# Editorial Preface

*From the Desk of Managing Editor...*

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

**Thank you for Sharing Wisdom!**

*Abstract*—In blockchain system, the problem of endless addition of transaction volume results in larger space occupation, heavier network transmission burden and the like. But the way of abandoning historical data is hindered by the characteristic of blockchain-tamper-proof. To solve this problem, this dissertation takes bitcoin system as an example, and gives a definition of expired transaction. By abandoning expired transactions and packing the rest transactions in several blocks into a new substitute block to replace old blocks, help to overcome the difficulty in clearing historical data. However, this solution fails to clear ineffective intermediate transactions. Thus, a follow-up solution is proposed, abandon the transactions whose outputs have been run out and retain the transactions where not all the outputs have been spent. Additionally, include records of the spending details of each transaction output, which allows us to clear ineffective intermediate transactions. In the end, an experiment is conducted to confirm the effectiveness of the two solutions as to clearing transactions.

*Keywords—Blockchain; endless addition; expired transactions; substitute; storage problem; consensus algorithm*

## I. INTRODUCTION

Blockchain [1] technology has become a new data storage technology with its decentralization, anti-tampering, and traceability. In addition to the field of digital cryptocurrency [2], it also enjoys promising prospects for application in the fields of data notarization [3], resource sharing [4] and supply chain traceability [5]. It is estimated that by 2027, 10% of global GDP will be stored through blockchain technology [6].

To realize decentralization and traceability, blockchain technology uses chain storage structure [7] and multiple complete nodes to save data copies in full. However, such a storage method inevitably causes endless addition of data, and its anti-tampering feature means once the data (even the wrong data) is uploaded, it cannot be modified or deleted. As time goes on, fast-growing data of block chain leads to space occupation, which has become a problem that blockchain technology has to face. In addition, when a new complete node joins the system, the full amount of data must be synchronized, resulting in an increase in the network load of other nodes. Currently, it takes several days for Bitcoin nodes to synchronize the full amount of data every time, and every node needs to verify the correctness of the transaction when it receives a synchronization block, which will consume massive CPU computing power.

In the following sections, an overview of solutions in bitcoin system and research field, is given firstly, and find that these ideas merely mediate the effects of the problem instead of solving it. Then we define the expired transactions, based on which gives a solution of re-packing to generate substitute block to replace old blocks safely and thus abandon historical data. But this solution can only clean about 20% transactions. To clean more middle expired transactions, give a follow-up solution by recording signals of unspent transaction outputs. Finally, we verify the correctness and effectiveness of two solutions by experiments to find the second solution can clean about 80% expired transactions. With comparison to traditional solutions, reusing consensus algorithm (Power of Work) to generate substitute block to replace old blocks safely, is a brand-new and effective idea in this field.

## II. SOLUTIONS IN BITCOIN

The most typical application of blockchain technology is Bitcoin. To make things easier, Bitcoin will be taken as an example. Bitcoin has been in operation for 12 years since 2019. As of February 14, 2021, there were 670,540 blocks and 18,628,343 bitcoins, with a total transaction volume of 1,232,212,522, a total data capacity of about 306 GB, a total number of 786,328,292 authentication addresses, and a market capitalization of 905.9 billion dollars [8]. According to statistics from BitNodes [9], there are currently about 10,000 complete nodes online at the same time in the entire network, and the disk space required by a single complete node is about 306 GB. Each complete node stores one copy of data, so the data capacity required by the whole system is about 3.1 PB. At present, it is growing rapidly at the rate of about 330,000 transactions per day [10]. With such high-speed transaction growth, the storage space occupation of Bitcoin has become an increasingly obvious problem.

Satoshi Nakamoto, the author of Bitcoin, once proposed a solution to the storage problem-space recycling. He believes that if the recent transaction has been included in enough blocks, the data before the transaction can be discarded to recover the hard disk space [1]. He pruned the expired transaction data, yet kept their Hash values to ensure that the Merkle root of the block is a verifiable value, as is shown in Fig. 1:
Fig. 1. Before and after Pruning Tx0-2 from Block [1].

The data before the transaction mentioned by Satoshi Nakamoto in that article can be described as follows: For example, Coinbase transaction is transferred from A to B, and then B transfers to C. If the two transactions are included in the block chain and are confirmed by sufficient subsequent blocks (more than six), the legality of the transaction can be confirmed. When the transaction from B to C is confirmed, the transaction from A to B, which is regarded as a transaction before the transaction from B to C, is no longer valuable in verifying the transaction. It only has retrospective value as an expired transaction.

Whether the pruning is correct or not, the block verification is unfailingly correct so long as the hash algorithm is not destroyed. In this regard, verifying the correctness of the pruning result will be a problem. In practice, Bitcoin does not use the above pruning strategies when solving this problem. Instead, it uses the following strategies:

*1) Use prune parameters.* Prune parameter is used to reduce the usage of local hard disk. When launching Bitcoin core for the first time, the software will require the user to select the folder location where the blockchain is stored. All users need to do is to create a setup document named "bitcoin. conf" under the root directory of this folder, and write the code prune=N, where the unit of n is MB. Among them, N is the blockchain size stored locally, and N=0 means no limitation and complete download; If a limitation is required, the minimum value is 550 (that is, 550MB). It should be noted that even if the -prune mode is started, the node will still need to download the data of the entire blockchain network, but instead of storing all the data, it will simply delete the old blocks after building the UTXO library. In addition, if the prune mode is started, data on the entire blockchain network will have to be downloaded again during re-scanning, and the client usage will be greatly affected.

*2) Provide SPV (Simplified Payment Verification)* lightweight client. In the SPV method, SPV nodes only store the header information of the block, not the complete data. Therefore, when a transaction occurs and the validity of the transaction needs to be verified, it downloads the latest block from the complete node. When it is verified that the transaction is packed into the block and the number of blocks generated after the block is greater than six, the transaction is thus verified. However, SPV nodes completely depend on complete nodes, and verify transactions by using simple payment verification method, so they are highly vulnerable to service denial attacks [11], witch attacks [12] and other attacks. In addition, it reduces the number of complete nodes, which will lead to a more centralized system.

*3) Use SegWit technology.* SegWit technology was officially activated on August 24th, 2017, with a block height of 481,824 [7]. SegWit thinks that the witness data (scriptSig) in the transaction input is the main contributor to the total transaction size. By migrating the witness data out of the transaction, the Bitcoin node can remove the witness data after verifying the signature, and the witness data does not need to be stored in the hard disk by all nodes, thus saving the storage space of a single node.

*4) Lightning network and SegWit technology in research and development stage.* Lightning Network [7] establishes a payment channel between the two parties in day trading, and pre-store part of the funds in the channel. The fund allocation plan after each transaction will be jointly confirmed while signing to declare invalid of the old version. When settlement is required, the final transaction result is written in the blockchain network for final confirmation. Since transactions only need to go through the blockchain when they are settled, the number of transactions submitted to the blockchain is greatly reduced.

The above solutions can optimize blockchain storage by being user-friendly and reducing the size and quantity of transactions submitted to the blockchain. However, they can neither clean out expired transaction nor address the root of the problem: endless addition of blockchain data. Therefore, they cannot solve the problem of increasing storage space essentially.

## III. SOLUTIONS IN RESEARCH FIELD

A great number of researches have so far been done on storage problems in the research field, and the solutions in the research can be divided into the following categories:

*1) Sharding strategy [13-15].* In this strategy, a complete block is divided into K blocks, each block is stored in a certain proportion of nodes, and the storage conditions of nodes are recorded. When a block is needed, data is obtained from these nodes to restore the block. This strategy reduces the storage space required by a single node. But if several nodes stored in a certain block are inaccessible, the block cannot be accessed. This is a chain storage strategy, according to which, all data are stored on block chain.

*2) Distributed storage strategy [16-17].* With the latest distributed storage technology, this kind of system distributes and stores blocks in RAID (Redundant Array of Independent Disks), Clouds, P2P [16] (Peer to Peer) or Elastic Chain [17], etc. Data can be accessed from these systems when needed. These systems can effectively guarantee the storage security and access efficiency of large-scale data. This is an off-chain storage method, which moves the data in the block to the off-chain, and only keeps the Hash of the data in the block for easy

searching and tamper-proofing. In the decentralized network, the problems of data centralization and the selection of the data remains storage.

*3) Editing [18] or deleting strategy [19].* The editing strategy uses secret sharing strategy to manage trap door keys, which enables multiple verifiers cooperate to manage the modification rights of data on the chain, and avoid a single or a small number of malicious verifiers to tamper with the data at will after getting the trap door, thus improving the security and credibility of blockchain data [18]. The deleting strategy adopts some consensus mechanisms. For instance, PoSpace (proof of space), based on the consensus mechanism of space proof, deletes the expired data after being agreed and signed by most users, and the structure of the blockchain remain unchanged [19]. The above two strategies can only modify or delete at the block level, that is, the whole block must be completely replaced, so the operation granularity is too large [18].

*4) Abandon strategy.* Bitcoin-Core [20] proposes a method to save storage space by deleting all blocks after UTXO (Unspent Transaction Output) library is built. In fact, some full nodes use UTXO library to speed up data verification. The prune parameter mentioned above also adopts this storage scheme. However, in this way, the UTXO library will be at the risk of being tampered with, and the node cannot provide block sharing services, which will further aggravate the centralization.

*5) Lightweight client strategy.* In addition to full nodes, different blockchain systems also define their own lightweight clients. These lightweight clients including SPV node in Bitcoin, Jaxx, Status and Trust Wallet in Ethereum do not store all data but only recent blocks. So, data verification completely depends on full nodes. They are not only vulnerable to attacks but will also exacerbate centralization. Therefore, this strategy, which is merely a scheme to improve the user experience, is not enough to tackle the increasingly growing data volume.

## IV. SOLUTION

Whatever in practice research, traditional solutions to blockchain storage space can neither clean out previous transactions nor stop new transaction data from adding. That means these solutions fail to solve the problem of increasing blockchain data. Obviously, the addition of new transaction data is unavoidable, so it's necessary to clean out expired previous transaction. To be exaggerated, in order to ensure the traceability of data, should expired transactions 10,000 years ago continue to be kept in the blockchain? The answer is definitely "no". However, cleaning out expired transactions can affect the traceability of previous data. So, need to clean out expired transaction data and meanwhile ensure the correctness of the blockchain traceability, which is the root of the problem. Next, describe how to identify an expired transaction, rise a corresponding solution and then elaborate on the design of the substitute block and substitute chain of the scheme.

### A. Expired Transactions

In Bitcoin system, transactions fall into two categories: Coinbase transaction and ordinary transaction (non-Coinbase). I will illustrate how they two can be deemed to be expired transactions according to different situations.

*1) Coinbase transaction.* Suppose the Coinbase transaction is transferred from A to B, and B transferred it to C. If the two transactions are included in blockchain and confirmed by a substantial number of subsequent blocks (more than 6), then the legality of the transactions is confirmed. When the transfer from B to C is confirmed, then that from A to B becomes an expired transaction since it no longer has the value of verifying a transaction but only had the value of tracing.

*2) Ordinary transaction.* The standard to judge whether an ordinary transaction is expired are as follows.

*a)* All the inputs of ordinary transactions are from expired transactions. As clean out expired transactions in advance, ensure all the ordinary transactions are from expired transactions by not finding such ordinary transactions in the unexpired transaction list.

*b)* All the outputs of ordinary transactions are spent before the expiration date.

What is expiration date? It should be noted that testing whether a transaction is expired or not at different time cut-off points (blocks) produces different results. For example, A transferred to B on February 5th, 2019, B transferred to C on March 5th, 2019, and C transferred to D on April 5th, 2019. If the deadline is March 8th, 2019, the transfer from A to B will be overdue. If the deadline is April 8th, 2019, both the transfer from A to B and the transfer from B to C are overdue.

What's worth mentioning is that to ensure the data are unalterable and traceable, many intermediate transactions cannot be defined as expired transactions. For example, a Coinbase transaction is transferred from A to B, and then B transfers to E, and E transfers to F. In order to make sure that the transfer from B to C is not miscalculated, the ordinary transaction from B to E (non-Coinbase transaction) is not defined as an expired transaction.

### B. Solution

This paper proposes a solution to the problem of blockchain storage. That is re-blocking. In this solution, a certain block is taken as the cut-off block. After calculation, the unexpired transactions of several old blocks before the cut-off block (until the cut-off block) are extracted, repackaged into blocks, and these old blocks are replaced with new blocks. Thus, a substitute chain comes into being. In this way, not only can the expired transactions be cleared, but also the unexpired transactions can be kept. While replacing blocks, if the replaced block converges the cut-off block, new cut-off blocks can be re-selected to produce a new generation of substitute blockchain, as is shown in Fig. 2.
Fig. 2. Alternatives for Old Blocks.

To ensure that the data are correct, only if the latest block accepts more than six subsequent blocks can it serve as the cut-off block, which can be defined as required. A suggested figure is 3 months, because accounts in recent three months are usually included in the bank's billing system, while those three months ago are regarded as old accounts.

Bitcoin system makes miners willing to dig through reward mechanism. But substitute blocks will not generate new bitcoin rewards. If there is no reward then who will produce the substitute blocks? Rewards generate incentives, so do punishments. If a malicious node takes the opportunity to clear unexpired transactions, it will cause asset losses. If someone wants to protect its' own assets then participates in the generation of substitute blocks. The participation of plenty of nodes will generate computing power, thus safeguarding the correctness of data.

*C. Design of Substitute Blocks*

In Bitcoin system, one block is composed of a block header and a block body. Coinbase transaction must be the first transaction in the block body, followed by other ordinary transactions. Except for the structure of Coinbase transaction in the block head and the block body, the rest of the substitute block is consistent with the general blocks. Next, this paper will provide explanation for the block header and Coinbase transaction structure in substitute blocks.

*1) Adjustment of the block header.* In order to construct the block header, the mining node needs to fill in six fields: version number, timestamp, extra nonce, Hash value of the previous block, Hash of the Merkel root and difficulty coefficient. The first version number of the substitute blocks is set as to 0XFFFF, and the version number of each version upgrade will be reduced by 1 every time it upgrades. The Hash of the previous block is the Hash of the previous substitute block or the Hash of the genesis block. In order to stay consistent with the original block as much as possible, other parameters of block header are the same as those of ordinary blocks.

*2) Structural adjustment of Coinbase transactions.* In bitcoin system, the result of double SHA256 operation on the block header is the Hash of the block, which needs to meet the requirement of difficulty coefficient. The Hash of the block header adjusts as the variable nonce changes until the block Hash meets the requirement of the difficulty coefficient. That's when the nonce is obtained. However, the mining capacity continues to improve. When the computing power of mining nodes reaches 4GH/s, the variations of nonce in the block

header will be exhausted within one second [7], and if the block Hash meeting the requirements is not found till now, the block cannot be generated. In order to solve the problem, introduce the Coinbase in the block body.

Like ordinary transactions, Coinbase transactions are divided into two parts: input and output. However, the input of the Coinbase is empty, and only the output is used to record the reward given by the mining node. Therefore, the empty input is used to fill in extra nonce. As the miners change the input of Coinbase, the Merkel root Hash in the block header changes accordingly so that it can meet the requirements of the difficulty coefficient.

Although part of the input of Coinbase is used to fill in extra nonce, the rest remains unused. Besides, the Coinbase transaction in substitute block does not produce an output, which means that the output is also idle. As a result, these idle spaces can be utilized to record all kinds of data that need to be recorded in the substitute block.

In Coinbase transaction, it's required to record the information of several merged blocks in block chain. To safeguard the correctness of data, add another two parameters intentionally: the Hash of the previous and next block of the original chain. These two parameters make it possible to have a two-way chain structure in the substitute chain, which helps the substitute chain to be attached to the original chain. This will be elaborated in the subsequent part about the design of substitute chain.

What needs to be recorded about Coinbase transaction in the substitute blocks are as follows:

*1)* Hash and time stamp of the cut-off block.

*2)* Block height of the final merged block in the original chain and the block height of the present block in the substitute chain.

*3)* The substitute block needs to connect blocks before and after it when replacing the original block, so need to record the total number of merged blocks in the original chain, the Hash of the first and the final merged block in the original chain as well as the Hash of the precious and the next block in the original chain.

*4)* Information about all the merged blocks, including the time stamp, version number, the number of unexpired transactions of the blocks on the original chain, details of which are in Table III.

*5)* Extra nonce is used to control the difficulty coefficient in Coinbase transaction.

Detailed information about the substitute blocks is shown in Fig. 3:

Next, solve the problem of how to record parameters mentioned above into the Coinbase transaction. The original input structure of Coinbase transaction is shown in Table I:

The input structure of Coinbase transaction of the substitute block in substitute chain is shown in Table II. Through Coinbase transaction, input an idle Hash and time stamp of the input transaction and stored the Hash and time stamp of the cut-off block. Store majority of information of the original chain and part of the information of the substitute chain into the addible transaction data.

Table III shows the original and substitute output structure of Coinbase transaction.

| variables | Locking-script | Locking-script | Extra nonce |

### D. Design of Substitute Chain

Connecting the above substitute blocks one by one gets a substitute chain. But there are two special blocks that cannot be merged into the substitute chain: the genesis block (stored by clients) and cut-off block (destination of the substitute chain).

Next, questions arise: how to deal with bifurcation, how to use consensus mechanism and what kind of driving mechanism to use, how to ensure data security, how to link to the original chain, how to reach consensus on the period duration, etc.

*1) Bifurcation:* If there is bifurcation in the original chain, choose the bifurcating block as the cut-off block. After substitution is finished, no new substitute chain produced until the problem of bifurcation is solved.

If there is bifurcation in the substitute chain, employ the principle of "short chain first". Then what if bifurcating chains are of equal length? The answer is, prevent such equally long bifurcating chains from existing. According to the design principle of POW (Proof of Work) consensus algorithm, the longer it last, the less likely that conflicts will arise; thus, prevent bifurcation from existing by extending the time of blocking of the substitute chain. It is unnecessary to produce substitute blocks at the same rate as new blocks; instead, produce substitute blocks twice as fast as the default speed. When a new generation of substitute chains is being produced and meeting bifurcation, such bifurcation can be ignored and thus wiped out.

*2) Consensus mechanism:* Although choosing POW consensus algorithm, yet, re-blocking bases on any safety consensus. POW algorithm can safeguard data security but that's through sacrificing the inefficiency of performance. If use other consensus algorithms, consider how to protect data security.

*3) Driving mechanism:* The driving mechanism of producing substitute chain is based on punishment rather than reward, as is mention above.

*4) Data security:* There are two kinds of nodes in the bitcoin system: lightweight nodes and full nodes. Main functions of full nodes include data storage, data verification and data sharing. Most full nodes are produced for the sake of mining.

Lightweight nodes are not plagued by the problem of space recycling. There are two kinds of full nodes: existing full nodes and newly added full nodes.

Existing full nodes in the bitcoin system have already been loaded with all the data, so when they receive substitute block, so long as the latter passes verification, the latter could be accepted; otherwise, the latter will be abandoned.

Talking about newly added full nodes, as expired transactions in old blocks have been cleaned out and the old blocks have been replaced with substitute blocks, some transactions cannot be confirmed. In this case, use the data confirmation strategy of lightweight nodes (based on POW consensus algorithm) to safeguard the correctness of data. If more than 6 subsequent substitute blocks are accepted, rest assured that the degree of data security of this substitute block is acceptable. But how about the ultimate 6 substitute blocks in the substitute chain? They do not have enough subsequent blocks (over six) to ensure the security of data; therefore, they cannot be linked to the original chain as substitute blocks. But set them aside for other nodes to use.

*5) Linking mechanism:* For the sake of data security, only blocks before the ultimate seven ones in the substitute chain can be linked to the original chain. The principles of linking are as follows.

According to the Hash of the next block of the original chain recorded in the last but seven blocks, corresponding block could be found in the original chain.

Make sure whether the Hash of the previous block (recorded in the original chain block) equals the Hash of the ultimate merged block listed in the last but seven substitute blocks.

Link substitute chain to the original chain after the blocks of both the chains has confirmed each other.

This means that any substitute block in the substitute chain can be linked to the original chain. So long as the substitute blocks at the linking area are confirmed by six subsequent blocks, such practice of linking is secure.

*6) A new generation of substitute chain:* A new generation of substitute chain can be reproduced in accordance with the predefined period rules only after the ultimate substitute block comes into being. Once one substitute chain fails to go through the whole substitute process, a new generation of substitute chain cannot be produced; otherwise, the substitute chain would be in disorder.

If there is bifurcation in the original chain which is not wiped out yet, the cut-off block can only converge the bifurcation area, failing to move further until the problem of bifurcation in the original chain is solved.

Besides, as is mentioned before, the substitute chain bifurcation can be ignored and wiped out when a new generation of substitute chain is being produced.
Fig. 4. Design of Substitute Blockchain.

Fig. 4 shows how a substitute chain can be linked to the original chain. The linking between the original chain and substitute chain is shown in dotted lines. This is because the two chains are linked together according to the association of block Hash, but they do not have real directivity association with each other.

## V. FOLLOW-UP SOLUTION

As is mentioned in the previous chapter, to make sure the temper-proof and traceability of data, some intermediate transactions cannot be cleaned out. For example, a Coinbase transaction is transferred from A to B and C, B transfers to E, and E transfers to F. If the transfer from B to E is cleaned out while that from A to B and C is retained, the bitcoin system would take it for granted that the bitcoins transferred to B by A are not spent. Because of this, ordinary (non-Coinbase) transactions from B to E cannot be cleaned out.

If record the fact that the bitcoins transferred from A to B have already been spent, B to E could be cleaned out. Such as retaining A to B and C transaction, and label the output of the transaction (for example, 1 means the output has been spent while 0 means the output hasn't been spent), as 10, which means the first output A to B has been spent but the second one A to C hasn't.

Since the information of merged blocks in the substitute blocks would be recorded, use the same way to retain the transactions were not all the outputs are spent and include the marks of these transactions' outputs. In this way, many

intermediate transactions can be cleaned out while data security is still assured. This is in fact the way used in UTXO (unspent transaction outputs) library.

Based on the follow-up solution, the principles as to how to deal with transactions have changed as follows:

If all the transaction outputs are spent, clean out this transaction.

If part of the transaction outputs is spent, retain this transaction, and record the spending details of the transaction output.

To record how each transaction output is used, use 1 byte to mark the spending details (0 or 1) of 8 transaction outputs, then calculate how many bytes are there in total through calculation. Suppose use 1 bit to mark one output. And there are 36 outputs that need marking, since 1 byte equals 8 bits, use 5 bytes to mark 40 outputs. Then 2 bytes are needed to store that data 5, the follow-up 5 bytes to record spending details (0 or 1) of 36 transaction outputs, the surplus 4 bits being filled in with the Fig. 1.

As the solution changes, the information of each merged blocks recorded in the substitute block should also change, i.e., the information of each merged blocks in the original chain should change, including the time stamp, version number, the number of unexpired transactions (n), the size needed to store the transaction outputs (2n bytes), the spending details of each transaction output recorded by subsequent bytes. The design is shown in Table IV.

TABLE IV. INFORMATION OF ONE MERGED BLOCK

| Size | Field | Description |
|---|---|---|
| 4 bytes | Version | Version number |
| 4 bytes | Timestamp | Time stamp |
| 2 bytes | Non-expire Transaction Number Size | Size of the number of unexpired transactions |
| Variable | Non-expire Transaction Number | The number of unexpired transactions n |
| Variable | Non-expire Transaction Output Flags Byte Number Per 2 Bytes | 2*n bytes, the number stored by every two bytes refers to the number of bytes used to record the spending details of each transaction output |
| Variable | Non-expire Transaction Output Flags | Record the output spending details one by one according to the bytes needed to record a transaction as stipulated before. If it takes less than 1 bytes, it is still regard as 1. |

Except the above changes, others are the same as before. But in this way, Coinbase transaction may become huge, which is a problem worth consideration.

## VI. EXPERIMENTAL ANALYSIS

Illustrate the correctness and effectiveness of the solutions mentioned above. The solutions are based on consensus mechanism. And since the correctness of POW consensus mechanism has been confirmed by bitcoin and many other decentralized systems, rest assured that the solutions are correct. Next, prove the effectiveness of the solution through an experiment.

How much space can the solutions in Sections III and IV save, respectively? According to the design of the algorithm, let's take the No.697546 block which get at the test time 2021-08-26 00:00 as the cut-off block and collect the data of each transaction from No.1 block to No.105,000 block along the block chain. In the solution mentioned in Chapter 3, if all the inputs of the transactions are from the outputs of expired transactions, and all the outputs have been used, then label such transactions as "expired transaction 1", otherwise as "unexpired transaction 1". In the design in Chapter 4, let's label unexpired transaction 1 whose transactions have been run out as "expired transaction 2", otherwise as "unexpired transaction 2".

Fig. 5 shows the data collected, including the number of expired transactions 1, the number of unexpired transactions 1 and additional expired transactions 2.

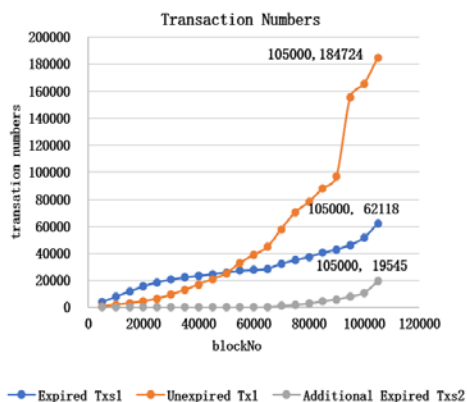

Fig. 5.    Total Expired and Unexpired Transaction Number.

Applying the third solution, in bitcoin system, expired transactions account for 74.8% of the total transactions at the No. 105,000 block, and account for 77% (the peak) at the No. 95,000 block. In contrast, applying the fourth solution, more expired transactions would be cleaned out. Statistics show that cleaning out expired transactions can effectively reduce storage space occupation, which means this solution is effective. The ratio of expired transaction 1 as well as the ratio of expired transaction 2 is shown as follows in Fig. 6.

Fig. 6.    Expired Transaction Ratio.

The above statistics only cover the data of the first 105,000 blocks. And how much space is unleashed? According to the solution mentioned in Section III, the expired transaction ratio will decrease after reaching the peak of 77%. And according to the solution mentioned in Chapter 4, the data of the change in size of the UTXO library would be gotten eventually. Due to the statistics of Bitaps [20], as of March, 21st, 2022 when this thesis is finished, there were 719,197,481 transactions, and 130,561,354 unspent transaction outputs in UTXO, and a total storage volume of 369.42 GB. Among them, the percentage of spent transactions is the same as that of the cleaned transactions. Roughly, the ratio of spent transactions to total transactions [(719 197 481-130 561 354)/719 197 481] reached 81.8%. Although the fourth solution does not make a big difference for the first 105,000 blocks, it will play an increasingly significant role in the recycling of subsequent blocks after the 105,000th block. So, the fourth solution is also an effective one.

## VII. CONCLUSION

The increasing popularity of blockchains reveals all the possibilities a decentralized ledger can offer. Nonetheless, blockchains also have their limits: the fast-growing data cause single full nodes to occupy larger storage space, which will bring increasingly heavy burdens to online transmission, CPU computing power and storage space.

Base on analyzing transactions in blockchain, propose a new solution: re-blocking. In this solution, pack unexpired transactions in old blocks into a new alternative block which constantly replaces old blocks. In this way, a substitute chain comes into being, which helps to clean out expired transactions in the bitcoin system and thus solve the problem of increasing data. we also prove the effectiveness of the solution by conducting an experiment in bitcoin system. Believe that this system would highly beneficial to blockchain applications.

Further researches:

*1)* Realize this idea to verify whether it works well in reality.

*2)* Whether split one chain into two chains, for storing expired transactions and unexpired transactions to retain historical information, and merge them two to one when necessary.

*3)* We only give experiments for the bitcoin system. In other systems like electronic medical record system and produce tracing system, further analysis is needed to define and clean expired transactions.

*4)* In this system, POW consensus algorithm is used to protect date safety. Although highly probable, it is to be confirmed: algorithms can reach a consensus is ok.

*5)* Once long bifurcation chains arise like in Ethereum, how can the solution work well.

*6)* The second solution would change the traditional system mechanisms greatly, not only to realization, but also to usage. And the Coinbase transaction will become very large. It should be considered.

# Blockchain Privacy Data Access Control Method Based on Cloud Platform Data

Biying Sun, Qian Dang, Yu Qiu, Lei Yan, Chunhui Du, Xiaoqin Liu

State Grid Gansu Electric Power Company Internet Division, Lanzhou, China

*Abstract*—With the improvement of digital informatization and openness of the smart grid, the security of all kinds of sensitive and private data in the power grid is inevitably facing severe threats and challenges. In this paper, we propose a privacy protection scheme for multidimensional data aggregation and access control in the cloud Internet of Things for smart grid. The scalable access control based on attribute encryption is used to determine the data security of power user data in the process of data information sharing in the blockchain under the large data traffic of the cloud platform, which is to achieve privacy protection and fine-grained access control for demand-side multidimensional data. By using the EBGN homomorphic encryption algorithm, the multidimensional data is encrypted, and each dimension can be decrypted separately using the corresponding private key. The multidimensional data aggregation at the gateway can aggregate the multidimensional data into cipher-text, and the control center does not need to decrypt the cipher-text data of each dimension, thereby simplifying the operation of the gateway and the control center and improving the security and privacy of the data. By encrypting the EBGN private key of each dimension through the cipher-text policy attribute encryption algorithm, the fine-grained access control at the dimension level is realized. The experimental results show that the proposed method can effectively improve the security of private data in the aspect of multidimensional data privacy protection, thus reducing the security risk of multidimensional data being illegally accessed. The research in this paper can effectively reduce the communication overhead and computational complexity, reduce the computational cost, and is suitable for data security and privacy protection of smart grid cloud Internet of Things.

*Keywords—Cloud platform; blockchain; private data; data encryption; access control*

## I. INTRODUCTION

The combination of smart grid and the Internet of Things promote the wide application of various network information sharing technologies in the power system, which greatly changes the way of life and work, but also brings a series of hidden dangers, among which the hidden danger of information security is the core. Due to the bidirectionality of smart grid information flow, and in order to reduce communication bandwidth and achieve flexible fine-grained analysis, multi-dimensional aggregation and access of smart grid data are needed [1]. Each data dimension contains sensitive and private information, which may be analyzed and utilized by different research organizations. For example, in data transmission, the leakage and tampering of data information such as power information and privacy information may cause security and privacy threats to power supply companies and customers and even serious economic losses. Therefore, the privacy protection and access control of blockchain is particularly important [2].

So far, many scholars have conducted extensive research on smart grid privacy protection based on data aggregation and access control. The schematic diagram of smart grid data aggregation and access architecture is shown in Fig. 1.

Terminal devices distributed in multiple links such as power generation, transmission, distribution, and power consumption are used for blockchain collection. The gateway aggregates the blockchain into data cipher-text for data transmission and instruction transmission with the control center [3]. The control center stores the collected data in the cloud server and can decrypt the data cipher-text of the corresponding dimension to determine the power supply strategy according to the total demand. The access authority can access the data information of the authorized dimension [4].

Due to the advantages of homomorphic encryption in data confidentiality and privacy protection, the cipher-text can be directly operated without decrypting the cipher-text. J. W. et al. [5] proposed a track protection method based on privacy clustering, which is used to resist continuous query attacks by adding Laplace noise to the track position count in the cluster. The radius-limited Laplacian noise is added to the trajectory data in the cluster to avoid affecting the clustering effect, and the noise cluster center is obtained according to the noise position data and the noise position count. J. Zhang et al. [6] proposed an algorithm to protect access to sensitive sites in privacy-preserving trajectory data release, which generalizes sensitive sites with sensitive regions and distorts sub-trajectories within sensitive regions based on privacy. K. Xue et al. [7] proposed a method to protect the release of road network trajectory traffic by using privacy technology. After counting the traffic value of the trajectory data of each road section, the method adds random noise satisfying differential privacy to the traffic value and then proposes a post-adjustment algorithm to solve the consistency characteristics of the traffic map. The complexity of smart grid architecture based on cloud Internet of Things not only makes the whole power system more intelligent but also brings a large amount of information data, which may contain a large number of sensitive information (such as security risks of nodes, voltage data of a certain place, etc.) and very important privacy information (such as user identity information, location information, etc.) [8]. The research on data access control is helpful to improve the user's access speed to the encrypted data, reduce the waiting time for users to access the encrypted data. At the same time, it is also of great significance to the network data security.
Fig. 1. System Architecture.

In the face of the large-scale and complex system of smart grid cloud Internet of Things, the above scheme is difficult to meet the security requirements of the system for data. In the smart grid cloud Internet of Things system, it also faces the problem of visitor access rights, which need to be revoked or updated in time.

In this paper, based on the attribute access control method and the data privacy protection requirements of the cloud Internet of Things on the demand side of the smart grid, a demand-side cloud Internet of Things blockchain aggregation and access control scheme is proposed, which completes the aggregation work of the blockchain and the fine-grained access control of privacy data. In the aggregation phase, Boneh-Goh-Nissim (EBGN) homomorphic encryption extended by wireless sensor networks is used to aggregate the blockchain into cipher-text, and CP-ABE encryption is used to perform fine-grained access control at the dimension level. Then, the implementation of the algorithm is introduced and the security of the scheme is proved, and a detailed comparison with other existing schemes is made in terms of functionality computation and communication overhead.

## II. RELATED WORK

### A. Data Aggregation

The establishment of secure information communication is the task of building the information security of smart grid cloud Internet of Things, and it is also the basis of achieving efficient communication and reducing communication overhead. Smart grid privacy protection schemes using data aggregation techniques during communication have been proposed in many studies [9]. The basic idea of these techniques is based on the use of an aggregator and a trusted authority connected to the user, as shown in Fig. 2.

In the smart grid, the analysis of all kinds of power data can not only be applied to the formulation of real-time pricing and power dispatching strategies but also may produce other commercial values. In order to carry out fine-grained analysis, it is necessary to collect the blockchain of each link of the smart grid. Taking the user side as an example, by analyzing the power consumption of air conditioning equipment at the user side in hot weather in summer, the power station can prepare enough power in similar hot weather later [10].

Fig. 2. Data Aggregation System Model.

### B. EBGN Homomorphic Encryption Algorithm

EBGN homomorphic encryption is an extension of the BGN homomorphic encryption scheme proposed by Boneh, Goh, and Nissim. It makes up for the limitation that BGN encryption cannot support blockchain encryption. Both BGN and EBGN support addition and multiplication homomorphisms, that is, the results of addition and multiplication operations performed on cipher-text match the results of the corresponding operations performed on plaintext [11]. Because multiplication homomorphisms are computationally expensive, only additive homomorphisms are considered in this paper. EBGN consists of the following computational structure.

Let $G$ be a group of prime order $p$. Let the generator of $G$ be $g$, and let $e: G \times G \to G_T$ be the bilinear pairing operation. DBDH assumes that a security parameter $\kappa$ is set if a quadruple $(g^a, g^b, g^c, e(g,g)^{abc})$ and a quadruple $(g^a, g^b, g^c, e(g,g)^z)$ cannot be distinguished by a non-negligible advantage by an attacker A in polynomial time, where $g^a, g^b, g^c \in G$, $a,b,c,z \in Z_P$. Then the advantage $ADV_A^{DBDH}(\kappa)$ of the attacker A is defined as:

$$ADV_A^{DBDH}(\kappa) = \left\| \Pr\left[A(g^a, g^b, g^c, e(g,g)^{abc}) = 1\right] - \Pr\left[A(g^a, g^b, g^c, e(g,g)^z) = 1\right] \right\| \quad (1)$$

*1) EBGN.KeyGen( $l, k$ ):* Generate $k+1$ primes $Q_1, Q_2, \cdots, Q_{k+1}$, where $|Q_i| = l, i \in \{1,2,\cdots,k+1\}$. Then, generate an elliptic curve $e$ of order $N = \prod_{i=1}^{k+1} Q_i$ and a group $g$ of points on its elliptic curve and have $ord(g) = N$,

where $ord(g)$ denotes the order of $g$. Next, randomly choose $k+1$ generators of $g$, namely: $g_1, g_2, \cdots, g_{k+1}$, such that $ord(g_i) = N, i \in \{1, 2, \cdots, k+1\}$. Finally, calculate $P_i = (N / Q_i) \cdot g_i, i \in \{1, 2, \cdots, k+1\}$ and $R = (N / Q_{k+1}) \cdot g_{k+1}$ through $ord(P_i) = Q_i$ and $ord(R) = Q_{k+1}$. The public key $PK_{EBGN} = (N, e, \{P_1, P_2, \cdots, P_k\}, R)$ and the secret key $SK_{EBGN} = (Q_1, Q_2, \cdots, Q_k)$ can be obtained.

*2) EGBN.Enc( $M_{S_i}$, $PK_{EBGN}$ ):* For the $k$-dimensional data $M_{S_i} = \{M_{i,1}, M_{i,2}, \cdots, M_{i,k}\}$ collected from the intelligent terminal $S_i$, $0 \le \Re_i \le N$ is randomly selected. The following calculations are made:

$$C_i = \sum_{j=1}^{k}(M_{i,j} \cdot P_j) + \Re_i \cdot R \qquad (2)$$

*3) EBGN.Add( $C_1, C_2, \cdots, C_n$ ):* Cipher-text aggregation is calculated as follows:

$$C = C_1 + C_2 + \cdots + C_n$$
$$= \sum_{j=1}^{k}(\sum_{i=1}^{n} M_{i,j} \cdot P_j) + \sum_{i=1}^{n} \Re_i \cdot R \qquad (3)$$

*4) EBGN.Dec( $Q_j, P_j, C$ ):* In the decryption process, in order to understand the *jth* dimension data in the dense aggregate data, the method $\lambda$ and Baby-step and Giant-step algorithms are required to calculate the discrete logarithm in the decryption algorithm, as shown below:

$$M_{d_j} = \sum_{i=1}^{n} M_{i,j}$$
$$= \log_{g_j'}((N / Q_j) \cdot C) \qquad (4)$$

Where,
$$g_j' = \prod_{i=1, i \ne j}^{k+1} Q_i \cdot P_j = N / Q_j \cdot P_j.$$

## III. DEMAND SIDE BLOCKCHAIN AGGREGATION AND ACCESS CONTROL ARCHITECTURE

This paper first presents a demand-side data aggregation and access control framework, as shown in Fig. 3.

The smart meter installed on the user side can collect various privacy information, such as the user's basic identity information and the user's electricity consumption data, as shown in Table I.

Secondly, smart meters or smart terminals can collect information data such as power information and power environment. A collector, a concentrator, and gateways at all levels are adopted through a Home Area Network, BAN (Building Area Network), and NAN (Neighborhood Area Network), which is uploaded to the control center and cloud server [12]. The collected blockchain is encrypted using EBGN homomorphic encryption in the in-home network HAN, and the blockchain is aggregated at the building area network BAN gateway. The control center can decrypt and access the fine-grained data of the corresponding dimension, that is, the total power consumption data in the region, and share the data with the access authority [13]. At the same time, the access organization can access the fine-grained data of its authorized dimension to analyze the related work.

Based on the above framework, Fig. 4 shows the demand-side blockchain aggregation and access control model in this paper, which includes five parts, namely, trust authority, smart meter, gateway, control center, and access authority.

TABLE I. DATA INFORMATION MAY BE PROVIDED ON THE DEMAND SIDE

| Data element | Description |
|---|---|
| Name | Account responsible party |
| Address | Place of service |
| Account | A representation unique to the account |
| Electricity information | Kilowatt-hour consumption recorded for the current billing period |
| Other information | Environmental monitoring, equipment load, fault, power quality, distribution transformer status, etc. |

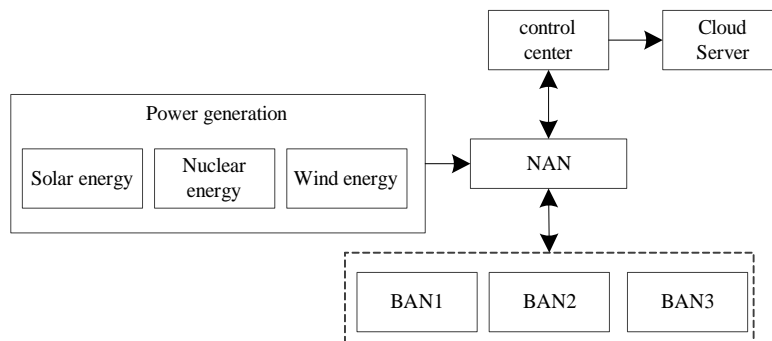

Fig. 3. Data Aggregation and Access Control Structure Block Diagram of Demand Side.
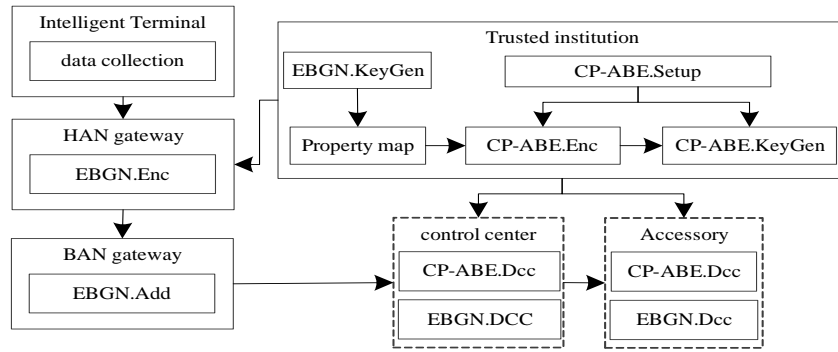

Fig. 4. Demand Side Blockchain Aggregation and Access Control Model.

The system model includes the following four operations: system initialization, blockchain encryption and aggregation, data access, and access permission update.

System initialization: The trusted authority performs the system initialization operation. First, the trusted authority generates the system parameters for EBGN and CP-ABE [14]. According to the access control policy of the control center and the access authority, the trusted authority generates the key of the CP-ABE and sends it to them. Next, it generates a mapping table indicating the mapping relationship between the public keys of the attribute set EBGN of the data. Finally, the trusted authority encrypts the EBGN key using the CP-ABE with the corresponding attribute set.

Blockchain encryption and aggregation: perform blockchain aggregation and encryption at the gateway. First, the data is categorized into multiple dimensions based on its attributes. Next, the gateway selects the corresponding EBGN public key from the mapping table and encrypts the blockchain. Finally, the cipher-text is sent to the superior gateway, and each gateway is responsible for aggregating all blockchains into one cipher-text [15].

Data access: In the data sharing process of blockchain, by using the CP-ABE key obtained from the trusted authority, the control center and each visitor can obtain the authorized data information of the corresponding dimension [16].

Access renewal: For key renewal of EBGN and CP-ABE, to revoke an accessor's access, the trusted authority first regenerates the EBGN's public and secret keys for the affected dimension. The trusted authority then re-encrypts the EBGN key and revokes the visitor's access to the corresponding attribute [17].

## IV. Implementation of Blockchain Data Control Scheme in cloud Platform Area

### A. Initial System Establishment

Given public parameters $l$ and $k$. A security parameter k is set if, in any probabilistic polynomial time, it cannot be successfully computed by attacker A with a non-negligible advantage. The security parameter l is sent to the attribute authority, and the attribute authority calculates its own master key. The trusted authority runs EBGN.KeyGen(l,k) and ABE.Setup () functions to generate system public parameters:

$$\begin{cases} PK_{EBGN} = \left( N, e, \{P_1, P_2, \cdots, P_k\}, R \right) \\ SK_{EBGN} = \left( Q_1, Q_2, \cdots, Q_k \right) \\ PK_{CP-ABE} = \left( G, g^{\sum GID}, U_{GID} \right) \\ MK_{CP-ABE} = \left( \alpha, \chi \right) \end{cases}$$

(5)

The first dimension is set as the total power consumption of the user. The corresponding EBGN public key is $P_1$, and the control center is granted access rights. If the key $Q$ of EBGN is used as the plaintext data encrypted by CP-ABE, the cipher-text encrypted by CP-ABE and the CP-ABE key generated for the control center and the visitor are as follows.

$$CT_i = CP - ABE.Enc\left( Q_i, \tau_i, PK_{CP-ABE} \right), i \in \{1, 2, \cdots, k\}$$ (6)

$$SK_{uj} = CP - ABE.KeyGen\left( S_{uj}, MK_{CP-ABE}, GID \right), j \in \{1, 2, \cdots, m\}$$ (7)

Where $S_{uj}$ represents the attribute set. $MK_{CP-ABE}$ represents the master key, and $GID$ represents the visitor identity. Let $SK_{u1}$ denote the key of the control center and $m$ denote the total number of visitors. The EBGN key $Q_i$ is encrypted according to the access structure $\tau_i$. Finally, the private data and the visitor are encrypted and accessed according to the attribute mapping table, and the key $SK_{uj}$ is sent to the visitor $uj$ (such as a control center) through secure communication [18].

### B. Blockchain Encryption and Aggregation

A terminal $S_i$ in an area collects $k$ types of data information according to different attribute sets, which is represented as $M_{S_i} = (M_{i,1}, M_{i,2}, \cdots, M_{i,k})$. The cipher-text after the value of $M_{i,j}$ of each dimension does not exceed the constant $B$ and the data information $C_i$ is encrypted by EBGN, which is shown below.

$$C_i = EBGN.Enc(M_{S_i}, PK_{EBGN})$$

(8)

After receiving all the cipher-text information $C_i$, the gateway performs data aggregation on the cipher-text information is in the following manner.

$$C = EBGN.Add(C_1, C_2, \cdots, C_n) \tag{9}$$

The gateway then sends the encrypted and aggregated data to the control center.

Taking the *jth* dimensional data $M_{i,j}$ in the data collected by the terminal $S_i$ as an example, the following calculation can be performed.

$$M_{i,j} = \sum_{l=0}^{|M_{i,j}|} 2^l \cdot M_{i,j,l} \tag{10}$$

$$P_{j,l} = 2^l \cdot P_j, \quad 1 \le l \le |B| \tag{11}$$

$$R_l = 2^l \cdot R, \quad 1 \le l \le |R| \tag{12}$$

The encrypted cipher-text is shown in the following calculation.

$$C_i = (\sum_{j=1}^{k} \sum_{l=0}^{|M_{i,j}|} M_{i,j,l} \cdot P_{j,l}) + \sum_{l=0}^{|\Re_i|} \Re_{i,l} \cdot R_l$$
$$= (\sum_{j=1}^{k} \sum_{M_{i,j,l}}^{|M_{i,j}|} P_{j,l}) + \sum_{l=0,\Re_{i,l}}^{|\Re_i|} R_l \tag{13}$$

Where $M_{i,j,l}$ denotes the *lth* bit of $M_{i,j}$ and $\Re_{i,l}$ denotes the *lth* bit of $\Re_i$.

### C. Data Access

For example, the first dimension is the total power consumption data. If the control center needs the total power consumption data $C_1$ in the access area, the control center first needs to download the cipher-text data of the EBGN key $Q_1$ from the trusted institution and perform CP-ABE decryption to obtain the EBGN key as shown below.

$$Q_1 = CP - ABE.Dec(CT_1, SK_{u1}, \tau, GID) \tag{14}$$

According to the key $Q_1$ and the aggregate cipher-text $C$, the control center may obtain the data information of the first dimension through the following calculation.

$$M_{d_1} = EBGN.Dec(Q_1, P_1, C) \tag{15}$$

Therefore, the control center can obtain the data information of the first dimension, that is, the total power consumption demand in the region. The control center sends the aggregate cipher-text $C$ to the visitor in order to share the power data to the access mechanism. Similar to the control center, each visitor $DA_{u_i}$ first needs to download the data

cipher-text $C_j$ satisfying his access policy [19]. Then, the EBGN key $Q_j$ of the *jth* dimension is obtained by decrypting $C_j$ as follows.

$$Q_j = CP - ABE.Dec(C_j, SK_{u_i}, \tau, GID) \tag{16}$$

Next, the visitor can obtain the specific data information of the *jth* dimension through the EBGN decryption algorithm, as shown below.

$$M_{d_j} = EBGN.Dec(Q_j, P_j, C) \tag{17}$$

In this process, in addition to updating access rights, only the control center and each visitor need to perform CP-ABE decryption. In addition, the control center cannot obtain the data information of all dimensions, so there is no need to decrypt and re-encrypt the data information of all dimensions.

## V. EXPERIMENTAL ANALYSIS

In this paper, the performance of the proposed scheme is analyzed in terms of computational cost and communication overhead. Although system initialization also incurs computational costs, it only needs to be deployed once, which has a negligible impact on smart grid performance. Therefore, only the efficiency of encryption, aggregation, and decryption is tested here in experiments.

In the experiment, we first compare the encryption efficiency of the proposed scheme with that of scheme 2 in [20] and scheme 3 in [21]. Scheme 2 uses super-increasing sequence and Paillier homomorphic encryption to achieve the privacy protection of blockchain aggregation. Reference [21] constructs a Scheme 3 scheme based on Paillier and ABE, which integrates data aggregation and access control.

Experiments were conducted using the LiDIA library and the MIRALC environment by running on a PC with a 4.6 GHz processor and 16 GB of memory. The length of the key is chosen to be $l = 256$ bits, and the length of the random number is chosen to be $|R| = 70$ bits so that the present security can be ensured. For Scenario 2, the blockchain is merged into one plain text before encryption, which is the simplest and most efficient super-incremental sequence. Scenario 2 and Scenario 3 are set the same, using the Paillier public key with a length of 1024 bits.

### A. Cost Calculation

For data aggregation, the experiment takes 10 milliseconds to perform 100 aggregations in the scheme in this paper. In that data access phase, only the CP-ABE is executed to decrypt the EBGN key of the authorized single dimension, and the key of all dimensions does not need to be decrypted, so the influence on the efficiency of data share is small. Since Scenario 2 and Scenario 3 need to perform more operations on the gateway and the control center, such as decrypting and re-encrypting the aggregated data on the control center.

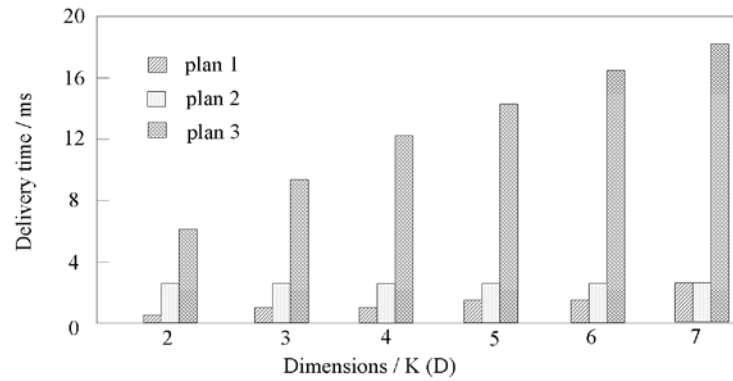
The experimental results are shown in Fig. 5.


Fig. 5.   Encryption Overhead in different Dimensions.

Since Scheme 2 always requires random numbers to be subjected to modular exponentiation, the encryption time of the blockchain does not increase with the number of dimensions. Moreover, Scheme 3 needs to generate multiple cipher-texts for the blockchain, and its encryption time increases linearly with the dimension. It can be concluded that the encryption time of the scheme in this paper is less than that of the scheme 2 when the dimension is $k < 7$. When $k = 7$, the efficiency of the scheme in this paper is similar to that of scheme 2.

### B. Communication Overhead

The communication overhead of the data information, i.e., the cipher-text of the EBGN in the scheme in this paper, is considered. According to the encryption algorithm, the length of the power data cipher-text is $2 \cdot (k + 1) \cdot l$ bits. When we choose the length of the key to be $l = 256$ bits and set $k = 7$, the length of the power data cipher-text is 4096 bits.

For Scheme 2, the cipher-text length of the blockchain is 2048 bits, which is the same as the cipher-text of one dimension in Scheme 3. The communication comparison between the scheme in this paper and the schemes 2 and 3 is shown in Fig. 6.

When $k = 7$ and $l = 256$ bits, the length of the power data cipher-text is 4096 bits in the scheme of this paper, which is twice of the cipher-text in the scheme 2. However, it is much smaller than the cipher-text 14336 bits in Scheme 3. The transmission of the cipher-text can be done immediately according to a common communication standard between the user and the building gateway. Compared with the encryption

time, the impact of communication on the timeliness of smart grid is basically negligible.

Compared with other schemes in terms of computation cost and communication overhead, the scheme proposed in this paper is more effective in the case of low dimensionality, which is suitable for the encryption efficiency requirements of smart grid, and can achieve flexible and fine-grained access control and permission update at the dimensionality level, so the scheme proposed in this paper is more flexible and practical.

### C. Privacy Protection Strength

The algorithm, PTM mechanism and GIPL mechanism are tested with different data sets. Firstly, the trajectory data is processed and then different random noises are added to the data. Then, the DTW value is calculated to represent the trajectory distortion, and the privacy protection performance of the trajectory data is analyzed. According to different distance thresholds, the experiment was divided into five groups, and the distance thresholds of each group were 100m, 300m and 500m, respectively. Each group of experiments was performed 100 times, and the final result was the average of the results of 100 times.

In a stationary user scenario, simulated data is used for experimental validation. In this scenario, because the user is in a static state, a trajectory sequence with all the same position points are simulated. There are 1000 identical position points in the trajectory sequence, so there is no need to set different distance thresholds, as shown in Fig. 7.

Fig. 6.   Cipher-text Length in different Dimensions.
Fig. 7.   Trajectory Distortion under different Privacy Budgets.

mechanism in this paper are decreasing, and the degree of privacy protection is also decreasing. However, no matter how the privacy budget changes, the trajectory distortion of the proposed algorithm is always smaller than that of PTM and GIPL.

The Geolife dataset is used for experimental validation in the low-speed running user scenario as shown in Fig. 8.

In Fig. 8, in the case of the same distance threshold, the trajectory distortion of the method proposed in this paper decreases with the increase of privacy budget, that is to say, in the case of the same distance threshold, as the privacy budget continues to increase, the closer the protected trajectory is to the original trajectory, the lower the degree of privacy protection is. Moreover, under the same privacy budget, the trajectory distortion of the proposed algorithm is always lower than that of PTM and GIPL.

In Fig. 7, with the increase of privacy budget, the trajectory distortion of the algorithm, PTM mechanism and GIPL

Fig. 8.   Trajectory Distortion of Geolife Data Set under different Privacy Budgets.

## VI. CONCLUSION

This paper explores the aggregation and access control of cloud Internet of Things blockchain on the demand side of the smart grid.

*1)* The related knowledge of smart grid data aggregation is studied, and the cloud Internet of Things data aggregation and access control privacy protection architecture on the demand side is proposed.

*2)* Based on this architecture, a blockchain aggregation and access control model is established. Encryption via EBGN preserves the priority of the blockchain and can decrypt each dimension separately using the corresponding key. By encrypting the EBGN key with a cipher-text policy attribute encryption algorithm, the scheme can achieve fine-grained access control.

*3)* The access rights can be updated flexibly and safely by regenerating the relevant parameters of EBGN and CP-ABE. Secondly, the security of privacy protection, access control, and access permission update of blockchain in this paper are analyzed and proved.

*4)* Through the performance analysis and comparison of the proposed scheme and similar schemes in terms of computing cost and communication overhead, it is shown that the proposed scheme has significant advantages in terms of computing cost and flexible fine-grained access control of blockchain in the face of a large number of smart grid demand-side terminals, large amount and variety of data, and the need for classification.

The research method in this paper realizes the encryption and aggregation of multi-dimensional data in the cloud Internet of Things. Each dimension can be encrypted with different public keys, and the multi-dimensional data is fused into a cipher-text. The EBGN private key of each dimension is encrypted by the cipher-text policy attribute encryption algorithm. The visitor is authorized to access the fine-grained data of the corresponding dimension, thus realizing the fine-grained access control of the multi-dimensional data.

In the privacy protection of the smart grid, this paper considers the privacy protection scheme on the demand side under the data aggregation model. It does not consider the smart grid marketing architecture, the home gateway smart community, and the privacy protection scheme under the vehicle networking model. In the future, the research on privacy protection schemes can be carried out under the multi-model of smart grid.

# Deep Convolution Neural Networks for Image Classification

Arun D. Kulkarni

Computer Science Department
The University of Texas at Tyler
Tyer, TX 75799, USA

*Abstract*—Deep learning is a highly active area of research in machine learning community. Deep Convolutional Neural Networks (DCNNs) present a machine learning tool that enables the computer to learn from image samples and extract internal representations or properties underlying grouping or categories of the images. DCNNs have been used successfully for image classification, object recognition, image segmentation, and image retrieval tasks. DCNN models such as Alex Net, VGG Net, and Google Net have been used to classify large dataset having millions of images into thousand classes. In this paper, we present a brief review of DCNNs and results of our experiment. We have implemented Alex Net on Dell Pentium processor using MATLAB deep learning toolbox. We have classified three image datasets. The first dataset contains four hundred images of two types of animals that was classified with 99.1 percent accuracy. The second dataset contains four thousand images of five types of flowers that was classified with 86.64 percent accuracy. In the first and second dataset seventy percent randomly chosen samples from each class were used for training. The third dataset contains forty images of stained pleura tissues from rat-lungs are classified into two classes with 75 percent accuracy. In this data set eighty percent randomly chosen samples were used in training the model.

*Keywords—Deep learning; convolutional neural networks; image classification; machine learning; object recognition*

## I. INTRODUCTION

Image classification can be defined as categorizing images into predefined classes. Traditionally, image classification is conducted in two stages- low-level processing and high-level processing or recognition. Low level processing deals with image enhancement, filtering, detecting regions of interest, and extracting feature descriptors. High-level processing deals with classification, where feature descriptors are used to train the classifier into predefined categories. The two stages are often implemented sequentially. First, feature descriptors are obtained and subsequently are classified. The main disadvantage of this approach is that accuracy of the classifier is dependent on the design of the feature extraction stage. Many machine learning algorithms such as decision trees, Support Vector Machine (SVM), neural networks have been used to classify feature vectors obtained from images. Machine learning algorithms are known to learn the underlying relationship in data and make decisions. Deep Convolution Neural Networks (DCNNs) are one of the best learning algorithms for understanding image content and have shown exemplary performance in image segmentation, detection, and retrieval tasks [1]. In the recent years DCNNs are preferred for image classification. DCNNs use multiple layers consisting of nonlinear information processing units for low-level as well as high-level processing. DCNNs are feedforward networks. In general, DCNNs consist of convolution and pooling layers that are grouped into modules followed by one or more fully connected layers. Convolutional layers are used for extracting features from the input image. In a convolution layer, inputs are convolved with a weighted kernel and the output is sent via a nonlinear activation function to the next layer. The purpose of pooling layers is to reduce spatial resolution of the features maps and achieve spatial invariance to input distortions and translations [2]. In earlier days, the average pooling was used, but recently the max pooling has become a common practice. Several convolution and pooling layers are stacked together. The fully connected layers are used for classification. DCNNs were successfully used to classify images in the ImageNet Large Scale Visual Recognition Challenge [3]. Recent developments in DCNNs were possible because of two main factors a) availability of faster computing resources such as Graphical Processing Units (GPUs) and b) availability of large, labeled image datasets Also, there were algorithmic improvements in Deep Neural Networks (DNNs). DCNNs commonly use the gradient decent backpropagation algorithm. There are some drawbacks with DCNNs. The first drawback is the use of Sigmoid activation functions that leads to saturation resulting into slow convergence of gradient descent. The problem becomes more severe as we move away from the output layer to hidden layers. The compounded effect of saturation at multiple layers is known as vanishing gradient [4]. In the backpropagation algorithm the mean squared error at the output layer is propagated backwards to the hidden layers to calculate the change in weights. To avoid the vanishing gradient problem, recent DCNNs use the entropy loss function with Rectified Linear Units (ReLU) in the output layer. The second drawback with DCNNs is overfitting that occurs due to the substantial number of parameters that are updated in learning. Overfitting usually occurs when the dataset is of the small size. Various regularization techniques such as the dropout or bagging are used to overcome this problem. The third drawback is due to the non-convex shape of the error function. The backpropagation algorithm is sensitive to the randomly chosen initial values of weights. The gradient descent algorithm may get stuck at a local minimum. To avoid this problem the model is initially trained with a few parameters and then more parameters can be added during the training. DCNN models trained with a large dataset and can

classify images with high accuracy. Many architectures for DCNN models have been used for image classification. In this paper we implement Alex Net using MATLAB deep learning toolbox. We use the model to classify three image datasets a) animal b) flower, and c) stained pleura tissue images. The outline of the paper is as follows. Section II describes related work. Section III deals with implementation Alex Net and results, and Section IV provides conclusions.

## II. RELATED WORK

Neural networks (NN) are biologically inspired and are used for object recognition, image classification. Neural networks have been used as associative memory to store and retrieve information. Associative memories function as content addressable memories. Neural networks learn from training samples and have been used for pattern recognition since the 1950s [5]. Feedforward networks with a backpropagation learning algorithm have been used as supervised classifiers [6]. Today several well-developed learning algorithms for multi-layer neural network models are available. These include a multi-layer Perceptron, feedforward networks with back-propagation learning, Boltzman machines, Hamming net, Hopfield net, neocognitron models [ 7, 8, 9, 10, 11] Huang and Lippmann [12] provide a comparative study of neural networks and conventional classifiers. Neural networks have been used to implement expert systems or knowledge-based system. The success of neural networks has led to deep neural networks (DNNs). Deep learning algorithms were available since late 1980s, However, DNNs were computationally expensive. Chellaplla [13] suggested using Graphical Processing Units (GPUs) to implement deep learning algorithms faster. Deep learning is a form of machine learning that enables computers to learn from experience and understand the world in terms of hierarchy of concepts [14]. DNNs are neural networks with multiple hidden layers. The multiple hidden processing layers has dramatically improved the state-of-the art visual object recognition. DNNs discover intricate structures in large datasets by using the backpropagation algorithm [15]. Convolutional neural networks (CNN) are special type of neural networks for processing data that have a known grid-like structure [16]. Various stages of a DCNN show topology resemblance to primate's ventral pathway of visual cortex [17]. DCNNs can learn internal representations from raw pixels. DCNNs are hierarchical learning models and can extract features [18,19,20]. Rawat and Wang [21] present a comprehensive review of DCNNs. DCNNs consist of a stack of convolution and pooling layers followed by fully connected layers. Convolution and pooling layers are used for features extraction. The max-pooling method is a wieldy accepted method in recent DCNNs. Scherer et al [22] have shown that the max-pooling method can capture the invariance and is effective in reducing the computational time. DCNNs have been used in many computer applications that include image and object classification, face detection, image segmentation, and gesture recognition. Recent DCNNs have ten layers of ReLU, hundreds of millions of weights, and billions of connections between units [15]. Machine learning community's interest in DCNNs grew after Image Net compaction in 2012, where Alex Net achieved record breaking results in classifying images from ILSVRC data set consisting of more than 1.2 million images in to one thousand classes. This was a landmark achievement that has revolutionized the computer vision field. Significant achievements in DCNNs are a) LeCun et al. [2] used a DCNN to classify 70,000 hadwritten images of digits in to ten classes. b) Fei-Fei et al. [23] used a DCNN to classify 9,146 color images from CALTECH-101 data set in to 101 classes. c) Krizhevsky [24] classified 60,000 images in CIFAR-100 data set into one hundred classes. d) Russakovsky et al [25] classified more than 1.2 million images from ILSVRC dataset into one thousand classes. LeNet was proposed by LeCun et al. [26]. Alex Net proposed by Krizevsky et al [3] was based on principles used in LeNet Simonyan et al. [27] proposed a DCNN model VGG Net that was made nineteen layers deep and used 3x3 filters. The use of small size filters could induce the effect of large size filters and provided computational simplicity by reducing the number of parameters. Nowadays, most new DCNN architectures are built upon the principle of simple and homogenous topology as introduced in VGG Net. Zhang et al, [28] provide the taxonomy of CNNs. Khan et al. [29] discuss intrinsic taxonomy present in the recent and prominent DCNN architectures reported from 2012-2020. They have classified DCNN architectures into seven categories, namely, spatial exploitation, depth, multi-path, width, feature-map exploitation, channel boosting, and attention-based. Stacking of multiple transformations deep and in parallel fashion showed good learning for complex problems [30, 31]. Google Net was the winner of the 2014-ILSVRC competition [32]. Google Net introduced the concept of inception block, which incorporates multi-scale convolutional transforms using split, transform, and merge idea. The textbook by Szelinski [33] describes deep learning techniques including deep feedforward networks, regularization, optimization algorithms, convolutional neural networks. We have implemented Alex Net using MATLAB deep learning toolbox and have analyzed three datasets.

## III. IMPLEMENTATION AND RESULTS

The simplified architecture of Alex Net is shown in Fig. 1. It contains eight layers: five convolution and three fully connected layers. Convolution layers serve as feature extractors. Inputs are convolved with learned weights to compute feature maps and results are sent through a nonlinear activation function. The output of the $k$th feature map $Y_k$ is given by (1).

$$Y_k = f\left(W_k * x\right) \tag{1}$$

Where x denotes the input image, $W_k$ is the convolution filter. The '*' sign refers to the 2D convolution operator. The purpose of the pooling layer is to reduce the spatial resolution and extract invariant features [21]. The output of a pooling layer is given by (2).

$$Y_{kij} = \max_{(p,q)\in R_{ij}}\left(x_{kpq}\right) \tag{2}$$

Where $X_{kpq}$ denotes elements at location ($p$, $q$) contained by the pooling region $R_{ij}$.
Fig. 1.    Alex Net Architecture.

Fig. 2. Illustrates the max pooling operation. Inputs are mapped from a convolution layer to the pooling layer. With a 4x4 mask, the maximum value in each 2x2 sub-area is mapped. The fully connected layers follow the convolution layers that interpret extracted features and perform high level reasoning. DCNNs use learning algorithms to adjust the free parameters in the network to obtain the desired output. The most common algorithm is the backpropagation learning algorithm. The commonly experienced problem with DCNNs is overfitting. This is due to the substantial number of free parameters that are adjusted during learning. The layers in the Alex Net are shown in Table I.

Fig. 2.    Max Pooling.

TABLE I.          LAYERS OF ALEX NET

|  | Input image | 224x224x3 (Channels) |
|---|---|---|
| L1 | Convolution Layer with a Pooling Layer | 96 kernels of size 11x11x3 |
| L2 | Convolution Layer with a Pooling Layer | 256 kernels of size 5x5x48 |
| L3 | Convolution Layer | 384 kernels of size 3x3x256 |
| L4 | Convolution Layer | 384 kernels of size 3x3x192 |
| L5 | Convolution Layer with a Pooling Layer | 256 kernels of size 3x3x192 |
| L6 | Fully Connected Layer | 4096 neurons |
| L7 | Fully Connected Layer | 4096 neurons |
| L8 | Fully Connected Layer | 4096 neurons |

We implemented Alex Net using MATLAB deep learning toolbox. We analyzed three datasets. There are described below:

Example 1: In this example we have considered the subset of animal dataset [34]. The original dataset has 37 categories with 200 samples in each category. For this example, we have selected only two categories. The dataset consists of four hundred images of cats and dogs that are obtained with distinct

backgrounds and with a variety of sizes and positions of these animals. We used seventy percent of randomly picked samples from each class to train Alex Net and thirty percent of samples were used for validation. Fig. 3 shows some randomly picked images from the dataset. Images in the dataset we resized to 224 rows x 224 columns. There were two units in the fully connected output layer. The DCNN was able to classify the dataset with 99.9 percent accuracy. Fig. 4 shows the graph for the accuracy and the loss function with iterations. Fig. 5 shows a few classified randomly chosen images with labels.

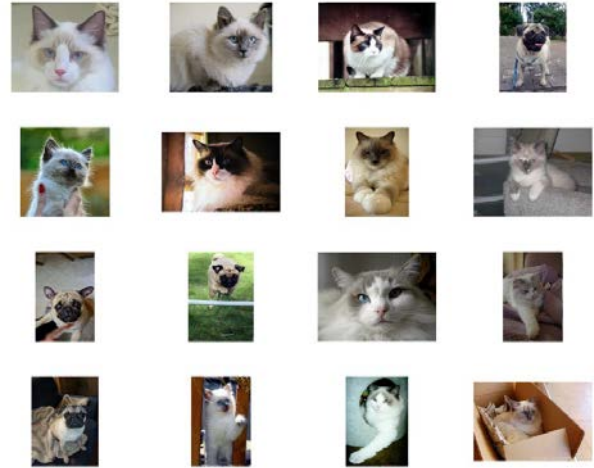

Fig. 3.    Sample Images from Animal Dataset.

Fig. 4.    Accuracy and Loss Function for Animal Dataset.

Fig. 5.    Classified Sample Images with Class Labels.

Example 2: In this example we have considered a subset of the flower dataset [35]. The subset consists of four thousand images of five types of flowers: daisy, rose, dandelion, sunflower, and tulip. The dataset contains images that are obtained with distinct color background and with a variety of sizes and colors of flowers. We used seventy percent of randomly picked samples from each class to train Alex Net and thirty percent of samples were used for validation. Fig. 6 shows some randomly picked images from the dataset. Images in the dataset were resized to 224 rows x 224 columns. There were five units in the fully connected output layer. The network took 256 minutes for training on Dell Pentium processor. The DCNN was able to classify the dataset with 86.6 percent accuracy. Fig. 7 shows the graph for the accuracy and the loss function with iterations. Fig. 8 shows a few classified images with labels.

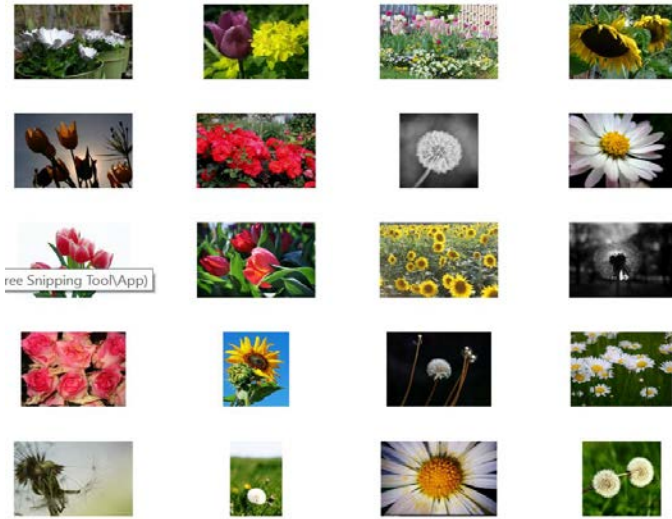

Fig. 6.    Sample Images from Flower Dataset.

Fig. 7.    Accuracy and Loss Functions for Flower Dataset.

