Apple dataset, Embrapa dataset, and Maize dataset with 96.67%, 94.24%, 93.66%, and 91.36% respectively.

Tuncer, A. [23] presents a new model for the detection and identification of plant leaf diseases. The proposed method is a hybrid deep neural network with Inception architecture and depthwise separable convolutions intended to reduce the number of parameters and computational costs but still has high data classification efficiency. The Inception architecture can extract image features in parallel and can combine features, while depthwise separable convolution separates the features to independently convoluted the spatial convolution of the input image and combine them as output from the convolution layer. The proposed model replaced 1×1 and 3×3 , 1×1 , and 5×5 convolutions with 3×3 depthwise and 1×1 pointwise convolution, and 5×5 depthwise and 1×1 pointwise convolution in the Inception block. The model consists of two blocks of Modified Inception architecture, four depthwise

separable convolution layers, and four pooling layers, followed by a fully connected layer and Softmax classifier. Experiment with the PlantVillage dataset of 30 classes. The results showed that the proposed method was able to achieve a plant disease classification accuracy of 99.27% and a 75% reduction in the number of parameters from the base CNN model. Like Hassan, M.S. et al. [24] convolution layer was replaced with a depth separable convolution to reduce the number of parameters and computational costs of the model.

Lee and Lin et al. [25] presents CNN architecture for potato leaf disease detection. The proposed model consists of one convolution layer with filter size 64, two convolution layers with filter size 128, three convolution layers with filter size 256, after the convolution layer, followed by a Pooling layer and a Dropout layer. There is a filter size equal to the convolution layer and finally, the Fully Connected layer that uses the Softmax function. In the experimental process to prevent overfitting, the number of cycles in the training model was increased to maintain the model's accuracy. The model presented was experimented with the potato leaf dataset from the PlantVillage dataset and compared the performance of the models presented with the VGG-16 and VGG-19 models. The results showed that the proposed method had the highest accuracy of 99.53%, followed by VGG-16 and VGG-19 with an accuracy of 98.15% and 48.55%, respectively, and the proposed method could reduce the number of parameters used by approximately 99.39%.

Jiang and Chen et al. [13] presents a model for real-time detection of apple leaf disease, the INAR-SSD model, developed the VGGNet model in combination with Inception in the process of extracting image features. Then use the Rainbow concatenation method to improve the integration of feature maps. Pooling and deconvolution will work together to create a feature map between layers. The proposed model adds two layers of Inception modules to the VGG-16 model network to improve the feature extraction capabilities of multi-scale images. Thus, the proposed model can detect diseases of various sizes on the same plant leaf. The model architecture consists of the first seven layers retaining the VGG-16 architecture, then the eighth and ninth layers are replaced by two modules of Inception, while the tenth to thirteenth layers retains the VGG-16 architecture. The Fully Connected layers were replaced by three convolutions: 1×1 , and the last layer was followed by the Softmax layer. The experiment was performed with a dataset of apple leaves obtained from laboratories and field photographs. The results showed that the proposed method has an accuracy of 97.14% in apple leaf disease identification and provides the highest accuracy compared to other CNN models such as AlexNet, GoogLeNet, InceptionV3, ResNet-101, ResNet-50, ResNet-34, ResNet-18, and VGGNet-16, it shows that the INAR-SSD model has a detection efficiency of 78.80% mAP and a detection speed of 23.13 FPS.

Nagi and Tripathy [26] presents a model for grape leaf disease identification using a lightweight CNN that reduces the number of parameters for calculation but still maintains high accuracy for grape leaf disease identification. The model presented is developed on the basis of the VGG-16 model which has a total of 16 layers, thus presenting the model by

reducing the number of layers of VGG-16 to 6 layers and adjusting the filter size of the convolution layer. The model consists of an input layer that receives input image size 128 x 128 pixels, the first convolution layer using filter size 128, followed by a Maxpooling 2x2 layer, and next, one convolution layer using filter size 64, Maxpooling 2x2, then followed by Flatten and Fully connected layer and in the output layer use Softmax function. An Adam optimizer was used to experiment with grape leaves from the PlantVillage dataset of 3,423 images. The results showed that the proposed method had the highest accuracy in disease identification of grape leaves 98.4%, compared to MobileNet, VGG-16, and AlexNet accuracy values are 98.1%, 96.6%, and 95.7% respectively. Furthermore, the proposed method can reduce the number of parameters to approximately two million parameters.

According to the research article, reducing the number of layers of the VGG-16 model can reduce the number of model parameters and computation time. But it still has higher classification efficiency, and using the Inception block can extract parallel image features, thereby reducing run time and obtaining full image features. With the use of CNN models, the disease of tomato leaves can be identified more accurately.

III. PROPOSED METHODS

In this section, we present the workflow of the proposed method. It contains a detailed dataset used for the experiment and describes in detail the VGG-16 model, the InceptionV3 model, as well as the Modified VGG-Inception which is a new model for disease identification of tomato leaves.

A. Dataset

In this experiment, we used the tomato leaf dataset from the Plant Village dataset [27], accessible from www.kaggle.com. This public dataset for image processing and computer vision contains 38 classes of diseased and healthy plant leaves, 14 different plants. In this work, we selected a dataset of nine classes of diseased tomato leaves and one class of healthy tomato leaves for a total of ten classes including Bacterial spot, Early blight, Late blight, Leaf Mold, Mosaic virus, Septoria leaf spot, Spider mites, Target spot, Yellow leaf curl virus, and Healthy as shown in Fig. 1 The image has an RGB color model with dimensions of 256 x 256 pixels, so it resizes the image to 224 x 224 pixels and removes the image's background before training the model. A total of 18,159 tomato leaf images were included, detailed in Table I, and the dataset was divided into three folders: training 70%, validation 20%, and test 10%.

B. VGG-16

VGG-16, developed by Simonyan, K. et al. [28] from Visual Geometry Group, Department of Engineering Science, University of Oxford, won the ImageNet Large-Scale Visual Recognition Challenge (ILSVRC) 2014. The VGG-16 consists of an input layer, a convolution layer, and an output layer, totaling 16 layers. The input layer receives image data size 224 x 224 pixels and is an RGB color image, thus having 3 color channels. The convolution layer consists of 13 Conv2D layers using filter size 64 of 2 Conv2D, 128 of 2 Conv2D, 256 of 3 Conv2D, and 512 of 6 Conv2D using kernel size 3 x 3 all

layers of the network, after Conv2D followed by a Maxpooling layer of 5 layers, size 2 x 2 strides equal to 2 all layers of the network and followed by 3 Fully Connected (FC) layers, 2 of which Fully Connected use 4096 classes and the last layer uses 1000 classes, while the output layer uses SoftMax as the activation function. The architecture of the VGG-16 model is shown in Fig. 2. The basis of the VGG-16 model is approximately 138.4 million parameters.

C. InceptionV3

InceptionV3 was developed by Szegedy, C. et al. [29] in 2015 and received first-place certification in the ImageNet Large-Scale Visual Recognition Challenge (ILSVRC) 2015. InceptionV3 is the 3rd edition of Inception. Its purpose is to increase the efficiency of image classification but to reduce the computational cost, parameters, and calculation time. The first architecture of Inception is shown in Fig. 3 using the principle of extracting features of parallel images, different filters size, resulting in feature maps of different sizes. This contains a convolutional layer 1x1, convolution layer 1x1, followed by a layer convolution layer 5x5, convolution layer 1x1, followed by a layer convolution layer 3x3 and the Maxpooling layer, followed by the convolution layer 1x1. And later InceptionV3 adjusted the architecture as shown in Fig. 4. InceptionV3 adjusts the filter size to be smaller. Base Inception used convolution layer 5 x 5, change to convolution layers 3x3 two layers. The architecture of InceptionV3 consists of layers convolution layer 1x1, convolution layer 1x1, followed by two convolution layers 3x3, convolution layer 1x1, followed by a convolution layer 3x3, and the Max pooling layer, followed by the convolution layer 1x1. Which the replacement Convolutional layer 5x5 to two convolutional layers 3x3, the number of parameters has been reduced from $(5 \times 5) = 25$ to $(3 \times 3) + (3 \times 3) = 18$ parameters.

Fig. 1. Sample of tomato leaves from the PlantVillage dataset.

TABLE I. DESCRIBES THE NUMBER OF CLASSES AND IMAGES OF THE DATASET

Class	Number of Images	Class	Number of Images
Bacterial spot	2,127	Mosaic virus	373
Early blight	1,000	Septoria leaf spot	1,771
Healthy	1,591	Spider mites	1,676
Late blight	1,908	Target spot	1,404
Leaf Mold	952	Yellow leaf curl virus	5,357
Total number of images			18,159

Fig. 2. Base architecture of the VGG-16 model.

Fig. 3. Base inception architecture.

Fig. 4. Base inceptionV3 architecture.

D. The Proposed Modified InceptionV3

The advantage of the InceptionV3 architecture is that the feature extraction of parallel images is distributed simultaneously, providing feature maps of different sizes and reducing the number of parameters and computation time. Therefore, in this work, the architecture of InceptionV3 has been improved by increasing the network width by having the number of layers. The convolution layer has been increased from three layers to four layers, as shown in Fig. 5. The optimized InceptionV3 architecture consists of layers. Convolution layer 1x1, convolution layer 1x1, followed by convolution layer 1x3, and convolution layer 3x1, convolution layer 1x1, followed by convolution layer 1x3 and convolution layer 3x1, and the Maxpooling layer, followed by the convolution layer 1x1. Extract features in parallel across the four convolution layers and reduces the number of features with the Maxpooling layer which is the

replacement of convolution layer 3x3 with convolution layer 1x3 followed by convolution layer 3x1 as convolution separation to be smaller and can reduce computational times.

E. The Proposed Modified VGG-Inception

In this work, we present an improvement on tomato leaf disease classification methods using Modified VGG-Inception. The proposed method was developed using VGG-16 as the base model in combination with the improved InceptionV3 block. The objective was to increase the accuracy of tomato leaf disease classification and reduce computation costs in terms of the number of parameters and processing time. The architecture of the proposed model is shown in Fig. 6. Reduced the number of layers of the VGG-16 model from 16 to 10 layers, and then added a block of modified InceptionV3 between the fourth and fifth layers of the VGG model. The proposed model consists of an input layer that receives image input as a 224 x 224 pixel, RGB color image. Then the first and second layers of the convolution layer use filter size 64, and next, the third and fourth layers use filter size 128, just like the base model of VGG-16. The next layer adds a block of Modified InceptionV3. The fifth to the seventh layer, the convolution layer uses a filter size of 256, followed by Maxpooling 2x2 and BatchNormalization at all layers using a kernel size 3x3 for all of the networks as with the base VGG-16 model. Then the eighth to the tenth layer is followed by a Fully Connected layer with 10 classes in the tomato leaf disease classification using the SoftMax function. Configure the parameters for the experiments of the presented model as in Table II.

Fig. 5. Modified inceptionV3 architecture.

Fig. 6. The proposed modified VGG-InceptionV3 architecture.

TABLE II. CONFIGURING PARAMETERS FOR EXPERIMENTS

Name of the Parameter		Parameter
1.	Optimizer	Adam optimizer
2.	Learning rate	0.001
3.	Batch size	64
4.	Epochs	50
5.	Training data	70%
6.	Validation data	20%
7.	Testing data	10%

IV. RESULTS AND DISCUSSION

This research presents a Modified VGG-InceptionV3 model aiming to improve the limitations of VGG-16, which is a large network and requires high computational costs to a lightweight network by reducing the number of parameters and computational costs, but the model still delivers high disease classification accuracy of tomato leaves and allows this lightweight model to be used on mobile devices or low-resource devices. The presented models were evaluated using the PlantVillage dataset of 18,159 tomato leaf images, nine classes of diseased leaves, and one class of healthy leaves. The image processing procedure resizes the image to 224 x 224 pixels and removes the background of the image. The dataset is divided into a training set of 70%, a validation set of 20%, and a testing set of 10%. Experiment using Adam as an optimizer, set the learning rate to 0.001, batch size to 64, and experiment with 50 epochs.

The proposed model is an improvement based on the VGG-16 model by reducing the number of VGG-16 layers from 16 to 10 layers and improving the InceptionV3 block by

increasing the number of convolution layers from 3 layers to 4 layers for a more fully distributed extraction of image features and resized the kernel size of the convolution layer in the InceptionV3 block from 3x3 to 1x3 and 3x1 instead to reduce the number of model parameters. The number of parameters of the Modified InceptionV3 block is shown in Table III. This can reduce the number of parameters by 58.42% from the base InceptionV3 block.

In the process of reducing the number of layers of the base model VGG-16, we experimented with adding a Modified InceptionV3 block to the VGG-16 network and then tried reducing the number of layers of the VGG-16 model layer by layer. The results of the experiment found that by reducing the number of layers of the VGG model, the number of layers with the highest accuracy of tomato leaves classification was obtained using the ten-layer VGG model, as shown in Table IV. In addition, as the number of VGG-16 layers is reduced, the number of parameters and processing time of the model are also reduced.

The results of the experiment showed that the use of the improved InceptionV3 block in combination with the base model VGG-16 reduced the number of model parameters from approximately 138.4 million to approximately 14.7 million. When reducing the number of layers of the VGG-16 model layer by layer until there are ten layers remaining, the highest accuracy for tomato leaf disease classification was 99.27%, and the number of parameters was reduced from approximately 14.7 million to 1,767,652 parameters, with an F1 score of 99.07%. But when reducing the number of layers of the VGG-16 model to nine and eight layers, there was a decrease in the number of model parameters but a decrease in accuracy. The proposed method has accuracy in classifying tomato leaf diseases according to the Confusion Matrix as shown in Fig. 7.

TABLE III. COMPARES THE NUMBER OF PARAMETERS OF THE INCEPTIONV3 BLOCK AND MODIFIED INCEPTIONV3 BLOCK

Base InceptionV3 Architecture			Modified InceptionV3		
Layers	Filter size	Parameters	Layers	Filter size	Parameters
Conv2D1_1	1x1, 32	4,128	Conv2D1_1	1x1, 32	4128
Conv2D1_2	3x3, 32	9,248	Conv2D1_2	1x3, 16	1552
Conv2D1_3	3x3, 32	9,248	Conv2D1_3	3x1, 16	784
Conv2D2_1	1x1, 32	4,128	Conv2D2_1	1x1, 32	4128
Conv2D2_2	3x3, 32	9,248	Conv2D2_2	1x3, 16	1552
MaxPooling	3x3	-	Conv2D2_3	3x1, 16	784
Conv2D2	1x1, 32	4,128	Conv2D3_1	1x1, 16	2064
Conv2D3	1x1, 32	4,128	Conv2D3_2	1x3, 32	1568
			Conv2D3_3	3x1, 32	3104
			MaxPooling	3x3	-
			Conv2D4	1x1, 16	2064
			Conv2D5	1x1, 32	4128
Total Parameters		44,256	Total Parameters		25,856

TABLE IV. COMPARE THE ACCURACY OF VGG-16 WITH THE MODIFIED INCEPTIONV3 BLOCK

Number of Layers (VGG-16 Model)	Accuracy (%)	Loss	Times	Parameter	F1 Score
16	94.70	0.2325	728s	14,715,108	92.44
15	97.70	0.0698	676s	12,355,300	97.07
14	99.12	0.0341	643s	9,995,492	98.85
13	98.86	0.0417	563s	7,648,996	98.41
12	91.44	0.2992	517s	5,289,188	89.32
11	97.10	0.0964	412s	2,929,380	96.10
10	99.27	0.0267	386s	1,767,652	99.07
9	98.69	0.0471	379s	1,177,572	98.32
8	97.75	0.0236	290s	1,029,988	97.20

class	0	1	2	3	4	5	6	7	8	9	Accuracy (%)
Bacterial spot	0	460	0	0	0	0	0	0	0	0	100
Early blight	1	0	231	2	0	0	0	2	0	0	98.30
Late blight	2	0	5	407	1	2	0	0	0	1	97.84
Leaf Mold	3	0	0	0	223	1	1	0	0	0	99.11
Septoria leaf spot	4	1	2	0	0	385	0	0	1	0	98.97
Spider mites	5	0	0	0	0	0	364	0	2	4	98.38

Healthy	8	0	0	0	0	0	0	0	0	353	100
Mosaic virus	9	0	0	1	0	0	0	0	1	0	97.83

Fig. 7. Confusion matrix.

TABLE V. COMPARING ACCURACY BETWEEN THE PROPOSED MODEL AND STATE-OF-THE-ART CNN

Model	Accuracy (%)	Loss	Times	Parameter
ResNet50	57.31	1.3035	699s	23,608,202
VGG16	86.19	0.4178	875s	14,719,818
Inception-V3	94.22	0.2311	196s	21,823,274
DenseNet121	94.42	0.1644	416s	7,047,754
MobileNetV2	98.59	0.0759	117s	2,270,794
Proposed Model	99.27	0.0267	386s	1,767,652

The class that can be classified with the highest accuracy is Bacterial spot, Yellow leaf curl virus, and Healthy with 100% accuracy, followed by Target spot and Leaf Mold with 99.37% and 99.11% accuracy respectively. The least accurate was Mosaic virus and Late blight with 97.83% and 97.84% accuracy respectively. Because of the diseased leaves of the Late blight class, the leaves are almost burnt brown to the extent that they resemble those in the Early blight class, so the model classified the leaves from the Late blight class as the Early blight class and mosaic virus disease, the leaves are pale green to almost yellow, similar to those with the Yellow Leaf Curl Virus class and Late blight class. In addition, to evaluate the effectiveness of the proposed model, we compared tomato leaf disease classifications using the methods presented against state-of-the-art Convolution Neural Network models including VGG-16, Inception-V3, DenseNet121, MobileNetV2, and ResNet50, shown in Table V. Comparative results showed that the proposed models had the highest accuracy in tomato leaf disease classification, followed by MobileNetV2, DenseNet121, Inception-V3, VGG-16, and ResNet50 with 98.59%, 94.42%, 94.22%, 94.22%, 86.19%, and 57.31% accurate, respectively. The proposed model uses fewer parameters than MobileNetV2, a lightweight model suitable for use on mobile devices. Although the proposed method takes longer to process, when comparing accuracy and loss values, the proposed method still gives better results.

V. CONCLUSION

This paper presents a new approach to improving the accuracy of tomato leaf disease classification. Improvement of the Modified VGG-InceptionV3 model based on the VGG-16 model in combination with the InceptionV3 block, reducing the number of layers of the VGG-16 model from 16 to 10 layers and improving the InceptionV3 block by adding the convolution layer from 3 layers to 4 layers. Tomato leaf disease was classified with the model presented by using the tomato leaf disease dataset from the PlantVillage dataset, with a disease identification accuracy of 99.27%. The proposed method can reduce the number of model parameters to 1,767,652 parameters, which is considered a lightweight but still highly accurate model for classifying tomato leaf disease. Compared with state-of-the-art CNN models such as VGG16, Inception-V3, DenseNet121, MobileNetV2, and ResNet50, the proposed method has the highest accuracy in tomato leaf disease classification. Therefore, in the future, the proposed model can be developed for use on small mobile devices and possibly classify more diverse plant leaf diseases to assess the effectiveness of the model.

Deep Neural Network Training and Testing Datasets for License Plate Recognition

Ishtiaq Rasool Khan¹, Saleh M. Alshomrani², Muhammad Murtaza Khan³, Susanto Rahardja⁴
University of Jeddah, College of Computer Science and Engineering, Jeddah, Saudi Arabia^{1,2,3}
Northwestern Polytechnical University, School of Marine Science and Technology, Xi'an, China⁴

Abstract—Modern society has made tremendous progress towards automation to increase the quality of life and reduce the margin of human error. Intelligent transportation systems are a critical aspect of this evolution. The core technology of these systems is the automatic identification of vehicles' license plates to monitor safety and control violations of traffic rules and other crimes. The research on license plate detection and recognition has gone a long way, from traditional computer vision techniques to features (color, shape, text, etc.) based classification and finally to modern deep learning structures. The deep networks comprising hundreds of layers require enormous amounts of training data. The training dataset should contain plates from different countries; otherwise, the system will be specific to only certain types of plates (from a country or province). There are several datasets collected by researchers containing large numbers of license plates from different countries. This paper provides a detailed survey of such datasets available in the public domain. Sample images from each dataset are shown, and details such as the dataset size, size of images, download link, and country of origin are provided. This survey will be a helpful reference for new researchers in the field for the tasks of training new networks and benchmarking their performances.

Keywords—License plate recognition; deep neural networks; public datasets

I. INTRODUCTION

License plate (LP) recognition has been a well-researched problem in the literature. The earlier works used certain features of the plates, such as height-to-width ratio, color of plate and text, font and color of text, and number and relative locations of alphanumeric, etc. [1-2]. These handcrafted features were generally specific to certain types of plates, and detection accuracy was low. The conventional object detection and recognition methods have recently been replaced by neural networks based deep learning techniques in the computer vision domain. This has resulted in improved accuracy and the ability to recognize license plates in more challenging environments [3-4].

One main issue associated with deep learning techniques is the requirement for large amounts of data for training and testing. Since these techniques are data-dependent, the data's variability and quantity make a difference in the results. Therefore, the dataset used for training a deep neural network (DNN) is important, and a DNN trained on a dataset cannot be fairly compared with another DNN trained on a different dataset. Moreover, the results reported in published literature cannot be reproduced or verified if the dataset is unavailable. Researchers working in this domain realize this issue, and

many have started sharing their datasets and algorithms in the public domain. This healthy trend increases confidence in the results presented in the literature, creates benchmarks for comparing new research, and serves as a starting point for new researchers entering the field.

Several surveys have been presented in the existing literature on the techniques used for license plate detection and recognition [5-6]. However, to our knowledge, no comprehensive survey has been carried out of datasets that can be used for training and testing the DNNs for LP detection and recognition. In this paper, we review these datasets and describe their characteristics, such as the sizes of datasets and dimensions of images. We also show some sample images from each dataset.

Most of the existing datasets contain English alphanumeric plates; hence, the networks trained on them cannot perform well on plates with text in other languages. Therefore, this paper also presents a new dataset comprising 2108 license plates from Saudi Arabia. These plates contain bilingual text in Arabic and English, which poses additional challenges to the research community. First, the DNN will need to be trained to ignore Arabic characters, some of which can be easily confused with certain English characters. For example, the English "l" and the first Arabic alphabet "alif" are written similarly; there are many other similarities. Secondly, to write two strings of text on the plate, the size of the characters is generally reduced to smaller than the characters on the license plates with only English characters, which makes them hard to be detected. For the presented bilingual dataset, we provide the ground truth, i.e., the text on the LP and the coordinates of its four corners, along with the images in the dataset, to make it more useful for the research community.

The next section briefly describes several datasets comprising images of vehicles and LPs. The criterion for including a dataset in this survey is that it was published in a journal or a conference paper or used in some scientific work to test or train a DNN. Section III briefly discusses some key observations that can be made from this survey. Finally, the paper is concluded in Section IV.

II. DATASETS IN PUBLIC DOMAIN

A. Application Oriented License Plate (AOLP) dataset

One of the earliest available and widely used datasets is the Application Oriented License Plate (AOLP) dataset containing Taiwanese license plates. Collected by Hsu et al., it comprises three categories named Access Control (AC), Law

Enforcement (LE), and Road Patrol (RP), containing 681, 757, and 611 images, respectively [7]. Sample images from each subgroup are shown in Fig. 1.

At access control locations, such as toll points or entrance and exit of an area under surveillance, the vehicles must stop at a fixed passage or move slowly. The AC subset of the AOLP dataset captures these scenarios. The camera is approximately 5 meters or less away from the car in these images. The camera pan is in the $[-30, 30]$ degrees range, and the tilt is between 0 and 60 degrees, where 0 degrees is assumed parallel to the ground. The ratio of the plate width to image width is between 0.2 and 0.25, and the plates are generally straight with an orientation of fewer than 10 degrees. Images are captured at different illuminations, including outdoor, indoor, day and night times, and various weather conditions. The size of the images is 352 x 240 pixels.

LE images have panning from -40 to 40 degrees, tilting from 20 to 70 degrees, and capturing distances less than 15m. The width of the license plate is 0.1 to 0.2 times that of the image and contains images captured by a roadside camera when the vehicle violated a traffic rule. LE images have a higher resolution of 640 x 480 pixels than AC and RP images in the dataset.

Finally, the RP images have panning from -60 to 60 degrees, tilting from 0 to 50 degrees, and capturing distances less than 15m. The width of the license plate is 0.1 to 0.4 times the image width, and the images were captured either with a handheld or a mounted camera. Road patrol purposes include

searching for lost vehicles, scanning for parking violations, and security checking in a restricted area. The image resolution in this dataset is 320 x 240.

B. Caltech Cars

Caltech Cars1999 dataset [8] consists of 126 car images having a resolution of 896 x 592 pixels. The images of parked cars during the daytime are included in this dataset. Another dataset Caltech Cars2001 [9], comprising 526 images at 360 x 240 pixels resolution, has also been made available by the researchers at the same link. The images in the Cars2001 dataset were captured on a highway; therefore, there is more variation in plate sizes and capturing distances and angles in this dataset. Sample images of both datasets are displayed in Fig. 2.

C. Peking University Dataset (PKU)

The Peking University dataset (PKU) is created by the National Engineering Laboratory for Video Technology (NELVT), a research group at Peking University China. The data set was captured by surveillance cameras, in China, during both day and nighttime [10]. Images in the data set are divided into five categories: G1 (810 images, 1082x727 pixels each), G2 (700 images, 1082x727 pixels each), G3 (743 images, 1082x727 pixels each), G4 (572 images, 1600 x 1236 pixels each), and G5 (1152 images, 1600 x 1200 pixels each). All images contain front number plates. The images have good quality, and the plates are easily readable. Some images in the G5 category have multiple cars. In Fig. 3, we have shown some images from G1 and G4 categories.

Fig. 1. Sample images from AOLP AC (top row), LE (middle row), and RP (bottom row) datasets Download link: <https://github.com/AvLab-CV/AOLP>.

Fig. 3. Sample images from PKU dataset category G1 (top row) and category G5 (bottom row) Download link: https://github.com/ofeeler/LPR/tree/master/pku_vehicle_dataset/images.

D. Synthetic Dataset

Bjorklund et al. [11] released a dataset of synthetic images for training CNNs. The synthetic plates were generated considering a wide range of conditions affecting the aspect of real plates. The synthetically generated text was projected on unconstrained backgrounds instead of cars. The authors argue that using license plates on unnatural backgrounds enhances the learning process's ability to account for large text and background variability. The major advantage of generating synthetic plates is that the laborious task of capturing and annotating thousands of plates is avoided. Plates can be generated in any pose, and the template can be changed to different fonts, shapes, and countries. The authors released a training dataset of 20,000 images containing plates and 20,000

images without plates, and a validation dataset of 2500 images with plates and 2500 images without plates. The images represent Taiwanese plates and have a resolution of 768 x 384 pixels. In Fig. 4, we have shown a few sample images containing plates.

E. University of Zagreb Dataset

Researchers at the University of Zagreb produced a database containing 500 images of Croatian license plates. The images contain rear views of cars, trucks, and buses under varying lighting conditions from various angles using a handheld digital camera. The typical sizes of the images are 1024 x 768 and 640 x 480. Some samples of these images are shown in Fig. 5.

Fig. 4. Sample images from the synthetic dataset by Bjorklund et al. Download link: <https://www.kaggle.com/datasets/tbjorklund/annotated-synthetic-license-plates>.

Fig. 5. Sample images from the University of Zagreb dataset of car. Download link: <http://www.zemris.fer.hr/projects/LicensePlates/english/results.shtml>.

F. Chinese Car Parking Data Set (CCPD)

The Chinese Car Parking Data set (CCPD) [12] is a comprehensive data set, 12 GB in size, containing over 300,000 images of Chinese license plates captured with a handheld camera by license plate inspectors across China. The images were acquired between 0730 and 2200 hrs. Each image has only one plate, and the typical resolution of the images is 720 x 1160 pixels. Detailed annotations of the images are provided, with the following information: area ratio of LP to entire image, horizontal tilt, vertical tilt, bounding box's top-left and bottom-right coordinates, exact coordinates of four vertices of LP, 7-letters LP number, brightness of LP region, and blurriness of LP region. The database provides splitting for training and testing subsets. Classification based on other features, such as blur, rotation, tilt, etc., is also available. A subset with challenging images is also part of the classification. The authors updated the dataset in 2020 with new number

plates containing eight digits, which are assigned to energy-efficient "green" vehicles. Sample images from CCPD are shown in Fig. 6.

G. National Technical University of Athens Dataset (NTUA)

The National Technical University of Athens released a dataset of the images of Greek license plates and categorized the content as still images and video. At this point, only one video is available, but there are a large number of images in the dataset, and they are divided into several categories based on certain characteristics (color, grayscale, and blurry images) and capture time (day or night). The images with shadows, dirt, and more than one vehicle and those taken from a close distance are stored separately. The images have different resolutions, and we found 1792 x 1312, 800 x 600, and 640 x 480 pixels images in the dataset. There are 716 images in total at this point, but the authors plan to keep adding more. Sample images of this dataset are shown in Fig. 7.

Fig. 6. Sample images from CCPD dataset Download link: <https://sites.google.com/site/avlabaolp/download>.

Fig. 7. Sample images from National Technical University of Athens' database of Greek plates. Download link: <http://www.medialab.ntua.gr/research/LPRdatabase.html>.

H. Federal University of Parana Dataset (UFPR-ALPR)

A Brazilian car dataset was released by the Federal University of Parana researchers. The dataset was referred to as UFPR-ALPR by the researchers, and it contains 4500 fully annotated images from 150 vehicles captured in real-world situations [13]. The camera and the vehicle were both moving, so several challenging scenarios were captured. Multiple images of a car taken from different angles are included in the dataset. Images are stored losslessly in PNG format and have a resolution of 1920 x 1080 pixels. Three cameras – GoPro Hero4, Huawei P9 Lite, and iPhone 7 Plus – were used to capture these images, 1500 with each camera, including 900 images of cars with gray LP, 300 images of cars with red LP, and 300 images of motorcycles with gray LP. The images are split into training, validation, and testing sets in a 40:20:40 ratio. Images are annotated with the following information: camera name, type of vehicle (car or motorcycle), manufacturer, model, and manufacturing year of car, position and text of the LP, and position of characters. Some representative images of the UFPR-ALPR dataset are shown in Fig. 8.

I. Kurpiel Dataset

A Brazilian video dataset released by Kurpiel et al. [14] comprises five videos. Under different weather conditions, the authors extracted 4070 plates in 1829 images taken at a resolution of 1920 x 1080 pixels. The plates are quite noisy, and the text is unreadable in many cases. Therefore, this dataset can be used for training and testing LP detection algorithms;

Fig. 8. Sample images from UFPR-ALPR dataset of Brazilian plates. Download link: <https://web.inf.ufpr.br/vri/databases/ufpr-alpr/>.

Fig. 9. Sample images from the dataset of Kuprial (copied from the original paper) Download link: <https://pessoal.dainf.ct.utfpr.edu.br/rminetto/projects/license-plate> (not accessible).

Fig. 10. Sample images of characters extracted in the Goncalves dataset. Download link: <http://smartsenselab.dcc.ufmg.br/en/dataset/banco-de-dados-sense-alpr/> (vehicles) <http://smartsenselab.dcc.ufmg.br/en/dataset/sense-segplate/> (characters).

however, recognizing text can sometimes be challenging or even impossible. Some samples of the LPs in this dataset are provided in Fig. 9. These are taken from the original paper. The download link is not working now, but we have included this dataset in our review, as interested readers might approach the authors directly and request access.

J. Goncalves Dataset

Another Brazilian database comprising 6,660 images with 8,683 license plate images from 815 different vehicles was accumulated by Goncalves et al. [15]. Images are divided into training (3595 images), testing (2360 images), and validation (705 images) subsets. These images have 1920 x 1080 pixels per image, and the license plate size varies from 5 x 12 pixels to 86 x 196 pixels, with an average of 22 x 57 pixels. These full HD images are stored in PNG format losslessly, one image taking 2.4 MB on average, which makes the total data size quite large. This database can be accessed by submitting a form to the authors and requesting access for non-commercial purposes. Extracted characters from license plates were shared in [16]. There are 101 on-track vehicles captured during the day with a digital camera in Full-HD resolution (1920x1080 pixels). Multiple frames are captured for each vehicle, 19.8 on average, each stored in PNG format (4.08 MB on average), making the total size of the database more than 8.5 GB. This dataset can be used in the license plate character segmentation problems. Some sample images of characters are shown in Fig. 10. The download links of both datasets are provided in the figure caption.

K. University of California, San Diego Dataset (UCSD-Calit2)

The database shared by the University of California, San Diego (UCSD-Calit2) comprises around 10 hours of video of cars entering and leaving the campus during various hours of the day. The still frames extracted from these videos were hand labeled; thus, the data for 878 cars was annotated. The dataset also comprises 291 car images taken in the car park using a handheld digital camera. The dataset was available at the following link, which is inaccessible now: <http://vision.ucsd.edu/belongie-grp/research/carRec>. We have provided this link, assuming that the website might be restored in the future or interested readers may want to approach the authors.

L. Spanhel Dataset

Spanhel et al. [17] shared a database comprising relatively low-quality images for the recognition of license plates. The authors captured 9.5 hours long from 8 different bridges on highways under different conditions. They used a boosted soft cascade classifier to detect LPs and tracked them across frames with a Kalman filter. Human observers recognized the plates across a sequence of frames and annotated the whole sequence with the text of the plate. This was an efficient approach to label multiple frames at once instead of doing them one by one. There are 76,412 color images of cropped license plates in this dataset, named ReId dataset. The authors also provided a high dynamic range (HDR) dataset, which is relatively smaller in size and contains 652 images taken at different exposure times. Images were cropped manually to obtain LP images. A few samples of plates taken from the ReId and HDR datasets are shown in Fig. 11. Since the images of cars were captured from

different distances and angles, the cropped images of plates have different dimensions.

M. AI Tunisia Hack 2019 Challenge Dataset

A license plate data set was made available in AI Tunisia Hack 2019 challenge. The data comprised 900 images of vehicles taken from the Internet and annotated manually for the coordinates of the bounding box containing the LP. A separate set of 900 images of extracted LPs was also provided in which the annotations mark the text of the LP. Thus, the first dataset can be used to train a network for the detection of LP, whereas the second dataset is specific to the recognition task. Sample images from both datasets are provided in Fig. 12. The images are truncated to show the cars and plates in both datasets; therefore, they have different sizes.

N. Platesmania

License plates from different countries can be downloaded from the Platesmania website, which contains license plates from more than 70 Asian, European, American, and African countries. The data set includes thousands of images. For example, there are 314830, 305643, and 190448 images of vehicles from Germany, France, and the US, respectively. Images are not annotated; hence, the researchers need to mark the bounding boxes and the plate text themselves before they can use them for training a network. A clear picture of the LP is provided with each vehicle image, but it is in image format and not the text, thus not of much use in the training task. However, the picture of the LP is quite clear, and OCR algorithms should be able to extract the text accurately. Some images of cars and their number plates from four different countries are shown in Fig. 13.

Fig. 11. Sample images from the ReId (top row) and HDR datasets (bottom row) of Czech Republic plates by Spanhel et al. Download link: <https://medusa.fit.vutbr.cz/traffic/> (not accessible now).

Fig. 13. Sample images of vehicles from Japan, Kyrgyzstan, Mexico, and Russia, from Platesmania. Download link: <https://platesmania.com/>

O. Stanford Dataset

The cars dataset developed by Stanford University researchers contains approximately 16,185 images of 196 cars, split into 8144 training and 8041 test images [18]. The number plates are not necessarily visible, and the dataset is meant to be used for identification of the car type and not the license plate. However, we have mentioned it here for interested readers, as these details can be important in an intelligent transport system. Images have different resolutions, typically 584 x 328, 634 x 357, or similar. Classes are made at the car make, model, and year level, e.g., the 2012 Tesla Model S or 2012 BMW M3 Coupe. Annotations are provided, including class labels and bounding boxes for all images. Initially, an evaluation server was set up for automatic evaluation and comparison with the provided results. However, it has been decommissioned now, but the manual evaluation can still be done by using the test dataset's ground truth. We have provided some sample images of this dataset in Fig. 14.

P. University of Jeddah License Plate Dataset (UJLP)

The license plates in Saudi Arabia have bilingual text, i.e., the digits and characters are written on top in Arabic and at the bottom in English, and this comes with its unique challenges. First, the recognition systems trained on English characters

must discard the Arabic text. Secondly, to fit both texts, the size of the characters is kept small. However, bilingual text offers a unique advantage: separate NNs can be trained on Arabic and English characters, and their results can be combined for higher accuracy. To the best of our knowledge, there has been no notable dataset of Saudi Arabian plates in the public domain. We have developed one consisting of 2108 license plates [19]. To make this dataset, we captured a large number of videos of parked and moving cars from a moving car using our mobile phones. We developed a customized software tool to extract the frames of interest from the captured videos. We also developed a tool for annotation which displays a frame and allows the user to mark the corners of the plate with mouse clicks. The coordinates of these corners are stored in a text file. The extracted images, the tools for extraction and annotation, and the annotation files are shared in the public domain and can be used for free for academic research.

The dataset captured from the traffic moving on the roads offers several challenges, such as variable size and orientation of the plates. Some samples are shown in Fig. 15. There are some very challenging images in the dataset, such as images of the plates partially covered with mud or with poor visibility due to low or bright light. This dataset can be very helpful in developing an LPR system for deployment in police cars.

Fig. 15. Sample images from the UJLP dataset. Download link: <https://github.com/ishtiaqrasool/2022-Electronics-Automatic-License-Plate-Recognition-in-Real-World-Traffic-Videos>.

III. DISCUSSION

A summary of the different characteristics of the datasets discussed above is presented in Table I. The second column in the table shows the size of the dataset, i.e., the number of images and plates (if available). The largest dataset is provided on the Platesmania website, which provides plates from many countries. However, this dataset was not particularly designed for LP detection and recognition research; hence, the images are not labeled. Among the labeled datasets, CCPD is the

largest, with 300,000 images of Chinese plates. The dataset of Czech Republic plates with 76,412 images is the next largest.

While comparing the detection and recognition results reported in different papers, the size of the dataset used for training must be considered; larger datasets would generally lead to better training and accuracy of the DNN. The quality of training images and the difficulty level of testing images are also important factors, and therefore the results reported using different datasets should be compared with caution.

TABLE I. SUMMARY OF THE REVIEWED DATASETS

Dataset	# of Images	Image Size	Country
AOLP	AC: 681 LE: 757 RP: 611	AC: 352 x 240 LE: 640 x 480 RP: 320 x 240	Taiwan
Caltech Cars 1999	126	896 x 592	USA
Caltech Cars 2001	526	360 x 240	USA
PKU	G1: 810 G2: 700 G3: 743 G4: 572 G5: 1152	1082 x 727 1082 x 727 1082 x 727 1600 x 1236 1600 x 1200	China
Synthetic	Plates: 20,000 (training) + 2500 (validation) Non-Plates: 20,000 (training) + 2500 (validation)	768 x 384	Taiwan
University of Zagreb	500	1024 x 768, 640 x 480	Croatia
CCPD	300,000	720 x 1160	China
NTU Athens	716	1792 x 1312 800 x 600 640 x 480	Greece
UFPR-ALPR	4500	1920 x 1080	Brazil
Kurpiel et al. [8]	4070 LPs in 1829 images	1920 x 1080	Brazil
Goncalves et al. [9]	8683 LPs in 6600 images	1920 x 1080	Brazil
UCSD-Calit2	878	N/A	N/A
Spanhel et al. [11]	76,412 (ReID) 652 (HDR)	Not fixed	Czech Republic
AI Tunisia Hack 2019	900	Not fixed	Tunisia
Platesmania	Millions of images	Not fixed	Different countries
Stanford [12]	16,185	584 x 328 634 x 357 or close	USA
UJLP	2108	1920 x 1080 720 x 1280	Saudi Arabia

The third column in Table I compares the resolution of images in different datasets. Training a DNN with a large number of layers is a slow process; therefore, the training datasets generally comprise images of small sizes. However, with enhancements in the computational capabilities of GPUs, training images of Full High Definition (FHD) resolution, i.e., 1920 x 1080 pixels are not uncommon, as can be seen in the table. The execution time of a trained DNN to process a test image depends on the hardware platform as well as the image size. These factors should be given due consideration when comparing the efficiency of different methods reported by their respective authors.

IV. CONCLUSION

A detailed survey of different datasets used for training and testing of deep neural networks for license plate detection and recognition was presented. Different characteristics of these datasets were discussed. The information compiled in this paper can serve as a valuable reference for advancing research in this domain and benchmarking.

ACKNOWLEDGMENT

This work was funded by the Deanship of Scientific Research (DSR), University of Jeddah, under Grant No. UJ-03-18-ICP. The authors would like to acknowledge and thank the technical and financial support provided by DSR.

Abstract—Fossil fuels, including oil, are the most important sources of energy. They are commonly used in various forms of commercial and industrial consumption. Producing oil is a complex task that requires special management and planning. This can result in a serious problem if the oil well is not operated properly. Oil engineers must have the necessary knowledge about the well's status to perform their duties properly. This study proposes a linear regression method to predicate the oil production value. It takes into account various independent variables, such as the pressure, downhole temperature, and pressure tubing. The proposed method can accurately reach a very close prediction of the actual production value by achieving very interesting results at the end of this study.

Keywords—Big data; machine learning; oil production; regression model; features; prediction; PySpark

I. INTRODUCTION

The current rapid evolution of science and technology causes more progress in the oil field development, especially with the increasing demand for petroleum resources worldwide. For instance, the prediction of crude oil production represents the capacity of the oil field in the future, and it also directly impacts the future planning for this field [1].

In the petroleum industry, oil production and its future prediction have always been the center of interest to many scientists and researchers. This is because oil plays an impactful and effective role in energy production. Naturally, oil is produced within oil wells. In fact, many factors influence the production of the well including internal geological factors as well as geological location, time, and production equipment which are considered external factors. These influencing factors make it hard for the prediction of oil production to be precise and accurate, especially when using traditional methods like curve analysis and mathematical modeling [2]. Nonetheless, the need to accurately predict oil production is a necessity. As a matter of fact, the efficient accurate prediction can help save manpower, the consumed materials, and the resources required for the extraction process in addition to enhancing the economical aspect of the oilfields [3].

Oil production has an influential role in improving the economy. It is also a part of the political aspects of developing and established countries. Fossil fuel is considered a common industrial energy source due to the fact that it's versatile, easily transported, accessible, and expensive [4], [5]. Moreover, the

oil serves various uses in industry, agriculture, energy transformation as well as commercial and residential services as shown in Fig. 1.

Fig. 1. Uses of fossil fuels and oil in multiple sectors: energy transformation, Agriculture, industrial, commercial, and residential

When discussing oil properties, it's important to mention that oil is found underground in porous rocks where rock strata are stacked above them creating pressure. This pressure is compensated by the pressure of the fluid (oil, gas, or water) which is in the reservoir. When drilling takes place, the fluid rises to the level of the surface because of the reservoir pressure. In addition, this lost fluid pressure is compensated by a displacement of the deeper fluid from underground to fill its place [6]. Consequently, the reservoir pressure decreases. It keeps decreasing gradually until it is no longer possible for the fluid to flow to the surface. In this case, a pump can be used to control the flow of fluid to the surface by controlling the difference between the pressure in the well and the reservoir pressure. Furthermore, the pump mode can be adjusted to have control over the bottom-hole pressure which can be a mode for setting the well's operations in the sense.

It is important to be able to predict the oil production rate or volume since it provides the engineers with useful information. As such, they can, in turn, evaluate and opti-

mize reservoir management-related issues. Unfortunately, it is extremely difficult to perform highly accurate predictions without taking into consideration the subsurface conditions [7]. On the other hand, computing technology and data analytic can help resolve this issue of oil production forecasting while maintaining the complexity of the relationships between the inputs and outputs [8].

Prediction is the process of producing estimations based on observations. Upon analyzing the observable occurrences, it is then possible to project the data to make future predictions for a similar type of occurrence. Often these observable data are too large, and no deductions or predictions can be done by simply observing them. Manual analysis and interpretation are both tiresome and time-consuming in addition to the great error margin [9]. Prediction techniques vary in their type and content as can be seen in Fig. 2, yet some of them are more advanced than others.

In oil and petroleum exploration and development, artificial intelligence (AI) has gained a remarkable spot as it can be the solution for the issues that arise in this field. Recent studies have shown that using data-driven models ensures better prediction results than experience-based prediction models [10]. It is important to mention that AI is involved in the prediction of oil and gas properties, optimization of well layout plans, and prediction of reservoir physical properties and that of oil production among others [11]. Fig. 3 illustrates the various interaction models that can be used for predictions including data-driven methods such as regression, classification, and dimensional reduction.

AI incorporates computational power and human intelligence in order to achieve reliable smart systems that can resolve extremely nonlinear and highly complex problems. Thus, AI paves the way for computers to make data-based decisions [12]. Machine learning (ML), on the other hand, is included within AI. It delivers statistical tools for big data analysis and exploration. ML is actually further subdivided into supervised, unsupervised, and reinforced learning.

Even though AI has been involved in E&P practices before, the recent expansion of digital techniques in the oil field made it increasingly involved in advanced predictive and prescriptive analytics [13].

Moreover, AI provides great potential in solving issues in almost all areas of the oil industry including prediction, classification, and clustering. The data-driven systems can locate and define the relationship between oil production and other data acquired from the field. This is achieved through using sensors and ML models. In reservoir engineering, combining ML techniques with data analytics has various benefits [14]. The studies show that this combination can help predict the bottom-hole pressure, optimize water flooding, and forecast hydrocarbon production.

ML algorithms include Support Vector Machine, K-means, decision tree, Apriori, neural networks, and Naive Bayes algorithm [11]. Linear regression is one of the basic regression techniques for forecasting, predicting, or estimating. In the past years, specifically in 1800, Gauss created a method called the Least Square Method for the purpose of suiting an equation according to linear parameters. A linear regression illustrates the existing relationship between a random factor with a

dependent factor, whose prediction or estimation is the center of focus in this study. In both research and statistical studies, linear regression is still frequently used [15]. Linear Regression as can be seen from Fig. 2 is one of the qualitative prediction methods.