Fig. 8.    Classified Output with Class Labels.

Example 3: In this example we have considered the stained pleura images of rat-lungs. These are pathological images representing positive and negative cancer cases. The dataset consists of forty images, twenty images in each class. We used eighty percent of randomly picked samples from each class to train Alex Net and twenty percent of samples were used for validation. Fig. 9 shows some randomly picked images from the dataset. Images in the dataset we resized to 224 rows x 224 columns. There were two units in the fully connected output layer. The DCNN was able to classify the dataset with 75 percent accuracy. Fig. 10 shows the graph for the accuracy and the loss function with iterations. Fig. 11 shows a few classified images with labels.

Fig. 11. Classified Output with Labels -Pleura Dataset.

## IV. CONCLUSION

In this research work, we have implemented Alex Net using MATLAB deep learning toolbox and have analyzed three datasets. The classification accuracy for the animal dataset was 99.01 percent. The classification accuracy for the flower dataset was 86.64 percent. Images of several types of flowers were obtained with various backgrounds, sizes, colors. In the flower dataset, many images in two categories sunflower and dandelion are similar. It is hard to distinguish between the two classes as these classes could be non-separable or overlapping classes in the feature space. In the case of pleura image classification, we obtained the classification accuracy of 75 percent. This because the sample size for the dataset was too small. The dataset contained only forty images, out of which 80 percent were used for training. Due to the substantial number of free parameters in the model and the small sample size of the training set, there is possibility of model overfitting. This may result in less accuracy. Also, training and testing images were selected randomly and sometimes we got 100 percent accuracy. We need a large dataset to evaluate this application. The DCNN presented in the paper can be used for other practical applications such as object recognition, military reconnaissance, medical image diagnosis, etc.

Many DCNN models are proposed in the literature. These models vary in the depth, width, activation functions, kernel size, and hardware implementation. It is possible to add layers to a DCNN to extract transformed domain features with the ring- and wedge-shaped filters to extract texture as well as scale and rotation invariant features. Also, it is not yet clear how image features or properties of image categories are represented in the DCNN models. In the case of neural networks, researchers have been able to extract knowledge in term of classification rules by tracing links in the neural net. However, in the case of DCNNs, due to the large number of free parameters, researchers have not been yet able to decode the DCNN models or extract the knowledge as how DCNNs make decision. It is an open area for the future research.

*Abstract*—This paper studies on the food distribution route planning problem for improving the customer satisfaction and the operator cost of food providers. In the first, the problem is formulated to a combinatorial optimization which is hard to be solved. Thus, a polynomial time algorithm is proposed to solve the problem, combining genetic algorithm and neighbourhood search, to increase the total amount of distributed food and reduce the distribution cost. The proposed algorithm employs the genetic algorithm with integer coding to decide the assignment of customers to distribution vehicles, and integrates the neighbourhood search strategy into the genetic algorithm to improve its performance. Experiment results show that the proposed method improved the distribution performance up-to 111.09%, 73.10% and 70.21%, respectively, in the distributed food amount, the cost efficiency, and the customer satisfaction.

*Keywords*—*Logistics; genetic algorithm; neighbourhood search; food distribution*

## I. INTRODUCTION

As the development of economy and society in the global, the requirement for the food quality is increasing continuously in most countries. In 2021, the cumulative retail value of grain, oil and food commodities reaches 1675.91 billion yuan, with an increase of 10.8% from 2020, in China [1]. Modern logistics and e-commerce promote the demand growth of food logistics. The main mode of food shopping is becoming from going to retailer to on-line ordering on Internet. Recently, the scale of e-commerce market for fresh food products is increasingly growth. For example, Chinese e-commerce market for fresh food products is increased with a compound annual growth rate at 25%, from 2016 to 2019, and its growth rate has greatly increased during the COVID-19 pandemic [2].

For food suppliers, especially for fresh food suppliers, an unreasonable distribution route strategy can decrease the user satisfaction [3] and increase the distribution cost [4]. Food logistics distribution planning method is an efficient way to address this issue [5]. Unfortunately, the distribution route problem is NP-hard [6], and thus cannot be solved exactly when it is large in the scale. Two kinds of approximate methods can be applied for solving large-scale route problems, heuristics and meta-heuristics. In general, heuristic-based methods can provide a local optimization solution fast. But they usually

have a limited performance in problem solving due to their local search strategies. Meta-heuristics can achieve a better performance than heuristics, benefiting from their global search abilities inspired by natural phenomena and laws [7].

Therefore, several existing works exploited various meta-heuristic algorithms to solve the food distribution route problem, for improving the distribution cost or time. But these existing works have some issues which restrict their practices. Some works focused on the single-station distribution problem. A part of works concerned food distribution in only one temperature range. Few works considered to exploit multiple temperature zone refrigerated vehicle for simultaneously distributing foods with different temperature requirements by one vehicle, to improve the usage efficiency of distribution vehicles. Therefore, in this paper, to improve the efficiency of multi-temperature food distribution, a router algorithm is proposed by integrating the neighbourhood search strategy into the genetic algorithm, with objectives of optimizing the amount of distributed foods and the cost for the food distribution. And extensive experiment results verify the performance superiority of our proposed algorithm.

The rest of this paper is organized as follows. Section II illustrates published works aiming at solving food distribution route problems. Section III routes the route problem concerned in this paper. Section IV presents our proposed distribution planning method. Section V evaluates our proposed method by simulated experiments. And finally, Section VI concludes the paper.

## II. RELATED WORK

Wang et al. [8] proposed a parthenogenetic algorithm-based method to address the route problem for flesh foods with a same temperature requirement, to optimize the customer value and satisfaction. Zhu and Wang [9] exploited ant colony algorithm to solve the distribution route problem for pharmaceutical cold chain logistics, aiming at completing a distribution task with minimal cost. Based on ant colony algorithm, Fang et al. [10] presented a distribution planning method to improve the operating cost and the green cost. Their method used A* algorithm to improve the slow convergence speed problem due to the insufficient pheromone in the initial

stage of ant colony algorithm. For optimizing the total cost of food distribution, Ren et al, [11] designed a knowledge based ant colony algorithm by integrating the elitist tabu search and the knowledge model of dynamic probability selection into ant colony algorithm. By integrating the mutation operator of simulated annealing into genetic algorithm, Li et al. [12] designed a distribution planning method for green fresh foods. These above works focused on the food distribution route problem for single-station, which limits their application scopes.

To address the multi-station problem, Prajapati et al. [13] proposed a heuristic method based on clustering algorithm, to optimize the transport distance and utilization of distribution vehicles. The proposed method first clustered customers, and then iteratively serviced a class of customers with minimal traveller's distance. This work didn't concern the temperature requirements of foods. Wang et al. [14] presented a hybrid heuristic method to optimize the distribution cost and the number of used refrigerator vehicles for fresh foods. This hybrid heuristic method first clustered customers according to their locations and requirements, and then, combine Tabu search and NSGA-II to solve the route problem, with the heuristic idea of using a vehicle to service customers with similar locations and requirements. Tsang et al. [15] exploited multi-objective genetic algorithm based on linear weighting method to improve the number of used refrigerator vehicles, customers' satisfactions and the transport time. These methods assumed there are sufficient refrigerator vehicles for satisfying all customer requirements by only one trip. These assumptions narrow down their application ranges.

Liu et al. [16] employed simulated annealing algorithm for optimizing the transport cost of cold-chain product distributions. This work assumed vehicles didn't return after finishing their distribution tasks, which results in an underestimation of the transport cost. Stellingwerf et al. [17] studied on the cold-chain distribution router problem to optimize the transport cost and the food quality. They modelled the problem into a mixed integer linear programming, and proposed to solve it by existing solvers for small-scale problems. This isn't applicable for solving large-scale problems. Ding [18] used the linear weighting method to transform three optimization objectives into one, for minimizing the distribution cost, the distribution time and the distribution risk, and applied ant colony algorithm with quantum bits to solve the distribution problem. All of these above works assumed each vehicle can transport only one kind of fresh foods. And thus they didn't consider to exploited the multiple temperature zone refrigerated vehicle [19], [20], which can distribute frozen, refrigerated and ambient foods by one vehicle at once. This can lead to a low usage efficiency of distribution vehicles by increasing the number of used vehicles, and thus increase the distribution cost.

Different from existing works, this paper focuses on the distribution router problem in multiple temperature ranges for the scenario of multi-station. This paper try to optimize the distribution efficiency by increasing the total amount of distributed foods and decreasing the total distribution cost, with limited distribution vehicles.

## III. PROBLEM STATEMENT

This paper focuses on the router problem for multi-temperature foods distributed by multi-station. Each distri-

bution station is equipped with several distribution vehicles for its food distribution. There are three kinds of foods to be distributed, ambient, refrigerated, and frozen foods. Each vehicle has ability for distributing one or more kinds of foods, considering the refrigerated vehicle with multiple temperature zones. The food supplier need to decide a router strategy to distribute foods to customers of various places from its food distribution stations. The aim of this paper is to provide a router strategy, which is deciding which vehicle is used to distribute foods for each customer, and deciding the distribution router of each vehicle, for optimizing the distributed food amount and the distribution cost. In this paper, each vehicle is assumed to be used once at most for the food distribution. When some customers' requirements cannot satisfied, the food supplier executes our method more times to distribute foods ordered by these customers. Each vehicle is return its original station for subsequent distribution tasks.

Assuming there are $S$ distribution stations, $s_k, 1 \leq k \leq S$. The location of station $s_k$ is $(x_k^s, y_k^s)$, where these two dimensions can represent respectively the latitude and longitude. There are $V$ vehicles, $v_i, 1 \leq i \leq V$. The loading capacities of vehicle $v_i$ for distributing ambient, refrigerated, and frozen foods are respectively $q_i^a$, $q_i^r$, and $q_i^f$. If $v_i$ cannot distribute refrigerated (frozen) foods, $q_i^r$ ($q_i^f$) is 0. Binary constants $a_{i,k}$ are used to represent whether $v_i$ is equipped in $s_k$. If $v_i$ is equipped in $s_k$, $a_{i,k}$ is 1, and otherwise, $a_{i,k} = 0$. There are $U$ customers, $u_j, 1 \leq j \leq U$, ordering various foods needed to be distributed. The amount of ambient, refrigerated, and frozen foods ordered by customer $u_j$ are respectively $qa_i$, $qr_i$, and $qf_i$. The location of $u_j$ is $(x_k^u, y_k^u)$. The distances between a station and a customer and between two customers can be calculated according to their locations, respectively.

Binary variables $z_{i,j}$, $1 \leq i \leq V$, $1 \leq j \leq U$, are used to represent whether the foods required by a customer is distributed by a vehicle. If $u_j$'s required foods are distributed by $v_i$, then $z_{i,j} = 1$, and otherwise, $z_{i,j} = 0$. To reduce the time of inspecting and tallying foods for customers for avoiding the decreasing of the customer satisfaction, all foods required by a customer are assumed to be distributed by only one vehicle, i.e.,

$$\sum_{i=1}^{V} z_{i,j} \leq 1, 1 \leq j \leq U. \tag{1}$$

A complete router strategy includes not only deciding the vehicle that distributes foods for each customer, but also deciding the distribution order for each vehicle when it serves multiple customers. Integer variables $o_j \in [1, U], j = 1, 2, ..., U$, are used to represent the decision of the distribution order. For a vehicle serving multiple customers, foods required by $u_{j1}$ are distributed before $u_{j2}$ if and only if $o_{j1} < o_{j2}$. As the distribution orders for any two customers are not identical when they are served by one vehicle,

$$\sum_{\substack{1 \leq i \leq V \land \\ j1 \neq j2 \land \\ z_{i,j1} \cdot z_{i,j2} = 1}} (o_{j1} - o_{j2}) \leq 0, 1 \leq j1, j2 \leq U. \tag{2}$$

For each vehicle, the accumulated amount of foods distributed is not exceeding its capacity, then the following

inequation hold.

$$\sum_{j=1}^{U} z_{i,j} \cdot qa_j \leq q_j^a, 1 \leq i \leq V, \tag{3}$$

$$\sum_{j=1}^{U} z_{i,j} \cdot qr_j \leq q_j^r, 1 \leq i \leq V, \tag{4}$$

$$\sum_{j=1}^{U} z_{i,j} \cdot qf_j \leq q_j^f, 1 \leq i \leq V. \tag{5}$$

For a vehicle, there is a cost to use it for food distribution, which is constituted of the startup and transport costs. The commonly linear model is used for evaluating the cost of a vehicle usage,

$$C_i = e_i + \int_l (c_i^{idle} + (c_i^{full} - c_i^{idle}) \cdot \frac{w_i}{q_i^a + q_i^r + q_i^f}) dl. \tag{6}$$

Where $e_i$ is the startup cost of $v_i$, which includes the driver wage, etc., and is usually considered as a constant. $l$ represents the transport route of the vehicle. $c_i^{full}$ and $c_i^{idle}$ are the costs per unit of transport distance respectively when $v_i$ is empty and full loaded. $w_i$ is the load varied with the transport route, for $v_i$. $\frac{w_i}{q_i^a + q_i^r + q_i^f}$ represents the utilization of $v_i$.

The food distribution can be see as three stages for each vehicle, food distribution from the station to the first customer, food distributions from a customer to another customer repeatedly, and return station from the last customer. In the first stage, their is an increased cost ($P1_i$) for distributing foods to the first customer, and the load of $v_i$ is the accumulated amount of foods required by all customers that the vehicle serves, $\sum_{j=1}^{U}(z_{i,j} \cdot (qa_j + qr_j + qf_j))$. $d_{i,j}^{su}$ is used to represent the distance between $u_j$ and the station equipped with $v_i$, which can be easily calculated by the locations of the user and the station. Then,

$$P1_i = \sum_{\substack{1 \leq j \leq U \wedge \\ z_{i,j} \cdot o_j = 1}} (d_{i,j}^{su} \cdot \quad (c_i^{idle} + (c_i^{full} - c_i^{idle})$$
$$\cdot \frac{\sum_{j=1}^{U}(z_{i,j} \cdot (qa_j + qr_j + qf_j))}{q_i^a + q_i^r + q_i^f})). \tag{7}$$

In the second stage, their is a distribution cost for each transport from one customer to another customer, where the transport distance is the distance between these two customers, and the load is the accumulated amount of foods needed to be distributed to customers that have not been served. $d_{jj,j}^{uu}$ is used to represent the distance between customer $u_{jj}$ and customer $u_j$. Then the cost in the second stage can be calculated by

$$P2_i = \sum_{\substack{1 \leq j \leq U \wedge \\ z_{i,j} \cdot o_j > 1}} ((\sum_{\substack{1 \leq jj \leq U \wedge \\ z_{i,jj} \cdot o_{jj} = o_j - 1}} d_{j,jj}^{uu})$$
$$\cdot (c_i^{idle} + (c_i^{full} - c_i^{idle})$$
$$\cdot \frac{\sum_{\substack{1 \leq jj \leq U \wedge \\ z_{i,jj} \cdot o_{jj} > o_j}} (z_{i,jj} \cdot (qa_{jj} + qr_{jj} + qf_{jj}))}{q_i^a + q_i^r + q_i^f})), \tag{8}$$

where $\sum_{\substack{1 \leq jj \leq U \wedge \\ z_{i,jj} \cdot o_{jj} = o_j - 1}} d_{j,jj}^{uu}$ is the transport distance from customer $u_j$ to its next customer $u_{jj}$ ($o_{jj} = o_j - 1$).

$\sum_{\substack{1 \leq jj \leq U \wedge \\ z_{i,jj} \cdot o_{jj} > o_j}} (z_{i,jj} \cdot (qa_{jj} + qr_{jj} + qf_{jj}))$ is the accumulated amount of foods required by customers with service orders after $u_j$.

After all customers have been served, in the last stage, the vehicle will return the station that is equipped with it, with idle load. The transport distance is the distance between the station and the last customer served, which is $\sum_{\arg\max_j\{z_{i,j} \cdot o_j\}} (z_{i,j} \cdot d_{i,j}^{su})$ for $v_i$. Therefore, the cost in the third stage for $v_i$ is

$$P3_i = c_i^{idle} \cdot \sum_{\arg\max_j\{z_{i,j} \cdot o_j\}} (z_{i,j} \cdot d_{i,j}^{su}). \tag{9}$$

Combining all of above costs, the total distribution cost for each vehicle can be calculated by Eq. (10).

$$C_i = e_i + P1_i + P2_i + P3_i, 1 \leq i \leq V. \tag{10}$$

Then, the multi-temperature food distribution router problem can be formulated by the following optimization problem:

$$\text{Maximizing}\{\sum_{i=1}^{V} \sum_{j=1}^{U} (z_{i,j} \cdot (qa_j + qr_j + qf_j)) - \sum_{i=1}^{V} C_i\} \tag{11}$$

Subjective to:

$$Eq.\ (1) - Eq.\ (10), \tag{12}$$
$$z_{i,j} \in \{0,1\}, 1 \leq i \leq V, 1 \leq j \leq U, \tag{13}$$
$$o_j \in [1, U], 1 \leq j \leq U. \tag{14}$$

The optimization objective is maximizing the accumulated amount of distributed foods and minimizing the total distribution cost. In practice, the maximization of the distributed food amount is considered as the major optimization objective, as it directly affects the customer satisfaction, and the cost minimization as the minor one. This can be implemented by weighting foods in kilograms (kg) and counting the cost in hundred-dollar units, because a vehicle has thousands of kilograms in loading capacity and it costs hundreds of dollars to distributed foods by the vehicle at a time, in real world. Eq. (refeq:z) and (14) define the value ranges of discrete decision variables. This problem is a combinatory optimization problem, which can be solved by some existing tools, e.g., Gurobi Optimizer [21] and lpsolve [22]. But the time exhausted by these tools are exponentially increased with the problem scale in general, which makes them not suitable for solving large scale problems. Therefore, in the next section, a food distribution router planning method is proposed based on genetic algorithm to provide a router solution in polynomial time.

## IV. Improved Genetic Algorithm-based Food Distribution

This section proposes a food distribution router planning method based on genetic algorithm (GA). To improve the performance of GA, the neighbourhood search (NS) strategy is integrated into GA, which helps to increase the diversity of populations. The proposed method, GANS, is outlined in Algorithm 1. As shown in the algorithm, at first, GANS initializes chromosomes by randomly setting the value of

---

12: **return**  $W - C$;

---

each gene (line 1 in Algorithm 1), where each chromosome represents an assignment of customers to vehicles. In each chromosome, There is a corresponding relationship between genes and customers, and thus its length is the number of customers. The value of a gene represent the vehicle allocated to the corresponding customer for its food distribution. After the chromosome initialization, GANS repeats the chromosome evolution by crossover and mutation crossovers as well as NS strategy (lines 2–9 in Algorithm 1).

In the stage of the chromosome evolution, a fitness function must be designed for evaluating the quality of each chromosome. In this paper, the fitness function is defined as the optimization objective (11), i.e.,

$$fitness = W - C, \tag{15}$$

where $W$ is the total amount of distributed foods, which is $\sum_{i=1}^{V} \sum_{j=1}^{U} (z_{i,j} \cdot (qa_j + qr_j + qf_j))$. $C$ is the total cost for food distribution, which is $\sum_{i=1}^{V} C_i$.

Given a chromosome, its fitness value can be calculated as following, shown in Algorithm 2. First, the chromosome is decoded into the assignment of customers to vehicles (line 1 in Algorithm 2). Then for each vehicle (line 2 in Algorithm 2), first fit heuristic method is applied for loading foods of customers assigned to the vehicle (line 3–11 in Algorithm 2). When foods required by a customer are loaded, their weights are accumulated to $W$ (line 7 in Algorithm 2). After food loading for a vehicle, its cost can be calculated by Eq. (10), and the cost is accumulated to $C$ (line 9 in Algorithm 2). In the end of Algorithm 2, the fitness value is achieved by $W - C$ (line 12 in Algorithm 2).

In each chromosome evolution, GANS first evaluates the fitness for every chromosome using Algorithm 2 (line 3 in Algorithm 1), and find the best fitness (new one). Then, if the best fitness is better than the current one achieved in preceding evolutions, GANS updates the current best fitness and the current best chromosome to the new best fitness and its corresponding chromosome, respectively (line 4 in Algorithm 1). After this, GANS evolves chromosomes by

crossover, mutation, and NS to generate offspring, and the selection operator to produce a new generation (lines 5–8 in Algorithm 1), as detailed following:

*Crossover*: For the crossover operation, each chromosome is picked with a certain probability, and the one-point crossover operator is performed for every two picked chromosomes to create two new chromosomes (offspring) (line 5 in Algorithm 1).

*Mutation*: For each chromosome, it has a certain probability to be mutated to produce a new offspring (line 6 in Algorithm 1). In this paper, the uniform mutation is chose due to its effectiveness for large-scale problems.

*Neighbourhood Search (NS)*: To increase the diversity of chromosomes for improving the global search ability of GA, we propose to integrate NS strategy into GA (line 7 in Algorithm 1). Specifically, for each chromosome, GANS randomly generates two points, and swaps genes in these two points, which generates a new offspring.

*Selection*: To realize the evolution, a selection operator must be performed for the population consisted of chromosomes in the current generation and new offspring produced by above operators, to produce a new generation (line 8 in Algorithm 1). GANS employs the tournament selection which retain the best chromosomes to the next generation.

After the generation evolution, GANS has the best chromosome with the best fitness. Then, by Algorithm 2, a distribution router strategy is provided from the best chromosome.

## V.  Performance Evaluation

To evaluate the performance of our proposed method, a simulated experiment environment is generated. In the simulated environment, as shown in Fig. 1, the distribution coverage is a square area from (-100, -100) to (100, 100) in km. Four distribution stations are respectively deployed on the points of (50, 50), (-50, 50), (-50, -50), and (50, -50). There are total 10 delivery vehicles. The probabilities of every vehicle having the abilities of distributing refrigerate foods and frozen foods are both 50%. The loading capacity of each vehicle is randomly set in the range [100, 1000] kg for each kind of foods. The startup cost is set as [1, 10] thousand dollars, randomly. The

transport costs of every vehicle are 0.5–1 and 5–10 dollars per kilometre respectively when the vehicle is empty and full-load. There are 100 customers randomly distributed in the service area. The probabilities of each customer requiring refrigerate and frozen foods are both 50%. The amount of foods required by every customer is randomly set in the range of [10, 100] kg.

GANS is compared with the following food distribution router planning methods:

- *Random method* randomly generates a customer assignment solution to vehicles, and uses Algorithm 2 to provide a router solution.

- *Greedy method* assigned every customer to the vehicle that can satisfy its requirements and is closest to it.

- *Particle Swarm Optimization-based method (PSO)* exploits PSO algorithm using Algorithm 2 for evaluating the fitness of particle positions.

- *Genetic algorithm-based method (GA)* is same to GANS except that GA doesn't use NS for its evolution.

The performance of each method is evaluated from the following three aspects. The amount of distributed foods, the cost efficiency, and the customer satisfaction. The first one metric is the major optimization objectives this paper focused on. The second one is the distributed food amount per dollar, which is the ratio of the distributed food amount to the total cost for the food distribution. For the customer satisfaction, the ratio between numbers of served customers and all customers is used to quantify it. The experiment is repeated 20 times, and the results are given in Table I, II, and III. For each time, the environment is identical for all methods' evaluation.

As shown in these results, GANS achieves 15.82%–46.70% more distributed food amount, 17.23%–71.53% higher cost efficiency, and 9.90%–47.18% better customer satisfaction, on average, compared with other methods. This indicates that GANS performs good in all of three aspects. This is benefited from the global search ability of GA and the improvement of NS strategy.

Compared with GA, GANS achieves 11.29%–30.61% more distributed food amount, 12.21%–27.63% higher cost efficiency, and 7.95%–21.87% better customer satisfaction. This verifies the effectiveness of integrating NS strategy into GA for the performance improvement.

## VI. Conclusion

This paper studies on the router planning problem for food product suppliers to efficiently distribute multi-temperature foods with several stations. First, the problem is formulated into a combinatory optimization problem. Then, a router planning method is designed based on genetic algorithm, and its performance is improved by integrating a neighbourhood

search strategy into the genetic algorithm. Experiment results prove that our method can obtain good performance in various aspects.

There are numerous crossover, mutation, NS, and selection operators that can be applied for GANS. The influences of these operators on the performance of GANS should be studied to implement algorithm instances with better performance for various food distribution scenarios. This is one of our future works.

# An Efficient System for Real-time Mobile Smart Device-based Insect Detection

Thanh-Nghi Doan

Faculty of Information Technology, An Giang University
Vietnam National University Ho Chi Minh City, An Giang, Vietnam

*Abstract*—In recent years, the rapid development of many pests and diseases has caused heavy damage to the agricultural production of many countries. However, it is difficult for farmers to accurately identify each type of insect pest, and yet they have used a large number of pesticides indiscriminately, causing serious environmental pollution. Meanwhile, spraying pesticides is very expensive, and thus developing a system to identify crop-damaging pests early will help farmers save a lot of money while also contributing to the development of sustainable agriculture. This paper presents a new efficient deep learning system for real-time insect image recognition on mobile devices. Our system achieved an accuracy of mAP@0.5 with the YOLOv5-S model of 70.5% on the 10 insect dataset and 42.9% on the IP102 large-scale insect dataset. In addition, our system can provide more information to farmers about insects such as biological characteristics, distribution, morphology, and pest control measures. From there, farmers can take appropriate measures to prevent pests and diseases, helping reduce production costs and protecting the environment.

*Keywords—Deep learning; real-time insect pest detection; YOLOv5; mobile devices*

## I. INTRODUCTION

Climate change has caused pests to multiply, grow quickly, and cause significant damage to the world's agricultural economy [1]. Pests are estimated to cost up to 40% of worldwide agricultural output each year, according to the Food and Agriculture Organization. At present, plant diseases cost the global economy almost $220 billion each year, while invading insects cost at least $70 billion [2]. Therefore, farmers in many countries have used a large number of different pesticides to protect crops and ensure the quality of agricultural products. However, due to a lack of specialized knowledge, many farmers have difficulty detecting and correctly identifying pests and diseases that cause crop damage. As a result, most farmers did not have reasonable pest control measures, including the indiscriminate and improper use of a large number of pesticides on a large scale. This not only increases production costs but also seriously pollutes the environment, destroys beneficial insects, disrupts ecosystem balance, and damages the health and living environment of humans and many other species. As a result, it is critical to research information technology systems in order to accurately, efficiently, quickly, and conveniently identify pests and diseases that harm crops. This system will aid in the resolution of the aforementioned issues, thereby contributing significantly to long-term agricultural development. Such a system must be designed for real-time identification, be simple to install and use, and be appropriate for farmers' level of knowledge and actual working conditions, where each farmer typically has a smartphone with a basic configuration. Therefore, an automatic system to identify pests on plants using inexpensive smart phones must be developed and deployed. The primary goal is to efficiently detect insects in real-time manner, providing farmers with greater convenience and mobility in early pest treatment. Although smartphones have penetrated a variety of industries, including manufacturing, medicine, and health care, use of mobile devices in agriculture has been slower. Farmers understand the need for mobile agriculture as technology advances, which not only allow farmers to execute agricultural activities more effectively using their phones, but also transform arable farming into smart agriculture. In this research, a real-time insect object detection system is built in the context of large-scale insect pest datasets. Our system is based on the YOLOv5-S model and has been integrated onto mobile devices with limited hardware configurations, making it ideal for farmers in the field.

## II. BACKGROUND STUDY

Much of the prior research has presented real-time image-based recognition systems for mobile devices based on various CNN architectures. To recognize leaves from images, the authors of [3] have developed a novel extraction and classification technique. The insect population and illness regions in the segmented images are then calculated using a region-labeling technique. A mathematical morphological algorithm is utilized to separate the items in the zones of adhesion. The proposed solution is tested in the field and deployed on mobile smart devices. The experimental findings reveal that the suggested technique has high efficiency and strong recognition performance. The authors of [4] have created a pest infestation early warning system for paddy farming that includes an Android application and a web-based application. The Agriculture Department will use the technology to identify insect infestations, locate them, and alert the early warning system. The technology will be able to enter the farmers' infestation data into databases. The data will be utilized by the agronomist to assess the paddy plot's risk in four stages. The number of pests, kind of pest, location, and present circumstances will be used to classify each stage. After the agronomist has completed their review, the system will send an email to the farmers informing them of the quality of their current paddy plot. The researchers from [5] suggested an image processing technique and a smartphone application to recognize and count insects. The nonuniform brightness of insect images obtained with mobile phones is released using a

sliding window-based binarization, and then connected domain-based histogram statistics are utilized to identify and count the insects in stored grain. Finally, testing using an Android application shows that the proposed technique can count random bug photographs from mobile phones with 95% accuracy, which is superior to the previous method. In [6], MAESTRO, a novel grasshopper identification framework that employs deep learning to recognize insects in RBG pictures, is demonstrated. MAESTRO uses a state-of-the-art two-stage deep learning training approach. The framework may be used on cellphones as well as desktop PCs. The authors of [7] offer an AI-based pest detection system that addresses the challenge of identifying scale pests using photos. Scale pests are detected and localized in the image using deep-learning-based object identification models such as faster region-based convolutional networks, single-shot multibox detectors, and YOLOv4. Among the algorithms, YOLOv4 had the highest classification accuracy, with 100% in mealybugs, 89% in Coccidae, and 97% in Diaspididae. A smartphone application based on the trained scale insect detection model has been developed to assist farmers in identifying pests and administering appropriate pesticides to reduce crop losses. The researchers at [8] have studied the best machine learning approach for developing a pest detection model for mobile information systems. The article [9] proposed a novel smartphone application that uses a deep-learning method to automatically categorize pests for the benefit of professionals and farmers. Faster R-CNN is used in the created application to do insect pest recognition using cloud computing. To assist farmers, a database of suggested pesticides is linked to the reported crop pests. This research has been validated for five distinct pest species. The suggested Faster R-CNN had the greatest accuracy in identification rate of 99% for all pest images analyzed. The study [10] provided a novel method for establishing the use of hand-held image capture of insect traps for pest detection in vineyards by embedding artificial intelligence into mobile devices. Their solution integrates many computer vision technologies to enhance numerous areas of picture quality and appropriateness. The extensive review [11] examines deep learning framework methodologies and applications in smart pest monitoring, with a focus on insect pest categorization and detection using field photos. The methodology and technical information created in insect pest classification and detection using deep learning are consolidated and distilled during multiple processing stages: picture collection, data preprocessing, and modeling strategies. Finally, a generic framework for smart insect monitoring is proposed, and future challenges and trends are discussed. In AlertTrap [12], SSD architecture implementation with different cutting-edge backbone feature extractors, such as MobileNetV1 and MobileNetV2, appears to be a viable solution to the real-time detection problem. SSD-MobileNetV1 and SSD-MobileNetV2 work well, with AP@0.5 rates of 0.957 and 1.0, respectively. YOLOv4-tiny surpasses the SSD family in AP@0.5 with 1.0; nevertheless, its throughput velocity is significantly slower, indicating that SSD models are better candidates for real-time implementation. They also ran the models via synthetic test sets that simulated predicted environmental disruptions. The YOLOv4-tiny tolerated these disruptions better than the SSD variants. By combining EfficientNet [13] and Power mean

SVM [14], the authors of the research [15] published the state of the art on insect image classification on the large-scale IP102 dataset with an accuracy of up to 71.84%. However, the abovementioned systems still have some limitations, such as the small number of pest identifications; the accuracy is not high; the equipment configuration requirements are high; and it is difficult to deploy in practice. They lack aspects such as geolocation recoding of recognized harmful pests, information about identified dangerous pests, and robust distributed mobile information frameworks. Currently, there is no real-time existing identification system for mobile devices. Therefore, this paper proposes a new real-time insect identification system with reasonable cost, efficiency, easy installation, and practical deployment on mobile devices with limited hardware configuration. Furthermore, this study also looks at lightweight network models and embedded terminal realizations, both of which are increasingly relevant and promising. The paper's main contributions are as follows:

- A novel real-time insect identification system that is ideal for mobile devices with restricted hardware configuration, easy to install, inexpensive, and user-friendly.

- The most current identification results using YOLOv5-S from the large-scale dataset IP102 are presented.

- A new system captures images and uses GPS to determine the distribution of insects in the field. This contributes to the development of a large insect database and insect distribution maps.

The rest of the article is arranged as follows. Section III describes the materials and methods used to evaluate our approach, including an overview of our system, the YOLOv5 model, and the pest insect image datasets. The experimental results and discussion are reported in Section IV. Section V presents the conclusions, limitations, and recommendations for future research.

## III. MATERIALS AND METHODS

### A. Overview of our System

An overview of our real-time insect identification system is shown in Fig. 1. Users can first use their mobile phones to photograph insects in a real-time manner, or they can use insect photographs found on the internet or images captured by bug traps. The YOLOv5-S model, which is already embedded into the mobile application, then identifies the insect image in real time, resulting in a very quick insect identification time. When an insect image is properly identified, the system will provide the user with detailed information on the insect, such as its name, biological characteristics, distribution, morphology, and control strategies. Our new insect recognition system can work in both online and offline mode. In the online mode, the insect identification information is sent to the Web server, which then processes and returns detailed insect information in JSON format [16]. Insect information can be viewed alongside similar images in the data warehouse. The user can also see a list of all insects, complete with detailed information and images. Users can upload insect images and shooting locations to update the data warehouse at the same time in this mode.

The entire database will be stored on the server in the online mode, making it suitable for mobile devices with limited hardware configuration and ensuring that information is always up-to-date. The application's speed, however, is determined by the available network bandwidth. In the offline mode, SQLite [17], a C-language package that creates a compact, fast, self-contained, high-reliability, full-featured SQL database engine, is used for storing insect information data on mobile devices. This mode will be very useful in cases where farmers' working environments do not have internet, such as in the fields far from urban areas, where internet, 4G, and 5G coverage are not yet available. However, in this mode, some application functions will be restricted.

### B. YOLOV5

YOLOv5 [18] is a single-stage object detection system. In one-stage object identification approaches, object detection is considered as a regression issue. It estimates the class probability and the coordinates of the bounding box that will contain the object in a single step on the input picture. The backbone, neck, and head are the three main components. YOLO is another name for the head layer. The model backbone's duty is to draw attention to the image's unique features. In YOLOv5, the model backbone is a CSPNet [19] structure. The CSPNet approach divides the feature map in the base layer into two parts; some reach the transition layer through the dense block, while the other half is directly integrated with the transition layer. This not only reduces model size but also increases inference speed [20]. In this study, the YOLOv5-S model is used to develop applications on mobile devices due to its small size and model parameters, GFLOPs calculation speed and high accuracy, and lack of requirement for high hardware configuration when compared to other YOLO models such as YOLOv4 [21], YOLOX [22]. As shown in Table I, the YOLOv5-S model is relatively small in size, with a network parameter of 7.3M and a disk size of 14.2 MB, making it suitable for mobile devices with limited hardware configuration. With a GFLOPs index of 17.1, the calculating speed of the YOLOv5-S is adequate. Furthermore,

when compared to other YOLO models, the indicators of $mAP^{val}@0.5$ and the speed of the YOLOv5-S model in Table IV and Table V are quite excellent.

TABLE I. NETWORK PARAMETERS OF YOLO MODELS

| Models | Params (M) | Size on disk (MB) | GFLOPs |
|---|---|---|---|
| YOLOv4 | 27.6 | 245.0 | 59.6 |
| YOLOv4-tiny | 5.88 | 23.1 | 6.8 |
| YOLOv5-S | 7.2 | 14.2 | 17.1 |
| YOLOv5-M | 21.2 | 40.8 | 51.4 |
| YOLOv5-L | 46.5 | 89.3 | 115.6 |
| YOLOv5-X | 86.7 | 167.1 | 219.0 |
| YOLOX-S | 9.0 | 68.5 | 26.8 |
| YOLOX-M | 25.3 | 193.0 | 73.8 |
| YOLOX-L | 54.2 | 413.0 | 155.6 |
| YOLOX-X | 99.1 | 757.0 | 281.9 |

### C. Datasets

To create the insect pest database for machine learning models, 2,335 photos of 10 distinct pest kinds were collected from internet data sources, as shown in Fig. 2. The dataset was then split into the following proportions: 70% of the samples were utilized for training, 20% for model evaluation, and the remainder for testing. As a consequence, the result dataset has 1634 images for training, 467 images for validation, and 234 images for testing, as shown in Table II. The LabelImg program [23] is utilized to manually label the insect objects and generate the .xml file containing object position information, which is then transformed into the .txt file that YOLOv5 can read. Because the IP102 data set has some constraints, such as the same class with numerous different insect stages such as larvae, caterpillars, and moths, achieving high identification efficiency is challenging. Therefore, the YOLOv5-S model was tested with 10 insect classes that were gathered by the agriculture expert volunteers.

TABLE II. THE NUMBER OF IMAGES IN THE INSECT10 DATASETS WITH 10 INSECT SPECIES

| No | Insect name | Train | Validation | Test |
|---|---|---|---|---|
| 1 | Acalymma_vittatum | 116 | 33 | 17 |
| 2 | Achatina_fulica | 258 | 74 | 37 |
| 3 | Alticini | 193 | 55 | 28 |
| 4 | Asparagus_beetles | 89 | 25 | 13 |
| 5 | Aulacophora_similis | 113 | 32 | 16 |
| 6 | Cerotoma_trifurcata | 86 | 25 | 12 |
| 7 | Dermaptera | 111 | 32 | 16 |
| 8 | Leptinotarsa_decemlineata | 234 | 67 | 33 |
| 9 | Mantodea | 185 | 53 | 26 |
| 10 | Squash_bug | 249 | 71 | 36 |
| | Total | 1634 | 467 | 234 |

In this paper, the new system was also evaluated on large-scale insect image datasets. However, collecting a large-scale insect pest image dataset is difficult due to the fact that, depending on the species and kind of insect pest, all insect pests go through several phases during their lifecycle. As a result, the insect pest pictures from the publicly available IP102 dataset [24] are used for evaluating the system. It comprises almost 75,000 photos from 102 agricultural insect pest categories. The IP102 collection includes 75,222 photos and 102 insect pest classifications, while the smallest category comprises just 71 samples. There are 18,983 annotated photos for the job of object detection. As in [24], the images with bounding box annotations were divided into training and testing sets of 15,178 and 3,798 images, respectively. Some sample images of the IP102 dataset are shown in Fig. 3.

Fig. 3. Some Images of Insect Samples in the IP102 Dataset.

## IV. RESULT AND DISCUSSION

### A. Experimental Setup and Training

All YOLO model training experiments were carried out on Google Colab using a Tesla K80 24 GB GPU. Algorithms are written in the Python and Keras programming languages. To train the models, the experimental setup is as follows: a learning rate of 0.01, an image size of 640 pixels, a batch size of 16, and 150 epochs for YOLOv5, YOLOX, and 2,000 epochs for YOLOv4. The Stochastic Gradient Descent [25] is used as the optimization algorithm. Devices with low configuration are utilized to conduct tests on mobile devices, as indicated in Table III.

TABLE III. SMARTPHONE DEVICE CONFIGURATION AND APPLICATION DEVELOPMENT ENVIRONMENT

| | |
|---|---|
| Smartphone hardware configuration | The Samsung Galaxy A30 is powered by a Samsung Exynos 7 Octa 7904 processor with MHZ and 8 cores. The powerful processor and 3000.0 MB of RAM give incredible performance, ensuring trouble-free operation of even the most complex program or game. The Samsung Galaxy A30 uses a microSDXC memory card. The phone carries over the 15.93-megapixel rear camera sensor at the back of the device. The front camera of the Samsung has 15.93. It gives us very high quality photos and videos with a great camera interface. The device has a 6.4-inch SUPER AMOLED display. It gives a decent display quality and a great gradation between warm and cold colors. The OS is Android 10. |

### B. Evaluation Metrics

Mean Average Precision (mAP) is a popular metric for assessing the performance of object detecting systems. The mAP computes a score by comparing the ground-truth bounding box to the detected box. The higher the score, the more precise is the model's detections. The mAP formula is based on the following sub metrics: Confusion Matrix, Intersection over Union (IoU), Recall, Precision. To create a confusion matrix, the experiments present four attributes: True Positives (TP): The model predicted a label and matched it correctly as per ground truth. True Negatives (TN): The model does not predict the label and is not a part of the ground truth. False Positives (FP): The model predicted a label, but it is not a part of the ground truth. False Negatives (FN): The model does not predict a label, but it is part of the ground truth.

In Equation (1), IoU denotes the overlap of anticipated bounding box coordinates with ground truth box coordinates. It explains how an object identification algorithm creates prediction scores. The definition of IoU is described in Fig. 4. Higher IoU implies that the anticipated bounding box coordinates are similar to the ground truth box coordinates.

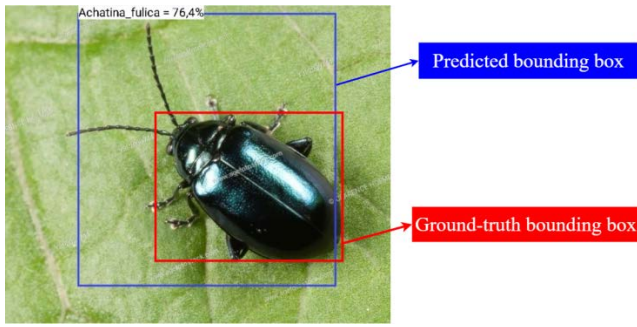
$$IOU = \frac{\text{area of overlap}}{\text{area of union}} = \quad (1)$$


Fig. 4.   IoU Definition.

In Equation (2), Precision refers to how successfully you can identify true positives (TP) from all positive predictions. In Equation (3), Recall measures how well you can find true positives (TP) out of all predictions (TP+FN).

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

$$Recall = \frac{TP}{TP+FN} \quad (3)$$

In Equation (4), Average Precision is calculated as the weighted mean of precision at each threshold; the weight is the increase in recall from the prior threshold. In Equation (5), Mean Average Precision is the average of the AP of each class. However, the interpretation of AP and mAP varies in different contexts. On the validation datasets, the mAP$^{val}$@0.5 means the average mAP with IoU thresholds over 0.5. The mAP$^{val}$@0.5:0.95 means average mAP over different IoU thresholds, from 0.5 to 0.95, step 0.05.

$$AP = \sum_{k=0}^{k=n-1}[Recall(k) - Recall(k+1)] * Precision(k) \quad (4)$$

$$n = number\ of\ thresholds$$

$$mAP = \frac{1}{n}\sum_{k=1}^{k=n} AP_k \quad (2)$$

$$AP_k = the\ AP\ of\ class\ k, and\ n = the\ number\ of\ classes$$

### C. Experimental Results and Discussion

The experiment was conducted to analyze the backbone of models, input image size, mAP@IoU:0.5 and mAP@IoU:0.5:0.95 metrics as a result of the training. Table IV and Fig. 5 show the results of four different model variations on the Insect10 dataset. On the Insect10 dataset, the numerical results in Fig. 5 demonstrate that the new mobile application has a relatively high success rate in precision, recall and mAP for pest object recognition. For instance, the detection performance of the Alcalymma insect has the lowest mAP@IoU:0.5 identification accuracy of 0.45, while the detection performance of Leptinotarsa has the highest at 0.979. Our application is based on the YOLOv5-S model, which was trained on Insect10 datasets with 10 different insect species. The actual results show that, when compared to other object detection methods, YOLO has a faster recognition speed and can almost identify objects in real-time manner. Fig. 7 shows some examples of successful insect recognition on mobile devices using the Insect10 datasets.

Our approach has also been evaluated on the large-scale dataset IP102 [24] to see how well it scales on these datasets.

As shown in Table V and Fig. 6, our system has achieved a promising performance of mAP$^{val}$@0.5 accuracy of 42.9% with the YOLOv5-S model. This result shows that the new approach outperforms several previous approaches that were reported in [24]. However, insect object detection was still more challenging using the IP102 dataset. The reason is that the insect pests in the image are difficult to detect due to their color appearance and the image backgrounds are very similar. In addition, the morphology of an insect pest issue, such as a moth, can vary substantially as it develops. Fig. 8 depicts some images of successful insect recognition using the IP102 dataset on a mobile device. This indicates that our approach offers several benefits over existing methods, including the ability to handle massive data sets with excellent accuracy. Moreover, this new system may also be implemented on low-cost mobile devices with minimal hardware configuration. In addition, as illustrated in Fig. 9, the usage of matching pesticides is integrated with the pest categorization findings to advise professionals and farmers. In the near future, this system will be implemented on new devices like the NVIDIA Jetson Nano Developer Kit [26], which have a higher hardware configuration, a lower cost, a smaller footprint, and a better level of durability.

The information on insect GPS location and density will be extremely useful for several Integrated Pest Management systems. Therefore, our systems are designed to allow users to automatically record this information. Then, a real-time insect distribution density map is created using this data, as illustrated in Fig. 10. This map will assist expert users in tracking and forecasting the density and evolution of insect infections over large areas. At the same time, it is possible to evaluate the potential effects of insect pests on agriculture and ecosystem production.

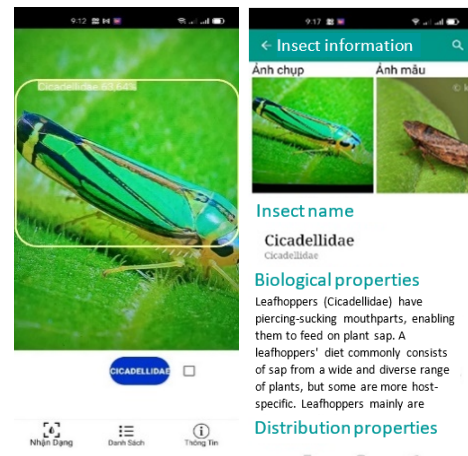

Fig. 9.    The user Interface Screen shows the Successful Insect Recognition and Detailed Insect Information on a Mobile Device.

Fig. 10.  The Insect Distribution Map was constructed based on GPS Location Information from the user's Insect Photos.

## V.    CONCLUSION AND FUTURE RESEARCH WORK

This paper presents an efficient system for real-time mobile smart device-based insect detection. Our system was developed based on the YOLOv5-S model because of its lightweight convolutional neural network and is thus suitable for mobile devices with limited hardware configuration. Moreover, insect pest detection and classification may be incorporated into hardware that farmers can utilize across a wide range of situations to safeguard their farms from pests. Therefore, our method has numerous advantages in terms of real-time insect identification, low cost, simple implementation, and practical implementation. The numerical results showed that the new system achieved 70.5% classification accuracy with mAP@0.5 on the Insect10 dataset and 42.9% accuracy with the large dataset IP102. This is the best insect pest detection result with YOLOv5-S ever reported from the largest insect dataset, IP102. However, these mAP accuracy results are still low when compared to the accuracy required for actual insect detection for agricultural production. Consequently, the next task will be to investigate more efficient recognition models in order to improve the accuracy and number of insects. Simultaneously, this work will be continued to study on better mobile devices, such as the NVIDIA Jetson Nano Developer Kit, which has a central processing unit, a graphical processing unit, a web camera, and currently only a low charge, allowing larger convolutional neural network models to be installed.

# Novel Framework for Enhanced Learning-based Classification of Lesion in Diabetic Retinopathy

Prakruthi M K[1]

Department of Computer Science and Engineering, Jain (Deemed to be University), Bengaluru, India

Komarasamy G[2]

School of Computing Science and Engineering, VIT Bhopal University, Bhopal, Sehore, India

*Abstract*—**Diabetic retinopathy is an adverse medical condition resulting from a high level of blood sugar potentially affecting the retina and leading to permanent vision loss in its advanced stage of progression. A literature review is conducted to assess the effectiveness of existing approaches to find that Convolution Neural Network (CNN) has been frequently adopted for analyzing the fundus retinal image for detection and classification. However, existing scientific methods are mainly inclined towards achieving accuracy in their learning techniques without much deeper investigation of possibilities to improve the methodology of type using CNN. Therefore, the proposed scheme introduces a computational framework where a simplified feature enhancement operation is carried out, resulting in artifact-free images with better features. The enhanced image is then subjected to CNN to perform multiclass categorization of potential stages of diabetic retinopathy to see if it outperforms existing schemes.**

*Keywords—Diabetic retinopathy; convolution neural network; classification; fundus retinal image; multi-class categorization*

## I. INTRODUCTION

The proposed study presents an analysis of the critical problem of diabetes called diabetic retinopathy (DR) that adversely affect the retina's blood vessels. The primary cause of this medical condition is a high blood sugar level which finally results in the leaking of blood vessels and causes swelling [1]. A person suffering from an advanced stage of diabetic retinopathy could also permanently lose their vision [2]. Hence, it is mandatory to undertake periodic retina assessments for diabetic patients to identify the early stages of diabetic retinopathy. The target of diagnosis and treatment of this condition is mainly to understand the specific state to resist the prominent threat of permanent blindness. This condition also results in lesions which are spots created by leaking fluids and blood in the area of the fundus retina [3]. Conceptually, there are two forms of lesions in diabetic retinopathy, i.e., bright lesion and red lesion, where hard and soft exudates characterize the former.

In contrast, the latter is characterized by hemorrhage and microaneurysm [4]. From the retinal image screening, microaneurysm can be found in red dots of darker origin while haemorrhage can be identified in more prominent spots. Apart from this, the yellow areas in the fundus retinal image represent hard exudates, while soft exudates are represented as fluffy white and yellowish spots. It is not feasible to manually evaluate diabetic retinopathy by an ophthalmologist as there are higher probabilities of outliers in its outcome and could

involve significant effort and time. Hence, such form of complications in the diagnosis of diabetic retinopathy is handled by computer-aided diagnosis, which can control effort, time, and cost during the complete diagnosis process [5]-[7]. To understand the stages of progression of diabetic retinopathy, there are five standard stage indicators of the retinal image as follows [8] [9]:

- No DR: Absence of any form of lesions in the retinal image.

- Mild DR: The retinal image is found with microaneurysm only.

- Moderate DR: The overall characteristic of the retinal image is more than the microaneurysm situation and less severe DR.

- Severe DR: There are multiple features of it. When there are significant intraretinal abnormalities within microvascular are in 1+ quadrant. There is the absence of any prominent sign of proliferative DR; this state is equivalent to severe DR. Apart from this if there are particular beading of veins in 2+ quadrant or there are more cases of 20 hemorrhage (intraretinal) in each of 4 quadrants, then this stage also represent severe DR.

- Proliferative DR: If the retinal image is witnessed with pre-retinal hemorrhage or neovascularization, it will represent this stage.

In the medical image-based diagnosis of diabetic retinopathy, there is a significant contribution of deep learning found in existing literature [10] [11]. Deep learning techniques can smartly identify the essential features from the input data subjected to either segmentation or classification tasks [12] [13]. It was also noted that diagnostical approaches using deep learning have majorly performed better in contrast to conventional techniques. One significant advantage of the deep learning technique is the independence from extracting or computing features from the medical image in the form of input. On the other hand, there is a need to carry out training that demands extensive data. It will imply that a higher quantity of trained data will assure better accuracy during the classification process.

On the other hand, there is a dependency on extracting features from the machine learning technique; however, they do not depend on massive trained data like deep learning techniques. In the case of diabetic retinopathy, the machine learning approaches are required to obtain the blood vessel

information, primarily followed by extraction of information related to the region of lesions in the form of features. These features will be used for classification. Various forms of operation carried out in the deep learning process are registration and detection of images along with retrieval, classification, and segmentation task. In this perspective, Convolution Neural Network (CNN), being one of the prominent deep learning techniques, is reported to be frequently used for classification as well as analysis of medical images [14]-[17]. Hence, these facts act as a motivation factor for undertaking CNN in the proposed study.

Currently, various research approaches are being carried out to classify diabetic retinopathy, where deep learning has played a significant role [18]-[20]. This diagnosis outcome is meant to assist the ophthalmologist in performing an early diagnosis of diabetic retinopathy concerning its various stages. Unfortunately, most of the existing approaches emphasize identifying the condition of diabetic retinopathy instead of exploring the appropriate stages of this critical medical condition. Another research problem studied from the trends of existing systems is the restricted and standard computational Framework for appropriately localizing the lesion region. Identifying the proper location of the lesion is essential to understanding the severity of diabetic retinopathy. Further, a significant research gap is found in the existing scheme where not enough emphasis is given towards feature enhancement of the fundus retinal images before subjecting it to deep learning techniques. Therefore, the proposed scheme addresses this problem with the following contribution:

- A simplified feature operation is carried out to the fundus retinal image using Gaussian blurring, while preliminary features are extracted using the Sobel Edge operator.

- An adaptive filter is applied using the fuzzy approach to ascertain the specific location in the fundus retinal image, generating different artifact-free and feature-enhanced images.

- The feature-enhanced image is then subjected to deep CNN with multiple convolution layers to analyze the fundus and classify DR stages.

All the above objectives are met to perform multiclass classification of DR with a particular emphasis on feature enhancement and its representation in the learning model. The paper's organization is as follows: Section II discusses various existing techniques for analyzing diabetic retinopathy, and Section III highlights the research gap. In contrast, Section IV introduces the research methodology being adopted followed by an elaborated discussion of algorithm implementation Section V. Section VI discusses the result analysis. In contrast, a discussion of the result is carried out in Section VII. Finally, Section VIII summarizes the proposed study contribution.

## II. RELATED WORK

Currently, various approaches are being evolved for classifying diabetic retinopathy stages. From this perspective, it is seen that machine learning has always played a dominant role. This can be seen in the review presented by Atwany et al. [12]. According to this study, deep learning offers a significant advantage in classification, but there is still a broad scope to improve the system's computational efficiency. The recent work of Abdelsalam and Zahran [21] used a Support Vector Machine using multifractal-based geometry system to diagnose and classify. The method has also used lacunarity parameters for accomplishing singular decisions. Another work carried out by Li et al. [22] has used an attention network with a unique grading system to identify the condition of macular edema. This paper aims to learn features based on disease-specific and disease-dependent attributes selectively. The feature maps were constructed using Convolution Neural Network (CNN) with different resolutions.

Study towards quantification in diabetic retinopathy is carried out by Okuwobi et al. [23], where region-of-interest is used, followed by estimation of hyperreflective foci to obtain better segmentation. Adoption of deep learning is also reported in work carried out by Qiao et al. [24] have used CNN for carrying out semantic segmentation for identifying microaneurysms. The technique has also detected lesions using a matching filter response. Further adoption of deep learning was witnessed in the work by Wang et al. [25], which has addressed the non-interpretability issues in its outcome. The model used the Kappa coefficient to assess the features of diabetic retinopathy. The idea is also to determine the severity score and build a relationship between severity scores and their corresponding features. The adoption of the neural network is seen in Zang et al. [26], where a rate dropout is designed to suppress the overfitting problem during classification. The recent work carried out by Zhou et al. [27] has emphasized improving transfer learning function to improve outcomes of classifying segmented lesions. Bilal et al. [28] emphasize detection techniques for classification. This model has presented the extraction of features as preprocessing to address the presence of abnormalities and support an effective segmentation technique.

Further the work implemented by Gayathri et al. [29] has presented a unique multiclass classification with the automated binary system. The study has used multiresolution features and different ranges of classifier e.g. J48, random trees, random forest, support vector machine, etc., over multiple datasets. The idea is to present a unique feature extraction model for assisting binary classification of retinal fundus images. Prakurthi et al. [30] proposed an on-demand preprocessing Framework capable of yielding different forms of high-quality images that could offer better clinical inference.

Hence, it can be seen that there have been various attempts in recent times to use machine learning in diagnosing diabetic retinopathy. Table I highlights the compact discussion of the studied literatures with respect to problems being identified by the researchers, adopted techniques to address the identified research problem, advantages, and limitation being identified from the adopted methodology. However, based on the summarized observation in Table I, it can be seen that irrespective of beneficial features, they are potentially associated with loopholes.

TABLE I.        SUMMARY OF RECENT CLASSIFICATION OF DIABETIC RETINOPATHY

| Authors | Problems | Technique | Advantage | Limitation |
|---|---|---|---|---|
| Abdelsalam and Zahran [21] | Early detection | Support Vector Machine, Multifractal Geometry | 98.5% of accuracy, extensive classifying performance | Not applicable for higher dataset |
| Li et al. [22] | Grading of macular edema | CNN, attention network | Enhanced grading performance | Highly iterative process |
| Okuwobi et al. [23] | Hyperreflective foci | Generation of region-of-interest | Effective segmentation performance | Not benchmarked |
| Qiao et al. [24] | Microaneurysm | CNN, segmentation | Better classification accuracy | It doesn't emphasize signal quality |
| Wang et al. [25] | Non-interpretability of deep learning | Kappa coefficient, deep learning | Simplification in image grading | It doesn't consider improving feature quality |
| Zang et al. [26] | Overfitting during classification | CNN, adaptive rate dropout | 95.7% of classification accuracy | Outcomes not benchmarked |
| Zhou et al. [27] | Overfitting during classification | Transfer learning function | The benchmarked model supports multi-disease identification | It doesn't emphasize preprocessing |
| Bilal et al. [28] | Early detection | Binary trees, K-nearest neighbor, support vector machine | Accuracy of 98.06% | The highly computational intensive process |
| Gayathri et al. [29] | Automated classification | Complex wavelets, multi-model classifiers | Accuracy of 99.7% | Demands higher computational resources |

Apart from the above-mentioned recent studies, there are also some notable contributions in the same area to prove the effectiveness of deploying machine learning techniques in classifying diabetic retinopathy. An important work carried out by Acharya et al. [31] has used a Support Vector Machine to carry out multiclass classification of various stages of diabetic retinopathy. The model carries out training over 300 stages of disease condition where the study outcome is witnessed with approximately 82% accuracy. The Support Vector Machine has been used to classify various consequential stages of diabetic retinopathy [32]. This study has accomplished a classification accuracy more than that achieved in [31]. Nayak et al. [33] have developed and constructed a framework using CNN where strategies of morphological processing are carried out along with an assessment of texture-based features. The core idea is to find the critical regions of the lesions associated with blood vessels and exudates where the study outcome has reported a more than 90% accuracy score. Another significant modeling is carried out by Pratt et al. [34], where CNN has been deployed for analyzing the data to look for multiple consequences of diabetic retinopathy with a capability to determine various levels of a medical condition. The modeling has been implemented over the Kaggle dataset, which has large fundus images where the outcome shows better accuracy. Adoption of CNN was also reported in Shaban et al. [35], where multiclass classification of diabetic retinopathy is carried out for four different stages.

Further, the modeling implemented by Dekhil et al. [37] has presented a study, especially on the Kaggle dataset [37]. The work presented by Gao et al. [38] has constructed an image dataset consisting of images of the fundus retina. At the same time, the study mainly discusses the informative utilization of such a dataset for identifying multiple severity stages in diabetic retinopathy. Therefore, it is noted that various research is being carried out towards analyzing fundus retinal images to identify different stages of diabetic retinopathy. The majority of them have reportedly used CNN owing to the advantage of its independence from feature engineering. However, after the adoption of CNN, there is still no significant improvement in the accuracy score of the studies [30]-[38], which demands further insights into addressing issues.

The following section briefs about the research gap explored from the existing research models.

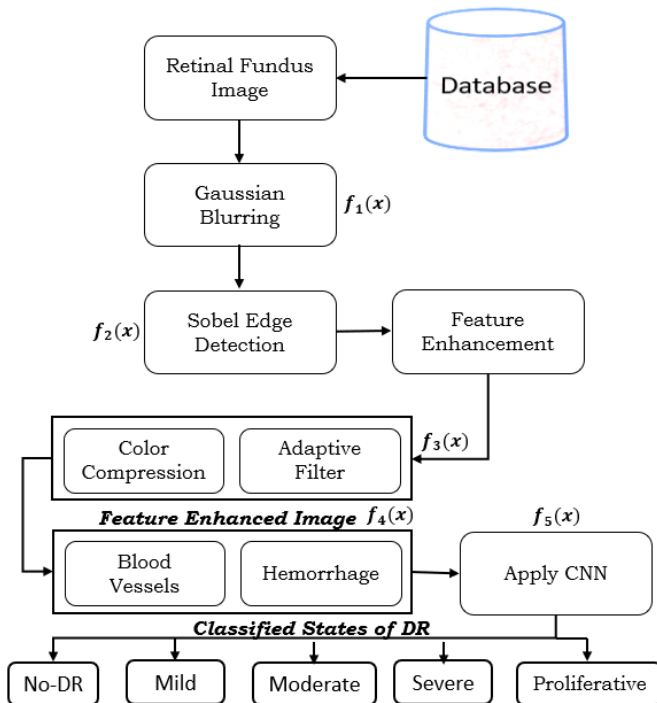
## III.    RESEARCH GAP

The primary research gap identified from the existing techniques is that simplified preprocessing operation has received little emphasis in increasing classification accuracy demands. Without simplifying preprocessing from the perspective of precise feature modeling, the majority of the computational load towards classification accuracy is borne by the classifier algorithm. The secondary research gap identified is that frequent usage of CNN in the classification process of diabetic retinopathy has not addressed the prominent dependency on large data size. Apart from this, CNN doesn't encode the respective position and orientation of an object, which may lead to less accuracy. Therefore, the quality constraints of the fundus image need to be taken care of during system modeling. The ternary research gap of the current study is that the adoption of frequently used machine learning models is relatively slower owing to the inclusion of iterative operation and extensive training process. Although preprocessing can reduce this, such an approach is significantly missing in the existing scheme. The following section outlines the solution to address this research gap.

## IV.    RESEARCH METHODOLOGY

The primary aim of the proposed system is to design and develop a novel classification framework that could effectively balance accuracy score and computational efficiency. However, for better standardization of an outcome, the proposed model is assessed with a standard dataset consisting of the fundus retinal images in diabetic retinopathy. The core aim of the present implementation model is to address the research gap identified in the prior section by improving upon

the methodology of implying frequently adopted machine learning for classifying multiclass stages of diabetic retinopathy with an approach of feature enhancement.

Fig. 1 highlights the adopted methodology of the proposed study, which uses an analytical research methodology scheme. The input of the retinal fundus image is subjected to precise feature modeling and representation using Gaussian blurring, which is then subjected to edge detection using the Sobel operator. The proposed system chooses to use Gaussian blurring as it is one of the simplified technique towards minimizing the noise as well as details present within an image. The prime parameters used for this purpose is the output image, size of Gaussian kernel, and standard deviation of kernel. Further, the scheme makes use of Sobel edge detection technique due to its simplicity in implementation process. One of the unique advantages of it is to offer a gradient magnitude with proper approximation. It is not only capable of identifying edges but also various perspective of orientation involved in it. Further, an integrated method of color compression and enhancement of blood vessels is used, resulting in a feature-enhanced image. This technique adoption significantly obtains an enriched set of distinct features without using many complicated and iterative steps, reducing the operational burden on the adopted CNN technique in machine learning. The classification results in five different DR states no-DR, mild, moderate DR, severe DR, and proliferative. The extensive analysis will be carried out further to justify the proposed methodology's scope that has effectively overcome the research gap. The following section illustrates the algorithm implemented to carry out the proposed classification.


## V. SYSTEM DESIGN

From the prior section, it is now known that the proposed system targets mainly the precise classification and identification of different states of DR for a given image of the retinal fundus. In the present study, the prime emphasis is given to extracting and representing the core features of the CNN model instead of performing any general preprocessing and recognition of the disease. The justification behind this is that there are currently various existing studies (as seen in Section II) that mainly deal with classification using multiple techniques. However, the classification process can be further improved if more appropriate features are extracted in due processing and analysis steps. The proposed scheme has adopted the Kaggle eye dataset [35], which consists of a higher number of fundus retinal images characterized by higher resolution. The presented method of classification makes use of CNN to perform the determination of variable states of diabetic retinopathy. Unlike conventional mechanisms, the proposed scheme chooses to upgrade the methodology of applying CNN. This upgrading scheme involves adopting an appropriate feature enhancement action toward the fundus retinal image. The prime hypothesis behind this adoption scheme is that if the features are improved, it will benefit the classification operation without much computational burden on the CNN module. It should also be noted that the proposed scheme also offers enhancement of contrast and other factors using the prior model [30]. Therefore, the core contribution of the proposed scheme is to introduce a simplified feature enhancement mechanism that cloud further enhances the learning algorithm's performance. The algorithmic steps of the proposed system methodology are as follows:

**Algorithm-1 DR States Classification**

**Input**: $i$(retinal fundus image)

**Output**: $i_{cl}$ (classified image)

**Start**

1.  Load i $\leftarrow$ $data.read$ $(file\_path, id\_code)$
2.  **for** each $i = 1:px$ **do**
3.  $i_{gs}=f_1(i)^{\sigma}$ // *gaussian smoothing*
4.  $i_{ed}=f_2(i_{gs})$ // *edge detection*
5.  $i_{fr}=f_3(i_{ed})$ // *feature representation*
6.  **for** each $i_{fr}$ **do**
7.  $i_c \leftarrow$ apply r2g($i_{fr}$) // *color compression*
8.  $i_{fe} = f_4(i_c)$// *feature enhancement*
9.  **end for**
10. $i_{cl}=f_5(i_{fe})$ // *DR State Classification*
11. **end for**

**End**

The discussion of the above algorithmic steps of the proposed scheme is discussed concerning the following operational blocks:

Fig. 1.   Adopted Methodology of Classification.

## A. *Feature Enhancing and Representation*

This algorithm's primary step (line-1) is to load all fundus images (i) from the local database. Further, the algorithm considers all the pixels $p_x$ of an input image $i$ (Line-2) to find that there are fair possibilities of the presence of certain features and noise that must be eliminated. For this purpose, the proposed scheme adopts the process of image blurring. The proposed method adopts a Gaussian smoothing scheme to perform feature extraction. The blurring mechanism is carried out using function $f_1(x)$ applied on input image $i$ to obtain a smoothed image $i_{gs}$ as an outcome (Line-3). Here, the function $f_1(x)$ represents one-dimensional Gaussian operation $G(x)$ numerically expressed as follows.

$$G(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{x^2}{2\sigma^2}} \tag{1}$$

While processing the input image, the mathematical expression in (1) is required to be expanded to form a two-dimension matrix. Therefore, the amended version of expression (1) can be now represented in the form of a two-dimensional matrix $G(x, y)$ as follows:

$$G(x, y) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{x^2 + y^2}{2\sigma^2}} \tag{2}$$

In the above expression (2) for image blurring of $f_1(x)$, the window size is assigned to simplify computation represented by a variable $\sigma$. The presented study considers $\sigma = 3$ while it is noted that this is applied to all the pixels present in an image and is not carried out selectively. The potential amount of noise in the input image is eliminated after using the Gaussian smoothing operation. After the convention of three entities of color (R, G, B), the presented algorithm is further applied to carry out this conversion. After the blurred image is obtained, the next part of the processing of an algorithm consists of getting edge-related feature information. A function $f_2(x)$ is constructed for this purpose which takes the input of smoothed image $i_{gs}$ and applies the Sobel operator to extract edge information of an image, i.e., $i_{ed}$ (Line-4). The next part of the implementation is associated with further performing a feature representation operation using a function $f_3(x)$ considering the input argument of edge information of an image, i.e., $i_{ed}$ (Line-5). The operation carried out by function $f_3(x)$ is multifold. Firstly, the color compression operation is initially carried out to reduce the complexity surface in feature enhancement and model learning. In this process, the recently obtained image ($i_{ed}$) is compressed to a lower dimension by removing the hue and saturation component of an image while retaining the luminance (Line-7). This process leads to the generation of lower dimension images without losing their clinical attributes and diagnostic properties.

On the other hand, the proposed system constructs an adaptive filter to enhance retinal image features such as hemorrhage and blood vessel, which are very specific to DR identification. The mechanism of the adaptive filter is applied using function $f_4(x)$, which is designed based on the soft computing approach of fuzzy logic. The function $f_4(x)$ takes an input argument of the color-compressed image, i.e., $i_c$. After processing it, the algorithm provides an enhanced image ($i_{fe}$) in the form of a precise feature representation of blood vessels

and hemorrhage. The mechanism of function $f_4(x)$ is discussed in algorithm-2.

---

**Algorithm-2 Adaptive Filter**

**Input**: $i_c$ (color compressed image)

**Output**: $i_{fe}$ (enhanced feature representation)

**Start**

1. Initialize threshold T=101
2. K = create kernel (T, 2)
3. Init SSIM = 0
4. Set SSIM_thresh = 0.8
5. While SSIM < SSIM_thresh
6. $i_{fe}$ = apply_filter(K)
7. Ux = average($i_c$)
8. Uy = average($i_{fe}$)
9. Sx = variance($i_c$)
10. Sy = variance($i_{fe}$)
11. L = $\frac{2.U_x U_y}{U_x^2 + U_y^2}$
12. C = $\frac{2.S_x S_y}{S_x^2 + S_y^2}$
13. SSIM = L × C
14. Optimize K with SGD

**End**

---

The above-mentioned algorithmic steps describe the procedure of adaptive filter, which adopted design characteristics of the fuzzy soft-computing approach. In the first step, the algorithm initializes an initial threshold value T for transforming each input image pixel according to whether it is inside or outside an acceptable range (Line-1). In the later process, the value of T is set automatically by stochastic gradient descent (SGD) to control the relative image intensity during the filtering operation. In the next step, the algorithm constructs a kernel K using argument T and filter size (2× 2), which returns a binary image after processing the input image (Line-2). Initially, kernel k is assigned with random values, and its operation will be optimized via SGD by computing the structural similarity index (SSIM). Therefore, the algorithm initializes SSIM equal to 0 and sets a threshold equal to 0.8 because the input and out images will carry no SSIM in the initial stage (Line-3&4). The SSIM is calculated in every iteration (Line-5) as well as it is checked if it is below the threshold, the algorithm applies a filtering operation that generates a binarized image, i.e., $i_{fe}$ (Line-6). In the subsequent steps, the algorithm computes a mean or average Ux and Uy of both input images, i.e., $i_c$ and obtained binarized image $i_{fe}$, respectively (Line-7&8). Similarly, the algorithm then computes variance Sx and Sy, respectively, for both $i_c$ and $i_{fe}$ (Line-9&10). The computation of average and variance values is done to determine the comparison factor such as luminance (L) and contrast (C) tone (Line-11&12) and based on which the SSIM is determined (Line-13). In this way, for each iteration, SSIM is computed, and accordingly, the kernel is optimized with the help of the SGD algorithm. Here, the adaptive filter uses thresholding to convert the image into a binary image. Finally, this is used for comparing with the original image to get SSIM. When the processed and

unprocessed images are similar, the while loop ends, and the image is returned.