Notably, the researchers of this study are highly motivated by the increasing importance of oil and fossil fuels production. Hence, the main objective of the study is to develop a system that can analyze the fed data and transform them into valuable inputs that can be used for oil production prediction in the future. The proposed system is based on Linear Regression which achieves high levels of accuracy. For a better understanding of the presented work, the developed model is evaluated to answer the following research questions:

(R.Q.1) *What factors directly affect the oil production value?*

(R.Q.2) *Can a Linear Regression model effectively predict the production value of oil based on different factors?*

This study is composed of three parts. The first part presents some related works to the prediction of oil production. These studies use different methodologies for the purpose of analyzing the data in the oil fields by presenting suitable models. Then, the methodology is the second part of this study which is explained in detail. This includes the levels of the structure of the dataset, implementations, importing the data, exploratory data analysis, data processing, data scaling, feature selection, and applying machine learning algorithms. The last part is the results part where the researchers explain that the linear regression method suggested by them has proven to be highly successful by having results that are really close to the actual results.

It is important to mention that this study has a high significance in the field of fossil fuels, especially in oil production. As such, it attempts to decrease and reduce the problems that may occur in the prediction process of oil production. The researchers highlight that this study with its simple method, linear regression, can achieve high and real results in comparison to other methods with much more complex features. Such a method can be flexible, practical, and effective for explaining and illustrating the process of successful oil predictions. It can add more knowledge and information for future research for the purpose of enhancing and saving the most significant source of energy for the upcoming generations.

II. RELATED WORK

When considering the topic of oil production, many studies come to light especially those that attempt to accurately predict the rate or volume of oil production. ML models are quite popular in this case. Nonetheless, many studies prefer to use linear regression specifically due to its many advantages.

Emeke and Bello addressed the issue of predicting the oil production volume in an area within Nigeria through linear regression techniques [16]. In their study, the authors have made use of MATLAB in analyzing the data acquired from the oil field from Kwale, Niger Delta. In addition, multivariate linear regression has been chosen as a model for its capability of housing multiple variables. For regression, the input variables are the metered volume, the basic sediment and

Fig. 2. Prediction traditional methods including qualitative, time series and quantitative methods

Fig. 3. Prediction tools including data-driven methods such as regression models

water, the volume correction factor, the metered factor, gross standard volume, API @60, and temperature among others. These data are collected over the course of several months, and the entire dataset is split into 70% for training the LR model and 30% for testing it. After that, a couple of models are considered (with different input variables) in contrast to the new generalized model which has been obtained by coefficient comparison and inspection of the lowest root mean square error value RMSE. One of the distinctive features of the new model is the exclusion of some factors like water percentage and basic sediment. As a result, the RMSE value for the new model is

much lower than the old one. Furthermore, the residual values are calculated to see the differences between the predicted values and the actual values, and the new generalized model, which are low, indicates a close prediction. In addition, the R-squared value is 0.9889.

In another study, Mgbemena and Chinwuko aim to predict the crude oil production value in Nigeria through implementing multiple linear regression [17]. In this study, the authors attempt to produce a daily, weekly, monthly, and yearly forecast. To do so, the authors initially analyzed many forecasting models before creating the LR model. The past historical data for the oil field are collected from the years 2010 to 2016. For linear regression, the least-squares equation is used. Overall, the performances of six models are compared. Among the graphical forecasting, 3-year simple moving average, 6-year simple moving average, 8-year simple moving average, least squares LR and the exponential smoothing with 0.1 or 0.6 as weighing factors, the Least Squares Linear Regression model have achieved the lowest mean squared error MSE value. This means that the lowest mean method makes a good prediction with minimal error. After the comparison, the authors developed their own multiple linear regression models to predict the daily oil production values. This model takes into consideration the number of natural wells which are flowing, the number of gas-lifted weak wells, and the amount unbiased compressors which are running. As a result of comparing the developed system's predicted value and the actual value, the system misses the direct hit point by 43 barrels per day, which is a very satisfactory result.

In their study, Kumar and his colleagues aim to develop

TABLE I. COMPARISON OF LITERATURE REVIEW STUDIES ACCORDING TO YEAR, AIM, AND APPROACH

Paper	Year	Aim	Approach
[16]	2019	To create a system that can accurately predict oil production in the field in Nigeria	Multivariate linear regression model has been developed taking into consideration the following factors: metered volume, gross standard volume, metered factor, and volume correction factor.
[17]	2020	To develop a model that can perform a precise forecast for oil production in Niger Delta Region	A comparison of many models has been performed, and the multiple variables regression model has been finally developed achieving very good results.
[18]	2019	To predict the oil and gas production rates based on Machine Learning	RapidMiner tool is used in addition to linear regression SET ROLE operator and APPLY MODEL operator.

a forecasting model based on machine learning to predict gas and oil production [18]. To execute the study, data has been acquired from sensors and processed, then the CRISP (Cross Industry Standard Process) model has been applied to the processed data. This involves understanding the data, preparing data, modeling, and evaluating. After that, the data is imported to Rapid Miner where correlation analysis is performed to check for existing relationships between them, the variables, and the dependent variable. Next, linear regression is applied based on the identified variables from the correlation analysis. Finally, data visualization techniques are used to visualize and discuss the data. Ultimately, six variables are chosen for input to achieve oil production and output prediction, including average wellhead temperature, average choke size, average gas lift rate, etc. Upon experimentation and testing, bottom-hole pressure has been found to be an important variable in predicting the average oil production rate. Table I presents a comparison between the literature review studies according to the year, aim, and approach.

III. METHODOLOGY

A. Dataset

The Norwegian oil and gas company Equinor has announced starting in June 2018, all of the data from the Norwegian continental shelf are available for research and study. This has given academic institutions, students, and researchers worldwide permission to use crucial scientific information in line with the Equinor Open Data License without the requirement for further written consent.

The Volve production data has been released in the form of an excel file which is made up of two (02) sheets, namely Daily Production Data and Monthly Production Data. Oil production estimation is one of the major duties of production engineers, depending on several operational parameters that include tubing differential pressure, bottom hole pressure, and wellhead pressure. This estimation process can happen as an effective way of applying empirical correlations or nodal analysis. Furthermore, physics is generally included in most of the literature work since it involves a lot of assumptions.

The researchers of this study are inspired to apply a completely different approach based on Data-Driven applications, such that physics is being taught to the computer based on data

only. This approach ensures that no complexity or assumptions are being made and that the results are purely generated from the fed data. Both linear and polynomial regression models are going to be used to predict the oil production from the date of the Volve field daily production. In the Norwegian North Sea, a hydrocarbon reservoir termed Volve has been operational for a couple of years between 2005 and 2016. Volve has a 54% recovery which is considered good. Additionally, the Volve dataset is considered the top open-source dataset for exploration and production in terms of completion.

B. Implementation

Apache Spark is a framework for data processing that can swiftly process operations on extremely large data sets and distribute processing operations over several computers, either individually or in conjunction with other distributed computing technologies. It is a super-quick machine learning and large data analytics engine. The Apache Spark community has published a tool, PySpark, to enable Python with Spark. Python programmers may work with RDDs by using PySpark.

1) *Spark MLlib*: Spark MLlib is used in Apache Spark to execute machine learning. Popular tools and algorithms may be found in MLlib. MLlib is a scalable Machine Learning library in Spark that offers both high-quality algorithms and high performance. Clustering, classification, regression, collaborative filtering, and pattern mining are examples of machine learning algorithms. Additionally, MLlib contains lower-level machine learning primitives like the general gradient descent optimization technique.

The main Machine Learning API of Spark is spark.ml. For creating ML pipelines, the library Spark.ml provides a higher-level API built on top of DataFrames. Below are some utilities for Spark MLlib:

- Pipelines
- Featurization
- ML Algorithms
- Persistence
- Utilities

2) *ML algorithms*: The core of MLlib is its ML algorithms. These include well-known learning techniques including collaborative filtering, clustering, regression, and classification. The goal of MLlib is to standardize APIs to make it simpler to integrate several algorithms into a single pipeline or workflow. The Pipelines API is one of the core ideas, and the scikit-learn project serves as an inspiration for the pipeline concept.

3) *Transformer*: An algorithm known as a Transformer may change one DataFrame into another DataFrame. Basically, a Transformer performs the transform () function, which adds one or more columns to one DataFrame to change it into another. For example: A feature transformer may take a DataFrame, read one column (for example, text), map it into another column (for example, feature vectors), and then produce a new DataFrame with the mapped column attached.

A learning model may use a DataFrame as an input, read the column containing feature vectors, predict the label for every feature vector, and then produce a new DataFrame with the predicted labels attached as a column.

4) *Estimator*: An algorithm which is known as an Estimator may be fitted to a DataFrame to create a Transformer. In terms of technical implementation, an Estimator uses the function fit(), which takes a DataFrame and outputs a Model, a Transformer. For instance, using fit() trains a Logistic Regression Model, which is a Model and subsequently a Transformer, from a learning method like Logistic Regression, which is an Estimator. Both Estimator.fit() and Transformer.transform() are stateless functions. Alternative notions may enable stateful algorithms in the future. Each Transformer or Estimator instance has a unique ID which may be used to provide parameters (discussed below).

5) *Featurization*: Selection, dimensionality reduction, feature extraction, and transformation are all parts of featurization. Feature extraction is the process of extracting features from raw data. Furthermore, the term "feature transformation" refers to the resizing, updating, or changing of features. In feature selection, a small subset of essential characteristics is chosen from a large pool of features.

6) *Pipelines*: A pipeline specifies an ML process by connecting several transformers and estimators. Additionally, it offers resources for building, assessing, and fine-tuning ML Pipelines. It is typical in machine learning to run a series of algorithms to analyze and learn from data. Such a process is represented by a pipeline in MLlib, which consists of a series of pipeline stages (Transformers and Estimators) that must be executed in a certain order. In this part, the researchers of this study utilize this simple method as an example. As such, the pipeline example below does the data preparation in the following order:

- Use the String Indexer method to determine the index of the category columns.
- Use OneHot encoding to present the category columns.
- Use the String indexer to locate the column of the output variable "label"
- VectorAssembler is used to assemble category and numerical columns. A transformer called VectorAssembler creates a single vector column from a provided list of columns.

C. Importing Data

The first step is to import the data, including three essential libraries, namely Spark which is used to import product data and to develop DataFrame, in addition to the Seaborn and Matplotlib libraries.

There are several parameters considered in the uploading of the dataset. It contains various data such as the good type being water injection or oil production, as the average downhole pressure, average drill pipe tubing, date of production, oil volume, average downhole temperature, gas volume, average choke size, average well-head temperature, average annulus pressure, average well-head pressure, water volume, and type of flow (production or injection). In addition, the data on oil production is documented based on the daily collection.

D. Exploratory Data Analysis

It is critical to perform exploratory data analysis in any machine learning approach, even though it is also time-consuming. This step is essential since upon encountering the data, it must be understood before continuing with the other steps. There are many processes included in the exploration of data, such as discovering patterns, checking assumptions, and spotting anomalies through visualizations and statistical summaries. Fig. 4 illustrates the distribution of acquired data of the seven wells.

Fig. 4. Distribution of data acquired from seven wells

Fig. 5 shows the ECDF plots of each of the wells. From these plots, it can be observed that 40% of the data points relative to well number 4 have zero bore oil production. For well number 5, the observations show that 20% of their data points have zero bore oil production. These indicate that there is no flow in these wells since zero bore oil production is different from not available NA values. Thus, when the seven wells are considered in this study. Well number 4 and well number 5 data should be eliminated, as they can't be used for training. On the other hand, well number 1 shows empty values in the ECDF plot, and well number 2 has some missing values. Hence, for these two wells, the ECDF of water injection volume is plotted to check if they are injectors.

Fig. 6 shows the water injection plots for wells number 1 and number 2. By analyzing the graph, it becomes clear that well number 1 is an injector well. On the other hand, data of well number 2 indicates that it is an injector in addition to being a producer.

Generally, wells can be either injectors or producers. When fluids are poured into the underground to be placed in porous geological formations such as limestone, deep sandstone, or a shallow soil layer, then the well has termed an injection well. Additionally, the injected fluid can be either water, salt water "brine", wastewater, or chemically treated water. On the other hand, a well specified for extracting oil or gas is called a production well. Fig. 7 shows the difference in well data between the two well types.

Fig. 5. ECDF plots for each of the seven wells

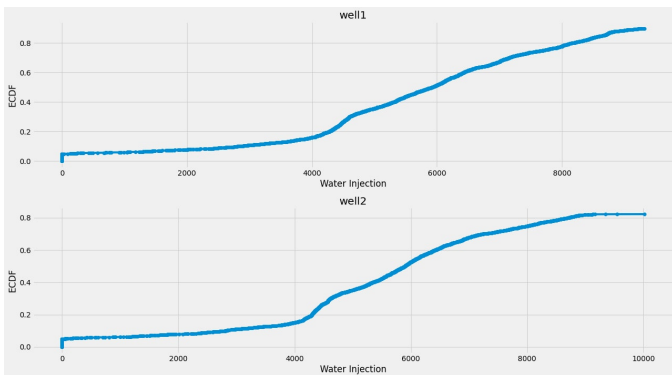

Fig. 6. ECDF plots for well number 1 and 2 referring to water injection data

Fig. 7. Well data for a production well in comparison to an injection well

E. Data Pre-Processing

Data preparation is the next step after data analysis. Pre-processing the data involves dealing with string formats inserted in a numerical column, negative values in permeability columns,

empty columns, null values, and theoretically incorrect values.

From analyzing the data using a box plot, it is evident that the data is highly skewed depending on the well, and missing data need to be fixed. The forward filling is the technique to be performed to fill in the missing data here. However, usually, in the case of missing data, the mean value is used, yet this cannot be the case in the data of this study since it is skewed. For this reason, the null value is filled with a value just above it.

F. Data Scaling

In order to prepare the data for machine learning approaches, data scaling or normalization should be done. The scaling process is meant to alter the numeric values within the columns into a common scale while keeping the differences in the range of values and maintaining the information. The data is transformed in a way that the features are within a specific range [0, 1].

$$x' = (x - x_{min}) / (x_{max} - x_{min}) \quad (1)$$

G. Feature Selection

Feature selection is also called feature engineering since the input features of the data are examined and evaluated for their importance and impact on the results. In this way, the features, that contribute to getting the precise predicted value and are correlated to the anticipated output, are chosen either automatically or manually. The importance of this step is explained when the accuracy of the model decreases when using irrelevant features is noticed. However, using highly correlated features is also tricky since it might lead to reducing the accuracy given that the input data becomes homogenous and lacking variability. It might also lead to data leakage which increases the accuracy beyond acceptance. For this reason, correlation heat maps must be generated. The correlation heat maps are generated to determine the highly correlated features. Fig. 8 shows the variation of oil production volume with respect to downhole pressure and temperature.

Fig. 8. Variation of oil volume with respect to downhole pressure and temperature

H. Applying Machine Learning Algorithm

Linear regression is one of the many existing regression methods, which are considered among the most important

machine learning and statistical techniques. In regression, relationships among the different variables are explored. For instance, applying regression in a company allows exploring how the salary of its employees changes according to their experience, education, their role in the company, etc. In this case, the data of each employee is a representation of one observation, and in this regression a problem, the dependent variable is the salary, whereas the independent variables are the role, education level, years of experience, etc.

In a regression analysis, a chosen phenomenon is considered with a group of observations, where each observation involves at least two features or variables. Then, an attempt of finding the relationship of dependency between the various features or variables occurs based on assumptions and further testing and analysis. Thus, regression not only finds how a phenomenon is influenced by a feature but also how the different features are related to each other. The outputs of regression are often denoted by y , whereas the inputs are denoted by x , such that the independent features can be put in a vector $x = (x_1, \dots, x_r)$ with r being the number of inputs.

Forecasting is one of the other uses of regression, where output can be predicted based on a set of predictors. Regression is used in many different fields, including economics, computer science, and the social sciences. The importance of regression increases with the increase of data volume and practical value of data.

Outputs, responses, and dependent variables are the terms used for the dependent features, whereas inputs, regressors, and predictors are the terms used for the independent features. In regression problems, there are often one continuous dependent variable and many continuous, categorical, or discrete independent variables.

Linear Regression is a simple supervised machine learning model. In this problem, the aim is to create a linear relationship between the dependent variable "Oil Production", and the other training independent variables. The linear equation will assign a coefficient to each training feature, and an intercept is added to the equation as well. Input instance –feature vector: $x = (x_0, x_1, \dots, x_n)$, and the predicted Output: $y = w_0x_0 + w_1x_1 + \dots + w_nx_n + b$, therefore, for parameters to estimate (PtoE) is represented as follow:

$$PtoE = \begin{cases} \hat{w} & := \hat{w}_0, \dots, \hat{w}_n: \text{feature } \frac{\text{weights}}{\text{model}} \text{ coefficients} \\ \hat{b} & : \text{constant bias } \frac{\text{term}}{\text{intercept}} \end{cases} \quad (2)$$

The variation of actual responses $y_i, i = 1, \dots, n$ occurs partly due to the dependence of the predictors x_i . However, there's also an additional inherent variance in the output.

The coefficient of determination R^2 resembles the degree of variation of y depending on x , through the particular regression model. If R^2 has a large value, it means that the model is highly capable of explaining the variation of the dependent variable according to the independent variables, thus it is a better fit. The value $R^2 = 1$ corresponds to $SSR = 0$.

The whole workflow of the represented system can be summed up in Fig. 9 Variables such as the downhole temperature, pressure, DP tubing, annulus press, and choke size are

considered as an input for our linear regression model, which can develop an output of predicted oil production volume based on these features.

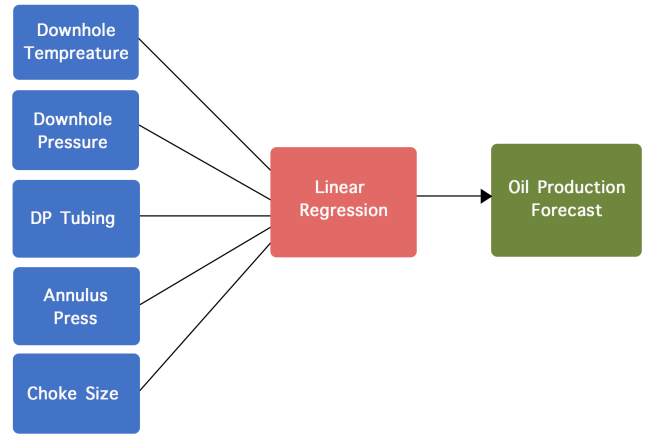

Fig. 9. Flow chart of oil production prediction system based on linear regression model

IV. RESULTS

Scatterplot and Matplotlib libraries are used to show how the model is predicting the oil production in comparison to the actual production volume (Fig. 10).

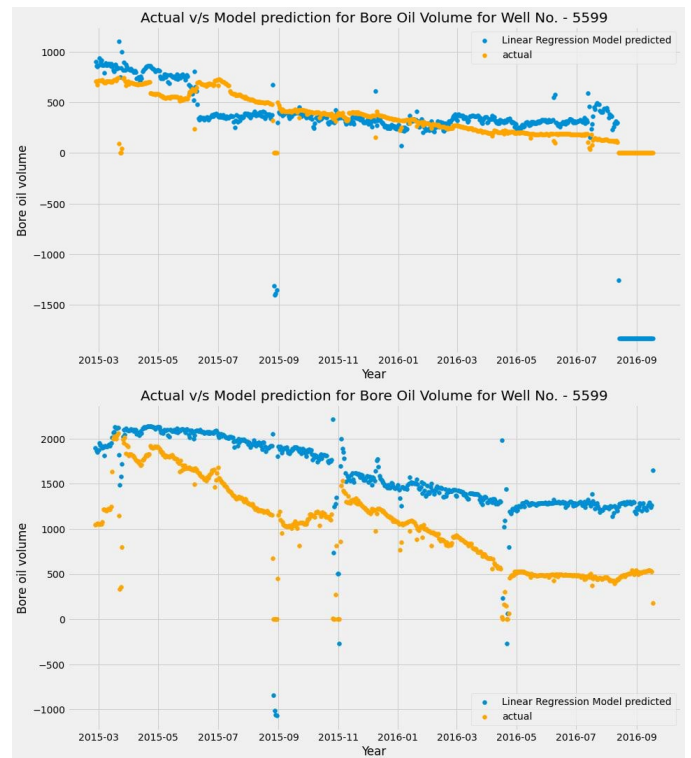

Fig. 10. Scatterplot and Matplotlib libraries using to show how the model is predicting the oil production in comparison to the actual production volume

$$RMSE = \frac{\sum_{i=1}^n (y_i - \hat{y})^2}{n} \quad (3)$$

RMSE	MSE
0.30292596179787934	0.2861434684281355

Mean Squared Error represents the average of the squared difference between the original and predicted values in the data set. It measures the variance of the residuals.

$$RMSE = \sqrt{MSE} = \sqrt{\frac{\sum_{i=1}^n (y_i - \hat{y})^2}{n}} \quad (4)$$

Root Mean Squared Error (RMSE) is the square root of Mean Squared error. It measures the standard of residuals.

Based on the above two results, it obvious that the model which is used in this study is correct and accurate because the mean absolute error that has been received after the analyses is 0 (MSE is 0.2 & RMSE is 0.3). This adds more advantages to the method used by the researchers of this study.

The results of this study can be explained by comparing the results of other studies presented in the literature review part. In study [16], the features used in the model are mostly related to volumes such as standard volume and metered volume. However, the model of this study, linear regression, takes into consideration much broader features such as temperature, pressure, and choke size that explains the system more. Moreover, in study [17], eight models have been used to make oil predictions which are very complex. Whereas, in this study, only a linear regression model has been used due to its simplicity and accuracy which have achieved really interesting results. Hence, a good prediction has been obtained in this study through only one mode. Furthermore, the researchers in this study haven't focused on each feature individually and which one is more important, but have favored getting a general model that takes all the features into account contrary to what Kumar and his colleagues have done in study [18].

V. CONCLUSION

Today, fossil fuels, such as oil, are the most important sources of energy. They are commonly used in various industrial and commercial sectors. However, their production is complex and requires special management and planning.

It is crucial that oil engineers are aware of the status of their wells and are able to perform their duties properly. In this study, they proposed a linear regression method to estimate the oil production value. This method can be used to analyze the various independent variables that affect the oil production process.

The proposed method would be able to accurately predict the oil production value. It can also achieve interesting results by analyzing the data collected during the study.

Abstract—There have been various pathfinding algorithms created and developed over the past few decades to assist in finding the best path between two points. This paper presents a comparison of several algorithms for pathfinding on 2D grid maps. As a result, this study identified Jump Point Search Block Based Jumping (JPS (B)) as a potential algorithm in term of five evaluation metrics including search time. The comparisons pointed out the potential algorithm and code optimization was performed on the selected JPS(B) algorithm, and it was named JPS(BCO). This paper also explores issues regarding the JPS(B) and how to resolve them in order to optimize access to the index pointer. The presented enhance JPS(BCO) is capable to search optimal path quicker than the original JPS(B) as demonstrated by experimental findings. An experiment of different size grid maps is conducted to validate the ability of the proposed algorithm in term of search time. The comparative study with original JPS (B) exhibits the enhancement that has more benefits on grid maps of different size in terms of search time.

Keywords—Comparative; jump point search; optimization; pathfinding; path planning

I. INTRODUCTION

Pathfinding algorithm has become one of the popular techniques to search for a path while avoiding obstacles at the same time. There have been numerous applications of pathfinding such as robotics, virtual reality [1], and commercial games [2]. In the past, pathfinding has traditionally focused on finding the shortest route. However, nowadays, it also focuses on finding the safest, cheapest, or most convenient route to avoid tolls, roads, or other obstacles [3].