### B. CNN Based DR State Classification

As known, CNN has the potential to resemble the conventional architecture of artificial neural networks. The prime target is learning variable forms of features associated with input images without any involvement of human intervention in the classification process. The proposed scheme implements CNN; the modeling details are highlighted as it can identify essential features without any dependencies from any user-based interaction. At the same time, there are few dependencies on carrying out preprocessing in CNN, making it a simplifier and speedy classification process. However, it cannot be denied that the application of CNN also introduces sophisticated calculations, a higher cost of memory, and uncertainty in performance. So, an improvement is required to revise the performance of CNN owing to the sensitive usage of medical images, where both accuracy and computational efficiency are demanded simultaneously. CNN architecture has various layers, ranging from convolution to polling and completely interconnected layers. A feature map is generated from this outcome of each layer that the other plays as an input argument for its successive layer. The input images associated with the activation map are subjected to a set of linear filters in the convolution layer. The purpose is mainly to obtain a variable number of features corresponding to the clinical state of diabetic retinopathy, e.g., blood vessels, curves, edges, etc. Hence, the proposed system defines its convolution layer $y(l, m, n)$ concerning the 3x3 dimension empirically represented as:

$$y(l,m,n) = \sum_{k=1}^{3}\sum_{i=1}^{3}\sum_{j=1}^{3} H_1 + H_2 \qquad (3)$$

In the above expression (3), the first component $H_1$ is equivalent to $w(l, i, j, k).x(i+m-1, j+n-1, k)$ while the second component $H_2$ is equivalent to $b(l)$. Table II highlights the configuration being used towards the development of CNN model.

TABLE II.    CONFIGURATION DETAILS OF IMPLEMENTED CNN MODE

| Layer | Shape | Param |
|---|---|---|
| Convolution Layer-1 (2D) | (598, 598, 32) | 320 |
| Maxpooling (2D) | (299,299,32) | 0 |
| Convolution Layer-2 (2D) | (297,297,64) | 18496 |
| Maxpooling (2D) | (148,148,64) | 0 |
| Convolution Layer-3 (2D) | (146,146,64) | 36928 |
| Maxpooling (2D) | (73,73,64) | 0 |
| Convolution Layer-4 (2D) | (71,71,64) | 36928 |
| Maxpooling (2D) | (35,35,64) | 0 |
| Convolution Layer-5 (2D) | (33,33,64) | 73856 |
| Maxpooling (2D) | (16,16,64) | 0 |
| Convolution Layer-6 (2D) | (14,14,64) | 73792 |
| Maxpooling (2D) | (7,7,64) | 0 |
| Convolution Layer-7 (2D) | (5,5,64) | 36928 |
| Maxpooling (2D) | (2,2,64) | 0 |
| Flatten | 256 | 0 |
| Dense 1 | 64 | 16448 |
| Dense 2 | 5 | 325 |

The gray level of an input image is represented by the variable $x$ $(i, j, k)$, while the weight of this is represented by $w$ $(l, i, j, k)$. The system also uses biases represented by $b(l)$ associated with the convolution layer. The system still consists of many preferences and weights, increasing the number of parameters. This challenge is mitigated by using a pooling layer where the activation map is subjected to subsampling which significantly enhances the robustness of the features that have been extracted. A set of linear filters can be further deployed to realize the pooling layer in the proposed CNN architecture capable of computing the mean pixel values retained within the masked area of the given feature map. The system can also choose to use a non-linear filter to realize the pooling layer capable of sorting all the values of pixels retained within a specific region of the input feature map, and thereby, max pooling is accomplished.

## VI. RESULT ANALYSIS

The results obtained after implementing the proposed algorithm concept discussed in the previous section are discussed in this current section. The proposed system chooses to perform five stages of classification of diabetic retinopathy, i.e., i) normal (no DR) image which doesn't have any trace of disease, ii) mild, iii) moderate, iv) severe, and v) proliferative stage of diabetic retinopathy. The proposed scheme deploys a simplified feature enhancement scheme to represent a specific feature of fundus images to the CNN model to get reliable classified states of DR. The evaluation of the proposed system is carried out on the standard dataset, namely APTOS 2019 blindness detection retrieved from Kaggle website. The dataset consists of 5590 fundus images, including both regular and DR with their ground truth in .csv file format. Among 5590, 3662 images are subjected to training CNN model, and 1928 images are considered for model testing. The experiment is performed on a standard 64-bit Windows environment with NVIDIA GEFORCE GTX graphics card, Intel(R) Core(TM) i5-9300H CPU @ 2.40GHz 2.40 GHz, and 16 GB RAM size. As shown in Fig. 2, the proposed scheme deploys seven convolution layers using the input of feature enhanced fundus image. The performance assessment of the presented system is carried out concerning precision, recall, and F1-score. The study also performs a comparative analysis where the proposed method is compared with the trained CNN, which does not include any feature enhancement module.

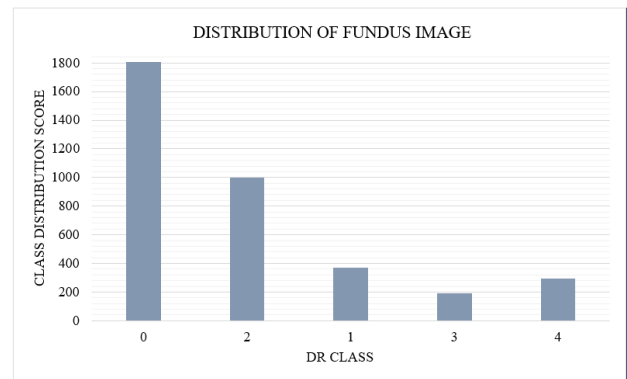


Fig. 2.    Class Distribution of Fundus Image in Training Set.

Fig. 2 exhibits the class distribution of the fundus images belonging to the training set. The DR label and its description are given in Table III. There is 1805 fundus image with DR state normal, 999 images with DR state mild, 370 images are subjected moderate DR state, 193 images are related to severe DR state, and the remaining 295 fundus images are subjected to Proliferative DR. Table III highlights the labels being used with respect to the different names of classes towards fundus image.

TABLE III. LABELS OF FUNDUS IMAGE

| Label | Class Name |
|---|---|
| 0 | No DR |
| 1 | Mild DR |
| 2 | Moderate DR |
| 3 | Severe DR |
| 4 | Proliferative DR |

Fig. 3 highlights the visual outcome of the enhancing operation where Fig. 3(a) showcases the original input image while Fig. 3(b) shows the edge detected enhanced image.

(a) Original Fundus Image.

(b) Feature Enhanced Image
Fig. 3. Visuals of Feature Representation Operation.

From Fig. 3, it can be seen that there is an evident visual outcomes of the enhanced features, while Fig. 4 highlights various stages of processing being carried out towards the sample of normal fundus images. Adopting the proposed scheme towards the involuntary classification method by CNN offers multiple beneficial perspectives. The primary beneficial perspective, as seen from the visual outcome of Fig. 4, is that such a classification system supports any telemedicine-related application for assessing stages of diabetic retinopathy. The secondary beneficial aspect of this scheme is that its accuracy

score is highly reliable as preprocessing and feature extraction operation is carried out well before subjecting it to the learning scheme. Hence, the inference of the outcome by any ophthalmologist has become quite a simplified process. The effectiveness of the proposed feature enhancement-based CNN is assessed by comparing it with CNN implemented without any feature enhancement or preprocessing approach. Table IV and Table V highlights the quantified outcomes for proposed system and existing CNN model, respectively towards assessing accuracy as performance parameters.

(b) Mild DR.

(c) Moderate DR.

(d) Severe DR.

(e) Proliferative DR.
Fig. 4. Visual Outcomes of Classification.

TABLE IV.     QUANTIFIED OUTCOME OF THE PROPOSED SYSTEM

| CNN With Feature Enhancement | | | |
|---|---|---|---|
| Label | Precision | Recall | F1 |
| 0 | 98.60% | 95.41% | 96.98% |
| 1 | 89.06% | 91.93% | 90.47% |
| 2 | 97.34% | 95.31% | 96.31% |
| 3 | 82.45% | 100% | 90.38% |
| 4 | 89.23% | 95.08% | 92.06% |

TABLE V.     QUANTIFIED OUTCOME OF THE STANDARD CNN MODEL

| CNN Without Feature Enhancement | | | |
|---|---|---|---|
| Label | Precision | Recall | F1 |
| 0 | 95.07% | 88.40% | 91.62% |
| 1 | 68.23% | 93.54% | 78.91% |
| 2 | 93.02% | 83.33% | 87.91% |
| 3 | 74.54% | 87.23% | 80.39% |
| 4 | 69.73% | 86.88% | 77.37% |

For an effective analysis, the proposed system is also compared with the existing works done in a similar interest research area by Sikder et al. [39] and Pratt et al. [34] as shown in Table VI.

TABLE VI.     NUMERICAL OUTCOMES OF COMPARATIVE ANALYSIS

| Parameters | Proposed | Sikder et al. [30] | Pratt et al. [33] |
|---|---|---|---|
| Precision | 95.65% | 90.4% | 82.3% |
| Recall | 95.36% | 89.54 % | 86% |
| F1 score | 95.42 | 89.97 % | 83.95% |

Fig. 5.    Comparative Performance Metrics.

Based on the entire analysis, it can be seen that the proposed system exhibits significant enhancement in its classification performance in comparison to normal CNN and existing studies concerning the precision, recall, and F1 score (Fig. 5). The prime reason behind this outcome is as follows: The work of Sikder et al. [30] involves using conventional feature extraction techniques and an applied ensemble learning approach. Although the ensemble learning technique has its advantage in the suitable decision-making process in the

classification task, the conventional feature extraction and image enhancement approach are not appropriate for applying to massive fundus images subjected to a higher degree of artifacts and impreciseness in feature generalization, unlike proposed scheme. At the same time, the work of Pratt et al. [33] has used a different approach unlike Sikder et al. [30]; however, they are more inclined towards classification without considering the need to enhance the primary input image first. Hence, the proposed system offers a better analysis of fundus images with classified states of DR and exhibits higher performance in different assessment cases. The proposed method identifies DR in an early stage and monitors its progression.

## VII. CONCLUSION

This paper has presented a simplified and unique computational modeling to carry out multiclass classification of the stages of diabetic retinopathy from a given fundus retinal image. The achievement of the proposed scheme is that unlike existing literature on classification techniques, the proposed scheme performs a sequential image feature enhancement and representation extraction prior to classification, making the accuracy score much more reliable and improving the computational burden of training by CNN and adopting two-dimensional Gaussian blurring with specific size of window assists in the simplified feature extraction process. Further feature extraction via Sobel edge detection, color compression, and enhancing the image concerning blood vessel and haemorrhage assists in better analysis of lesion in fundus retinal image. Another significant achievement is towards its potential for categorizing different DR states based on their criticality. The CNN was used with seven convolution layers with a Maxpooling layer. The quantified achievement of study is that the study outcome shows that the proposed scheme offers approximately 6% improvement over existing work and approximately 12% over another existing scheme. The feature enhancement's introduction increases the CNN classification performance and reduces the surface of computational complexity by representing specific features in the training and pattern generalization phase. In future work, the proposed system can be extended toward analyzing failed test cases due to the poor visual quality of images, which can be addressed by integrating it with our on-demand preprocessing Framework. Also, further optimization will be carried out over CNN and customization will be applied to the feature enhancement technique.

# Hybrid Pelican Komodo Algorithm

Purba Daru Kusuma, Ashri Dinimaharawati

Computer Engineering, Telkom University, Bandung, Indonesia

*Abstract*—In this work, a new metaheuristic algorithm, namely the hybrid pelican Komodo algorithm (HPKA), has been proposed. This algorithm is developed by hybridizing two shortcoming metaheuristic algorithms: the Pelican Optimization Algorithm (POA) and Komodo Mlipir Algorithm (KMA). Through hybridization, the proposed algorithm is designed to adapt the advantages of both POA and KMA. Several improvisations regarding this proposed algorithm are as follows. First, this proposed algorithm replaces the randomized target with the preferred target in the first phase. Second, four possible movements are selected stochastically in the first phase. Third, in the second phase, the proposed algorithm replaces the agent's current location with the problem space width to control the local problem space. This proposed algorithm is then challenged to tackle theoretical and real-world optimization problems. The result shows that the proposed algorithm is better than grey wolf optimizer (GWO), marine predator algorithm (MPA), KMA, and POA in solving 14, 12, 14, and 18 functions. Meanwhile, the proposed algorithm creates 109%, 46%, 47%, and 1% better total capital gain rather than GWO, MPA, KMA, and POA, respectively in solving the portfolio optimization problem.

*Keywords—Metaheuristic; Pelican Optimization Algorithm; Komodo Mlipir Algorithm; portfolio optimization algorithm; LQ45 index*

## I. INTRODUCTION

Optimization is a prevalent work that has been implemented in many areas. Optimization is essential because it aims to maximize results or minimize cost or effort. Optimization is also important because in any human process, whether the scope is individual or institution, it has a specific goal or objective. Contrary, the resources needed to execute this work are limited. The term cost can be translated in many ways, such as travel distance, consumed energy, production cost, penalty, unserved requests, and so on. On the other hand, the term result can also be translated into many ways, such as sales, profit, served customers, accuracy, and so on. In the production process, optimization is widely used, such as in the flow-shop scheduling [1], batch-shop scheduling [2], assembly line balancing [3], procurement [4], and so on. In transportation and logistics, optimization is implemented in route planning [5], storage management [6], and so on. Optimization is also implemented in finance, such as in portfolio optimization [7], option pricing [8], credit risk assessment [9], bankruptcy mitigation [10], etc.

Metaheuristic algorithm is a popular method used in many studies conducting the optimization problem. This popularity comes from its flexibility in facing the limited computation resources. Moreover, the metaheuristic algorithm is flexible enough to tackle various objective functions, from simple to complicated ones. This advantage cannot be obtained from the exact method that needs an excessive computational resource, especially in solving a complicated problem with high dimension space [11]. However, as an approximate method, a metaheuristic algorithm does not guarantee the true optimal solution but only the acceptable or near optimal one [11]. In many metaheuristic algorithms, several parameters also must be adjusted. Proper adjustment can improve its performance, while misjudgment can worsen its performance.

Many metaheuristic algorithms are inspired by nature or behavior, especially the animal behavior during mating and foraging. This circumstance occurs due to the similarity between these behaviors and the metaheuristic algorithm. An animal has a certain degree of uncertainty during mating and foraging. In foraging, even if it is searching for a food source or hunting prey, the animal still does not know the actual location of the food source or prey. Based on it, a random search with a certain degree of certainty is conducted. Although animals have a certain degree of similarity during foraging, there is a specific strategy conducted by every animal. On the other hand, the mating process can generate new descendants from the selected parents. These descendants inherit the characteristics of their parents. Some descendants are better than their parents while the others are worse. Several metaheuristic algorithms adopt this circumstance. In several algorithms, the improvement is created by mating a selected solution with the best solution. Several algorithms that adopt foraging behavior are particle swarm optimization (PSO) [12], ant colony optimization (ACO) [13], grey wolf optimization (GWO) [14], marine predator algorithm (MPA) [15], artificial bee colony algorithm (ABC) [16], Etc. Meanwhile, several algorithms that adopt the mating process are genetic algorithm (GA) [17], evolutionary algorithm (EA) [18], Etc. Several algorithms, such as the red deer algorithm (RDA), combine mating and foraging [19].

Among many shortcoming metaheuristic algorithms, there are two brand-new algorithms that is firstly introduced in 2022. The first is Komodo Mlipir Algorithm (KMA), and the second is the Pelican Optimization Algorithm (POA). The animal's behavior inspires both algorithms. The behavior of Komodo dragon during foraging and mating inspires KMA [20]. Meanwhile, POA is inspired by the behavior of pelicans during foraging [21]. In their first appearance, both algorithms beat several algorithms. POA outperformed genetic algorithm (GA), particle swarm optimization (PSO), teaching-learning based optimization (TLBO), grey wolf optimizer (GWO), whale optimization algorithm (WOA), gravitational search algorithm (GSA), tunicate swarm algorithm (TSA), and marine predator algorithm (MPA) [21]. On the other hand, KMA outperformed six algorithms: GA, success-history based parameter adaptation differential evolution (SHADE), linear population size reduction SHADE with ensemble sinusoidal differential

covariance matrix adaptation with Euclidean neighborhood (LSHADE-CnEpSIn), equilibrium Optimizer (EO), MPA, and slime mold algorithm (SMA) [20].

Despite their outstanding performance, these algorithms are still not popular as brand-new algorithms. Studies conducting these algorithms to solve optimization problems are still hard to find. Based on this, it is challenging to explore these algorithms further. Moreover, as brand-new algorithms, the opportunity to improve and modify these algorithms is widely open.

The objective and scope of this work are as follows. This work proposes a new metaheuristic algorithm that hybridizes both shortcoming algorithms: POA and KMA. Through hybridization, the proposed algorithm is hoped to combine the strength of both algorithms and, on the other hand, tackle the weakness of both algorithms too. Based on this objective, the scope of this work is to develop new algorithms that hybridize both POA and KMA and then evaluating this proposed algorithm through simulation.

The methodology conducted to this work is as follows. First, the mechanics and strategy in both KMA and POA are explored and reviewed. This exploration is needed to analyze their strength and weakness. Then, the proposed algorithm is developed by hybridizing both algorithms. After that, this proposed algorithm is challenged to solve the theoretical and real-world optimization problems so that its performance can be evaluated. The proposed algorithm is implemented to solve the 23 benchmark functions. These functions represent the theoretical optimization problem. These functions are popular in many studies that propose a new metaheuristic algorithm. Meanwhile, the portfolio optimization problem is chosen as the real-world optimization problem. In this simulation, the proposed algorithm is compared with four shortcoming metaheuristic algorithms: GWO, MPA, KMA, and POA. GWO and MPA represent algorithms that have been implemented and modified in many studies. Meanwhile, KMA and POA are chosen because this proposed algorithm is the improved version of these algorithms. Several findings regarding the simulation result are then analyzed deeper.

There are several contributions regarding this work. These contributions are as follows.

*1)* This work proposes a new algorithm that hybridizes two brand-new algorithms: POA and KMA.

*2)* This work modifies the swarm movement in the first phase of POA by replacing the randomized target with a more deterministic target.

*3)* This work adopts the behavior of three types of Komodo in KMA to be implemented in the swarm movement in the first phase with several modifications.

*4)* This work modifies the second phase by replacing the agent's current location with the problem space to control the local problem space.

The remainder of this paper is structured as follows. The mechanics of POA and KMA are reviewed in the second section to analyze their strengths and weaknesses. Based on this review, the proposed algorithm's model is presented in the

third section. The simulation regarding the proposed algorithm is explained in the fourth section. The more profound analysis regarding the simulation result and the findings are discussed in the fifth section. In the end, the conclusion and future research potential regarding this work are summarized in the sixth section.

## II. RELATED WORK

Komodo Mlipir Algorithm (KMA) is a brand-new algorithm that adopts the behavior of the Komodo dragon during mating and foraging. This algorithm is a population-based algorithm consisting of several autonomous agents. Each agent represents the solution. These agents are classified into three groups based on their quality: big male, female, and small male [20]. Each type of agent has a specific role and mechanics. The big males are agents whose qualities are better. The females are agents whose quality is mediocre. In the end, the petite males are agents whose quality is worse. The proportion of these groups is fixed and set manually before the process begins. The rank to determine the group's members is updated in every iteration.

The big male adopts foraging behavior by searching for prey [20]. The big male moves based on its current location and other big males. The big male moves toward the better big males and moves away from the worse big males. The big male does not take account of the female and small male.

The female conducts the mating process. There are two possible mating strategies for every female: sexual reproduction or asexual reproduction (parthenogenesis) [20]. Sexual reproduction is achieved by mating the female with the highest quality big male. Each female produces two descendants. The first descendant is close to the female, while the second descendant is close to the highest quality big male. Then, the best descendant between them will replace the female current's location. In parthenogenesis, a female creates a descendant randomly within the problem space.

Like a big male, the small male implements foraging [20]. The small male moves toward the cumulative of big males. As a worse solution, the small male should get closer to the better solutions (big males) to improve its quality.

Meanwhile, the Pelican Optimization Algorithm is a brand-new algorithm that adopts the pelican behavior during foraging. POA is a swarm-based intelligence. This algorithm consists of a certain number of agents (pelicans). As a swarm intelligence, collective intelligence is used or shared among the pelicans [22]. In this algorithm, the randomized target represents collective intelligence. POA consists of two steps that are executed sequentially in every iteration.

There is a global target in the first phase where all pelicans will move based on this target [21]. This global target is selected randomly within the problem space at the beginning of every iteration. The pelican can choose two possible movements. If this target is better than the pelican's current location, the pelican will move toward this target. Otherwise, the pelican will move away from this target. In POA, an acceptance-rejection strategy is adopted. The pelican will move to this new location only if this new location is better than its current location.

In the second phase, the pelican flies around its current location [21]. Although this term is not relevant in some circumstances, it can be seen as a local or neighborhood search. In this phase, a new location is selected randomly within the pelican's local problem space. The width of this local problem space declines gradually due to the increase of the iteration. It means that the local problem space is wide enough in the beginning, and it can be seen as an exploration. On the other hand, this investigation moves to exploitation as the iteration goes. Besides iteration, the local problem space is also determined by the agent's current location. Near zero current location makes the width of the local problem space narrow, although in the early iteration. Like in the first phase, in this phase, the pelican moves toward the new location only if this new location is better than the pelican's current location.

Based on the detailed description of KMA and POA, the comprehensive comparison between these algorithms is as follows. KMA splits the population into three groups. Each group represents a distinct strategy. But each agent conducts only a single procedure in every iteration. On the other hand, in POA, there is not any population split. Every agent is treated equal and conducts the same strategy. Each agent acts these two actions in every iteration.

The swarm movement toward a better solution and away from the worse solution is also conducted in both algorithms. In KMA, the big males move toward better big males and move away from the resultant of worse big males. Moreover, petite males move toward the resultant of big males. On the other hand, each pelican moves toward a randomized target if this target is better than the pelican's current location and avoids this randomized target if this target is worse than the pelican's current location. This strategy can be seen as improving the current solution based on the guidance of the better solution or avoiding the possible worse solution. Both algorithms choose a different method in determining the target in the swarm movement. POA selects the target randomly within the problem space. On the other hand, in KMA, only big males can become the target.

Random search is also conducted in both algorithms but in a different way. In POA, this strategy is undertaken in the second phase so that all agents work this strategy in every iteration. In KMA, the random search is implemented only by the female when it chooses parthenogenesis. It means that with the same population size, the probability of conducting the random search in POA is higher than in KMA.

There is a difference between KMA and POA regarding the local problem space in the local search strategy. In KMA, the local problem space width is fixed based on the problem space. In POA, the local problem space is reduced gradually as the iteration increases. Reducing the local problem space during the iteration can make the system focus on the exploration in the early iteration and then transform to the exploitation. At the end of the iteration, the system focuses on exploitation. The advantage of this strategy is that the system can concentrate on exploring any space within the problem space to find the region where the optimal global solution exists. After that, the system will improve the solution within this region. Moreover, the agent will not be thrown away to any areas within the

iteration in the later iteration, so it should start the searching. Contrary, fixed local problem space width is essential when the system still fails to find the region where the optimal global solution exists. The system can escape from the optimal local trap, although the iteration is not in the early phase.

Acceptance-rejection strategy is conducted only in POA. Meanwhile, KMA does not adopt this strategy. Acceptance-rejection has strengths and weaknesses, so not all algorithms adopt this strategy. By implementing this strategy, the agent moves to a new solution only if the new solution is better than its current solution. There is no probability of a worsening situation. But the system may be stuck in a case, such as the local optimal, when it fails to improve the current solution. On the other hand, without accepting this strategy, the system may go to a worse situation. Some algorithms, such as MPA, partially adopt this strategy. In MPA, the prey may move toward the worse solution. Contrary, the predator moves to a new location, only this new location is better than the predator's current location.

This review shows that both KMA and POA have several strengths and weaknesses. Based on this circumstance, there is the possibility of improvement by hybridizing these algorithms. Several parts that can be modified are as follows. First, modification can be conducted in the swarm movement. Second, change also can be shown in the random search.

## III. PROPOSED MODEL

This section will present the detailed model of the proposed algorithm. This model consists of the conceptual model, pseudocode, and mathematical model. The conceptual model explains the framework and general mechanics of the algorithm. The pseudocode formalizes the structure of the proposed algorithm. In the end, the mathematical model describes the detailed formulation of processes and methods within the algorithm.

The conceptual model of the proposed algorithm is as follows. This proposed algorithm uses POA as its main framework. The proposed algorithm consists of two phases. The first phase is the swarm movement toward the target. The second phase is the randomized movement within the local problem space. Like in POA, these phases are conducted sequentially in every iteration.

In the first phase, four possible movements can be chosen by every agent. The first movement is the movement toward the global best solution. The second movement moves to the middle between the current location and the international best solution. The third movement is the movement related to the randomly selected agent. The fourth movement is jumping across the global best solution. KMA inspires the first, second, and third movements. The first movement is the modification of the minor male movement. The second movement is the modification of the mating process of the female with the best quality big male. The third movement is the modification of the significant male movement. MPA inspires the fourth movement. In the fourth movement, the agent's new location is obtained based on the current global best solution movement away from the related agent. The main objective of the fourth movement is to improve the global best solution. In this first

phase, the agent will move to the new location, whether this new location is better or worse. It is different from POA, where the pelican will move to the new location only if this new location is better than the pelican's current location.

In the second phase, every agent searches for a new location within its local problem space. This method also occurs in POA. In this phase, the similarity between the proposed algorithm and POA is that the local problem space is reduced gradually due to the increase of the iteration. The exploration to exploitation strategy is also adopted in the proposed algorithm. Meanwhile, there is a difference between the proposed algorithm and POA. In this proposed algorithm, the local problem space width also depends on the problem space width. It is different from POA, where the agent's current location affects its local problem space width. Like in POA, in this phase, the agent moves to the new location only if it is better than the current location.

Like many metaheuristic algorithms, this proposed algorithm consists of two steps. The first step is initialization. The second step is iteration. The agent's initial location is randomized within the problem space during the initialization. It follows uniform distribution so that the opportunity of every place is equal. The improvement is conducted during the iteration. Each time an agent moves to a new location, the global best solution will be updated in every process. The global best solution is an entity that stores the best answer so far. This best solution is applied among all agents. This international best solution is updated to its new value only if this new solution is better than the current global best solution. The global best solution becomes the final solution at the end of an iteration.

This framework is then transformed into the pseudocode and the mathematical model. The pseudocode of the proposed algorithm is shown in Algorithm 1. There are several annotations used in the pseudocode and mathematical model. These annotations are as follows.

| 25    e**nd for** |
| 26    **end** |

All agents' initial location is determined randomly within the problem space in the initialization. This process is formalized using (1). Equation (1) shows that the lower and upper bound to become the boundaries of the problem space. These boundaries represent the single dimension problem space. Each dimension has its limits in the multiple dimension problem space, and (1) is applied in all dimensions.

$$x = U(b_l, b_u) \tag{1}$$

In the first phase, the movement is selected randomly based on the value of a generated random number. The distribution of this random number follows a uniform distribution. This random number is formalized by using (2). Then, the movement is selected based on the location of this random number related to the thresholds.

$$r = U(0,1) \tag{2}$$

In the first movement, the agent moves toward the global best solution. This first movement is chosen if the generated random number is less than the first threshold. This process is formalized by using (3). Equation (3) shows that the movement length is uniformly randomized. It also depends on the step size. A bigger step size makes the agent moves closer to the global best solution. On the other hand, a smaller step size makes the agent moves closer to its current location.

$$x' = x + s.U(0,1).(x_{best} - x) \tag{3}$$

In the second movement, the agent moves to the middle between its current location and the global best solution. This movement is chosen if the generated random number is between the first and second threshold. This movement represents the deterministic version of the first movement. This movement is formalized using (4).

$$x' = \frac{x_{best} + x}{2} \tag{4}$$

In the third movement, the agent moves related to the selected agent. This agent is chosen randomly among the set of agents. This movement is selected if the generated random number is between the second and third threshold. If this agent chosen is better than the agent's current location, then this agent will move toward the selected agent. Else, this agent will move away from the designated agent. This process is formalized by using (5) and (6). Equation (5) formalizes the agent selection. Equation (6) formalized the movement related to the selected agent.

$$x_{sel} = U(X) \tag{5}$$

$$x' = \begin{cases} x + s.U(0,1).(x_{sel} - x), f(x_{sel}) < f(x) \\ x + s.U(0,1).(x - x_{sel}), else \end{cases} \tag{6}$$

In the fourth movement, the agent's new location is obtained from the direction of the global best away from the agent's current location. This movement is chosen if the generated random number is higher than the third threshold. This process is formalized by using (7). This movement is conducted to exploit the location near the global best.

$$x' = x_{best} + s.U(0,1).(x_{best} - x) \tag{7}$$

This agent's new location is then used to update the global best. As mentioned in the conceptual model, the new solution will replace the global best current solution only if this new solution is better than the global best solution. This process is formalized by using (8).

$$x'_{best} = \begin{cases} x, f(x) < f(x_{best}) \\ x_{best}, else \end{cases} \tag{8}$$

The agent searches for a new location within its local problem space in the second phase. This process is formalized by using (9) and (10). Equation (9) formalizes the candidate for the new location. Equation (10) states that this candidate will only replace the agent's current location if it is better than its current location.

$$x_c = x + \left(1 - \frac{t}{t_{max}}\right)(2U - 1)\left(\frac{b_u - b_l}{d}\right) \tag{9}$$

$$x' = \begin{cases} x_c, f(x_c) < f(x) \\ x, else \end{cases} \tag{10}$$

Based on this explanation, the complexity of the proposed algorithm can be presented in the Big O notation as $O(2t_{max}.n(X))$. Based on this notation, it is shown that the complexity of the proposed algorithm is linearly proportional to the maximum iteration or the population size. The number 2 represents the two phases that are conducted in every iteration.

## IV. SIMULATION AND RESULT

Four simulations are conducted to evaluate the proposed algorithm's performance in this work. The first simulation is conducted to evaluate the proposed algorithm's performance in solving the theoretical mathematic optimization problem. The second simulation is conducted to assess the sensitivity of the algorithm, related to its performance. The third simulation is conducted to evaluate the proposed algorithm's performance in solving the real-world optimization problem. The fourth

simulation is conducted to evaluate the convergence of the algorithm in solving the real-world optimization problem.

In the first simulation, the proposed algorithm is challenged to solve the 23 benchmark functions representing the theoretical optimization problem. These functions are commonly used in many studies that suggest new metaheuristic algorithms, such as darts game optimizer (DGO) [23], hide objects game optimizer (HOGO) [24], KMA [20], RDA [19], POA [21], and so on. The list of these functions can be seen in Table I. These functions can be clustered into three groups based on their similar characteristics. The first group represents the high dimension unimodal functions. This group consists of function one to function seven. The second group represents the high dimension multimodal functions. This group consists of function eight to function thirteen. The third group represents the fixed dimension multimodal functions. This group consists of function 14 to function 23.

TABLE I.          BENCHMARK FUNCTIONS

| No | Function | Dim | Problem Space | Target |
|----|----------|-----|---------------|--------|
| 1 | Sphere | 10 | [-100, 100] | 0 |
| 2 | Schwefel 2.22 | 10 | [-100, 100] | 0 |
| 3 | Schwefel 1.2 | 10 | [-100, 100] | 0 |
| 4 | Schwefel 2.21 | 10 | [-100, 100] | 0 |
| 5 | Rosenbrock | 10 | [-30, 30] | 0 |
| 6 | Step | 10 | [-100, 100] | 0 |
| 7 | Quartic | 10 | [-1.28, 1.28] | 0 |
| 8 | Schwefel | 10 | [-500, 500] | -4189.8 |
| 9 | Ratsrigin | 10 | [-5.12, 5.12] | 0 |
| 10 | Ackley | 10 | [-32, 32] | 0 |
| 11 | Griewank | 10 | [-600, 600] | 0 |
| 12 | Penalized | 10 | [-50, 50] | 0 |
| 13 | Penalized 2 | 10 | [-50, 50] | 0 |
| 14 | Shekel Foxholes | 2 | [-65, 65] | 1 |
| 15 | Kowalik | 4 | [-5, 5] | 0.0003 |
| 16 | Six Hump Camel | 2 | [-5, 5] | -1.0316 |
| 17 | Branin | 2 | [-5, 5] | 0.398 |
| 18 | Goldstein-Price | 2 | [-2, 2] | 3 |
| 19 | Hartman 3 | 3 | [1, 3] | -3.86 |
| 20 | Hartman 6 | 6 | [0, 1] | -3.32 |
| 21 | Shekel 5 | 4 | [0, 10] | -10.1532 |
| 22 | Shekel 7 | 4 | [0, 10] | -10.4028 |
| 23 | Shekel 10 | 4 | [0, 10] | -10.5363 |

The more detailed explanation related to the characteristic of these functions is as follows. The unimodal function is a function that has only one optimal solution [25], which is the optimal global solution. There is not any optimal local solution in this function. Contrary, the multimodal function is a function that has multiple optimal solutions [25]. One optimal is the optimal global solution that becomes the target of the optimization. The other optimal solutions are the local optimal.

In this function, the algorithm can be trapped in the local optimal so that the global optimal cannot be found until the iteration ends [25]. The high dimension function represents the function that has a flexible number of adjusted parameters that construct the solution. The dimension can be one and up to unlimited (hundreds or thousands). A higher dimension makes the problem more challenging to optimize. It means that more iteration or population size is needed. The fixed dimension function represents the function that its measurement is static or final. Although the dimension is static and usually low, it does not mean that this function is easy to solve.

These 23 benchmark functions also represent optimization problems with various problem space. The problem space ranges from very narrow, such as in Quartic and Hartman 6, to the very large, such as in Schwefel and Griewank. Most of these functions are centralized at 0. Meanwhile, in several functions, such as Shekel 5 and Hartman 3, the problem space central is not at 0.

In this simulation, the proposed algorithm is compared with four other algorithms: GWO, MPA, KMA, and POA. In general, these four algorithms are new. All these algorithms adopt the foraging mechanism of the animal. Meanwhile, these four algorithms have their distinct mechanics. GWO represents algorithms that every agent moves toward certain (three) best solutions or three global best solutions. MPA represents the movement of several couples of predators and preys where the predator represents the local best solution for its prey. KMA represents algorithm that combines the foraging and mating. POA represents the algorithm that all agents move toward the randomized global target. GWO and MPA also represent the shortcoming algorithms that have been widely studied, improved, and implemented. Meanwhile, KMA and POA represent brand new algorithms that are not popular yet.

The setup of all these five algorithms is as follows. The maximum iteration is set 200 that represent low iteration. The population size is set 20. In MPA, the fishing aggregate devices are set 0.5. The reason is to make balance strategy between finding the alternative randomly within the local problem space and the two randomly selected predators. In KMA, the proportion of the big males is 40%. The reason of this proportion is to make almost balance population between the big males and the small males. Meanwhile, the only one female configuration is chosen based on the recommendation in the first appearance of KMA. There is only one female. The rest population are the small males. The mlipir rate is set 0.5. This rate is chosen to speed up the movement of the small males. Meanwhile, there is not any parameter setting in GWO and POA because these algorithms do not have any adjusted parameter. In the proposed algorithm (HPKA), the proportion is equal, and the step size is set 2. This step size is chosen to so that the local problem space width is wide enough but not too wide. This parameter setting is also can be seen in Table II. Meanwhile, the first, second, and third thresholds are set to make balance proportion between among the movements. The simulation result is shown in Table III. The best result is written in bold font.

The result shows that the proposed algorithm is a good metaheuristic algorithm. It can find the acceptable optimal solution in all 23 benchmark functions. It means that the proposed algorithm is good in solving both unimodal functions and multimodal functions. Moreover, the proposed algorithm also can find the true optimal solution in solving the Six Hump Camel.

Table III also shows that the proposed algorithm is competitive enough compared with other sparing algorithms. It performs the best in solving five functions: Step, Penalized 2, Six Hump Camel, Branin, and Hartman 6. One function is the high dimension unimodal function while the other four functions are the fixed dimension multimodal functions. Compared with other four algorithms, the proposed algorithm is better than GWO, MPA, KMA, and POA in solving 14, 12, 14, and 18 functions respectively. It is also shown the GWO is very powerful in solving the high dimension unimodal functions but weak in solving the fixed dimension multimodal functions. Contrary, KMA is very powerful in solving the Shekel 5, Shekel 7, and Shekel 10.

The second simulation is conducted to evaluate the algorithm sensitivity. In this work, the sensitivity analysis is focused on the formation of the agents due to four possibilities of action chosen by every agent. Like in the first simulation, in this simulation, the proposed algorithm is implemented to solve the 23 benchmark functions. Meanwhile, the maximum iteration and the population size are not chosen to be explored deeper. It is because based on the general model of metaheuristic algorithm, where the quality of the algorithm can be improved by increasing the maximum iteration or the population size theoretically but with the expense of the computational resource and time. On the other hand, the formation does not affect to the complexity or computational consumption. In Table IV, the proportion is presented in a set that contains the proportion of the first, second, third and fourth options consecutively. The first scenario represents the first movement dominant strategy. The second scenario represents the second movement dominant strategy. The third scenario represents the third movement dominant strategy. The fourth scenario represents the fourth movement dominant strategy. The result can be seen in Table IV. The best result is written in bold font.

TABLE II.    PARAMETER SETTING

| Parameter | Value |
|---|---|
| $n(X)$ | 20 |
| $t_{max}$ | 200 |
| $s$ | 2 |
| $T_1$ | 0.25 |
| $T_2$ | 0.5 |
| $T_3$ | 0.75 |

Table IV shows that the relation between the proportion of the options and the algorithm's performance is various; depends on the problem (function) to be solved. There is not any proportion that is the best among other proportions. In some functions, a proportion may be better. But in other function, other proportion is better. Meanwhile, the different proportion affects significantly, especially in solving the unimodal functions. A proportion produces much better result rather than other proportions. Meanwhile, the different proportion affects less significantly in solving multimodal functions. Moreover, the proportion does not affect the result in solving the Six Hump Camel, Branin, and Hartman 3 functions.

The third simulation is conducted to evaluate the proposed algorithm in solving the real-world problem. In this work, the proposed algorithm is challenged to tackle the portfolio optimization problem. A portfolio is a set of valuable and productive assets that is owned by individual or institutions [26]. This asset can be property, stock, bond, gold, and so on. Portfolio represents the wealth of the entity. As a portfolio, an individual or institution should distribute its asset into several options [26]. The objective of this arrangement is to protect its value in the context of maximizing the profit and avoiding the lost. The profit may come from the revenue that is generated from the utilization of the asset or the increasing value of the asset in certain timespan. On the other side, lost may come from the value depreciation or reduction of the asset. Based on it, the portfolio optimization problem can be defined the arrangement of assets in the most optimal way in facing its objective.

In this work, the portfolio optimization problem focuses on the stock. The stock represents the ownership of a proportion of a company. The profit of stock comes in two ways: capital gain and dividend. Capital gain is the increasing value of a share at the end of a certain timespan. The common timespan can be daily, monthly, year-to-date (YTD), year-on-year (YOY), and five years. The dividend is a portion of net profit distributed to the company's owner or stockholder. The stock price represents the market value of a share of a company.

The selected stocks are the ten best companies listed in the LQ45 index. LQ45 index is a list that consists of 45 companies whose share is traded on the Indonesian Stock Exchange (IDX) [27]. These companies are selected because their market capitalization is the biggest, and they are very liquid [27]. These ten companies come from several industrial sectors, such as oil and gas, mining, and banking. The list of these companies is shown in Table V. Table V contains three information: the company's code, current price, and year-to-date capital gain. The current price and capital gain are presented in rupiah per share. The data is obtained from Google, which refers to the Indonesian Stock Exchange.

The stock optimization problem scenario in this work is as follows. The objective is maximizing the total capital gain. The total capital gain is obtained by accumulating the capital gain earned from all held shares. The capital gain refers to the year-to-date capital gain in Table IV. On the other side, there are several constraints used in this optimization. The allocated investment is one billion rupiahs. It means that the bought stocks cannot surpass the total investment. All stocks in

Table IV must be represented in the investment portfolio. The purchasing price refers to the current price in Table IV. The purchasing unit for every stock is presented in the lot. A lot refers to 100 shares. The investment ranges from 50 to 200 lots in every stock. Based on this scenario, this portfolio optimization problem can be seen as a high dimensional problem. The number of dimensions is 10. The problem space for every dimension is between 50 and 200.

The simulation scenario related to this portfolio optimization problem is as follows. The population size is set at 20. The maximum iteration is set at 200. The proportion among possible actions is equal. Like in the first simulation, this proposed algorithm is benchmarked with four algorithms: GWO, MPA, KMA, and POA. The result is shown in Table VI.

Table VI shows that the proposed HPKA algorithm is very competitive among algorithms in solving the portfolio optimization problem. Its total capital gain is the highest among GWO, MPA, KMA, and POA. The total capital gain created by the proposed algorithm is 109%, 46%, 47%, and 1% better than the GWO, MPA, KMA, and POA respectively.

Based on the statistic comparison, it is shown that the proposed algorithm is more stable than POA due to its lower standard deviation. Meanwhile, MPA performs as the most stable algorithm due to its lowest standard deviation. Besides, the stability of KMA is also low and it is close to MPA. Ironically, GWO becomes the most unstable algorithm.

The fourth simulation is conducted to observe the convergence of the proposed algorithm in solving the portfolio optimization problem. In this simulation, there are three values of the maximum iteration: 50, 100, and 150. In this simulation, the proposed algorithm is still compared with these fourth algorithms. The result is shown in Table VII.

TABLE V. TEN BEST COMPANIES IN LQ45 INDEX

| No | Code | Current Price | YTD Capital Gain |
|----|------|---------------|------------------|
| 1 | MEDC | 545 | 83 |
| 2 | ITMG | 29,975 | 10,350 |
| 3 | ADRO | 3,180 | 810 |
| 4 | INCO | 6,850 | 2,090 |
| 5 | PTBA | 3,710 | 1,040 |
| 6 | UNTR | 29,775 | 7,950 |
| 7 | MDKA | 4,610 | 570 |
| 8 | ANTM | 2,340 | 0 |
| 9 | BBNI | 8,450 | 1,725 |
| 10 | HRUM | 10,125 | -375 |

TABLE VI. PORTFOLIO OPTIMIZATION PROBLEM SIMULATION RESULT

| No | Algorithm | Total Capital Gain | |
|----|-----------|--------------------|--------------------|
| | | Average | Standard Deviation |
| 1 | GWO | 191,827,306 | 48,601,823 |
| 2 | MPA | 274,425,133 | 5,323,910 |
| 3 | KMA | 273,280,387 | 7,949,071 |
| 4 | POA | 398,494,240 | 20,245,548 |
| 5 | HPKA | 401,824,087 | 16,252,005 |

TABLE VII.    SIMULATION FOR CONVERGENCE ANALYSIS

| No | Algorithm | Total Capital Gain | | |
|----|-----------|---------------------|------|------|
| | | $t_{max} = 50$ | $t_{max} = 100$ | $t_{max} = 150$ |
| 1 | GWO | 208,336,875 | 189,973,268 | 192,619,037 |
| 2 | MPA | 272,722,150 | 273,976,306 | 276,707,756 |
| 3 | KMA | 259,277,675 | 268,501,294 | 268,033,687 |
| 4 | POA | 402,265,771 | 416,313,431 | 408,763,771 |
| 5 | HPKA | 416,847,431 | 404,039,878 | 406,785,637 |

Result in Table VII shows that all five algorithms achieve their convergence in the low maximum iteration. It means that these five algorithms do not need high maximum iteration to find the near optimal solution or acceptable solution. Comparing between POA and HPKA, the gap between these two algorithms is narrow.

## V. DISCUSSION

In general, the result proves that the proposed algorithm is a good and competitive metaheuristic algorithm. It is very competitive in solving theoretical optimization problem and real-world optimization problem. Its performance is better than KMA and POA in solving most of benchmark functions and the portfolio optimization problem. It means that this hybrid version is better that its origins, whether it is POA or KMA. More profound analysis regarding the findings will be discussed in the following paragraphs.

Table II shows that the proposed algorithm is better than the basic POA. This circumstance happens in most functions in all three groups: high dimension unimodal, high dimension multimodal, and fixed dimension multimodal functions. This result proves that selecting the best solution for the target is better than the randomized target for the swarm movement. Through guided movement toward the global best solution, the probability of the improvement will be higher than the randomized movement, whether it is the randomized jump as conducted in the first option or the half jump as conducted in the second option.

Table II also shows that the proposed algorithm is better than the KMA. This circumstance also occurs in most benchmark functions, exceptionally high dimension unimodal and high dimension multimodal functions. The proposed algorithm is less competitive than the KMA in solving fixed dimension multimodal functions. This circumstance shows that the mechanics of the proposed algorithm consists of four optional movements and the iteration-controlled exploration-exploitation strategy is better than the three fixed movements in KMA.

The result also strengthens the no free lunch theory. As stated in this theory, developing a general-purpose algorithm better for solving all problems is almost impossible [28]. The proposed algorithm may be less competitive than GWO in solving the high dimension unimodal functions where GWO is superior in these functions. On the other hand, GWO loses its superiority in most multimodal operations, whether they are high dimension or fixed dimension. The proposed algorithm is also significantly superior to GWO in solving the portfolio optimization problem. On the other hand, the proposed algorithm is slightly better than the POA in solving a portfolio optimization problem. However, the proposed algorithm is significantly superior to POA in solving theoretical optimization problems.

The simulation result shows that the effectiveness of specific algorithms should not be measured by challenging them to solve only the theoretical optimization problem. In the end, any optimization algorithm must be challenged to solve the real-world optimization problem. On the other hand, the circumstance in real-world problems is various. Many problems, especially in the operational research or finance, are simpler to be presented using integer or mixed-integer programming. The problem space is often integer, such as the number of production units, vehicles, assigned employees, shares, and so on. Moreover, the objective function is also simple, such as maximizing the total sales or profit. This objective can be presented by accumulating the weighted parameters. As an integer problem, precision is not needed. It is difficult to achieve a much better result in the integer-based optimization problem. This circumstance also becomes the reason why many well-known old-fashioned algorithms, such as genetic algorithms, are still used widely in many studies in operational research and finance. It is different from the engineering optimization problem, where many parameters are presented in floating-point numbers. In this case, the high precision algorithm becomes more relevant.

The simulation result also shows that the effectiveness of the metaheuristic algorithm also depends on the tuning mechanism of its adjusted parameters. Many metaheuristic algorithms are equipped with several adjusted parameters. The algorithm will perform well when these parameters are adjusted properly. On the other hand, the algorithm will perform poorly when these parameters are not adjusted properly. This circumstance becomes the nature of metaheuristic algorithms so that they can tackle many optimization problems in flexible ways. Based on this circumstance, it is not wise to judge some algorithms are better than others. However, the phenomenon of beating the elder algorithms is common in many shortcoming studies that propose new metaheuristic algorithms. Although the old-fashioned algorithms, such as genetic algorithm, simulated annealing, tabu search, and PSO, have been beaten many times, their popularity is still high because they are simple and flexible to modify. Commonly, the effectiveness of an algorithm can be improved simply by increasing the iteration or enlarging the population size.

There are several challenges and questions regarding this circumstance. Many metaheuristic algorithms are designed based on fixed adjusted parameters. It means that these adjusted parameters can be changed manually. It will be challenging in the future to propose an adaptive algorithm where the parameters can be tuned automatically during the iteration. It means there is logic in this future algorithm that can learn the behavior of the optimization environment (objective and problem space), and then it reacts based on its knowledge.

## VI. CONCLUSION

The proposed algorithm, namely the hybrid pelican Komodo algorithm, has been proposed in this work. This algorithm is developed by hybridizing the pelican optimization and Komodo Mlipir Algorithms. The work has demonstrated the outstanding performance of the proposed algorithm as a metaheuristic algorithm. It can tackle the two main objectives: finding near-optimal (acceptable) solutions and avoiding local optimal. Through simulation, the proposed algorithm is successful in solving the theoretical optimization problem and real-world optimization problem. It best solves five functions: Step, Penalized 2, Six Hump Camel, Branin, and Hartman 6. The proposed algorithm is better than GWO, MPA, KMA, and POA in solving 14, 12, 14, and 18 functions, respectively. In solving the portfolio optimization problem, the proposed algorithm creates 109%, 46%, 47%, and 1% better total capital gain than the GWO, MPA, KMA, and POA, respectively. Based on its positive result, this work shows that improving the current algorithms through modification or hybridization is as important as proposing a new algorithm with a new name.

There are several future research potentials regarding this work. This work is just one modification of the existing algorithms (KMA and POA). There are many other ways to modify and improve these two shortcoming algorithms. These algorithms can be hybridized with other battle proven algorithms. Besides, it will be challenging to implement these two algorithms to solve many other optimization problems so that the effectiveness of these two algorithms can be observed better to make the ground base for further development.

*Abstract*—This research's objective is to identify lacking elements in various effectors utilized in current physical training for cyclists. This encompasses both virtual reality-based system and indoor conventional training. Another objective is to identify user's acceptance from the use of vProCycle; which acts as the primary instrument of this study. Virtual Reality (VR) technology is a computer-generated simulation experience where immersive surroundings replicate lifelike environments – and is used for cyclists' physical training. Distinctive combinations of stimulus effectors (such as altitude, wind-effect, visuals, audio etcetera) have been applied to simulate actual world training environment. This is in order to increase the fidelity of presence for the participants involved, with emphasis on the five human senses. However, in this research the focus is only on hearing, sight, and interaction. The methodology of this mixed-mode pilot study is inclusive of 2 cyclists as participants and a 30 minute training session inside the hypoxic chamber room, whereby they have experienced a VR visual route replica of L'Étape du Tour, France. Variables composed of distinctive stimulus effectors are employed during the training, and survey interviews are utilized to gain users' insight. Results from this pilot study on the presence level indicate that the cyclists' have given high scores. This high score means that the cyclists were immersed while using the vProCycle system. In addition, the cyclists' also gave a high score on the level of technology acceptance towards using vProCycle. The main contribution from this study is to understand how various combinations of stimulus effectors can be applied in a VR-based training system.

*Keywords*—*Virtual reality; sense of presence; technology acceptance; stimulus effectors*

## I. INTRODUCTION

This research focuses on Virtual Reality (VR) physical cycling training that highlights several preferred stimulus effectors. Subsequently, this study proposes a new indoor cycling setup that includes the identified effectors. In the sports field, VR-based applications have been employed in several distinctive sports such as boxing, soccer, tennis, cycling, etc. VR has been in sports since the year 1990. In most VR applications, it requires a high-end computer in order to run [1]. Other than sports, VR can also be applied for exercising purposes. In addition to that, VR technological applications are also used to visualize realistic 3D modeling, interaction, data acquisition, analysis, product design, education, and even for medical practices. In terms of cyclists' physical training aims, VR-based applications have been found to gain its popularity [1,2,3]. An advantage of VR is that VR can induce a sense of being mentally or physically present in another place because VR allows individuals to interact with the environment [2]. Further advantages of VR are also noted by Sherman et al. [2], where he has stated that the VR environment can be manipulated in specific and reproducible measures. Sherman et al. [2] used these advantages to train participants to use a rowing and paddling pace strategy for a cycling race. Sherman et al. [2] also mentions that the VR exercising environment does not need to be limited to only a single person. Other individuals such as a coach, teammates, or opposing competitors, may be present even if they are physically located in another place.

In the context of cycling sports, interaction will occur based on how much physical effort from the body is applied to a machine (i.e. Kinetic Road Machine), and this interaction process is known as exertion interface noted by Alhadad et al. [1]. Kinetic Road Machine is one of the most well-known smart trainers available in the current market. A smart trainer is a machine which allows the cyclists to mount their bicycle back wheel, as shown in Fig. 1. Smart trainers are mounted onto the back wheel which have a feature to create a resistance effect. Meanwhile, ergometer is used to detect the motion speed that interactively changes the view in real-time.

Fig. 1. Smart Trainer Machine (in Red Circle).

In a more advanced VR-based cycling application, devices such as motion capture video systems, infrared beams, and wearable sensors can be used to generate haptic effects; which then translate physical actions into virtual activity. Thus, in general, a VR computer-based sport can be an alternative for an athlete to interact with the virtual environment.

## II. Literature Review

In this research, several literatures were reviewed to identify the current status of effectors integrated into a VR-based physical training. According to the Oxford dictionary (2021), the meaning of effectors refer to a substance that carries out a response to the stimulus. This definition is also similar in physiological terms. Meanwhile, a stimulus refers to a substance or event which evokes a specific functional reaction from the human body. From the literature review it is found that stimulus-effectors such as snow, water, wind-effect, and many others can be applied in particular events to trigger a specific body reaction. In a VR-based training, several stimulus-effectors can be applied as replication of an actual life experience.

According to Lim et al. [3], "VR technology creates a stimulation across arrays of effectors and is attached to devices to create an immersive virtual reality system". Until now, the commonly used VR effectors among cyclists comprise of visual, audio, and interaction. It is suggested by a few researchers that adding more effectors on top of the regular ones (i.e. audio, visual and interaction) will generate a significantly more immersive experience. In the area of sports, researchers have used various combination effectors to improve athletes' physical condition [3].

In various studies, different sets of combination effectors are applied to achieve specific objectives such as to increase performance, check physical fitness level, and improve body endurance [4,5,6,7]. In relation to cyclist physical training, it is suggested by the researchers that the following six main effectors; altitude, uphill elevation climb, wind-effect, visuals and audio, interaction and temperature are utilized. The strength and weakness of the effectors' piled as a combination are also identified based on the literature review.

The first stimulus-effector in this research called altitude and temperature. Altitude is referred to as the height of an object or point in relation to sea level or ground level [4]. There are two primary types of altitude training, and they are known as acclimatization and acclimation. Acclimatization is the natural outdoors and acclimation involves indoor training. In acclimatization the actual outdoor oxygen level is used during the training, while for acclimation oxygen level is generated. During a VR–based physical training, cyclists often conduct their training at a simulated high altitude with the aim to train their lungs to perform less oxygen intake [4, 5, 6].

During altitude and temperature training, three main factors may impact the cyclists' body and they are; atmospheric pressure, reduction of oxygen molecules in the air, and colder temperatures as the altitude gets higher from sea level [8]. The first factor which is atmospheric pressure, affects the cyclist as the altitude gets higher. Changes to atmospheric pressure may lead to a situation where there is

less oxygen in the cyclists' blood to carry to their muscles [9]. When cyclists train with less oxygen intake, their muscles may adapt accordingly, which means that the cyclist does not need to breathe harder or more when they are at sea level altitude. Most of the Olympic cyclists are trained at 1000 meters above sea level. At that level, the body will take in at least 20 percent lesser oxygen. This is caused by a reduction of oxygen in the atmosphere compared to sea level. Generally, higher altitudes of 5000 and above are considered dangerous due to the amount of oxygen molecules being below 17% in the air [8,9].

In a paper by Lei et al [5], they have mentioned that there is a significant impact when integrating altitude and temperature within VR-based applications. In Lei's [5] research, a setup involving a special room replicated the environment's altitude of 1000 meters above sea level; whereby the users were required to wear a HMD. The amount of oxygen was based on that height. It is to be noted that his experiment was conducted in multiple sessions. The findings from her research show that the cycling speed has improved where the difference between the first and the final sessions was greatly significant. Furthermore, Lei [5] also studied the effects of physical sport equipment such as a ball. Lei's [5] findings show a positive outcome where athletes have improved their accuracy as the participants were able to aim and kick the ball directly into the goal post.

Another essential research conducted by Mujika et al. [6] highlighted the measurement of altitude using the Meters Above Sea Level (m.a.s.l) technique. In his research, the user is also required to wear a HMD. Altitudes can be controlled indoors for training by using a chamber room. This chamber room can simulate any hypoxic environment by both latitude and longitude. Latitude is the angular distance of a place north or south of the earth's equator. On the other hand, longitude is the angular distance of a place east or west of the Greenwich meridian. As the latitude is higher above sea-level, fewer oxygen molecules are in the air and this consequently makes temperature to get colder. The longitude of a location can also determine the temperature on Earth. For example, the equator has different temperatures near the south and north poles. During the experiment, three different levels of altitudes were tested: low, medium, and high. Low altitudes represent the sea level where, at this altitude, the percentage of oxygen molecules is 20.9. This is the standard level of oxygen required by the human body to breathe normally. Meanwhile, at medium altitude (between 3000 and 4000 feet), the percentage of oxygen molecules is between 18.6% and 17%. Next at 5000 feet is considered as high altitude, whereby the oxygen may reach below 17% in the air.

Mujika's et al. [6] experiment involved the usage of a hypoxic dose, a timer, and confounding factors. Hypoxic dose is a medication given to the participating cyclists at an early stage. It helps cyclists to adapt themselves during altitude training. Meanwhile, a timer refers to a load periodization where it involves progressive cycling of various aspects in a training program during a specific period. Lastly, confounding factors used by Mujika [6] involved the use of simulated altitude, such as Meters Above Sea Level (m.a.s.l) and oxygen intake. Simulated altitude refers to the pressure and oxygen molecules available to the users while using a VR-based

system similar to that of a real-life situation. This training was conducted over multiple sessions. The impact of the training depicts that VR-based training enhances athletes' muscle buffering capacity which subsequently improves athletic physical fitness. This study also suggested that simulated altitude is incredibly effective to train athletes' endurance.

The only difference between Mujika's [6] and Lei's [5] study is that in Lei's [5] study, she did not include multiple high altitude studies.

The second effector preferred by many cyclists for training purposes is called an uphill elevation climb. Uphill elevation climb is a stationary cycling training simulated by the resistance effect on the back wheel. This resistance effect gives the cyclist the sensation of cycling uphill as they would in the real world. A back-wheel resistance machine is a piece of hardware that makes it possible to ride a bicycle with an uphill climb effect. This machine consists of a frame, a clamp, a roller on the back-wheel, and a motor which provides resistance [8, 9]. However, Yap et al. [7] has stated in his paper that the combination of back wheel resistance together with the common effectors (visual, audio and interaction) is not realistic enough to imitate an actual real life event. Many researchers have also suggested adding more varieties of different effectors to the current stationary training method.

In relation to the back-wheel resistance, Farrow et al. [8] have used HMD and uphill elevation climb to study a haptic effect. In his study, he highlighted that enjoyment levels and the force needed to paddle increases when haptic effects are experienced. Back-wheel resistance machines can be equipped with sensors that monitor the cyclists' physical fitness. Physical characteristics such as power output, cadence, virtual speed and heart rate are among the metrics that can be transmitted electronically [8]. Analyzing these physical outputs can help to fine-tune the athlete's training sessions. These sensors can also monitor data such as speed, distance traveled and time duration [8,9].

The effector of the uphill elevation climbing effect using bicycle was created using many different methods such as rollers on the back-wheel, attaching machines directly on to the bicycle wheels with the utilization of a 3D platform. One of the most popular methods in virtual reality to create the simulation of an uphill climb is by using a machine attached to the back wheel. The machine would cause resistance on the back wheel depending on the virtual environment as seen by the cyclist. In Farrow's [8] experiment, athletes' force and enjoyment levels were tested using HMD. The effector uses haptic effect from having the athletes paddle on the bicycle with resistance based on the VR system. In the study conducted by Farrow [8], he stated that with exercise enjoyment, athletes were still able to improve physical fitness using VR to train. In his findings, his results demonstrated that VR-exercise is an effective intervention as well as being credible to increase enjoyment while training [8,9]. It was calculated that 20 participants 222 were needed to identify a statistically significant gap in mean power output between 223 tracks and conditions (effect size = 0.67), with a power of 0.8 and alpha set at 0.05.

In Farrow [8] research, they developed a stationary bike reality simulation training with a back-wheel resistance device. The research was conducted using a back wheel road machine, which creates a virtual environment simulating an uphill climb. In his research, the users select the cycle path using a human–machine interface [9,10]. The stationary bicycle is used as an assisting training device that was proposed to help riders undertake simulation-based training before cycling on a real cycle path. The result of this research calculated the riding speed and accumulated the mileage as well as time-trial. Each riding session recorded distinctive elements such as mileage, time duration, average speed, and the route chosen. The results of his study using the Kinetic road machine shows that it had improved the cyclist's average speed when riding.

The third effector preferred by the cyclists during physical training is called wind-effect. Wind-effects can be used to enhance the experience and improve cyclists by exposing them to a more naturally aesthetic environment. This wind is created by using a fan. In order to simulate the wind-effect during cycling and enhance the cycling experience, a real time wind speed is needed to be generated [9, 11].

The wind speed can be measured in kilometers per hour. Integrating wind-effects for cycling training is used for endurance training focused on adaptive hypoxic training. Coaches train their athletes in a condition where the cyclist is required to paddle at maximal speed at a setup with high wind speed [9, 10]. The effect of the wind physical training is measured by the cyclist's speed together with the amount of wind speed in kilometers per hour. When used for training purposes, cycling in the wind can potentially cut one's speed in half with the same effort expended as when there is no wind. This means that the cyclist has to work twice as hard to generate the same output. The measurement from wind-effect training can be seen by the cyclist's energy output, and distance traveled in a specified time trial as in Petri et al. [9].

Research conducted by Schwind [10] found that the usage of HMD in VR sports has widely changed the way simulated sports are practiced. However, he claimed that experts still understand only a little about the use of antecedents for cyclists' sports applications. He examined attitudinal and norm-based factors that influence users' continuous intention towards sport applications usage. His research consisted of 362 sport practitioners where basic realism fidelity was integrated into the system. The results indicated that all attitudinal factors and norm-based factors have optimistically affected users' acceptance towards the inclusion of sport applications. His findings portrayed a promising acceptance level to all stimulus effectors of uphill elevation climb and wind-effect.

The last two effectors; visual and audio, are often integrated into cycling physical training aiming to produce highest fidelity of realism. A Virtual reality system renders visuals for the users to experience in a controlled virtual environment. The environment visuals are usually based on the user's bodily interactions, such as while the user rotates their head during HMD utilization, and the visuals are viewed according to the orientation of the head. Also, while using

virtual reality force feedback on bodily interactive motion, the visuals can move the 3D user's avatar in the virtual environment. This force feedback bodily interaction is what makes the VR sports exercise experience more pleasurable. Another effector is sound-effect that the user can auditorily hear while they are immersed in the virtual environment. Sound-effects in the virtual environment are 3D-surrounding. In VR, the 3D-surround sound effect uses multiple audio cue channels to stimulate the effect of an object's sound from the distance; the sound is sighted from 3D-surround sounds that come together with visuals as the two effectors complement one another for a realistic experience.

In a research conducted by Yap et al [7], a HMD with a fully immersive 360 degree view and 3D audio was used. Inside the HMD, one view is for the user's right eye and the other view is for the left eye. These two stereo views were fused by the viewer's perceptual system in the same way as humanistic right and left eye views of natural scenes [7]. The HMD system must also compute the synthetic views, track the viewer's location, and viewing orientation in the virtual world to create the correct right and left eye views. The latest VR technologies allow the development of better and cost-effective spatially immersive visualization and audio systems. His findings showed that 38 out of 50 preferred to display the simulation in HMD in comparison to non-VR-based displays such as on projectors and monitor screens.

In another research conducted by Koivisto et al. [11], he identified that users' characteristics may influence the quality of the VR experience. He also stated that users' characteristics may be influenced by the quality of the VR system. For example, the quality between visualizing through a monitor screen and using a HMD will give different impacts on the users' immersion level. It involves progressive cycling of various aspects of a training program during a specific period. Koivisto et al. [11,12] used a questionnaire method called the International Physical Activity Questionnaire (IPAQ). By using IPAQ, he found significant improvements compared to VR and non-VR visuals as well as audio.

The study conducted by Ng [13] shows that motivated cyclists using VR virtualization can contribute greatly to achieve training purposes. Ng identified research gaps in the areas of virtual reality (VR) sport applications from a systematic literature review of VR sport applications research. It showed that different physiological and psychological factors have been investigated by conducting experiments on the use of these applications in the study by Alhadad et al [1], Neumann et al. [14]. However, in Ng's study, different task purposes, like training, competition or socializing, do influence the perceived benefits which have not yet been examined. Moreover, it is unclear whether perceived benefits and risks affect actual behaviour outside laboratory environments. His study showed a significant difference in the risk assessment perceived by the cyclists.

Based on the seven papers as discussed above, six effectors have been identified. Those effectors are altitude effect, uphill elevation climb effect, realistic audio and visuals, wind-effect, realistic interaction and temperature. The

details of each of these stimuli are further explained in the following subtopics.

Through the seven main effectors as mentioned, it is noticed that many researchers have used effectors. However, the combination of implementing all stimulus effectors together into one complete system has not yet been established.

### III. FINDINGS RESULTS FROM AUTHOR'S PREVIOUS STUDY

This paper is a continuation from the authors' previous research as published in "A literature review on the usage of Technology Acceptance Model for analyzing a virtual reality's cycling sport applications with enhanced realism fidelity." [15,16] and "A literature review on the effects of 6-Dimensional virtual reality's sport applications toward higher presence." [16]. During the author's previous research, several selected stimulus effectors were identified. These findings were done by conducting a questionnaire interview session and feedback gathered from recreational cyclists who have undergone current stationary indoor training in professional gyms. In the last two papers, the number of interviewees was 30 in quantity, whereby all were conducted at a professional gym.

In the Table I, it shows the list of stimulus effectors used in the current setup for a conventional indoor cycling training.

TABLE I. CYCLING TRAINING STIMULUS EFFECTORS SETUP REQUIREMENTS

| Stimulus effectors | Current setup (Available Y/N) | No. of cyclists have experienced the simulator | No. of cyclists that recommend the stimulus effectors |
|---|---|---|---|
| Uphill elevation climb | Yes | 30 | 30 |
| Altitude | No | Nil | 28 |
| Wind-effect | Yes | 25 | 28 |
| Visual and sound | Yes | 28 | 28 |
| Interaction | Yes | 30 | 30 |
| Temperature | No | Nil | 28 |

Table I shows the usage of stimulus effectors for cycling training. The data is gathered from the interview conducted with 30 recreational cyclists between the ages of 18 years and 50. Out of the 30 cyclists, 20 were male and the latter 10 were female. Column one of Table I shows the six stimulus effectors identified from the interview as discussed in the previous paper [15,16]. In the "current" setup, it is found that altitude and temperature stimulus effectors are not being integrated. It is also identified as shown in the table that all participants were trained with uphill elevation climb and interaction. As for visual and sound, only 28 participants used a device to display their physical or other visual activities during a training session. While cycling in the gym, the standard setup includes a big screen in front of the cyclist. However, some cyclists often watch or listen to other

technological sources such as mobile phones and tablets. This action of extra displays can cause distraction while they undergo a training session. As for wind-effect utilization while training, every stationary bicycle comes with a built-in fan. Despite the availability of the fan feature, only 25 cyclists out of 30 actually employed it during training. Table I also portrays the number of cyclists who felt that using stimulus effectors while training is of great importance. A majority of the cyclists perceived all six stimulus effectors as necessary for the purpose of cycling training.

From the findings listed in Table I, it has been identified that the six stimulus effectors are important towards creating a highly effective training platform among cyclists. The combination of two or three stimulus effectors have already been experimented by other researchers as discussed in the literature above. In this paper, the combination of all six stimulus effectors is proposed, which deem it as distinctive from other researchers as cited in the literature review section. In the following sections (4.0), the implementation of the proposed VR setup with the combination of stimulus effectors to meet the requirement of a current cycling training system will be explained in detail.

## IV. Hardware and Technology Requirement

Table II shows the list of technology providers that fulfill the requirements for a cycling training system. The six effectors are matched to a specific technology to provide a distinguished experience for the user.

Table II shows a list of effectors and their technology providers integrated into the vProCycle system. The effectors employed are audio and visuals, altitude, uphill elevation climb, temperature, wind-effect, as well as paddling interaction.

From the literature, it was found that with distinctive stimulus effectors, the cyclist had experienced a higher level of immersion and presence. This situation is similar to the experience gained by the cyclist during their training in the real world.

Many literature encourages the use of more distinctive stimulus effectors for a better VR application out-put. The individual stimulus effectors have already been investigated. However a comprehensive study on a VR application that consists of several stimulus effectors have not been maximized.

TABLE II.    List of Effectors and Technology Provider

| List of effectors and technology provider | | |
|---|---|---|
| No. | Effectors | Technology provider |
| 1. | Audio and visuals | HMD |
| 2. | Altitude | Altitude chamber room |
| 3. | Uphill elevation climb | Backwheel resistance machine |
| 4. | Temperature | Altitude chamber room |
| 5. | Wind-effect | Fan |
| 6. | Realistic paddling interaction | Blue-tooth device |

## V. Implementation of VR-Based System with Stimulus Effectors

From the findings where the providers and effectors have been matched, the following setup design inclusive of all the six stimulus effectors was generated. Before discussing in detail about the proposed setup, a few current cycling training systems are discussed here.

As shown in Fig. 2(a), (b) and (c), the cyclists are conducting their training using a conventional setup where they are not complementing the training with VR technology visual and audio. In Fig. 2(a), the cyclist is interactively viewing the cycling track based on the paddling speed. However, there is no interactive resistance applied while cycling as viewed when climbing uphill. Fig. 2(b) shows a combination of both external visuals (i.e. big screen TV) and a backwheel resistance that simulates the effect of cycling uphill. Fig. 2(c) shows the training setup done inside a chamber room where no VR is applied. However, the cyclist gets the effects from temperature, humidity and latitude control. VR is also applied as mentioned in the LR, however with a limited combination of stimulus effectors. Based on all the existing setups as discussed above, it is found that there is no setup that exists yet that integrates all the components comprehensively. As a result, a new setup is then proposed.

Fig. 2.    Traditional Training without VR (a), (b), (c).

Fig. 2 shows a traditional training without VR and with back wheel resistance (a). Fig. 2(b) shows a traditional training without VR with big screen and backwheel resistance to stimulate uphill climb. Fig. 2(c) shows a cycling training without VR in an altitude chamber room. From the findings as discussed above, the following design setup involves all the six stimulus effectors.

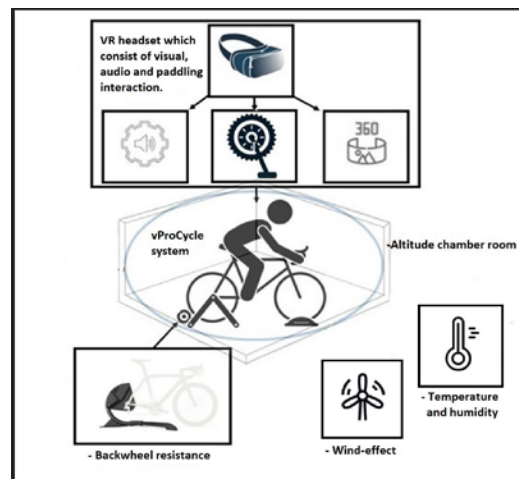

Fig. 3.    Proposed Setup of VR Cycling Training System.