Maps and graphs are common methods for representing environments in pathfinding. Most pathfinding algorithms consider the pathfinding environment as a key attribute to determine navigation performance [4]. Navigation meshes, grid maps, and waypoint graphs are three popular pathfinding environments. The superiority of one pathfinding environment over another has been debated for many years. A few advantages and limitations of the most common pathfinding environments used in games are summarized in [5]. Grid maps are the most popular pathfinding environment due to the simplicity and ease of use [6]. Furthermore, it is also relatively fast to generate a grid map and it only includes two categories

of cells: passable and block able [7]. The movement of an agent in grid map is limited to eight possible directions. Every vertical and horizontal movement in the grid has one cost unit, while the diagonal movement has a cost of 1.4 units.

Over the past decades, the performance of the pathfinding has been evaluated through various comparisons and analysis. Recently, [8] has compared traditional pathfinding which is A* algorithm and Depth First Search (DFS) with state-of-the-art algorithms, Jump Point Search (JPS) and Subgoal Graph. By testing the four algorithms on eight different grid maps, the author discussed several of the advantages and disadvantages of each algorithm according to the grid maps. As another example, [9] also compared two well-known algorithms: A* and Iterative Deepening A* (IDA*). They concluded that when there are no obstacles on the map, IDA* generally performs better than A*. However, when it comes to memory and time usages, IDA* may perform worse if opponent characters are in parallel positions and blocked by obstacles.

On the other hand, [10] conducted an analysis to compare performance of A* and Basic Theta* algorithm. Results from this study indicate that the A* and Basic Theta* algorithms have both similar completeness and time taken, but the A* has the benefit of searching less nodes, while the Basic Theta* algorithm returns shorter results.

Despite being one of the oldest algorithms, A* is still being favored to be included in the various researches for comparison. Although there are numerous researches in the literature on the comparative analysis of several pathfinding algorithms, however, to date, there have been very few research on the comparative analysis of Jump Point Search algorithm. This paper aims to compare A* and four versions of Jump Point Search using source code which are made available by the author [6]. The total five algorithms which included in this study are A*, JPS, JPS(B), JPS+, and JPS+ (P).

One of the evaluation metrics that is commonly used in comparisons and analyses is the amount of time taken during search. In video games [11], search and rescue (SAR) [12], and unmanned aerial vehicle (UAV) navigation [13], the search time is one of the most critical aspects. Therefore, the key motivation for this study is to reduce the search time.

Apart from comparing the pathfinding algorithms, this paper will also discuss code optimizations on the potential algorithm JPS(B) which are derived from the preliminary analysis. The code optimization yields a slight increase in terms of the search time. Thus, the fundamental objective and contribution of the current paper aim to present a comparative analysis on several pathfinding algorithm and a slight code optimization to the potential algorithm. This comparative analysis is important to other researcher for evaluating the performance of pathfinding algorithm and the code optimization performs on it.

In the remainder of the paper, the sections are arranged as follows. In Sections II, reviews of related works on JPS algorithms and descriptions of the JPS are provided. The methodological approach for the experimental setup was explained in Section III. Experimental result is presented in Section IV, while JPS(BCO) optimization and result is discussed in Sections V and VI, respectively. Conclusions and recommendations for future work are presented in Section VII.

II. RELATED WORKS

It was found that most pathfinding algorithms are based on A*, regardless of whether they are single or multi-agent pathfinding. A* algorithm was successful in solving pathfinding problems, and since that, numerous studies have concentrated on improving and optimizing A* algorithm. Path scoring is used by A* algorithm to determine the optimal path from the initial node to the end node [14]. Another prominent pathfinding algorithm is the Jump Point Search (JPS) which is the successor of A* variants introduced by [15]. They affirmed that the JPS accelerated more than A* and JPS has gain many attentions from other researcher after that.

Using JPS, an undirected and eight-connected grid map can be identified and eliminated from many path symmetries through combination of A* search and pruning rules. JPS algorithm utilizes pruned neighbor rules to determine which nodes should be searched while jump points are determined by their location relative to forced neighbor. Later in 2014, enhanced JPS is presented in [6] which includes four varieties of enhancement which includes jumping by block, new pruning rules and adds a pre-processing step prior to searching process.

The existing literature on JPS is extensive and focuses particularly on describing some of the more recent developments and enhancements. A summary of the research on JPS's improvement can be found in Table I.

Based on Table I, it is shown how JPS has been enhanced and applied to several areas, including home service robots and even in logistics for AGV. Most of the improvements were focused on reducing search times, which are considered valuable even for a few seconds. Apart from that, the aim is to minimize or shorten the path length as shown in (Ma et al., 2019). The related works conclude that the trends in optimizing the JPS algorithm focus on faster search times, which is also the motivation for this study.

TABLE I. SUMMARY OF JPS'S ENHANCEMENT

Ref.	Explanation		
	Objectivity	Description	Application
[16]	Improve waiting steps and movement steps	IJPS combines JPS with Congestion control in two stages: online and offline mode.	Autonomous Ground Vehicle (AGV)
[17]	Decrease search time and secure distance for robot and the barrier	SD-JPS merge the idea of a jump point with the node domain matrix to suggest a different jump point and limitation that satisfy the JPS 's quick search results and achieve the secure distance between the robot and the barriers	Robotic
[18]	In addition to identifying the direction of the next path point relative to the current path point, it uses vector cross product to verify connectivity between the previous and last points of each original point.	Enhancements are presented in this paper to minimize redundant path points and optimize path length by shortening paths. In order for a robot to move, its pose must be adjusted in points, so the vector cross product and the vector dot product are applied.	Home Service Robot
[19]	Using grid signage, the grid environment is pre-processed, and a valuation function is used to determine the optimal path through the grid.	To improve the path efficiency, this algorithm optimizes the open list with the minimum binary tree, and enlarges the weight coefficient to choose the appropriate valuation function.	Radar simulation system
[20]	The InvJPS algorithm attempts to resolve the problem of inventory-driven pathfinding in the literature	When used in inventory-based variants of game maps, InvJPS maintains JPS's optimality guarantees and its symmetry breaking benefits.	Video Games

III. EXPERIMENTAL SETUP

Original source code from [6] can be downloaded from <https://bitbucket.org/dharabor/pathfinding>. The given source code consists of several pathfinding algorithm in the same program. In Table II, an overview of the five pathfinding algorithms selected for comparison is presented in detail.

Table II shows that all algorithms were unweighted, except for the A* algorithm. A weighted version of A* algorithm is also available as used in [21] for their enhancements. However, for the purpose of simplification and standardization, only the unweighted version of the algorithms has been considered in this study, and the weighted version has been discarded.

While the given source code is in C++, [6] developed the code on Linux 20.04. Computer with Windows 10 operating system were used for the purpose of this study. Therefore, an Oracle VM VirtualBox 6.1.30 and Ubuntu 20.04 platform was used to match the original platform.

TABLE II. OVERVIEW OF PATHFINDING ALGORITHM USED IN THIS STUDY

Algorithm	Algorithm name (source code)	Description	Unweighted	Weighted
A*	astar	Traditional algorithm which utilizes an open list and close list to store each visited and unvisited nodes.	✓	✓
JPS	jps	Enhance A* by utilizing a jump point to skip unnecessary nodes by following two set of pruning rules.	✓	X
JPS (B)	jps2	In order to boost the original JPS's performance, it uses block-based jumping	✓	X
JPS+	jps+	This algorithm differs from original JPS as it adds pre-processing to the search method	✓	X
JPS+ (P)	jps2+	This algorithm similar to JPS+ which use pre-processing and also enhance pruning rules	✓	X

The computer has a minimum specification of 3.40GHz Intel Core i7-6700 processor with 4MB of RAM and 8MB of L3 cache. The first test data consists of four benchmark problem sets which were generated by [22]. Maps are taken from commercial games that are standards for 2D benchmarking. Only four maps and problem sets were selected to be included in the study. A description of the four selected benchmark files is presented in Table III.

From Table III, it is apparent that this selection of benchmark file was made to represent different dimension and problem sets complexity. For example, arena file represents smallest dimension which is 49x49 while orz700d contain 3880 problem sets with 1260x1104 dimension.

The comparison analysis relies on a five-evaluation metrics; the descriptions of these metrics can be found in Table IV.

The evaluation metrics used in this analysis are similar to those in [6] as shown in Table IV.

TABLE III. DESCRIPTION OF BENCHMARK FILES USED IN THIS STUDY

Map's name	Preview	Dimension	Number of problem set	Maximum length in scenario
arena		49 x 49	130	51.84
den501d		338 x 320	1170	466.90
brc202d		481 x 530	2550	1019.05
orz700d		1260 x 1104	3880	1551.98

TABLE IV. EVALUATION METRICS USED IN THIS STUDY

Metrics	Description
Total of expanded nodes	Since time is usually a hardware and software dependent factor, it is recommended to also determine the total number of expanded nodes in the search.
Total of generated nodes	An indicator of how many nodes are added to an open list after they are generated.
Total of touched nodes	Number of nodes undergoing evaluation, which may result in an update to priority queue.
Search time	Search time is measured in microseconds (wall clock time) which represents how long it takes the algorithm to find solution to the problem. Milliseconds are equal to microseconds multiplied by 1,000.
Memory cost	Metric that measures how much memory in bytes the algorithm uses in finding the end result.

IV. EXPERIMENTAL RESULT ON ANALYSIS OF PATHFINDING ALGORITHMS

Using the experimental procedure described by [23], all experiments were repeated 10 times and the average results calculated for each evaluation metric. A complete disconnect from the internet is kept throughout the experiment to prevent any disruptions caused by unwanted activity. Based on the five-evaluation metrics described previously, the following section discusses the results of the analysis. Results for the expanded nodes (average) are depicted in Table V.

To measure algorithm performance during pathfinding, the average of expanded nodes is an important criterion. In general, as the number of nodes grows, it takes longer time to find the path. Based on Table V, out of five algorithms, there is a tie between JPS (B) and JPS+ (P), whereas JPS+ (P) wins the remaining three benchmark files. Table IV and Table VII compare the result in term of generated nodes and touched nodes, respectively.

TABLE V. COMPARISON RESULT IN TERMS OF EXPANDED NODES

Algorithm	Expanded nodes (average)			
	arena	den501d	brc202d	orz700d
A*	31.42	5862.18	15997.63	29104.21
JPS	4.87	196.80	578.16	919.00
JPS (B)	1.55	113.43	342.81	479.53
JPS+	3.90	195.86	577.22	918.09
JPS+(P)	1.55	113.43	342.81	479.53

TABLE VI. COMPARISON RESULT IN TERMS OF GENERATED NODES

Algorithm	Generated nodes (average)			
	arena	den501d	brc202d	orz700d
A*	99.05	6100.47	16294.91	29497.70
JPS	11.11	224.03	606.61	951.14
JPS (B)	10.94	151.64	386.26	527.28
JPS+	9.46	222.27	604.85	949.36
JPS+(P)	11.05	151.80	386.45	527.44

TABLE VII. COMPARISON RESULT IN TERM OF TOUCHED NODES

Algorithm	Touched Nodes (Average)			
	arena	den501d	brc202d	orz700d
A*	274.07	48830.13	133876.84	247457.73
JPS	17.05	465.26	1336.50	2177.84
JPS (B)	13.69	334.51	1022.47	1565.88
JPS+	14.45	462.73	1333.97	2175.27
JPS+(P)	13.92	335.51	1023.80	1567.10

In Table VI, the average generated nodes that are injected into the open list show JPS+ to be the winner for the arena file, while JPS (B) is the winner for the rest of the files. In Table VII, in term touched nodes, JPS (B) is the most excellent for all four benchmarks file as it exhibits the smallest number of touched nodes in average. In terms of search time, the obtained result is presented in Table VIII.

In Table VIII, in terms of search time in microseconds, JPS+ is the winner for arena, while JPS+ (P) for the rest of three benchmark files. This situation is because the JPS+ and JPS+ (P) is based on pre-processing enhancement, thus, it will speed up the search time.

For the final evaluation metrics, the algorithms were compared in terms of memory in bytes. The comparison result is depicted in Table IX.

Based on Table IX, the lowest memory consumption for arena file is A*, while JPS (B) is the top algorithm for the rest of the files.

As a continuation of the analysis described previously, this study includes further calculations to find the potential and superior algorithm for further code optimization. To identify the superior algorithm among five previously tested algorithms, a scoring method was used.

TABLE VIII. COMPARISON RESULT IN TERMS OF SEARCH TIME

Algorithm	Search Time (microseconds)			
	arena	den501d	brc202d	orz700d
A*	18.86	3510.18	12111.38	24633.38
JPS	7.01	86.00	238.84	414.97
JPS (B)	3.36	69.91	206.85	319.55
JPS+	2.37	73.52	220.77	332.63
JPS+(P)	2.57	57.88	171.90	268.09

TABLE IX. COMPARISON RESULT IN TERMS OF MEMORY

Algorithm	Memory (bytes)			
	arena	den501d	brc202d	orz700d
A*	6182968	6551496	7215324	8400304
JPS	6183768	6301944	6721476	7513048
JPS (B)	6183728	6301904	6721436	7248744
JPS+	6239296	8224656	10925668	30021816
JPS+(P)	6239256	9017384	12775476	40856424

TABLE X. OVERALL SCORE FOR THE SUPERIOR ALGORITHM

Algorithm	The Superior Algorithm (Overall)				
	arena	den501d	brc202d	orz700d	Total score
A*	1	0	0	0	1
JPS	0	0	0	0	0
JPS (B)	0.5	3	3	3	9.5
JPS+	2	0	0	0	2
JPS+(P)	2	2	2	2	8

For this experiment, each winner algorithm receives a score of 1 and a score of 0.5 for a tie situation. Scoring calculation has been summarized and presented in Table X.

Table X shows that according to five evaluation metrics as explained previously, JPS (B) is the superior and potential algorithm among the five algorithms tested in the given source code. Thus, JPS(B) is the chosen algorithm for further testing and code optimization which will be explained in the following section.

V. JPS(B) CODE OPTIMIZATION

For the implementation of JPS(B), the use of vector is widely utilized in the program’s code as highlighted in Fig. 1.

As depicted in Fig. 1, JPS (B) in its implementation spends numerous of its time accessing the vector, thus, impeding, and slow down the overall process to search the path. For example, there are 130 scenarios in arena.scen benchmarking file, and it requires almost 1448 method invocation by the syntax “jp_ids_at(i)” in the loop. Every time the program runs the syntax “at(i)” to access the vector’s element, compiler will do a range checking. When the program trying to access an element that does not exist in the vector, it throws an exception. Errors will be more easily found using this checking procedure through the syntax “at(i)”. However, as mentioned earlier, the syntax “at(i)” will cause overhead to the overall program in terms of search time.

In this code optimization for JPS(B), the original implementation access values from the “std::vect” class by using syntax “at(i)”. The implementation is changed from syntax “at(i)” to syntax “[i]” to access the vector as highlighted in Fig. 2.

The two differ significantly: “at()” checks boundaries while operator “[]” does not. Thus, this will result in a reduction of overhead for the program’s code since the syntax for accessing the vector has been changed.

```

uint32_t searchid = problem->get_searchid();
uint32_t id_mask = (1 << 24) - 1;
for(uint32_t i = 0; i < jp_ids_.size(); i++)
{
    // bits 0-23 store the id of the jump point
    // bits 24-31 store the direction to the parent
    uint32_t jp_id = jp_ids_.at(i);
    warthog::jps::direction pdir = (warthog::jps::direction)*(((uint8_t*)&jp_id)+3);

    warthog::search_node* mynode = nodepool->generate(jp_id & id_mask);
    neighbours_.push_back(mynode);
    if(mynode->get_searchid() != searchid) { mynode->reset(searchid); }

    if((current->get_g() + costs_.at(i)) < mynode->get_g())
    {
        mynode->set_pdir(pdir);
    }
}

```

Fig. 1. Snippet for JPS(B) source file.

```

uint32_t searchid = problem->get_searchid();
uint32_t id_mask = (1 << 24)-1;
for(uint32_t i = 0; i < jp_ids_.size(); i++)
{
    uint32_t jp_id = jp_ids_[i];
    warthog::jps::direction pdir = (warthog::jps::direction)*(((uint8_t*)(&jp_id))+3);
    warthog::search_node* mynode = nodepool->generate(jp_id & id_mask);
    neighbours_.push_back(mynode);
    if(mynode->get_searchid() != searchid) { mynode->reset(searchid); }

    if((current->get_g() + costs_[1]) < mynode->get_g())
    {
        mynode->set_pdir(pdir);
    }
}

```

Fig. 2. Snippet for JPS (BCO) source file.

VI. RESULT AND DISCUSSION FOR CODE OPTIMIZATION OF JPS (BCO)

Based on the results of previous preliminary tests, it is necessary to gain a good understanding of the JPS (B) algorithm in order to optimize it.

In the given source code implementation, JPS (B) were noticed to make good use of vectors and it can be manipulated to take advantage to shorten the search time. In JPS (B) source code, the way vectors are accessed has been modified, and the optimized code version is named JPS (BCO). The following Table XI is the comparison between JPS (B) and JPS (BCO) in terms of search time. The same four benchmark files were selected as used in previous preliminary testing. The experiment is also repeated 10 times and the average is calculated as shown in Table XI.

Based on Table XI, for the comparison, in terms of expanded, generated, and touched nodes, there are no differences between the JPS (B) and JPS (BCO). This is also the same with memory consumption. It is because the changes made to the vector did not affect any nodes. However, the result was placed in the same table as search time, to demonstrate the differences of overall performance.

TABLE XI. COMPARISON OF JPS (B) AND JPS (BCO)

Evaluation metrics	Algorithm	arena	den501d	brc202d	orz700d
Expanded nodes	JPS (B)	1.554	113.429	342.806	479.533
	JPS (BCO)	1.554	113.429	342.806	479.533
Generated nodes	JPS (B)	10.938	151.638	386.259	527.278
	JPS (BCO)	10.938	151.638	386.259	527.278
Touched nodes	JPS (B)	13.692	334.507	1022.475	1565.875
	JPS (BCO)	13.692	334.507	1022.475	1565.875
Search time (micro seconds)	JPS (B)	4.987	98.240	273.451	430.474
	JPS (BCO)	4.021	90.212	264.906	416.608
Memory (bytes)	JPS (B)	6185888	6304568	6719204	7245720
	JPS (BCO)	6185888	6304568	6719204	7245720

Fig. 3. Boxplot of result of JPS (B) and JPS (BCO).

In terms of search time, the average result is shown in microseconds which is much smaller unit than second and milliseconds. For arena file, the average search time using JPS (BCO) is only a microsecond shorter than JPS(B) performance. For the rest of the three benchmark files, each represents 8.0, 8.5 and 13.9 microseconds of faster acceleration in terms of search time. In order to provide a clear understanding of the code optimization results, a comparison of JPS(B) and JPS(BCO) search times is shown in Fig. 3.

From Fig. 3, in this boxplot, average time for JPS(B) take longer time in microseconds than JPS(BCO). In this modification of vector access's syntax, switching from “at()” to operator “[]” was a straightforward fix, but it resulted in a speed boost for the average of search time.

VII. CONCLUSION

Several pathfinding algorithms were compared including the well-known and traditional algorithm A*. The preliminary comparisons identify JPS(B) as a potential and the superior algorithms among the five tested algorithm. Thus, this paper performs a code optimization to the JPS(B) and called it as JPS(BCO). JPS(BCO) enhance JPS(B) performance by slightly shorten the search time.

In future, several modifications to the code implementation need to be studied in order to improve and enhance the performance of the JPS(B) significantly. The optimization should aim to improve not only the search time, but other evaluation metric such as total expanded nodes. Generally, it is not necessary to record time across platforms or machines for total expanded nodes to prove their performance, since the average is constant regardless of the platform.

In conclusion, this study has provided insight into potential and superior algorithms among JPS family members. As a result, this proposed work presents a comparison of existing

algorithms. Apart from that, this study improved the JPS(B) search time through code optimization. The direction of future research can be explored in other areas, such as SAR and UAV navigation for pathfinding optimization.

ACKNOWLEDGMENT

This research was conducted during the main author's study leave under the 2019 Academic Training Scheme for Bumiputera (SLAB) scholarship scheme. A special thanks is extended to the Ministry of Education Malaysia and Universiti Teknologi MARA for the generous funding and support. It is with great appreciation that this research is being conducted with the assistance of postgraduate students from the Media and Game Innovation Centre of Excellence (MaGICX) at Universiti Teknologi Malaysia (UTM).

Integrating User Reviews and Issue Reports of Mobile Apps for Change Requests Detection

Laila Al-Safoury, Akram Salah, Soha Makady

Department of Computer Science-Faculty of Computers and Artificial Intelligence, Cairo University, Cairo, Egypt

Abstract—There is abundance of mobile Apps released continuously on the App store, where developers are required to maintain these Apps to attain user satisfaction. Developers should consider all user feedback, as they are important resources for planning of next App's release. In order to consider user feedback, many platforms host mobile Apps and allow users to submit their opinions, such as: Google Play App store and Github Open-Source Development platform. The automated consolidation of user feedback from such platforms, and transforming it into a list of change requests would result in satisfying users across different platforms, and their analysis helps developer to reduce cost of time and effort to plan for the new release of the mobile App. In this paper, a framework is proposed which integrates user feedback from different sources and analyzes them using a state-of-art user reviews analysis tool to obtain a list of change requests, such list is further examined for similarity to remove duplicates and prioritize the identified change requests. A prototype is designed to implement the proposed framework and applied to AntennaPod. Consequently, the framework experimentation results show that reviews and issue reports can be analyzed almost equally despite the difference of text's nature.

Keywords—User review; feedback analysis; mobile app maintenance; text similarity

I. INTRODUCTION

The mobile App stores play an important role in distributing software products from different domains. In 2022 according to Statista website¹, Google Play store offers 3.3 million Apps for Android, while App store roughly includes 2.11 million Apps for iOS. The number of Apps increases over the years as they are widely discovered, purchased, and updated through the mobile App stores (e.g., Google Play store and App store). Recently, researchers have studied the effect of App stores on software engineering practices [1, 2], while others have analyzed the benefit of using user reviews for software engineering [3, 4].

One of the most essential resources for the requirements elicitation activity is user reviews [5], which is offered by App stores allowing users to evaluate the downloaded Apps and to express their opinions [6]. App reviews are textual feedback associated with a star rating that indicates user satisfaction from one to five, where one is the lowest rate and five is the highest rate. However, the analysis of user reviews manually for extracting user needs is a challenging and time-consuming task [7]. As stated by Pagano et al. [8] 23 reviews per day are

submitted in non-popular mobile Apps approximately and on average 4,275 reviews per day are received in popular Apps, such as Facebook. Besides, the feedback is usually written as unstructured text which cannot be parsed and analyzed easily.

Automated approaches are required to handle the consolidation of large amount of reviews and to perform review analysis tasks, such as: classifying feedback into maintenance tasks [9] or classifying feedback based on predefined topics [10] or based on user intention [11]. For example, reviews had been classified by Sorbo et al. into four intention categories based on user's intention while expressing their opinion such as information giving (opinion), information seeking (question), feature request (improvement or new feature), and problem discovery (bug report) [11].

In a recent review analysis survey [4], it had been raised that App store reviews can be integrated with other feedbacks available for developers to attain users' needs from more than one source, such as: Github [12, 13] and tweets [14, 15]. Since a mobile App can be hosted across platforms, such integration would demand a lot of manual effort from the App developer a lot of time and effort from App developer. The manual effort entails filtering manually such a large number of users' feedbacks from more than one platform to produce a list of change request which might still include duplicate change requests from different platforms.

In this paper, Google Play App store² reviews and Github³ issue reports are integrated. GitHub is a leading open-source software development platform worldwide, it has more than one million android open-source repositories, four million issue reports, and 69K contributors in 2022⁴. Accordingly, Github is a good candidate as an additional source for integration since there are a reasonable number of mobile Apps exists on both platforms. The proposed framework aims at combining Google Play reviews and Github issue reports for a certain App's version release to obtain a list of change requests which includes bugs and feature requests submitted by users from both platforms and to group similar change requests for producing a list of unique change request. This list guides App's developers in planning for next release to meet further users' satisfaction, while eliminating the manual needed developer effort to analyze each platform's feedbacks separately, and the possible error proneness of such process.

This paper is organized as follows: Section II presents a brief background overview and motivating example which

¹<https://www.statista.com/statistics/276623/number-of-apps-available-in-leading-app-stores/>

² <https://play.google.com/>

³ <https://github.com/>

⁴ <https://github.com/search?q=Android>

demonstrate the importance of the proposed framework. Section III, discusses the related work of issue reports and user reviews integration and compares between the previous work and the approach proposed. Section IV introduces the proposed framework used for integration users' feedback to obtain a unique list of informative user feedback of two intentional category types. Section V describes a case study for applying the framework's phases using a dataset and it also discusses the evaluation metrics used for evaluating the framework's results. Section VI presents the results of the case study and its discussion. Finally, Section VII concludes the study and explains the future avenues.

II. BACKGROUND AND MOTIVATION EXAMPLE

In this section, the Google Play store's reviews and Github's issue reports are introduced to illustrate their attributes, also the importance of users' feedbacks integration across different platforms is explained further.

Fig. 1. Example of Google app review.

The App reviews are considered as one of the main framework inputs, therefore, it is important to understand the metadata associated per user review. As illustrated in Fig. 1, an example is provided by Google Play App store where a user named "Jon Dean" submitted a review on 12 May 2022, rated the App by "4 stars", and stated a bug experienced while using Antenna pod App version 2.5.2 (i.e., a podcast manager and player App). As shown in Fig. 1, each review has a date, user name, title, body, rate, number of likes, and a reply.

Fig. 2. Example of Github issue report.

In Github platform, for each App's release there are a set of issues submitted by users to be received by App developers to inform them whether there is a bug or a feature request to be considered in the following release and sometimes users might ask a question, when the issue is executed, it became a closed issue else it remains as an open issue. In Fig. 2, a user named "PersimmomKnob" submitted issue #4210 in Github platform, the user expressed a desired feature request regard sorting subscription feature, and it was labeled as feature request (not all issues are labeled). As shown in Fig. 2, each issue has a date, an id., open or closed issue label, user name, title, body, label (type of issue), number of likes, comments, and Assignees (i.e., members who works on this issue to be solved).

TABLE I. ANTENNAPOD MOBILE APP ISSUE REPORTS AND REVIEW EXAMPLES

Feedback Type	Description
Review	Downloads don't show in the downloads folder. <u>Podcasts dont seem to download automatically.</u> I like the design though...
Issue Report	When I add the Feed http://podcast.hr2.de/derTag/podcast.xml it shows all files/episodes as 0 Byte. <u>They are not automatically downloaded.</u> I can download manually and listen to every episode. Every time the feed updates the first entry vanishes (even when downloaded) until everything is gone. Recent version (0.9.8.0) from play store on Android 4.1.1.
Issue Report	When the automatic download updates the feeds and a new episode is found, that <u>episode is not downloaded immediately.</u> Instead AntennaPod will wait for your custom set update interval (2h in my case). Leaving the house with an undownloaded episode is a bit annoying, especially when the download would have only taken a few seconds on your wifi. I did not test if that issue appears when setting a high update interval, but if it does one would receive all new episodes only after a high delay. My personal fix is to regularly check for new podcasts and hitting the update button manually, but I would like AntennaPod to be purely push- and not pull-style.

In Table I, an example of AntennaPod mobile App's version 0.9.8.0 reviews from Google Play⁵ and issue reports from Github⁶ where users express the same problem regard not being able to download their podcast automatically (i.e., underlined sentences). In contrast to reviews, the issue reports are more detailed and all sentences are focused in describing one problem rather than stating more than one information. The problem is expressed using different keywords, such as "download automatically" is similar to "download immediately" and "Podcasts" is similar to "Episode" as a podcast consists a set of episodes. Accordingly, the automation of integrating reviews and issue reports prevents the challenges of manual integration, such as: time-consuming, error prone and redundancy. Besides, the automation is needed to (i) handle the different usage of phrases which is challenging automatically to group all such reviews and issue reports, which express a bug or a feature request, into one list, and (ii) consider the rate at which the same problem is reported from different platform as a possible priority/importance indicator for that problem.

III. RELATED WORK

A few approaches address integrating user reviews and other resource and most of those researches aims at using one source of data to enrich the other for a specific purpose which fulfill their proposed approach's purpose. Such approaches are discussed below in order to explain their aims and the differences between the proposed framework and their work.

Zhang et al. [12] proposes an approach for tagging the unlabeled Github issue reports using labeled issue reports and user reviews. Github issue report have an associated label, which define the type of this issue report (i.e. bug or feature request), and this label are optionally added which leads into some unlabeled issue reports. On the other hand, user reviews are classified into bug and feature request using a tool then both labeled issue reports and classified reviews are used as input for calculating text similarity between unlabeled issue

⁵ <https://play.google.com/store/apps/details?id=de.danoeh.antennapod>

⁶ <https://github.com/AntennaPod/AntennaPod/issues>

reports and the input. On the contrary, the proposed framework focuses on integrating both reviews and issue reports for filling all issue reports' labels, which helps the developer to filter issue reports according to its label without dealing with redundant issue reports.

Zhang et al. [13] introduces an approach for grouping user reviews as a cluster which addresses bugs and feature requests of a certain mobile App, along with relevant issue reports for enriching the cluster of user feedback. This approach utilizes user feedback clusters for linking each cluster to set of relevant code classes (i.e., affected classes if this group of bugs or feature requests is implemented). The classes are obtained through calculating the text similarity between classes' names and text of reviews and issue reports within each cluster producing a ranked list of classes recommended for each cluster. The paper integrated reviews and issue reports for enriching the reviews' cluster for recommending more accurate classes, which guides the developer on having a list of classes recommended per each cluster, unlike the proposed framework, if an issue report is not similar to any review, then it will be excluded, also if there are a number of similar issue reports that are not similar to any review, they will be excluded.

Yadav et al. [15] proposes a framework to analyze the users' feedback, from Google Play store and Twitter, by embedding their semantics. The framework classifies the feedback into two classes of bug reports and feature requests then it investigates whether the approach can identify the similar feedbacks. This paper is an example for integration using Twitter, where user can express their opinions regard mobile Apps through posting a tweet with a limited 140 character. On the contrary, the proposed framework uses different type of information which Github issue report where users are able to write in more details as shown in Table I and they are not limited to express their opinions briefly using limited short text.

IV. PROPOSED FRAMEWORK

In this framework, as shown in Fig. 3, the Google Play App store is used as a source of reviews while Github is used as a source of issue reports where both reviews and issue reports form feedback inputs. There are three main phases which process the input to produce a unique change request list, which are explained as follows:

1) *Feedback pre-processing*: Each feedback has a text which is divided into sentences and pre-processed by applying Snowball Stemming [16].

2) *Feedback classification*: Each sentence is parsed using Stanford Typed Dependencies (STD) [17] then mapped to a set of 246 natural language processing (NLP) heuristics⁷ to obtain the sentence's structural patterns associated with one of user's categories. Additionally, each sentence is analyzed to get sentiment annotator using Stanford CoreNLP [18] for improving the accuracy of intent classification. Both structural patterns and sentiment features are used as an input for a pre-

trained Machine Learning [19, 20]. The output of this phase is a list of change requests classified as bug or feature request.

3) *Text similarity calculation*: According to previous work [12], cosine similarity measure and BM2F model were used for calculating textual similarity between issue reports, while Jaccard similarity is used for calculating textual similarity between issue reports and reviews because it performs better when data is sparse. The output of this phase is a unique change requests list where similar change requests are grouped.

For applying phase 1 and phase 2, there are a set of publicly-available App review mining tools according to the recently published survey [4]. SURF (Summarizer of User Reviews Feedback) was used in other research papers and they showed promising results [12, 13]. For input processing, SURF is used as a tool which summaries the feedback written by users to assist developers in figuring out user needs and dealing with an abundance number of reviews. The tool works as follows: (i) classifies user's intention determining the type maintenance task required to fulfill user's needs, (ii) gathers sentences of the same topic, (iii) receives user feedback in XML format and also generates the output in XML format which allows integrating them in third party frameworks, and (iv) produces a visualized report for browsing the summaries easily.

Moreover, SURF is constructed based on User Reviews Model (URM) [21, 19] which categorizes each sentence contained in App reviews into two dimensions: (i) the user intention: It is user's goals when writing a review (such as: Information giving, Information seeking, Feature request, Problem discovery, or other), and (ii) the review topics: It finds the most relevant topic(s) belong to this review (such as: App, GUI, Contents, Pricing, Feature or Functionality, Improvement, Updates/Versions, Resources, Security, Download, Model, or Company).

Fig. 3. Proposed framework phases.

Fig. 4. Example of output report.

⁷ <https://www.ifi.uzh.ch/seal/people/panichella/Appendix.pdf>

Not all of the change request sentences will appear on the output report in case it did not match an intention type or one of the predefined topics. Moreover, a sentence can be dismissed from the output report due to the sentence scoring which is calculated to select 2/3 of total sentences having the highest scores will be included on the report. The rewarding factors of sentence scoring are: (i) sentences classified as feature requests or bug reports, (ii) sentences related to specific topics, (iii) longer sentences, and (iv) sentences containing frequently discussed features. Afterwards, the output report is obtained in XML format which can be easily browsed through visualized utility supported in the SURF replication package⁸. As illustrated in Fig. 4, the topics are listed in rows where each topic has four types of intention categories colored differently, each type has number of sentences extracted from xml input file, and the sentences appear when you click on the number.

The SURF tool produces XML file report which includes each feedback’s sentence and its user intention category. In this paper, the sentences are considered as change request, if it is classified as bug or feature request, extracted to form a list of change requests, then the text similarity is applied for reducing the list size by grouping similar sentences into one change request.

V. FRAMEWORK CASESTUDY AND EVALUATION

A case study is applied on the proposed framework using an open-source dataset for implementing and evaluating the phases of the framework. In this section, the details of such case study (section 5.1) and evaluation (section 5.2) are presented to address two research questions: (RQ1) ‘Can the framework classify the users’ reviews and issues to obtain a list of change requests?’; (RQ2) ‘To what extent the framework is capable of classifying all the change requests into bug or feature request accurately?’; (RQ3) ‘Does the framework similarity percentage is reasonable and worth to be a part of the proposed framework?’.

A. Experimental Case Study

In phase 1, the dataset used for the experimentation had been publicly shared by [12], it includes top 17 popular android open-source mobile Apps which are available in both Google Play store and Github. The user reviews and the issue reports were collected for each App during a specific period which is different from App to another, where the dataset includes 20,135 issue reports and 43,649 reviews. The framework is applied on “AntennaPod” App which includes 1108 Github issue reports and 2082 Google Play reviews, such data was collected from 3 August 2012 till 9 January 2018. Particularly, App version 0.9.8.0 was selected as input which is gathered from 19 October 2013 to 26 February 2014 (i.e. before version 0.9.8.1 publishing date on 27 Feb 2014) and it has 43 issue reports and 50 reviews.

Additionally, the date attribute in issue xml file had been added to the dataset for obtaining the version of App in which the issue was submitted.