Fig. 3 shows the proposed setup of the VR cycling training system with the combination of various effectors. As previously stated, the elements encompass uphill elevation climb, altitude, temperature, wind-effect, interaction, visual, and audio. This proposed VR cycling training system is named as the "vProCycle system".

The selected effectors and technology providers must match the requirements of the current cycling system, hence the methodology is justified in the next section.

## VI. Experimental Methodology and Results

In this section, the generated vProCycle is used for the experiment and will be discussed in detail. Through this vProcycle cycling training system, the sense of presence and users' immersion rate in the virtual environment are both evaluated. In addition, the technology acceptance of the cyclist is also to be determined. The first stage of the experiment involved a pilot study by two well- trained cyclists. After the data is collected from the pilot study, the vProCycle system is then further tested in experiment 1.

## VII. Pilot Study and Objectives

The objective of the pilot study is to evaluate whether the designated reaches a high fidelity of VR presence level from using the vProCycle system. Another objective is to evaluate their acceptance or outlook towards the technology when using vProcycle.

## VIII. Pilot Study Setup Requirements and Design Materials

In this subsection, the cyclists' setup requirements and design materials used to conduct the pilot study are identified. The figure shows a visual of the setup requirement and design materials utilized throughout the pilot study.

Fig. 4 shows the setup requirements and design materials during the pilot testing. This pilot test is conducted at Institut Sukan Negara (ISN). ISN is a Malaysian government agency - and it is established to provide sports science services, conduct research and development in the sports spectrum. Specifically, the study was conducted inside a hypoxic chamber. A stationary bicycle was used in the experiment whereby it was mounted on a back wheel machine. The machine is used to create an effect of resistance to the back wheel of the bicycle to simulate an uphill elevation climb. The paddles were also equipped with a Bluetooth sensor that sends signals to the HMD. This indicates that the bicycle is being paddled for it to move in the virtual environment. When the cyclist paddles forward, the visuals in the HMD change accordingly to the motion speed of the paddles. The HMD provides a complete 360ºaudio of the virtual environment sound to the cyclist participating. The visuals used in this study was a 360º view of L'Étape du Tour, France, as recorded by a 360 camera.

Fig. 4. Pilot Study Setup.

Fig. 5. A Sample Visual of L'Étape du Tour, France.

Fig. 5 shows a sample visual of the cyclist's view in the HMD while undergoing the pilot study. As mentioned earlier, another effector applied in the system is wind-effect. The wind-effect is generated by a fan placed at one and a half meters in front of the cyclist. The overall listed requirements and design materials are placed in a hypoxic chamber room; which controls the altitude, temperature, and humidity in the designated area. During the pilot study, a 1x9 MTB gear setup mountain bicycle was mounted onto the back wheel machine. This bicycle was selected to test the detected changes on the back wheel elevation climb-effect. This climb-effect is computer generated and controlled by the virtual reality program, which means that it adjusts the resistance of the wheel. This is executed by gripping or releasing of the rotation wheel as the virtual landscape changes. The session of this experiment was conducted for 30 minutes.

## IX. Pilot Study Cyclists' Requirement

The pilot study involved identifying the basic requirement of the cyclist participating. The first requirement is that the cyclist must be above 18 years old. The second is that the cyclist must have the experience of participating in a cycling state event and have completed the flag-off time limit.

## X. Pilot Study Tools Settings

The pilot study tool settings were that both cyclists are required to cycle at least 30 minutes in a virtual environment based on the Google map view of L'Étape du Tour, France. L'Étape du Tour map view is an official, professional cyclist training route. This route is 13 kilometers in length, with an altitude of 1,800 to 2,000 meters above sea level. The temperature level at this location is between 18°C to 26.5°C and at this altitude, the oxygen molecules in the air is about 20 percent lesser than at sea level. On this route, there are a lot of uphill elevations in narrow turns, which indefinitely creates a physical challenge when cyclists train at that exact location.

## XI. Pilot Study Result

In this study, two participants were involved, one male and one female. The data collected were divided into two categories: (1) sense of presence level and (2) technology acceptance. Presence is measured using a questionnaire based on the Witmer and Singer Presence Questionnaire [3], which uses a Likert scale from 1 to 7. The indicator of the Likert scale is the lowest of 1 being not immersive and 7 being highly immersed. An example of the questions used are "When you bicycle forward, did the feeling of moving forward in the virtual world seem realistic?" and "When you paddled the bicycle, did you feel the movement speed as realistic according to the change of view?" The two participants were required to answer a series of questions addressing each effector. The presence questionnaire was given after the cyclists had undergone a training session using vProCycle.

## XII. Pilot Study Result: Sense of Presence

Results of the cyclists' sense of presence data can be used to determine whether the vProcycle system is credible in creating the sense of realism as though they were cycling in L'Étape du Tour, France. The table shows the results of the cyclists' sense of presence using vProCycle system.

The number of questions asked in relation to the effectors listed in Table III were: 14 questions related to visuals, 5 questions on audio, 6 questions on altitude, 6 questions on the uphill elevation climb, 3 questions on temperature, 3 questions on wind-effect and lastly, 7 questions on interaction. Table III shows the cyclists' sense of presence using the vProCycle system. The first effector listed is "visual". The score given by the male cyclist is 4.1 out of 7, which indicates that the visuals are moderate for him. On the other hand, the female cyclist rated the "visual" with a score of 5.1 out of 7, which is considered upper-moderate. Secondly is audio effects, whereby the male cyclist gives it a score of 5.2 and simultaneously, a score of 5.6 by the female cyclist, which indicates that both cyclists give the audio presence level an upper-moderate score. Thirdly, in regard to the altitude-effect,

the male gives it a score of 5.4 out of 7 while the female gives it a score of 5.7. Both rated the altitude-effect score as highly immersive, an almost exact replica of being at the high altitude of the L'Étape du mountain. Fourth is on the uphill elevation climb, where the male gives it a score of 2.6 out of 7 and the female gives it a score of 4.5 out of 7. This signifies that the uphill elevation climb has the lowest score out of all the other effectors. An open-ended interview session gained insight on why the male cyclist gave the very low score on the uphill elevation climb. It was mentioned that the maximal 10 degrees angle uphill inclination that the VR back wheel machine produced does not feel immersive. This is in liaison as the visuals appeared to look like more than a 10 degrees angle slope. Fifth is regarding the temperature, whereby both participants scored a 5.3 out of 7. This indicates that the temperature simulation within the VR immersion experience was very realistic. Sixth is on the wind-effect, the male gives it a score of 5.3 out of 7 while the female gives it a score of 5.66. This indicates that both cyclists found the wind-effect to be quite similar to lifelike surroundings. Lastly is the paddling interaction, whereby the male cyclist gives it a 4.5 and the female cyclist gives it a 4.6. Both cyclists gave the paddling interaction a reasonably decent, high score. All the scores from the questionnaire were added, then averaged based on the effectors.

TABLE III. Pilot Study of the Cyclist Sense of Presence

| No. | Effectors | Male cyclist (Average) | Female cyclist (Average) |
|---|---|---|---|
| \multicolumn{4}{l}{The cyclists sense of Presence using vProCycle system} | | | |
| 1. | Visuals | 58/98 = 4.1 | 72/98 = 5.1 |
| 2. | 3D Audio | 26/35 = 5.2 | 28/35 = 5.6 |
| 3. | Altitude | 27/35 = 5.4 | 27/35 5.4 |
| 4. | Uphill elevation | 16/42 = 2.6 | 32/42 = 4.5 |
| 5. | Temperature | 16/21 = 5.3 | 16/21 = 5.3 |
| 6. | Wind-effect | 16/21 = 5.3 | 17/21 = 5.66 |
| 7. | Paddling interaction | 32/42 = 4.5 | 33/42 = 4.7 |

## XIII. Pilot Study Result: Technology Acceptance

This section explains both cyclists' technology acceptance using vProCycle system during the pilot study. All the scores from the questionnaire were added then later averaged based on the independent variables of TAM. The number of questions asked in relation to the independent variable listed in Table III are composed of 8 questions related to perceived usefulness, 7 questions on ease of use, 4 questions on behavioural intention to use, and 5 questions on attitude towards usage.

Table IV shows five independent variables of TAM. Those variables are: perceived usefulness, perceived ease of use, attitude towards using, behavioural intention to use, and actual use. The first independent variable is "perceived usefulness", the male cyclist rated it a 7 while the latter gave it a 5.5. This shows that both cyclists found it quite useful; using vProCycle as a hypoxic cycling training. The second variable is "perceived ease of use"; the male ranked a score of 5.7 while

the female gave it a score of 6.2. This implies that the vProCycle system was very easy to use by both cyclists. The third variable is "attitude towards using vProCyle", where the male rated 5.6 while the female gave a 5.6. This signifies that the cyclists' attitude towards using vProCycle is incredibly positive. The fourth independent variable is on the "behavioural intention to use", the male puts a value of 6 while the latter gives it a score of 6.75. This indicates that both cyclists would have the intention to continually use vProCycle. The last variable is called "actual use", with the male giving a score of 7 and the female cyclist a score of 6. Both cyclists highly recommended vProCyle to be used for hypoxic training.

TABLE IV.     PILOT STUDY OF THE CYCLISTS' TECHNOLOGY ACCEPTANCE
TOWARDS USING VPROCYCLE

| The cyclists' technology acceptance towards using vProCycle | | | |
|---|---|---|---|
| No. | Independent variables of TAM | Male cyclist | Female cyclist |
| 1. | Perceived Usefulness | 49/56 = 6.18 | 44/56 = 5.5 |
| 2. | Perceived Ease of use | 40/49 = 5.7 | 44/49 = 6.2 |
| 3. | Attitude towards using | 28/35 = 5.6 | 28/35 = 5.6 |
| 4. | Behavioural intention to use | 24/28 = 6 | 27/35 = 6.75 |
| 5. | Actual use | 21/21 = 7 | 18/21 = 6 |

## XIV. PILOT STUDY AND ISSUES

It was advised by ISN that some cyclists may encounter hypoxemia which may lead to nausea, headache, dizziness or even vomiting. Fortunately, none of the participants encountered any of the symptoms of hypoxemia during this study.

Another issue was related to the uphill elevation climb. This is when the cyclist sees an incline of greater than 10 degrees steepness slope angle; while the back wheel machine can only create a maximum of 10 degrees. Some cyclists may expect to get greater resistance when encountering a stiff uphill climb as the hill has a steepness of 60 degrees. However, there is a device that can go up to 60% but is not currently available in VR. From the open interview in relation to the uphill elevation climb, the middle score is given only in relation to the back wheel resistance compared to the elevation climb that is visible in the HMD. There is a solution available that gives a better uphill climb using other devices. However, that device will not be used in the VR environment.

## XV. PILOT STUDY CONCLUSION

From the pilot study, it was highlighted that both the sense of presence in the VR cycling stimulation and technology acceptance of vProCycle were given high scores as well as positive feedback. This suggests that further testing can be conducted for professional cyclists. The test conducted in experiment 1 will be explained in detail below. In experiment 1, additional data from a heartbeat reader will be collected on top of other data similar to the pilot study executed.

## XVI. CONCLUSION

In conclusion, this paper shows how vProCycle offers new possibilities to understand and experience VR potential to be used for cycling training; when combined with a combination of stimulus effectors. It is to be highlighted that distinctive stimulus effectors do greatly influence the presence level of participating cyclists. This presence level is experienced by a realistic simulation integrated with the system. This simulation creates an experience as though the cyclist is cycling in the distinctive actual real environment. This high level of presence thus generates a positive outlook in terms of the users' acceptance towards the generated VR-based system.

However, there were also a few research limitations in this study, inclusive of the possibility that the participants may encounter hypoxemia which may lead to nausea, headache, dizziness or vomiting. In this pilot study, the cyclists who had undergone training using vProCycle did not encounter any hypoxemia experience. In addition, the availability of the hypoxic chamber room is limited and costly. As a result, conducting an experiment is limited by the financial and chamber room availability. Some recommendations for future studies may include the usage of backwheel resistance machine that can increase the elevation uphill climb resistance more accurately. In this pilot study the Kinetic machine used to stimulate resistance on the backwheel can only create a resistance equivalent to 10 degrees uphill slope. This specific machine was selected due to the ability to connect to the virtual reality devices. Other backwheel machines currently do not have the features to connect to the virtual reality devices. The cyclists during an open interview did mention they would like to have a higher resistance to the back wheel when climbing steep slopes as viewed in the HMD.

In addition, the 360 degree visuals provided by Google viewed inside the HMD were picture to picture based. In the future, a fully recorded video moving forward based on the cyclist paddling should be used if it is available.

Moreover, the wind-effect simulation speed generated by the fan is constant at all times. It is recommended that future researchers integrate the bicycle with a wind speed-based technology to simulate a realistic effect while inside the virtual environment.

Also, a stationary bicycle with tilting slope effect machine can be used for the cyclist to experience how to tilt their bicycle according to the virtual environment. This tilting slope effect can be achieved by using a motion platform that can tilt according to the body movement of the cyclists'.

This paper focuses on TAM analysis and the perception of presence using vProCycle. Based on cyclist's feedback to the TAM questionnaire, cyclists have given a high acceptability level towards using vProCycle. A positive correlation between TAM and also perception of presence shows that this combination may produce a positive outlook.

The contribution and innovation of this research includes the setup of the vProCycle system with a more comprehensive stimulus effectors. These combinations consist of an uphill

elevation climb, altitude, temperature, wind-effect, interaction, visual, and audio. For future research, researchers may integrate more stimulus effectors such as weather effect, road surface and light visibility.

*Abstract*—Conventional classification algorithms do not provide accurate results when the data distribution (class sizes) is unequal or data is corrupted with noise because the results are biased towards the bigger class. In many real life cases, there is a requirement to uncover unusual/smaller classes. There are a bundle of examples where importance of smaller/rare class is much-much higher than the bigger class for example- brain tumor detection, credit card fraud or anomaly detection and many more. This is usually called as problem of imbalance classes. The situation becomes worst when the data is corrupted with extra impurities like noise in data or overlapping of class or any other glitch in data because in this scenario traditional methods produce more poor results. This paper proposed a fast, simple and effective data level hybrid technique based on fuzzy concept to overcome the class imbalance problem in noisy condition. To appraise the classification performance of the offered technique it is tested with 40 UCI real imbalanced data sets having imbalance ratio ranges from 1.82 to 129.44 and compared with 12 other approaches. The outcome specifies that the presented hybrid data level technique performed better and in a fast manner when compared to other approaches.

*Keywords—Data level approaches; undersampling; oversampling; fuzzy concept; imbalanced data-sets; classification*

## I. INTRODUCTION

Classification methods are very useful in solving many real life problems. In the research literature, so many classification techniques are proposed like Decision Tree, SVM, Neural networks etc. These classification techniques work efficiently in classifying the balanced data-sets wherein the number of instances in the classes are approximately equal. Their internal design favors the balanced data-sets. These techniques fail to detect classes when used with imbalanced data-set, because as per their internal design the results in case of unequal size of classes deviate towards the bigger class. These algorithms ignore the smaller class as noise.

In real life situations, sometimes there is a need to detect exceptional cases e.g. credit card frauds, tumor detection, fraudulent telephone calls, shuttle system failure, text classification, oil spill detection, web spam detection, risk management, information retrieval, intrusion detection, earthquake and nuclear explosion, helicopter gear-box fault monitoring [1-4], etc. In such cases, Traditional Classification Algorithms do not work well. This problem is identified as Class Imbalance Problem (CIP). Class Imbalance problem is the classification problem wherein we are using traditional

classification algorithms to classify data with unequal size classes and our objective is to identify smaller class from the data. Researchers have addressed this problem in various diversified ways and a new field of research has emerged under the name Class Imbalance Learning (CIL) and it is evolving day by day. In many papers it is referred to as dealing with IDS (Imbalanced data sets) or with rare cases or dealing with skewed data sets (SDS) or skewed distributions. The smaller class in CIL is known as minority class and bigger class is known as majority class.

Class Imbalance Problem does not exist if the purpose is to identify majority class, it actually exists because the purpose is to identify minority class. The ratio of the number of majority to minority class data instances is called imbalance ratio. The problem becomes more risky as this ratio increases i.e. when data-set is highly imbalanced. The techniques proposed by researchers to solve the Class Imbalance Problem are majorly classified into data-level approaches (Pre-processing techniques), algorithm level approaches and their hybrid forms [5-6]. In data-level approach, the researchers have tried to balance the data-sets before applying traditional classification algorithms so that results may not be overwhelmed by the majority class [7-15]. In algorithm level approaches, the researchers have worked upon the internal algorithm structure and tried to work upon the sensitivity of algorithm towards the majority class. These algorithms come under the category of cost sensitive algorithms [16-35]. Third approach is the hybrid form, which is the combination of data-level and algorithm level approaches. The advantage of data level approaches is that, the researcher will work at the data level and balance the data before classification and hence same classification algorithms can be used. This paper proposed a fast and robust hybrid data level approach based upon fuzzy logic. The proposed method can work with any level of imbalance data. It is tested with 40 UCI real world imbalanced data sets and its performance is compared with 12 other methods. It is observed that performance of proposed method is best compared to other methods. Rest of the paper is organized as follows. Section II explains the background information required to develop the method. Section III describes the proposed approach followed by conclusion in Section IV.

## II. BACKGROUND INFORMATION

This section explains various techniques and terms, which are required to develop the proposed approach.

## A. Density Oriented Fuzzy C means (DOFCM)

Density oriented FCM is a robust clustering approach, which identifies and removes noise from the data based upon the density of the data [36, 37]. It uses density factor (neighborhood membership) to remove the outliers from the data. Density factor of DOFCM is defined as:

$$DensityFactor(D) = \frac{\eta^i_{neighborhood}}{\eta_{max}} \ \forall \ i \ in \ D \qquad (1)$$

Where $\eta^i_{neighborhood}$ is the total number of points around $i$

$\eta_{max}$ is the maximum number of points around any point in the whole D. D is the complete data-set.

DOFCM clusters the data into clusters using the following Objective function:

$$DOFCM_{Obj\_fun} = \sum_{l=1}^{c+1} \sum_{m=1}^{n} u^{\zeta}_{lm} d^2_{lm} \qquad (2)$$

Where $d_{lm}$ is the distance between center of a cluster '$l$' and a point '$m$' in the data-set. $u_{lm}$ is the fuzzy membership between '$l$' and '$m$'. $\zeta$ is the fuzziness index. The membership equation for DOFCM is as below:

$$u_{lm} = \begin{cases} \dfrac{1}{\sum_{j=1}^{c} \left(\frac{d_{lm}}{d_{jm}}\right)^{\frac{2}{\zeta-1}}} \forall \ l,m \ if \ densityfactor \geq Threshold \\ 0 \qquad if \ densityfactor < Threshold \end{cases} \qquad (3)$$

## B. Modified SMOTE

Chawla et al. in 2002 proposed Synthetic Minority Oversampling approach (SMOTE) [7]. This approach randomly selects candidate points and uses interpolation method to generate synthetic points in between the selected candidate points. Although the method is very simple but the limitation of existing SMOTE is that, it is not effective in case the data-set is corrupted with noise. In that situation, SMOTE method may select noise points as the candidate points (Fig. 1) and generate synthetic data within the candidate points. This situation may end up by generating more noise points within the data-set.

In the proposed approach, authors have used the variation of existing SMOTE method in order to avoid the limitation. The proposed method doesn't use random approach to select candidate points. It uses those points as candidate points which have large fuzzy membership values, which means the selected points will be close to the center of the minority class. It then uses interpolation method to generate the synthetic data between selected candidate points and the center of the minority cluster. Fig. 2 shows the process of synthetic data generation in case of modified SMOTE. In the figure, 'c' is the center of cluster, 'r' is the selected candidate point and 'n' is the synthetic point generated through interpolation. This approach intelligently generates the synthetic points by selecting only those points as candidate points, which are close to the center point; hence works on the limitation of existing SMOTE.

Fig. 1. Limitation of SMOTE

Fig. 2. Modified SMOTE.

## C. Performance Criteria

Proposed approach used AUC (Area under the curve), F-measure and G-mean (Geometric mean) performance criteria's, which are majorly used by researchers in case of imbalanced data-sets, to compare the performance of proposed approach with their counterparts. As the focus of imbalance data sets is majorly to identify minority class so author considered minority class as the positive class in the confusion matrix (Table I) as mentioned.

AUC is a plot of false-positive rate on x-axis and true positive rate on y-axis. It is the best method to compare the performance of multiple classifiers. It is represented quantitatively by ROC and is calculated as the arithmetic mean of True Positive rate and True Negative rate.

$$AUC = \frac{TruePos_{Rate} + TrueNeg_{Rate}}{2} \qquad (4)$$

Where $TruePos_{Rate}$ represents the amount of positive data categorized as positive and $TrueNeg_{Rate}$ represents negative data, which is correctly identified as negative.

TABLE I. CONFUSION MATRIX

|  | Minority (Positive) | Majority (Negative) |
|---|---|---|
| True | TP (True Positive) | TN (True Negative) |
| False | FP (False Positive) | FN (False Negative) |

F-measure is the harmonic mean of precision and recall. Recall is the rate of total positive data, which is correctly identified as positive and Precision is the rate of correctly identified positive data out of total identified positive data. Recall is also known with the name as Sensitivity or True positive rate.

$$F - measure = \frac{(1+\gamma^2).Recall.Precision}{\gamma^2.Recall+Precision} \qquad (5)$$

Where

$$Recall = \frac{TruePos}{TruePos+FalseNeg} \qquad (6)$$

$$Precision = \frac{TruePos}{TruePos+FalsePos} \qquad (7)$$

$'\gamma'$ parameter is used to set the importance of recall or precision.

Geometric mean represents the accuracy of every class. It is the geometric mean of True positive rate and True negative rate. It considers the performance of both the classes.

$$G - Mean = \sqrt{TruePos_{rate}.TrueNeg_{rate}} \qquad (8)$$

### III. PROPOSED METHOD

#### A. Description of the Proposed Method

This paper proposed fast, robust and effective hybrid data level approach based upon fuzzy concept to handle the imbalanced data. It is called fast and robust because it can handle any amount of noise in the data-set and has least time complexity compared to other methods. It is the most effective approach in case of real time datasets because of its noise resistant nature. It can work with any level of imbalance situation. (Refer to Section III-B). Fig. 3 and Fig. 4 show the algorithm and model of the proposed approach.

---

*Input: Imbalance Data corrupted with noise (I-DS)*
*Output: Balanced Dataset (B-DS)*

*Step 1: Cluster the dataset (I-DS) into minority and majority class using DOFCM clustering approach.*
*Step 2: Record the Fuzzy membership values of minority and majority data points.*
*Step 3: Reduce the size of majority class by removing those points whose fuzzy membership value is low.*
*Step 4: Enhance the size of minority class by using modified SMOTE concept (Refer to Section II-B)*
*Step 5: Combine the modified minority and majority class to generate balance dataset (B-DS).*

---

Fig. 3. Algorithm of Proposed Method.

#### B. Results and Simulations

To assess the performance of proposed approach, it is tested with 40 UCI real time imbalanced datasets [38] having an imbalance ratio ranging from 1.82 to 129.42. The properties of 40 UCI data sets are listed in Table VI (Appendix A). MATLAB R2018A [39] and Python framework are used to do the simulations. Its performance is compared with 12 other approaches namely RUSBoost [40], SMT-ENN [43], BalanceRandomForest (BRForest)[42], One Sided Selection (OSS) [43], ADASYN [44], SVMSMOTE [45], SMOTETomek (SMT-TL)[46][41], BorderLineSMOTE (B-

SMT) [45], Edited Nearest Neighbor (ENN) [47], Condensed Nearest Neighbor (CNN) [48], Neighborhood Cleaning Rule (NCR) [49] and GradiantBoosting (GBoosting)[50]. In these simulations, authors have used Decision Tree method (C4.5) as the base classifier because in most of the research papers, C4.5 is widely used by the researchers to compare the methods in imbalance domains [51, 52]. Table II, Table III and Table IV list the AUC, G-mean and F-measure values of all the methods corresponding to 40 UCI real time imbalanced data-sets. Table V lists the average execution time against every method. As it is not possible to plot all the values hence authors plotted the average values of AUC, G-mean and F-measure in Fig. 5, Fig. 6 and Fig. 7. Average execution time in seconds is shown in Fig. 8.

#### C. Visual Interpretations and Discussions

It is observed from the Table II, Table III, Table IV and Fig. 5, Fig. 6, Fig. 7 that the performance of proposed data level hybrid method is best and consistent compared to all other methods irrespective of any imbalance ratio. It is seen that CNN performed worst in every case. The performance of RUSboost, GBoosting, ENN, OSS, NCR varies with the variation in imbalance ratio. Their performance degrades with the highly imbalance data-sets (abalone-19). Performance of SMT-TL, SMYSVM, ADASYN, B_SMT and SMT-ENN is almost similar in case of every data-set.

In case of execution time (Table V, Fig. 8), it is reported that the execution time in case of proposed method is least compared to other methods. Other methods are also taking less than one second in execution except CNN, which took the maximum time (up to three seconds).

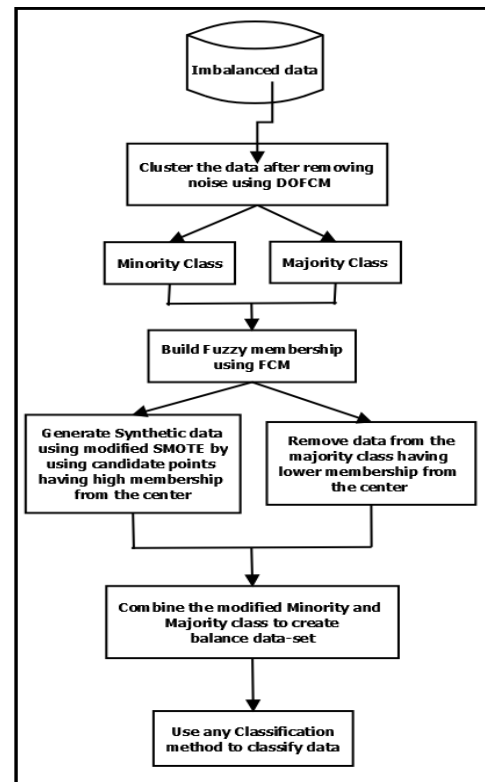

Fig. 4. Model of Proposed Method.

TABLE II.     AUC VALUES OF 13 APPROACHES

From the simulations and observations, it is concluded that proposed method is a robust and fast approach to balance the data because it works consistently for any kind of data set within least time.

## IV. Conclusion

In this paper, authors proposed fuzzy based fast and robust hybrid data level approach to balance the data. Its performance is tested with 40 UCI real time data-sets (Imbalance ratio- 1.82 to 129.44) and is compared with 12 other methods. After conducting the simulations, it is observed that proposed method can perform consistently with any level of imbalanced data compared to others and converge with the least execution time.

# Proctoring and Non-proctoring Systems

## A Comparative Study of Online Exam Scores for an Arabic Translating Course

Yusring Sanusi Baso

Department of Arabic Studies, Faculty of Cultural Science
Hasanuddin University, Makassar, Indonesia 90245

*Abstract*—This research describes learning achievement assessment technology, especially proctor technology. This study compares and contrasts proctoring and non-proctoring procedures used for online exams. The sample case used was the test scores of students enrolled in Hasanuddin University's Indonesian Arabic translation course. The research method used was a non-experimental quantitative method that compared students' online test results using proctoring and non-proctoring systems during online exams. The test scores of 101 students (40 male and 61 female students) from two different classes were sampled. The results of the tests for both classes were collected six times: three times using the proctoring method and three times using the non-proctoring system. A trend analysis was performed on the data. SPSS 26 was used to analyze the data via the two-way ANOVA procedure. The results indicate that the online proctoring system resulted in lower test scores than the online non-proctoring system, while the variables of class and gender did not affect the learning results.

*Keywords*—*Proctoring system; comparative study; Arabic translating course; online exam*

## I. INTRODUCTION

Academic dishonesty has long been a concern of academicians. As the number of online courses offered by universities has increased dramatically, so too has academic dishonesty; due to the inherent chances for academic dishonesty that online courses present students. This includes students collaborating on individual assessments and students using sources during tests that are prohibited—e.g., using notes and/or the textbook during a closed-book exam. Internet plagiarism is also on the increase as a form of academic dishonesty [1]. Academic dishonesty is a global problem that affects universities in many places. Moreover, multiple studies have shown an increase in cheating and plagiarism over the last few decades, with various explanations and ideas. The rising market for online education is a relatively new element of both higher education and academic dishonesty. Online education has established a permanent presence in global education marketplaces over the last decade and is considered to present new chances and problems regarding academic dishonesty [2].

As online college courses grow more widespread, concerns about academic integrity continue to arise. The prevention of cheating during unproctored online exams has gained significant attention [3]. Academic dishonesty is unethical, and exam cheating is more dangerous than other forms[2], [4]–[8], [9]. Online education will continue to expand, posing new obstacles. One major issue in this is the validity of online assessments. Questions concerning cheating arise, such as whether the individual taking the examinations is a registered student. Student self-reporting has been used to assess online assessment cheating. In a previous study, unproctored online students' exam results were found to be identical to other groups' scores, but their time spent on the exams was much more than that spent by the other groups. Due to the extra time spent by unproctored students, it is likely that they looked up answers during tests [10].

Integrity and adaptability are two of the most fundamental issues of real-time online examination monitoring systems. Several studies have been conducted to examine how dishonest students behave during remote assessments and possible safeguards against this. Reports and online submissions can help reduce academic dishonesty, according to Guangul and colleagues 2020 [6]. An optimization-based anti-collusion technique for distant online testing was developed by Li et al. [11] to minimize the benefits of collusion. A review published by Pettit and colleagues [12]–[14] provides advice on how to improve candidate authentication and prevent cheating.

Many methods exist to ensure the validity and reliability of online tests, such as deploying an on-site proctor or a real-time supervisor system [1], [15]–[22], [18]. One of these real-time online supervisor systems is Sikoola [23], which delivers real-time online monitoring services that take advantage of laptop webcams that students use in online exams. Sikoola, an online exam app that takes students through the exam procedure and monitors their progress, is used to connect students to the exam. Students are asked to log in according to the identity sent to their respective emails, usually one day ahead. After logging in, students must check the network to find out whether their internet access is good or not. If the student does not check the network, then the student cannot continue to the next stage. Next, students must check the laptop or PC webcam used for the exam. This webcam will record all the behavior of the examinees. If the webcam of the laptop or PC does not work, then the student cannot enter the online exam page. Students are expected to read all the rules of this online exam to avoid recordings that are considered dishonest in the exam.

The primary goal of this study is to compare the results of two different models of skills exams for translating Indonesian scripts into Arabic, namely, online exams using Sikoola, which utilizes an examinee dishonesty monitoring feature, and online exams using a Chamilo-based learning management system that is not equipped with a dishonesty surveillance feature.

To summarize the methods of this study, two websites, https://ujian.sikoola.com and https://sikola.unhas.ac.id, were employed in the investigation. The Sikoola tests utilize video surveillance tools and other features to detect and record dishonesty during online exams. While the URL sikola.unhas.ac.id gives the exam questions, it does not include a function that tracks whether a student has been dishonest during the exam

Based on this explanation, the researcher wants to address the following research questions:

*1)* Is there a difference in test scores between students who use Sikoola and Sikola in translation courses?

*2)* Is there a difference in the mean of the two classes sampled in this study?

*3)* Is there a difference in the mean of the scores acquired by female and male students utilizing the two systems?

## II. Materials and Methods

The research method used herein is a non-experimental quantitative method that compares students' online test results using proctoring and non-proctoring systems during online exams in Arabic Translation Skill.

### A. Population and Sample

The experiment was carried out within Hasanuddin University's Arabic Language Study Program, part of the Faculty of Cultural Sciences. The participants were second-year students. In this inquiry, two different classes of academic levels are portrayed. These students were responsible for programming the Indonesian–Arabic Translation course in the last semester of the 2021/2022 academic year. At the time of the experiment, they were all between the ages of 19 and 21. The first class had a total of 52 students, with 20 men and 32 women in attendance. The second class was limited to 20 men and 29 women, with a total of 49 students.

Exams were held six times over the course of three successive weeks. Tests were administered every week following the lecture schedule. The supervised test was administered at the beginning of the lecture, and the unsupervised test was administered at the end of the session. Thus, students were required to take a test twice a week on the two different systems.

The initial test materials included the criteria for translating complete sentences in Arabic, known as al-mubtada wal khabar in Arabic. The second piece of exam content focused on the Arabic ash-shifah wal maushuf, which translates as "the adjective phrases." The third and final test's material was a sentence that contains the Arabic term for possessive phrases, al-mudhaf wa mudhaf ilaih, which is referred to herein as the third test material

### B. Study Design

Tests were administered six times. Each class was tested three times on the website https://ujian.sikoola.com, which contains the camera surveillance function and other elements that record dishonesty during the exam, and three times on the website https://sikola.unhas.ac.id, which does not utilize

dishonesty recorders. There were 10 questions for each exam and a maximum score of 100. Ten points were given to each item. It should be noted that this exam was conducted online. Students were permitted to take the exam from any location with an adequate internet connection.

Even though these students were already aware of the two websites used in this research, they were reminded to adhere to exam procedures. The lecturer repeatedly encouraged students to check their network connections throughout the online exam before starting the exam. Additionally, students were required to utilize a laptop/PC equipped with a camera. If a student's laptop/PC camera was not functional, they would be unable to take the online exam.

Students must check the network and camera function on the website equipped with a dishonesty recording feature before the exam. If the internet network is not good, students cannot continue to check the camera. Checking the internet network is an absolute requirement in online exams to reduce complaints from examinees. Some examinees or students sometimes do not realize that their internet network connection is poor. Students or examinees should find an excellent place to access the internet with the internet network checking feature.

In the screenshot of Fig. 1, the instruction language used is still in Indonesian. The use of Indonesian is prioritized considering that students are not familiar with English and it is not the official language.

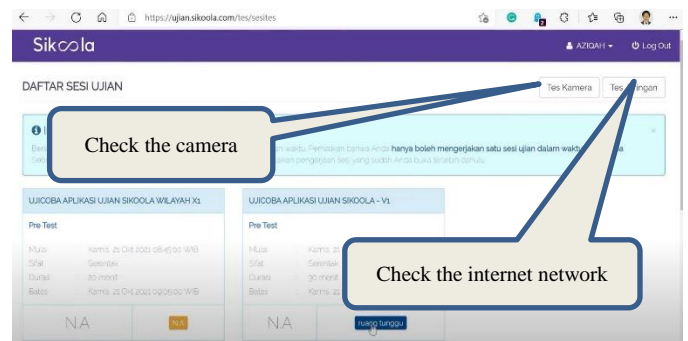

Fig. 1. A Screenshot of What Students See when they enter the Exam Question Room.

Examinees who have verified their network and camera will be taken directly to the exam page. This page contains critical information, including questions, question numbers, cameras, and remaining time information, as shown in Fig. 2.

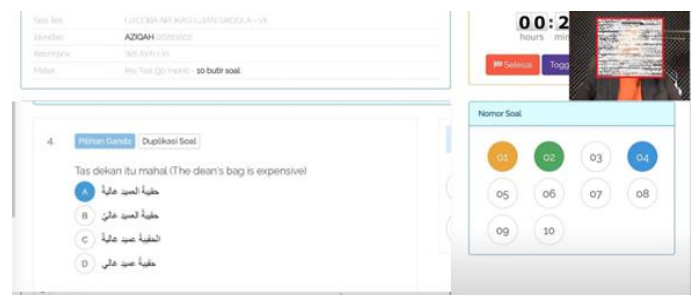

Fig. 2. An Image of the Questions on the Exam.

On the right, each question number has a color. The blue color shows the number of the question being worked on. The yellow color means that the question has been answered, but the examinee is still unsure of their answer. Therefore, examinees can reread the questions and revise their answers. The green color means that the question has been answered, and the examinee is sure that their chosen answer is correct. The white color represents a question that has not been answered. The Sikoola application allows examinees to work on questions in any order. Examinees can work on the questions they think are easy first and then answer the remaining questions. The color on the number is beneficial for examinees in solving each of these exam questions.

The above Fig. 2 also shows the Arabic exam questions and the number of each question. The exam questions were almost the same, but the words that made up the sentences were different only in alif-lam (mainly like "the" in English) and harakat (marking). Many things can change the meaning of a word, like where alif-lam is and how each last letter is marked. Therefore, students need to pay close attention to each word to find the best translation.

A camera view is displayed at the top right of the examinee's monitor screen. This live recording is transmitted to the online exam supervisor for review as can been seen in the following Fig. 3. The Sikoola application takes screenshots of events every five seconds. Sikoola saves the screenshots to its server.

If an examinee opens another browser or taps on a page other than the exam page during the exam, the Sikoola system will deliver a warning. This warning will occur after 20, 30, or even more seconds, depending on the test parameters. As long as a notification appears on the screen, the examinee's mouse and keyboard are rendered inoperable. After the warning period has expired, the OK button will become active. If the examinee hits the OK button, the warning will be removed.

Online exam designs with dishonesty recording features are likely to be a helpful tool for monitoring online exams, especially when the exam participants number in the hundreds.

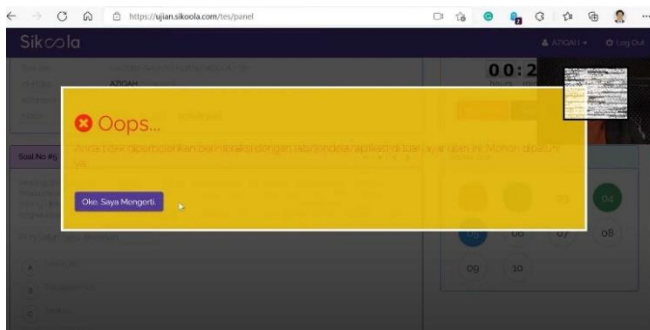

Fig. 3.  An Example of a Warning from the Sikoola System when a Student Opens another Browser or uses the Keyboard to Copy–Paste.

## C. Statistical Analysis

SPSS 26 was used for statistical analysis. The Wilson score interval method was used to obtain the 95 percent confidence intervals for prevalence estimations. Pearson's Chi-squared test was used to compare categorical factors. The Shapiro–Wilk test for normality and Levene's test for homogeneity were employed to determine whether there was a statistically significant difference in the variances of the two systems. To evaluate the variations in scores, a General Linear Model was used. The variables analyzed were the exam system, the student's gender, and their interactions. The mean and standard deviation were used to express the data (SD). A p-value of 0.05 was used to indicate statistical significance.

## III. RESULT

The researcher conducted this analysis via the two-way ANOVA test using SPSS 26. As a result, the researcher first determined the normality and homogeneity of the data. As shown in the Table I, the value of Sig. 0.164 > 0.05 indicates that the standardized residual was normal. The findings indicate that the data are normally distributed, as illustrated in Table I.

TABLE I.    TEST OF NORMALITY

| | Kolmogorov-Smirnova | | | Shapiro-Wilk | | |
|---|---|---|---|---|---|---|
| | Statistic | df | Sig. | Statistic | df | Sig. |
| Standardized Residual for SCORE | 0,05 | 202 | ,200* | 0,99 | 202 | 0,164 |
| * This is a lower bound of the true significance. | | | | | | |
| a Lilliefors Significance Correction | | | | | | |

Concerning the variance of the examined variables, it should be noted that Sig 0,103 > 0.05 indicates that the variance is homogeneous, as referred in the Table II.

Additionally, as evidenced by the data in the Table III, there are two system variables, two class variables, and two gender variables.

TABLE II.    LEVENE'S TEST OF EQUALITY OF ERROR VARIANCES A,B

| | | Levene Statistic | df1 | df2 | Sig. |
|---|---|---|---|---|---|
| SCORE | Based on Mean | 1,734 | 7 | 194 | 0,103 |
| | Based on Median | 1,619 | 7 | 194 | 0,132 |
| | Based on Median and with adjusted df | 1,619 | 7 | 164,944 | 0,133 |
| | Based on trimmed mean | 1,78 | 7 | 194 | 0,093 |

|  |  | Total | 84,99 | 7,010 | 202 |

To address the research questions, the Table V summarizes the findings of the two-way ANOVA statistical test:

*1)* Sig 0.000 < 0.05 means that there were significant differences in the test output results based on the SYSTEM variable used in this study. In other words, there were differences in student test scores in the exam when using the system https://ujian.sikoola.com as a proctoring system or the system https://sikola.unhas.ac.id as a non-proctoring system;

*2)* As evidenced by the value of Sig 0.071 > 0.05, there was no variation in student test scores based on class variables;

*3)* Similarly, there was no difference in scores between male and female students, as evidenced by Sig 0.234 > 0.05.

TABLE V.    TESTS OF BETWEEN-SUBJECT EFFECTS

| Dependent Variable: SCORE |  |  |  |  |  |

a R Squared = ,798 (Adjusted R Squared = ,791)

Some examinees' attempts to unfocus or engage in academic dishonesty are revealed via proctored online examinations. Unethical conduct includes opening the website and hitting the keyboard, which is deemed an attempt to access another application besides the opened exam page, as seen in Table VI.

TABLE VI.    ACADEMIC DISHONESTY

| Classes | Gender | Unfocus | Efforts |
|---|---|---|---|
| CLASS A | Male | 16 | 18 |
|  | Female | 17 | 18 |
| CLASS B | Male | 17 | 18 |
|  | Female | 15 | 19 |

## IV.  DISCUSSION

The COVID-19 pandemic has compelled teachers and students to alter their academic activities, one of which is assessing a student's acquired knowledge. According to certain studies, the acceptability of new approaches has been consistent across countries [24]–[26]. The primary reasons for

student opposition (to the online format) varied in various studies but included the risk of cheating or even receiving lower grades due to a lack of concentration [27], [28]. The former of these is easily overcome by employing a proctoring system during the remote electronic examination (like Sikoola, as was used in this study).

Sikola [29] is the website used to administer online exams without proctoring features in this study. This webpage is based on Chamilo [30]. Similar to other Learning Management systems (LMS), the LMS Chamilo application has an exercise menu. This menu has a variety of questions ranging from conventional types like multiple-choice questions to multiple-choice questions that force examinees to think more carefully in deciding their responses, such as multiple-choice questions with a degree of certainty.

The proctored website for online examinations is Sikoola. Sikoola is a program built exclusively for tests. The website Sikola's online exam elements are likewise owned by Sikoola. The only difference between the two is the proctoring system capabilities in terms of online examinations.

The statistics in this study demonstrate that student test scores were lower when distant electronic examinations were proctored. The proctoring system's documentation of the online exam process revealed that some students were flagged as dishonest throughout the exam. The information gathered was the appearance of notifications from examinees who wished to access a website other than the exam page. Another piece of information supplied by the system is the copy–paste usage of the keyboard. It is natural for the test taker's score to be lower when the exam is proctored. Additionally, the research indicated no difference in test scores when considering the class and gender variables.

The employment of a proctoring system during remote electronic examinations does assist institutions in educating students to always be truthful throughout exams. However, examinees complained that the employment of a proctoring system during the remote electronic examination drained a significant amount of credit from them; however, this assertion was not backed up by reliable statistics. Another student complaint apart from credit is the internet network. Some students who live outside the city frequently express dissatisfaction with the city's internet network. Students report having difficulty taking online tests due to insufficient internet availability. Students who experience this difficulty frequently want a policy requiring them to take a follow-up exam.

Therefore, under these conditions, the researcher took the initiative to prepare an online exam model for Arabic translating skills by utilizing an application to monitor student's behavior during online exams. The internet access check tool, the PC/laptop camera, and keyboard usage monitoring are just a few of the features required to monitor the translation skills test from the application. This program is anticipated to determine the strength of a student's internet connection. This feature's purpose is to educate students about the status of their internet access. Thus, if internet access is inadequate, the instructor is no longer held responsible for slow loading of the substance of the questions being worked

on. The difficulty, however, returns to students who are unprepared for online exams.

Another must-have feature is a surveillance camera. Every modern laptop, by and large, is equipped with a camera. This camera can be used when the owner is taking an online exam; for example, the camera can be compelled to turn on to capture the laptop's owner sitting in front of the screen. This online exam application system can periodically record the behavior of the laptop owner.

Additionally, an application that can monitor students' laptop keyboard usage is considered necessary for online tests. This cheating tracking tool instantly tells the laptop/PC owner if someone attempts to use the keyboard during an online exam. Thus, if students try to open another browser (new window) to search or copy and paste, the proctoring system will block the examinee's screen. As a result, students who attempt to cheat on online tests will be identified and may face disciplinary action.

The following Table VII summarizes the elements of Sikoola that enable it to monitor and record dishonesty during online exams.

TABLE VII.  LECTURERS CAN SELECT FROM THESE VARIOUS FEATURES WHEN PRAPARING FOR ONLINE EXAMS

| FEATURE | CHOICES | | DESCRIPTION |
|---|---|---|---|
| Is time flexible? | No | Yes | A flexible period can be set if the participants do not begin the exam simultaneously. Participants can begin the exam within the chosen time range using flexible mode. |
| Minimum completeness criteria | Filled with a minimum passing grade | | Minimum requirements for completion are used to determine whether or not a participant passes the exam. If the lecturer is going to do remedial work, only examinees who do not meet the passing grade are permitted to take it. |
| Stop the timer when offline? | No | Yes | When the examinee cannot connect to the server, for example, during a power outage, the countdown timer can be paused to ensure that processing time is not shortened when the participant reconnects. |
| Activate test tokens? | No | Yes | The organizer may need activation of the test token. Participants who do not know their exam token are unable to begin the examination. The institution's supervisor/admin can view the exam token. Every 30 minutes, the exam token will change. |
| Require camera? | No | Yes | If you select YES, all participants must consent to camera access. If this is NOT permitted, the participant will be unable to continue the examination. Ascertain that all examinees comprehend how to use the browser's camera. |

| | | | |
|---|---|---|---|
| Enable network checker? | No | Yes | If you select YES, all participants will be required to click the network check button. If NO, the individual is unable to proceed with the examination. |
| Enable snapshots? | No | Yes | If this option is enabled, when the examinee's webcam is recognized as being out of focus in front of the exam screen, a snapshot from the examinee's webcam is saved and can be downloaded in .zip format once the test concludes (up to 7 days after the exam, after which the system will delete it). Please keep in mind that this option is only effective if your examinee is obliged to stare at the exam screen constantly. If your examinee needs to draw on paper, keeping their face down, this option should not be activated. |
| Enable Live Score? | No | Yes | By enabling Live Score, institutions can track test taker acquisition in real time via the session administration menu. Please utilize this function only when necessary. If it is not critical to the institution, we recommend that it is disabled. Important! For the time being, the maximum number of participants in a session that can activate this function is 500, and the sessions must be concurrent. |
| Screen block duration | No | Yes | When participants engage with other tabs/windows/applications outside the test screen display, their screen may be blocked (they will be unable to answer/change questions). Enter the duration in seconds during which the participant will be blocked. If it is set to 0, no screen blocking occurs. Take note that this approach of screen blocking is relatively basic but quite successful for participants in general. |
| Check screen ratio? | No | Yes | If the screen ratio check is performed, the system will verify the participant's browser size every three seconds. If the screen size is deemed unsuitable, the test page will be blocked briefly. Before participants can proceed with the exam, they must alter the screen size. This method is intended to minimize the likelihood of participants exploiting the split-screen feature to launch additional windows/applications. |
| Allowed devices | PC/ laptop | Mobiles or tablets | The type of gadget that participants may use to work on this session is entirely up to them. Leave it as-is for unlimited access from any device. |

| | | | |
|---|---|---|---|
| Limit participant browser? | No | Yes | This restriction only allows specific browsers to be used. Specify the allowed browsers, e.g., Edge, Chrome, Safari, etc. |
| Limit internet provider | Specify the allowed internet provider | | If the test is not being run in a dedicated room or no IP address limitations are required, leave the room selection blank. |
| Show final result? | No | Yes | If desired, the outcome (points gained) will be shown to participants. Additionally, improper problem solutions will be revealed if this option is enabled. These displays are offered to participants only after completing their work on the questions. |
| Show rank? | No | Yes | This feature will display the ranking order of participants. |
| Show errors? | No | Yes | This feature will indicate whether the participant's response was incorrect. Caution should be exercised when activating this function, as it may create stress for individuals. |
| Show discussion? | No | Yes | This setting is only available if displaying errors is also enabled. After the test/test period is declared complete by the system, incorrect answers will be revealed along with the answer key and discussion (if applicable). |
| Show Done button? | No | Yes | This button allows the participant to exit the exam/test even if there is still time remaining. |
| Thorough discussion? | No | Yes | When the complete discussion option is enabled, all answers are shown to participants at the conclusion of the test, regardless of whether they were answered correctly or wrongly. |
| Engaged teachers | Fill in the teacher's name | | This field is optional. The test session outcome report is accessible solely to the specified teacher when completed. However, if it is left blank, no teacher will be able to view the test results. |
| Supervisors involved | Filled with the supervisor's name | | This field is optional. Supervisors may be assigned only to monitor the exam's progress. |
| Report model | Selected from the provided options, including standard reports, sorting, personality | | If you are unsure, use the Standard report model. Specific report models require the development of a question package to meet specific criteria; please consult us if your institution requires this. |
| Additional information | Filled with additional information | | Fill in the required information that has not been provided in the online exam system. |
| Show feedback form? | No | Yes | This feature will display feedback from the answers given by the examinees. |

Based on the facts, it was discovered that students were murmuring while taking online tests. This behavior is regarded abnormal, and as a result, the lecturer talks with the mumbling examinee by asking about his or her mouth. Evidently, the response to the inquiry was unexpected; hence, he had to read with his mouth jumbled to comprehend what he was reading. Obviously, this is an entirely different explanation from the lecturer's opinion that the student was muttering because he was reading the exam questions to his colleague standing in front of him, even though the PC/laptop used for the exam was not recorded. This fact also demonstrates that Sikoola's proctoring method must be improved, particularly in capturing students' voices during online exams.

## V. CONCLUSION

A proctoring system is a web-based program that assists instructors and students with online exams. In the case of Arabic translation examinations, the test scores of students who utilized the proctoring system were lower than the test scores of students who took the exam without using the proctoring system. Additionally, this study established that class and gender variables did not affect test scores. The online exam system variable—more precisely, the proctoring method used during the online exam—impacted the test score. A proctoring system in online exams can keep the examinees from engaging in dishonest behavior. Further improvements can be made to the proctoring system program to enhance its capabilities to record and track dishonesty during online exams.

According to recent findings, academic dishonesty appears prevalent among students enrolled in Arabic Translation courses. It is believed that, with the implementation of the proctored system, this unethical behavior among students would be eliminated in the future. One of the functions of higher education is to instill values in students, instilling the belief that academic dishonesty is unethical and should be avoided at all costs.

*Abstract*—Groundnut is an important oilseed crop in the world, and India is the second-largest producer of groundnuts. This crop is prone to attack by numerous diseases which is one of the most important factors contributing to the loss of productivity and degradation in the quality; both of these finally result in a low agricultural economy. Therefore, it is necessary to find better and more reliable automation solutions to recognize groundnut leaf diseases. In this paper, a deep learning based model with progressive resizing is proposed for groundnut leaf disease recognition and classification tasks. Five major categories of groundnut leaf diseases namely leaf spot, armyworms effect, wilts, yellow leaf, and healthy leaf are considered. The proposed model was trained with and without progressive resizing while it was validated using cross-entropy loss. The first of its kind dataset used for training and validation purposes was manually created from the Saurashtra region of Gujarat state of India. The created dataset was imbalanced in terms of a different number of samples for each category. To handle the imbalanced dataset problem, the extended focal loss function was used. To evaluate the performance of the proposed model, different performance measures including precision, sensitivity, F1-score, and accuracy were applied. The proposed model achieved state-of-the-art accuracy of 96.12%. The model with progressive resizing performed better than the traditional core neural network-based model built on cross-entropy loss.

*Keywords*—*Groundnut leaf disease recognition; progressive resizing; deep learning; neural network*

## I. INTRODUCTION

The groundnut crop plays an important role in the agricultural export commodity and edible oilseed economy of India. In the year 2019 alone, total groundnut acreage and production in India were 3.931 million hectares and 6.862 million MT respectively (IOPEPC, 2019)[1], but still, the average yield is low. Disease attack is a major factor contributing to the loss of productivity, quality, and early death of the leaves (Konate et.al., 2020)[2]. Therefore, it is necessary to take steps toward developing a fast and accurate groundnut leaf disease recognition methodology to increase productivity sustainably. This will be of great significance to the various stakeholders. Till now almost no commercial tools are available for accurate recognition of groundnut leaf disease and very less quality research articles are published for the same. One of the key reasons behind this might be a lack of

benchmark datasets available for groundnut leaf disease recognition research and experiments.

In this research, the groundnut leaf dataset was created manually from the Saurashtra regions of Gujarat. Initially, all images were captured in fixed background squared format with the size of 3000x3000 pixel (3 color channels), and then final datasets were prepared in different sizes of images including 32x32, 64x64, 128x128, and 256x256. Based on the thorough review of the literature and a comprehensive review carried out by (Ngugi et al., 2020; Chouhan et al., 2020; Kaur et al., 2019) [3-5] on methods used in leaf disease recognition using image processing, machine learning, and deep learning techniques, it was derived for the current research work that very few researchers have worked on groundnut leaf disease recognition. Chen et al. (2019) [6] used spectral index and disease index based on their correlation in leaf spectrum range between 325nm to 1075nm. Their results showed that near-infrared regions' canopy spectral reflectance decreased as the disease index increased. In the regression model, normalized difference spectral indexes were R938, R761 with the value of R2 up to 0.68 for peanut leaf spot disease detection. Based on the index model high fit between estimated and observed values, they concluded that the model could be used for peanut leaf spot disease detection. For groundnut disease classification (Chaudhary et al., 2016)[7] proposed an improved Random Forest Classifier using instance Filter-Resample and attribute evaluator methods for balancing the class distributions of the multi-class dataset. The proposed method was also applied on five different datasets such as Diabetes, Soybean, Audiology, Vote, and Breast Cancer, and obtained the value of the F1-measure in the range between 0.89 and 0.97. They advocated that the result of their method was effective when the dataset is unbalanced in terms of the number of samples varying among different classes. Ramakrishnan and Sahaya (2015) [8] applied a backpropagation algorithm for groundnut leaf disease detection and classification. Initially, RGB was converted into HSV and then plane separation and color features extraction steps were carried out. Dong et al. (2019)[9] applied a capsule network for peanut leaf disease recognition with the use of dynamic routing to overcome the problem of rotational invariance and spatial relationships. Their empirical observations showed that the recognition accuracy of the capsule network is 82.17% which is better than the

---

*Corresponding Author.

corresponding value of 81.14% of the convolutional neural network. It is notable to mention here that the capsule network was originally proposed by Sabour et al. (2017) [10]. Vaishnnave et al. (2020)[11] used a convolutional network for groundnut disease classification and claimed higher accuracy for training and testing on the PlantVillage dataset, but the fact is, till now no benchmark image dataset for groundnut diseases is released or published by PlantVillage (PlantVillage, 2020) [12].

Since the introduction of Deep learning, many state-of-the-art benchmark architectures such as DenseNet (Huang et al., 2017) [13], Deep residual learning (He et al., 2016) [14], Inception-v4 (Szegedy et al., 2017) [15], GoogLeNet (Szegedy et al., 2015) [16], VGG (Simonyan and Zisserman, 2014) [17] and AlexNet (Krizhevsky et al., 2012) [18] have been found to give an incredible performance for object detection and various computer vision tasks. Many researchers have also used these architectures for transfer learning for plant disease recognition e.g. (Fuentes et al., 2018) [19] have used R-CNN, AlexNet, GoogLeNet for the identification of tomato leaf disease, (Liu et al., 2018)[20] have used AlexNet for apple leaf disease detection, (Kaya et al., 2019; Barbedo 2019; Brahimi et al., 2018; Mohanty et al., 2016)[21-24] have used multiple benchmark architectures for multiple plant disease recognition.

In recent times, convolutional neural network-based methods are great in demand for plant leaf disease recognition due to automatic deep feature extraction. For corn leaf disease recognition and classification (Waheed et al., 2020) [25] proposed an optimized dense convolutional neural network model. Ji et al. (2020) [26] proposed a Convolutional Neural Network-based architecture for multi-label learning for crop leaf diseases recognition and severity estimation. To overcome the problem of the unbalanced dataset (Zhong and Zhao, 2020) [27] have proposed DenseNet-121 as the backbone network and used three methods regression, multi-label classification, and focus on loss function to identify apple life disease and obtained test accuracy of 93.51%, 93.31% and 93.71% respectively which was better than the accuracy of 92.29% obtained by traditional multi-classification method with a cross-entropy loss function. Sethy et al. (2020) [28] used different CNN architectures based on deep features using a support vector machine to identify rice leaf disease.

Self-attention CNN-based architecture was proposed by (Zeng and Li, 2020) [29] for crop leaf disease recognition. Zhang et al. (2019) [30] have used global pooling dilated convolutional neural network for cucumber leaf disease identification. Karlekar and Seal (2020) [31] proposed CNN-based SoyaNet for soybean leaf disease classification. Their proposed network obtained higher precision, recall, and f1-score value compared to the other nine state-of-the-art models.

Almost all the existing CNN-based architectures designed for leaf disease recognition and classification perform well at some level in terms of precision, recall, f1-score, and accuracy. However, the time complexity and model generalization are major problems when CNN-based architecture is trained and optimized on the high volume of small and large images or in a real-time environment due to the range of features and number of layers in the architecture. In this paper, a CNN-based architecture with progressive resizing for model generalization, optimization, and performance improvement is proposed.

## II. MATERIALS AND METHODS

### A. Dataset

Based on the best knowledge of related literature, almost no benchmark dataset of groundnut leaf disease is publicly available for research. The dataset for the current research was created manually and comprised of five major groundnut leaf classes, viz. leaf spot, armyworm effects, wilts, yellow leaf, and healthy leaf. All major types of symptomatic leaves were plucked manually from the plants and put onto the fixed background to capture the images. Initially, all the images are captured in squared format with the size of 3000x3000 (3 color channels), and then later all the captured images are resized in different sizes of 32x32, 64x64, 128x128, and 256x256 for model development using progressive resizing. The created dataset was divided into a ratio of 80:20 for training and testing. All the classes and corresponding labels considered for this research are shown in Table I.

The distribution of training and testing datasets is depicted in Fig. 1 which also indicates that the dataset is imbalanced as the distribution is not in equal proportion for each class. This was solved using the Focal loss function and is discussed in section 2.4 in detail. According to the data presented in Fig. 1, the most commonly occurring leaf disease in the groundnut crop is Leaf Spot which contributes the largest proportion, except healthy leaf, in the dataset. Similarly, the least proportion in the dataset is comprised of groundnut wilts. Notably, it is also a more harmful disease.

### B. Proposed Network Architecture

The well-known terminologies used in CNN such as a convolutional layer, pooling layer, filters, fully connected layer, etc., are not addressed here to rule out redundancy.

Model built on the standard convolutional neural network works well when input images are fixed in size. The model gives good accuracy when feeding larger images but it takes a long time and uses more computation power during the training phase. Scale-up and scale-down are required during training when input images are very small and large, respectively.

TABLE I. GROUNDNUT LEAF DISEASE CLASSES AND CORRESPONDING LABEL

| Class Name | Class Label |
|---|---|
| Groundnut Yellow Leaf | 0 |
| Groundnut Wilts | 1 |
| Groundnut Leaf Spot | 2 |
| Groundnut Healthy Leaf | 3 |
| Groundnuts ArmywormsEffect | 4 |

(a) Training Dataset.　　　　　　　　　　　(b) Testing Dataset.
Fig. 1.　Data Distribution for Training and Testing.

In this research, we have considered progressive-resizing methodology (originally proposed by Jeremy Howard, 2018) [32] for training a model to improve the recognition rate and for the model generalization. The workflow of progressive resizing for the proposed work is as follows:

Phase-1: The first model was trained on small images with the size of 32x32 with 3 color channels.

Phase-2: The next model was trained on upscaled images with the size of 64x64. Here, the layers and weights used in the previous smaller scale model were incorporated during training.

Phase-3: The third model was trained on 128x128 images; the output of phase-2 was fed as the input of phase-3. Each model is responsible to find some new features and patterns which were hidden in a previous smaller-scale model.

Phase-4: The final architecture was built and trained using the size of 256x256 images. Each larger scale model incorporates the previous smaller scale model in its architecture.

The proposed model was started to be built on 32x32 sizes and then scaled up to 4X, where X was the initial size of input images. Each phase of the proposed network was trained on the specific size of images and extracted some features. The trained model was saved with their weights and the weight was not changed in further training. Each subsequent phase was

responsible to extract additional findable features which were hidden and not found in the previous phase of the network. Models built on small-size images generalize well to larger input sizes and they take less time in processing (Howard, 2018) [33]. The proposed combined architecture is depicted in Fig. 2.

In order to introduce nonlinearity into the model, Rectified Linear Unit (ReLU) was used in each convolution operation The ReLU function, F(x) = max(0, x), returns x for all values of x > 0, and returns 0 for all values of x ≤ 0.

*C. SoftmaxLoss*

Here, the Softmax loss is categorical cross-entropy loss which is computed based on class probability generated by Softmax activation and using cross-entropy loss function. It has been referred to as f(s$_i$) and defined as follows:

$$f(s)_i = \frac{e^{s_p}}{\sum_j^C e^{s_j}}$$

Where s$_i$, is a network score of each class i in C.

In this research specifically disease classification, labels are considered as one-hot, which means only positive class C$_p$ were considered in cross-entropy loss which can be defined as follows:

Cross-Entropy = $- \sum_i^C t_i \, log(f(s)_i)$

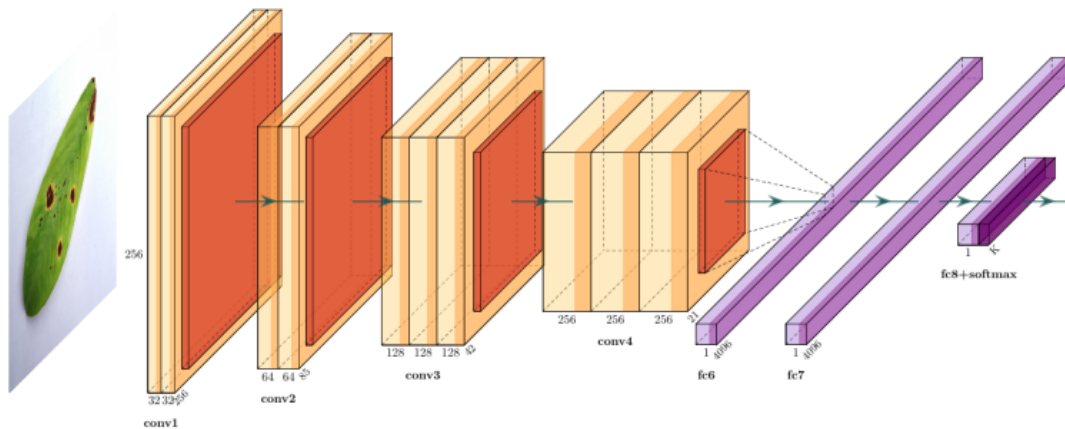

Fig. 2.　Proposed CNN based Architecture [Image by Author].

Target vector t only contained non-zero elements. We can write the following equation for cross-entropy loss after discarding the elements of summation which are zero because of target labels, so $t_i = t_p$.

$$Cross\text{-}entropy = -log\left(\frac{e^{s_p}}{\sum_j^C e^{s_j}}\right)$$

Where $s_p$ is a score of positive class in CNN.

### D. Focal Loss

The proposed classification also involved the problem of the imbalanced dataset. Some classes have a very small number of samples whereas some other classes contained almost double the number of samples. The network trained using an imbalanced dataset makes the network biased towards learning in favor of the classes having a higher number of samples while the remaining classes go under-looked. To tackle the class imbalance problem, a focal loss function with the multiplication of cross-entropy loss function with modulating factors was used. The Focal Local loss function is an improved version of cross-entropy loss which is made by adding focusing and balancing parameters in the cross-entropy loss function. This enhances the efficiency of the network and improves the results of misclassified observations. The focal loss function was originally proposed by Facebook AI Research (Lin et. al., 2017) [33] for binary classification in the object detection task. We have extended the concept of focal loss for multi-class classification. The general form of the focal loss function is:

$$Focal\ Loss = -(1 - p_t)^\gamma log(p_t)$$

The focal loss for multi-class classification can be derived as follows:

$$Focal\ Loss = -(1 - f(s)_i)^\gamma log(f(s)_i)$$

Where gamma ($\gamma$) is focusing parameter and $f(s)_i$ is softmax used for multi-class classification in cross-entropy. If $\gamma = 0$, then this equation is equivalent the equation of cross-entropy loss. Tunable focusing parameter $\gamma$ should be $\geq 0$. Gamma ($\gamma$) controls the shape of the curve. The higher value of gamma ($\gamma$) reduces the loss of well-classified observations at some level. In this equation $(1 - f(s)_i)^\gamma$ is considered as modulating factor.

Finally, focal loss function can be defined with balancing parameter for imbalanced data as follows:

$$Focal\ Loss = -\alpha(1 - f(s)_i)^\gamma log(f(s)_i)$$

Where, alpha ($\alpha$) is a balancing parameter. In this case, alpha refers to the weights used in the network, and small weights were assigned to dominating class while higher weights were assigned to the rare class.

### III. Result and Discussion

The training parameters used for the proposed model are shown in Table II. The model was trained on different sizes of images starting from 32x32x3and the final model was trained on 256x256x3 images. After doing many experiments, the final batch size and learning rate were set to 32 and 1e-3 respectively. Optimizer Adam was used with the decay of 1e-5.

TABLE II. Training Parameters

| Parameter | Settings |
|---|---|
| Final Input size | (256,256,3) |
| Batch size | 32 |
| Learning Rate | 1e-3 |
| Optimizer | Adam with decay of 1e-5 |

The distribution of testing data for each category is shown in Table III.

TABLE III. Distribution of Test Dataset

| Class | Number of Samples |
|---|---|
| Groundnuts Healthy Leaf | 333 |
| Groundnuts Armyworms Effect | 263 |
| Groundnuts Wilts | 160 |
| Groundnuts Leaf Spot | 293 |
| Groundnut Yellow Leaf | 240 |

The core CNN-based model without progressive resizing was evaluated using cross-entropy loss with different statistical measures, as shown in Table IV. The maximum and minimum F1 scores obtained were 0.934773 and 0.853771 for leaf spot and Wilts categories respectively. The average accuracy was reported to be 0.918823. The evaluation of the proposed model with progressive resizing and cross-entropy loss is shown in Table V. The result shows that the accuracy of 0.949381 obtained in progressive resizing is better than the accuracy of 0.918823 obtained with the core CNN model.

TABLE IV. Cross Entropy Loss without Progressive Resizing

| | Precision (%) | Sensitivity (%) | F1 score (%) |
|---|---|---|---|
| Groundnuts Healthy Leaf | 0.929509 | 0.919712 | 0.924585 |
| Groundnuts Armyworms Effect | 0.929019 | 0.937031 | 0.933008 |
| Groundnuts Wilts | 0.857722 | 0.849856 | 0.853771 |
| Groundnuts Leaf Spot | 0.938732 | 0.930847 | 0.934773 |
| Groundnut Yellow Leaf | 0.919686 | 0.928934 | 0.924287 |
| Weighted avg | 0.920766 | 0.918823 | 0.919774 |

TABLE V. Cross Entropy Loss with Progressive Resizing

| | Precision (%) | Sensitivity (%) | F1 score (%) |
|---|---|---|---|
| Groundnuts Healthy Leaf | 0.963758 | 0.958712 | 0.961228 |
| Groundnuts Armyworms Effect | 0.961034 | 0.960001 | 0.960517 |
| Groundnuts Wilts | 0.913827 | 0.901834 | 0.907791 |
| Groundnuts Leaf Spot | 0.962093 | 0.959823 | 0.960957 |
| Groundnut Yellow Leaf | 0.942003 | 0.943748 | 0.942875 |
| Weighted avg | 0.952575 | 0.949381 | 0.950971 |

The results of the proposed model without progressive resizing using focal loss ($\gamma=2$) is shown in Table VI. The average accuracy of 0.930404 was reported which is better

than the accuracy of 0.918823 achieved in cross-entropy loss. The training-validation accuracy and training validation loss using the focal loss function are depicted in Fig. 3(a) and Fig. 3(b) respectively. Here, focal loss down-weighted the easy observations and focused training on hard observations of imbalanced classes.

The evaluation results of the proposed CNN-based model with progressive resizing using focal loss function is shown in Table VII. The obtained average accuracy was 0.961229 which is better than the accuracy obtained in all other cases. Basically, setting the value of γ> 0 reduces the relative loss for well-classified observations, for the proposed model we obtained a higher accuracy when γ=2 set. The minimum F1 score was reported for the Groundnuts Wilts class and the maximum F1 score was reported for the Groundnuts Armyworms Effect class. The training and validation accuracy and loss for CNN-based model with progressive resizing using focal loss function is depicted in Fig. 4(a) and 4(b), respectively.

TABLE VI. Focal Loss (Γ=2) without Progressive Resizing

| Categories | Precision (%) | Sensitivity (%) | F1 score (%) |
|---|---|---|---|
| Groundnuts Healthy Leaf | 0.937483 | 0.929594 | 0.933522 |
| Groundnuts Armyworms Effect | 0.932743 | 0.942032 | 0.937364 |
| Groundnuts Wilts | 0.896029 | 0.88 | 0.887942 |
| Groundnuts Leaf Spot | 0.9488 | 0.948921 | 0.948860 |
| Groundnut Yellow Leaf | 0.926023 | 0.929782 | 0.927899 |
| Weighted avg | 0.931809 | 0.930404 | 0.931088 |

## IV. Conclusion

CNN-based architecture with progressive resizing was proposed to classify groundnut leaves into classes, namely, healthy leaf, armyworm effect, groundnut wilts, yellow leaf, and leaf spot which happen to be the most occurring disease in groundnut leaves. The proposed architecture with and without progressive resizing was evaluated using cross-entropy loss and focal loss functions. The obtained results of the proposed model without progressive resizing were 91.88% and 93.04% using cross-entropy loss and focal loss respectively while the average accuracy of the proposed model with progressive resizing using focal loss was 96.12%. Based on the empirical results, it is concluded that the progressive resizing-based model is a more generalized model and it was trained on different scales starting from the small-scale images of 32x32 size while the final model was built using 256x256 size images. The results obtained on different scenarios show that the CNN-based model with progressive resizing outperforms the core CNN-based architecture while the focal loss function helped out to deal with the imbalanced dataset problem. In the future, we plan to implement the proposed concept to recognition of diseases in real-time farm fields by combining computer vision technologies.

# A Proposed Architecture for Smart Home Systems Based on IoT, Context-awareness and Cloud Computing

Samah A. Z. Hassan[1]

Information Systems Department, Faculty of Computers & Information, Suez University, Suez, Egypt

Ahmed M. Eassa[2]

MIS Department, Faculty of Management
MTI University, Cairo, Egypt

*Abstract*—The main objective of this paper is to propose a simple, low cost, reliable and scalable architecture for building Smart Home Systems (SHSs) that can be used to remotely automate and control home appliances, using microcontroller. The proposed architecture aims to take advantage of emerging technologies to make it easier to develop Smart Home systems and to provide more management by expanding its capabilities suitably. The suggested design intends to make it easier and more convenient for many applications to access context data, as well as providing a new schematic guide for creating as complete and comprehensive Smart Home Systems and data processing as possible. Related topics like smart homes and their intelligent systems will be addressed by examining prior work and proposing the authors' opinions in order to suggest the new architecture. The proposed advanced architecture's building blocks include Classic Smart Homes, Internet of Things (IoT), Context-awareness (CA), Cloud Computing (CC), and Rule-based Event Processing Systems (RbEPS). Finally, the proposed architecture is validated and evaluated by constructing a smart home system.

*Keywords*—*Smart Home Systems (SHS); Internet of Things (IoT); Context-awareness (CA); Cloud Computing (CC); Rule-based Event Processing Systems (RbEPS); Smart Home System architecture*

## I. INTRODUCTION

Time, money, and energy are very valuable things. Smart Home Systems (SHSs) save time and reduce their owners' stress by ensuring homes are secured even when they are far away. Also, they save money and reduce the amount of effort put every day into running household helping owners having a better life [1], as they alert them of any change, allow users to control their homes when they are out, add safety through appliance, secure home through automated door locks [2], and increase peace of mind and convenience through temperature adjustment and lighting control [3, 4].

The proposed architecture is based on work done by [5], Internet of Things (IoT), Context-awareness (CA), Cloud Computing (CC) and Rule-based Event Processing Systems (RbEPS). Researchers frequently classify the problem of control as one of end-user programming, which causes them to think about research and assessment in terms of device control. End-user programming, on the other hand, gives the user some power over reprogrammed or learning-only systems [6]. The proposed architecture composition incorporates essential traits

and technologies from each of the four main paradigms. In the construction of smart homes, the Internet of Things (IoT) plays a significant role. IoT allows for remote management of mobile users/devices/sensors by utilizing an internet connection [5,7,8]. Practically anything in a home might be associated with the Internet via IoT, allowing for remote monitoring and control of all connected objects regardless of time or location [9,10]. Smart homes need to detect, expect and react to home activities to improve families' lives through socially appropriate and timely assistance [11]. In CA, Sensors can be attached to residential systems like air conditioning, lights, and other environmental devices. Computer intelligence is embedded into home devices by attaching sensors to them in order to monitor/control home appliances' functionalities and detect/measure home conditions/context. CC provides scalable infrastructures and platforms for accessing home devices and developing, managing, and executing home services anywhere at any time, in terms of processing power and/or storage space. The RbEPS allows building and controlling a full advanced smart home [5]. Scaling system capabilities, interestingly, might easily transcend some unseen threshold, leaving families feeling at the mercy of, rather than in charge of, technology [6].

There are four specific problems which are addressed for this kind of computing environments, which are: (1) How to combine and integrate the building blocks. (2) How to acquire, distribute, and store context data. (3) How to create means for Smart Home service discovery; for example, how sensors can discover resources in the nearby. (4) Because there is no universal standard for IoT interoperability, it is difficult for devices from various manufacturers to connect with one another.

The following section, the Related Work section, states the main four paradigms' definitions and descriptions. Secondly, the paper presents the proposed architecture which contains new milestones based on previous work to integrate and link the main four paradigms. Thirdly, the proposed architecture is examined by building an intelligent Smart Home System (SHS). Then, the paper is concluded in section four and finally, the future work is stated.

## II. RELATED WORK

A Smart Home can make things easier as it provides great convenience for users by remotely controlled via Internet. It appears smart and intelligent because its computer systems are

capable of monitoring a wide range of activities. For example, the lights will automatically turn off as soon as the sun rises [3]. In addition, such systems also provide security and safety for their users [1]. Developing such kind of systems are made easier with the rise of services provided by IoT, CA, CC, and RbEPS, which are discussed in the following subsection.

*A. Related Paradigms*

A Smart Home has advanced automatic systems for monitoring, controlling, and automating home capacities with electronic devices throughout the house [12]. It is a central system that can control and create communication between nearly all aspects of the house, which includes lighting, heating and air conditioning, security systems, gas and electric fireplaces, irrigation systems, doors, appliances, and more coming all of the time [13]. A Smart Home may be described as a residence which is equipped with modern technology sensors, appliances and devices that can be controlled, accessed, and monitored remotely in order to deliver services to the home's residents [14]. Smart Homes provide unlimited number of services, as [5]: (1) Measuring Home Conditions, (2) Managing Home Appliances, and (3) Controlling Home Access.

Smart home systems use services provided by Internet of Things (IoT). Academicians, researchers, practitioners, scientists, professionals, innovators, developers, pioneers, and corporate leaders have all come up with their own definitions for the Internet of Things. The initial version of the Internet, according to all definitions, was about data created by people, while the following iteration is about data created by things/objects [15]. The Internet of Things' purpose is to allow things to connect with anything and anybody at anytime, anywhere, and utilizing any path/network and service [16]. According to [16], IoT is classified into three categories interacting through internet, which are: (1). Things/machine to things/machine, (2) People to machine/things, and (3) People to people. The author in [17] defined IoT as "group of infrastructures interconnecting connected objects and allowing their management, data mining and the access to the data they generate." While [18] defined it as "an open and comprehensive network of intelligent objects that have the capacity to auto-organize, share information, data and resources, reacting and acting in face of situations and changes in the environment".

Context-aware computing is used to enhance Smart Home Systems. It is concerned with computer systems' ability to collect contextual knowledge to provide better services. Rather than considering mobility as a problem to be solved, context-aware computing attempts to take advantage of its inherent characteristics. A new breed of applications has emerged that increase user-app interaction by seeing/detecting the surrounding environment. Context-aware applications consider both explicit and implicit input. This contextual data is inferred from the application's surroundings. Context-aware applications are defined in terms of their flexibility, adaptability, reactivity, responsiveness, and sensitivity to context. The most prominent definition is defined by Dey et al. In [19], "Context is any information that can be used to characterize the situation of an entity. An entity is a person, place, or object that is considered relevant to the interaction between a user and an application, including the user and applications themselves". Also [20] defined context as "any continuous/discrete, dynamic/static, fixed/mobile, self-initiated/non-self-initiated, synchronous/asynchronous and volatile/nonvolatile available data that describe or characterize a principal entity. A principal entity may be a person or an object. Each principal entity has a set of elementary, mandatory and unique attributes. A principal entity has an associated one termed complementary entity. A complementary entity describes the principle one and contains any selective, secondary, inferred or profiling attributes. Its aim is to give more insight and details about the principal entity according to the application requirements. This data when captured, triggers specific events or enables interaction/querying with an application at certain time and responds depending on the current context at the time of service/output delivery".

As systems based on IoT need a huge amount of data to be stored, Cloud Computing paradigm is used. There have been many definitions of Cloud Computing by different researchers since it can and does mean different things to different people. The National Institute of Standards and Technology (NIST) defined cloud computing informally as [21]: "a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction" while [22] defined cloud computing as "a paradigm which enables unlearned users as well as well-educated developers to create, develop, customize, migrate, deploy, and/or manage legacy, custom, and/or new applications over the Clouds' infrastructure by providing ease of use tools, programing languages, services and/or hardware resources on the basis of a predefined Service Level Agreement (SLA) with the possibility to reconfigure/change application features explicitly by users or implicitly/dynamically by Cloud providers such as scaling, deployment and/or resource allocation".

Event processing systems react to events in the system's environment or user interface and able to perform operations on events, such as: reading, creating, transforming, and deleting events. These systems examine events or streams of events before taking automated actions. Anything that occurs at a given moment and can be documented is referred to as an event. Pre-defined decision tables or more powerful machine learning algorithms can be used to analyze data, and there are a variety of actions that can be taken, from generating a new event to modifying a customer's experience to scaling cloud resources up or down. The key characteristic of event processing systems is that the circumstance of events is unpredictable and the system must be able to deal with these events when they occur [23]. While event processing is concerned with detecting events from large event clouds or streams in almost real-time, reaction rules are concerned with the invocation of actions in response to events and actionable situations [24].

TABLE I.     A COMPARISON OF RELATED SMART HOME SYSTEM ARCHITECTURES AND THE PROPOSED ARCHITECTURE

| Paper | Purpose | Technologies | Layers / Components |
|---|---|---|---|
| [5, 2019] | An architecture for integrating classic smart home, IoT, and cloud computing. | IoT, Cloud Computing, and rule-based event processing. | **(1) Sensors:** not IoT sensors, used to collect internal and external data which transferred via the local network to server.<br>**(2) Processors:** used to process sensors' data and perform local and integrated actions.<br>**(3) APIs:** A collection of external software components used to process sensors data or manage actions.<br>**(4) Actuators:** used to execute commands in the server or other control devices.<br>**(5) Database:** used to store, analyze, present, and visualize the processed data. |
| [25, 2019] | An architecture for big data-driven processing and management. | IoT and Cloud Computing. | **(1) Physical Layer:** includes three types of sensing technologies and devices for health, energy, and security and safety.<br>**(2) Fog-computing Layer:** includes sensor hubs for simple data processing and computing.<br>**(3) Network Layer:** includes gateway and communication protocols.<br>**(4) Cloud-computing Layer:** It is used for extensive processing, computing and for data communication. It includes Data Stream Management System (DSMS), Data Lake, Real-time processing system, and Batch processing system.<br>**(5) Service Layer:** includes two main types of data views for operational and analytical data.<br>**(6) Session Layer:** provide standards and APIs to exchange data between services and application layers. The RESTFUL APIs and URL-based communication are used in this layer.<br>**(7) Application Layer:** includes all the applications which are subscribed to use or exchange data-driven services with such as domestic applications and/or third-parties. |
| [26, 2019] | An architecture for managing heterogeneous data from third parties. | IoT and Cloud Computing. | **(1) Device Layer:** includes connected IoT devices such as sensors, actuators, and/or appliances.<br>**(2) Gateway Layer:** provides the ability to communicate with different smart devices. It also interacts with databases for data storage.<br>**(3) Application and Service Layer:** provides the main services related to health and energy. |
| [27, 2021] | An architecture for discovery of resident behavior patterns. | IoT and Machin Learning. | **(1) Presentation Layer:** provides an interface for users to get access to the system.<br>**(2) Security Layer:** provides modules; such as authentication module, to ensure secure access to the platform's functions.<br>**(3) Control Layer:** includes necessary methods/modules; such as user control and automatic control modules, to access connected device's functions.<br>**(4) Communication Layer:** provides communication between different modules and elements through APIs such as REST.<br>5) **Data Layer:** provides data of interest and/or information needed for other modules. It consists of device data, device history, user data, house data, and configuration rules.<br>**(6) Devices Layer:** includes the communication technology necessary to control and monitor devices such as sensors and IoT devices. |
| [28, 2021] | An architecture for home integration and automation with security services | IoT | **(1) Application Layer:** provides services such as health care, security, video monitoring, entertainment, etc.<br>**(2) Network Layer:** uses internet to transmit information to application level.<br>**(3) Sensing Layer:** guarantees that data from all connected devices/sensors are transferred to the network layer after processing. |
| [29, 2021] | An architecture for providing secure and safe environment and reducing energy consumption. | IoT, Cloud Computing, and Edge Computing. | **(1) Device Layer:** used to integrate sensors into the system to collect data.<br>**(2) Broker Layer:** used to transmit data and commands from different sensors to the service layer.<br>**(3) Service Layer:** used to receive data from the broker layer to make one or more of the following features; data management, software management, personal cloud, and data aggregation.<br>**(4) Application Layer:** used to implement a user-friendly dashboard to manage and control IoT devices.<br>**(5) Cloud Layer:** used to store home data as a long-term storage for future analysis. |
| The proposed architecture. | For controlling smart home systems based on context awareness. | IoT, Cloud Computing and Context-awareness. | **(1) Data Collection Layer (DCL):** used to sense and collect data from various devices.<br>**(2) Data Management Layer (DML):** used to manage the collected data.<br>**(3) Context Formulation Layer (CFL):** used to formulate a context based on the collected data, while the fourth one.<br>**(4) Service Inference Layer (SIL):** used to infer specific activities and tasks according to the formulated context.<br>**(5) Service Management Layer (SML):** used to save/manage all this data, information, and/or context. |

## B. Related Architectures

Table I compares among some related Smart Home System architectures done by [5,25,26,27,28,29] and the proposed architecture in terms of purpose, used technologies and consisted layers/components.

## III. CONTRIBUTION

### A. The Proposed Architecture

As stated in Table I, the proposed architecture composed of five phases achieved by five layers as shown in Fig. 1. The proposed architecture adds a context-awareness layer; data formulation layer, to formulate meaningful data from small pieces of data collected by sensors/actuators.

The first and second layers belong to IoT, the third layer belongs to context-awareness, while the fourth layer is for Rule-based Event Processing Systems, and the fifth one belongs to Cloud Computing in addition to IoT and context-awareness. All of the architecture layers are discussed as follows:

- Data Collection Layer (DCL): This layer is responsible of collecting data from various user devices, sensors, actuators and/or databases (DBs). Smart actuators are devices, such as valves and switches that conduct activities such as turning items. Sensors collect internal and external home data, which is used to measure home conditions and recognize its context. Sensors are linked to both the home and the devices that are connected to it. Users can control the output of smart actuators related with household appliances (Smart Remote), such as lighting and doors, using User Devices (APIs).

- Data Management Layer (DML): The main job of this layer is to provide required data to the Context Formulation Layer (CFL) through the Data Acquisition component. All data collected in the DCL is sent across the local network to the smart home server (Data Storage), which stores the processed data collected from sensors and/or cloud services. It will be used for data analysis, data visualization, and data presentation. For future usage, the processed data is saved in the associated database. The Monitor is specifically designed to collect data; context attributes, in the environment by collaborating with some type of sensor equipment, and properly associate it with a context, whilst Listeners allow users to subscribe to changes to specific data.

- Context Formulation Layer (CFL): A single sensor, in most circumstances, only gives a fraction of contextual data diversity and is susceptible to several constraints. In order to fully understand and increase benefits of captured data, it must be refined by aggregation, transformation, interpretation, filtering, and splitting. These refinements bridge the gap between the raw sensor output and the level of abstraction required by applications through one of the following operations. Although there is enormous amount of low-level context data, it is suggested to store it for better monitoring and auditing as well as expanding context usage. Context Storage provides a data pool with a history of all contextual data obtained. This history can be used to access entities' prior contexts, deduce their activities, make conclusions about their requests, anticipate future situations, and analyze sensor performance. Based on [11], context main operations and their usage are described in Table II.

- Service Inference Layer (SIL): The Service Inference Layer's (SIL) responsibility is to infer appropriate context services which are related to the formulated context given by previous layer and/or any acquired/reasoned context. The inference process is based on Access Control for security reasons. Context Services are controlled by the Access Control component, which ensures that client requests are authenticated correctly. The access control list, which specifies what the requesting clients can access, and the means for authenticating the client, are the two main aspects of this component.

- Service Management Layer (SML): The management of any component included in this architecture is done by this layer. The Data/Context/Service Management is for managing any process related to data, context, and/or services such as context formulation/acquisition, service inference and/or storing data/context while the Device/Sensor Management responsibility is to manage devices/sensors such as attach/reattach them to the Smart Home System. The Communication management component is responsible of managing protocols, technologies, and/or tools needed for the communication process. Also, this layer is responsible of the management of Data/Context Storage, Context Services and/or the Cloud.

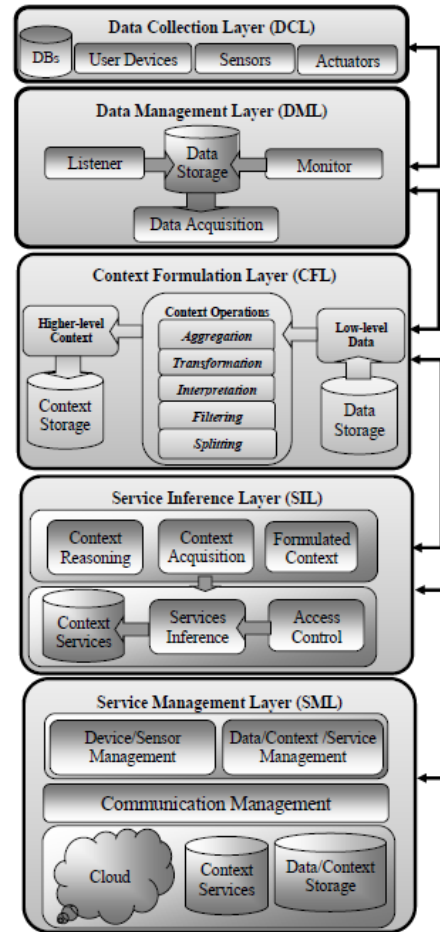

Fig. 1. The Proposed Architecture.

TABLE II. CONTEXT OPERATIONS

| Operation | Usage |
|---|---|
| Aggregation | To construct a higher-level context from a variety of logically connected context data collected from various sensors. |
| Transformation | To convert context data into an appropriate format. |
| Interpretation | For reusability, the same attributes may be interpreted differently in different contexts. |
| Filtering | To select an appropriate context by filtering in different context data values. |
| Splitting | To extract the sensed attribute according to the needed data/format. E.g., extract hours from timestamp. |

## B. Mapping the Proposed Architecture

In this section, an implemented Smart Home system (SHS) is build based on the proposed architecture, as shown in Fig. 2, SHS consists of eight main components which are described in the following Table III.

## C. Applying the Proposed Architecture

The proposed architecture was applied to implement a Smart Home System using the following hardware: (1) Arduino Uno microcontroller board, (2) ESP32 chip microcontroller with integrated Wi-Fi and dual-mode Bluetooth, and (3) Sensors & Actuators such as: (Solenoid Valve, 4x4 keypad, R305 Optical Fingerprint Scanner Sensor, FC-28 Soil moisture Sensor, rain sensor, photoresistor sensor, PIR sensor, DHT11 Sensor, and MQ2 gas sensor), while the software needed for implementation is as the following: (1) Arduino Integrated Development Environment (IDE). Code is written in C++ with an addition of special methods and functions. (2) IFTTT Driver, which is a software platform that links multiple developers' applications, devices, and services in order to trigger one or more automations involving those applications, devices, and services. (3) MQTT, which is an "IoT" connectivity protocol. It was created to be a very light weight publish/subscribe messaging service. (4) an account on the Ubidots cloud by which events are sent, triggered, and brought via Email, SMS, Telegrams, or Voice Call based on a customized design rule created in the application.

A SHS complete scenario may be detailed as: (1) The owner enters the smart home by inputting his/her password on the keypad or finger on the fingerprint sensor. The door will open in case of a known owner, otherwise an alarm will be fired, and a message will be sent to the owner if three tries to open the door are failed. (2) When the owner enters the house, his/her motion will be detected by the motion detection sensor. The light will be automatically turned on. It will be opened and closed using Google assistant or Ubidots cloud. In the night, lights out-of-doors will be turned on based on signals got from the photoresistor sensor. (3) If the temperature sensor detects temperature increase to a certain degree and the motion detection sensor detects that there is a movement in the room, the air conditioner will be opened and a message to inform the owner will be sent. (4) When the soil sensor detects that the quantity of water in soil decreases, the solenoid valve of water will be opened until the value of sensor will be increasing and a message will be sent to owner to monitor the condition of soil through the cloud. (5) When the rain sensor detects that it's raining, a message will be sent to the owner that rains fall outside. (6) If the gas sensor detects a gas leak, an alarm will be fired, and a message will be sent to the owner. (7) If someone asked to open the garage door, the Infrared obstacle avoidance sensor module detects there is a car inside the garage or not. The door will be opened using Google assistant if there is no car inside.

When any specific activity occurs, SHS gets to work. Table IV, shows some defined activities and related actions inferred according to those activities.

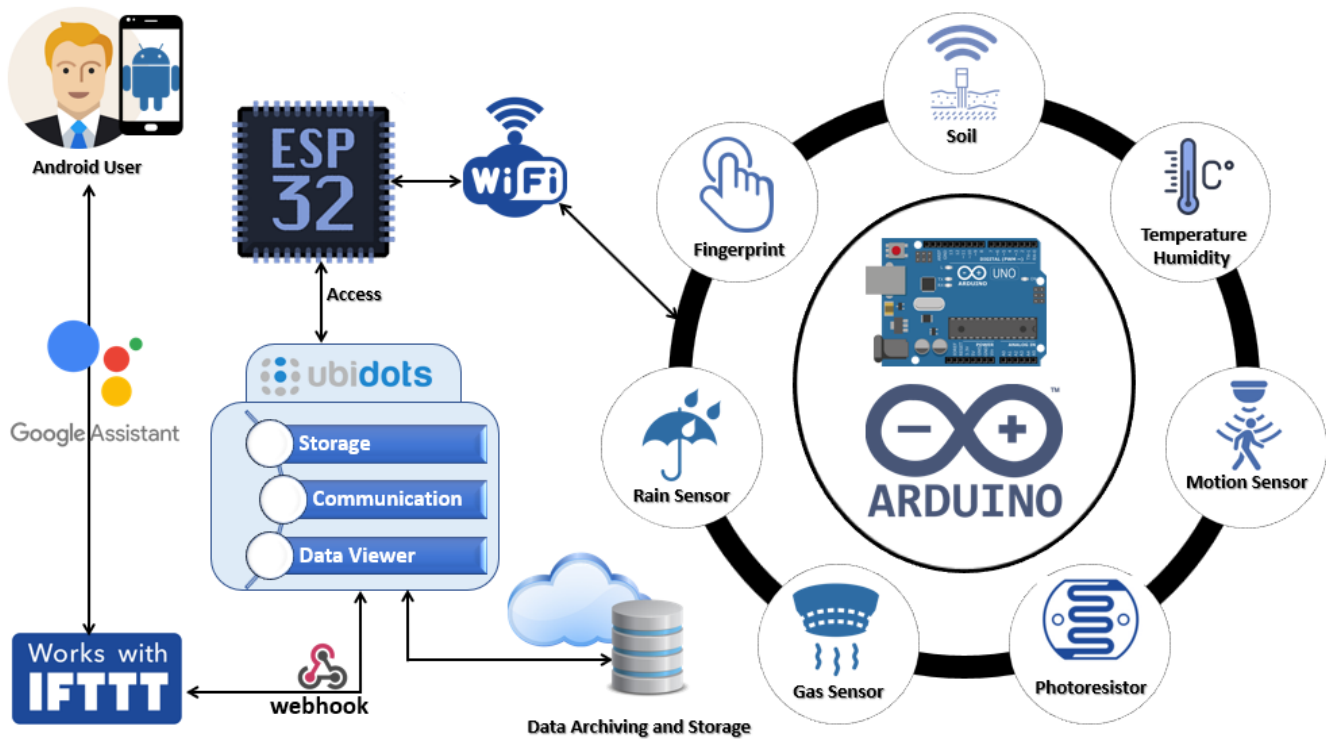

Fig. 2. The Implemented Smart Home System (SHS).

TABLE III.     THE PROPOSED ARCHITECTURE MAIN COMPONENTS

| Component | Description | Usage |
|---|---|---|
| **User Device** | Allows users to regulate the outputs of smart actuators connected to home appliances (Smart Remote) mobile phone. | Control the connected home devices from smart home app (IFTTT). |
| **Home/Residential Gateway** | Permits a small network, known as a Local Area Network (LAN), to be connected to a larger network, known as a Wide Area Network (WAN). | It connects home elements with the Internet via Wi-Fi. |
| **ESP32** | The ESP32 is a family of low-cost, low-power system-on-a-chip microcontroller that incorporate implicit Wi-Fi and dual-mode Bluetooth. | The principal usage of this board is dealing with all communication, sensor readings, and outputs. |
| **Ubidots** | Ubidots is an Internet of Things (IoT) data analytics and visualization company. It keeps dots from devices into variables, and these dots have timestamps associated with them. A "dot" or a data-point is framed each time a gadget refreshes a sensor esteem in a variable.<br>The following items are found in each dot:<br>- **Value**: A numerical value. Ubidots takes values of up to 16 floating-point in length.<br>- **Timestamp**: Unix Epoch time, in milliseconds. If not determined, then servers will assign one upon reception.<br>- **Context**: A set of unlimited arrangement key-value pairs with no restrictions. Latitude and longitude coordinates of GPS devices. | It is the cloud by which the computing and storage takes place on servers in a data center, instead of locally on the user device. It enables users to access files and applications from almost any device. So, users can control their home anywhere.<br>Sensor data is transformed into useful information for corporate choices, machine-to-machine interactions, educational research, and increased global resource economization. |
| **IFTTT** | Stands for "If This Then That", known as IFTTT is a freeware web-based service that builds applets, which are chains of basic conditional statements. | IFTTT helps connecting different applications and devices, manage them from Google assistant in phone. |
| **Database** | A repository for storing data collected from sensors and/or cloud services that has been processed. | Utilized for data processing, data visualization, and data display for future usage. |
| **Google Assistant** | This service works with Google Home or Pixel devices. It's incredibly flexible. | Used to create custom voice commands for home control, send updates, and more. |
| **Webhooks** | Webhooks are the way by which apps can send automated messages or information to other apps when something happens. | Used for speaking between online accounts and receiving automatic notifications when something new occurs. It is used to send data from one application to another automatically. |
| **Sensors / Actuators** | Collect data from both inside and outside the home. They are connected to the home and to the gadgets that are connected to the home | Used to capture data and send it to the smart home server on a regular basis across the local network. |
| **- Fingerprint** | It is one of the most secure methods for detecting and identifying authorized persons. | Used to make pretty sure about security needs. |
| **- Soil Sensor** | Determine the volumetric water content in soil. | It aids home owners Knowing their gardens' specific soil moisture conditions for helping them better managing their irrigation systems. |
| **- Temperature/humidity** | Measures the temperature/humidity and converts input data into electronic format for recording/monitoring. | This sensor may simply be connected to any microcontroller, such as an Arduino or a Raspberry Pi, to measure temperature and humidity in real time. |
| **- Motion** | Designed to detect and measure movement. | Used to detect the movement of home owners to perform highly specific functions. |
| **- Photoresistor** | Light sensitive resistors most often used to indicate the presence or absence of light, or to measure the light intensity. | Utilized when it is required to detect the presence and absence of light or measure the light intensity. |
| **- Gas Sensor** | The gas sensor is an electrical device that detects the presence of gas in the atmosphere. | Utilized to detect the presence of gases such as LPG, propane, methane, hydrogen, alcohol, smoke, and carbon monoxide in the air. |
| **- Keypad** | A keypad is a set of buttons arranged in a block or "pad" which bear digits, symbols, or alphabetical letters. Pads mainly include numbers are called a numeric keypad. | Used for the entry of PINs including Point of Sale payment devices, ATMs, vending machines, combination locks and digital door locks. |
| **- Rain sensor** | The rain sensor module is a simple tool for detecting rain. It is a rain-activated switching gadget. | When a raindrop falls through the rainy board, it can be used as a switch, as well as for gauging rainfall intensity. Rain sensors have two primary applications: (1) is a water-saving device that is attached to an automatic irrigation system and causes the system to shut down if it rains. (2) is a device that protects the interior of a car from rain and allows windscreen wipers to operate in automated mode. |

TABLE IV        SHS MAIN ACTIVITIES AND ACTIONS

| Service | Activity | Initialization | Sensor/Device | Input | Processing | Output/Action |
|---|---|---|---|---|---|---|
| Smart Lighting system — Inside home. | Owner enters the home. | Owner movement. | A passive infrared sensor (PIR). | Signal from the motion detection sensor. | The system detects there is a movement. | The light automatically turns on. It will be opened and closed using Google assistant or Ubidots cloud. |
| Smart Lighting system — Outside home. | | Sun set. | Photoresistor sensor. | Signal from the photoresistor sensor. | The system detects that it is night. | Lights out-of-doors will be turned on only in the night. |
| Smart Security system — Fingerprint | A person puts his/her finger on the fingerprint sensor. | Detecting finger on fingerprint sensor. | Fingerprint sensor. | Person fingerprint. | The system compares between this fingerprint and enrolled fingerprints; then sends a signal to door lock and alarm. | 1) If the fingerprint/password is known: the door will open. 2) If a wrong fingerprint/password was entered three times: turn alarm on and send owner a message that there was an attack. |
| Smart Security system — Keypad | A person enters his/her password. | Entered password in the keypad. | keypad 4*4 standard device. | The entered password. | The system compares between the entered password and saved ones, then sends a signal to door lock and alarm. | |
| Smart watering system. | No or less water in soil. | The quantity of water soil decreases. | FC-28 Soil moisture sensor. | The value of soil sensor. | Solenoid valve of water opens. | The solenoid valve of water will be opened until the value of sensor increases. A message to owner will be sent to monitor the conditions of soil through the cloud. |
| Smart Rain system | Rain drops fall on the sensor. | The rain drop fall. | Rain sensor. | The value of the rain sensor. | The sensor detects that it's raining. | A message will be sent to the owner that it's raining. Store that in the database weather session. |
| Smart Temperature | A certain temperature degree has reached and there is a movement. | The temperature degree increases | DHT11 Precision humidity & temperature. | Temperature degree and movement in the room. | Temperature will adjust by opening air conditioner. | Temperature will adjust by opening air conditioner and a message was sent to inform the owner. |
| Smart Gas system | A gas leak is detected by the gas sensor. | There is a gas leak in the home. | MQ2 smoke, gas, liquid-field module. | The gas sensor's value. | The gas sensor detects the leak and alerts the alarm system. | The owner will receive an alert message, and the alarm is fired. Data is stored in the database. |
| Smart Garage door | Detecting car in the garage. | A person asked to open the garage door. | Infrared obstacle avoidance sensor module. | Number of cars inside. | Detect if there is car inside or not and send a signal to door lock. | Unlock the garage door if there's no care inside using Google assistant. |

## IV. CONCLUSION

Smart homes are large systems that comprise a variety of technologies and applications that can be utilized to provide home protection and control. They have wireless communications, sensors, monitors, and tracking connections.

An efficient technique for smart home systems was presented and implemented in this paper. The proposed architecture shows how to combine benefit features from IoT, Context-Awareness, Cloud Computing and Rule-based event processing systems paradigms to facilitate the building of Smart Home systems in a more systematic manner.

The implemented system has been subjected to a range of tests and experiments. These experiments demonstrate the concept of employing ultrasonic sensors to create a house navigator that can measure and control temperature in all rooms, detect any fires, water leaks, smoke, and/or detect any motion in the home. Furthermore, these experiments demonstrate how to observe and track the home by sending messages to the owner about actions that have occurred, as well as how to secure it using an access code.

Three microcontroller system designs were used to create a central control system for the entire house. These designs were for home access control, temperature validation, and a control board system that would connect all of the security and control circuits.

## V. FUTURE WORK

Regarding the proof-of-concept system developed by this work, it is understood that it provides a subset of a fully functional smart home system. Therefore, the first recommendation would be to develop and implement other areas. Additionally, future work should also include the implementation of the core as a web service and the development of a web-based user interface to accommodate heterogeneous web-based clients.

There are several improvements that might be made to the existing system to improve sensing and detection accuracy. There are also a variety of different sensors that can be utilized to improve the security and control of the home.

# Shallow Net for COVID-19 Classification based on Biomarkers

Mahmoud B. Rokaya

Department of Information Technology, Taif University, Taif, Saudi Arabia
Department of Mathematics, Faculty of Science, Tanta University, Tanta, Egypt

*Abstract*—In many cases, especially at the beginning of epidemic disaster, it is very important to be able to determine the severity of illness of a given patient. Picking up the severe status will help in directing the effort in a proper way. At the beginning, the number of classified status and the available data are limited, so, in such situation, one needs a system that can be trained based on limited data to give a trusted result. The current work focuses on the importance of the bioscience in differentiation between recovered patients and mortalities. Even with limited data, the decision trees (DT) was able to distinguish between recovered patients and mortalities with accuracy of 94%. Shallow dense network achieved accuracy of 75%. However, when a 10-fold technique was followed with the same data, the net achieved 99% of accuracy. The used data in this work was collected from King Faisal hospital in Taif city under a formal permission from the health ministry. PCA analysis confirmed that there are two parameters that have the greatest ability to differentiate between recovered patients and mortalities. ROC curve reveals that the parameters that can differentiate between recovered patients and mortalities are calcium and hemoglobin. The shallow net gives an accuracy of 92% when trained using calcium and hemoglobin only. This paper shows that with a suitable choosing of the parameters a small decision tree or shallow net can be trained quickly to decide which patient needs more attention so as to use the hospitals resources in a more reasonable way during the pandemic. All codes and data can be accessed from the following link "codes and data".

*Keywords*—*COVID-19; pandemic; shallow net; deep learning; decision trees; ROC curve; PCA analysis; biomarkers*

## I. INTRODUCTION

During the early days of any pandemic, it is very important to provide a quick and sheep tool to detect infected people [1]. Also, it is very important to provide a tool to differentiate between the degrees of infection [2]. Moderate infections can be treated at home [4] but severe cases need to be under intensive care [3]. Intensive care needs huge resources that might not be available especially in areas that suffer from the low quality of health services [5]. Also, providing a service to differentiate between moderate cases and intensive cases should be with low cost for developing and especially for use [6].

This work will explore developing a cheap tool based on few data that can be collected at the early days of the pandemic. COVID-19 is an example of pandemic related to respiratory system but affects all body systems [7].

Many studies concentrated on detecting and clustering the cases based on images of lunges [8, 9, 10, 11]. Few papers give some interest to the levels of essential body parameters like hemoglobin, vitamins, and mineral levels as a tool to differentiate between categories of severe and light infections [2, 12, 13]. Most of these papers consider only one aspect to analyze and use as a tool of detection. Few papers discussed or proposed an intelligent tool to classify the infection degree [2, 14, 15]. No work discussed the computation cost of such tools and its validity to be applied in poor areas where health services might not be available.

In this work, the proposed solution can be applied based on the available resources, (Resources here means the availability of data and the availability of computing resources). Decision trees can be used in the case of availability of few cases with a good number of parameters, but it needs a suitable computing resource to be distributed over cloud or edge environments [16]. Another alternative is the shallow nets. Shallow nets do not need a big number of parameters and in many cases, it can achieve an accepted accuracy [17]. Based on experienced works in the pandemic domain, a suitable and limited number of parameters can be proposed to be used as the classification parameters. Providing such limited number of parameters might be expensive and cannot be provided in a suitable time [18]. So, getting a good sample of complete data to be analyzed using "reduction dimensionality tools" will help to reduce the number of parameters [19].

In this work, PCA and ROC curves will be used to determine the most important parameters. Also, the work will check the validity of training a shallow net on these limited set of parameters. The results ensure that training a shallow net on carefully reduced set of parameters will produce a light model that can differentiate between the patients' classes with a high suitable accuracy.

The remaining of this paper will continue as follows. Section II provides information regarding related works. The methods are explored in Section III. Detailed experiments and results are explored in Section IV. Finally, the whole paper is concluded in Section V.

## II. RELATED WORK

This part will explore studies made to detect COVID-19 using AI approaches and different studies based on the type of data. Some studies depended on X-Ray images, then studies that use a mix of X-Rays and other symptoms. Also, it will explore studies that either used an AI for purpose different from detecting COVID-19 or used a different type of data.

Finally, studies that tried to review works related to AI and COVID-19 will be reviewed.

Based on images for X-Rays, some papers proposed a method to predict and detect COVID-19. For example, Qayyum et al. proposed a new depth-wise dense network to compete the ordinary convolutional layers in detecting COVID-19 based on analyzing image of lungs x-rays for suspected cases [7]. Sharma et al. proposed a deep learning model for quick identification of COVID-19 infected patients based on chest X-ray images. They implemented a variety of methods for data augmentations [8]. Jin et al. proposed a deep convolutional neural network for quick COVID-19 detection [9]. Vaid et al. developed a deep learning model that consists mainly of convolutional neural networks to improve the accuracy of detecting and predicting COVID-19 cases based on chest X-ray scans [10]. Based on Chest CT, Harmon et al. applied a series of deep learning algorithms to classify patients with COVID-19 [11].

Since the X-Rays images do not provide a quick tool to detect COVID-19 early enough, some works tried to combine X-Rays images with additional data in one model for more efficient system. For example, Ming et al. developed a method to separate between patients with COVID-19 and healthy individuals depending on clinical and laboratory testing data and imagining data. They developed a deep learning model for feature extraction then fed these data to three machine learning models for the classification process [2]. Attaullah et al. proposed a method that depends on X-Rays images and labeled patients' symptoms for early detection of COVID-19. All features are fed to a deep learning model that can benefit from the characteristics of patients' symptoms in early detection of COVID-19 and X-rays images that can define the type of infection [12]. Depending on a combination of chest CT and clinical symptoms, exposure history and laboratory testing, Mei et al proposed an AI algorithm for quick and accurate diagnosis of cases with COVID-19.[13]. Mario et al. proposed a machine learning method to detect risk COVID-19. They used historical data that include medical history, demographic data, as well as COVID-19-related information. The aim of their work is to differentiate between recovered patients and mortalities [14].

Some works tried to explore problems other than detecting or classifying COVID-19 patients. Also, some works implemented non-ordinary data for classifying or detecting COVID-19 patients. For example, JAMSHIDI et al. proposed intelligent framework to help physicians and researchers in detecting and treating COVID-19. The framework depends on unstructured and structured data that are fed to three types of deep learning net to implement each different data type [20]. Laguarta et al. proposed a method that depends on Cough Recordings only. Based on cough recordings of biomarkers can be extracted and used to monitor the patient in real time mode to detect COVID-19 in low cost [21]. Nawaz et al. used artificial intelligence methods to analyze hidden pattern in COVID-19 genome and then used these patterns to evaluate the ability of predicting nucleotide base(s) from historical data. Also, they used AI to analyze the mutation possibilities in the structure of COVID-19 genome [22]. Based on patients' self-reported symptoms, Obeid et al. proposed convolutional neural network for predicting COVID-19. The algorithm was fed by unstructured patient data collected through telehealth visits to predict COVID-19 possible infection [23].

Since there are a plenty of works related to AI and COVID-19, many works presented a review for these works to define the main trends in these works and try to define the main factors that direct these studies and affect their results. For example, Ahmad et al. compared between methods for predication COVID-19 depending on decision tree properties, the method can predict COVID-19 cases although there is imbalance in data availability [24]. Vaishya et al. reviewed possible application of AI in COVID-19. The study aimed to define the important application and their possible usages in the future to deal with pandemic like COVID-19 more effectively. The study results show that there is a proper application for screening, analyzing, prediction and tracking of current patients and future patients [25]. Shi et al. focused on reviewing works done during COVID-19 pandemic focusing on the integration of AI with X-ray and CT. They reported COVID-19 research works in enhancing the available technologies in the field of image acquisition scanning and image protection methods. Some works provide means to increase the accuracy of segmentation diagnosis, and follow-up methods [26]. Swapnarekha et al. reviewed methods proposed on decision trees, SVM and neural networks as well as statistical and mathematical models for COVID-19 detection. The work analyzed the factors that affect the efficiency of the classification method like the classification method and the impact of COVID-19 on the nature of data. Also, they discussed important research directions on COVID-19 research [27]. Ilyas et al reviewed many works that tried to classify patients with COVID-19 based on chest x-rays. Basically, all studies tried to develop a method for automatic detection of COVID-19. Varieties of deep learning models were built to overcome the difficulty to decide if the pneumonia was caused by COVID-19 or another cause [28]. Albahri et al. performed a study to review the proper AI studies in the field of detecting and predicting COVID-19 infections. The study tried to propose a systematic model to evaluate AI techniques for COVID-19. The work revealed the importance of combining between multi approach in the classification process [29]. Murphy et al. evaluated AI system for detection of COVID-19 based on chest X-Raya images. Six experts evaluated each testing image and their evaluation compared to the results of the AI system. AI system could outperform the experts and achieved an area 0.8 under ROC curve [30]. Piccialli et al. discussed the role of AI in facing COVID-19 pandemic. The work shows that AI alone cannot be enough without human clinical skills to detect or predict COVID-19. However, AI approved that it could play a significant role in health emergency and complex scenario of such pandemic. [31].

Recently, algorithms based on the intelligent behavior of animals and insects have been adopted in research and classification methods, such as the behavior of bees in swarm optimization techniques for medical diseases detection [32, 33], which aims to predict and classify diseases.

Also, depending on the characteristics of cooperative birds, hawks, methods for searching for preys by field detection have been developed [34]. The bat's radar feature was also relied

upon to develop research methods that depend on the concept of echo as a basis for the research process [35].

Despite huge amount of works presented to tackle the COVID-19 pandemic, few works concentrated on studying the importance of reasonable use of resources in hospitals especially in poor areas in the world. This work presents a cheap and quick approach that can be built quickly on a well-chosen data set to develop a light model that consumes a little computation power and less data to differentiate between severe and light cases during pandemic. The proposed model enables the decision-maker stationed in the place of receiving infected cases to identify severely infected cases that need intensive care inside the hospital from those that can be sent home to complete treatment safely.

## III. METHOD

Fig. 1 explains the steps followed in this work. A shallow net consists of three dense layers was used to classify a number of samples. Also, a decision tree was built for the same purpose. The results reflect a huge gap between the accuracy of decision tree and shallow net. A cleaning and investigation process based on PCA and ROC curve determine which parameters have the main role in discrimination between recovered patients and mortalities. The shallow net was retrained using the principal components to show that a shallow net with suitable and carefully chosen parameters can

help effectively to separate early between patients who have light conditions and can easily recover with normal care and the severe patients' instances who need a special care.

A sample of 1000 recovered patients and 900 mortalities during 2020 from the records of patients in King Fasial hospital was retrieved to distill the data related to COVID-19. 53 parameters were collected according to data availability and doctors' recommendation for analysis. These data include information related to age, nationality, gender, blood analysis, minerals and vitamins levels. The main hypothesis in this study is to be able to differentiate between recover patients and mortalities based on a few numbers of samples. Also, with the aid of principal component analysis (PCA) and Receiver Operating Characteristic (ROC) curve a simple weak learner can be built to differentiate between recovered patients and mortalities. To this end a shallow net was designed as appears in Fig. 1. Also, a decision tree was built to support the shallow net. The decision tree was trained using only 10% of data to explore the validity of the data to be used in the case of availability of few samples especially in the beginning of the pandemic and the number of levels was tuned to be three.

All codes were written using python 3.10; however, ROC curve was implemented using SPSS. A specific code was written for the decision tree, PCA and the shallow net. All codes were run on a machine "11th Gen Intel(R) Core (TM) i7-1165G7 @ 2.80GHz 2.80 GHz" and 16.0 GB for RAM.

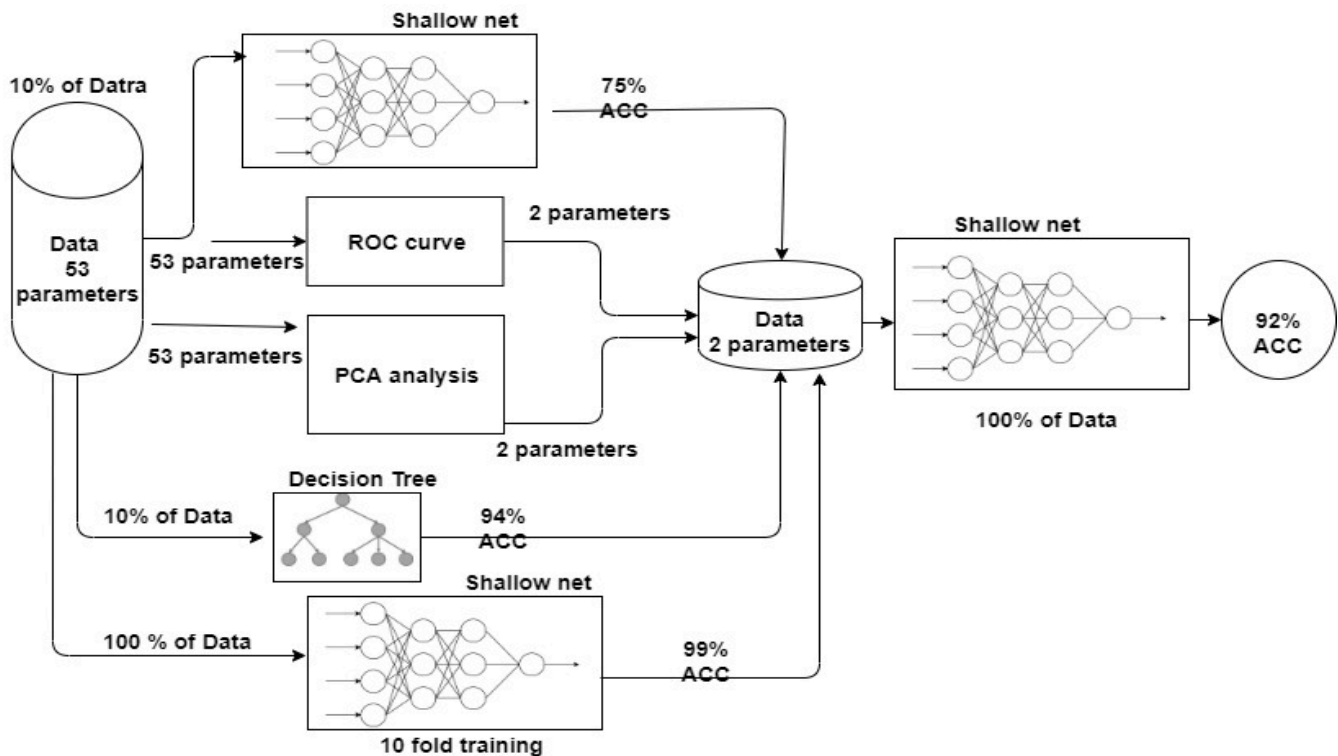

Fig. 1. Method Steps and Stages.

## IV. RESULT AND DISCUSSION

The 53 parameters are divided into sets. Demographic parameters include (sex, age and nationality), vitamin sets, minerals set, extra. ROC curve was produced for each group and any parameter with area curve under the reference line was excluded. This gradual process leads to filter all the 53 parameters into two parameters, namely, calcium and hemoglobin (HEMO).

Table I says that hemoglobin and Calcium has at least one tie between the positive actual state group and the negative actual state group. Also, the area under the curve of calcium is 0.963 and the area under the curve of hemoglobin is 0.938. This means that both calcium and hemoglobin have a high ability to discriminate between recovered patients and mortalities with Bayes to the calcium ability.

Fig. 2 shows the structure of the used shallow nets used in the experiments. The first net used the whole 53 parameters as inputs while the next net used only two parameters. Fig. 3 represents final ROC curve. ROC curve expects that based on only two parameters; the shallow net can achieve a compete performance using the whole parameters. This assumption has been proved in the following sections.

A piece of code was written using python 3.10 to perform the PCA analysis to explore the nature of the data classes and determine the number of principal components. Fig. 4 gives the simulated graph of PCA results. The results ensure that there is a separable two classes and the fact that there are two principal components. This ensures the conclusion that was expected in Fig. 2 through gradual manual reduction of parameters using ROC curve. A 10% of the shuffled data using NumPy shuffle function was kept for training a decision tree and a shallow dense net. The decision was tuned to three levels. The final accuracy of the decision tree is 94% on test data. This result was expected since it is known that decision tree gives the optimal results if it is used with separable classes as given based on the PCA analysis. The shallow dense net failed to give a near result. Fig. 5 gives a comparison between the decision tree and the shallow dense net based on 10% of Data.

Fig. 2. Shallow Net Model in the Case of 53 and 2 Parameters.

Fig. 3. Final ROC Curve.

TABLE I. AREA UNDER THE CURVE FOR HEMO, CALCIUM

| Test Result Variable(s) | Area | Std. Error[a] | Asymptotic Sig.[b] | Asymptotic 95% Confidence Interval | |
|---|---|---|---|---|---|
| | | | | Lower Bound | Upper Bound |
| HEMO | .938 | .006 | .000 | .927 | .949 |
| CALCIUM | .963 | .005 | .000 | .953 | .972 |

Accuracy and loss results of the shallow net using 10 % of data without folding

Results of implementing decision tree, final accuracy on test set is 94%
Fig. 5.    Implementation of Decision Tree and Shallow Net using 10% of Data.

The whole data was divided into 10 % for final testing and 90% for training. Using 90% of the data, a 10-fold training for the shallow net was done. In each fold the training data were divided into 10 % for validating and 90 % for training as appear in Fig. 6. Then re-trained the resulting model using the whole training data (90 % of the whole data). Following this technique, a 99% of accuracy was achieved. Fig. 7 shows the loss and accuracy when applying 10-fold method. Usually during the early pandemic days, it is not easy to provide such huge number of parameters to be tested. The results show that we can get a close result under suitable choosing of the parameters (two parameters in the case under consideration), which might be done based on the advice of doctors responsible for monitoring the pandemic and will lead to optimal trained model or under quick analysis of carefully selected sample data. Fig. 8 shows the 'accuracy and loss of the resulting model using only two parameters.

## V.    CONCLUSION

This paper addressed the need of a light model with fewer data to differentiate between moderate patients and severe cases so as to use the hospitals resources more reasonably. The work begins using a real, officially collected and reviewed data under the supervision of expert doctors to determine which are the most suitable set of parameters that can be used to differentiate between recovered patients and mortalities. The number of parameters were 53. This number is not huge for ordinary computation available on any prepared machine for deep learning training and the results that achieved using decision trees (94% of accuracy) or 10-fold training (99% of accuracy) ensures that the used parameters can effectively differentiate between recovered patients and mortalities. However, it is better to get a light model with very few parameters (two parameters in this work) and achieve a reasonable result. Using the results of ROC and PCA analysis, the shallow net trained using two parameters achieved 92% accuracy on testing data. So, using a few carefully chosen parameters and a light architecture of shallow net, a light model that needs a very limited computation resources can be built to differentiate between moderate and sever patients during the early days of pandemic like COVID-19.

# Advanced Medicinal Plant Classification and Bioactivity Identification based on Dense Net Architecture

Banita Pukhrambam, Dr. Arun Sahayadhas

Department of Computer Science and Engineering
Vels Institute of Science, Technology and Advanced Studies, Pallavaram, Chennai, 600117, India.

*Abstract*—**Plant species identification helps a wide range of stakeholders, including forestry services, botanists, taxonomists, physicians and pharmaceutical laboratories, endangered species organizations, the government, and the general public. As a result, there has been a spike in interest in developing automated plant species recognition systems. Using computer vision and deep learning approaches, this work proposes a fully automated system for finding medical plants. As a result, work is being done to classify the correct therapeutic plants based on their images. A training data set contains image data; this work uses the Indian Medicinal Plants, Photochemistry, and Therapeutics (IMPPAT) benchmark dataset. Convolutional Neural Network (CNN) with DenseNet algorithm is a classification system for medicinal plants that explains how they work and what they're efficient. This study also suggests a standard dataset for medicinal plants that can be found in various parts of Manipur, India's northwest coast state. On the IMPPAT dataset, the suggested DenseNet model has a recognition rate of 99.56% and on the Manipuri dataset; it has a recognition rate of 98.51%, suggesting that the DenseNet method is a promising technique for smart forestry.**

*Keywords—Indian medicinal plants; convolutional neural network; DenseNet; IMPPAT dataset*

## I. INTRODUCTION

In Siddha, Unani, Ayurveda, and homeopathic medicines, there are around 8,000 herbal cures. Herbal plants are used for medical purposes by nearly 75% of the migrant population, according to survey results [1]. Drugs are used to make herbal medicines in both developed and developing countries, and India's economic importance is taken into account. For accurate plant categorization, more taxonomic traits of a plant are collected from the images.

The most prevalent approach for classifying medicinal plants is by manual identification. To begin, people use their eyes, noses, hands, or other human organs to obtain information about the full plant or specific sections (leaf, flower, fruit, or bark) [2, 3]. They will identify therapeutic plant species based on either references or personal experience. However, the practice has shown that such an identification approach is time-consuming, inefficient, and strongly reliant on people's knowledge and subjective experience.

Computer-based automated image identification is now widely employed in practice, thanks to advancements in image processing and pattern recognition technologies. Because plant leaves are simple to gather, recognize, and catch, they are frequently employed as the primary foundation for identifying medicinal plants. To categorize medicinal plants and transmit their distinct medicinal purposes, this study employs a Convolutional Neural Network (CNN) with the DenseNet method.

## II. LITERATURE SURVEY

This section discusses the method of systematic literature review for research published in Automated Medicinal Plant Taxonomy. Researchers have explored a variety of methods to extract traits and automatically identify plant species. Many characteristics, such as color, form, texture aspects, and so on, are combined in most of these approaches [4-6]. To acquire the optimum discriminant characteristics for recognizing unique plant species, the Hybrid Feature Selection (HFS) technique is applied [7,8].To classify the leaves, the system in [9] employs to train the dataset, use decision trees, and variables such as lengths, breadth, aspect ratio, dimension, leaf boundary, and form of property are extracted from the leaves.

They introduced a new approach for categorizing plant leaves in [10, 11], which uses the Maximum Margin Criterion (MMC) to reduce the dimensionality and the Radial Base as new form storage. In [12-14], the researcher combined shape and textural features from leaf images to classify the medical plants. Researchers from India's Western Ghats reported on a computer vision approach for recognizing Ayurveda medicinal plant species in [15, 16]. Using the K-NN classification approach [17], a collection of SURF and HOG features were extracted from leaf pictures for identification.

Researchers [18-20] devised a CNN-based plant identification tool called CNN codes to collect bottleneck features. Finally, SVM was used to train these CNN codes for classification. D-Leaf, fine-tuned Alex Net, and pre-trained Alex Net are three different Convolutional Neural Network (CNN) approaches used to pre-process the leaf images and extract the properties [21, 22]. According to the analysis, identifying several traits such as form, vein, color, and texture would also have a substantial impact on the classifier's accuracy. Higher accuracy may affect the development of medicinal plant use in medicine, as well as the automatic detection identification number, which would have a significant impact on environmental conservation and

preservation. Therefore, this work uses Convolutional Neural Network (CNN) with DenseNet algorithm to classify the medicinal plants and convey their respective medicinal uses [23-24].

### III. PROPOSED METHODOLOGY

The proposed DenseNet Classifier-based medicinal plant classification system is discussed in this section. The suggested system's block diagram is shown in Fig. 1. For classifying medicinal plants, the suggested system has four stages: image acquisition, image pre-processing, segmentation, and classification.

#### A. Preprocessing Adaptive Vector Median Filter

This research work used a combination of an Adaptive Vector Median Filter and an average detection filter to reduce high-density impulse noise from feature extraction. A windscreen is used to process a W (5x5) image that has been influenced by noise sources. Using the non-causal region, the non-causal linear forecasting error for the pixel in question will be computed initially. Let Ix be the pixel undergoing operation, y be the related non-causal area, and W (5x5) be the non-causal region. The pixel window of W $_{(5x5)}$ is calculated using equation (1).

$$W_{(5 \times 5)} = P(a, b), x - 2 \leq a \leq x + 2, y - 2 \leq b \leq y + 2 \quad (1)$$

Where $I(a, b)$ = Processing region of inside pixel.

$$I(a, b) = [I(a, b) R, I(a, b)G, I(a, b) B] \quad (2)$$

The R, G, and B channels make up each pixel in a color image. A substantial correlation exists between pixels in the two-dimensional surroundings. The current pixel value is calculated using this method as a weighted linear combination of the adjacent noise clean pixels. As an outcome, the particles' unity may be lost when aggressive input affects an image. The workflow for preprocessing is shown in Fig. 2.

Fig. 1. Block Diagram of Proposed System.

Fig. 2. Flow Chart of Pre-Processing.

#### B. Segmentation –Fuzzy C Means Clustering

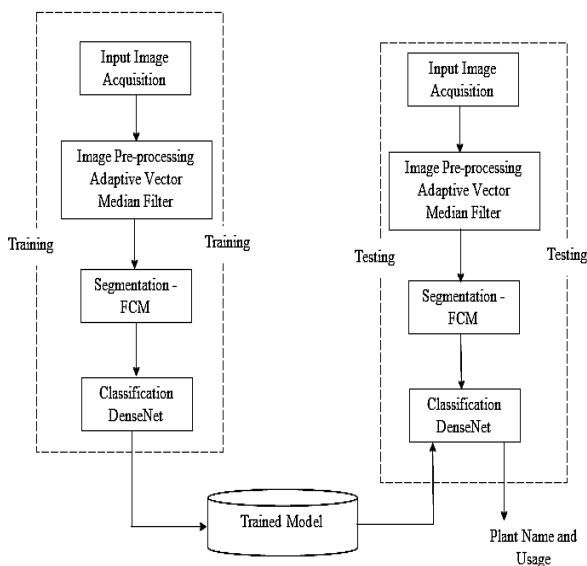
In image processing, fuzzy C – Means clustering has proven to be a very useful strategy for segmenting elements in an image. Unlike other clustering techniques such as k-means segmentation that requires particles to belong to only one classification, FCM permits pixels to belong to several clusters with various class labels. The Fuzzy C - Means (FCM) algorithm is a widely used fuzzy inference approach. It's based on Ruspini's fuzzy partitioning technique; therefore fuzzy c- space for X is discussed below.

For clustering, the Fuzzy C-Means (FCM) algorithm is commonly used. The FCM algorithm's performance is determined by the initial centroids and/or the initial membership value. If a better initial pinpoint the exact that is close to the actual final data point can be found, the FCM algorithm will converge very quickly, reducing processing time significantly. K-means is one of the most basic unsupervised learning algorithms for dealing with the well-known clustering problem. The procedure follows a simple and easy method for classifying a given data set using a fixed number of clusters (assume k clusters). The central concept is to define k centroids, one for each cluster. These centroids should be housed cleverly.

$$M_{fcm} = \{U \in U_{Cn}: u_k \in [0,1]\} \quad (3)$$

$$\sum_{i=1}^{\in} u_{ik} = 1, 0 < \sum_{k-1}^{n} u_{ik} < n\} \quad (4)$$

Where

$U_{cn}$ = real c*n matrices c = integer Value with the range of 2<c<n.


$x_k$(k=1,........n) = vector in $R^p$, $u_{ik}$ = membership value for k in cluster i(i = 1, .....,c)

The primary purpose of FCM analysis is to find the best fuzzy c-partition and prototype while keeping the feature subset to a minimum.

$$J_m(U,V;X) = \sum_{k=1}^{n}\sum_{i=1}^{c}(u_{ik})^m |X_k - V_i|^2 \qquad (5)$$

Where

V = cluster center ($v_1$, $v_2$, .........,$v_c$) $V_i \in R^P$, $||.||$ = Norm of Euclidean

m = Exponent of weighting [1,∞).

The FCM algorithm is a fuzzy constraint minimization technique that uses alternating minimization to minimize the criterion Jm. Choose a value for c, m, and a tiny positive variable; use a clustering $U_0$ with t=0 as the iteration number in random design. The FCM algorithm is a fuzzy constraint minimization approach that minimizes the criteria $J_m$ using minimization that alternates. Choose a value for c, m, and a tiny positive variable, then construct a clustering $U_0$ at random using t=0 as the number of iterations. It's a two-step incremental method; approach is illustrated in the diagram below. The U $^{(t)}$ i (i=1, c) method is used to determine the membership values.

$$V_i^{(t)} = \frac{\sum_{k-1}^{n}(u_{ik}^{(t)})^m X_k}{\sum_{k-1}^{n} u_{ik}^{(t)})^m} \qquad (6)$$

Given the new cluster centers $V_i^{(t)}$ update membership values $u_{ik}^{(t)}$

$$u_{it}^{(t+1)} = [\sum_{j=1}^{c}(\frac{|x_k-v_i^{(t)}|^2}{|x_k-v_i^{(t)}|^2})^{\frac{1}{m-1}}] \qquad (7)$$

The | U $^{(t+1)}$-U $^{(t)}$| is the difference of Gaussians Pyramid. By deleting a low pass filtered copy first, the image's pixel-to-pixel correlation is decreased. The variance and entropy of the difference or error image are low, and the low pass filtered image can be described with a lower sample density. When you cycle the procedure at large enough scales, you have a pyramid data structure. Assume that I represent the original image and J represents the applied low pass filter. The method ends when the specified number of repeats is reached. The term "Laplacian Pyramid" is misleading because each level (i.e., image) is created by smoothing with two Gaussians of different sizes, then deleting and subsampling.

### C. Convolutional Neural Network with DenseNet Classifier

Deep Learning (DL) is proposed because approaches can learn substantial characteristics from input images at multiple convolutional levels, which is comparable to how the real brains functions, this is the most prevalent architecture. DL can tackle complex issues successfully and quickly, thanks to its high classification accuracy and low error rate. The composed view of DenseNet architecture is shown in Fig. 3.

The convolutional layer, pooling layer, fully connected layer and activation functions are the essential components in the DL model. In this study, CNN was combined with the DenseNet Classification approach to acknowledge plants. The

vanishing gradient problem induced by network depth is likewise addressed by this network. The connection designs of all layers are employed to ensure that the maximum amount of information may travel across levels. Each layer gets input from the layers above it and communicates its feature maps to the layers below it in this configuration. By concatenating the local characteristics at each layer, information is transmitted from one level to the next. This network architecture minimizes the need to remember redundant data, reducing the number of parameters to learn significantly (i.e., parameter efficiency).

DenseNet121 does not suffer from generalizing and performed admirably for categories with a little training data set. In this work, Dense Net was used, and Fig. 4 shows a compressed version of it. DenseNet alternates dense and transition blocks with fully-connected layers and a nonlinear activation classifier. So based on this BN layer, Convolutional Layer (Conv) and leaking rectified linear unit layers are merged with the cascaded format in a dense block such as BN-Conv-LReLU.

The first BN-Conv-LReLU is generating 4r output features using 1x1 kernels, where r is a pre-defined value of 32 in this work. The dense block increases the number of maps by connecting output feature maps to the ability to segment. During the transition, a convolutional unit is used, followed by average max pooling with a pool size of 2x2. The transition construction's goal is to find the best combination of extracted characteristics produced by a large number of convolutional layers while saving time and money. The number of output feature maps in the transition block in this exercise is equal to the number of input nodes.

Fig. 3. Composed View of Dense Net Architecture.

Table I shows the DenseNet structure and output, assuming that the input images are 128x128 and the input image size is 128x128, respectively. The algorithm uses the Indian Medicinal Plants, Phytochemistry, and Therapeutics (IMPPAT) benchmark dataset to classify medicinal plants, and it also has a dataset from the Manipuri district.

## IV. RESULT AND DISCUSSION

The proposed medicinal plant classification system's implementation results and performance analysis are discussed in this section. Table II contains information about the dataset utilized in this study.

The simulation result of training and validation accuracy and Training and Validation Loss of proposed CNN with DenseNet classifier is shown in Fig. 5 and Fig. 6. By using CNN DenseNet the training and validation accuracy is 99.45% and 99.26% against IMPPAT Dataset. By using CNN DenseNet with IMPPAT dataset the training and validation loss is 0.05MSE and 0.065MSE. By using CNN DenseNet the training and validation accuracy is 99.68% and 99.41% against own dataset. By using CNN DenseNet with its own dataset the training and validation loss is 0.041MSE and 0.052MSE.

TABLE II. DATASET DETAILS

## A. Performance Analysis

The classifier's performance is assessed by different statistical measurements, such as sensitivity, specificity, accuracy and F1-score. Table III shows the comparing the suggested CNN-DenseNet Classifier-based medical plant classification with existing approaches in terms of total classification ratio analysis. CNN-DenseNet gives good results compared with conventional methods. The sensitivity, specificity, accuracy, and F1-score of CNN-DenseNet against the IMPPAT dataset are 99.25%, 99.56%, 99.78%, and 0.61. The sensitivity, specificity, accuracy, and F1-score of CNN-DenseNet against own dataset is 98.12%, 97.56%, 98.01%, and 1.25.

TABLE III.     PERFORMANCE ANALYSIS OF CLASSIFICATION

| Methods | | Classification Sensitivity (%) | Classification Specificity (%) | Classification Accuracy (%) | F-Measure (%) |
|---|---|---|---|---|---|
| SVM | | 89.46 | 91.23 | 89.49 | 15.03 |
| SVM-PCA | | 90.06 | 91.56 | 89.11 | 12.06 |

| CNN-Google Net | | 98.16 | 98.08 | 98.26 | 2.65 |
| CNN-DenseNet | IMPPAT Dataset | 99.25 | 99.56 | 99.78 | 0.61 |
| | Own Dataset | 98.12 | 97.56 | 98.01 | 1.25 |

## B. Real Time Experimental Evaluation

This section discusses the working function of real time medical plant recognition using Mat-lab with webcam of proposed CNN-DenseNet Method.

The Real Time Experimental Evaluation of the proposed CNN-DenseNet Method-based medical leaf identification system is shown in Fig. 7. By using the CNN-DenseNet Method, the medical plants are identified and also suggest the bioactivity of that particular plant. In Fig. 7 the identified leaf name is a Gale of Wind and it's widely used to clear jaundice.

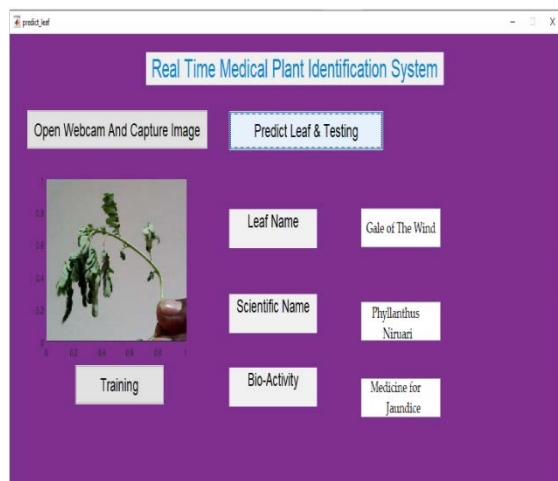

Fig. 7. Real Time Experimental Evaluation.

## V. CONCLUSION

A unique deep learning-based technique for automatically identifying and detecting medicinal plants and their applications was examined in this study. The Indian Medicinal Plants, Phytochemistry, and Therapeutics (IMPPAT) benchmark dataset were used in this study and used its dataset, which is common in Manipuri, a state on India's northeastern coast. From gathering the images required for training and validation to data preprocessing and segmentation, and eventually training and perfectly alright the deep CNN-DenseNet, the entire method was covered. The performance of the newly designed model was evaluated through a series of experiments. CNN-DenseNet has 99.25% sensitivity, 99.56% specificity, 99.78% accuracy, and 0.61 percent F1-score against the IMPPAT dataset. CNN-DenseNet's sensitivity, specificity, accuracy and F1-score against the own dataset are 98.12%, 97.56%, 98.01%, and 1.25%, respectively. The challenge of recognizing medicinal plant species was also solved in this study by analyzing leaf photos taken straight from their habitat, regardless of lighting conditions. We intend to build and develop a system that automatically recognizes plant species by analyzing not just leaf photos but also images of other sections of the plant taken directly in their environment, regardless of complicated backdrops or lighting conditions.

## VI. FUTURE WORK

A deep learning based detection approach is proposed in future work to recognize and classify the different types of plant actions. Future capturing the abnormal leaf image that contains activation of different leaf and finding specific part of area with more improved efficiency (per-packet classifications) and accuracy of these detections.

*Abstract*—**Writer identification is the domain of documents image analysis which is popularly sound in many applications like banking, academic professional in Optical Character Recognition (OCR) Signature verification remains one of the most important entities to authenticate document in these applications. In view of technical breakthrough, we have focused on short words signatures which are very hard to verify as they raise issues of ambiguities. From the geometrical studies of signature-based images, it is stated that the morphology of directional transformations (MDT) is right to extract the suitable features in case of short words for writer identification. MDT takes the data in the form of Structure Element (SE). The directional morphological structures (DMS) of SE are used as a key factor for performing morphological operations on the signature images. We have adopted Markov chains and Fisher Linear Discriminant (FLD) for computing the gradients from line features corresponding to the word. Neural network is used to evaluate the proposed model. In case of training and testing of the signature, images of short words leave-one-out are followed. Our purposed model is tested on NIST database for extracting the words length with three letters. It is observed that a very simple architecture of neural network achieved 100% satisfactory results using short words.**

## I. Introduction

The document in digital world can be authenticated from unique and confidential mark referred as signature. For developing an automated hand signature based authentication system, the researchers have supported at large scale to several real life applications used in banking, academic and defense. Their main objective is that the documents are kept safe from illegal access and forgery. From a decade, it is observed that many cases of forensic and legal research paid serious attention to develop an automated signature verification system. The research of hand written signature matches with the problem of Optical Character Recognition (OCR), which is a broad area of computer vision and image processing domains. In OCR, the algorithms used for signature verifications follow the segmentation of signatures into characters, then by formatting the characters, it finds the word with highest matching score. For the developing system of writer verification, both signatures and handwritten text are used as complimentary components. From the mechanism of the information collected from the users, the verification system can be categoried as static and dynamic. When, text used for authentication is extracted from any document, it is referred to as static signature verification whereas, in dynamic verification the users' information is collected with help of electronic devices like sensing tip-pressure, pen-based computer screening etc. Dynamic signature verification requires more processing efforts as compared to static signature verification. Dynamic verification considers the complex information like neurological health and real-time circumstances when signature is collected. Chaabouni et al. (2011) also observed that more reliability and robustness can be added in signature verification with dynamic approach [1].

The research of writer identification is the main motive behind the task of signature verification. In image processing literature, every object may have important pattern to characterize the feature of the objects. The pattern recognition recommended several sets of algorithms which can support to avoid the complex process of dynamic verification. But reliability remains a challenging issue with all pattern recognition based static approaches since document is generally affected due to its chemical dating process which badly impacts the static signature verification system. Lorigo et al. (2006) [2] also mentioned important significances by designing various pattern recognition based verification systems. All the approaches focused on the basics presented in [11] for developing a better pattern recognition system. Further, Wu et al. (2014) [3] performed experiments in offline mode with text-independent approach. They experimented three major languages, English, Arabic and Chinese. Another approach presented by Newell et al. (2014) [4] utilized basic image features which are referred to Oriented Basic Image

Feature Columns (OBIF) for developing a writer identification system.