</Manager>
```

Fig. 5. Example of dataset review and issue XML files.

As shown in Fig. 5, the dataset stores reviews and issue in form of XML format, where a set of attributes are defined for each review and issue report. In reviews, the xml file contains user name, date, user rating, review title, and review text (body), on the other hand, the issue reports xml file contains label, issue id., issue URL, description (body), title, and date.

In phase 2, the SURF tool requires the input in form of XML file, where attributes should be written in a specific format (as shown in Fig. 6). Accordingly, the attributes of the dataset xml files has to be converted to fit SURF tool input prerequisite specification in attributes naming (e.g. the review title attribute is named as <title> in issue report xml file, it has to be changed into <review_title> for all stored issue reports to fit SURF input file). For all reviews and Github issue reports of a version App, the naming of attributes are changed to match SURF input file, all non-English feedback are removed because the tool only process English text, then both feedbacks are gathered in one file for to be processed by the tool.

Fig. 6. SURF tool input XML file format [11].

TABLE II. SURF CLASSIFIED SENTENCES FOR DATASET

Source of Classified Sentence	Number of Sentences
Total Sentences (S)	70
Feature Requests in Reviews (R _F)	9 (7)
Bugs in Reviews (R _B)	4 (4)
Feature Requests in Issues (I _F)	19 (14)
Bugs in Issues (I _B)	10 (9)

⁸ <https://github.com/panichella/SURF/tree/SURF-v.1.0>

In Table II, when SURF tool is used to process the input only 70 sentences were classified while the rest did not appear in the output XML report. The SURF tool does not provide a sentence in output report unless it is able to classify its intention type (i.e., according to “predefined patterns” matching) and also if it is able to classify its topic (i.e., based on “topic words dictionary” matching). Additionally, sentence scoring results is reduced by 30% of total sentences according to four factors which are previously mentioned. As shown in Table II, the number of sentences per each type is mentioned and the number of correctly classified types is written between brackets. For example, the tool classified nine review’s sentences as feature requests and compared to the manually labeled 19 sentences mentioned in Table IV only 7 sentences were classified correctly. According to the results mentioned in Table II, RQ1 is answered:

Answer to RQ1: the framework is able to classify both reviews and issues using the same approach explained previously in Section IV.

TABLE III. CHANGE REQUESTS SIMILARITY FEATURES

Change Request	Issue	Review
Login Dark Theme	2	0
Auto Delete	1	3
Auto Download	2	1
Pause Frequently	0	2
Stop Playing	1	2
fix widget	0	3
Download Scheduler	0	2
Less Cache	0	2
skip back	1	1
Total	7	16

In phase 3, the list of change requests is studied manually to analyze the repeated requests, the results are depicted on Table III which lists the name of the addressed feature, and the number of issues or reviews mentioned this feature as a bug or a feature request having similar change request. There are nine change requests which had been expressed by more than one user whether in Github or Google Play store platforms.

B. Case Study Evaluation and Results

After executing the framework, the dataset’s sentences are manually classified and labeled to be used in evaluating the accuracy of the framework’s output. Thus, the input is divided into a set of sentences to be manually classified for obtaining the user intention type for each sentence to be used as a ground truth. For splitting the input into sentences, a natural language toolkit (NLTK) has been utilized in python program which offers NLP methodology implementation.

As shown in Table IV, the total number of sentences in the dataset are 252, part of these sentences belongs to issue report extracted from Github platform (135 sentences) and the other sentences belong to reviews extracted from Google Play store (117 sentences). The manually labeled sentences show that 16% of reviews’ sentences are feature requests while 23% of

reviews’ sentences are bugs, on the other hand, 17% of issue report’s sentences are feature requests while 39% of issue report’s sentences. Those percentages show that, in such dataset, only half of the total sentences are useful for the developers as they state the changes requested by the App’s users.

For evaluating accuracy of the change request list’s output sets (i.e. list of sentences), both ground truth’s four sets (MI_B , MI_F , MR_B , and MR_F) shown in Table IV and SURF tool’s produced sets (I_B , I_F , R_B , and R_F) shown in Table II are used to measure recall and precision which are a well-established metrics reported in Equations 1 and 2.

$$\text{Recall} = \frac{TP}{TP+FN} \quad (1)$$

$$\text{Precision} = \frac{TP}{TP+FP} \quad (2)$$

TABLE IV. MANUALLY CLASSIFIED SENTENCES FOR DATASET

Source of Sentence	Number of Sentences
Total Sentences (MS)	252
Google Play Reviews (MR)	117
Github Issue Reports (MI)	135
Feature Requests in Reviews (MR_F)	19 (16%)
Bugs in Reviews (MR_B)	27 (23%)
Feature Requests in Issues (MI_F)	23 (17%)
Bugs in Issues (MI_B)	53 (39%)

In particular, TP represents the number of true positives reviews/issue reports classified correctly; False Positive (FP) is the number of reviews/issue reports classified incorrectly by the approach; and False Negative (FN) is the number of correct reviews/issue reports (i.e., manually classified as bug or feature request) that are not classified by the approach.

For applying accuracy measurement, three variables are required to calculate precision and recall as in equation (1) and (2), shown in Table V. Also, F-measure is used as it combines both recall and precision by calculating the harmonic mean of precision and recall to obtain the overall accuracy of the proposed approach, known as the F-measure in Equation 3:

$$\text{F-measure} = 2 * \frac{\text{Precision} * \text{recall}}{\text{Precision} + \text{recall}} \quad (3)$$

After calculating accuracy measurements, it is noticed that precision of bug is better than feature request (i.e. the ability of predicting change requests correctly), as shown in Table VI and Table VII, for both inputs issue reports or reviews. On the other hand, the recall of feature request is better than bug (i.e., the ability of to find all manually labeled relevant cases) in both issue reports and reviews. The SURF tool is able to predict the intentional type as they follow predefined textual patterns, such as: bug patterns “[something] is missing” and “[someone] has an issue”, but these patterns are not sufficient for covering all sentences expressing bugs and feature requests to be matched with the dataset. According to the results mentioned in Table VI and Table VII, RQ2 is answered:

TABLE V. THE CALCULATION OF ACCURACY MEASUREMENTS' VARIABLES

Accuracy Measure	TP	FN	FP
Bug Issues	Numbers of issues sentences classified as "bug" and manually labeled as "bug".	Numbers of issues sentences manually labeled as "bug" but not classified as "bug".	Numbers of issues sentences not manually labeled as "bug" but classified as "bug".
Feature Request Issues	Numbers of issues sentences classified as "feature request" and manually labeled as "feature request".	Numbers of issues sentences manually labeled as "feature request" but not classified as "feature request".	Numbers of issues sentences not manually labeled as "feature request" but classified as "feature request".
Bug Reviews	Numbers of reviews sentences classified as "bug" and manually labeled as "bug".	Numbers of reviews sentences manually labeled as "bug" but not classified as "bug".	Numbers of reviews sentences not manually labeled as "bug" but classified as "bug".
Feature Request Reviews	Numbers of reviews sentences classified as "feature request" and manually labeled as "feature request".	Numbers of reviews sentences manually labeled as "feature request" but not classified as "feature request".	Numbers of reviews sentences not manually labeled as "feature request" but classified as "feature request".

TABLE VI. CLASSIFICATION EVALUATION OF SURF RESULTS FOR ISSUE REPORTS

Change Request Type	TP	FN	FP	Precision	Recall	F-measure
Bug	9	44	1	90%	17%	29%
Feature Request	14	9	5	74%	61%	67%

TABLE VII. CLASSIFICATION EVALUATION OF SURF RESULTS FOR REVIEWS

Change Request Type	TP	FN	FP	Precision	Recall	F-measure
Bug	4	23	0	100%	15%	26%
Feature Request	7	12	2	78%	37%	50%

Answer to RQ2: The experiment's precision was better than recall which affect negatively in F-measure, which means that the tool is able to classify most of the sentences correctly but it is not able to detect all relevant sentences in the used dataset. A few of modifications are exerted in Section 6 for enhancing the results of the tool used in phase 3.

The output list is reduced using similarity calculation to reduce the total number of change requests (CR); thus, each sentence S_i text is compared to other sentences. If S_i is similar to one on more sentences, then they will be grouped as one change request, else nothing will change. The evaluation is

performed by calculating the percentage of reduction using CR which is the total number of change requests' sentences before reduction (i.e., before grouping) and unique change requests (UCR) which is the total number of unique change requests' sentences, shown in Equation 4.

$$\text{Reduction Percentage} = \frac{\#UCR * 100}{\#CR} \quad (4)$$

According to Table III and Equation 4, the total number of repeated change requests is 23 change requests (i.e., 7 issues and 16 reviews), the change requests list will be reduced from 252 into 238 (i.e., reduced by 6%). According to such results mentioned, RQ3 is answered:

Answer to RQ3: The framework's output of the similarity percentage is slightly reduced in phase 3 compared to the original change request list produced from phase 4, this observation is related to the nature of selected App's version dataset which needs to be investigated for other Apps' dataset.

VI. RESULTS ENHANCEMENT AND DISCUSSION

In this section, the impact of adding the title of the change request (e.g., review or issue report) is investigated to the change request body as an input to phase 2. Then, the output of phase 2 is evaluated to check whether the added topic may improve the recall values. Additionally, the patterns of SURF tool were studied to examine their sufficiency for covering all types of sentences belongs to bug or feature request.

Another experimental trial has been performed for enhancing the results, which is adding the title of the change request into the beginning of the body. Because SURF tool only considers the review/issue report's body without including its title, i.e., it is a sentence-based classifier, although the title might contain valuable general information about the bug or feature request itself while the body includes extra explanatory information. Also, including the title might increase the fourth factor of sentence scoring which increase the feature discussed. In Table VIII, the evaluation results slightly changed only in review input, and it was a minor change where an extra bug was classified by SURF correctly (i.e., increasing recall and f-measure) and a feature request where misclassified (i.e., decreasing precision and f-measure).

As shown in Table IX, when the sentences are changed to follow the predefined SURF pattern, such in all examples except the third one (i.e., begin with the pattern by splitting the sentence), the SURF tool was able to classify the sentences correctly. Additionally, the position of the pattern affects the ability of classification, since the tool is not able to detect the pattern when it is embedded in the middle of a long sentence. It is noticed that papers [12, 13], explained in Section II, used SURF tool and both mentioned obtaining high overall accuracy of 91.36% and 95.64% respectively which are stated to be acceptable results. Although, this study uses the same dataset as paper [12] but the accuracy obtained was 77% as not all of the dataset was used, only one version of an App.

TABLE VIII. CLASSIFICATION EVALUATION OF SURF RESULTS FOR REVIEWS INPUT (INCLUDING TITLE)

Change Request Type	TP	FN	FP	Precision	Recall	F-measure
Bug	5	23	0	100%	19%	31%
Feature Request	7	12	2	70%	37%	48%

TABLE IX. ALTERING SENTENCES ACCORDING TO SURF PATTERNS

SURF Pattern	Original Sentence	Altered Sentence
“[something] can be fixed by [something]”	My personal fix is to regularly check for new podcasts and hitting the update button manually, but I would like AntennaPod to be purely push- and not pull-style.	This <u>can be fixed by</u> regularly checking for new podcasts and hitting the update button manually, but I would like AntennaPod to be purely push- and not pull-style.
“[something] should be fixed”	The widget needs fixing since it doesn't always work.	The widget <u>should be fixed</u> since it doesn't always work.
[someone] could/should add/provide/offer/integrate [something]	Congrats for your job in this App, its so amazing and for me almost perfect, I don't know if its hard to do or not, but if you could add the auto delete of the podcast when we finish it will be good.	Congrats for your job in this App, its so amazing and for me almost perfect, I don't know if its hard to do or not. <u>if you could add</u> the auto delete of the podcast when we finish it will be good. Thanks!
	Wish i could schedule when it downloads the podcast.	Wish <u>i could add</u> a schedule when it downloads the podcast.

VII. CONCLUSION AND FUTURE WORK

The users' contribution in expressing their opinions is considered as an important source for evolving mobile Apps and for better release planning. Mobile App can be distributed on many platforms where each platform allows users to submit their feedback for other users and App's developers to ask questions, state information, report a bug, or suggest a modification. Accordingly, the integration of more than one feedback source assists developer to satisfy large number of users which increase App's rating. Because of the large amount of feedback provided by users, an automatic tool for feedback analysis is required. In this paper, the proposed framework analyzed Google Play reviews and Github issues to filter them and to extract change requests out of the integrated feedback. After performing two trials, the accuracy results of reviews and issue reports showed slightly different values which proves that the nature of both textual feedbacks did not affect results after using the same tool. Despite the tool was able to classify the integrated inputs into bugs and feature requests, it was not able to extract all of them. Besides, the similarity can assist on reducing the number of change requests to decrease of the time needed for developer to check the list of change requests. In the future, we are interested in including more Apps feedback from dataset to be able to evaluate whether the results' insights are repeated using other versions or other Apps. Also, the similarity will be automated

and examined in larger dataset versions and Apps to evaluate further the effect of reducing the list of change request. Finally, other analysis tools can be investigated for producing better results of the integrated users' feedback classification.

Research on Quantitative Security Protection Technology of Distribution Automation Nodes based on Attack Tree

Yinfeng Han*, Yong Tang, Xiaoping Kang, Hao Jiang, Xiaoyang Song

Ningbo Power Supply Company, State Grid Zhejiang Electric Power Company, Zhejiang, China

Abstract—In order to improve the security of distribution automation system nodes and ensure the safe operation of distribution network, a quantitative security protection technology for distribution automation nodes based on attack tree is proposed. This paper analyzes the factors of node risk assessment of the distribution automation system, and through the evaluation and analysis of node vulnerabilities; it discovers the faulty nodes in the distribution automation system in advance. Based on the node vulnerability evaluation results of the distribution automation system, the risk of the distribution automation system is comprehensively evaluated using the attack tree. Establish the distribution network control model under network attack, locate the fault node, and use trusted computing technology to design trusted distribution terminals. When the amount of data is large, more effective symmetric encryption algorithm SM4 is required to achieve node security protection in the distribution network automation system. The experimental results show that the method has high fault node location accuracy, low reliability calculation time, and the distribution automation system network has certain robustness, which fully verifies the application effect of the method.

Keywords—Attack tree; security protection; risk assessment; fault node location; trusted computing; SM4 encryption algorithm

I. INTRODUCTION

A distribution grid failure is an unpredictable situation that can cause the entire system to operate unbalanced. For various reasons, faulty nodes may appear between regions of the distribution network [1,2]. Illegal access to the power grid to steal power is very likely to cause the access point to become a faulty node, which will lead to unpredictable technical problems in the power system. In addition, due to this part of illegal access to unaccounted electricity consumption, from an economic point of view, this problem will seriously affect the income of the power company. Therefore, the research on quantitative security protection of distribution network automation system nodes is urgent [3,4].

Literature [5] proposes a network security protection method of distribution network automation system based on independent security chip, designs a dual protection scheme based on "network layer + application layer", and proposes a one-time password authentication protocol based on the combination of SM2, SM3 and SM4 national secret algorithms and message authentication codes, so as to realize bidirectional identity authentication and business data encryption between distribution master station and distribution terminal. Ensure the

integrity and confidentiality of communication data, and solve the network security protection problem of distribution network automation system. Literature [6] proposes an active distribution network security protection method based on trusted computing. Firstly, the information security problems existing in the power generation, transmission, distribution and utilization of the active distribution network are analyzed. Then, referring to the design of power distribution automation system, the overall security and reliability protection scheme is proposed for the regional energy Internet. According to the scheme, a trusted chain is established to ensure the reliability of nodes, network connections and applications. Finally, an example is given to verify the scheme. SM2 and SM4 encryption algorithms are mainly used for data transmission and storage. Considering that the downlink data will have a large number of repeated cryptographic operations. Batch certification method is adopted. By using Merkle hash tree to merge multiple authentication requests, the data processing efficiency is improved. In addition, some scholars have proposed the key technologies of information security protection of active distribution network. Firstly, the characteristic model of active distribution network architecture is analyzed, and the trusted protection environment model of active distribution network is described in combination with the existing typical application mode of active distribution network security protection; Secondly, the embedded trusted distribution terminal is designed for the application scenario of the embedded distribution terminal, and the active distribution network networking model based on the IEC61850 standard is designed for the information flow interaction and data analysis between the various levels of the active distribution network; Thirdly, in view of the complementary coupling and flat management structure requirements of the active distribution network, combined with the supporting role of the active distribution network for the regional energy Internet, the prefecture-level regional energy based on multi-level energy-information routers and energy-information switches is defined. Based on the Internet system model, a trusted in-depth protection system for prefecture-level regional energy Internet security based on Trusted 2.0 technology has been constructed. Finally, combined with the advanced nature of Trusted 3.0 technology, starting from energy nodes, with trusted computing as the basic idea, autonomous controllability as the goal, and safety immunity as the characteristic, the trusted protection scheme is further optimized and adjusted, its safety protection has certain engineering application and reference value.

In order to improve the security of distribution automation system nodes and ensure the safe operation of distribution network, a quantitative security protection technology for distribution automation nodes based on attack tree is proposed. This paper analyzes the factors of node risk assessment of the distribution automation system, and through the evaluation and analysis of node vulnerabilities; it discovers the faulty nodes in the distribution automation system in advance. Based on the node vulnerability evaluation results of the distribution automation system, the risk of the distribution automation system is comprehensively evaluated using the attack tree. Establish the distribution network control model under network attack, locate the fault node, and use trusted computing technology to design trusted distribution terminals. When the amount of data is large, more effective symmetric encryption algorithm SM4 is required to achieve node security protection in the distribution network automation system. Finally, the experiment proves the effectiveness of the design method.

II. QUANTITATIVE ASSESSMENT OF NODE RISK DISTRIBUTION NETWORK AUTOMATION SYSTEM

A. Risk Assessment Factors of Distribution Network Automation System Nodes

It is very important to take an effective quantitative risk assessment method to objectively and accurately assess the risk degree of the power distribution system to ensure the safe, stable and reliable operation of the power distribution system. Here, for the node risk of the distribution network automation system, the node voltage over-limit risk and the line power flow over-limit risk are mainly considered. Each risk is represented by the probability of occurrence, and the risk of the distribution system is measured by establishing a comprehensive system over-limit risk index.

1) The probability calculation of the node voltage exceeding the limit is shown in formula (1):

$$U_i = Q_r(U_i > U_{i\max}) = 1 - [K(U_i) - K(U_{i\min})] \quad (1)$$

In the formula: U_i is the voltage amplitude of node i ; $U_{i\max}$ and $U_{i\min}$ are the upper and lower limits of the node voltage; $K(U_i)$ is the probability distribution function of the voltage amplitude of node i .

2) The probability calculation of line power flow exceeding the limit is shown in formula (2):

$$Q_r(F_j) = 1 - Y(G_j) \quad (2)$$

In the formula: F_j is the conveying capacity of branch j , MVA; G_j is the rated conveying capacity of branch j , MVA; $Y(G_j)$ is the probability distribution function of the conveying capacity of branch j .

3) The output change of the distributed power generation in the distribution network may cause the node voltage and line power flow to have the risk of exceeding the limit. In order to evaluate the various kinds of over-limit risk R_f separately, a comprehensive over-limit risk index is defined here, such as formula (3) as shown:

$$R_f = \frac{1}{M} \sum_{i=1}^M (P_g - P_f) \quad (3)$$

In the formula: M is the number of system nodes or lines; P_g and P_f are the over-limit probabilities of node voltage or branch power flow before and after access to distributed power. This index can be used to measure the comprehensive risk of exceeding the limit of voltage and power flow of the distribution system, which is referred to here as the comprehensive risk of exceeding the limit of node voltage and the comprehensive risk of exceeding the limit of line power flow.

B. Node Vulnerability Assessment of Distribution Network Automation System

When the nodes in the distribution network automation system are disturbed or influenced by the outside world, it is easy to cause successive failures of the components in the system, resulting in large-scale power outages. Through node vulnerability assessment and analysis, the faulty nodes in the distribution network automation system are found in advance, and the improvement of these faulty nodes will reduce the possibility of accidents in the distribution network automation system.

The power distribution network can be simplified as an undirected weighted sparse graph with M nodes and L edges by the complex network definition. The traditional complex network theory has its statistical characteristics, such as characteristic path length, degree, clustering coefficient and betweenness, and can be directly used as an index for risk assessment of distribution network automation system nodes. This paper considers that the structure of distribution network and transmission network is different, so these statistical characteristics need to be improved to meet the structural characteristics of distribution network.

The traditional node degree is defined as the number of nodes connected to the node, and the average degree of the network can be obtained by averaging the degrees of all nodes. The node degree can reflect the importance of the nodes in the network, that is, the node with a larger degree is more important in the network, and the more vulnerable it is. When the distributed power source is connected, the number of system nodes is not changed. Therefore, the node degree of the node connected to the distributed power source should be increased by 1. The calculation formula is:

$$S_i = s_{idp} + 1 \quad (4)$$

In the formula: S_i is the degree of access to the distributed power node; S_{idp} is the degree of the original node of the access to the distributed power node.

Since the distribution network is mostly radial network, which is relatively sparse compared with the transmission network, it is difficult to compare the differences between nodes with the same degree only considering its own node degree. The idea of cohesion is introduced here, and the node degree is calculated considering the influence of the nodes connected with node i :

$$MS_i = \frac{S_i}{S_i} \times \int_i^M D_{iM} \quad (5)$$

In the formula: \bar{S}_i is the average degree of nodes; D_{iM} is the set of all nodes connected to node i .

It is difficult to judge the vulnerability of a node scientifically and comprehensively only by a single node vulnerability index. The node vulnerability index proposed based on the complex network theory mainly analyzes the vulnerability of the node from the structure. The voltage over-limit risk index analyzes the node's vulnerability from the aspect of fault risk. Combining the two, it is proposed that the node's comprehensive vulnerability index can make up for the shortcomings of the two and make a comprehensive judgment.

In this paper, the structural vulnerability index obtained based on the complex network theory is given weight by using the analytic hierarchy process [7,8] (AHP). Through consulting experts, it is equally important to set the node degree and the node intermediate number, and the node active power injection power is more important. The comparison matrix can be obtained by applying the analytic hierarchy process:

$$S = \begin{bmatrix} 1 & 1 & 1/3 \\ 3 & 3 & 1 \\ 1 & 1 & 1/3 \end{bmatrix} \quad (6)$$

The matrix satisfies the requirement of consistency, and the weights of node degree, node betweenness and active power injection power are obtained as 0.2, 0.2 and 0.6, respectively. The structural vulnerability index MS_i of the distribution network node i based on the complex network theory obtained by the AHP is:

$$Mw_i = 0.2 \times Ms_i + 0.2 \times Mq_i + 0.6 \times Mr_i \quad (7)$$

Due to the differences in the units and orders of magnitude of the above indicators, they cannot be directly added. The unit and order of magnitude of the indicators should be normalized first. In this paper, the maximum value of each indicator is taken as the benchmark for normalization, and the data is normalized to [0,1] interval.

Combined with the risk theory, the structural vulnerability index of node i is multiplied by the risk value of the node as the comprehensive vulnerability index of node i , and its expression is:

$$M_i = MS_i \times M_{w_i} \quad (8)$$

C. Comprehensive Risk Assessment of Distribution Network Automation System

Based on the node vulnerability assessment results of distribution network automation system, the attack tree is further used to comprehensively evaluate the risk of distribution network automation system.

1) *Definition of attack tree*: The attack tree model [9,10] is a method of modeling security threats to the system, which represents each attack against the system in the form of a tree structure. The root node of the tree represents a goal to be achieved by a network attack, and the leaf nodes represent possible means to achieve this attack purpose. Each path from the root node to the leaf node represents a complete attack process to achieve this attack goal. The nodes of the attack tree are divided into two types: AND (AND) nodes or OR (OR) nodes. Among them, and node means: only after all child nodes are implemented, this node can be implemented, and the task will continue to be passed up; or node means: as long as one of the child nodes has been implemented, this node can be implemented, and the task will be up first-level delivery.

2) *Stage division of intrusion process*: Every complete invasion process will be very complex, and any two kinds of invasion are also very different. Therefore, it is very difficult and unrealistic to model the whole intrusion process. Similarly, it is unrealistic to use a single attack tree to model all intrusions and attacks against the distribution network automation system. The constructed attack tree will be very large, which is not conducive to analysis and maintenance.

Based on the above reasons, this paper considers dividing the intrusion process into several stages, and each stage has a stage target, and models these stages respectively. By modeling in stages, the complexity of constructing the attack tree can be greatly reduced. Specifically, a complete intrusion process can be divided into the following seven stages:

a) *Host survey*: search for a distribution network automation system node as an attacked target.

b) *Vulnerability discovery*: Discover the security loopholes on the target distribution network automation system nodes.

c) *Target penetration*: use the security loopholes of the distribution network automation system nodes to obtain unauthorized access rights.

d) *Privilege escalation*: Obtain privileged privileges on the nodes of the distribution network automation system.

e) *Hidden and hidden*: cover up the activity track, in order to prepare for the next invasion of the distribution network automation system node.

f) *Grab information*: obtain and modify the data and information on the nodes of the distribution network automation system.

g) *Springboard attack*: Use the controlled node as a springboard to launch attacks on other nodes.

In the following, according to the stages of the attack process, each stage is regarded as the root node of an attack tree, and an attack tree is constructed for each stage of the network attack.

3) *Comprehensive risk assessment*: Comprehensive risk assessment is an important process of risk management, and the risk is often expressed by the product of the loss caused by the event and the probability of the event, namely:

$$R_h = L_h \times P_h \quad (9)$$

In the formula: L_h is the loss caused by the event; P_h is the probability of the event occurring.

The root node in the attack tree represents the ultimate goal of the attacker, so the ultimate goal of the risk assessment based on the attack tree is to determine the risk value of the root node of the attack tree, the attack path that affects this value, and the attack method most likely to be exploited by the attacker, so that technicians can formulate corresponding defense countermeasures according to the risk assessment results. The specific steps of the comprehensive risk assessment method for distribution network automation system based on attack tree proposed in this paper are as follows:

a) Determine the attack target and establish the attack tree model of the system.

b) Select the appropriate evaluation index, and quantify the index of the attack tree leaf node.

c) Calculate the probability P_h of leaf node (attack event) occurrence.

d) Calculate the probability P_s of attacking the root node of the tree (that is, the attacker successfully achieves the final attack target).

e) Analyze the loss L_t caused by the realization of the attack target of attacking the root node of the tree, and use formula (9) to calculate the risk value of the root node.

f) Analyze the attack sequence and calculate the probability P_{hi} of each attack sequence.

g) Judging and analyzing the attack paths and methods most likely to be exploited by attackers according to the results of comprehensive risk assessment.