The remaining structure of the papers is as follows: Section II illustrates the descriptive analysis of recent state-of-the-art on signature verification. Section III represents the proposed mythology of short signature verification model. The dataset along with experimental settings is presented in Section IV. After giving a detailed insight on result and discussion, the Section IV concludes the signature verification system with the future recommendation.

## II. RELATED WORK

Signature verification can be considered as a collective project of different schemes of optical character recognition. Every character in a particular signature preserves the unique identity of the users. Detecting such a unique identity of every individual user for the authentication of a digital verification system is quite a tedious task. For the sake of convenience, the morphological studies of short signature can utilized to verify the user. Kumar et al. (2014) [5] proposed a writer authentication system referred as graphemes which extracts the documents' features using wavelet and Fourier descriptors. Taking the advantages of morphological features, Zois et al. (2000) [7] derived the feature vector from the horizontal profile of the projection from the given signature images. The developed projection function can easily match the signature image verification. Online text-independent scheme for signature verification ensured more advantages against offline system. Zhang et al. (2016) [8] proposed an end-to-end framework which verifies the users in text-independent online mode. They used recurrent neural network (RNN) for matching the short words in signature image. Looking towards avoiding the overhead in online mode, Wu et al. (2014) [9] followed offline text-independent scheme for writer verification. They mainly focused on handcrafted Scale Invariant Feature Transform (SIFT) and final outcome goes through training, registration and identification of signature images. In both the cases, offline and online schemes, neural network and machine learning algorithms play a very important role. Kumar et al. (2019) [12] presented a detailed state-of-the-art neural networks with deep learning methodology. According to Lippmann et al. [13], the author discussed the significance of optimal transformations and emphasized on the consideration for the advancement of control structure of data items which reduce the signature image quite hard to process.

In the early stage of authentication system, offline signature verification has been quite popular in several departments of academic and administration [17]. At that time, classical feature extraction methods have produced satisfactory results [18, 15]. But for matching the recently raised issues, automated feature learning is incorporated with deep network architectures [6]. Among all, deep network, the convolution neural network (CNN) remains a buzz technology. In [19], Day et al. developed a loosed Siamese Convolution Network (SCN) which follows the contraction of signature images for user verification. Following deep learning as an agent of higher performance, Shariatmadari et al. [20] proposed a hierarchical CNN easily capable to extract the signature patches from the given images. In same direction of research, hybrid CNN with

two-channel is presented in [21] which produced satisfactory performance in offline signature verification. Image surface-based deep learning methods are referred to as region based signature verification algorithms [22]. For real-time signature verification system, a human neurology based motor signature model is developed [23]. The motor signature CBCapsNet model works on capsule based CNN for offline signature verification [24]. Another Graph based CNN (GCNN) improved the task coevolution kernel for signature verification [25].

The concept of short length words with machine learning addressed the issues discussed in the literature. In our proposed writer verification system, the feature elements are the transition matrix of Markov chains. These features mark the alternation of the morphological directional transformation (MDT) from the line features and accordingly the gradient updates along with the image of the word. The neural structure of signature images helps in accessing the separability of the clusters which are designed on high dimensional space. In case of deciding the regions formation, a theoretical insight is presented based on the limitation of perceptron. The input layers of perceptron draw the linear (N-1)-D subspaces from the feature space of N-D dimension. In the base work presented by Stanley et al. (2007) [14] NIST Special Database is used for 19 features components. The noticed gap of the research is highlighted in extracting few short words like "the" or "end" for test training a very simple neural network. Another side, for developing a digital signature verification system security issues can motivate the researchers extend at higher state-of-the-art [16].

## III. PROPOSED METHODOLOGY

The proposed writer verification system follows the short signature images. In testing the proposed model NIST database is used for extracting these words where total ten writers are allocated as source of data collection. In this dataset, the signature of unknown person is also considered and classified according to the person belonging to the group of signatures. The methodology is slightly irrelevant of the literature used and followed in baseline of research. The following steps are considered while designing and developing the proposed signature verification model: 1) Preprocess steps of the signature images of the short word capture from unknown person, 2) The step of thresholding to isolate the short words from the background, 3) Extract the orientation features by means of MDT. The descriptive short words signature verification algorithm can be pointed as follows-

- Develop a feature descriptor by updating orientation with Markov chain. The feature vector is generated from the components used in transition matrix. Fisher Linear Discriminant (FLD) approach encourages reducing the dimension of signature image.

- The capability of cluster separability is enhanced by simplest neural architecture in the predetermined feature space. The performance is enhanced when morphological transformation is applied at different lengths of line segments.

- The feature space is characterized to the clusters separability with architecture of neural network.

### A. NIST Database-19(SD-19)

The NIST database is generated from the thousands of writers with repeating single text only once. SD19 is the updated web released NIST special dataset. SD19 consists of binary images of 3669 (ref. Fig. 1) samples of handwriting forms (HSF). The text page consists of the hand printed digits and alphanumeric characters. The detailed information of text is explained for characteristic of signature images by Stanley et al. (2007) [14]. HSF from NIST-SD-19, special database provide an opportunity to discriminate the text with short length coming very frequently from the different writers. This helps in generating cluster of the words appearing many times from each writer.

Specially noted from Fig. 1, the text word 'the' is repeated six times and the text word 'and' is repeated three times. In case large number of writers, the verification with short words is expected suitable to develop a robust system.

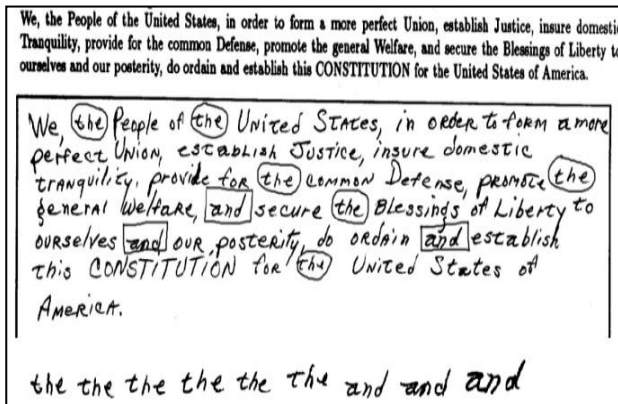

Fig. 1. Six Replicas of the Word "the" and Three for the Word "and" have been Extracted to Uniquely Represent the Specific Writer.

### B. Directional Morphological Transformations

The task of preprocessing targets the isolation of the text word taken from HSF form. For preserving the important information, the background image of text and directional features are transformed into thin line. The results of preprocessing steps performed on short word are shown in Fig. 2.

Fig. 2. The Thresholding of Word Image after Applying the Negative and Line-thinning Operations.

The approach of applying MDT on processed short word included generating the negative of the word image. On the black background of word image, the thinning operation is performed using morphological operations. This helps in maintaining the strong line features of the word. Fig. 2 refers to the thinned image after applying MDT with structure element

(SE). In this way, the feature localization of dominating directionality is achieved to perform easiest clustering. Fig. 3 shows the directional structure elements of length three. The fitting of SEs on any part of the line image indicates that the image is oriented towards the SE. The measures of fitness function of SE on line image are determined by morphological operation called opening [6]. During the process of opening, fitting of SE on line image also measures the originality of the line image. Fig. 4 demonstrates the impact of fitting SE with length three on vertical line image, contains the text letter 'h'.

Fig. 3. Directional Morphological Structuring Elements with Length 3 Pixels, from Left to Right: Vertical, Horizontal, 45 Degrees, and 135 Degrees.

Fig. 4. Processing of the Letter 'h' in the Word 'the' with Morphological Opening using a Vertical Directional Structuring Element of Length 3.

In detail, morphological operation 'opening' is responsible for the directionality of line image in each location the specific word. Here in our experiment the word 'the' is chosen from HSF form. Fig. 4 shows the pixel by pixel scanning from left to right. As shown in Fig. 3, each strip follows the opening operation separately with each of the four given directional SEs. The operation of opening is adopted as a margin by adding the one line of pixels around the strip. The selection of best SEs is determined by the strip which remains unaffected after applying operation with majority of pixels on word image. The set of SEs determines the specific strip responsible for signature verification. The best fit of SEs can be determined in alternation from the stochastic process of Markov model. In this way, Markov model enables the selection of SEs and strips for better designing for signature verification.

Fig. 3 represents the sequence of 4 best fitting SEs on line image. The sequence of four SEs adopts morphological operation on word image 'the'. Fig. 5 presents the line image of word 'the' along with its best sequence of the fitting with directional SEs. Each number of the sequence corresponds to structuring elements, e.g., zero corresponds to the blank space.
Fig. 5. The Word 'the' in the Image 'f0000_1_1.tif' from the NIST SD-19 and the Related Sequence Directed SEs of Figure 3, which fits along the Word.

First order Markov Chain models (FMCs) are used to generate feature vector for writer identification. The various orientations of SEs are governed by alternation with FMCs to the best fit of specific location of word in line image. The different states in Markov chain map the oriented SEs following the property of probabilistic states. That means (ref. Equation-1), every previous strip determines state of SEs in the following strips.

$$Pr\big(r_j(k)|r_j(k-1), r_m(k-2), \dots, r_n(1)\big) = Pr\big(r_i(k)|r_j(k-1)\big) = t\left(\frac{i}{j}\right) \tag{1}$$

Where the subscript $r_n$ stands for the various oriented states of the SEs. In this work, the oriented states take five values from 0 to 4 and k is spatial variable corresponding to the movement performed around the word image. State 0 refers to blank space or SE does not present in that state. Fig. 5 shows all possible sequence the oriented SEs of word image 'the' from SD19 database. It is informative to note that absences of SEs indicate the blank which means the gap is between the two words. As represented by Equation-2, the matrix T allocates the all possible probabilities t (i/j) making a square matrix referred as the transition matrix T. The $i^{th}$ row of the transition matrix T assigns each of the previous states to $j^{th}$ column of the next state. The specific probability value in transition matrix T verifies the signatures.

The transition T allocates the second order statistics of oriented SEs. From the experiments performed, it is observed that the feature vector writer identification follows Equation-3, which transforms the transition matrix into one Dimensional vector v of length 25.

$$T = \begin{pmatrix} t_{11} & \cdots & t_{51} \\ \vdots & \ddots & \vdots \\ t_{51} & \cdots & t_{55} \end{pmatrix} \xrightarrow{rd} \begin{pmatrix} t_{11} \\ t_{12} \\ \vdots \\ t_{15} \\ t_{51} \\ \vdots \\ t_{55} \end{pmatrix} \xrightarrow{rd} \vec{v} = \begin{pmatrix} v_1 \\ \vdots \\ \vdots \\ \vdots \\ v_{25} \end{pmatrix} \tag{2}$$

The dimensionality reduction is achieved by performing a linear transformation W. Here we used Fisher Liner Discriminant (FLD) transformation for accomplishing the task of dimensionality reduction. The vector space generated $w_i$ vectors generate a new spaces in which every vector 25-dimensinal.

$$Y_i = W^t v_i \tag{3}$$

Where each vector $y_i$ is transformed into $v_i$. The transformed function $J(w)$ (ref. Equation-4) is maximized with the concept presented in [10] which helps for separating all the clusters.

$$J(w) = \frac{w^t S_B w}{w^t S_W w} \tag{4}$$

The Eigen vales solution of transformed vector spaces of W follows Equation-5.

$$S_B W_i = \lambda_i S_w w_i \tag{5}$$

where, $S_W$ is referred as the Within-Scatter-Matrix(WSM) and $S_B$ the Between-Scatter-Matrix(BSM). From the solutions of Eigen value problems, the most important concept is the significance of the largest eigenvalue. It means the sum of the first two largest eigenvalues can indicates the cluster separability among the reduced 2-D feature matrix. Therefore, the capabilities of clustering of the directional SEs with length three and five are useful to demonstrate short words 'the' and 'and' in SD19 dataset. The combination of these SEs gives a 50-D feature vector correspondence to the largest eigenvalue. For the word 'the' Table I show sequences of Eigen values.

The information of separability of words gives the square root of the relevant eigenvalue. It is observed that approximately, 65% of the information for cluster separability is determined by three directions related to the first three largest eigenvalues. Fig. 6 presents the difference among the clusters generated against ten writers. It is clearly noticed that all the clusters are separable. But we target to three largest eigenvalues. The remaining Eigen values can be utilized to support the separability. Fig. 6(a) and Fig. 6(b) demonstrate the objectives of ten clusters summarized in three most suitable directions. All the available inputs of separability information to the neural network enhance the higher separability performance with short words.

TABLE I. TEN LARGEST EIGEN VALUES CORRESPONDING TO MOST PROMINENT DIRECTIONS OF CLUSTER SUPERAGILITY IN 5-D FEATURE SPACE FOR THE WORD PERCEPTRONS

| $\lambda$ | 363 | 121 | 47 | 32 | 14 | 11 | 7 | 5 | 4 | 1 |
|---|---|---|---|---|---|---|---|---|---|---|
| Sqrt($\lambda$) | 19 | 11 | 6.8 | 5.6 | 3.7 | 3.3 | 2.6 | 2.2 | 2 | 1 |

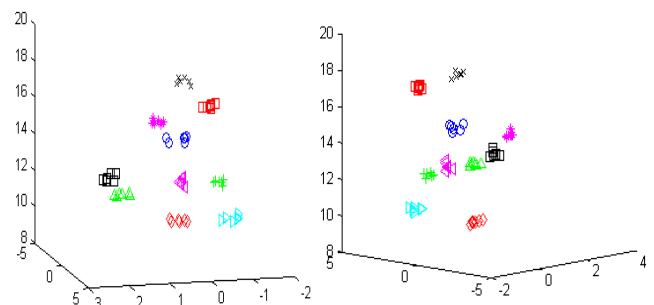

Fig. 6. Two different Aspects of the same 3-D Feature Space are given in (a) and (b).

## C. Space Seperability

The limitation of classical multilayer Neural Networks (NNs) has been addressed by Lipmann et al. [11]. In their work, the following things can be summarized as key points:

- The first layer of perceptron considers the linear subspaces of (N-1)D dimensional from that of N-D dimensional feature space.

- The upper layers second and third target to create convex and non-convex decision regions from the original surface by combining all the linear subspace of the above layers.

The simplest neural structure is supposed to be more suitable to separate the feature space by separating the populations of clusters. The same concept is explained in Fig. 6. More clearly to understand this concept of separability, the subfigure of Fig. 7 gives a suitable example. Fig. 7(a) shows the requirement of one linear subspace while two different populations are separated, whereas four populations require two subspaces (ref. Fig. 7(b)). In Fig. 7(c), it is shown that there subspaces divide the 2D feature space into seven regions.

From this study, it is a very basic question to ask how many separable regions can be generated from a given n-dimensional feature space. It can be answered that by considering a region A with n dimensions in which m hyperplanes with n-1 dimensions can occupy the normal position. Then the separated regions r(A) can be determined accordingly the Equation-6.

$$r(A) = 1 + \binom{m}{1} + \binom{m}{2} + \cdots + \binom{m}{k} + \cdots + \binom{m}{n} \qquad (6)$$

For understanding the concept of separability of region, it is clear that (n-1)-D subspaces are needed to separate ten populations. According to this inference, Fig. 6 should have more than three subspaces for generating ten separated regions. But, this is not a valid inference in case the structure combines the (n-1) D linear subspaces which are generated from the first layer of the perceptron.

The same concept is presented in Fig. 6 that the clusters having best separability in 2D space follow Fisher Linear Discriminant as given in Equation 5. The Fig. 8 shows the position of cluster which are separated by two dimensional subspace. The population is separated by utilizing only two layers in which three and four perceptron are used (ref. Fig. 9). It is clear that shape of the clusters reduce the linear subspace into curved shape for separating the population. The writer separability is nicely visualized in Fig. 8.

Fig. 7. Maximum Number of Separable Regions in a 2-D Feature Space. (a) Two Regions are Defined with One Linear Subspace. (b) Four Regions are Defined with Two Linear Subspaces. (c) Seven Regions are Defined with Three Subspaces in General Position.

Fig. 8. The 2-D Space Representation with Maximum Separability Received by Applying FLD.

Fig. 9. The Separated Feature of Fig. 8, after Applying Simple Neural Network Architecture with Two-layer Containing 3 and 4 Perceptrons.

## IV. RESULT AND DISCUSSION

In our experimental set up, the classification of the signature verification is performed with very simple neural networks. Two words 'and' and 'the' with the three unit length of SE from NIST DB19 database are considered for the experiments of signature verification. Another set of experiments are performed on the word 'the' with joint of SEs with length of three and five units. Following data statistics were used for performing the experiments to discriminate the writers based on short signature.

- Total ten writers are selected from NIST DB19 database. Each of writers generates the words 'and' and 'the' three and five times separately.

- DMT is applied on SEs of length of three and five units to generate a 25-D feature word vector. It helps to test classification separability.

- The vector generated the SEs length of three and five units which are merged to perform writer identification only with one 50-dimensional vector.

- The generalization and clarification capabilities are tested using classical neural network by training from 50-D vectors with leave-one-out method.

*1) Classification with word 'and':* In case of simple classification with word 'and', total ten clusters are generated in which each vector is 25-D belonging to feature space. According to the appearance of the word 'the' in NIST database, the strength of cluster is decided. In our experiments, 'the' appears six times so, each cluster contains six members. The training of neural network follows the complicated neural architecture of the perceptions. We extend the set of experiments by adding more layers and neurons in each layer. The selecting strategy of the clusters out of ten members depends on the training of neural network. Therefore, 5five members from the clusters are used for training. In second and third layers, 3-4 neurons are considered suitable to separate the ten clusters. From the training and testing results, it is observed that clusters correctly classified are excluded from this network. It excluded the specific members from the clusters with random frames.

*2) Classification with word 'the' and SEL-3:* In case of classification of the word 'the', proposed model produced similar results to discriminate the writers. Accordingly three times appearance of the word 'and', each of ten clusters maintains the word 'and' 3 times. The structure of this network also follows two-layer architecture with three and four neurons respectively. All the excluded clusters are classified with leave-one-out method from the trained neural structure.

*3) Classification with word 'the' and SEL-5:* In this network model, each of the ten clusters is generated with six members with the word 'the'. Each of the word is dynamically replaced since the new information is added using DMT on SEs with 5 unit length. Ten writers corresponding to 10 clusters are separated by using two-layer architecture of three and four neurons respectively. In this case also, the satisfactory performance is achieved by leave-one-out method.

## V. CONCLUSION AND FUTURE RECOMMEDATIONS

The research problem of signature verification requires developing an authentication system for making digital media safe and secured. In this paper, we proposed the solution of signature verification based on the information contained in short text of signature. More specifically, the concept of short signature is attributed to that particular person for asking simply key letter of the signature. Proper matching of lowest features extracted from the short signature suits better to train with simple architecture of neural network. Before the classification process, morphological transformation is applied on the lines of the short word. Markov chain model is adopted for the alternation of the directional information of short signature. Fitting all the directional structuring elements provide normalized information to analyze the performance of signature verification. The feature space generated from the elements of transition matrices of Markov model is the outcome of fitting directional structuring elements. For resolving the issue with high dimensionality features Fisher Linear Discriminant is ensured to provide suitable insights in reducing the dimension. It results in better separability of short words verification.

We also achieved the significant improvement on the separated writers' clusters. This proposed network of ten user writers is very simple with two layers consisting of three and four perceptrons for developing signature verification system. Dimensionality issues can be entertained as sounding future recommendation to deal with the problem of large samples collected from the users of different ethnicity. There is another side open for tackling the problem of neurological conditions in dynamic signature verification.

# Face Mask Wear Detection by using Facial Recognition System for Entrance Authorization

Munirah Ahmad Azraai[1], Ridhwan Rani[2], Raja Mariatul Qibtiah[3], Hidayah Samian[4]

Faculty of Technical and Vocational Education, Universiti Tun Hussein Onn, Parit Raja, Johor, Malaysia[1, 2, 4]

Department of Electric and Electronic, German Malaysian Institute, Kajang Selangor, Malaysia[3]

*Abstract*—A Face Mask Wear Detection Device for Entrance Authorization is designed to ensure that everyone wears a face mask at all times in a confined space. It is one of the easiest methods to lower the rate of coronavirus infection and hence save lives. Asthma, high blood pressure, heart failure, and many other chronic conditions can be fatal to those who are infected by the novel Coronavirus (nCoV-21). Consequently, the goal of this research is for face mask wear detection devices that help to reduce the rate of Novel Coronavirus infection on-premises or in public places by ensuring that customers comply with Standard Handling Procedures (SOP) set by the Ministry of Malaysian Health (MOH). Customers' faces are recognized by this device whether or not they are covered by a face mask upon entry into a facility. Additionally, the use of this device can contribute to ensuring compliance with the maximum number of customers allowed on the premises. A facial recognition system is the goal of this study that uses technology designed as an individual disciplinary aid and follows the safety procedure at this critical time. This research was developed using the engineering design process development model which has four phases namely; identifying the problem, making possible solutions, prototype development and testing and evaluating the solution. Results indicate that the developed product can function effectively. Experts have discovered that using this product helps people stick to their face mask routines. The design of this product has improved, which means that the overall quality of the product is elevated to be capable of performing as intended in terms of intelligent technologies.

*Keywords—Face recognition; face detection; face mask; coronavirus; intelligent system*

## I. INTRODUCTION

COVID-19 is the group of viruses that infect humans through inhalation and contact to the point of death which is transmitted by the SARS-CoV-2 virus, which is a new type of virus from Novel Coronavirus (2021-nCoV). This can lead to lung injury (ALI) and respiratory distress syndrome (ARDS) which affects lung failure and results in death [1]. The current COVID-19 pandemic caused by the novel SARS-CoV-2 Coronavirus (2021-nCoV), first detected in late 2019 in Wuhan province, China, has spread rapidly worldwide and has infected more than 10 million individuals on 29 Jun 2020 [2].

Standard Operating Procedures (SOP) are work instructions and detailed guidelines for work that are documented in writing by the responsible party. SOPs detail the repetitive work processes that will be carried out or followed in the organization. They keep a record of how activities are carried out to support and facilitate quality data as well as consistent compliance with technical and quality device requirements [3]. The development and application of SOPs are an essential part of a successful quality device since it provides information to individuals performing tasks effectively, and facilitates consistency in the quality and integrity of the product or result.

Face masks are made of fabric that works to prevent germs from entering the human body through respiration. Face masks are respiratory protection used as a way to protect individuals from inhaling harmful substances or contaminants in the air. Respiratory protection or face masks are not intended to replace the preferred method of eliminating disease but are used to adequately protect the wearer [4]. However, hygiene is a widely accepted method of preventing the spread of disease infection. Washing hands with soap have been recommended as a primary and cost-effective preventative measure to prevent bacterial infections that cause influenza-related respiratory illnesses [5].

The National Health Council (NSC) issued Standard Operating Procedures (SOP) to ensure the reduction of Novel Coronavirus (2021-nCoV) infections among Malaysians are still not fully complied with. The National Security Council (NSC) in Malaysia still has a few citizens who don't abide by the NSC's SOPs. It is necessary to conduct surveillance at all building entrances to address this issue. However, a large number of people will be affected by this change. The current staff is unable to monitor and care for all of the areas that the public uses.

Consequently, this study is intended for customers who enter a business. The purposes of this study, which focus on three key areas, are as follows:

- Design a face mask wear detection device.

- Develop a face mask wear detection device.

- Test the functionality of this device designed to detect faces and to determine whether the customer is wearing a face mask properly or not.

Artificial Intelligence (AI) must be utilized to simplify efforts to halt the spread of the COVID-19 virus and find solutions to all of the challenging detection issues outlined above.

## II. Related Work

Facial recognition is a technology that is becoming increasingly prevalent today. Images taken with this technology can be compared to a database of reference images. In addition, pattern recognition is an important aspect of the field. Automatic Teller Machines (ATMs), e-banking systems like Maybank2u and CIMB Click, and computer logins for security gates and computer networks are just a few instances of security systems that rely solely on pass numbers. Unauthorized individuals who come into possession of this route number will be able to use it in place of the original owner. However, one's face is inalienable as one's own. In this way, the current security system can be enhanced by utilizing facial recognition technology. As stated by Lee, H.S et al., if the facial image recognition path number is compromised, it will constitute the best security feature [6].

According to Yaaseen, M. S. et.al, facial recognition is the most difficult aspect of picture analysis since it involves the human body [7]. Facial recognition is a problem of pattern recognition, and its primary goal is to identify reasoning from facial expressions that are not fixed. Since the 1980s, facial recognition has been a widely discussed topic aimed at solving several practical problems. Face recognition uses biometric methods, which is a distinguishable and quantifiable characteristic that is used to label and describe specific individuals to identify personalities primarily by their faces.

It is shown in Fig. 1, how the basic structure of face recognition works in its simplest form. The facial features are captured and stored in a database during the first stage. It is performed in the extraction stage to find or remove specific facial features. The database will be evaluated by comparing it to previously captured facial features for reference. A comparison is made between the features that were captured and the features that were registered in the database based on the extraction and process reference [8]. According to previous studies, several conclude that there are numerous facial recognition techniques, including:

### A. Holistic Matching Method

Sereen et al. [9] used this method to make a match when the captured facial features are crooked or the facial expressions don't match the database system. This method has unique characteristics, such as pattern points. The difference between the distances between the two eyes will aid in distinguishing the various facial angles of each individual. This method makes use of 2D technology to aid the expertise.

### B. Feature-Based Method

Shen Li et al. [10] discussed this type of feature-based recognition which is an improvement on previous methods of recognition technology. Features detected on 2D images use geometric classification and facial structure in terms of points, lines or areas. The data obtained from those features are converted to mathematical data.

Fig. 1. Basic Structure of Face Recognition.

### C. Hybrid Method

HiviIsmat Dino et al. [11] designed a system using the holistic matching method and the feature-based method, this hybrid method employs 3D technology. The hybrid model is the result of the advancement of the previous two methods, with the exception that it uses more accurate and sophisticated recognition. This type of hybrid recognizes more features on the face known as facial node points and identifies the face more deeply.

### D. Skin Texture Analysis Method

Shepley developed a Skin Texture System Analysis using facial recognition technique by converting unique lines, patterns, and spots visible on an individual's skin translated into mathematical space. Therefore, skin texture analysis is more sophisticated compared to the Hybrid type [12].

### E. Thermal Cameras Method

Arthur et al. [13] proposed thermal face verification to recognize faces using thermal cameras, which is a more advanced face recognition method. As shown in Fig. 2, this technique measures the rate at which heat is emitted from individuals or other sources of heat. The object's heat output determines the image that is produced.

Fig. 2. Camera Thermal.

A number of previous studies employing various face recognition-related technologies have been identified in the Table I. Nonetheless, the study has provided suggestions for improving this system. Among previous research are shown in the following tables [14]-[16].

Table II depicts the commercially available products that are relevant to this study. An overview and theoretical description of the face mask wear detection device for determining whether a person can enter a building has been presented in this review. The researcher can use this literature review to identify the hardware, equipment, and software required to continue the study.

## III. METHODOLOGY

The methodology section describes all the necessary information that is required to obtain the results of the study. Six work steps need to be done by the researcher to develop a Face Mask Wear detection Device. There are four phases underway to develop a face mask wear detection device for entry into the premises. Phase 1: Determining the Problem and Background of the research, Phase 2: Making Solutions Possible, Phase 3: Prototype Development and Phase 4: Test and evaluate the solution.

### A. Research Design

Problem analysis is the initial phase of the study conducted to identify problems that arise and set the direction of product development as well as identify the function of the product to be developed. At this stage, the objectives and goals of the study are determined based on the problem factors that exist. This determination is made to ensure that the development process is carried out following the objectives and purposes of the study and is used as a guide throughout the development period.

Furthermore, suggest solutions to problems encountered. Problem-solving in the study conducted is a step taken to propose appropriate solutions and methods to be applied throughout the development process done by developing or proposing some solutions that are capable of overcoming the problems encountered.

Data collection has been done for customers that follow SOPs when entering premises. Based on the data, most of the customers failed to wear mask properly when entering a premise. This also violates the limit of customers on a premise. Thus, the customer's failure to comply with SOPs during the endemic is the problem statement for this research.

The selection of this problem-solving method consists of several factors that influence the development process of the Face Mask Wear Detection Device by using the Facial Recognition System for Entrance Authorization which consists of the design method, material to be used, required functionality and complexity of the development method. Lastly, create a form of control model capable of solving the problems encountered by developing a prototype.

### B. Development Procedure

Engineering Design Process (EDP) is a process for solving problem statements that occur and can be used in almost any situation [17]. The use of this model helps to study and understand the problem and its possible solutions at each step or phase of the research process. EDP is a process that includes steps that can be repeated, although not always in the same sequence but still guided by the objectives of the study. Furthermore, several steps cover several aspects such as planning, designing, testing, and refining the design. This process is often initiated based on clear research objectives and goals and is a journey process aimed at solving problems (National Academy of Engineering, 2020). Based on Fig. 3, six work steps need to be done by the researcher to develop a Face Mask Wear Detection System for Premises Entry Permission. There are four phases carried out to develop the system [18].

The stages of product development that have been completed in the creation of the face mask wear detection system. By adhering to this methodology, the success of product development is made more systematic [19]-[21].

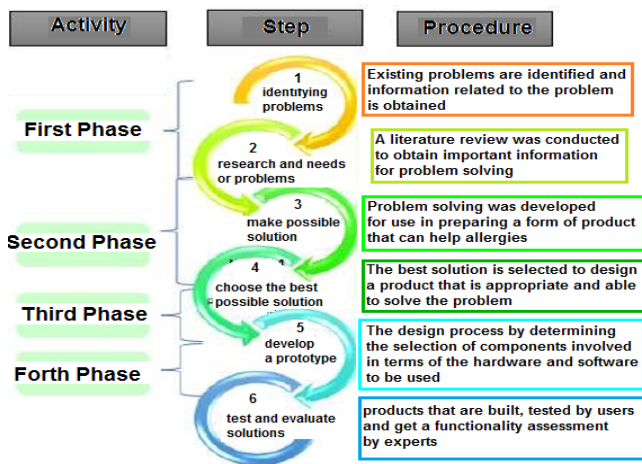

Fig. 3. Phases in Product Development.

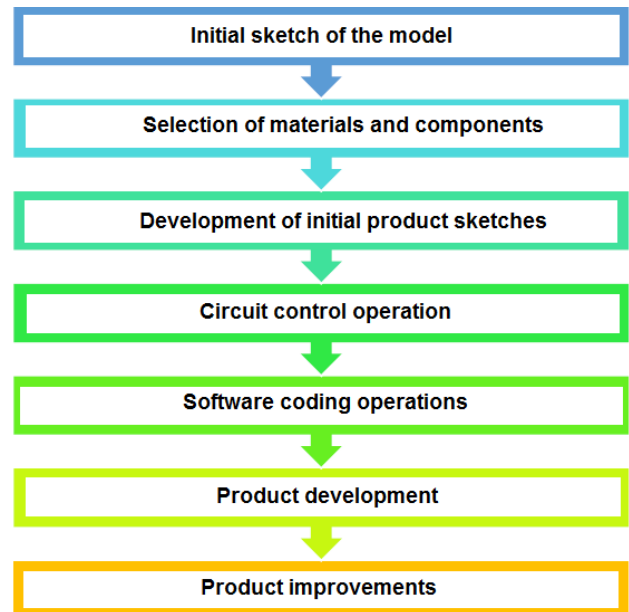

Fig. 4. Product Development Process.

Fig. 4 illustrates the stages of the product development process of the SOP Compliance Testing Device and the Application of Face Mask.

### C. Model Development

The model development is influenced by suitability and user-friendliness. It is always used according to the objectives of the study. The design produced must be durable, easy to move, lightweight, affordable and easy to work with users. Therefore, the researcher proposed a model for the use of face mask detection device for entry into the premises based on the suitability and needs of users. Fig. 5 shows a model sketch of a face mask wear detection device for entrance authorization.

### D. FaceMack Detection Method

The system will start by tracking the physical distance with the device using an IR sensor. Then proceed with the recognition of the physical face by using the ESP32-CAM module. The client image is detected and matched with the image that is in the user database but if, the distance setting is not reached by the IR sensor, the ESP32-CAM Module is inactive and the LCD will display "Take a step back to re-scan".

Fig. 5. Model Sketch of A Face Mask Wear Detection Device for Entrance Authorization.

On activation of ESP32 - CAM, it will detect the physical face whether the customer is wearing a face mask or not. The calculation of the percentage of customer face recognition implemented by the ESP32-CAM will be sent to the Arduino Uno for further decision.

If, the percentage is equal to or greater than 99%, the LCD will display "Mask: (percentage)" and "ENTER ALLOWED" and the Servo will rotate 90 degrees clockwise and it will rotate 90 degrees counterclockwise after a few seconds delay. While the percentage is less than 99%, the LCD will display "Mask: (percentage)" and "PLEASE WEAR MASK" as well as the Servo will not rotate. The process is illustrated in Fig. 6.

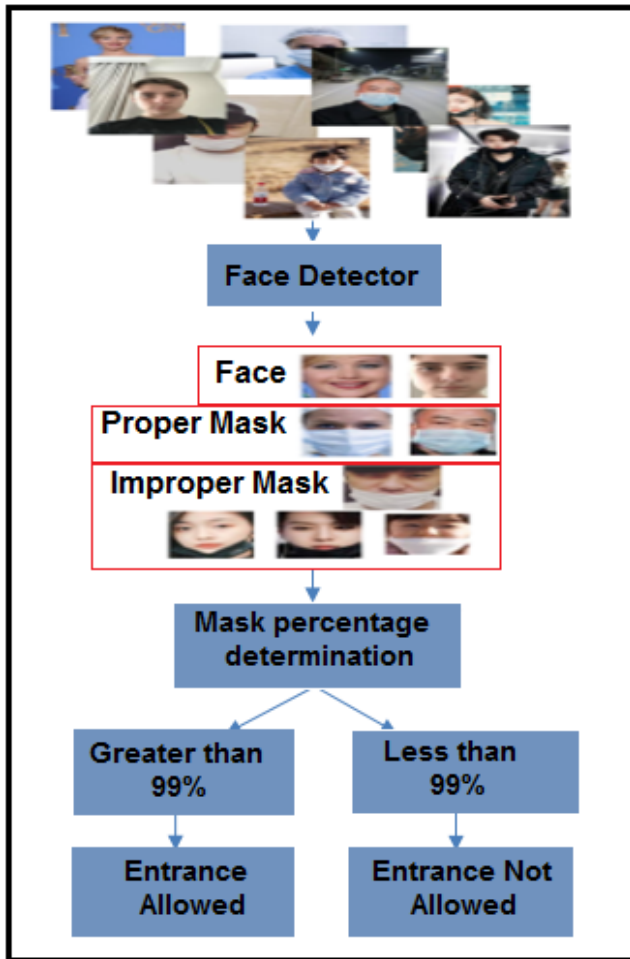

Fig. 6. A Fowchart for Methods Aiming to Identify Wearing Mask Conditions.

## IV. RESULT AND DISCUSSION

The face mask wear detection device for entry into the premises has several key components required to complete the entire system and be able to operate properly and effectively. This main component has been conducted a functionality test so that researchers can identify whether it can operate well and under the requirements of the operation.

### A. Facial Recognition Functionality Analysis (ESP32-CAM)

In the development of this product, facial recognition technology is utilized to compare database images with captured images. The researcher has devised a testing method that involves measuring the distance between the prototype and the human face to determine the functionality and effectiveness of facial recognition. Setting the test distance scale from 0 cm to 100 cm and measuring the recognition time required to detect the face yielded data from three different angle view which is left, front and right angle view. The data collected was recorded for the front angle view, left angle view and right angle view of the facial recognition effectiveness test in Table III, Table IV, and Table V, respectively.

Based on the collected analytical data, the researcher can identify the distance that must be determined for the system to initiate facial recognition. This is to ensure that face recognition is performed by a single person at a distance from the customer in front of the device. The researcher used an IR sensor to support the system by setting the distance between the customer's face recognition and the distance set by the customer. Fig. 7 shows the IR sensor's detection distance for initiating facial affirmation in the following way.

TABLE III. LEFT ANGLE VIEW OF FACIAL RECOGNITION EFFECTIVENESS TEST

| No | Left Angle View | | |
|---|---|---|---|
| | Distance (cm) | Detected | Time to detect(s) |
| 1 | 0 | No | - |
| 2 | 10 | No | - |

| 9 | 80 | No | - |
| 10 | 90 | No | - |
| 11 | 100 | No | - |

Fig. 7.   Operating Face Recognition Area.

Another aspect of facial recognition that requires investigation is the rate of recognition. This is since researchers must examine the percentage of faces detected in clients who wear face masks in a variety of ways. As a result, the researchers created various face mask wear variations and tested the detected face rate to reduce the device's error rate in determining which customers were correctly wearing face masks.

Fig. 8 presents the fact that the consumer is not concealing their face resulting in 80% of displays on the LCD.

Fig. 8.   The Device Displays "Please Wear the Mask".

Fig. 9.   The Device Displays "Enter Allowed".

Since the customer is concealing their identity with a face mask, the LCD has a display rate of 100% as shown in Fig. 9.

Fig. 10.  Side View of Customer's Face.

Since the customer is not wearing a face mask, 60% of the displays on the LCD are visible even inside view as shown in Fig. 10. Data analysis is to determine the percentage value of wearing the mask for the proper way of wearing the mask. The images recorded by ESP32-CAM were compared to face shapes in the database and made face detection results. The percentage value of wearing the mask for the prototype to allow the customer to enter the premises is above 98%. The gate was controlled by a servo motor the rotation is $90^\circ$.

Arduino Uno programming is carried out using an Arduino IDE where the Arduino Uno circuit is connected to a face mask wear detector device for premise entry permission and connected to the laptop port using a Universal Serial Port (USB) cable. In this product two components need coding namely ESP32-CAM and also Arduino Uno it is written in C ++ language through the Arduino IDE platform. ESP 32 CAM needs to use CH340G USB to TTL Serial Converter to send code from PC into ESP32-CAM while Arduino Uno only uses USB Printer Cable B Type for Arduino Printing to transfer code from PC to Arduino Uno.

## V.   CONCLUSION AND FUTURE WORK

The purpose of the face mask wear detection by using a facial recognition system for premise entry permission is to assist customers in determining whether they are wearing a face mask or not. The overall functionality of this system, which is designed to detect this face, has been thoroughly tested so that it can perform as expected. The percentage of

customer face recognition achieved using the codes (coding) set in the ESP32-CAM will be sent to the Arduino Uno for further consideration. If a percentage equal to or greater than 99% is calculated, the bar will be raised to allow entry into the premises. While calculations with a percentage less than 99% are not permitted.

The development of a product necessitates careful and systematic planning to be successfully implemented.

The researcher can learn about the benefits and drawbacks of the product development process based on this discussion. As a result, the study contributes to create a face mask wear detection device and follow SOPs to self-discipline to properly wear face masks. The study produces a face mask wear detection device to improve the efficiency and ease of use of Covid-19 transmission. The system's functionality is being tested to detect faces and determine whether or not the customer is wearing a face mask. Ensure that the number of customers does not exceed the limits set by the premises' owner by reducing the labour cost. Another contributions that can be highlighted in this manuscript is the use of real data obtained by testing the level of effectiveness face-to-face and the provision of accurate results. Furthermore, the two levels emphasised which are proper and improper, are to form a system that will be used to assist researchers in taking into account the mask's position factor.

Since there is currently a limit to how far a sensor can detect, the results may be skewed if we don't make the above-mentioned improvements. However, without the above-mentioned body temperature monitoring system, the objective and interpretation of the results will not be affected because the scope of analysis will be different. It is only beneficial to enhance the functionality of the system.

In the future, some improvements and refinements to this existing system have been proposed by researchers as opportunities for others to participate. The following suggestions can be implemented such as combining this facial recognition technology with a body temperature monitoring system for online health monitoring and;it is advised to include a product efficiency analysis by calculating the average error rate of face detection at a distance.

*Abstract*—**With the increasing of criminal actions, people use various surveillance techniques to create a sense of security. One of the most widely used surveillance technique is installing CCTV cameras at various locations. On the surveillance systems, there are other supporting devices apart from CCTV cameras. One of such supporting devices is a hard disk to save the recorded data. The recording on CCTV has two modes: motion detection mode and continuous mode. The continuous mode will record continuously, which affects the amount of hard disk space used. Motion detection mode records one event only, not all recordings, saving hard disk space, however, it may miss some events. Based on these two modes, compression technology is required. The current compression technology applies the ROI method. A ROI (Region of Interest) is the part of the image that wants to filter to form some operations against it. ROI allows coding differently in certain areas of the digital image to have a higher quality than the surrounding area (background). This paper offers a novel approach to saving the foreground frame generated from the ROI method and compressing it. The novel approach will be applied to the AVI, MJPEG 2000, and MPEG-4 video formats. The decompression process is used to restore the original video data to measure the method's performance. To measure the proposed method's performance, it will compare the compression ratio and Peak Signal-to-Noise Ratio (PSNR) with the traditional method without implementing the ROI-based method. The PSNR value in this paper, that measures the quality of the compression result,s are above 40 dB. It indicates that the resulting video is similar to the original video. The ROI-based compression method can increase the compression ratio 5-7 times higher than the existing method for lossy AVI format video. While on MJPEG-2000 and MPEG-4 format video, it increases the compression ratio 7-15 times and 1-3 times, respectively. The PSNR value for the proposed method is above 40 dB, which indicates that the reconstructed video is similar to the original video, even though the pixel values have changed slightly.**

*Keywords—Compression; decompression; foreground; region of interest; video surveillance systems*

## I. INTRODUCTION

The increasing criminal actions result in people using various surveillance techniques to ensure security and manage communities to create a sense of security [1, 2]. One commonly used surveillance technique is to use video surveillance cameras installed in several places [3]. The development of the internet also supports the increase in surveillance cameras to analyze the recordings [4]. Video surveillance is currently an active field of research that aims to analyze video captured by cameras. This functionality makes it suitable for security applications, object identification and tracking, gender classification, et al. [5].

Nowadays, CCTV is facilitated by remote location monitoring with mobile phones. CCTV does not stand alone but has other supporting devices [6]. These supporting devices are used to monitor and record image objects seen by CCTV cameras [7]. CCTV cameras that produce a low-quality video which is generally recorded at a resolution of 352x240 and have a frame rate of 30 fps, occupy 10 GB of storage in one day [8].

The footage on CCTV is mainly stored on secondary storage devices. CCTV recording equipment has two modes, continuous and motion detection [9]. In continuous mode, CCTV will record continuously so that the hard disk capacity runs out quickly because it stores all the information captured by the camera without choosing whether the data is needed or not. In motion detection mode, also called event recording mode, CCTV only records when specific events occur. Because it only saves when an event occurs, the hard disk capacity does not run out quickly. Its limitation is that not all events are held because CCTV only stores when an object is moving, so some information is lost [10]. A video compression technique is needed that can combine the two modes' advantages.

Several types of video compression used in CCTV are Motion JPEG (MJPEG), Motion JPEG 2000 (MJPEG 2000), MPEG-4, and H.264 [11, 12]. MPEG-4 can be three times more efficient in compression than MJPEG. When the number of frame rates is less than 5-6 frames per second, then MPEG-4 will be less favorable. MPEG-4 uses H-264 video compression and will be efficient when bandwidth conditions are limited and stable. MJPEG uses the Discrete Continuous Transform (DCT) algorithm, while MJPEG 2000 uses the Discrete Wavelet Transform (DWT) algorithm to produce better image quality at higher compression levels. On MJPEG 2000 it is possible to perform a decompression process with a lower resolution representation than the original image, so it is suitable for motion detection algorithms [12].

Video contains data redundancy by which the differences can be recorded within frames or between frames. There are two types of video compression, based on the structure's color component (spatial redundancy) and based on changes between frames (temporal redundancy). The first type is based on the

fact that the human eye cannot distinguish colors well enough because it is affected by the object's brightness. While the other type only encodes the changing frames and directly stored the rest data [13].

The frame changes because there is movement in the object (foreground) captured in the video. Each frame in video data generally contains objects (foreground) and background. The foreground and background detection processes are based on Region of Interest (ROI) that was chosen. It allows different encoding in some regions of the digital image to have a better quality than the surrounding area (background) [14]. ROI is a part of the image that you want to filter to perform some operations.

The application of ROI uses the Max-shift method. In [15], the Max-shift method is used to choose the ROI on an image. The Max-shift method works by shifting the bit-plane from the selected ROI so that it occupies a higher position than the surrounding bit-plane (background), where the shift is conducted to the maximum extent resulting in the maximum quality on foreground compared to the surrounding area. ROI can also reduce the size of the data volume.

Based on these descriptions, this research offers a compression and decompression technique for video surveillance systems by applying a modified ROI method. Modifications are made by using a cropping process to the foreground by implementing the ROI method. And then compress the foreground frame so that the background does not change. The proposed method is implemented on three types of video compression format, lossy video compression in AVI, MJPEG 2000, and MPEG-4.

The rest of this article is as follows; Section II describes the related works of the proposed method. Section III describes the dataset and explains the detail of the proposed method. Section IV describes the results and discussion. The paper is concluded in Section V.

## II. RELATED WORK

In a technical review paper conducted by Seagate in 2012 showed that the compression techniques, used to store CCTV footage, can result in a decrease in quality and have little effect on video size [8]. Seagate conducted the review using a very large variation in hard drive recording capacity based on 24x7 video streaming resolutions. With many security applications requiring dozens of cameras and streaming 24x7 video, this can result in storage volumes reaching hundreds of gigabytes.

Cisco estimates that bandwidth usage for data globally will grow 71% in 2017 and forecasts an annual growth rate of 46% from 2017 to 2022 [16]. A CCTV camera connected to the internet with a stable video stream to the cloud will share a usage share of 2% and will grow seven times to increase to 3% by 2022 [17]. Based on the growth of data usage from 2019 to 2020, it is predicted in [18] that video data usage will continue to increase until 2025. It is due to the size of the recorded storage capacity depending on the hard disk installed (typically 160 GB, but some are up to 1 TB), whereas many security applications require dozens of cameras and 24x7 video streams and result in storage volumes running up to hundreds of Gigabytes.

Recordings are mostly stored on secondary storage devices such as hard disks. So, to reduce storage space, a compression technique is applied. In some research, it is recommended to use cloud storage for CCTV footage using IP Camera and storage using NVR (Network Video Recorder) [16, 19]. The limitations are that it requires a fast internet connection on each CCTV camera and requires a large bandwidth when transmitting. So, the storage method using DVR is still being used.

Research on compression to reduce data volume has been conducted by developing motion detection recording modes [20]. In [21], other providing motion detection information, the CCTV video processing also provides two other output that is face detection information and identification information. ROI based method to classify and detecting vehicles was given in [22].

In [23], the author designs a lossy and lossless algorithm by applying ROI to video compression. This algorithm design applies lossy and lossless video compression to raw video. Raw video in the form of cif or qcif is an uncompressed image file. The proposed approach is in which the selected ROI area is based on the human face (face detection). The limitation of this study is that it does not show any effect on data volume.

## III. MATERIAL AND PROPOSED METHOD

Fig. 1 is describing the research framework. There are two stages in this research, the compression stage, and the decompression stage. This stage is generating a modified algorithm design from the proposed research topic. The result of this algorithm design will be implemented in MATLAB software.

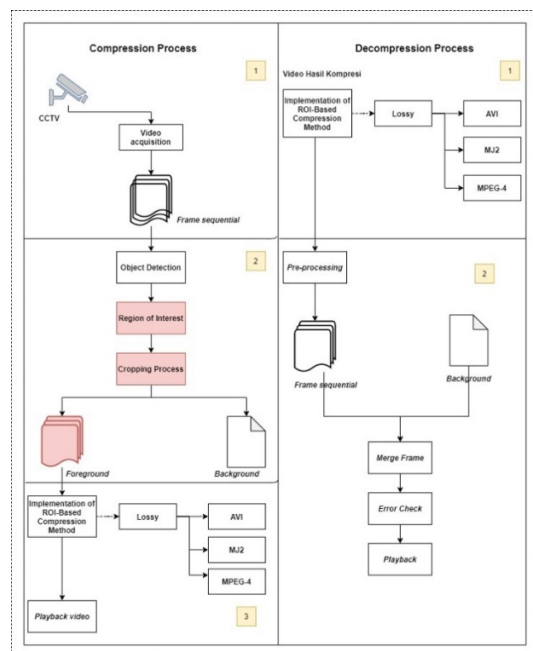

Fig. 1.   The Research Framework.

The research phase begins with video acquisition. Video acquisition here is intended to collect video data used in this research. The next stage is to separate the video into some

consecutive frames (sequential frames). Frames (digital images) are collection of pixels such as RGB or YCbCr. It is continued by video compression process. The difference between this proposed method and the common traditional compression method by AVI, MJPEG 2000 and MPEG-4 is that on this research the compression was implemented on the cropped frame. Based on the ROI method, the cropping process was held on the foreground frame that separates it from the background. At the compression stage, there are three stages: object detection by applying the background subtraction algorithm, followed by determining the ROI area to be separated between background and foreground, and third one is cropping process. The DCT algorithm will compress the foreground cropping results for AVI and MPEG-4 video formats and the DWT algorithm for MJPEG 2000 video format.

The decompression stage consists of three stages, namely, reading the compressed video, merging the foreground and background of each sequential frame, and generating the reconstructed video. The merging of the foreground and background of each sequential frame begins with the pre-processing stage. The pre-processing process is performed by reading the length of the video, determining the minimum and maximum of the width and height of each sequential frame. Next, separate the video data into sequential frames. After getting the sequential frames, read the background frame and combine it with the sequential frames based on its maximum width and height. Perform an error check on the mixed results to see whether each frame can be merged correctly.

### A. Video Acquisition

Video acquisition is the process of capturing or scanning video so that digital video will be obtained [24]. In the video acquisition process, several factors need to be the main concern in the process. These factors are the types of acquisition tool, camera resolution, lighting techniques, zooming techniques (enlarge and reduce the camera) and the angle of data collection [25].

Each type of camera has its characteristics. Therefore, this research uses some different cameras. It consists of 1 CCTV camera and two non-CCTV cameras with different camera resolutions, i.e., 1.3 MP for CCTV cameras and 5 MP and 13 MP for Non-CCTV cameras. The video capture process is conducted simultaneously. The three cameras are placed at the height of one meter from the ground and distances two meters from the observed object. The dataset at the research location was taken at night, requiring additional artificial light. The object of this research focuses on the coordinated movement of objects that move at a certain speed that can be captured by the camera and it consists of an object only, a remote-controlled toy car.

### B. Sequential Frames

Video is a collection of images that are recorded sequentially, and their movements are according to a function of time. After the video acquisition process, frames from the video will be separated [26]. The frame splitting stage begins by reading the length of the image on the video to find out how many frames the video has. Next will be determined the size of the image that is the width and height of the image.

### C. Object Detection using Background Subtraction Method

After sequential frame stage, next is detecting the object. Video acquisition in this research uses a static camera so that it does not move and the point of view of taking the objects is fixed. The resulting background remains same from the beginning of the video to the end. It makes the research direction focuses on the movement of objects, so the algorithm used for object detection is the background subtraction algorithm [26].

The initial step to be conducted is to read the first frame of the video data. This initial frame will be used as the background frame. The next step is to apply edge detection using the background subtraction method to produce a foreground mask. This foreground mask will be used as a reference for the next stage. The background image is the frame that will be compared with the next frame (second frame, third frame, etc.), and then the result is reduced to get the difference. The difference will be used to detect the movement of the object. The result of image reduction is converted into a greyscale image. If there is a change in the value of a particular pixel, assign value 1 (marked in white). If there is no change in the pixel value, give the value 0 (marked in black). The difference from this greyscale image will produce a foreground mask.

### D. Region of Interest

After getting the foreground mask by applying background subtraction algorithm, it will use the foreground mask as the area of interest for ROI. ROI area is marked by a bounding box, which is a box with x and y coordinates representing the width and length of the detected object [27]. Building the bounding box requires a background image, foreground image, and foreground mask. In making a bounding box, start by measuring the size in the region of the image. Then read the foreground mask generated by the background subtraction algorithm. Continue with displaying the box from the bounding box so that it will visually illustrate the separation.

### E. Cropping Process

At this stage, a cropping process is conducted from the ROI results. The input image from the previous stage will be read and then cropped to get a new image. Image cropping in general, can be done based on the coordinates, the number of pixels or the results of zooming a certain area.

This research uses the foreground's width and height information to calculate the intersection point's coordinates after reading the bounding box image. The image cropping process is conducted based on the intersection point coordinates. The result of this stage is a sequential frame containing only objects and a background frame. Sequential frames have objects (foreground) that will be used as input for the compression stage, while the background frame will be saved for the decompression stage. It will merge the foreground and background later in the decompression stage.

### F. Implementation of ROI-based Compression Method

This stage implements a lossy compression method in AVI, MJPEG 2000 and MPEG-4 video compression formats on the cropped foreground frame. The lossy compression method is a

compression method that removes some information from the original data during the compression process, such as reducing the pixel value but does not significantly cross the limits of the visual perception of the human eye.

The AVI and MPEG-4 video formats use the DCT transformation algorithm, while the MJPEG 2000 video format uses the DWT transformation algorithm [28]. A quantization process will be applied to each video format to reduce the amount of information needed to represent the frequency so that unnecessary information can be eliminated. The entropy coding process is conducted after the quantization process is complete. The result of this process is a compressed image where for the AVI video format, it will be saved using a bitmap (.bmp) file, while for the MJPEG 2000 it will be saved using a JPEG 2000 file (.jp2) and for the MPEG-4, it will be saved using a JPEG (.jpg) file. The last step is to combine all compressed foreground frames into a video file for each video formats.

### G. Implementation of ROI-based Decompression Method

The decompression process aims to restore the compressed image into an image representation like the original image [29]. It begins by reading the compressed video for three formats and then saving the information about the length of the video, minimum and maximum value of the width and height of each sequential frame. After separating, the video into a sequence of frames, combine the background and foreground for each frame. It turns the frame sequence into a video representation.

### H. Cropping Process

The proposed method performance evaluation measures include compression ratio and Peak Signal-to-Noise Ratio (PSNR). The performance of a data compression algorithm can be measured by calculating the compression ratio. It measures the physical substance, how much capacity the original compressed file has. The compression ratio (CR) is defined as the ratio of the size of the original data (uncompressed) and the size of the compressed data, which is expressed by (1) [13].

$$CR = \frac{x}{x\prime} \tag{1}$$

where x = the size of the original data (bytes), and x' = the size of the compressed data (bytes). The compression ratio is closely related to how much memory space can be saved.

Calculating the quality of the decompressed image can be done by calculating the PSNR value. To calculate PSNR, it takes the Mean-Square Error (MSE) value given by (2) [13]:

$$MSE = \frac{1}{CM.N} \sum_{i=0}^{M-1} \sum_{j=0}^{N-1} [|I(i,j) - R(i,j)|]^2 \tag{2}$$

where, I (i, j) represent the original image before compression, while R (i, j) represents the compressed image, C represents the color component of the image where C=1 for binary images or grey level, C=3 for color images and the size

of the image is N x M. A significant MSE value indicates that the deviation or difference between the reconstructed and original images is quite significant. Meanwhile, for calculating the PSNR value we can use (3) [13]:

$$PSNR = 10log_{10}(\frac{max_1^2}{MSE}) = 20log_{10}(\frac{max_1}{\sqrt{MSE}}) \tag{3}$$

where, max1 is the maximum value of a pixel in the original image I. The smaller the MSE noise value, the higher the PSNR value, the higher the image quality. On the other hand, the higher the MSE noise value, the smaller the PSNR value, the lower the image quality. Typical values for PSNR in the lossy image and video compression are between 30 dB and 50 dB, where higher is better [30, 31]. Values above 40 dB are usually considered very well, and values below 20 dB are usually unacceptable [31, 32]. When the two images are identical, the MSE value will be zero, which will result in infinite PSNR [31].

## IV. Results and Discussion

### A. Result of Video Acquisition

Table I shows the specifications of the video used. Data was taken with three cameras, one CCTV camera and two non-CCTV cameras, with different specifications to produce three video data. The video acquisition is held at night, so it requires additional lighting, which is placed in front of the object.

TABLE I.    Specifications of the Video used

| Video Name | Number of frames | Video file sizes |
|---|---|---|
| Car1 | 157 frames | 138.87 MB |
| Car2 | 294 frames | 290.70 MB |
| Car3 | 175 frames | 461.43 MB |

### B. Result of Sequential Frames

On this stage, the results of sequence frames are saved in BMP format. For video Car1, the data size of each frame is 676 KB with the time required for sequential frame processing is 6.765 seconds. While for video Car2, the data size of each frame is 1 MB with the time required for sequential frame processing is 12.607 seconds. For the third video, the data size of each frame is 2.7 MB with the time required for sequential frame processing is 9.095 seconds. Fig. 2 gives examples of frame sequential results from three video data.

Fig. 2.    Example of Frame Sequential Results.

## C. Result of Object Detection using Background Subtraction Method

The background subtraction method takes the difference from the frame value by calculating it based on subtracting the current frame from the predefined background frame. Video input in sequential frames will be separated from the first frame by the next frame. The resulting image will be converted into a grey-level image. The grey-level image will be filtered and binarized to determine the foreground and background edges threshold.

Fig. 3 gives examples of object detection resulting from three video data, which shows the difference between foreground and background. The foreground is marked in white, while the background is marked in black. The time required for the object detection process in the first video is 6.763 seconds. While the time required for the object detection process in the second and third video is 13.140 seconds and 9.348 seconds, respectively.

Fig. 3. Example of Object Detection Results.

## D. Result of Region of Interest

Fig. 4 gives examples of the result of applying the ROI method on three video data. The yellow box can be seen visually as a separation sign of the foreground and inside the yellow box, while the background area is outside the yellow box.

## E. Result of Cropping Process

The result of the bounding box process will be the input image for the cropping process. This cropped image contains information about the object of interest from each sequential frame. The cropping process will only keep the foreground from the sequential frame to produce a new image. The new image that contains information about the object will later become the input image of the compression process.

Fig. 4. Example of ROI Results.

Fig. 5. Example of Cropping Process.

Fig. 5 gives examples of the cropped images from three video data. The sizes of the resulting frames have a different size according to the size of each bounding box.

## F. Result of Implementation of ROI-based Compression Method

Table II shows video compression results and the time required to perform the compression process based on this proposed method. It can see in Table II that the sizes of compressed data with the ROI-based compression method are smaller than the size of the original data. For example, on the first video, Car1 with AVI format, the compressed data size is 1.50 MB, much smaller than the original video size of 138.87 MB (Table I).

## G. Processing Time for Implementation of ROI-based Decompression Method

Table III shows the time that it takes to process the decompression stage. All sequential frames result from combining background and foreground frames, will then be saved in AVI, MJPEG 2000 and MPEG-4 video formats. For each video playback process, the processing time will be calculated. The reconstructed video from decompression method will be used later to count PSNR.

## H. Compression Ratio and PSNR Values

Compression ratio that is calculated by (1) is defined as the ratio of the size of the original data (uncompressed) and the size of the compressed data. Table IV gives the comparison of compression ratio between the result by proposed method (with ROI) and existing method (without ROI).

TABLE II. THE RESULTS OF VIDEO COMPRESSION USING THE ROI-BASED COMPRESSION METHOD FROM THE DATA CIDEO

| | Video compression format | Size of compressed data with ROI's | Processing time (seconds) |
|---|---|---|---|
| Car1 | AVI | 1.50 MB | 0.904519 |
| | MJPEG 2000 | 0.61 MB | 0.978303 |
| | MPEG-4 | 0.11 MB | 0.981535 |
| Car2 | AVI | 2.12 MB | 1.837451 |
| | MJPEG 2000 | 1.12 MB | 1.790168 |
| | MPEG-4 | 0.15 MB | 1.772530 |
| Car3 | AVI | 1.45 MB | 3.526940 |
| | MJPEG 2000 | 0.61 MB | 3.324557 |
| | MPEG-4 | 0.19 MB | 3.473233 |

TABLE III.    PROCESSING TIME FOR VIDEO DECOMPRESSION USING THE ROI-BASED COMPRESSION METHOD

|  | Processing time for AVI format videos (second) | Processing time for MJPEG 2000 format videos (second) | Processing time for MPEG-4 format videos (second) |
|---|---|---|---|
| Car1 | 0.321361 | 0.314064 | 0.215553 |
| Car2 | 0.208899 | 0.193403 | 0.153938 |
| Car3 | 0.180601 | 0.192206 | 0.112877 |

In Table IV, the compression ratio of the proposed method (with ROI) in all cases is higher than the compression ratio of the existing method (without ROI). So, it can claim that this proposed method works better in compressing the video data than the current method if it uses a compression ratio to measure the performance.

Table V gives the result of PSNR calculation using ROI-based compression method from three video file formats. The higher PSNR value means the higher reconstructed video quality (result of decompression process). On the other hand, the smaller the PSNR value, the lower the video quality.

TABLE IV.    PERFORMANCE COMPARISON OF THE COMPRESSION RATIO FOR THE PROPOSED METHOD (WITH ROI) AND WITHOUT ROI ON VARIOUS VIDEO

|  | Video compression format | Original size data (a) | Size compressed data without ROI (b) | Size Compressed data with ROI (c) | Compression ratio without ROI (a/b) | Compression ratio with ROI (a/c) | Improved compression ratio (b/c) |
|---|---|---|---|---|---|---|---|
| Car1 | AVI | 138.87 MB | 10.3 MB | 1.50 MB | 13.4825 | 92.58 | 6.8667 |
|  | MJPEG 2000 |  | 7.05 MB | 0.61 MB | 19.6979 | 227.6557 | 11.5574 |

TABLE V.    PERFORMANCE OF THE PROPOSED METHOD BY PSNR

|  | PSNR for AVI format videos with ROI (dB) | PSNR for MJPEG 2000 format videos with ROI (dB) | PSNR for MPEG-4 format videos with ROI (dB) |
|---|---|---|---|
| Car1 | 56.9328 | 52.3866 | 64.2107 |
| Car2 | 62.7869 | 57.8663 | 63.1144 |
| Car3 | 51.0671 | 46.9997 | 46.8808 |

In Table V, all PSNR values are above 40 dB, indicating that the reconstructed video resulting from decompression is similar to the original video.

## V.   CONCLUSION AND FUTURE WORK

This paper proposes an ROI-based compression-decompression method that separates foreground and background on each sequential frame by the background subtraction method. Based on experiment results, for all videos that were acquired, this proposed method gives better results in compression ratio and PSNR values compared with existing methods (without ROI). That is, it increases the compression ratio and PSNR values.

The results of increasing the compression ratio for the video compression method with ROI on the AVI compression video format are 6.8667, 7.4057, and 5.3172. The results of increasing the compression ratio for the video compression method with ROI on the MJPEG 2000 compression video format are 11.5574, 7.3839, and 15.7541. At the same time, the results of increasing the compression ratio for the video compression method with ROI on the MPEG 4 compression video format are 1.9091, 3.2105, and 2.789. The ROI-based compression method can increase the compression ratio 5-7 times higher than the existing method for lossy AVI format video. While on lossy MJPEG-2000 and MPEG-4, it increases the compression ratio 7-15 times and 1-3 times, respectively.

The results of the PSNR value for the video compression method in the AVI compression video format are 56.9328, 62.7869, and 51.0671. The PSNR values for the video compression method in the MJPEG 2000 compression video format are 52.3866, 57.8663, and 46.9997. And the results of the PSNR value for the video compression method in the MPEG-4 video compression format are 64.2107, 63.1144, and 46.8808. The PSNR value for the proposed method is above 40 dB [31, 32], which indicates that the reconstructed video is similar to the original video, even though the pixel values have changed slightly.

This study only uses one object, while there can be more than one object in the field (crowd people). The camera used in this study is still, while the camera used in CCTV may be a camera that moves which results in changes in the background. So further research can be conducted to detect more than one object, moving cameras, or changes in the camera's background.

*Abstract*—Designing an automation system for the agriculture sector is difficult using machine learning approach. So many researchers proposed deep learning system which requires huge amount of data for training the system. The proposed system suggests that geometric transformations on the original dataset help the system to generate more images that can replicate the physical circumstances. This process is known as "Image Augmentation". This enhancement of data helps the system to produce more accurate systems in terms of all metrics. In olden days when researchers work with machine learning techniques they used to implement traditional approaches which are a time consuming and expensive process. In deep learning, most of the operations are automatically taken care by the system. So, the proposed system applies neural style and to classify the images it uses the concept of transfer learning. The system utilizes the images available in the open source repository known as "Kaggle", this majorly consists of images related to chilly, tomato and potato. But this system majorly focuses on chilly plants because it is most productive plant in the South Indian regions. Image augmentation creates new images in different scenarios using the existing images and by applying popular deep learning techniques. The model has chosen ResNet-50, which is a pre-trained model for transfer learning. The advantage of using pre-trained model lies in not to develop the model from scratch. This pre-trained model gives more accuracy with less number of epochs. The model has achieved an accuracy of "100%".

*Keywords*—*Image augmentation; geometric transformations; transfer learning; neural style learning; residual network*

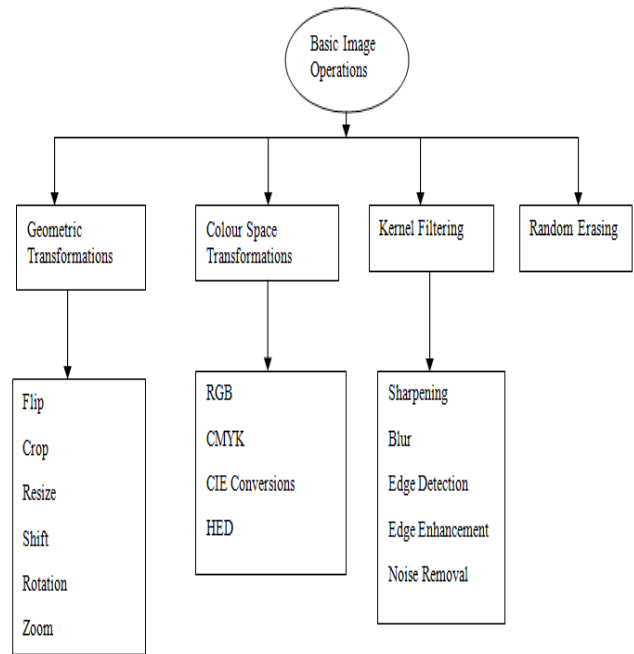
## I. INTRODUCTION

The main goal of the data augmentation technique is to develop the model which is capable of handling the input that is unknown to the system and to develop a generalized training model. The proposed system focused on chilly plants but there is a situation where it can get similar leaf images of chilly but it is really chilly. So the proposed system uses the neural style learning to combine images of different plants and produce a new synthetic image. The image augmentation acts as a pre-processing step in the deep learning area to train the model. The proposed paper discusses the basic image manipulation operations, deep learning[5] and meta-learning techniques that can be performed on the image. The image augmentation operation is classified into two ways as shown in Fig. 1.

Offline mode stores the different augmented images in the hard disk, which requires high configuration of processor and RAM to run the program. Online mode utilizes the cloud services to store the image and it uses GPU's to run the program [19]. Google CoLab is an open source tool that run huge amount of images at a faster rate. Among the two types augmentations namely offline and online modes, this paper considers the online augmentation techniques since all the operations are performed in cloud using GPUs due to which waste of disk space is reduced. The offline data augmentation is preferred for the smaller datasets; the newly created images will be stored in the disk. This offline process is time-consuming and is expensive whereas in online or real data augmentation the transformation images occur randomly on different batches and the model is trained with more cases in each epoch in this method [8]. There three ways to generate augmented images as shown in Fig. 2.

Fig. 1. Modes of Image Augmentation.

Fig. 2. Different Ways of Image Augmentation Techniques.

*1) Basic image operations:* The basic image operations include geometric transformations, which is a sequence of steps consisting of rotations, flip, resize, shift, zoom, crop, and adding of noise operations [9]. It also includes color space transformations; in general, images are composed of RGB color convention but for efficient processing of the data the image has to be transformed into gray-scale or other color saturation values. The basic operation also includes kernel filter, using convolution neural networks, the region of interest is extracted from the image. The image is stored as a two-dimensional matrix and the filter performs a dot product between the input and filter layers and the values are added to get a single value in each position. Kernel filtering helps in edge detection, image sharpening, and blurring operations [10]. The latest improvement has included random erasing techniques to erase the pixels in the image by selecting a rectangular region, an area is selected based on the probability which is calculated with help of aspect ratio and area ratio. It plays a vital role in image classification, object detection, and person re-identification. It can be easily integrated with the neural networks and it can use on pre-trained models. The basic image operations categories are presented in Fig. 3.


*2) Deep learning approaches:* These approaches consist of adversarial training, this type of approach is highly needed in the models where Gaussian noise is injected and images are transformed with worst-case perturbations, this results in incorrect answer with high confidence values [11]. Deep learning also involves neural style transferring technique which helps to create new images by blending images especially when the model has content or style reference images. It uses two different distance functions, one is used to identify the differences in terms of content, and the other is used to identify the differences in terms of style. The third and important approach is the usage of GAN models, an unsupervised technique that can generate new images by learning from the patterns that exist in between the input image. GAN's consists of two components: generator to create new images by training the model and discriminator for classification purpose [12, 13]. In GAN's, the generator takes input as a fixed-length vector, which is known as "Noise Vector" for producing the salt and pepper noise images because most of the plants have smoked layer above them. Generator produces outputs samples that belong to the domain of leaves but with different styles. Discriminator takes the input from the domain and outputs a binary value based on the prediction performed. The task of this component is predict whether the scanned image is a real or augmented image. Higher the misclassification produced by this component higher will be accuracy of system because more number of augmented images has passed the test. So in designing the GAN, the major focus should be on layers of the generator. The general architecture of GAN is presented in the Fig. 4.

Fig. 3.    Summary of Basic Image Operations.

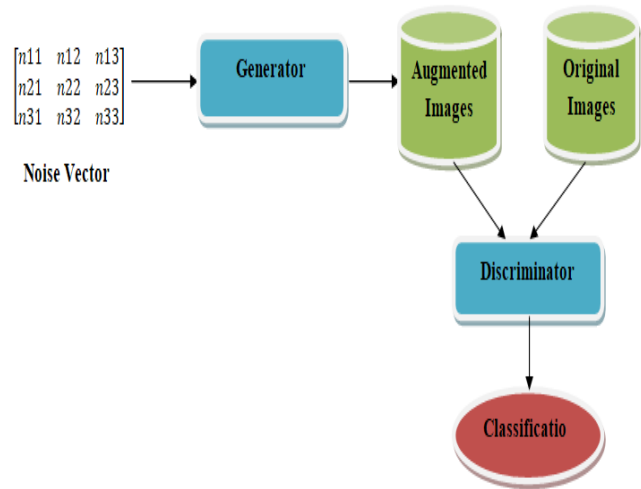


Fig. 4.    GAN Architecture.