III. QUANTITATIVE SECURITY PROTECTION OF DISTRIBUTION AUTOMATION NODES

A. Construction of Distribution Network Control Model under Network Attack

There are two types of network attacks for multi-node systems: centralized attacks and decentralized attacks. A decentralized attack is to launch an attack on all nodes in the area, which has a wide range of influence, but requires a higher degree of control of the attacker. Concentrated attack is to launch an attack on the nodes in the area in a targeted manner. This method has a small direct impact. However, if the attack is launched against the weak nodes in the area, the target can be destroyed at a lower attack cost. Therefore, this paper mainly considers the impact of centralized attacks.

The ultimate purpose of physical attack is to destroy the power infrastructure. It is a direct effect on physical equipment. With the subjective will of the attacker, it can directly cause the abnormal operation of a large number of physical equipment, and even cause a cascading failure to cause the collapse of the power system, with great destructive power, but the concealment is weak and the attack cost is high. The network attack takes the information space as the entrance, exploits the vulnerability of the distribution network and its nodes to destroy the distribution network automation system, and finally achieves the purpose of causing large-scale power outages. Compared with physical attacks, network attacks are not easy to be detected, have a long incubation period, and have low attack costs, but they can achieve significant damage.

To sum up, network attacks can covertly realize the attacker's intention and destroy the normal operation of the distribution network automation system. In order to study the scenario where the distribution network is attacked by the network, a distribution network control model is established on the basis of the comprehensive risk assessment of the distribution network automation system. The evaluation index of the distribution network includes power supply quality, economy, safety, etc., which is called the controlled quantity in this paper, denoted by G . In general, these controlled quantities are determined by the protection action, dispatch control and user behavior of the power company, which can be described as:

$$G = R(e, v, z) \quad (10)$$

In the formula: e is protection action; v is scheduling control; z is user behavior.

Formula (10) is a nonlinear equation, and the solution of the equation is related to the input (e, v, z) and the initial state of the distribution network. In the traditional distribution network, user behavior is reflected in daily life and production activities, and is a random variable that conforms to certain laws. At this time, the distribution network is mainly controlled by dispatching and protection. The dispatching system and protection device control the distribution network according to the state detection quantity to ensure that the controlled quantity G meets the requirements of the stable operation of the distribution network.

Unlike normal scheduling, protection, and user usage behavior, attack behavior is unpredictable. Therefore, malicious control behavior is introduced into the distribution network control model, which can be expressed as:

$$G = R(e, v, z, U) \tag{11}$$

In the formula: U is the aggressive behavior.

Also, the total formula (11) is a nonlinear equation. U is sent by an attacker, and the attack may cause the controlled quantity G to deviate from the safe and stable operation requirements of the distribution network, causing a safety and stability accident. Fig. 1 is a schematic diagram of the distribution network control model under network attack.

B. Fault Node Location

Based on the simulation analysis of the distribution network control model under network attack, the voltage array of the distribution network nodes is obtained. According to the operation characteristics of the distribution network automation system in each iteration; the presence of fault nodes is detected. The difference between the measured voltage array and the estimated voltage array is:

$$\Delta V = V_\alpha - V_\beta \tag{12}$$

In the formula: V_α is the measured voltage array; V_β is the estimated voltage array. ΔV is zero in the absence of faulty nodes.

The area where the faulty node exists is displayed through the abnormality matrix elements, and the peak value of the elements in the faulty node area A_d shows the faulty node closest to the fault location in the distribution network automation system. The faulty node is defined as follows:

$$\forall x \in A_d : x_i \geq x_k \tag{13}$$

This method can detect the existence of the faulty node and determine the location of the faulty node. The flow chart of the positioning method is shown in Fig. 2.

C. Realization of Quantitative Security Protection for Distribution of Automation Nodes

1) *Logical architecture and overall hardware structure of trusted power distribution terminal*: In order to protect the nodes of the distribution network automation system, the trusted computing technology [11,12] is comprehensively used to design a trusted distribution terminal based on trusted computing, with access control as the core and security management as the support. The trusted power distribution terminal is based on the trusted platform of the hardware layer as the root of trust, and the trusted cryptographic module provides cryptographic computing services for the trusted computing platform. In order to give full play to the computing function of the trusted cryptographic module, it is also necessary to implement the trusted service management platform module based on the security protocol at the operating system layer. The logical architecture of the trusted power distribution terminal is shown in Fig. 3.

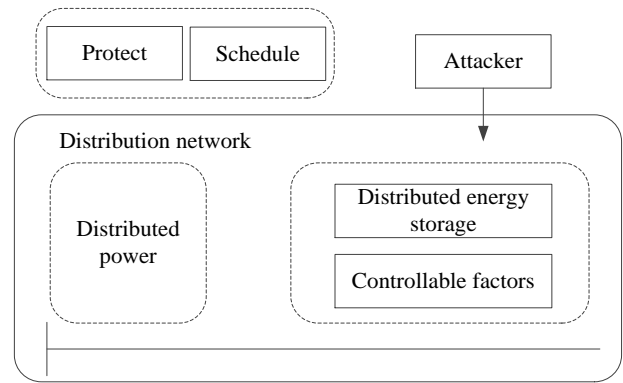

Fig. 1. Schematic diagram of distribution network control model under network attack.

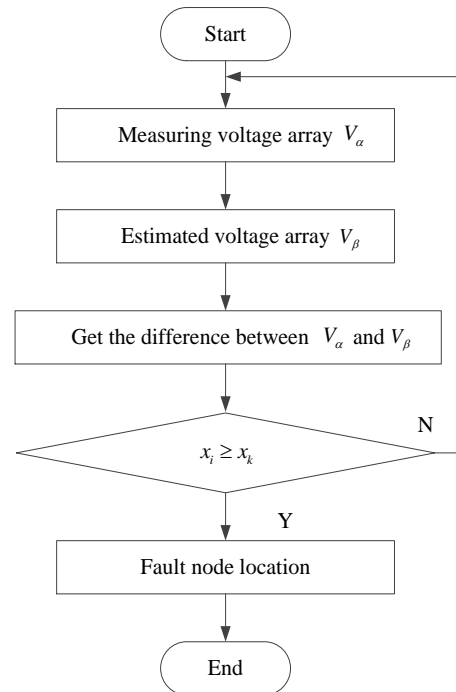

Fig. 2. Flowchart of fault node location.

Fig. 3. Logical architecture of trusted power distribution terminal.

Fig. 4. Overall hardware structure of trusted power distribution terminal.

The overall hardware structure of the trusted power distribution terminal is shown in Fig. 4, which mainly includes microprocessors, human-computer interaction and communication interfaces [13,14]. The microprocessor consists of a watchdog, a memory, a timer and a trusted chip: the trusted chip is the core for realizing the trust and provides the root of trust for the trust chain; the memory is mainly responsible for the storage and memory functions; the timer realizes the timing and computing functions. The watchdog provides system resilience against transient failures [15-17]. The trusted control module is the core component of trusted computing. The root of trust is implanted inside to realize the root of trust control function, so as to combine password and control to realize active control and active defense of the nodes of the entire distribution network automation system. While measuring the mainboard controls, it also provides security computing capability support for the measurement mechanism of the software system.

2) *Software design of trusted power distribution terminal:* The distribution network automation system node is a device that can operate and control independently in the distribution network automation system [18, 19]. It is the basic object of constructing the distribution network automation system. The logical architecture and overall hardware structure of the trusted power distribution terminal have been introduced above, and the following will focus on the analysis of the trusted power distribution terminal software.

The control function application interface is a bridge connecting the software system and the hardware platform. When the hardware layer is powered on, the trusted control module will measure the motherboard controls, and complete the hardware environment and configuration settings through secure boot, thereby establishing a trusted chain. Provide support and services for the software layer. While processing information flow and energy flow, nodes have different processing capabilities of information, so the specific implementation will be set according to the functional requirements of nodes.

Nodes usually perform denoising, compression and other processing operations on data, and these operations will be recorded in PCR for metric protection. The node usually stores the collected data locally for a period of time, and then submits it to the superior node unit, or submits it to the superior node

unit in time; therefore, data information storage is very important. For a small amount of collected data d , this paper adopts the domestic SM2 asymmetric encryption algorithm [20], and the encryption method is expressed as:

$$d_s = \omega_{TCM}(d, \theta_{PCR}, \mu_d) \quad (14)$$

In the formula: d_s is data encryption; ω_{TCM} is TCM algorithm; θ_{PCR} is the expected value of PCR, only when the expected value can be decrypted; μ_d is the node encryption public key. When the amount of data is large, the more efficient symmetric encryption algorithm SM4 is used, namely:

$$d_s = \omega_{SM4}(d, \theta_{PCR}, \mu_{SM4d}) \quad (15)$$

In the formula: ω_{SM4} is the SM4 encryption algorithm; μ_{SM4d} is the symmetric key.

When the system needs to use data, it will first obtain the current PCR value of the system and compare it with the expected value. Only when the comparison result is consistent, it will use the key stored by itself to decrypt it, so as to ensure the integrity and confidentiality of the distribution automation system nodes, and thus realize the quantitative security protection of the distribution automation nodes.

IV. EXPERIMENTAL VERIFICATION ANALYSIS

In order to verify the effectiveness and application effect of the distribution automation node quantitative security protection technology based on the attack tree, an experimental study is carried out.

The IEEE33 node standard distribution system with a voltage level of 10kV is selected as the analysis object. For the distribution network with multiple nodes, the method in this paper, the method in the literature [5] and the method in the literature [6] are used to carry out the quantitative safety protection test of the distribution automation nodes. In order to ensure the accuracy of the experimental results, MATLAB software is used to process the experimental results.

1) *Fault node location effect:* In order to verify the safety protection effect of the method in this paper, compared with the method of literature [5] and literature [6], the fault node location accuracy of the three methods is analyzed. The fault node location accuracy will have a certain impact on the quantitative safety protection of distribution automation nodes. The higher the accuracy of fault node location, the better the quantitative safety protection effect of distribution automation nodes. The specific experimental results are shown in Fig. 5.

2) *Time-consuming test of trusted computing:* Secondly, it is time-consuming to test the trusted computing of the method in this paper, the method in the literature [5] and the method in the literature [6]. The test results are shown in Table I.

Fig. 5. Comparison results of fault node location accuracy.

TABLE I. TRUSTED COMPUTING TIME-CONSUMING TEST RESULTS/S

Iterations/time	The method of this paper	Literature [5] method	Literature [6] method
1	3.62	5.21	4.32
2	3.70	5.30	4.52
3	3.84	6.26	5.24
4	4.25	6.68	5.97
5	4.29	7.19	6.32
6	4.40	7.24	6.65
7	4.54	7.85	7.57
8	5.62	8.54	7.85
9	5.85	9.25	9.25

3) *Network robustness test of distribution network automation system:* Finally, the robustness of the distribution network automation system network is tested under the condition of increasing number of fault nodes. The specific test results are shown in Fig. 6.

Fig. 6. Network robustness test results.

V. DISCUSSION

The effectiveness of the design method has been experimentally analyzed in the previous section, and the following conclusions can be drawn:

1) It can be seen from Fig. 5 that the node positioning accuracy of the distribution network automation system of this method is the highest among all methods. With the continuous increase of the number of iterations, the fault node positioning accuracy curve continues to grow, and the highest value of the fault node positioning accuracy reaches more than 80%, which shows that the method in this paper has a good security protection effect of distribution automation node quantification. In contrast to the other two methods, although with the continuous increase of the number of iterations, the fault node location accuracy is gradually improved, but there is still a certain gap between the fault node location accuracy and the method in this paper. This is because the method in this paper analyzes the risk assessment factors of the nodes in the distribution automation system, and through the evaluation and analysis of node vulnerabilities, the fault nodes in the distribution automation system are found in advance, so as to improve the positioning accuracy of the fault nodes.

2) According to the data in Table I, the method in this paper, the method in literature [5] and the method in literature [6] have a certain increase in the time-consuming of trusted computing in the process of increasing the number of iterations, but the overall increase in the method in this paper is small, indicating that the trusted computing efficiency of the method in this paper is high, and the minimum trusted computing time is only 3.62s, which shows that the quantitative security protection of the distribution automation nodes of the method in this paper is faster, which is beneficial to improve the security of the power system. This is because the design method took the lead in analyzing various factors and carried out analysis on the basis of grasping the overall factors, thus reducing unnecessary time waste and improving efficiency.

3) According to the network robustness fluctuation test results in Fig. 6, it can be found that after the number of fault nodes increases, the robustness of the distribution network automation system network does not fluctuate greatly, and the overall fluctuation has certain regularity, which indicates that the security protection effect of this method is good, and the network attack cannot be cracked. This is because this method uses trusted computing technology to design trusted distribution terminals. When the amount of data is large, a more effective symmetric encryption algorithm SM4 is required, which can better achieve the node security protection in the distribution automation system.

VI. CONCLUSION

In order to improve the security of distribution automation system nodes and ensure the safe operation of the distribution network as the research goal, a quantitative security protection technology based on attack tree for distribution automation nodes is proposed. Analyze the factors of node risk assessment of the distribution automation system, evaluate the node vulnerability of the distribution automation system, and comprehensively assess the risk of the distribution automation system using the attack tree. According to the evaluation results, the distribution network control model under network attack is constructed, the fault node is located, and the trusted distributed terminal is designed using trusted computing technology to achieve the node security protection of the distribution network automation system. The research results show that the fault node location accuracy of the method in this paper is high, the maximum fault node location accuracy is more than 80%, the trusted computing time is low, and the minimum trusted computing time is only 3.62 seconds. Moreover, the robustness of the system network fluctuates little, and the overall fluctuation has certain regularity, which shows that the method has certain effectiveness, and has certain application value and advantages in this field. However, as other performance indicators were not analyzed in the analysis process, there may be some deficiencies, which will become the focus of the next study.

Analysis and Detection of Tomatoes Quality using Machine Learning Algorithm and Image Processing

Haichun Zuo

School of Electrical and Computer Engineering,
Nanfeng College Guangzhou, Guangzhou
Guangdong, 510970, China

Abstract—Grading of agricultural products methods based on artificial intelligence is more important. Because these methods have the ability to learn and thus increase the flexibility of the system. In this paper, image processing systems, detection analysis methods, and artificial intelligence are used to grade tomatoes, and the success rate of grading these methods is compared with each other. However, the purpose of this study is to obtain a solution to detect appearance defects and grade and sort the tomato crop and provide an efficient system in this field. A visual dataset is created, to investigate the approach of image processing and machine learning based on a tomato image. Tomato models are placed individually under the camera and samples are classified in a lighting box away from the effects of ambient light. Data sets have been used in three types of first, second, and third quality categories. It should be noted that quality category one has the best quality and quality category two has the medium quality and category three has the worst quality. Also, each data class contains 80 samples. Using tomato appearance such as size, texture, color, shape, etc. Image processing is performed for extract features. Tomato images are pre-processed for optimization. Then, to prepare for classification, the dimensions of the images are reduced by principal component analysis (PCA). Three categories of an artificial neural network, a support vector machine, and a decision tree are compared to show the most efficient support machine. The analysis is examined in two classes and three classes. The support vector machine has the best accuracy compared to other methods so this rate is 99.9% for two classes and 99.79% for three classes.

Keywords—Machine learning; image processing; product category; tomato quality rating

I. INTRODUCTION

Farmers usually separate healthy and damaged tomatoes according to their size and quality [1,2]. The acceptable quality of tomatoes makes separating the healthy from the bad more accessible, and it prevents the spread of rotten tomatoes among healthy ones [3,4]. Damaged tomatoes are either sold at a lower price, or discarded. Sorting tomatoes in the traditional way are still done by old people, which takes a lot of time. Relying on a product defect alone can lead to a fundamental error by relying on human inspection. The desire to carry quality tomatoes with undivided defects has a great impact on customer feedback and satisfaction. In this study, Image processing and machine learning technology are used. In this way, an image of a tomato is taken, and the presence of defects is automatically detected in a computer vision system to

distinguish healthy from damaged tomatoes, using the concept of a developed system [5,6].

Every day, intelligent systems with industrial applications are increasing. The most important biological processes in the production of crops are the classification of vegetables and fruits. Still, such processes are done manually in a country like Egypt based on a database [7]. After wheat, tomato is the eighth most used crop. The global production of tomatoes is reported to be about 159 million tons for 144 countries. Fresh fruit revenue in 2011 is about \$582 trillion [8]. The performance, quality, and weight of the products are excellent in five countries including the United States, China, India, Turkey, and Egypt. Although very important in the production of previously mentioned tomatoes, there is very little literature on the works. In recent years, tomato grading has become very important, especially with the detection of diseases, due to new market restrictions. Therefore, the need for new technologies in the process of separation and product quality monitoring has increased.

Daily, millions of people use tomatoes and vegetables, that's why it is one of the most popular food products in human life. However, labor costs have increased as the workforce ages, making many farms less profitable. As mentioned, tomato is a popular food product among people, so with the increase in population, tomatoes need to be produced more. An effective solution to control quality and reduce costs is to use a robot instead of human labor to harvest tomatoes. Therefore, most researchers have spent the past few decades building robots to harvest fruits and vegetables [9,10]. Tomato color is the main indicator for the detection of ripening. Different steps are taken to produce tomato fruit. These stages change the tomato's color from green to light pink, then to pink, then to bright red, and finally to red, which categorizes them into different categories [11,12]. The closer the tomato is red, the better its quality. and leads to an increase in prices for companies. The storage time for a quality harvest is about 70 to 75 days in total. The time stages of tomato ripening include 21 to 28 days for green, 15 to 20 days for light pink, 7 to 14 days for pink, 5 to 6 days for bright red, and 2 to 4 days for red [13,14]. Therefore, improving the tomato classification system is an important task for designing a crop robot. In recent years, machine vision and pattern recognition methods have been well received by researchers, especially in the processing or sorting of many intelligent agricultural products. According to EU regulations on processed vegetables and fruits, the main condition is that the tomatoes arrive intact, completely red,

fresh, without rotting and cracks in satisfactory condition, and without damage. The sorting and grading method is done manually. As mentioned, the manual method has low accuracy, high cost, and high effort [15,16]. Efficiency sorting governs how the product is delivered through packaging lines and quality standards. Therefore, as stated above, it can be concluded that the importance of this research is the requirement of high accuracy, high speed, and low cost is very important for sorting using machinery tomato detection. The effective solution is the use of mechanical sorting machines for tomatoes. But mechanical sorting machines can only classify tomatoes according to size and weight.

Now, with the advancement of technology and the introduction of vision devices, it covers the limitations of mechanical devices. New generation machines classify tomatoes with high accuracy, high speed, and low cost [17,18]. In 1985, Sarkar et al. reported the first tomato classification based on machine vision. This study is about the classification of tomatoes according to their size, shape, color, and defects [19-21]. Classification of products is an important step in the packaging and storage processes, which image processing is one of the practical tools in the field of post-harvest technologies. Izadi et al., obtain an algorithm for detecting physical defects [22] and degree tomato product classification and providing an efficient system in this field [23-25]. The specific objectives of this research are to develop a computer vision system and develop an efficient image processing algorithm, to create an accurate and accurate detection algorithm, and to create different classifications for classifying tomatoes into different grading categories [26-30]. One of the purposes of this study is to develop an image processing algorithm and develop a computer vision system, which is used immediately after harvesting tomatoes. Therefore, the time of the process of picking and classifying tomatoes is greatly reduced, in addition, due to the high accuracy of the optical device, quality sorting is done.

Given that image processing and machine vision are one of the current technologies in the world, the main task of a researcher in the field of using machine vision in agriculture is to extract the properties of objects in digital images using these technologies [31-33].

The most important sensory feature of fruits and vegetables is the appearance that affects the market value, priority, and consumer choice. Although sorting and grading are done by humans, it is inconsistent, time-consuming, variable, subjective, heavy, expensive, and easily affected by the environment. Hence, a clever fruit grading system is needed. Therefore, the motivation of this study is to provide a method of quality detection and automatic grading for many tomato disorders.

Most agronomic disorders are observed according to roots, stems, leaves, and fruits based on the type and causes of damage. Fruit images are used for diagnostic purposes. The image acquisition method used to collect the data set ensures that the entire fruit is examined. In the first part, general fruits, especially tomatoes, are introduced. The second part presents the general method of grading tomatoes based on fruit, image processing algorithm, classification methods, machine learning

systems, neural network methods, and application of appearance features, color recognition, and texture recognition in detail. In the third section, the proposed methods are introduced and the steps related to the method are described from an algorithmic point of view. In the fourth part, the proposed method is implemented on the set of images, and the evaluation criteria are evaluated. Finally, the fifth part will end with a conclusion.

II. RELATED WORKS

The most advanced image-based tomato detection method is shown in this section.

Malik et al [49] proposed a Watershed segmentation method was utilized to separate the clustered fruits according to ripe tomato identification algorithms, which were based on the HSV color space. The Otsu segmentation algorithm was used by Arum Sari et al. [50] to multiply the Cb and V channels from the YCbCr and YUV color spaces, respectively, when categorizing tomatoes into 6 separate groups.

Using the color space $L^*a^*b^*$, Yin et al. [51] segmented ripe tomatoes using K-means clustering, and Indriani et al. [52] divided tomatoes into 5 groups using the HSV color space, Gray Level Co-occurrence Matrix, and K-Nearest Neighbor. To segment and localize ripe tomatoes in a greenhouse, Huang et al. [53] employed the $L^*a^*b^*$ color space. Goel and Sehgal [54] used fuzzy rule-based classification through the RGB color space to distinguish the fruits from the background.

Some studies use edge detection operations like the Canny [55] or the Sobel [56] operators as suggested in the Zhang [57] and Benavides et al. [58] investigations, respectively, to enhance detection and produce better segmentation.

III. CRITERIA AND DATA SETS

In this section, in the first stage, the criteria used in this study, including sensitivity, specificity, and accuracy are examined. The data set to be evaluated is then introduced.

A. Criteria

Contrast is one of the most important criteria for determining image quality. The contrast shows the difference between the darkest and lightest parts of an image. When the contrast of the image is low, the difference between the brightness of those points is small. As a result of low image contrast, the image will fade. One way to increase the contrast of a low-quality image is the Histogram Equalization smoothing technique. It changes the values of the gray surfaces of the image to cover the entire range from 0 to 255 per pixel.

1) *Sensitivity*: Sensitivity is one of the performance evaluation criteria of binary classification tests, and it is also used in artificial intelligence. Sensitivity measures the ratio of positively identified positives, meaning that the classifier can correctly identify the data in classes. The terms "positive" and "negative" do not mean profit, but the existence or non-existence of a condition. For example, if caries is caries, "positive" means "caries" and "negative" means "healthy". In many sensitivity tests, the degree to which positive cases are ignored is called positive, so false negatives are rare.

Sensitivity is considered to be the correct positive ratio (the percentage of tuples that are positively labeled and their class is actually positive). The sensitivity parameter is obtained based on Equation (1) [34].

$$Sensitivity = \frac{TP}{TP+FN} \quad (1)$$

Where TP is the correct number of first-class predictions, and FN is the incorrect number of second-class predictions.

2) *Specificity*: Specificity measures the proportion of negatively identified negatives (for example, the percentage of healthy tomato samples that are correctly identified as not rotten). Characteristic is the category in which real negatives are classified in this way, so false positives are rare. A sensitive test seldom ignores a real positive (for example, no caries is shown despite caries). The specificity parameter is obtained based on Equation (2) [35].

$$Specificity = \frac{TN}{FP+TN} \quad (2)$$

Where TN is a true negative, or healthy samples of tomatoes are properly identified as healthy. The FN is right, it's wrong.

3) *Accuracy*: Accuracy is the most intuitive measure of performance and is simply the ratio of the predicted correct observations to the total observations. It may be thought that our model is the best if we are very careful. In general, accuracy is a valuable measure when there is a symmetric data set where the negative, positive, and false positives are approximately the same. Therefore, to evaluate the performance of your model, you should look at other parameters [36].

$$Accuracy = \frac{TP+TN}{TP+FP+FN+TN} \quad (3)$$

Accuracy is also used as a statistical criterion that a binary classification test correctly identifies or removes a condition. In

a classification task, the accuracy for a class is the number of actual positives divided by the total number of elements labeled positively related to the class (i.e. the sum of the actual positives and False positives are items that are incorrectly labeled as belonging to the class). The recall is defined as a positive number divided by the total number of elements that actually belong to the positive class, (i.e. the sum of false positives and false negatives are those that do not have a positive classification label) [37,38].

B. Data Sets

One of the important factors in quality recognition and model evaluation is the use of appropriate data sets. Given that in this study, with the help of image processing and machine learning, the proposed solution to determine the quality of tomatoes is presented. Therefore, it uses data sets in three types of first, second, and third-degree quality categories. It should be noted that quality category one has the best quality and category three has the worst quality, and also each data class contains 80 samples. An example of images related to different types of tomatoes can be seen in Fig. 1. The data set is graded into three categories in terms of quality, which include first grade (best quality), second grade (medium quality, or small healthy-slightly spoiled-immature), and third grade (worst quality). In this study, in order to improve the quality of images and eliminate their potential noise, the data preprocessing method has been used. Methods including applying the median filter [39], calculating the area in an image [40], the optimal local pattern and the matrix of gray surface occurrence [41], the Local Binary Pattern method (LBP) [42], and LAB color channel [43] are used in the step of extracting the shape, color, and texture characteristics. Then, the dimensions are reduced by Principal Component Analysis (PCA) to prepare the vector for classification [44]. Three classification models are used, including the decision tree [45], the support vector machine [46], and the artificial neural network [47]. These classifiers are compared to measure the performance of different classifiers on datasets.

Fig. 1. Tomato sample image of class (a) first grade, (b) second grade, (c) third grade.

IV. PROPOSED METHOD

This article, with the help of features related to the shape, texture, and color of tomatoes, offers a suitable solution for quality recognition and analyzes the effect of using image processing methods in quality recognition using machine learning. The purpose of using preprocessing operations on the data set is to improve its quality and then extract the appropriate feature from them to compare with other methods and also by selecting the appropriate features finally with the help of the proposed algorithms the ability of the machine learning model in support vector machine algorithms, the artificial neural network and the decision tree are examined.

With the decreasing trend of the labor force and also the advancement of technology in order to mechanize agricultural operations, there is a possibility to distinguish the quality of agricultural products. Product quality ultimately leads to post-evaluation economic justification for continuing to grow crops. There are several factors in identifying tomatoes in different quality categories. Classification of agricultural products causes, in addition to harvesting at the right time, also causes the supply of products to be done in a timely manner, to reduce their quality and eliminate first-class products and turn them into second-class products. And three and prevent losses due to waste of time. One of the most important processes in the classification and maintenance of products is their grading and sorting, for which the use of image processing techniques is an important step in this area. The use of machine vision systems makes the post-harvest stages fast, easy, cheap, and with high accuracy, and on the other hand, reduces inspection time, quality assurance, and product grading.