*3) Meta-Learning approaches:* These approaches are used to balance the data between the real world and the simulated world. Recently Google has designed a novel method known as "AutoAugment", it is a policy-based approach to identify the best augmentation suited for the dataset. The search space of the AutoAugment has 5 sub-policies with 2 operations each. This process of AutoAugment will save us a lot of time in checking and applying all the possible combinations of operations that can be performed to increase our dataset size. The selection of operation to be performed is based on the dataset system supply, this automatic selection of operation is acquired from the reinforcement learning. Fig. 5 illustrates the process of Auto Augmentation using the optimizers.
Fig. 5. Auto Augmentation Process.

The design considerations for augmentation involve train-time data augmentation to reduce the generalization error and test-time data augmentation to improve predictive performance. The most important operation that should be performed is resizing operation that all the images should be of the same size and some pixel scaling and normalization operations should be performed.

The paper first presented introduction section, which describes about different augmented images generation techniques in online mode. The second section literature analyzes the previous works to identify the gaps in the research. The proposed model section discusses about the basic image operations along with the ResNet-50 CNN for classification [15]. The results section discusses about both proposed results along with the compared results of previous works in terms of every metric. The last section i.e., conclusion presents the advantages of pre-trained model then it extends the section by coining the limitations of the present work.

## II. LITERATURE REVIEW

Many Research Scholars and Scientists are continuously working on various plant diseases to improve the quality of production using machine learning and deep learning techniques. All these researchers have considered the controlled conditions and obtained the plant images from PlantVillage dataset. The application of computer vision and deep learning techniques has given good accuracy systems for automatic detection of diseases in plants.

Quan Huu Cap[1] developed a Generative Adversarial Networks known as "LeafGAN", which act as a data augmentation tool by creating new diseased images from the healthy images. This system preserves the background of the image as well as generates the images of high quality. The core component of this model is LFLSeg, which is a label-free and weakly supervised segmentation module. In this model, it uses feature maps to extract the segmentation information[6], and this in return helps the model to learn about dense and interior regions of the leaf images implicitly. The output of the segmented image is projected as a heat map so that it calculates the probability of each pixel in the final decision. Finally, this model has boosted the diagnosis system and it solved the problems that arise due to the overfitting of the data.

Haseeb Nazki[2] proposed Pipelined Generative Adversarial Networks for plant disease detection to address the problem of imbalanced data shifting. The working of this model consists of two major components. The first component is AR-GAN, which is used for generating the data augmentation synthetically by translating an image from one domain into another domain. A parameter known as discriminator decides whether an image belongs to a particular domain or not. Based on the dataflows and loss functions, the image is reconstructed so that its performance is improved over cycle GAN. AR-GAN has a network that has an activation reconstruction for feature extraction. The second component is RESNET-50 CNN for disease detection with the same configuration as the baseline with RELU as activation functions [16]. The network is fine-tuned by using ImageNet pre-trained weights.

Daniel Ho[3] suggested a population-based augmentation algorithm, which uses a dynamic strategy. The main goal of this algorithm is to optimize the hyperparameter by using schedule learning policies. The PBA first runs a gradient descent algorithm on each epoch and then it does the evaluation on the validation data. Truncation selection is applied to the bottom 25% of the data based on the weights and top25% of the data based on the hyperparameters.

Sungbin Lim [4] proposed the Fast AutoAugment Algorithm based on density matching. The model constructs a search space for the images and defines two efficient operations known as calling probability and the magnitude. The search strategy uses the probability distribution on a pair of training datasets, the values are parameterized and evaluated the accuracy and loss values. The performance is measured by comparing the amount of the data that is similar in both datasets and it uses K-fold stratified shuffling. At last, the policy is explored by using Bayesian Optimization by employing a kernel density estimator. Table I illustrates the advantages and disadvantages of the previous works.

TABLE I.        COMPARATIVE ANALYSIS

| S.No | Author Name | Algorithm Name | Merits | Demerits |
|------|-------------|----------------|--------|----------|
| 1 | Quan | LeafGAN | The classification process by taking the segmented images is easy for the GAN | The model has used traditional segmentation approach for feature extraction. The annotation process is difficult |
| 2 | Haseeb | ARGAN | The residual component used tries to minimize the loss function at every iteration | The usage of ImageNet which less number of leaf images for knowing the weights of the layer has reduced the accuracy of the model. |
| 3 | Daniel | PBA | During the process of distribution of data the model has wisely chosen mixture of top and bottom layers of data for validation purpose | The learning policy implemented by the population is difficult since all the combinations of learning policies are to be computed |
| 4 | Sungbin | Fast Auto Augment | The model uses the probability to construct the search space. This helps the model to have very small search area to recognize the desired regions | The density parameters are found using the optimization technique based on bayes theorem. But since it is applied for K-fold, it is very expensive process |

## III. PROPOSED MODEL

The aim of the proposed model is to develop basic online augmentation techniques along with convolutional neural networks[7] and calculate the accuracy for the identification of bacterial blight disease in chilly plants.

### A. Basic Image Augmentation Operations

The main advantage of these geometric operations is that even though various operations are performed on these images, the features of the image remain the same. All these operations are performed with the help of ImageDataGenerator class of the Tensorflow library and all the images captured will have different dimensions so to maintain all the images with the same dimensions the common operation of resizing is applied to all the images [18].

*1) Rotation:* The basic operation that can be applied to any image to change the orientation of the image is rotated. The rotation angle is specified in terms of degrees which can accept the values from 0 to 360 in the clockwise direction. [14].

*2) Flipping:* It is an extension of rotation operation. Flipping operation is used to perform the transposition of a row and column pixels. Here, two types of flipping operations can be performed. Depending on the nature of the images, either of the horizontal or vertical flips can be applied.

*3) Shearing:* The process in which the pixels can be shifted from one position to another position either horizontally or vertically is known as "Shearing". Here, the dimensions of the mage remain the same i.e., few pixels will be clipped off.

*4) Cropping:* In general, the images contain a region of interest at various locations. To find that location the best operation that one can use is cropping the image at the required place. Since the proposed system is a classification model, the output generated by the model should be the subset of the whole image.

*5) Zooming:* Zoom operation either adds new pixel values or interpolates pixel values. Let us consider the value specified is x then zoom performs 1+x and 1-x operations around the pixels of the image. It helps in the uniform sampling of the image.

*6) Brightness or contrast:* This operation is used to perform either to darken or brighten the image. This operation mainly helps the model to train the system under various lighting conditions. Here, we can specify the minimum and maximum value as a percentage. A value of less than 1.0 darkens the image and a value greater than 1.0 brightens the image. All the sub sections of Fig. 6 show the output of different image operations on the chilly leaves. The order of selection for these operations doesn't have any impact on the augmentation and classification process [20]. There are many image manipulation operations but the proposed system implements only five of the important operations so that the burden on the neural network gets reduced.

### B. Basic Geometric Image Operations Algorithm

Step 1: All the images should be of the same size. To do this, we apply to rescale the images to 1/255, because the minimax pixel value is 255.

Step 2: Image is rotated to $40^0$ to make the image out of the frame and used nearest neighbor fill interpolation.

Step 3: Apply both horizontal shift and vertical shift with 20%.

Step 4: Apply the sheer range and zoom range of 20%.

Step 5: Apply horizontal flip.

The algorithm will give the augmented images as follows. A sample screenshot is shown in Fig. 7.

### C. Applying Convolution Neural Networks

2D convolution takes an image as input and passes it through a kernel filter to calculate the dot product. The weighted matrix is converted into a feature matrix. These features are important to find the nearest weights to identify the region of interest. This helps to reduce the number of pixel operations to perform. In the proposed paper, the model uses padding with value as the same, which determines the amount of the pixels to be added to the image and add layers with pixel value as zeros. In general, the pixels stored in the center are used more than corners and edges. So to preserve the edge's information, padding helps a lot. The same value for the attribute padding is illustrated as follows:

(a)

(b)

(c)

(d)

(e)
Fig. 6.    (a) Output of Images Generated Randomly at the Angle of 95 Degrees, (b) Output Images Generated by Performing Horizontal Flip, (c) Output Images Generated by Performing Shearing Operation with Both width and Height, (d) Output Images Generated by Performing Zoom, (e) Output Images Generated by Performing Brightness.

Fig. 7.    Screenshot of Augment Images Created using the Online Data Augmentation Process.

Let, the number of layers to be added be as the border of an image be (wXw) and the image size be (mXm). After padding the image, the size of the image becomes as (m+2w). (m+2w). Let the kernel filter size be (yXy), then after applying the kernel filter, the output image size is (m+2w-y+1). (m+2w-y+1). The padding maintains the same size as of input image by using the notation shown in equation (1).

$$length\_padding = \frac{[(m+2*w)*(m+2*w)]*y^2}{m*m} - \qquad (1)$$

The transfer function or activation function determines the output of the node in the neural network. This converts the corresponding output into binary values. The proposed paper uses ReLU, a nonlinear transfer function, which gives the output as the maximum value of the input. It is a widely used transfer function because it implements backpropagation and as well as it doesn't activate all the values simultaneously [17]. The equation of the function is shown in (2).

$$f(input\_feature) = 0, if\ input\_feature < 0$$

$$= 1,\ if\ input\_feature >= 0 - \qquad (2)$$

The proposed system uses the CIFAR-100 predefined dataset with 100 class labels using the ResNet-50 to get the proper weights for training the network. After training the model, the augmentation techniques can create different feature maps and sometimes lower resolution pixels may contain important structural elements. So, these issues can be solved by designing pooling layers. The pooling layers create a subset of feature maps for each operation separately. It

detects the features irrespective of augmentation and noises contained in the image. In the proposed paper, the model used the max-pooling layer. It takes the maximum value that occurs in the filter applied. The main advantage of pooling in smaller datasets is it can avoid the overfitting problem by implementing the dropout regularization mechanism. For having a good performance, the dropout value for the hidden layers can be between 0.5 and 0.8.

Now the pooled feature map should be transferred into the column, because the neural network can accept only the long vector of inputs. Then, a dense layer is applied to the neural network, which calculates the dot product of the input image and weighted data i.e., kernel, and added to the bias value with the usage of activation function to optimize the model. Finally, the model is compiled with the help of Adam optimizer, it updates the network weights iteratively based on the training data. It is popular for its fastness by updating velocity and momentum parameters as shown in equations (3) & (4).

$$Momentum_i = \beta * Momentum_{i-1} + (1 - \beta) * gradientvalue - \qquad (3)$$

$$Velcoity_t = \alpha * velocity_{t-1} + (1 - \alpha) * momentum_i - \qquad (4)$$

The extracted features from the chilly plants after training the model are presented in Fig. 8. This figure shows the layer by layer output of CNN for better visualization of essential features.

Fig. 8. Screenshot of Feature Maps after Every Layer in CNN.

## IV. EXPERIMENTAL RESULTS

Since the model uses the pre-trained model ResNet-50, the number of trainable parameters get reduced from 1,67,300 to 10,400. So the model can claim that it has good dimensionality reduction. The system to overcome the drawbacks of the machine learning models it stacks layers of network to learn the complex features with efficient learning rate. The proposed system uses that stacked layer architecture which consists of a pile of conv2d, activation and batch normalization layer. The major advantage of this network lies in reducing the dimensions drastically at every step of training. The model also uses the best estimators like using Adam optimizer, learning rate as 0.5 and others. The systems presents a sample summary of the training model in the Fig. 9 to understand the underlying parameters.

Fig. 10. Evaluation Metrics in all Epochs.

Fig. 10 shows the accuracy for every iteration by setting the epoch value to 15. It computes accuracy and loss of training data and it also computes the accuracy and loss of validation data. From the figure, it is evident that the model has started with good accuracy of "91.22" and slowly it has reached to 100% accuracy.

The evaluation of deep learning algorithms is measured using the both training and testing data. Fig. 11 visualizes the metrics obtained in the Fig. 10 as a graph for the users to understand the nature of the system. Fortunately, in case of training data, the model performed stable by getting more accuracy for training than testing data and more over it has increased gradually. In the loss graph, it is clearly evident that the loss is also decreasing gradually. The loss rate is also very less.

The below section compares the output of the proposed model with the previous works studied in the literature section to prove the efficiency of the model. Fig. 12 visualizes the graphs obatined by the algorithms in terms of different metrics. X-axis repesents methodology and Y-axis represents the measuring scale.

Fig. 11. Screenshot of Training, Test Accuracy.

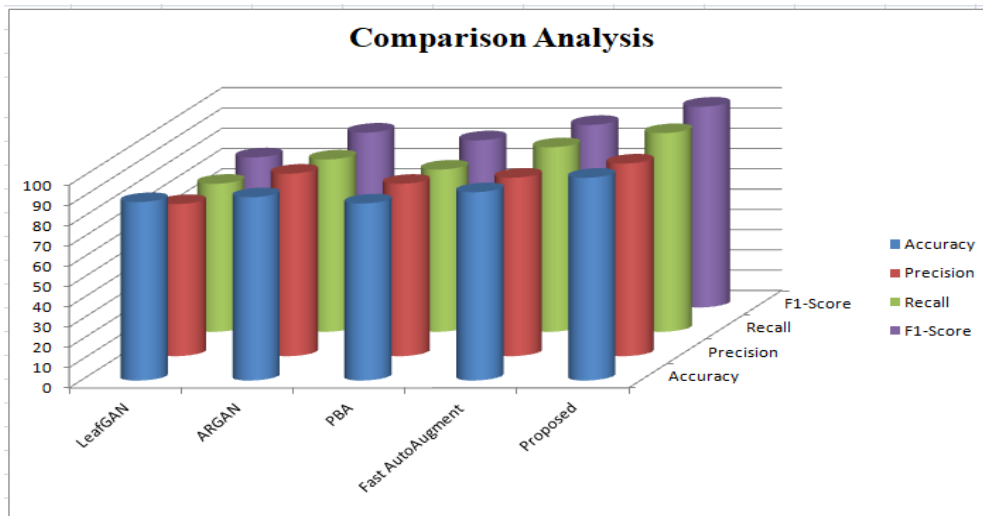

Fig. 12. Comparison Analysis over Metrics.

## V. CONCLUSION

In a real-time environment the conditions are uncontrolled and the system may face problems like labeling of disease dataset, and addressing the data imbalance problems. The size of dataset is smaller in size in the real-time environment so they cannot work properly. The traditional systems take a lot of computations to select and apply all the possible geometric transformations. So, the proposed system by designing a good policy schema like using pre-trained model to gets the weights of neural networks and applying five basic transformations to create augmented images helps the model to design an accurate system. In future, the model can be transformed to use GAN approaches to create images because the model has achieved 100% accuracy whose state is claimed as "Overfitting".

# Towards the Smart Industry for the Sustainability through Open Innovation based on ITSM (Information Technology Service Management)

Asti Amalia Nur Fajrillah, Muharman Lubis, Arariko Rezeki Pasa
Department of Information System, Telkom University, Bandung, Indonesia

*Abstract*—The Indonesian coffee industry has become a trend that has a strategic role and potential for the livelihoods of the business people in it, as well as Indonesia's economic growth. One of the trends that stole attention is the concept of smart industry, the concept of a digital-based industry that is highly relevant to technological developments in this era. When companies want to implement a smart industry, companies need a strategy to implement IT (Information Technology) so that the investment spent is right to build the company's targets. This study aims to design a systematic IS/IT strategy to realize the concept of smart industries that are effective. The analysis and design method used is the Ward & Peppard framework which consists of two phases, namely the input and output phases. The input phase consists of internal business analysis, external business, IT internal and external. The output stage includes the design of IT management strategies, business information systems and IT strategies. The results of this study are in the form of a portfolio of IT designs at the Margamulya Coffee Producers Cooperative consisting of business strategy designs and IT management.

*Keywords—Smart industry; Ward and Peppard; IS/IT strategy*

## I. INTRODUCTION

Industry 4.0 requires many companies to use these technologies to move to a digitally connected industrial environment, providing regulatory and legal flexibility for additional ubiquitous, cloud-based production. It is management and can provide hands-on training and innovative education [1]. After a successful implementation, some potential benefits can be recognized, but the resulting effects are not always obvious. In addition, the impact of making changes to the current production environment, and therefore the risks, is difficult to predict. If you know the consequences of your changes, you can always look forward to them in multiple steps and can easily modernize and change your manufacturing company [2]. Coffee is the third largest contributor to foreign exchange for plantations for Indonesia with a total plantation area of 1,227,787 ha. The level of coffee production in Indonesia reached 11,491,000 tons in the period 2016-2017 while occupying the position of the 4th largest coffee producer and exporter in the world. Based on company status, the Indonesian coffee industry is divided into three categories, namely smallholders, government, and private.

Smallholders are plantations owned by households and are not a legal business entity. In general smallholder farmers form a legal community called the Cooperative. Meanwhile, with a land area of 96.19%, smallholder farmers are the largest contributor of all types of coffee producers, both private and government. With this strategic role and potential, Indonesian coffee smallholders are expected to continue to grow amid global competition. However, Indonesian coffee smallholders have complex problems, namely low-quality control, inadequate infrastructure, climate change, socio-economic conditions and technological limitations. In the end, these problems have caused various losses in the Indonesian coffee industry such as vulnerability to price fluctuations, crop failure and low productivity. The benefits of smart industry for organizations is that product development can be faster, save resources, improve productivity, increase the need for skilled labour, increase investment, make optimal decision making, engineering. Business processes become dynamic, and can give birth to new business models and new ways to create added value. However, in Indonesia, technological issues are included as one of the main problems that hinder the development of the industrial sector, especially in the type of Small Medium Enterprises (SMEs).

The method used to design information system in the KPKM is the Ward & Peppard framework. The strengths of Ward & Peppard's framework are, in the business analysis phase that can design business strategies before entering the IT strategy design phase, the classification between the definitions of IS and IT is structured to facilitate the strategy to be understood, the existence of external analysis that can take into account factors outside the company that affects the company's business processes, and the steps taken do not have to be sequential so that they can prioritize which steps are most likely to be done. This framework is divided into 2 stages, namely the input and output stages. The input phase includes analysis of internal business, external business, IT internal and external. At the output stage consists of designing business strategies, IS, IT and IT management that will produce a portfolio of what Information Systems will be needed to support the company's business processes. The output produced in this study is in the form of a portfolio of strategy designs. It is hoped that this strategy can help coffee cooperatives in realizing the application of smart industries to increase the competitive advantage and productivity of cooperatives and can be a solution to smallholder problems in general and specifically on the object of study.

## II. LITERATURE REVIEW

### A. Digital Transformation

A coffee shop lifestyle as a trend in modern society can be a good business opportunity as competition intensifies among entrepreneurs. The growth of coffee shop consumers is accompanied by the growth of entrepreneurs, who are now very popular with the youth. The most important thing about having a coffee shop is promoting on social media. Using filters on social media or application in the phone is a very valuable way for someone or a product to convey expectations to consumers [3]. One such potential tool for coffee farmers is to foster a strong awareness of profitability across their geographic regions given the importance of scenario planning in the coffee production cycle. Understanding the spatial characteristics of profitable producers can provide better decision-making insights into production and management decisions in the coffee industry, even across the globe [4]. This digital transformation has become one of the pillars of industrial strategy that has completely changed the job patterns of the majority of industrial applications, and companies need their employees to understand and use the new developed business models. Therefore, interests of this transformation are characterized by mastering the process of digitization of operations, redefining of business lines, good data analysis, and rapid integration within the organization [5], which collaboration and data sharing become the key consideration.

The adoption of smart industry concepts, including operating procedures, technologies and systems, is dependent on human factors. Training, professional function, well-being, human performance, and physical and mental health are factors that influence the decisions and behaviors of one or more productive organizations. Human workers want to enter the market, stay in the market, building their careers, earned fair wages, stability, intellectual growth, learning, and / or professional achievement. On the other hand, companies generally want the best possible human performance to improve productivity [6]. The limitations and requirements placed on the devices and systems used depend heavily on the application chosen and the layers considered [7]. In addition, ensuring adequate production of coffee plantations requires government support for additional investments in construction that have a negative impact on the ecosystem [8]. Despite the apparent efforts of the scientific community to articulate the vision of strategic alignment of IT and business, IT and business are inevitably dynamic so that organizations can be applied to the real world. Contributions to this topic grow very rapidly, but the relationship between assumptions and conclusions is inconsistent and inconsistent. The main reason is that the proposed model is highly conceptual and detached from the actual reality of the organization [9], [10].

### B. Profit Optimization

The main goal of the transition to the smart industry is to enable organizations to monitor machines and equipment directly in real time by implementing smart operations using machines that can analyze their data and predict when maintenance will take place. It also improves supply chain management through product tracking, logistics tracking, inventory management, and scanning real factory process cases to clear processes in use and verify compliance with designed business processes [5]. Interestingly, at certain countries, the number of profit was earned from coffee industry has the power in economic to strengthen the national currency through hexport import trading [11]. Of course, critical factors can be linked to the support from government regulation related to the tariff barriers [12]. Therefore, ultimate developments, especially post-harvest processing, can add value to coffee products, open up business and employment opportunities, and can lead to a wider multiplier effect [13].

In the coffee industry, some by-products are produced during the production and consumption of coffee, which makes them an important waste from an environmental point of view, preventing the worst in the future, and detrimental to long-term operations [14]. One way to increase quality awareness is to emphasize brand personality. When communicated properly, there are personal characteristics that are preserved to create value for potential customers in increasing the quality of the brand itself [15]. The upgrade process with appropriate technology allows company to better respond to competitors in the globalized market through high added value activities, achieving a better positioning process in the international market and help promote it. It may have a positive impact on the sector or industry by improving value chain practices to improve performance, increase return on investment, and ultimately improve profits [16].

### C. Innovation Ecosystem

Rapidly changing topics are underway for a future where less has and more is shared. Home appliances are connected via the Internet of Things (IoT), and homes are powered by renewable energy. New entrepreneurs take inspiration from the success of the founder's last wave, in which several web services are available to facilitate entrepreneurship and improve access to capital. Industry 4.0 is an industry approach that addresses all aspects of the industrial operating model, including culture, management responsibility, and interaction with regulators that require companies to consider new models in the ecosystem [17]. Most industries began with some kind of invention, such as telephones, light bulbs, radios, and television. Credits for the invention are awarded to the inventor, while credits for establishing the industry are awarded to entrepreneurs who establish new companies. There is the required question on the exact definition on what happens before industry, and not just how it emerged or who the perpetrator is involved but when they participate and how they participate [18]. In the technology-intensive industries, the teamwork process is often complicated by dispersed interests among industry participants. Such competition can hinder teamwork, as industry participants fail to advance their own interests and the interests of the industry as a whole to gain legitimacy.

Like the history of the Industrial Revolution, innovation also has evolved in several stages. In the beginning, it can be defined as a closed or regulatory binding innovation, in which the most of new ideas are the result of the organization's in-house research and development to develop its own core competencies such as Bell Labs and NASA. The second stage is collaborative innovation in which the organization collaborates with outside sources or partners for value chain

innovations such as Apple, Dell, Zara, and Boeing. Therefore, the third stage is open innovation, as organizations search for new sources of innovation internally and externally. This is very similar to the crowdsourcing innovation that the most famous ones are NineSigma, InnoCentive, and YourEncore. Then, the trend is shifting to Innovation 4.0 or co-innovation where the organizations develop an innovation ecosystem to evaluate and approximate the ideas generated through all useful sources, including in-house research and development, collaboration, open sourcing and co-creation with clients and partners to create an implementation plan [19].

The future of the ecosystem should be seen as a new paradigm as a set of cutting-edge technologies that support effective and accurate engineering decisions in real time by introducing various ICT technologies and integrating existing technologies [20]. The innovation ecosystem concept put more emphasis on value creation and collaboration where the companies co-evolve capabilitie around a new engagement method or mechanism to support new product, satisfy customer need and incorporate to the advancement process competitively [21]; the question of who belongs in an ecosystem and who does not cause the natural and natural problems of the ecosystem structure. The diversity in the types of participants, their roles, and their interconnectedness means that issues are not distributed evenly among the participants. The interconnectedness of ecosystem participants also raises the issue of how ecosystems are coordinated and managed. In many cases, there are central companies that coordinate services for the system. These firms may control the technology or brand architecture that drives the value of the ecosystem, and coordination may depend on the management of the architecture in regards to organizing access to specific common platforms. Indeed, a large subset of the literature proposes platforms as tuning artifacts used by pivotal firms, services, tools, and technologies that other members of the ecosystem can use to enhance their unique performance characteristics [22].

## III. METHODOLOGY

The smart future should help innovate and develop smart solutions to complex problems and ensure a human environment with dynamic change. This is due to natural phenomenon, the deliberate design of human ingenuity, or the cooperation of individuals and can be classified as incremental (exploitative), radical (exploratory), ambidextrous (responsive) and disruptive (destructive) [19]. In this case, Ward & Peppard framework was adopted. By using the business and IS/IT environment analysis as an input, the output of this framework consists of business/IS strategy, IS/IT strategy, and IT strategy. There are several analyses used to generate business/IS strategy, the step by step shown in the following Fig. 1, Business Environment Analysis, which started from business environment analysis on both internal and external side.

This business environment analysis aims to assess the strength-weakness factors from the internal environment and the opportunities-threat factors from the external environment. These strength and weakness factors are internal factors that are generated from the business processes that occur within Margamulya coffee producer called KPKM. While the

opportunity and threat factors are external factors that explain things that can affect the business processes within the organization, both direct and indirect.

Fig. 1. Business Environment Analysis.

The next step is to align the business strategy generated from previous analysis into IS/IT strategy needed by KPKM. Critical Success Factor Analysis (CSF) used to map the main factors considered in achieving the organization's vision and mission. Based on the results of CSF, an information system (IS) to be developed was formed, which indirectly support the KPKM business strategy. Those information systems are mapped using McFarlan quadrant.

The last step in Ward & Peppard framework is generate the IT strategy and infrastructure to support the IS strategy. IT requirements are carried out by mapping IS/IT strategic principles with IS requirements.

## IV. RESULT AND ANALYSIS

### A. Internal Analysis

In the formulation of the IS strategy at KPKM, the first step taken is a business analysis from both internal and external sides. Analysis of the business environment aims to see and assess the strength - weakness factors of the internal environment and the opportunities - threat factors of the external environment. These strengths and weaknesses are internal factors that are compiled from the business process that occurs so that the advantages and disadvantages of KPKM are obtained. On the business process, the opportunity and threat factors are external factors that explain things that can affect the running of an organization's business processes, both direct and indirect. Many manufacturers are already leveraging smart plant components in areas such as advanced planning and scheduling with real-time production and inventory data, or augmented reality for maintenance. But a true smart factory is a more inclusive effort, going beyond the manufacturing floor to impact businesses and the wider ecosystem. Smart factories are essential to a wider digital supply network and have multiple aspects that manufacturers can leverage to better adapt to changing markets. On the one hand, industrial policy is designed to encourage exporters by offering special treatment to preferential sectors, such as tax exempt periods, large investors' access to land, and special credit terms [23].

Many manufacturers are already leveraging smart plant components in areas such as advanced planning and scheduling with real-time production and inventory data, or augmented reality for maintenance. But a true smart factory is a more comprehensive effort that goes beyond the manufacturing floor and impacts businesses and the wider ecosystem. Smart factories are essential to a wider digital supply network and have multiple aspects that manufacturers can leverage to better

adapt to changing markets. Based on activity internal to the analysis value chain, subsequently carried out the analysis by doing the identification of the factor of strength and weakness of the activities of internal compiled from the business to get things that become advantages and weaknesses of KPKM in the business, which is based on SWOT analysis in Table I, Internal Analysis.

TABLE I.    INTERNAL ANALYSIS

| S /W | Internal Condition Indicator | Internal Activities |
|---|---|---|
| **Strength** | Has a unique coffee taste characteristic | Cultivation |
| | A good brand image with the various champions that have been achieved | Marketing and cultivation |
| | reliable, has various certificates both national and international | Audit |
| | Has relationships with various business sectors | *Public Relations* |
| **Weakness** | Low accountability | Production, Finance and secretary |
| | A less transparent financial system | Finance |
| | Low Documentation | Finance and marketing |
| | The capital system still depends on the bank | Finance |

### B. Root Cause Analysis

Root Cause analysis is used to identify the root of the problem which becomes weakness KPKM with the results of this analysis will be processed into input as can be seen in Table II, Root Cause Analysis, that later on use as the requirements needed to produce reference solutions. Most organizations cannot focus on just one type of innovation, exploitative or exploratory. Many organizations have specific core competencies that are built over time, which can continually improve these capabilities to increase your productivity to generate additional financial benefits. However, in a volatile and rapidly changing market environment, we cannot focus on improving our existing core competencies. Therefore, exploratory innovation is essential. An important strategic issue for enterprises is to balance exploitative and exploratory innovations, making use of their existing core competencies, while striving to develop new competitive advantages through exploratory innovations. When workplace problems occur, the immediate symptoms are hard to overcome. In other words, the root cause has not been addressed and needs to be fixed multiple times. Organizations that can strike the right balance between the two types of innovation can not only alleviate the tension between two major pathways to innovation, but they can also pursue the synergies between their strengths. In this way, an eye-catching innovation is a rapidly changing market setting where organizational strategies are global, technological advances, dynamic changes, global urbanization trends, and environmental sustainability initiatives to create competitive advantage [19]. To commercialize new technologies, licensing is often used to existing companies rather than by step-by-step, which is the traditional method of technology transfer.

TABLE II.    ROOT CAUSE ANALYSIS

| Problem ( *Effect* ) | Cause ( *Cause* ) |
|---|---|
| Low Accountability | There is no recording process |
| Financial System Lack of Transparency | Financial accountability systems are less informative |
| Low Documentation | Document storage is still paper based |
| | Document storage is not organized and centralized. |
| The financial system is not yet independent | The financial capacity of cooperative members is inadequate |

### C. Requirement Analysis

Requirement analysis is the process of determining user expectations for an application that has been created or modified. In short, it includes every task that is performed to identify the needs of different stakeholders within the organization environment, at certain extent may relate to the culture. Therefore, it means analyzing, documenting, validating and managing software or system requirements that are high-quality documented, workable, measurable, testable and traceable requirements that help identify business opportunities and systems. It is defined to facilitate design. An entrepreneurial process can take place in any enterprise or organization and hence even the government can host such a process. The government's role in entrepreneurship is particularly wide-ranging, given that the decisions and policies adopted can contribute directly to the development of entrepreneurial activity in the sector by both private and public companies [23]. The coffee industry is attracting attention as a product that a large proportion of consumers around the world buy frequently daily at social events, as well as the interest of non-governmental, governmental, multilateral and development professionals with early adoption of certain standard in developing the strategy. Therefore, it is not surprising that coffee remains at the forefront of sustainability initiatives going beyond other agro-industries in response to the growing interest in sustainability [24].

Typically, IT management stakeholders use the integration of enterprise applications strategically from the top down rather than technically from the bottom up. Initially, through the systematic integration of BPM technology, knowledge management technology and social software, supporting the value-added processes of modern enterprises would be an entirely new IT quality. In a good organization, all value-added processes, whether formal or tightly organized and informal, and social processes are subject to management and IT support [26], [27]. The Table III, Requirement Analysis shows the requirement analysis by aligning internal activity and objective of the organization based on internal activity identified in the organization.

### D. External Analysis

External analysis means investigating the company's industry environment, including factors such as competitive structure, competitiveness, dynamics, and history. At the macro level, external analysis includes macroeconomic analysis, global, political, social, demographic and technical analysis. The primary purpose of external analyzes is to identify opportunities and threats in an industry or any sector that drives

profitability, growth and volatility. Firms make decisions on sustainability issues based on available information and management is responsible for considering the best information. In the case of sustainability, decision makers often face complex and ambiguous scenarios, and as a result, they do not make fundamental changes to enhance the company's sustainability. It is also true that companies are becoming more interested in developing environmentally friendly and healthy products, so they should prioritize profits in decision-making and not use them as an excuse to not take any action [24]. It is possible to increase profits while protecting the environment by reducing waste or emissions, in which most occasion, societies still ask more due to the expectation of the industry to take active role in the issues of environmental and ecological.

To complete and support the external analysis, companies need to conduct a survey of the political, economic, social and technical situation of the industry, which is also known as PEST analysis as can be seen in Table IV, PESTEL Analysis. In politics, the analysis on issues such as international trade barriers and changes in the regulatory environment consists of several issues in the economy, such as interest rates, exchange rates and inflation. On the other hand, social demography raises the issue of changing populations and age groups, while technical issues represent scientific progress, research and development investments, and emerging technologies. The main purpose of PEST analysis is to use business plans to test major external shifts in the industry, and strategies must be updated to align with common industry trends. In fact, this data helps organizations get to know their customers better, and suggests increasing sales, especially in the form of differentiating marketing strategies and creating targeted marketing. Companies can also change their supply chain and adapt to obtain more accurate data from their partners [28].

TABLE III.    REQUIREMENT ANALYSIS

| Internal Activity | Objective | Requirements |
|---|---|---|
| Production, Secretary & Finance | Increase accountability | There is periodic reporting of information from each division to the central management |
| | | The existence of a clear and efficient format and recording procedure. |
| Secretary & Finance | Increase the role of information documentation | The documentation process is digitized |
| | | All cross-sectional documents are integrated and can be managed centrally. |
| | | Cooperative documents can be stored safely and can be accessed easily by those who need them |
| Finance | Increase Financial Transparency | The existence of regular reporting in a shorter period of time (per week to per month) |
| | | Financial statement information consists of a complete and accountable collection of data elements |
| | Has an independent financial system | There is access or media that makes it easy for each member to find out the results of cooperative financial reports |
| | | Increase the income and welfare of members |

TABLE IV.    PESTEL ANALYSIS

| PEST (EL) | External Environment | Impact on Organization |
|---|---|---|
| Political | The West Java Provincial Government is specifically paying attention to the coffee industry with the campaign "World Quality Java Preanger, Towards the World Market" | **O-1** Create opportunities to massively market products and receive assistance in various forms (subsidized tools, seeds and training) |
| | Jokowi, as the president, will issue a policy on forest land use under a 30-year contract | **O-2** Cooperatives will find it easier to collaborate with borrowers and sponsors. |
| Economy | Trends in world coffee consumption and foreign currency fluctuations greatly affect the selling price of coffee | **O-3** The selling price of Gunung Tilu coffee can be high |
| | | **T-1** The selling price of Gunung Tilu coffee could be lower |
| | Vulnerability of IJON practice | **T-2** Causes farmers to sell coffee at a lower price and not distribute it to the cooperative |
| Social | The number of coffee industry players in the Bandung Regency environment in particular. | **O-4** Must have relations among themselves because of the need for imports which must have a certain quota |
| | | **O-5** In terms of marketing, in general, between them can complement each other's customer demands. |
| | | **T-3** When the demand for Preanger (West Java) is low, a similar coffee industry can become a competitor |
| | participation of the international community through certification | **O-6** Can guarantee the welfare of farmers |
| Technology | The role of ICT in the industrial world has developed rapidly, therefore adequate infrastructure is needed by cooperatives | **O-7** Can provide competitive advantage, efficiency and various other advantages if implemented properly |
| | | **T-4** If it cannot adapt to developmental conditions, it will be difficult for the competitiveness of KPKM to increase. In the end, it was difficult for KPKM to advance to the level of an independent exporter. |
| Environment | Unpredictable climate change | **T-5** The emergence of various diseases in plants, aham appears and has the potential for crop failure |
| Regulation | The Indonesian government regulates the operation of cooperatives Law 25 of 1992 where the Law requires cooperatives to regulate several principles, capital, business processes and organizational structures that must exist in cooperatives | **O-8** Facilitates cooperatives in shaping their organizational principles and forms. |
| | Law 19 of 2013 regulates agricultural cooperatives in importing, extension services, and land empowerment | **O-9** Make it easy for cooperatives to import and minimize the potential for fraud by competitors |

After defining the strengths, weaknesses, opportunities and threats of the organization, a business strategy is mapped based on a matrix of strengths-opportunities (SO), weaknesses-opportunities (WO), weaknesses-threats (WT) and weaknesses-opportunities (WO) as shown in the following Table V, SWOT analysis.

Based on the SWOT analysis, a business strategy is generated as shown in Table VI, Mapping Business Analysis. Then the new business strategy is then being compared with the old business strategy as depicted in Table VII, Comparison Analysis.

TABLE V.        SWOT ANALYSIS

|  | Strength (4 factors) | Weakness (4 factors) |
|---|---|---|
| **Opportunities (8 factors)** | Strengthen the role of *branding* and marketing functions. [1] | Following international coffee certification. [2] Technology optimization to improve internal / external transparency, customer service quality and data utilization. [3] |
| **Threats (6 factors)** | Carry out research and development efforts [4] Collaborate with organizations that specialize in agriculture and / or meteorology [5] | Implementing an integrated SI, especially in the production, membership (HR), finance and reporting business processes [6] Improvement of education methods and capital systems [7] |

TABLE VI.        MAPPING BUSINESS ANALYSIS

| Internal Business | External Business | Business strategy |
|---|---|---|
| **S-1** Has a unique coffee flavour characteristic | **O-1** Opportunities are created to market massively products and receive assistance in various forms (subsidized tools, seeds and training) | Strengthen the role of *branding* and marketing functions |
| **W-5** The capital system still depends on the bank | **O-5** International Community Can guarantee the welfare of farmers | Following international coffee certification |
| **W-1** Low accountability W-2 A less transparent financial system | **O-6** Can provide competitive advantage, efficiency and various other advantages if implemented properly | Technology optimization to improve internal / external transparency , customer service quality and data utilization |
| **S-1** Has a unique coffee flavour characteristic | **T-2** The selling price of Gunung Tilu coffee could be lower | Conduct research and development efforts |
| **S-4** Has collaborated with various business sectors | **T-6** Bad weather causes crop disease and crop failure | Cooperate with organizations that specialize in agriculture and / or meteorology |
| **W-1** Low accountability **W-2** A less transparent financial system | **T-5** If it cannot adapt to developmental conditions, it will be difficult for the competitiveness of KPKM to increase | Implementing an integrated SI, especially in the production, membership (HR), finance and reporting |

|  |  | business processes |
|---|---|---|
| **W-5** The capital system still depends on the bank | **T-3** Causes farmers to sell coffee at a lower price and not distribute it to the cooperative | Improving education methods and capital systems |

### E. IT Business Alignment Strategy

The points to be considered in the preservation of the coffee industry relate to the role of the natural environment and characteristics of the ecosystem, the existing traditional agricultural knowledge and local farming practices, and the socio-economic conditions of the agricultural community [25]. Consider the development of same concept of smart but different field, the input-output development model, which considers a diverse set of smart city domains, characterizes the externalities of resources, productivity, applications, and establishment processes. "Resources" relates to human resources, knowledge, creativity, ICT infrastructure, and financial assets. Productivity is categorized as "dynamic productivity" and "management and leadership capacity" that adds value to resources and turns them into intended outputs. "Applications" are related to outputs, and "externalities" are management and regulation, technology, governance, policy contexts, people, economic infrastructure, and environmental conditions [29], [30]. Undoubtedly, there is also widespread criticism of the concept of intelligence in relation to an important and important issue that is the fairness of one of the beneficiaries of the smart industry strategy and do local citizens benefit from their investments more than economic and political actors [31].

Increased social distancing affects the number of interactions, the potential for knowledge and creativity sharing, and trust in society. Digital or technological disparities are specific issues that some smart action can address by providing all citizens with access to technology or specific knowledge. While the technology itself opens the gaps, it is taken for granted that smart concepts have a promise to bring them to an end. This has to be anticipated and planned for both cases as there has to be a balance between efficiency and equity that is of course required the support from the government such as the regulatory and tax incentive [32], [33]. In aligning the cooperative business strategy into the KPKM strategy where the information on the analysis process is needed to identify the needs that are in line with the business strategy, which in this case using the Critical Success Factor (CSF) analysis which is used to map the main factors that concern the organization in achieving the organization's vision and mission. Based on the results of observations and interviews, a CSF was obtained for each of the KPKM Business Plans as in Table VIII, Business Plan below. Further based on CSF, the information system is mapped using McFarlan quadrant which divided into four (4) types namely Strategic (St), High Potential (HP), Key Operational (KO), and Support (Sup). The result of mapping analysis can be seen in Table IX, Mapping Using McFarlan Quadrant.

TABLE VII.    COMPARISON ANALYSIS

| No. | Old Business Strategy | New Business Strategies |
|---|---|---|
| 1 | Improve member welfare | Improve member welfare |
| 2 | Expanding the types of products / services | Expanding the types of products / services |
| 3 | Build credibility of cooperatives to stakeholders who have the potential to prosper farmers. | Build credibility of cooperatives to stakeholders who have the potential to prosper farmers. |
| 4 | - | Increase member loyalty and trust |
| 5 | - | Improve product quality |
| 6 | - | Maintain the continuity of the organization |
| 7 | - | Improve service quality |
| 8 | - | Increase market segmentation and penetration |
| 9 | - | Developing an independent capital system |

TABLE VIII.    BUSINESS PLAN

| Strategic theme | Strategy Explanation | CSF | Information Needs | SI Strategies and SI Needs |
|---|---|---|---|---|
| Increased member income | Maximizing the income of each member | Good knowledge and skill | • Knowledge level of member<br>• Member profile<br>• Member needs<br>• Types of training and development | Create a system that can measure and provide information related to member performance and training information.<br> - IS (Information System) training and member profiles integrated into HRIS.<br> - Features measuring the level of knowledge of members integrated in HRIS. |
| Build company credibility towards stakeholders who have the potential to prosper farmers. | Increase trust in consumers, potential consumers as well as partners and prospective partners | Participation in national and international certifications | • Level of certification readiness<br>• Audit report | • Creating a special system related to certification including the specifications for the audit report and documentation requirements.<br>• Creating a reporting system for each part of the cooperative that is centralized to the core board.<br>• Determine the format and recording procedure.<br> - Create an IS Audit |
| Increase member loyalty and trust | Accountability and transparency of assets. | There is informative data on assets and finance | • Subsidies and external assistance<br>• Cooperative finance<br>• Asset and borrowing records | • Realizing the financial reporting mechanism consisting of complete and accountable data elements.<br>• Make it easy for members to access and find out the results of financial reports.<br>• Become a media for routine cooperative financial reporting.<br> - IS Finance<br>• Create IS that can record and notify members regarding old and new assets<br> - IS Asset Management system |
| Expanding the types of products / services | Have product / service innovations in accordance with market needs | Marketing effectiveness<br>The quality of the type of product / service | • Criteria for segmenting prospective customers<br>• Position of organization among competitors<br>• Detailed product / service innovation research | Making IS that can help make organizational decisions in terms of marketing and product / service development.<br> - Customer Relationship Management<br> - IS Marketing<br> - Business Intellegent |
| Improve product quality | Have good product development and production management | • Can consistently maintain product quality<br>• Possess innovative and efficient cultivation and processing techniques | • Product specifications<br>• Type of product processing<br>• Recommendations for cultivation and / or processing innovations | • Build IS that can record and analyze the production process, and can provide suggestions related to improving the quality of cultivation and production.<br> - IS Cultivation and Production |
| Organizational sustainability | Guarantee the regeneration of cooperative | • Have authentic documentation both on the | • Annual Meeting result<br>• Company Profile<br>• Documents of each section | • Creating a reporting system for each part of the cooperative that is centralized to the core board. |

| | | | |
|---|---|---|---|
| management | management and function side of each division of the cooperative.<br>• Cooperatives are able to compete with competitors | of the cooperative | • Determine the format and recording procedure.<br>• Making IS that can digitize the cooperative strategy record (Annual Meeting) and the work of each section.<br>• Keep cooperative documents safely and easily accessible to those who need them .<br>• Making cross-sectional documents can be integrated at the same time can be managed centrally.<br>  - Archive feature in IS Asset Management<br>  - Profile feature on cooperative websites |
| Improve service quality | Improve the quality of service to customers and potential customers | Have services and provide information that can be accessed at any time by customers or prospective customers and can accommodate suggestions or criticism | • Information on services and product variants<br>• Cooperative location and contact information<br>• Payment information | Create various e-banking or fintech features and handle purchasing services<br>- Multi paymnet purchase system<br>- Feature services are contained in the Website |
| Has an independent capital system | Transfer of capital originating from the bank to members and sponsors | Each member is able to contribute a large amount of capital | • Member profile<br>• Member financial level | Provide information on the financial capacity and condition of members (health, children's education, etc.)<br>- Financial data of members in HRIS |

TABLE IX. MAPPING USING MCFARLAN QUADRANT

| Information Systems (IS) | Function | Type | Explanation |
|---|---|---|---|
| Human Resource IS | A system for monitoring the welfare conditions and performance of cooperative members | Sup | This system is only used to support the performance of KPKM members |
| IS Audit | A system for conducting audits and measuring certification readiness. | St | This system can increase the trust of stakeholders who have and will collaborate with KPKM. |
| IS Finance | A system for calculating, recording and managing cooperative finances in detail, accurately and transparently | Sup | This system supports the performance of the KPKM in terms of financial management |
| *Asset Management* | A system that records and manages asset data. Starting from procurement, repair to borrowing assets. | Sup | This system supports the performance of the KPKM in terms of asset management |
| *Customer Relation Management* | A system that analyzes and predicts customer behavior as a decision support tool 3 | St | This system is used to support the performance of the KPKM in identifying customer needs |
| IS *Marketing* | A system that manages all product marketing activities carried out by the marketing department from measuring the performance of the marketing team, achieving sales targets to designing marketing strategies. | HP | With this system, it is hoped that KPKM can improve the performance of marketing activities |
| BI | System To provide information on policy indicators quickly and accurately to cooperative administrators in setting policies. | St | If this system does not exist, the cooperative management will not have accurate information |
| IS Cultivation & Production | A system that helps monitor, manage and make decisions regarding cultivation and production activities | KO | This system helps and provides accurate data about the efficiency, effectiveness and development of cultivation and production processes. |
| Official Website | Help market cooperative products and services, display cooperative profile information, and become a medium for customer service. | HP | With this system, KPKM can facilitate promotional activities and services to customers |
| *Multi paymnet purchase system* | Providing an electronic transaction system through various types of payment methods that make it easier for customers to make transactions. The methods referred to are ATM, *Internet banking, Mobile Banking,* and *E Money* | KO | The absence of this system will make it difficult for KPKM transactions with customers who are familiar with using online-based payments |

Information:

*) Types of Information Systems are classified based on the McFarlan quadrant which is divided into 4 types: *Strategic* (St), *High Potential* (HP), *Key Operational* (KO), and *Support* (Sup).

From the results of the identification of the information system using the CSF method, the results of the needs for the JPIC information system were obtained. The requirements for the JPIC information system can be mapped into the SI strategy portfolio using the McFarlan matrix. Starting with the situation in which all production activities are traditional, industrial cavitation can be considered as a situation in which companies in one country switch to more modern technology and the industrial sector in another country cannot participate in this movement. But in some industries, there are huge multitudes: access to cloud technology, predictive analytics, and IaaS services for both virtual data centers and storage systems, and the use of Monitoring Surveillance and Data Acquisition (SCADA) [34], [35], [36]. KPKM does not yet

have an existing technology-based information system, so the GAP between the existing IS & IT portfolio and the targeting business process is entirely new with the matrix for the SI-KPKM strategy can be seen in Table X, Matrix Strategy. The service operation manages the services the company is currently using, focuses on service management practices.

TABLE X.    MATRIX STRATEGY

| Strategic | High Potential |
|---|---|
| -IS Audit<br>-CRM<br>-BI | *- Official Website*<br>-IS *Marketing* |
| **Support** | **Key Operational** |
| *-Human Resource* (HRIS)<br>-IS *Asset Management*<br>-IS *Finance* | -IS Cultivation and Production<br>*- Multi payment purchase system* |

One of the most important technologies is blockchain technology. In theory this is a clever industry concept that can provide many features such as replacing slow manual steps with fast automation, tracing the origin and characteristics of goods, including raw materials, semi-finished products and finished products. Information that includes passengers, timely payments, insurance and customs payments, and information to regulators about cargo and passengers includes participants such as exporters, importers, and carriers [37]. There are other technologies that are important components of a smart industry, which is the Internet of Things (IoT) provides convenience for continuous spatial analysis over a relatively large coverage area by optimizing between remote sensing and GIS to develop an ecosystem for digital innovation [38]. The growth of new digital industrial technology, also known as Industry Revolution 4.0, is an innovation that allows data to be aggregated and analyzed between machines, with faster and more efficient operations of high-quality products at a lower cost [39]. Other technologies, such as autonomous robotics, cloud computing and augmented reality, can also be seen as supporting the smart industry. Unfortunately, there are certain deficiencies related to the presence of a deteriorated educational system with low training of engineers where a lot of technology transfer but a low absorption capacity due to the small investment of local companies in research and development together with weak infrastructure to support smart industry concept with significance delay and no emphasis on the development of electronic product and weak articulation [40]. To understand the IS strategy in Table X, Matrix Strategy, we describe the application architecture layers consisting of the front office, middle office, and back office as shown in the Fig. 2, Layers of Propose KPKM Application Architecture.

Once the IS strategy has been defined, the IT and infrastructure are generated to support the information system. IT requirements are generated by mapping IS/IT strategic principles and IS requirements. The IT strategy can be seen in Table XI, IT Strategy.

Innovation is a tool to promote the sustainable development of education and attract the attention of teachers, educators and researchers around the world. The introduction of new concepts and technologies into the curriculum and the removal of old concepts and techniques is sometimes referred to as curriculum innovation [41]. The increasing social role of the coexistence of robots, humans, and technology is a precursor to unknown and possibly fundamental changes, but there is no single human perspective to this change [42]. Shifting product development to concurrent engineering mode requires industrial engineers to be actively involved from the initial concept design stage. Therefore, it increases product safety and participation in environmental issues, affecting individual workplaces and society as a whole. Code of Ethics is discussed in [43], [44]. Interestingly, the leading position of such new technological systems that support smart concepts is believed to be of great benefit to the economic catch-up and long-term competitiveness of developing countries [45].

### F. Smart Industry based on Innovation Ecosystem

In terms of innovation, the position and support for employing research and development in the private sector has the strongest impact on patents for all sources of knowledge. In short, the quality of research in the university is very important to contribute to the smart industry [46]. Innovative companies are not isolated, self-sufficient entities, but are very environmentally friendly. This inclusion can have a significant impact on the innovation process, and it is not too far to assume that not all types of environments are equally suitable for a particular type of R&D activity [47]. The production elasticity of spending on R&D can be interpreted as an indicator of the productivity of inputs in the innovation process, and hence the efficiency of the innovation system in a given region. In particular, good availability of inputs for this kind of process, extensive division of innovative work, and superb knowledge among local stakeholders, either in the public research institute or in the private sector brings the flexibility to be relatively high if the site is spread out within company [48]. However, the smallholder coffee sector continues to suffer from a lack of efficient and effective support services such as publishing, credit and input supply. In particular, there is no for-profit company engaged in the growth and dissemination of improved coffee beans [49].

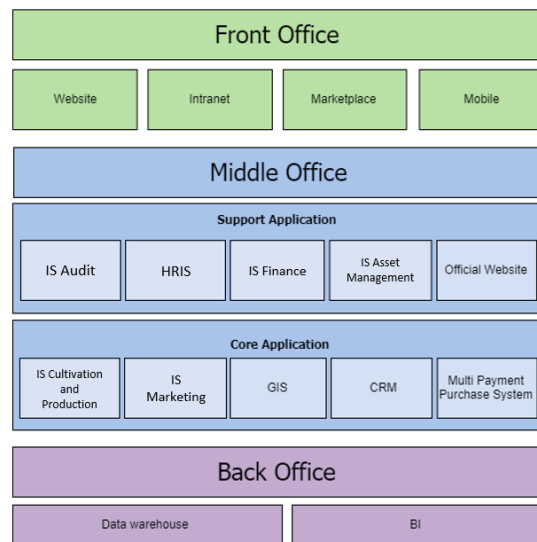

Fig. 2.   Layers of Propose KPKM Application Architecture.

TABLE XI.    IT STRATEGY

| IS/IT strategy based on Int & Ext analysis | Information System (IS) | Information Technology (IT) | Information |
|---|---|---|---|
| The development of IS / IT integration is in line with the business strategy | IS Marketing and Strategy Archive system Multi paymnet purchase system; BI; CRM | Web Server (APACHE); Database Server (MySQL); Platform (PHP); Multipayment Purchase System; BI; CRM | CRM software is recommended to use a third party, namely "FarmLogics". On the other hand, the ATM, Mobile Banking, E-Wallet applications will be connected via the server. |
| Appropriate IT security infrastructure (not under / over protective ) | | Unified Threat Management (UTM); Intrusion Detection System (IDS) | UTM and IDS are needed to deter and detect attacks from external parties |
| IS / IT development in managing and utilizing data | IS Finance; IS Asset Management | DSS; Intranet; Web Server (APACHE); Database Server (MySQL) | The DSS application on IS Finance will be integrated with SI Cultivation and Production to conclude a series of decisions. On the other hand, IS Asset Management will actively record internal borrowing transactions. |
| Development of a data exchange system with the government and certificate providers | IS Audit and Certification | Web Server (APACHE); Database Server (MySQL); Intranet | Data and information exchange system with internal and external auditors. |
| The development of IS / IT supports the level of production and quality of plantation products | IS Cultivation and Production | GIS; Web Server (APACHE); Database Server (MySQL); Android SDK (Java); Intranet | IS Production involves many technologies where GIS will generate geographic plantation information, while SDK will generate technical information (such as seed moisture, moisture content, etc.) |
| Increasing the number and competence of human resources who are experts in the IS / IT field | HRIS | Android SDK (Java); Web Server (APACHE); Database Server (MySQL); Intranet | HRIS uses an integrated and centralized application and website platform on the web server. |
| Adjustment of infrastructure capacity ( network , server , storage ) that supports integrated IS / IT | | LAN network between offices, cafes and warehouses; Core Switch | LAN networks are needed for the acceleration and security of the internal information exchange process. |

Fig. 3.    New Network Topology.

To better understand the proposed infrastructure topology can be seen in Fig. 3, New Network Topology.

Due to the factors and their influence on the adoption of improved coffee production technology, access to credit, availability of non-farm income, level of education, availability of manpower and access to extension services, it is assumed that it has become evident to have a major influence on the adoption of scale. , The gender and age of farmers do not have a significant influence on adoption, suggesting that the improved coffee technology is primarily size, gender and age neutral. On the other hand, the decision to adopt agricultural technology for coffee households depends on their economic situation, farm characteristics, and institutional effectiveness [50]. On the other hand, other descriptive results show that there is a significant difference between employers and non-employees in terms of number of livestock ownership, spades or shovels belongings and model farming. This indicates that the ownership number is a typical farmer in which adult education and the possession of pruning shears have been found to have a positive effect on the adoption of coffee technology. On the other hand, family marriage and radio ownership negatively affected coffee technology adoption. Educating farmers through formal or informal programs, increasing production skills to strengthen and increase the number of exemplary farmers, providing pruning shears and improving the livestock sector focused are good policy recommendations where the presence has been disclosed [51]. On the other hand, the results of the multivariate model showed that the adoption was positively associated with improved recruitment of corn strains and the abandoned cows, which will enhance the adoption of other agricultural technologies. The land area, television, and radio ownership also have positively and significantly influenced the adoption of the improved coffee varieties while the distance to all-weather roads has a negative in decreasing the adoption of coffee varieties due to the remoteness of farmers from roads in all weather conditions. The size of the land and the education of the household heads also have a positive and significant impact on the adoption of improved varieties of maize but the distance between TLU and city area has a big negative effect [52].

TABLE XII.  IS/IT MANAGEMENT STRATEGY

| No. | IS / IT Management | Classification | Description |
|---|---|---|---|
| 1 | Making good IS / IT governance based on *best practices* | Regulation and governance | Design and use IS / IT governance that refers to *best practices* in the JPIC environment |
| 2 | Procurement and improvement of HR competencies in the IS / IT domain | HR | Recruit human resources in accordance with the needs of the cooperative as well as conduct training and briefings. |
| 3 | Addition of IS / IT division | Organizational Structure | Creating a special section that handles Cooperative IS / IT issues |

Aside from infrastructure topology, following in Table XII is the proposed IS/IT Management Strategy for KPKM.

Specialty coffee is standardized throughout the coffee processing cycle, from selecting the criteria for growing coffee to brewing coffee for customers, with an emphasis on fruity, floral and citrus flavors. The coffee is rated higher organoleptic, which in fact that the coffee grounds must be able to pass the side or elementary grading and cupping tests [53]. The economic value of the coffee beans depends on the quality of the flavor, but the quality and quality of cupping for the three types of coffee varies greatly depending on the type and amount of compounds present in the esteemed beans [54]. Unfortunately, in many cases, all used warehouses can be classified as substandard, a condition that accelerates quality deterioration due to moisture loss, coffee weight loss and compensation between management and store managers [55]. After all, coffee has been cultivated, processed, roasted and brewed for many years, and coffee beans make up about 50% of coffee cherries, and it produces a large amount of by-products. In fact, coffee is the second largest commodity after oil and the second most popular beverage after water, and most coffee product manufacturers face high prices for imported raw materials and energy, which is a major factor [56]. Production processes such as extraction and drying are both energy intensity and environmental issues from many studies that have been identified to improve the quality of the flavor and other attribute within the coffee [57], [58].

In order to find out how significant the contribution of the proposed IS/IT strategy in optimization of the smart industry concept, measurements are conducted using the smart industry readiness index. The following Table XIII is the result of smart industry measurement.

TABLE XIII.  SMART INDUSTRY MEASUREMENT

| Dimension | Index | | | | | | Information | |
|---|---|---|---|---|---|---|---|---|
| | 0 | 1 | 2 | 3 | 4 | 5 | Existing | Targeting |
| Vertical Integration | | | | | | | Undefined | Intelligent |
| Horizontal Integration | | | | | | | Undefined | Intelligent |
| Integrated Product Lifecycle | | | | | | | Undefined | Intelligent |
| Shop Floor Automation | | | | | | | Basic | Basic |

| | | | | | | | Existing | Targeting |
|---|---|---|---|---|---|---|---|---|
| Enterprise Automation | | | | | | | None | Flexible |
| Facility Automation | | | | | | | None | Basic |
| Shop Floor Connectivity | | | | | | | None | Interoperable and Secure |
| Enterprise Connectivity | | | | | | | None | Interoperable and Secure |
| Facility Connectivity | | | | | | | None | Interoperable and Secure |

To Be Index

## V. CONCLUSION

In short, smart industry refers to a more responsive organization or company that allows all components in the supply chain to be shared in the form of an innovation ecosystem and uses smart technology to work with a variety of partners. The alignment IT and business strategy can guarantees the most effective transparency and collaboration, which is expected to eliminate the complexity of the existing problems with the development. Organizations manage relationships with different stakeholders, balance the three aspects of social, economic and environmental sustainability, to support green initiatives and plan using information and communications technology. It needs to link the systems and coordinate smart industry integration. It governs with a focus on the needs of customer-driven enterprises, especially using information and communication technology to make decisions, involve multiple stakeholders, and use collaborative methods with internal control and external cooperation.

Further research can describe more specific on the business strategy side. As for IS/IT strategy, further research can provide additional parameters such as financial by adding a Break Event Point to the technology investment list, in order to measure the readiness of cooperative organizations in implementing smart industry.

University of Energy and Natural Resources, Ghana[3, 5, 6]

*Abstract*—This systematic review relied on the Preferred Reporting Items for Systematic reviews and Meta-Analysis (PRISMA) statement and 37 relevant studies. The literature search used search engines including PubMed, Hindawi, SCOPUS, IEEE Xplore, Web of Science, Google Scholar, Wiley Online, Jstor, Taylor and Francis, Ebscohost, and ScienceDirect. This study focused on four aspects: Machine Learning Algorithms, datasets, best-performing algorithms, and software used in coronary heart disease (CHD) predictions. The empirical articles never mentioned 'Reinforcement Learning,' a promising aspect of Machine Learning. Ensemble algorithms showed reasonable accuracy rates but were not common, whereas deep neural networks were poorly represented. Only a few papers applied primary datasets (4 of 37). Logistic Regression (LR), Deep Neural Network (DNN), K-Means, K-Nearest Neighbors (KNN), Support Vector Machine (SVM), and boosting algorithms were the best performing algorithms. This systematic review will be valuable for researchers predicting coronary heart disease using machine learning techniques.

*Keywords—Coronary heart diseases; algorithms; datasets; ensembling algorithms; machine learning; artificial intelligence*

## I. INTRODUCTION

The rate at which people are losing their lives due to cardiovascular disease (CVD) is devastating, with the World Health Organization (WHO) estimating annually 17.9 million deaths globally. The heart and blood vessels [1] are the centers of CVD. There are several types of CVDs, such as coronary heart disease (CHD), abnormal heart rhythms (arrhythmias), and heart muscle disease (cardiomyopathy) with CHD being the primary type of CVD [2], contributing to approximately 64% of all CVDs [3]. Men are mainly affected by CHD compared to women.

In most cases, CHD begins in the fourth decade of life and progresses with age [4]. Recent statistics indicate that continentally, for CVD and CHD, Europe has (44%, 24%), North America (32%, 19%), Latin America and Caribbean (27%, 14%), Asia (35%, 16%), Africa (18%, 9%), and Australia (31%, 16%) respectively making a global percentage of 33% of deaths due to cardiovascular disease in general and 16% of deaths due to coronary heart disease [5]. The most precise method for diagnosing CHD is angiography, but it is invasive and expensive [6]. CVD is a global problem and a leading cause of death in Ghana [7]. Early detection and prognosis are critical for reducing the disease burden. Artificial Intelligence (AI) assists in identifying critical indicators of cardiac disease. AI helps determine disease history and supplies appropriate treatment [8]. AI has several benefits as identified in the literature. These include timely decision-making, helping surgeons perform complex surgeries and tasks, providing accurate cardiovascular imaging, reducing the risks of complex treatments, enhancing cardiology knowledge about patient behavior, and improving computer-aided diagnosis [8]. Artificial Intelligence and Machine Learning Algorithmic research focus on inexpensive, rapid, and non-invasive methods to accurately diagnose all CHD using high-level performance metrics, including Accuracy, precision, specificity, and sensitivity.

AI and machine learning allow computers to find, quantify, and interpret correlations between variables to improve patient care by algorithmically learning optimal data representations[9]. Machine-learning algorithms can sift through considerable amounts of cardiovascular data, making it easier to uncover predictive, diagnostic, and therapeutic options for various cardiovascular diseases. There are three types of machine learning algorithms: unsupervised, supervised, and reinforcement learning [10]. Supervised learning is a robust approach that uses machine language to classify and interpret labelled cardiovascular data [11]. For instance, in supervised learning, a physicist may seek to determine whether a particular electrocardiogram represents sinus rhythm or coronary artery, or ventricular fibrillation? Thus, supervised learning requires a dataset with predictor variables, also known as features in machine learning terminology, and labelled outcomes [9]. Unsupervised learning attempts to uncover the underlying structure or correlations between variables in a dataset [12]. This dataset was trained without explicit labels, and the algorithm clustered the data to identify the underlying patterns. Based on behavioural psychology, reinforcement learning employs a different strategy in which a software program operates in a pre-determined environment to maximise a reward. The main objective of this systematic literature review was to determine which supervised machine learning algorithms exhibit the best

results for coronary heart disease prediction. In this systematic review: 1) the authors identified studies that employed machine learning techniques to diagnose coronary heart diseases in this systematic review; 2) to determine the most utilized supervised machine learning algorithms for coronary heart disease prediction; 3) to evaluate the performance of supervised machine learning algorithms relative to selected features such as Accuracy, specificity, sensitivity, and precision; and 4) to analyze the data sources for predicting coronary heart disease. The outcomes of this review will contribute to policy directions, practice, and further research on cardiovascular diseases, mainly coronary heart disease. The following sections are as follows: Section II, Materials and Methods, Section III, Literature Review, Section IV, Discussion, and the final part is Conclusion and future work.

## II. MATERIALS AND METHODS

This systematic review adopted the Preferred Reporting Items for Systematic reviews and Meta-Analysis (PRISMA) statement. PRISMA is a collection of elements used to report systematic reviews and meta-analyses [13]. This approach is intended to help report reviews and assess randomized trials [14], but may also be used as a foundation for reporting systematic reviews [15]. Following the PRISMA approach, this study considered research questions guiding the review, literature search criteria, and selection criteria.

### A. Literature Search Criteria

Our selection criteria identified relevant published research and review papers by using keywords such as cardiology, cardiovascular disease, coronary heart disease, ischemic heart disease, coronary artery disease, machine learning algorithms, machine learning techniques, data mining, and artificial intelligence in cardiovascular disease. This study adopted composite literature search criteria which combine keywords using Boolean operators such as AND, --, ",", ~, and OR. The search engines used included PubMed, Hindawi, SCOPUS, IEEE Xplore, Web of Science, Google Scholar, Wiley Online, Jstor, Taylor and Francis, Ebscohost, and ScienceDirect. Furthermore, the search outcome produced over 563 papers, of which 37 were deemed appropriate based on the selection criteria of this study.

### B. Selection Criteria

The study utilized peer-reviewed papers published in the English language only. Table I lists the exclusion and inclusion criteria used in this study. These peer-reviewed papers focused on the application of Machine Learning Techniques in investigating CHD. The selection criteria excluded non-peer-reviewed articles such as Dissertation, theses, books, chapters, etc. were excluded from the review.

TABLE I.     ARTICLE SELECTION CRITERIA

| Features | Inclusion Criteria | Exclusion Criteria |
|---|---|---|
| Language of Publication | English language | Not in the English Language |
| Research Type | Peer-reviewed | Thesis/Dissertation, case studies, books, reports, and magazines. |
| Research Focus | Related to ML techniques in CHD. | Not related to ML and CHD |
| Context | Global | Not Applicable (N/A) |

## III. RESULTS

A literature search of the above databases identified 563 publications (Fig. 1). Screening by title indicated that 374 papers did not meet the selection criteria for this review. Additional screening by abstract revealed that 75 studies did not match the focus of the review. In contrast, full-text screening of the remaining papers revealed that 108 articles were related and did not apply machine learning techniques to CHD. Therefore, these papers were excluded from the final list. Finally, 37 articles on the implementation of ML algorithms in CHDs were included in this review.

The reference lists of the 37 studies used in this review are listed in Table II. In the literature, it was found that these papers focused on three major areas: 1) CHD Prediction, 2) CHD detection, and 3) CHD diagnosis using ML techniques. A significant proportion of the studies aimed at predicting CHD were based on risk factors and classification methods. The retrieved papers covered 2014, 2016, 2017, 2018, 2019, 2020, and 2021. Fig. 2 depicts the rate of the collected publications on the phenomenon over the periods. The number of publications varied slowly over time except from 2018 to 2019, which saw a significant increase (from 3 to 12 papers). Our search results revealed no studies on CHD prediction using ML methods in 2015 and before 2014. This may be explained by the limited access to open datasets and the arguably emerging nature of ML methods before 2014. The focused nature of the topic and its accompanying paper selection process can also be attributed to the absence of studies in 2015. The number of publications on this phenomenon decreased from 12 in 2019 to 7 in 2020.

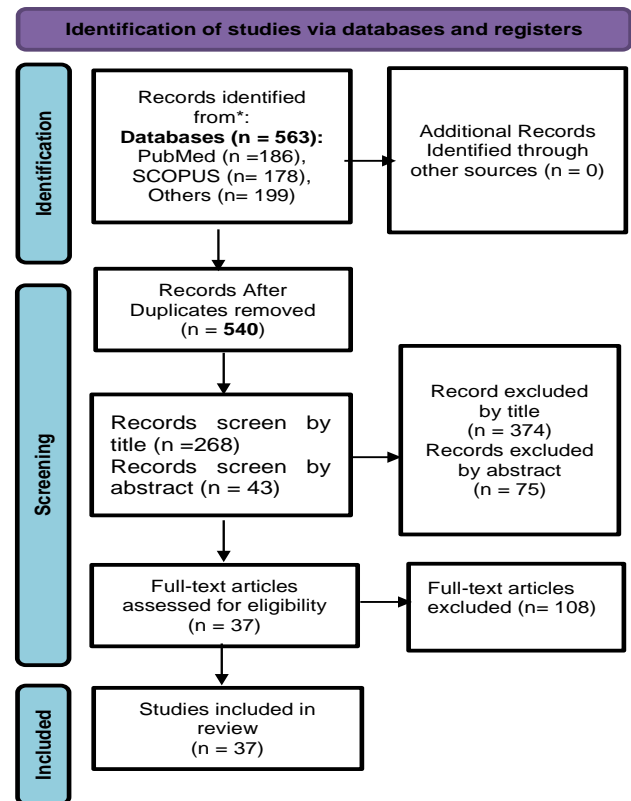

Fig. 1.   PRISMA Flow Diagram.