For this purpose, the proposed design has been developed according to Fig. 2 in order to determine the quality of tomatoes. Accordingly, in order to increase the quality of images by applying preprocessing operations by changing the dimensions of images to the size of 400×300 , converting color images to gray, Contrast Enhancement, and applying a median Filter. In the next step, the properties related to texture, shape, and color are extracted, so that in the next step, with the help of Principal Component Analysis (PCA), the most useful features are evaluated according to certain parameters using machine learning. Using the right data set plays an important role in achieving a reliable model. The use of appropriate hardware to some extent causes the image obtained from the cameras to be of good quality. In addition, the application of a series of algorithms and software methods causes images in the data set to have better quality. To improve the quality of images and eliminate their possible noise, preprocessing methods are used. First, the dimensions of the images are changed so that all the images by different dimensions are converted to 400×300 , then the color images are converted to gray, the contrast is improved and the median filter is applied.

A. Feature Extraction

The median filter is the non-linear filters used to remove noise. To calculate the median in the 3×3 neighborhood, we have 9 cells, which after sorting them, we put the value in the middle of the array in output. One of the important features of this filter is maintaining the edges and their position without

displacement. Fig. 3 shows a good example of the function of this filter in simple language.

To extract the shape feature, the appearance of the tomato and the space occupied by it has been used. In other words, according to Fig. 4, the path area within the boundary of an area is declared as a scale.

The LBP and Gray Level Co-Occurrence Matrix (GLCM) are some of the items used to extract image texture information. The LBP is one of the methods that can easily produce suitable features for high-precision tissue classification. In the usual LBP method, the histogram is used to extract features. It is a powerful tool for tissue analysis because the local binary model uses both statistical and structural characteristics of the tissue. In the LBP operator, local texture patterns are extracted by comparing the value of the adjacent pixels and the value of the central pixel and are finally represented by binary codes.

Fig. 2. Proposed method for detection the quality of tomatoes.

Fig. 3. The example of how to apply the median filter.

Fig. 4. How to calculate the area in an image.

Fig. 5. The LBP basis method.

Local Binary Pattern (LBP) is another development of the local binary patterns. In order to identify the maturity stage of object feature representation, textural information provided by the local binary pattern (LBP) method was utilized [59]. The LBP transforms any local 3 3 picture region into a particular binary pattern. LBP basically contrasts the intensities of a center pixel (i_c) and its eight surrounding neighbors (i_k ; where $k = 1, 2, \dots, 8$). If $i_k > i_c$ is true, the k -th nearby pixel would receive a value of 1; otherwise, it would receive a value of 0. When an image rotates on the screen, all the neighbors will rotate around the center pixel in one direction. This rotation effect leads to different values for the local binary pattern. To this end, researchers have introduced a new development of the binary local pattern that is independent of rotation (the LBP with constant rotation). The expression independent of rotation here does not refer to spatial changes related to changes in light or different objects. Independent of rotation to eliminate the adverse effect of rotation, a circular bit rotation operator is used to the right to obtain all the binary codes that can be generated with these bits with several repetitions and then the minimum decimal value of the binary pattern (Fig. 5) [48].

In tissue statistical analysis, tissue properties are calculated through statistical distributions of compounds observed for grayscale in a particular position relative to each other. A matrix is also a matrix event, whose number of rows and

columns is equal to the number of grayscale levels used in the image. That is, if the number of gray surfaces is up to G , then the dimensions of the matrix of the event in question are equal to one matrix $G \times G$. The matrix P , $P(i,j|\Delta x, \Delta y)$ represents the number of iterations of the relationship between two pixels separated by a pixel distance $(\Delta x, \Delta y)$, and is defined by the neighborhood relation that one of the pixels has a gray i degree and the other has a gray j degree, as shown in Fig. 6.

In tissue statistical analysis, tissue properties are calculated through statistical distributions of compounds observed for grayscale in a particular position relative to each other. A matrix is also a matrix event, whose number of rows and columns is equal to the number of grayscale levels used in the image. That is, if the number of gray surfaces is up to G , then the dimensions of the matrix of the event in question are equal to one matrix $G \times G$. The matrix P , $P(i,j|\Delta x, \Delta y)$ represents the number of iterations of the relationship between two pixels separated by a pixel distance $(\Delta x, \Delta y)$, and is defined by the neighborhood relation that one of the pixels has a gray i degree and the other has a gray j degree, as shown in Fig. 6.

L, A, B color mode is used to extract the color feature. This color fashion is the most complete color space designated by the International Committee on Lighting and describes all colors visible to the human eye. The three coordinates L, A, B are shown in Fig. 7.

Fig. 6. Gray Level Co-occurrence Matrix (GLCM).

Fig. 7. L,A,B color channels.

The L indicates the intensity of light. The L=0 black and L=100 indicate the scattering of full light. A's position varies between green and red, negative values represent green and positive values represent red. The B Its position varies between blue and yellow, negative values B indicate blue colors and positive values represent yellow colors.

In order to reduce the dependence and noise of bands in images with a large number of bands, the methods of reducing the dimensions of the feature space are used. One of the most well-known methods of reducing the size of the feature space is the principal component analysis method. As the name implies, it can identify key components and help us analyze a series of features that are more valuable instead of examining all the features. In fact, PCA extracts those features that give us more value. After collecting samples and performing preprocessing steps and after extracting and selecting features, machine learning techniques such as support vector machine algorithms, artificial neural networks, decision tree, and k-means clustering are used to evaluate the model.

V. RESULTS AND DISCUSSION

What has been presented in the previous sections is a description of the problem of examining the quality of tomatoes using machine learning and image processing. In fact, the background, challenges, and necessities of the study have been analyzed. In this section, by presenting a method based on machine learning along with image processing techniques, the problem of quality recognition of tomatoes is improved, and

the proposed method is examined in terms of implementation and evaluation. The proposed steps are then evaluated step by step.

A. Preprocessing and Feature extraction

As mentioned earlier, after applying any type of processing algorithm and pre-processing evaluation, the data set is introduced. For this purpose, preprocessing goals are performed by changing the dimensions of the images to 400 × 300, changing the color channels from three channels to one channel, or in other words, turning the color image to gray, improving the contrast, and applying a median filter. In fact, after these steps, the images in the data set become images like Fig. 8.

According to the data set and based on their differences in different qualitative categories, different types of features are obtained according to Table I.

Fig. 8. An example of a tomato image, (a) before preprocessing, (b) after preprocessing.

TABLE I. TYPES OF FEATURE EXTRACTION USED

Feature	Category	Output
Area	Shape	A numerical value
Local Binary Pattern	Texture	A 300×400 matrix
Gray Level Co-Occurrence Matrix	Texture	A 255×255 matrix
L,A,B color model	Color	A matrix of $300 \times 400 \times 3$

Agricultural products such as tomatoes in the ripe state, as well as in the post-ripening period may be damaged. Based on this, the characteristics of color, shape, and texture cause the quality of tomatoes to be recognizable in different periods, and tomatoes of suitable quality have the best shape, color, and texture. On the other hand, the size of the tomato causes the difference in the first and second quality degrees to be distinguishable. Applying these features together causes the learning model to be able to distinguish each of these quality degrees in the later stages.

B. Feature Selection

As the number of features increases, the dimensions of the feature space also increase. On the other hand, not all of these features are useful, but their presence may even cause the model to be too compatible with the data set, or so-called overfitting. In the PCA method, with the help of feature removal and extraction methods, an attempt is made to separate important features from less important features. And further, reduce the size of the feature by removing minor features. Fig. 9 shows well how the data set is distributed under different PCA components.

PCA has three different components, each of which is well represented in each data class in the data class. A basic component is a normalized linear combination of the main predictions in the data set. Component # 1, component # 2, and component # 3 are the basic components. Component # 1 is a linear combination of the main predictions that contains the largest variance in the data set. This component determines the direction of maximum changes in the data. The higher the range of changes in component 1, the more information there is in this component. Component # 2 and then component # 3 will be important. Fig. 9(a) shows that with the prediction components, the accuracy has reached 89.8% and shows the high accuracy of the diagnosis with only components # 3. Fig. 9(b) is created by the Principal Component Analysis Tool. The principal component coefficients for each variable, the principal component score, are also displayed.

C. Validation

After extracting and selecting the appropriate features, the conditions for learning the model are provided. Accordingly, the evaluation criteria of each of these techniques are expressed as a prediction matrix and the parameters of accuracy, sensitivity, and specificity. It is important to note that in this article we classify two classes for the quality class by merging the first and second class into one class (these two classes differ slightly in size and appearance of products) and the third class in another class, as well as three classes for First, second and third-degree qualitative grading, has been used in three different data classes. The prediction matrix is used to evaluate the performance of the proposed classifier. The predicted label

for each sample can have four possible states, including true negative (TN), true positive (TP), false negative (FN), and false positive (FP), as shown in Table II.

The detect components represent the number of samples that are correctly classified, while the main diameter components in the table represent errors. The prediction matrix is the result of evaluating the results of two neural network classes according to Table III. For example, 159 instances of class one has been correctly identified and two instances of data class one has been incorrectly predicted to belong to class two.

Fig. 10 shows a comparative trend of the accuracy of different classifications. Accordingly, the support vector machine has the best accuracy compared to the others, so that even its accuracy in two-class data in the case of merging first- and second-class products is better than three-class classification.

Fig. 9. Accuracy of classification performance of data set (a) component # 1 and component # 2, (b) component # 1 and component # 3.

TABLE II. PREDICTION MATRIX

		Prediction class	
		Class 1	Class 2
Real class	Class 1	TN	FP
	Class 2	FN	TP

TABLE III. NEURAL NETWORK PREDICTION MATRIX

		Prediction class	
		Class 1	Class 2
Real class	Class 1	159	2
	Class 2	1	58

Fig. 10. Performance accuracy of data classification.

Fig. 11. Comparison of sensitivity and specificity of data classification performance.

According to Fig. 11, after the vector machine, the artificial neural network support performs better in the sensitivity criterion and the decision tree in the specificity criterion. But as a general result, it can be seen that compared to the neural network, the decision tree has the same performance as the support vector machine.

In this section, in the first step, in order to prepare the data set for the next stages of preprocessing operations. In the next step, by extracting the feature with the help of features related to texture, shape, and color and by selecting the features using principal component analysis and support vector machine classifications, artificial neural network, and tree, the decision is applied. The results show that the use of this method has better results compared to other methods and also the integration of the first and second quality grade also improves the accuracy of identification.

VI. CONCLUSION

The most important sensory feature of fruits and vegetables is the appearance that affects the market value, priority, and consumer choice. Although sorting and grading are done by humans, it is inconsistent, time-consuming, variable, subjective, heavy, expensive, and easily affected by the

environment. Hence, a clever fruit grading system is needed. This paper provides an in-depth overview of various methods such as preprocessing, segmentation, feature extraction, and classification that focus on fruit and vegetable quality based on color, texture, size, shape, and defects. Using the appearance characteristics of tomatoes such as color, shape, size, and texture, image processing operations have been performed with MATLAB software to extract the mentioned features. Furthermore, the proposed algorithm can be used for some other types of image data because the proposed LPB feature representation enables to represent the object which can be presented better performance. In the future, a system can be set up that reads images on the rails simultaneously and processes them in video images. Algorithms such as deep learning are introduced that can be more efficient in real-time processing. Thus, the study method can be developed for future work with deep learning algorithms.

Abstract—This research work dealt with the indiscriminate theft of electric power, reported as a non-technical loss, affecting electric distribution companies and customers, triggering serious consequences including fires and blackouts. The research focused on recommending the best prediction model using Machine Learning in electrical energy theft. The source of the information on the electricity consumption of 42372 consumers was a dataset published in the State Grid Corporation of China. The method used was data imputation, data balancing (oversampling and under sampling), and feature extraction to improve energy theft detection. Five Machine Learning models were tested. As a result, the accuracy indicator of the SVM model was 81%, K-Nearest Neighbors 79%, Random Forest 80%, Logistic Regression 69%, and Naive Bayes 68%. It is concluded that the best performance, with an accuracy of 81%, is obtained by using the SVM model.

Keywords—Energy theft; non-technical losses; machine learning; support vector machine

I. INTRODUCTION

In the world, 70% of electricity consumption is lost and 30% in the Caribbean and South America, of which Peru stands out with 7% according to the Inter-American Development Bank [1]. Electricity losses are categorized into two categories: energy delivered to customers (unpaid energy) and losses generated in transmission and distribution lines, which are inherent to electricity transmission. Likewise, non-technical losses comprise the majority of losses in electricity networks and can account for more than 40% of the total electricity produced [2]. These types of losses are attributed to different sources, the most important and common being the alteration of metering equipment, illegal connections to the electrical grid, and energy theft [3]. Regarding distribution in Peru, annually, electricity theft generates losses of 103 million soles, equivalent to 207 GWh, for the companies providing the service [4]. However, this type of loss not only affects these companies but also the offenders themselves and people in the surrounding area, causing various accidents such as electric shocks, fires, and power outages.

According to [5], as presented in Table I, a division is made into countries, utilities, and society, which are categories represented in non-technical effects or consequences in which electric power has many losses.

The background of the respective research is based on multiple studies that have been conducted in many countries, designing intelligent systems that help to deal with this problem, mainly using Machine Learning techniques, which will be presented below:

In 2018, wide convolutional networks (CNNs) were used for one-dimensional data, and deep convolutional networks (CNNs) were used for two-dimensional data. The one-dimensional data were converted into two-dimensional electricity consumption data [6]. On the other hand, a study was carried out in which SVM was applied, using customer consumption data and the total energy distributed by the supplier, which allowed the calculation of the errors produced by electricity meters [7].

In 2019, a combination of neural networks, employed for the conversion of a one-dimensional dataset into a two-dimensional one, and random forests were used to perform customer classification [8]. In 2020, the k-nearest neighbors algorithm and empirical mode decomposition were used to extract the most important attributes from the dataset and obtain good accuracy in detecting energy theft [9]. Another study used a text convolutional neural network (Text-CNN) to effectively extract periodic features about energy consumption and detect electricity theft [10].

In 2021, several classification algorithms were compared, the main one being lightGBM, a fast algorithm based on decision trees, which achieved an accuracy of 84% [11]. Other algorithms compared are logistic regression, with an accuracy of 71%, stochastic gradient descent, with an accuracy of 65%, and decision tree, with 86%.

TABLE I. THE MAIN CONSEQUENCES OF NON-TECHNICAL ASPECTS OF POWER THEFT

Countries	Utilities	Society
Increased use of scarce natural resources	Negative impact on the economy and finances	Total or partial outages
Increased contamination	Reduction of power plant efficiency	Increase in electricity rates
Increased use of public funds	Reduced capacity to upgrade the power system	Fires

According to [12], they proposed that for feature learning (classified into theft and non-theft), a deep convolutional neural network was used. Smart counters at different epochs provided data that was used for SVM training. The time interval of 15 minutes that the smart meter had to record the data through a source coming from the residential and industrial sector which is comprised of 26530 consumers which is the product of data collection.

In the study of [13], the authors evaluated 23 classifiers using the F1 score as a performance parameter. They used as a basis the data of a Brazilian company oriented to the electric power industry, with 261,489 consumers, with approximately 1400 fields. From the results obtained, they concluded that the classifiers (ensemble methods) are the most appropriate, allowing the identification of non-technical cases of electric power loss. The F1 score of 0.45 is the result of the gradient boosted three and an accuracy of 66.50% (actual field inspections) with respect to the rotation forest.

II. MATERIALS AND METHODS

The procedure that was applied as a solution for electricity theft detection encompassed in the respective workflow is basically made up of five parts: data set acquisition, preprocessing, data balancing, feature extraction, classification, and acquired data set, shown in Fig. 1.

According to Fig. 1, the parts of the workflow will be detailed as follows:

A. Dataset Acquisition

The method of data collection was done through smart meters. The data comes from the daily consumption of electric energy belonging to the State Grid Corporation of China (<http://www.sgcc.com.cn/>), which was founded on December 29, 2002, and which supplies more than 1.1 billion inhabitants, covering 88% of the national territory. The description of the dataset used is presented in Table II.

According to Table II, we have the temporality range of the data, which comprises from January 1, 2014 to October 31, 2016 (approximately 147 weeks). The file size is 167 MB (175,194,613 bytes) in csv format, with respect to the data structure of the dataset is divided into customers who steal electricity amounting to 3615 (8.55%) and normal customers who consume electricity amounting to 38757 (91.5%) of which add up the total amount of records in 42372 (total customers).

B. Preprocessing

Usually, the electricity consumption represented by the dataset is constituted in some cases by erroneous and missing values and this is caused by problems in smart meters, storage with many problems, unreliability in transmission of metering data and others [20]. For the recovery of missing values in the content of the dataset of the respective research is the interpolation method [21] which is represented through the following formula 1:

$$f(x_i) = \begin{cases} \frac{(x_{i+1} + x_{i-1})}{2} & \text{if } x_i \in \text{NaN}, x_{i-1} \text{ and } x_{i+1} \notin \text{NaN} \\ 0 & \text{if } x_i \in \text{NaN}, x_{i-1} \text{ or } x_{i+1} \in \text{NaN} \\ x_i & \text{if } x_i \notin \text{NaN}. \end{cases} \quad (1)$$

Where:

x_i : Attribute of electricity consumption data

NaN: Non-numeric value

Next, the technique for the recovery of missing data was applied, using the average electricity consumption of each customer for which missing values were substituted. In addition, outliers were found, very different from the rest, which were restored using the equation of the three sigma rule, shown in the respective formula 2

$$f(x_i) = \begin{cases} avg(x) + 2 * std(x) & \text{if } x_i > avg(x) + 2 * std(x) \\ x_i & \text{otherwise} \end{cases} \quad (2)$$

where:

std(x) : typical deviation

avg(x): mean value of x

Fig. 1. Arch Workflow.

TABLE II. DESCRIPTION DEL DATASET UTILIZADO

Description	Value
Temporal range of data	01/01/2014 – 31/10/2016
Dataset file size	167 MB (175,194,613 bytes)
Normal customers consuming electricity	38757 (91.5%)
Customers stealing electricity	3615 (8.55%)
Total customers	42372
Cases with missing data	Approximately 25%.

C. Feature Extraction

In order to classify the consumers, characteristics were extracted from their electricity consumption records. The characteristics used were the following: mean, standard deviation, peak to peak, skewness, median absolute deviation, entropy, and kurtosis.

D. Data Balancing

The dataset being used has been found to be imbalanced, with a greater amount of data representing people who are not stealing electricity compared to those who are stealing, which complicates the classification process. To balance the data, techniques such as oversampling and undersampling can be applied. For oversampling, a technique called SMOTE was often used, in which new instances are synthesized from other instances using the k-Nearest Neighbors technique [14]. However, it is suggested to use a subsampling technique in conjunction with the SMOTE technique [15]. For this research work on the dataset, the random subsampling technique was applied, dividing the data into disjoint training and test sets that are randomly partitioned several times [22].

E. Classification

According to [23], the classification process allows to obtain different classes, but based on a grouping of outputs through one or more input variables. In the research, a set of algorithms were applied for this purpose, each of which will be detailed below:

The SVM algorithm is designed to find the optimal separating hyperplane between classes based on support vectors (extremes of the class distributions). The training data are separated into classes using boundaries, which results in the maximization of the distance between the various data sets and the boundary [16].

The training dataset, consisting of n cases represented by $\{x_i, y_i\}$, $i = 1..n$, where $y_i \in \{1, -1\}$, is used to form a classifier for accurate generalization. A hyperplane is defined as:

$$w * x_i + b = 0 \quad (3)$$

Where there is a normal vector denoted by w and a point x, where both are in the hyperplane and b is the bias. And each point in the sample must satisfy:

$$y_i(w * x_i + b) > 1 \quad (4)$$

The k-Nearest Neighbors algorithm is a supervised classification algorithm that classifies or predicts based on proximity, which is calculated using various distance metrics [17]. In this study, we will use the Manhattan distance, defined as:

$$\text{Manhattan Distace} = d(x, y) = \sum_{i=1}^m |x_i - y_i| \quad (5)$$

Random forest is a supervised classification and regression algorithm that performs well on classification problems. It builds a set of decision trees and bases the final output on majority voting in classification problems. The decision tree algorithm for regression and classification is constructed by evaluating questions and node splits, which contribute to the further reduction of Gini impurities when answering [18].

Logistic regression is a classification algorithm that aims to predict or explain the values of a qualitative target variable as a function of a set of qualitative or quantitative explanatory variables. It is an extension of linear regression that uses the logit function for qualitative classification [19]. The logit function is defined as:

$$\text{logistic}(\eta) = \frac{1}{1 + \exp(-\eta)} \quad (6)$$

Following the calculation of the conditional probabilities of which one event occurs with respect to the other, is the concept of Bayes Theorem of which naive bayes is a classification algorithm which is defined by the following respective formula:

$$P\left(\frac{A}{B}\right) = \frac{P\left(\frac{B}{A}\right) * P(A)}{P(B)} \quad (7)$$

III. RESULTS

The results were obtained based on the preprocessing of the data, totaling 33,009 instances, of which 20% were used for testing and 80% for training to predict the respective model to be compared. The processed dataset is shown in Table III.

TABLE III. PROCESSED DATASET

Characteristic	Value
Total Instances	33009
Train Instances	26407
Test Instances	6602

A. Support Vector Machine Algorithm

After experimenting with different kernels to determine the optimal kernel for classification using the Support Vector Machine, the results of this experiment are shown in Table IV. The RBF (Radial basis function) kernel was chosen.

TABLE IV. COMPARISON BETWEEN THE ACCURACIES OBTAINED USING DIFFERENT KERNELS

Kernel	Accuracy
Linear	75%
Polynomial	67%
RBF	80%
Sigmoid	72%

The parameters chosen were "gamma": 0.5 and "C": 100, obtaining an accuracy of 81%. Fig. 2 and Table V show the results through the classification report and the confusion matrix as follows.

B. K-Nearest Neighbors Algorithm

Using the Manhattan metric, the best number of neighbors for this classification was 5, as shown in Fig. 3, obtaining an accuracy of 79%. The results obtained in the confusion matrix and ranking report using these two parameters are defined in the following graphs (as seen in Fig. 4 and Table VI).

Fig. 2. Confusion matrix of the SVM based detection model.

TABLE V. SVM ALGORITHM CLASSIFICATION RESULT (DETECTION MODEL)

	Precision	Recall	F1 - score	Support
0	0.83	0.89	0.86	4387
1	0.75	0.64	0.69	2215
Accuracy			0.81	6602
Macro avg	0.79	0.77	0.78	6602
Weighted avg	0.80	0.81	0.80	6602

Fig. 4. Confusion matrix of the k-nearest neighbors based detection model.

TABLE VI. CLASSIFICATION RESULT OF THE K-NEAREST NEIGHBORS ALGORITHM (DETECTION MODEL)

	Precision	Recall	F1 - score	Support
0	0.86	0.81	0.84	4387
1	0.66	0.75	0.70	2215
Accuracy			0.79	6602
Macro avg	0.76	0.78	0.77	6602
Weighted avg	0.80	0.79	0.79	6602

C. Random Forest Algorithm

The parameters chosen were 'max_depth': 20, 'n_estimators': 100, 'max_figures': 'auto', 'criterion'='entropy', achieving an accuracy of 80%. The following classification report and confusion matrix are determined by the following graphs (Fig. 5 and Table VII).

The following classification report and confusion matrix were generated using the parameters 'max_depth': 20, 'n_estimators': 100, 'max_figures': 'auto', 'criterion': 'entropy', which resulted in an accuracy of 80%. The results are shown in Fig. 5 and Table VII.

Fig. 5. Confusion matrix of the random forest based detection model.

TABLE VII. RANDOM FOREST ALGORITHM CLASSIFICATION RESULT (DETECTION MODEL)

	Precision	Recall	F1 - score	Support
0	0.81	0.92	0.86	4387
1	0.79	0.57	0.66	2215
Accuracy			0.80	6602
Macro avg	0.80	0.75	0.76	6602
Weighted avg	0.80	0.80	0.80	6602

D. Logistic Regression Algorithm

This model was trained using 1000 iterations and the inverse of the regularization strength 'C' as 10, obtaining an accuracy of 69%. The classification report and the confusion matrix results were obtained, which are determined through the following graphs (Fig. 6 and Table VIII):

Fig. 6. Confusion matrix of the logistic regression based detection model.

TABLE VIII. LOGISTIC REGRESSION ALGORITHM CLASSIFICATION RESULT (DETECTION MODEL)

	Precision	Recall	F1 – score	Support
0	0.69	0.98	0.81	4387
1	0.76	0.11	0.20	2215
Accuracy			0.69	6602
Macro avg	0.72	0.55	0.50	6602
Weighted avg	0.71	0.69	0.60	6602

E. Naive Bayes Algorithm

The default parameters for classification were used for this algorithm, obtaining the following results (see Fig. 7 and Table IX).

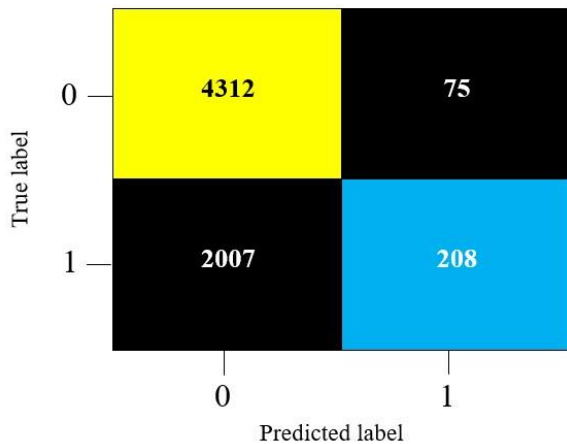

Fig. 7. Confusion matrix of the naive bayes based detection model.

TABLE IX. CLASSIFICATION REPORT OF THE NAIVE BAYES BASED DETECTION MODEL

	Precision	Recall	F1 – score	Support
0	0.68	0.98	0.81	4387
1	0.73	0.09	0.17	2215
Accuracy			0.68	6602
Macro avg	0.71	0.54	0.49	6602
Weighted avg	0.70	0.68	0.59	6602

Table X shows a consolidation of the results obtained from the percentage values of the accuracy indicator of all the proposed models.

TABLE X. LIST OF RESULTS OF THE ACCURACY VALUES OF THE PROPOSED MODELS

Machine Learning Models	Accuracy
Support Vector Machine	81%
Random Forest	80%
K-Nearest Neighbors	79%
Logistic Regression	69%
Naive Bayes	68%

As shown in Table X, the SVM model has a higher accuracy indicator score of 81%.

IV. DISCUSSION

The research of [6] focused on making a comparison of CNN, SVM, LR, RUSBoost models in order to know who has the best prediction. The accuracy result of the SVM model was 0.772, contrasting with our research that also developed a comparison of models such as SVM, RF, KNN, LR and NB, having the best accuracy results of 0.81 for SVM and 0.80 for RF. If we compare the SVM model results of both researches, there is an improvement of 0.038 (3.8%) in favor of the present research. Likewise, the research of [8], also makes a comparison of models such as CNN-RF, CNN-GBDT, CNN-SVM, CNN, SVM, RF, LR and GBDT, the SVM model has an accuracy of 0.77, compared with the present research, achieving an improvement of 0.04 (4%). Next, we have another research by [10], which proposes a new model (TextCNN) for electricity theft detection and also makes a comparison with traditional machine learning models (LR, SVM), the SVM model has an accuracy of 0.70, compared with the present research, achieving an improvement of 0.11 (11%). The SVM model has been compared for all research, however, this model compared with the research [6], which uses the CNN model, results in an accuracy of 0.92 (92%) and the research [10], whose model is Text-CNN whose accuracy value is 0.90 (90%), although it is true that both have better performance, however more computing power is needed when identifying consumers who steal electricity.

V. CONCLUSIONS

This research proposed an electricity theft detection model based on Support Vector Machine using electricity consumption information obtained from the State Grid Corporation of China, achieving a maximum detection accuracy of 81%.

The models have limitations because it was not possible to correctly classify about 25% of the electricity theft cases, which may be due to the lack of data on electricity thieves compared to those who did not steal electricity. However, we attempted to solve this problem using data balancing techniques (oversampling and under sampling).

The experiments conducted show that the system using SVM performs better than most of the other prediction

systems tested, such as Logistic Regression, Random Forest, and K-Nearest Neighbors, while the Naive Bayes model does not correctly fit this problem.