### A.  Algorithm

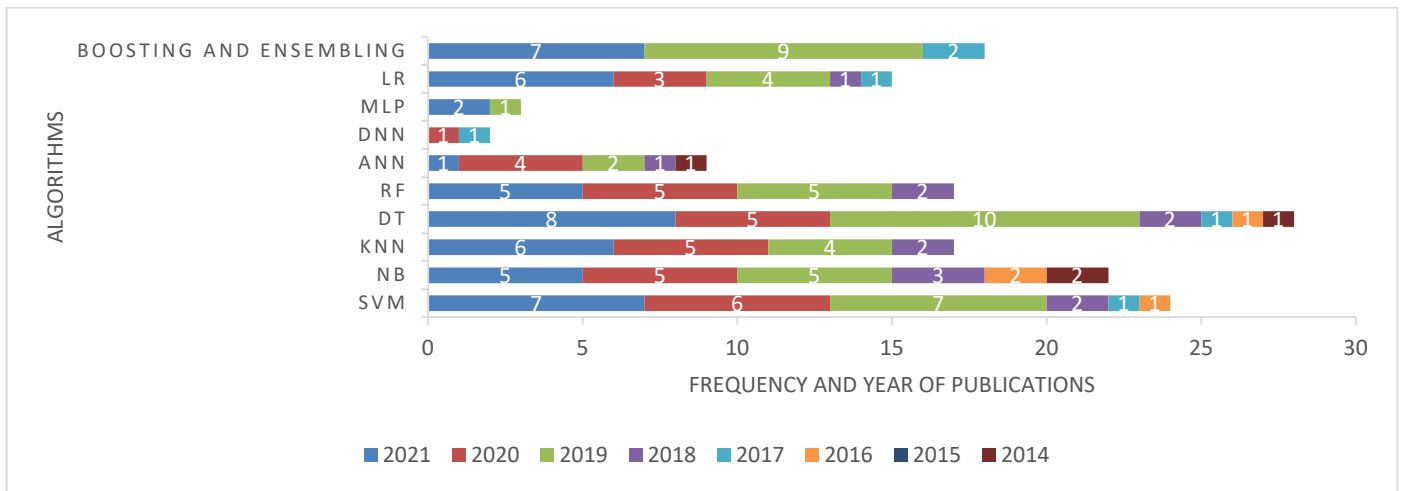
This review considers all reported algorithms applied in previous studies. Table III and Fig. 3 show a group of algorithms applied in the 37 papers and the number of papers that adopted these methods. The review revealed that the most frequently used machine learning algorithms was Decision Tree (n=26, 24%), followed by support vector machines (n=24, 22%), Naïve Bayes (n=23, 21%), K-Nearest Neighbors (n= 19, 17%) and random forests (n=18, 16%). All studies employed multiple algorithms. Few employed five (5) (DT, KNN, SVM, RF, and NN) supervised learning ML algorithms and compared their predictive performance [18]. More than 95% of the studies employed supervised classification algorithms to process features. From Fig. 3, it can be observed that SVM, DT, and KNN retained their popularity. DT has attracted more attention in this field than the other algorithms. Over the periods (2014, 2016, 2017, 2018, 2019, 2020, and 2021), at least one article has been published using DT. SVM and Naïve Bayes have almost the same usage frequencies as DT. Another frequently used method is Logistic regression. Although Deep Neural Networks have demonstrated high predictive power, they have recorded few applications in the field of CHDs. 2017, 2019, and 2021 recorded an increasing usage of boosting and assembling techniques from 2 to 9 publications and a slight decrease to 7 in 2021. From Table II, it is noticeable that XGBoost, Adaboost, Boosted DT, and other ensemble techniques were applied. In addition, while no paper reported the application of reinforcement methods, only one article used an unsupervised algorithm (K-Means) to predict CHDs, although the algorithm performed well. Computational-intelligence-based methods, such as neural networks, have recorded the lowest number of applications.


Fig. 3.   Shows the Yearly usage Frequencies of Popular ML Methods for CHD Prediction.

TABLE III.     ML ALGORITHMS APPLIED IN OBSERVED WORKS

| Algorithms | No. of Papers |
|---|---|
| Support Vector Machine | 24 |
| Naïve Bayes | 23 |
| K-Nearest Neighbors | 19 |
| Decision Tree | 26 |
| Random Forest | 18 |
| Neural Network | 14 |
| Regression | 17 |
| Boosting & Ensembles | 19 |

*B. Algorithm Performance Metrics*

One of the most crucial processes in the machine learning prediction process is model evaluation. A model's performance can be assessed using a variety of metrics. During the training process, measurements are frequently performed on unseen samples. The model performance measurement metrics used in the included studies were Accuracy, Precision, Recall/Sensitivity, Specificity, and F1 Score. The review revealed that the most used evaluation metrics in CHD prediction are Accuracy, followed by Recall/Sensitivity, F1 Score, Precision, and Specificity. Table IV shows that out of the 37 papers included, 36 reported the accuracy scores of the models used for the prediction. Supplementary Fig. 4 shows the usage percentages of the metrics in the investigated articles. This analysis focused on examining the performance of the algorithms applied in previous studies. However, because it is not advisable to "directly compare the efficiency of two algorithms or systems if they were evaluated on different datasets" [13], the evaluation of the best-performing algorithms is based on the datasets used. Drawing on the most used evaluation method (i.e. Accuracy), the best performing algorithms were determined based on the mean values of the accuracy scores of the models obtained from the 37 papers. As clinical data and study scope differ greatly among disease prediction studies, a comparison can only be made after a consistent benchmark on the dataset and scope are established. Therefore, only studies

that implemented multiple machine learning methods were selected to compare the same data and disease prediction. The authors determined the best-performing algorithm for the phenomenon by comparing the mean accuracy scores of the models that utilized the same datasets. Table V lists the algorithms used on the different datasets and the computed mean scores in terms of specificity, Recall/sensitivity, precision, F1 score, and Accuracy. The current study draws on the computed average scores of the 36 studies to rank the most performing algorithms.

Thus, the higher the accuracy of an algorithm, the higher is the chance of making an accurate prediction. Fig. 5 indicates that among the common algorithms applied on the Z-Alizadeh Sani Heart Disease Dataset, LR (87.51%) had a higher predictive accuracy rate, followed by RF (86.07%), NN (85.74%), SVM (85.55%), KNN (75.72%), NB (68.34%), and DT (68.95%). For the Statlog Heart Disease Dataset, the DNN (98.15%) algorithm obtained the highest predictive accuracy score, as shown in Fig. 6. On this dataset, SVM, LR, NB, NN, and KNN obtained accuracy scores greater than 90%, indicating that these algorithms make significant contributions to disease predictions. Only four algorithms (DNN, DT, KNN, and SVM) have been applied to the long beach dataset so far per the findings of this review. In terms of the best performance, Fig. 7 shows that the DNN has a higher predictive accuracy score compared to the remaining algorithms for the long beach dataset. Fig. 8 and 11 show that the MLP-NN algorithm obtained the highest accuracy rates on the Framingham (73.4%) and South African Heart Disease datasets (73.4%).

TABLE IV.     ALGORITHM PERFORMANCE METRICS APPLIED IN THE OBSERVED STUDIES

| Metric | Number of studies |
|---|---|
| Accuracy | 36 |
| F1 Score | 15 |
| Precision | 13 |
| Recall/Sensitivity | 20 |
| Specificity | 10 |
Fig. 4.  Number of Algorithm Performance Metrics Applied in Observed Studies.

TABLE V.  ALGORITHM PERFORMANCE BASED ON EVALUATION METRICS AND DATASETS

| Dataset | Sample Size | Algorithms | ACC | F1 | Recall/Sensitivity | Specificity |
|---|---|---|---|---|---|---|
| Z-Alizadeh Sani Heart Disease | 303 | DT | 68.95 | 85.31 | 90.77 | - |

Fig. 5.    Best Performing Algorithm - Z-Alizadeh Sani Heart Disease Dataset.

In the KHANNES and Cleveland heart disease dataset, it was found that the ensemble algorithms performed better than single algorithms. This is evident from Fig 7, Fig. 9, Fig 10, and Fig. 11, respectively. In Table VI, the primary dataset names and metrics and the corresponding machine learning algorithms used to predict them are discussed. This table also describes the best-performing algorithm for each model. From the clinical data obtained from primary sources, it was observed that the SVM algorithm is applied most frequently (in all four datasets), followed by the NB algorithm (in 3 datasets). Although AdaBoost has been considered the second least number of times, it showed the highest percentage (i.e. 90.12%) in revealing superior Accuracy followed by SVM.

## C. Datasets and Data Source

In machine learning, datasets must be trained to test models for accurate predictions. In the studies reviewed in our research, two primary data sources were observed: (1) open access; and (2) unpublished primary datasets (Fig. 13). The open-access datasets employed in these studies include the Z-Alizadeh Sani, Cleveland, Statlog, Framingham Heart Study, South African Heart Disease, Long Beach, and KNHANES datasets. These datasets can be accessed from the UCI machine learning data repository. The open-access group comprises thirty-six studies and five databases (Table VII), but some datasets were used in more than one study. For example, [32][30] used the Cleveland Heart disease dataset obtained from the UCI database. The dataset contained 303 patients with heart diseases. According to the homepage of the dataset, most researchers allude to utilizing a subset of 14 of the 76 features. The subset includes sex, age, maximum heart rate achieved, chest pain type, serum cholesterol in mg/dl, fasting blood sugar, resting blood pressure, resting electrocardiographic results, exercise-induced angina, ST depression, number of major vessels and diagnosis of heart disease (the predictable attribute), and the slope of the peak exercise ST segment. Out of the 37 papers used in this study, ten (10) articles used the dataset to study the prediction of CHDs. The second most popular dataset used in previous CHD prediction studies was the Z-Alizadeh Sani heart disease dataset. The dataset contains features arranged into four groups: demographic, symptom and examination, ECG, and laboratory and echo features. It categorizes patients into CAD or Normal if their diameter narrowing is greater than or equal to 50%, and otherwise as Normal. The dataset was employed in six studies and is accessible from the UCI Repository. The Statlog heart disease database has 13 attributes that include age, sex, chest pain type (4 values), resting blood pressure, serum cholesterol in mg/dl, fasting blood sugar > 120 mg/dl, resting electrocardiographic results (values 0,1,2), maximum heart rate achieved, exercise-induced angina, old peak = ST depression induced by exercise relative to rest, the slope of the peak exercise ST segment, number of major vessels (0-3)

colored by fluoroscopy, and thal. Two researches used the Framingham dataset, which is openly accessible on Kaggle.com. The data is from an active cardiac study on Massachusett and Framingham residents. The classification objective was to determine the patient's 10-year risk of CHD. The dataset contains more than 4,000 patient information and 15 features. Every feature is a prospective risk indicator. The risk indicators include behavioral, medical, and demographic factors. One study used a Dataset obtained from the Korean National Health and Nutrition Examination Survey VI (KNHANES-VI) to develop a CHD prediction model. These studies reported 25,340 records without previous myocardial infarction or angina from the KNHANES dataset.

### D. Software/Tools used for the CHD Prediction

Machine learning-based approaches are commonly used to predict CHD. Several tools and programming techniques are used for developing the models for the predictions. The reviewed studies utilized different software for the analyses. These software/tools were categorized into programming and data mining software (Fig. 12). The programming software for machine learning data analysis reported by the studies includes Python programming environments such as Jupyter Notebook and the R programming environment RStudio. WEKA, MATLAB, and Rapid Miner are the commonly used data mining software for CHD prediction in these studies. Of the 27 papers reviewed, 63% (17 articles) reported on the software used. Out of these, 65% used data mining tools, while the remaining 35% used programming technologies. A comparison and evaluation of the different algorithms showed the highest prediction accuracy with the programming tools. Several algorithms, such as DT, RF, SVM, NN, and LR, have been tested on the Framingham Heart Disease dataset, for example, using Rapid Miner and R. The results showed that DT, RF, SVM, NN, and LR achieved accuracy rates of 84%, 78%, 68%, 71%, and 66% with R. Accuracy values obtained with Rapid Miner were as follows; DT (62%), RF (63%), SVM (68%), NN (68%), and LR (67%). The evaluation results show that the accuracy, specificity, and recall values of the various algorithms improved with R.

TABLE VII.    SOFTWARE USED FOR ML DATA ANALYSES

| Study | Software/Tool | Algorithm | Accuracy |
|---|---|---|---|
| [41] | WEKA | J48, BF Tree, REP Tree, NB Tree | 55.77, 62.04, 60.06, 60.06 |
| [18] | R | LR, DT, RF, SVM, NN, KNN | 87.64, 79.78, 87.64, 86.52, 93.03, 84.27 |
| [45] | R | SVM, ANN | NR |
| [49] | R | DT, Boosted DT, RF, SVM, NN, LR | 84, 84, 78, 68, 71, 66 |
| [49] | Rapid Miner | DT, Boosted DT, RF, SVM, NN, LR | 62, 62, 63, 68, 68, 67 |
| [22] | Python | DT, LR, KNN, NB, SVM | 82.45, 83.12, 81.12, 83.14, 86.03 |
| [19] | WEKA | DT, NB, SVM | 70.70, 71.60, 71.00 |
| [26] | WEKA | SVM, MLP NN, KNN, LR | 73.80, 73.40, 73.20, 72.70 |

## IV. DISCUSSION

This study systematically reviewed 37 studies that utilized machine learning algorithms for CHD prediction. Following the review questions, the study sought to identify the ML algorithms used for CHD predictions, evaluation techniques used and best-performing algorithms, the dataset used, and the software used for the analysis. The outcome of this review highlights the state-of-the-art ML Algorithms applied in predicting CHDs, their performance, and gaps future studies should pay attention to. The results show that previous studies have focused on supervised machine learning classification-based algorithms for observed algorithms. The review indicated that Decision trees, support vector machines, naïve Bayes, and K-Nearest Neighbors were the most utilized algorithms in CHD prediction studies, followed by Random Forest, Logistic Regression, Neural Network, and Bagging and Ensemble algorithms. There is insufficient application of innovative and sophisticated ensemble algorithms such as XGBoost despite gaining popularity as "an ensemble method that has empirically proven to be a highly effective approach by gaining the best results in numerous machine learning competitions" [13]. For CHD prediction using ML, only one study [20] implemented XGBoost. Adaboost, Boosted Decision Tree, and Bagging have received minimal attention

despite their promising performance. Moreover, only one study employed the K-Means clustering algorithm. ML approaches can solve regression and clusterization problems, but such works were not observed in the reviewed articles. Many predictions were performed through binary options selection only. The review also revealed that in all the experimental works, single studies applied and compared multiple algorithms (e.g., five to ten algorithms in a single paper). This variety is considered to be more appropriate than a single algorithm for CHD prediction. Similarly, no study has reported on the use of the RL method. This could be due to the complexity of the RL algorithms, and the lack of relevant data, as pointed out by [13]. Nonetheless, the application of RL in medicine is rapidly gaining attention and requires a closer examination in CHD. State-of-the-art algorithms remain outside existing studies. Thus, the application of cutting-edge ML algorithms in CHD remains immature.

This systematic review also focused on investigating the most performing ML algorithms for CHD prediction based on reported evaluation techniques. The study identified five (5) performance measurement metrics for model evaluation. These are as follows precision, F1 Score, Accuracy, specificity, and recall/sensitivity. This number is considered sizeable for comparing and understanding the research results. Including other metrics such as AUC in future studies is imperative. AUC is regarded as a better measure of classifiers than Accuracy due to its unbiased nature on the test data. In terms of best-performing algorithms, the findings showed that boosting algorithms perform better than single algorithms for CHD prediction in terms of Accuracy comparison. This result contradicts the findings of [51] because the authors measured the performance of the algorithms using the AUC evaluation metric. In general, the overall analyses show that the Accuracy of ML algorithms are mostly between 0.8 and 0.9+ in CHD prediction. This indicates that the predictive ability of ML algorithms in CHD is promising, particularly with LR, DNN, K-Means, KNN, SVM, and boosting algorithms. However, there may be methodological barriers to matching clinician-level Accuracy. For example, there are insufficient cases for model training and testing. Therefore, further studies comparing ML models and human expertise are required. In addition, the optimal cut-off for Accuracy remains unclear in the examined studies. For instance, an AUC score of 0.95 or more is recommended, but this is not clear with Accuracy.

The review also indicated that out of the 37 studies, only five (5) employed primary clinical datasets. It is suggested that such data be used in future studies to increase the commitment to predicting real-life CHDs in local environments. This allows for comparing the results and seeing the real advantages or disadvantages of the proposed algorithms. The study also suggests that the publication of primary clinical datasets and research papers will positively impact future developments. The review found no standard guidelines for data partitioning. Most studies used a 10-fold cross-validation technique and a 70/30 or 80/20 splitting method for the training and validation sets. In addition, because the sample size of most datasets was relatively small, the pooled results could be biased. This systematic review shows that most studies employed data mining tools more than programming

software, including R, Python (Jupyter Notebook, Google Collab, etc.). In general, the predictive performances in terms of the accuracy scores of the algorithms (i.e., SVM, DT, NN, RF, LR, and Boosted DT) obtained with the data mining software improved with R and Python on the same dataset. However, the runtime of a given algorithm is also crucial because if such a system is to be employed in intensive care units, a speedy decision needs to be made.

### A. Gaps and Future Research Directions

This novel work represents the first systematic review of machine learning predictions in CHDs. Given that predicting diseases can help draw attention to avoidable interventions, it is imperative to know the state-of-the-art predictive models, their predictive performance, the nature of datasets, and the technologies for analysis. This review is important because it offers an opportunity to improve these models. Based on the findings of this study, future researchers should consider the following gaps:

*1)* A lot more studies employing XGBoost, deep neural networks are anticipated.

*2)* Limited studies focused on clustering and RL algorithms.

*3)* More studies employing ensemble algorithms, such as the ensemble of Logistic Regression (LR) and Support Vector Machine are suggested for improved prediction.

*4)* Nearly half of the included studies were conducted in the USA or China. Studies from Oceania, Africa, and the Americas (outside the USA) were limited. This may be partly due to the limited availability of traditional structured health data. Further studies from the perspective of developing countries are required.

*5)* A dominant reliance on small sample-sized datasets in the included studies. Considering that this may impact the performance of machine learning algorithms, studies with higher data sample sizes are required.

*6)* Included studies rarely assessed predictive performance in terms of AUC, which is posited to be the best accuracy measurement metric for classifiers. Future studies may focus on having AUC as a model performance metric measure.

## V. CONCLUSION

Although CHD predictions using machine learning applications are being widely researched, many issues remain unaddressed. This study employed a systematic literature review technique to investigate the state-of-the-art ML algorithms used for CHD predictions, evaluation techniques used and best-performing algorithms, the dataset used, and software used for the analyses. The study revealed that a variety of algorithms can be applied to CHD predictions. However, all approaches belong to a class of supervised learning classification methods; most studies utilize published data, whereas fewer studies use primary clinical data. LR, DNN, K-Means, KNN, SVM, and boosting algorithms were found to be the best performing algorithms for CHD prediction; and programming data analysis techniques such as R, and Python were found to produce higher predictive scores than data mining tools such as Rapid miner, WEKA, and

MATLAB. This study has some limitations. For instance, only papers from multidisciplinary peer-reviewed databases were, but we did not include articles found in the gray literature. Theses and book chapters are excluded. Considering that CHD is the third cause of total global deaths, understanding the most performing algorithms and software environment for predicting or diagnosing the disease will guide health practitioners and researchers in making proactive decisions to reduce the dangers. The study discovered that the DT algorithm was used the most (in 28 studies), followed by the SVM method (in 24 studies). However, the LR, DNN, K-Means, KNN, and SVM algorithms performed better in comparison. LR demonstrated the highest accuracy, 52 percent, in 8 of the 37 investigations where it was used. This was followed by DNN, which came out on top in 41% of the experiments analyzed.

*Abstract*—**Human Activity Recognition (HAR) has become a well-liked subject in study as of its broad application. With the growth of deep learning, novel thoughts have emerged to tackle HAR issues. One example is recognizing human behaviors without exposing a person's identify. Advanced computer vision approaches, on the other hand, are still thought to be potential development directions for constructing a human activity classification approach from a series of video frames. To solve this issue, a deep learning neural network technique using Depthwise Separable Convolution (DSC) with Bidirectional Long Short-Term Memory (DSC-BLSTM) is proposed here. The redeeming features of the proposed network system comprises a DSC convolution that helps to reduce not only the number of learnable parameters but also computational cost in together training and testing method The bidirectional LSTM process can combine the positive and the negative time direction. The proposed method comprises of three phases, which includes Video data preparation, Feature Extraction using Depthwise Separable Convolution Neural Network algorithm and DSC-BLSTM algorithm. The proposed DSC-BLSTM method obtains high accuracy, F1-score when compared to other HAR algorithms like MC-HF-SVM, Baseline LSTM Bidir-LSTM algorithms.**

*Keywords—Activity recognition; long short-term memory (LSTM); deep learning; feature extraction*

## I. INTRODUCTION

The Human Activity Recognition (HAR) system, a broadly used pattern recognition system discussed by [1], can be separated into numerous parts such as feature extraction, sensing segmentation, post-processing and classification ([11], [15]–[19]). HAR systems can be classified into two categories acceleration-based and time-based. Acceleration-based techniques need several accelerometers to be used for data gathering, but time-based techniques normally require the use of additional cameras to gather data. The drawback of the acceleration technique is that it can cause discomfort to the human body when performing behavior such as running, lying down and walking.

The different human activities to be observed in this paper include hand washing, punching, kicking, yoga, riding a bike, curling hair, ice skating etc. The benefit of a vision-based system is that the sensor works without attaching to the body.

The detection of performance depends on illumination surroundings, screening angle, and extra factors. The paper proposed a system that uses a kinetics data set [3] and a MobileNetV2 structure with Bidirectional Long Short-Term Memory (Bidir-LSTM) classification ([4], [25]) to solve this problem. This can decrease the actions of the handcraft procedure and boost the accuracy [20].

Human activity recognition is the problem of recognizing and classifying specific human actions executed in video frames. An instance of such a human action could be kicking or pull-ups. A classification can be trained on specific instances of an activity (training set) and then tested on a specific instance of an activity (test set). The aim of the system is to recognize the proper class of action to which a video frame belongs, or further generally, to recognize and appreciate what the human is doing in the video frames [13].

MobileNetV2 is 2D resource efficient architecture. It implements of MobileNetV1 using depth-wise separable convolutions. It establishes 2 novel sections: 1) linear bottlenecks among the layers, and 2) shortcut connections among the bottlenecks. The design is following the dimension that reduces amount of channels and extracts as much as information by depth-wise convolution after decompressing the data. This convolutional module permits reducing memory usage during inference ([21], [23]).

The objective of this Human activity recognition is to extend the deep learning approaches currently being developed, specifically targeting classification and potentially training/retraining on constrained computing environments. However, an integration of Depthwise Separable Convolution with LSTMs incurs significant computational expenses and prevents the network from running in real-time. To solve this problem, this paper introduced a Depthwise Separable Convolution with Bidirectional-LSTM (DSC-BLSTM) principles to reduce computational costs.

The rest of the paper is organized as follows: Related work is detailed in Section 2. In Section 3, proposed methodology of video frame extraction and Depthwise Separable Convolution with Bidirectional-LSTM (DSC-BLSTM) are described. In Section 4, experimental results and discussion are described finally conclusion portion is in Section 5.

## II.   RELATED WORK

Das and Chakrabarty [5] have presented human gender detection system approach. The Silhouettes from Center for Biometrics and Security Research (CASIA) step are portioned to recognize main body locations and to produce equivalent point-light demonstrate. The attributes such as two dimensional coordinates of main body locations and combined positions are mined from the point-light present. The attributes are categorized using Support Vector Machines (SVM) and Hidden Markov Model (HMM). The revision performs a detection rate of 76.79 percent and 69.18 percent with 100 subject data using SVM and HMM correspondingly.

Hammerla et al., [6] authors use sensor data that contains different motions, explored deep, convolution and recurrent approaches on these datasets. A new proposal has been put forth for regularization of recurrent networks. They have concluded that discovered recurrent networks outstripped the state-of-art and illustrated sample by sample prediction of physical activity.

Munzner et al [7], has evaluated PAMP2 and RBK dataset with convolutional neural network. The article illustrates the outperformance of early fusion technique over late -hybrid fusion by improvising F1 -score on RBK dataset.

M. Panwar et al., [8], discussed various developments that had taken place in human activity recognition using different machine learning approaches. Though, feature engineering has conquered conventional techniques connecting the complicated procedure of best feature selection. This difficulty has been mitigated by using a new method based on deep learning framework which automatically mines the positive features and decrease the processing cost.

A. Jain and V. Kanhangad [9] proposed a descriptor-based approach for action prediction using built-in sensors of smart-phones. Gyroscope and accelerometer sensor signals are obtained to recognize the behaviors achieved by the client. The authors described a histogram of gradient and centroid signature-based Fourier descriptor that are utilized to mine feature or attribute sets from these signals. Attribute and gain level synthesis are discovered for in order fusion.

A. Ignatov [10] presented a user-independent deep learning-based approach for online human activity classification. The authors proposed Convolutional Neural Networks for local attribute extraction jointly with plain arithmetical attributes that conserve information regarding the large-scale form of time series. Moreover, they investigated the crash of time series length on the identification accuracy and boundary it up to one second that builds potential and permanent real-time action prediction.

## III.   PROPOSED METHODOLOGY

The proposed Depthwise Separable Convolution with Bidirectional-LSTM (DSC-BLSTM) technique performs to test the experimentations that were accomplished with kinetics-400 dataset [3]. The DSC-BLSTM algorithm successfully detects the human activity in video frames and is grouped into different activity classes. The overall DSC-BLSTM workflow is illustrated in Fig. 2.

### A.   Video Frame Extraction

Video frame extraction is executed with Kinetics 400 action recognition dataset of action videos, accumulated from YouTube. With 306,245 short trimmed videos from 400 action categories. It is one of the largest and most widely used dataset in the research community for benchmarking state-of-the-art video action recognition models [24], described in Fig. 1. Since some YouTube links are expired, so could only download 234,584 of the original datasets, thus missing 11,951 videos from the training set, which are about 5%. This leads to a slight drop in performance of about 0.5%. The example video frame extraction result of riding camel video illustrated in Fig. 3.

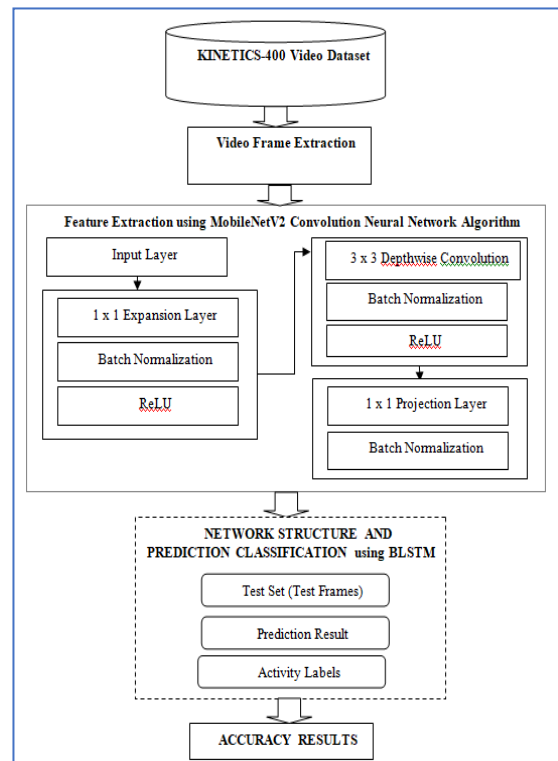

Fig. 2.   Proposed DSC-BLSTM Algorithm Flow Diagram.
Fig. 3.    Video Frame Extraction Result.

### B. Feature Extraction using Depthwise Separable Convolution Neural Network Algorithm

The Feature extraction using MobileNetV2 convolution network using DSC is a factorized form of the standard convolution. The initial feature extraction layer is a 1 x 1 expansion layer. It increases the data (enhancing the number of channels) that flows through it. It does the opposite of the projection layer. The each video frame gets expanded based on the expansion factor [22]. This is a hyper parameter to be found from different architecture trade-offs. The default expansion factor is 6. A normal convolution is separated into a DC and a 1 x 1 PC. Instead of applying each filter to all the channels of the input like the standard convolution, the DC layer applies one filter to one input channel, then a 1x1 PC is employed to combine the outputs of the DC. DSC helps to reduce not only the number of learnable parameters but also the computational cost in both training and testing process. The flow diagram of DSC is described in Fig. 4.

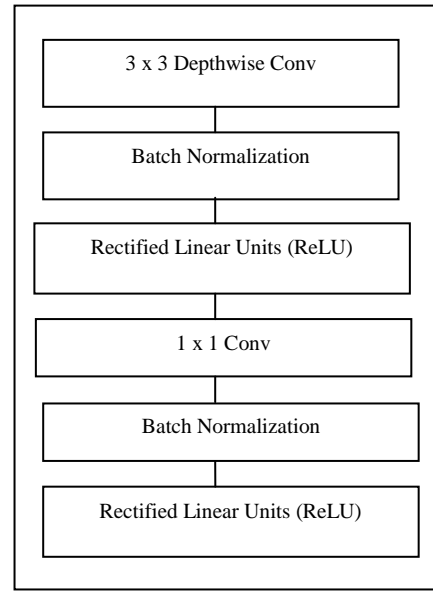

Fig. 4.    Flow Diagram of DSC.

The proposed system of DSC is performed by 2 layers: 1) Depthwise Convolutions (DC) and 2) Point wise Convolutions (PC). The every input (contribution) channel (contribution depth) is applied by a filter with DC PC is a simple 1 x 1 convolution, is used to build linear permutation of the result of DC layer. MobileNets utilize equally batchnorm and ReLU nonlinearities layers. DC with single filter for each contribution channel can be written as:

$$Fmap_{k,m,n} = \sum_{a,b} Dw_{i,j,n} \cdot F_{k+i-1,m+j-1,n} \quad eqn. \tag{1}$$

where Dw is the DC kernel size $Dw_{k*}Dw_{K*}$ N where $n^{th}$ filter in Dw is functional to the $n^{th}$ channel in F to create $n^{th}$ channel filtered result of feature map Fmap.

DC cost is defined by,

$$Dw_k \cdot Dw_k \cdot N \cdot D_F \cdot D_F \quad eqn. \tag{2}$$

The grouping of DC and 1 x 1 PC is called DSC which was formerly introduced by [11].

DSC cost is defined by equation 3,

$$Dw_k \cdot Dw_k \cdot N \cdot D_F \cdot D_F + N \cdot M \cdot D_F \cdot D_F \quad eqn. \tag{3}$$

By stating convolution as a two-step procedure of filtering and combining to obtain decrease in calculation is,

$$\frac{Dw_k \cdot Dw_k \cdot N \cdot D_F \cdot D_F + N \cdot M \cdot D_F \cdot D_F}{Dw_k \cdot Dw_k \cdot N \cdot D_F \cdot D_F} = \frac{1}{N} + \frac{1}{Dw_k^2} \quad eqn \tag{4}$$

Fig. 5.   Depthwise Separable Convolutions base Model Result.

MobileNetV2 uses 3 x 3 DSC take on among eight to nine times less computation than normal convolutions having less accuracy. By exploring the network in simple terms that are proficient to simply explore network topologies to discover an excellent network. The proposed training model is defined in Fig. 5. The entire layers are trailed by batchnorm and ReLU nonlinearity with the exclusion of the last completely connected layer which has no nonlinearity and brought into a SoftMax layer for classification.

### C. Depthwise Separable Convolution with Bidirectional-LSTM (DSC-BLSTM)

According to [2], [12], authors described LSTM as an expansion of recurrent neural networks. Appropriate to unique architecture, which conflicts the disappearance and ignition gradient issues, it is fine at managing time series issues up to a positive depth. LSTM conserve information from inputs that has previously passed through it via the hidden state. Unidirectional LSTM only conserve information of the precedent because of the simple inputs it has observed from the past. The bidirectional LSTM will process the inputs with one from past to future and one from future to past and what varies this approach from unidirectional is that in the LSTM processes backwards to protect information from the future and using the two hidden states that are combined in some point to protect information from together past and future. Bidirectional LSTM (see Fig. 6) comprises of 2 LSTM cells, and the result is resolute. The bidirectional LSTM presented result is not only associated to prior information but also connected to consequent information. The overall DSC-BLSTM flow diagram is illustrated in Fig. 7.

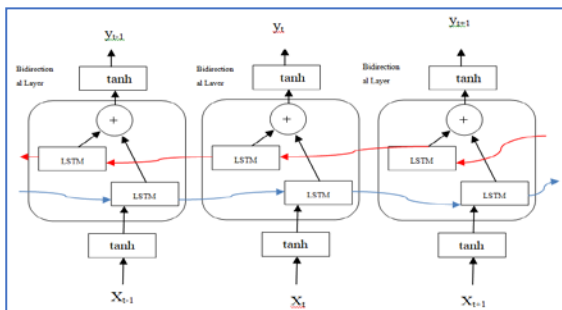

Fig. 6.   Bidirectional LSTM Construction.

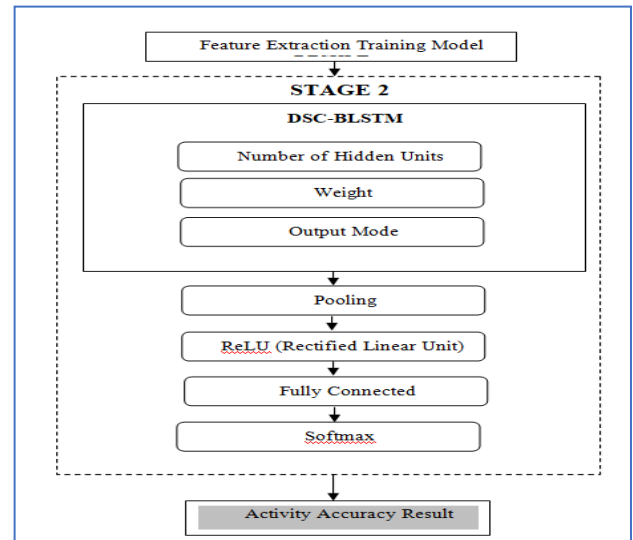

Fig. 7.   DSC-BLSTM Flow Diagram.

---

**Algorithm: DSC-BLSTM Pseudo code**

---

**Input:** Continuous Video Frames *f*, Class Labels C
**Output:** Predicted activity class with accuracy score
**Preparation:**

1.  Video Data Preparation
2.  Feature Extraction using Depthwise Separable Convolution Neural Network (DSC)
3.  Depthwise Separable Convolution with Bidirectional-LSTM (DSC-BLSTM)

**Steps:**

**While** (video frame)
1.  Frame *f* ← Extract frames from videos

    //Fix sample duration (i.e., frames taken per loop/iteration) = 16 frames per iteration and sample size (i.e., Frame width size) = 112pixels wide
2.  *M* ← Create trained model using DSC method

**End While**

3.  **for** t = 1 to n **do //** where *n* represents number of video frames
    a.  frame *f*(t) ← Read the test video frame.
    b.  Apply *f(t)* to DSC Model // *Calculate Similarity matrix value of test frame f(t) with trained model*
    c.  Predict activity Class label with frame *f(t)* using (DSC-BLSTM)
4.  Label Predicted activity ← Result class label
5.  Display predicted activity class with accuracy score

**End for**

---

The DSC-BLSTM algorithm takes these three inputs Model M, classes C and test video frames f. Initially, load the trained human activity recognition DSC model M and contents of the class labels C file. After that, test frames are grouped and resized with defined sample duration (i.e., number of frames for classification) and test size (i.e., the spatial dimensions of the frame). Next, test input video frames are looped over the amount of essential test frames (i.e., duration of 16 frames per loop) and read a test frame from the video stream. The test frame streams are forwarded to the network model for checking the distance matrix (i.e., similarity) between train model M and test frame f model outputs. The outputs matrix is passed through Bidirectional LSTM process to get the activity label. Finally, the maximum classes of label are the predicted activity for the processed frame. The Table I shows the parameters, symbol with the corresponding value of the proposed system implementation.

TABLE I. PARAMETERS DESCRIPTION

| Parameter Name | Symbol | Value |
|---|---|---|
| Total Classes | C | 400 action classes |
| Frame Duration | Sample_duration | 16 frames per iteration |
| Sample window Size | Sample_size | 112 pixel wide |
| Training Model | M | 2000 Videos model |
| Test video frame | f | - |
| Total Number of Frames | n | Total no of frames in a video |

## IV. EXPERIMENTAL RESULTS AND DISCUSSION

### A. Experimental Environment

The results have been estimated with the proposed DSC-BLSTM algorithm. The results are implemented with Intel I5-6500U series 2.71 GHz, x64-based processor, 8GB main memory, and run on the Windows 10 operating system using python 3.8 simulations. This paper is implemented with Kinetics 400 action recognition dataset which consists of 2000 videos as training dataset with 21 classes that includes massage, Ice Skating, Yoga, Playing, Pull ups, Pushing, Reading, Tasting, Skating, Side Kick, Filling, Crawling, Waiting, Washing, Making Pizza, Kicking, Jumping, Curling, Dancing, Massage, Shaving and Shooting. The resulting parameters of Ice-Skating activity are described in Fig. 8 to Fig. 10.

### B. Discussion

This section presents a detailed analysis of experimental outcomes through the proposed method on the basis of accuracy measures such as precision, recall, accuracy, and F1-score. The proposed algorithm consists of three main stages. These three main stages include the video frame extraction which is performed first in which datasets are normalized to get better results. The accurate results will give more accuracy. In the second step, feature extraction is implemented using Depthwise Separable Convolution Neural Network algorithm. In this step, features is implemented separately based on DSC to get the best features are stored in trained dataset. In the third step, features are fused, while in the final stage, results are taken through the classification learner. In video frame

extraction, all individual frames are stored as images to detect the activity from the image. After the frame extraction, MobileNetV2 convolution network using DSC method to create a feature model from extracted images. Finally, Depthwise Separable Convolution with Bidirectional-LSTM (DSC-BLSTM) classifier to discover the similarity matrix value of test frame with trained model to attain the prediction activity result. Combining DSC-BLSTM have achieved higher accuracy than the other classification learners on the "MC-HF-SVM, Baseline LSTM and Bidir-LLSTM algorithms", respectively.

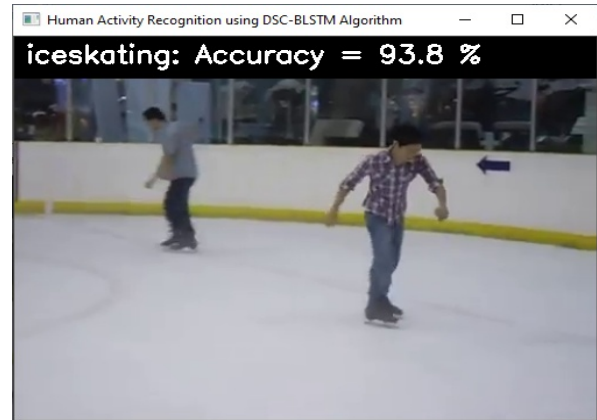

Fig. 8. HAR Result of Ice Skating with Accuracy.

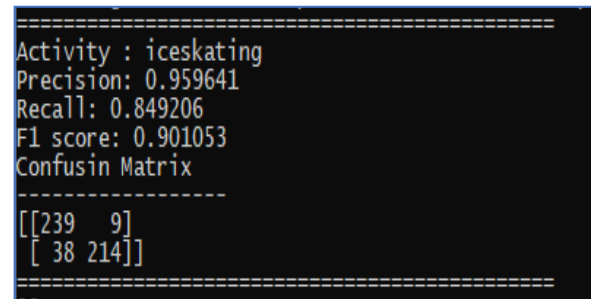

Fig. 9. HAR Result of Ice Skating Performance Measure of Precision, Recall, F1 Score and Confusion Matrix.

Fig. 10. Overall DSC-BLSTM Training Loss and Accuracy Plot Result.

## C. Evaluation Index

To evaluate the performance of the proposed model for HAR, the followed metrics [26] were used for evaluation generally.

$$Accuracy = \frac{tp+tn}{tp+fn+fp+tn} \qquad (5)$$

$$Precision = \frac{tp}{tp+fp} \qquad (6)$$

$$Recall = \frac{tp}{tp+fn} \qquad (7)$$

$$F1-score = \frac{2 \times Precision \times Recall}{Precision+Recall} \qquad (8)$$

The proposed DSC-BLSTM method substantiates with high Accuracy and F1-score ratio when compared to other HAR algorithms like Multiclass Hardware-Friendly Support Vector Machine (MC-HF-SVM) [7], Baseline LSTM [14], Bidirectional Long Short Term Memory (Bidir-LSTM) [4] algorithm. As a result of the improved human activity recognition presentation, there is a higher accuracy. The proposed DSC-BLSTM method proves high Accuracy and F1-score ratio when compared to other HAR algorithms like Multiclass Hardware-Friendly Support Vector Machine (MC-HF-SVM) [7], Baseline LSTM [14], Bidirectional Long Short Term Memory (Bidir-LSTM) [4] algorithm are described in Table II and Fig. 11 shows the comparison chart.

In Table III shows the comparison of precision, recall, accuracy and F1 score with kinetics 400 dataset of test videos prediction activity measures and Fig. 12 shows the comparison chart.

TABLE II. COMPARISON OF ACCURACY AND F1 SCORE WITH EXISTING AND PROPOSED DSC-BLSTM ALGORITHM OF KINETICS 400 DATASET

| Methods | MC-HF-SVM | Baseline LSTM | Bidir-LSTM | DSC-BLSTM |
|---|---|---|---|---|
| Accuracy | 89.3 | 90.8 | 91.1 | **93.8** |
| F1-Score | 89.0 | 90.8 | 91.1 | **92.637** |

Fig. 11. Comparison Measures of Accuracy and F1 Score Chart.

TABLE III. COMPARISON OF TEST VIDEOS PREDICTION ACTIVITY MEASURES OF PROPOSED DSC-BLSTM ALGORITHM OF PRECISION, RECALL, ACCURACY AND F1 SCORE WITH KINETICS 400 DATASET

| Prediction Activity | Precision | Recall | Accuracy | F1-Score |
|---|---|---|---|---|
| Ice Skating | 96.25 | 91.66 | 94 | 93.90 |
| Yoga | 94.23 | 90.87 | 92.60 | 92.52 |
| Playing | 91.56 | 90.47 | 91 | 91.01 |
| Pull ups | 95 | 90.47 | 92.80 | 92.68 |
| Pushing | 95.08 | 92.06 | 93.60 | 93.54 |
| Reading | 91.49 | 89.68 | 90.60 | 90.58 |
| Tasting | 92.68 | 90.47 | 91.60 | 91.56 |
| Skating | 93.56 | 86.50 | 90.20 | 89.89 |
| Side Kick | 94.34 | 86.11 | 90.40 | 90.04 |
| Filling | 95.08 | 84.52 | 90.00 | 89.49 |
| Crawing | 96.39 | 84.92 | 90.80 | 90.29 |
| Waiting | 89.23 | 92.06 | 90.40 | 90.62 |

## V. CONCLUSION

This paper analyzed the advancement of Human Activity Recognition (HAR) concepts in the field of deep neural network technique. The proposed work presents a Depthwise Separable Convolution with Bidirectional long short-term

memory (DSC-BLSTM) algorithm adapted to the HAR task. This system seeks to improve the accuracy of activity recognition by leveraging the robustness in feature extraction and classification model. The results were impressive and worked well after we used the DSC-BLSTM method in the HAR system. The result is shown as 93.8%, and is more recognizable than the other HAR algorithms like MC-HF-SVM, Baseline LSTM, Bidir-LSTM algorithms.

## VI. Conflict of Interest

The authors declare no conflict of interest

*Abstract*—**Robotics in the construction industry has been used for a few decades up to this present time. There are various advanced robotics mechanisms or technologies developed for specific construction task to assist construction. However, not many researches have been found on the quality assessment of the finished structures. This research proposes a quality assessment robot that will assist in performing the assessment of the internal works of a building by assessing a quality assessment criterion in the Malaysian Construction Industry Standards. There are various assessment criteria such as hollowness, cracks and damages, finishing and jointing. This paper will focus on the wall evenness using a camera mounted on a mobile robot with a Mecanum wheel design. The wall evenness assessment was done via projecting a laser leveler on the wall and capturing the images by using a camera, which is later processed by a central controller. Results show that the deviation calculation method can be used to differentiate between even and uneven walls. Pixel deviations for even walls show values of less than 15 while uneven walls show values of more than 20 pixels.**

*Keywords—Construction industry standards; internal works quality assessment; vision; Mecanum wheels*

## I. INTRODUCTION

In this era of Industrial Revolution 4.0, many technologies are being used in various application areas. Internet-of-Things, virtual reality, data analytics, additive manufacturing and robotics are some of the interesting technologies that have accelerated various manufacturing sectors throughout the current years. In the construction industry, robotics has been applied since the early 1980's. In the Japan visit, Dr. James S. Albus from National Bureau of Standards [1] and six construction companies (Taisei Corporation, Takenaka, Hazama Gumi Ltd, Shimizu Construction, Kumagai Gumi Company and Toshiba Nuclear Group) had large research on budgets for construction robotics. There are many related researches of cooperative or multi-robots that were proposed in construction environment, such as multi-robot teleoperation using humanoid and legged robots [2], multi-robot material deposition using autonomous mobile robot extruder platform [3], human-robot collaboration for interior finishing [4] and distributed climbing strut robots that was used for guiding construction [5]. There were also studies on simulating robots in construction via haptic control for drywall installation, painting, welding, bolting and concrete pouring [6]. In another

research, a robot was proposed for monitoring the work progress in a building construction site [7] and a façade cleaning robot was proposed in [8].

However, not many researches have been focused on the automated internal or external works of finished building or construction sites. At present, the quality assessment is performed by manual inspection by a human assessor or a panel of assessors. This is tedious and tiring work because assessors usually complete a substantial amount of sample houses or buildings within a few days. The research of a custom-built quality assessment robot could reduce the burden of human inspectors by carrying out assessment of some criteria of the structure quality. A bridge statics assessment robot for flood evacuation planning was designed by Maik Benndorf et al. in [9]. This is an example of an external structure assessment that uses vibration measurement sensors mounted on an Unmanned Ground Vehicle equipped with a robotic manipulator. For internal works, a custom-designed quality assessment robot was proposed by Rui-Jun Yan et al. [10]. In assessing the different criteria, Rui-Jun Yan attached several devices for the quality assessment robot, Quicabot. A thermal camera was used to assess the hollowness of the ground and walls, an RGB camera to detect cracks on the ground and walls, a laser scanner to measure the evenness of the ground and walls and alignment of two connected walls while an inclinometer to measure the inclination of the ground.

The use of laser projection and vision sensors were seen in other applications. Andrzej Sioma used laser and a camera to measure the surface defect of a ceramic tile [11]. The longitudinal rip of conveyor belt detection was performed by Xianguo Li et al. using laser-based machine vision in [12] because of the use of such belt mechanisms to transfer materials or products. Other than that, bubble defects on tire surface were also detected by Hualin Yang et al. in [13] by using laser and machine vision. Daniel Lopez-Escogido et al. [14], detected small defects in PCB using 2-D high precision laser sensors, which investigated high errors of units of micrometers due to the small outline of Surface-Mount-Devices (SMD).

Jorge Rodríguez-Araújo and Antón García-Díaz [15] investigated in-line Defect Classification and localization in Solar Cells for Laser-Based Repair. This is because the faulty

cells need to be identified to be repaired. In [16], Dong-Gi Woo et al. used multi-lasers to perform the inspection of the surface of a car door chassis by using a robot arm manipulator projecting the lasers in different poses, which could be used as a 3D measurement system. Other than that, Ting Lei et al. [17] used laser vision to identify thermal deformation of tube sheet welding by using a Cartesian robot, CCD camera, hoop assembly, laser sensors and single-line lasers. A combination of line scan camera and frame camera was used to detect product surface defects by applying the ideas of both surface grayscale image and depth image simultaneously [18] in which Zhen Liu et al. claim the accuracy of 0.13mm within a measurement of 500x300x200 mm$^3$. In [19] Simone Pasineet et al. investigated in-line monitoring of laser welding using vision system, which applied thresholding, binarization and blob-counting to robustly detect joint and obtain optimal acquisition of the melt pool during welding.

The weld seam detection and feature extraction of butt-welding was investigated by Wang Xiuping et al. [20] in which the laser stripe edges were detected. The welding was performed by a welding robot arm manipulator. Feature extraction of butt-joint was also investigated by Yuanyuan Zou et al. [21] which used three-line stripe laser vision sensor. The algorithm uses Laws texture energy filter, Canny operator, thresholding and textural feature; laser stripes were used as its feature points.

Although there is not much research or references in the area of building quality assessment using robots, the idea of using laser projection and image acquisition and processing has been used in some applications mentioned previously, i.e. weld seam identification, and defect detection of tiles or panels.

For this paper, our objective is to explore and propose quality assessment of a criterion in the Construction Industry Standards for internal works, which is the wall evenness assessment. We propose the use of laser projection and image processing for the assessment. A custom-made mobile robot was designed and developed for the assessment, which can be further upgraded to include assessment of other criteria such as hollowness, cracks and damages, wall alignment and others. The advantage of our method is the use of cost-effective devices such as laser leveler and standard High Definition (HD) USB cameras.

## II. The Construction Quality Assessment Robot

The robot for the quality assessment of internal works was custom-built as shown in Fig. 1. Fig. 1(a) shows the 3D drawing of the robot and Fig. 1(b) shows the actual robot. It is a mobile robot equipped with the sensors used for assessment. The base of the robot which is mostly rectangular is driven by four planetary geared motors connected to couplings of the Mecanum wheels to enable multi-direction motion of the mobile robot. The details of the components are shown in Table I.

As described in Table I, there are several parts that are required for the robot to function. It includes the robot base, power supply, controllers, sensors and tapping rod mechanism. The robot structure is custom-built using the frames consisting

of 20 x 20 aluminum profiles with a square base of 300 x 300 mm$^2$ size.

Fig. 1. 3D Drawing of the Assessment Robot, (b) Actual Robot.

TABLE I. Quality Assessment Robot Components

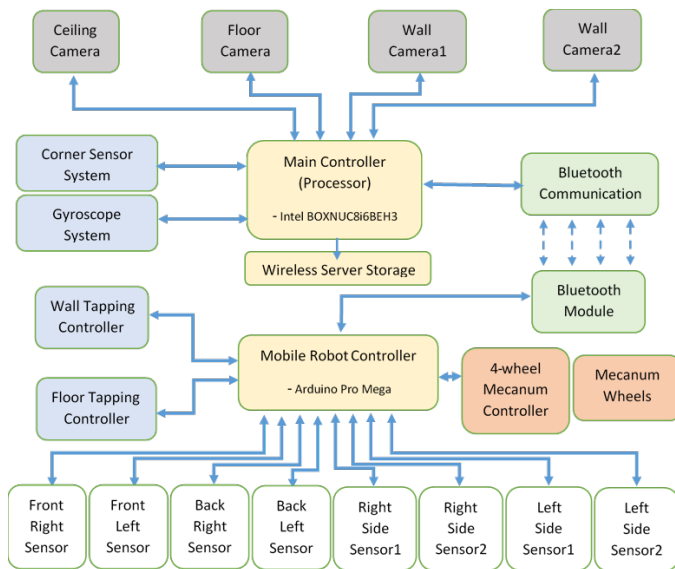
| Main Part | Sub-component | Details |
|---|---|---|
| Robot base | Planetary-geared DC motors (4) | 24V 148RPM 18kgfcm 45mm |
| | Coupling (4) | 10mm Key Hub for 152mm Mecanum Wheel |
| | Mecanum wheel (4) | 152mm |
| | Structure | Aluminum Profile 2020, 300mm length each |
| | Motor Drivers (2) | 10Amp 5V-30V DC Motor Driver (2 Channels) |
| Power supply | 36 V DC Batteries | Rechargeable Lithium Ion 36V Batteries with BMS |
| | | |
| | DC-DC converters | 24V, 9V |
| | | |
| Controller | Mobile Robot Controller | Arduino Pro-Mega |
| | Data acquisition and Processing | Intel BOXNUC8i6BEH3 (Intel i5) |
| | Display | 13.3 inch USB-C Monitor |
| Sensors | Ranging sensors (8) | Time of Flight (TOF) VL 53L0X |
| | Corner alignment sensor | Time of Flight (TOF) VL 53L0X |
| | Camera (4) | 2MP Webcam |
| | Laser leveler Gimbal | 1-axis, mounted with camera |
| Tapping Rod | Slider | V-Slot Y-axis slider with Belt Buckle |
| | Servo Motor | 4.5 – 6.0V RC Servo Motor |
| | Aluminum | V-Slot Aluminum Profile (Black Anodized) 2020 |
| | Tensioner | Timing Belt Tensioner 2020 |


Fig. 2. Overall Block Diagram of the Quality Assessment Mobile Robot.

The overall block diagram of the Quality Assessment Robot is shown in Fig. 2. It consists of two main parts/controllers, which are the Main Processor and the Mobile Robot Controller. The main controller parts consist of the Central Processing Unit (CPU), four High Definition (HD) cameras, the corner sensor system and the gyroscope sensor system. The Mobile Robot Controller controls the four motors which are connected to the Mecanum wheels, the two tapping rod mechanisms which actuate the tapping rod motion and the interface with the eight (8) proximity sensors (Time-Of-Flight sensors).

The reason for using four cameras simultaneously is to enable four snapshots that can be taken which cover two walls (lower and upper), floor and ceiling view. This method can save time because it captures images at the same time, rather than moving a camera in different angles to capture the four images. The mechanical motion is only for the navigation of the mobile robot base. For the purpose of quality assessment, the obstacle detected using the proximity sensors is the wall it faces. Two sensors are placed at each side of the robot for the robot to navigate around its surroundings. The front side has two sensors to sense the wall facing the robot, the right side has two sensors to sense the right wall, the left side has two sensors to sense the left wall and the rear side has two sensors to sense the wall facing the robot's rear.

The mobile robot controller actuates the tapping rod movement, which is the wall tapping rod mechanism and the floor tapping rod mechanism. The wall tapping rod mechanism is located at the right side of the robot while the floor tapping rod mechanism is placed at the front side of the robot, as shown in Fig. 3. This tapping mechanism which consists of a tapping rod, a microphone and sliding mechanism, is used to assess the hollowness of the wall and floor by acquiring the sound waves recorded by the microphone attached to the tapping mechanism. However the tapping mechanism is not the focus in this paper.

Fig. 3. The Wall-tapping Mechanism and Floor-tapping Mechanism.

The main processor controls the overall data acquisition of the mobile robot, such as image acquisition and processing, corner sensor data acquisition and evenness data acquisition. The pictures of the main processor-connected components are shown in Fig. 4.

Fig. 4. (a) The Floor Camera and Lower Wall Camera Connected to the CPU, (b) The Laser Leveler, Upper Wall Camera and Ceiling Camera.

The four cameras consist of a camera for the floor image capture, a camera for the ceiling image capture, a lower wall camera for capturing the image with the laser leveler projected lines and an upper wall camera to capture the upper wall area. These cameras are connected to the CPU and controlled by a custom-developed software. The laser leveler is attached on the upper frame of the robot, at a suitable height for the lower wall camera to capture the image. The other two cameras are located on the tapping rod holding frame, which is the upper wall camera and the ceiling camera.

There are two external sensor systems connected to the CPU; the corner detection sensor system and the gyroscope/accelerometer sensor system. These two sensors will record data and send it to the CPU for storage and processing. The data collected by the CPU (images, accelerometer readings, corner sensor readings) are stored in the wireless server data storage provided. The wireless server is accessed via the Wi-Fi network established between the CPU and the server. For the robot to move, the main controller will send commands to the mobile robot controller, which is connected to the CPU using Bluetooth Serial Port connection.

The simultaneous multi-assessment capability of the mobile robot is the clear advantage, acquiring different data for different criteria in the Quality Assessment System in Construction (QLASSIC) Construction Industry Standards. Its purpose at this time is not to replace the human assessor completely, but to assess some criteria. Hence it will lessen the burden of the human assessor and save time to complete a full assessment.

III. THE WALL EVENNESS ASSESSMENT USING VISION-BASED APPROACH

For this paper, we will focus on the wall evenness assessment using vision-based approach. The intention of applying the mobile robot into the construction assessment is to assist in assessing compliance with the Malaysian Construction Industry Standards (CIS). In the Standards, the wall surface evenness is considered "comply" if the deviation of wall surface is within 3mm, measured by 1.2m spirit level and steel wedge held by a human assessor. When the spirit level is placed on the wall, the steel wedge will be inserted in areas where there is space between the spirit level and the wall. This space should be within 3mm. This method using human assessment will depend on the consistency of human assessor evaluation. While some assessors take large samples of the wall in a room, others may only take samples of wall that he/she sees as a probable defect. This is due to the large number of rooms that the assessor is assigned to evaluate. This inconsistency is due to the human factor.

Thus, to assist the assessment, the mobile robot will help in acquiring images and later processing the images to determine wall evenness. By using a mobile robot, the image acquired will be at consistent distances set in the mobile robot controller program. The arrangement or setup of the mobile robot to acquire the images is illustrated as shown in Fig. 5.

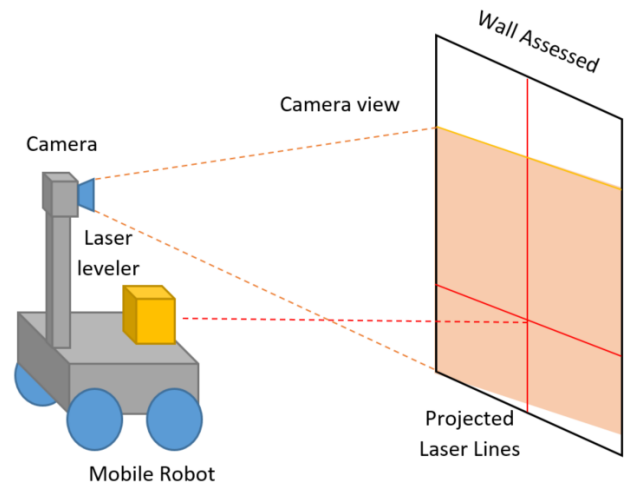

Fig. 5. Illustration of Image Capture of Wall for Surface Evenness Assessment.

The idea is to project the laser lines from the laser leveler to the wall facing the robot. At the same time, the camera mounted on the mobile robot will be able to view the laser lines on the surface of the wall. Then the image will be captured by the camera that contains the picture of the wall with the projected laser lines. The lines will not be deflected/deviated if the surface of the wall is even. If the lines are broken or deviated, it is an indication of non-compliance to the surface wall evenness criteria.

When measuring the wall, the robot navigates around by using the proximity sensors to slide left to be while maintaining its front to be parallel with the wall. This sliding motion is only possible by using the Mecanum wheels arrangement using the four DC motors driving the wheels. The sliding motion is shown in Fig. 6 and the motion of the robot inside a rectangular-shaped room is shown in Fig. 7. The robot in Fig. 7 is facing the wall on the right side. In short, the robot will automatically navigate around a rectangular-shaped room and stop evaluation once it reaches the fourth corner (start position).

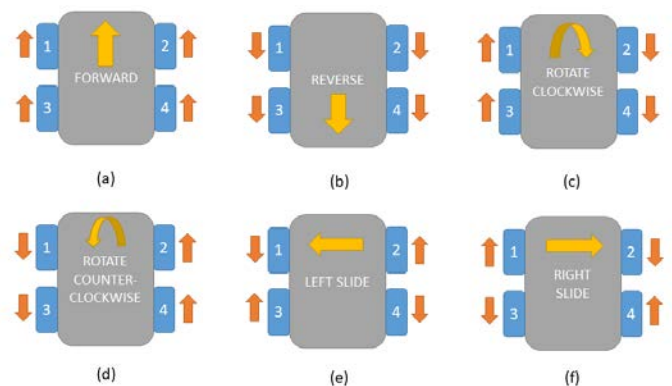

Fig. 6. Illustration of Mecanum Wheel Motions.

The Mecanum wheel motions (top view) in Fig. 6 shows the six different motions used for the mobile robot. The wheels are labeled as 1, 2, 3 and 4. With the right combination, different motions can be realized. The basic motions labeled as (a), (b), (c) and (d) shows the forward, reverse, rotate clockwise and rotate counter-clockwise motions of the mobile robot base. The other two motions, (e) and (f) are the sliding motions, in which (e) is left-slide motion while (f) is right-slide motion. Although the Mecanum wheels allow a lot more motions such as diagonal motions, the six motions in Fig. 6 is sufficient for the quality assessment mobile robot.

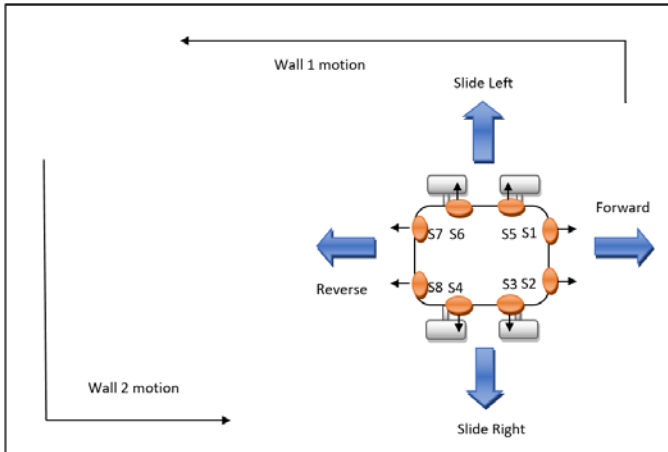

Fig. 7. Illustration of Sliding Motion during Wall Assessment.

The motion of the robot in the rectangular shaped room in Fig. 7, is performed by using the proximity sensors, for example, for the sliding left motion, sensors S1 and S2 will be used to follow the wall, while sensors S5 and S6 will be used to detect the first corner (top right in Fig. 7). After arriving at the corner, the robot will rotate itself counter-clockwise until it sensors the wall by using sensors S1 and S2. After that, it will perform the sliding left motion until it reaches the wall corner, completing the Wall 1 motion in Fig. 7. Similarly, Wall 2 motion will be performed after Wall 1 motion. During the sliding motion, the robot will stop momentarily, to acquire the images of the wall to be processed later. This is because if the robot acquires images while moving, the image might be blurred and causes difficulty for image processing. For a wall motion, there could be several images acquired, depending on the length of the wall. The distance between the robot and the wall is set at 60cm. If the distance is too short, the images captured will not cover enough area of the lower wall.

The image processing that needs to be done on the captured camera image, is HSL color filtering, Grayscale Conversion, Thresholding. By defining the range of acceptable color for the Red Laser line using HSL, the processing of the image will produce a black and white image. The white connected dots in the image will show the laser lines while the other colors will be turned to black.

Next, further image processing can be done, such as convex hull identification from blob, which will produce coordinates of the edges of the hull covering the vertical and horizontal laser line. The next step is to draw a red line from the top edge to the bottom edge to compare with the white lines of the laser leveler. The details of all these processes will be explained and shown in Section IV.

## IV. RESULTS AND ANALYSIS

For the site-testing of the mobile robot, the images are acquired from a finished housing area in Pulau Sebang, Melaka in September 2021. Additionally, the Skyworld Quality Center was also visited for another site-test for the mobile robot, in October 2021. The process for the image processing on the acquired images is shown in Fig. 8.

The results of image acquisition and processing are shown in Fig. 9.

The image in Fig. 9(a) shows a clear red-line projected image captured by the camera on a white-colored wall surface at the first site test, a house in a residential area in Pulau Sebang. The images acquired from the second site test at Skyworld Quality Centre are shown next in Fig. 9(d). This time the color of the wall is not white, but light yellow and the wall is uneven. Nevertheless, the red lines are still seen in the images. The sample image in Fig. 9(d) shows a slightly deflected vertical line.

The images in Fig. 9(a) are then color-filtered using Hue, Saturation, and Luminance (HSL) filtering from AForge library in Visual Studio (C #Net). The values used for HSL is 320 – 50 for Hue, 40%-100% for saturation and 40%-100% for luminance. These values are suitable for the red lines from the laser leveler. The results of the HSL filtering are shown in Fig. 9(b). For the image in Fig. 9(d), the same process is applied and the result image is shown in Fig. 9(e).

It can be seen in Fig. 9(b) and Fig. 9(e), the red lines were successfully seen and other backgrounds were eliminated. The next process is the Grayscale filtering and the Thresholding to ensure the image consists of only black and white colors for the next process to take place. For grayscale filter, the parameters are the values suggested from the AForge Grayscale filter library (0.2125, 0.7154, 0.0721). Grayscale filtering results are shown in Fig. 9(c) and Fig. 9(f).

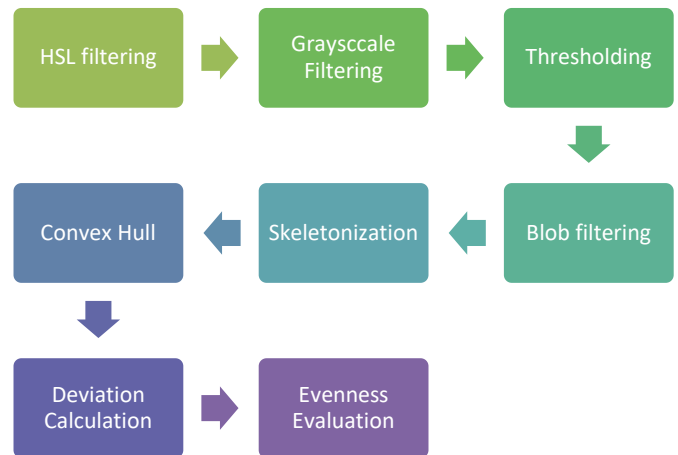

Fig. 8. Image Processing Method for the Wall Evenness Quality Assessment.
Fig. 9.  Image Processing Results; (a) Image Acquired for Even Wall, (b) HSL Filtering on Even Wall, (c) Grayscale Filtering on Even Wall, (d) Image Acquired for Uneven Wall, (e) HSL Filtering on Uneven Wall, (f) Grayscale Filtering on Uneven Wall, (g)Thresholding Result on Even Wall, (h) Convex Hull of Even Wall, (i) Connected Edge Lines for Pixel Deviation of Even Wall, (j)Thresholding Result on Uneven Wall, (k) Convex Hull of Uneven Wall, (l) Connected Edge Lines for Pixel Deviation of Uneven Wall.

The next process after grayscale filtering is thresholding. For thresholding, the value set to allow the line to be converted to white color is 80. Values of grayscale below 80 will be turned to black color. This is to ensure that the Blob filtering process can take place, as it only receives black and white images. Thresholding results are shown in Fig. 9(g) and Fig. 9(j).

After thresholding, blob filtering is then applied, and then skeletonization. This is because blob filtering will extract blob sizes which are more than a certain width and height, in this case it is set at a width of 70 and height of 70. Any blobs smaller than this size will be neglected because it may consist of small errors which are not from the red line processed. Skeletonization is later applied to ensure that the line is thin for the next process.

Once skeletonization has been completed, the convex hull determination is performed to detect the top, bottom, most-left and most-right points that cover the blob. This is to ensure that

the lines are all in one blob. The convex hull results are shown in Fig. 9(h) and Fig. 9(k). It can be seen that in convex hull draws the limits of the up, bottom, left and right edges of the lines. These edge points can be used as reference for the deviation of the line to determine evenness.

The next process is to draw a reference line from the top-most and bottom-most points of the convex hull. This is done by using a different color, to differentiate between the projected laser line (processed) and the reference line. The reference line is drawn in red color, while the processed lines are in white. The results are shown in Fig. 9(i) and Fig. 9(l).

After drawing the red line, it can be seen that the uneven wall from Fig. 9(l) has (white) lines deviating from the reference line. From Fig. 9(i) and Fig. 9(l), the deviation from the drawn red reference line can be calculated by using (1);

$$D_{wr} = \frac{\sum(P_{w_i} - P_{r_i})}{i_{wr}} \tag{1}$$

Where $D_{wr}$ represents the indicator value for deflection between white and red dots, Pw represents the coordinates of the white dot, $P_r$ represents the coordinates of the red dot and $i_{wr}$ represents the number of white and red dots used in the process. If this indicator value is large, then it means that there are a lot of deflections of the white red with the red line. This can be used to classify that the wall is uneven. The distance between the camera and the wall set is 800mm. The resolution of the image captured is 1920 x 1080. The results of the tests for the uneven and even wall images are shown in Table II. The values are the average deviation of pixels from the reference line. The results obtained for six images, and three images are uneven walls.

TABLE II.    AVERAGE PIXEL DEVIATION FOR EVEN AND UNEVEN WALL

| Criteria | Image | Even Wall Image | Uneven Wall Image |
|---|---|---|---|
| Deviation (pixel) | 1 | 13.39 | 53.18 |
| | 2 | 10.99 | 25.98 |
| | 3 | 11.36 | 30.57 |

Based on the results in Table II, the Even wall results shows that pixel deviation is lower than 15. The uneven wall has higher values of more than 20 for the images captured. The proposed method has shown that the deviation of the line is quantifiable and can be used to differentiate between even wall and uneven wall surface. At present, the deviations are measured for the vertical lines, but could be extended to horizontal lines in the future.

## V.    CONCLUSION

This research proposed a new method of assessing the wall surface evenness for quality assessment of internal building works. This approach uses vision-based method by capturing the images of the wall with the projected laser lines. The robot captures images of the wall in front while sliding to the left and pausing during capturing images to ensure the images are stable. The motion was implemented using four Mecanum wheels. Results show that the pixel deviation values can be used as an indicator to distinguish between even wall and uneven wall surface. The uniqueness of the proposed method is the use of fast image processing technique that does not use training data sets and the use of cost-effective devices such as laser-leveler and standard High Definition USB cameras available in the market instead of high cost sensors [10].

At present, the results shown are from concrete walls with a single color. Future work includes the testing of mixed wall colors and different wall surface types such as wood, foam or other types of materials. Other criteria should also be investigated, such as wall hollowness, cracks and damages.

*Abstract*—**Human's cherished and respectable desires could be fulfilled by social integration through interaction with their friends and families. These kinds of interactions are critical for the elderly, particularly for someone who has retired. Online social communities could assist them and offer a beneficial impact on the elderly. However, because the elderly people are hesitant to use new technology, researchers have attempted to integrate specially built social networking applications into simple user-interface gadgets for the elderly through the context aware systems. A proper understanding amongst the aged and the supporting community people is needed for optimal execution of the platform. The study presents a 4W framework (Who, What, Where, When) to effectively comprehend and portray the online social interaction community model's application in assisting the elderly in satisfying their unmet needs, as well as to improve the system's efficiency in addressing the elderly's unfulfilled demands. It is essential to discover what the users are keen on and provide a chance for the community group to take good decisions by utilizing the insights gained from these events.**

*Keywords—Online social community; elderly's unmet needs; 4w framework; elderly's requirements*

## I. INTRODUCTION

Nowadays, digital media has grown ubiquitous and are easier to utilise through tablets, internet as well as the smartphones. As so much information, services, goods, and people are most often exclusively available on the internet, staying online has now become more attractive [1]. Furthermore, an age group is not a fixed category. Several elder people have grown up with digital media and they do not need to stop even when they reach the age of 65 [2]. Since they might lose some links with their co-workers when they retire, they gain more free time to spend with their families and friends. However, when it comes to their digital media requirements and preferences, elderly people are the least studied age groups, and researchers know only little about the differences in their use [3]. Through online support platforms and other means, the resources streaming through social media could assist both the younger and older persons.

People become much more sensitive when they grow old and feel socially isolated. This is primarily because of various factors like residing alone or in rural areas, as well as health factors such as health issues, mobility issues, and so on [4]. Elderly people suffer both physically and mentally when they are left alone. It is also vital to maintain the elderly as active and make them participate in society, both cognitively and

physically. Social networks could provide emotional support to elderly individuals, which is important since social integration is necessary to meet basic human requirements like being connected and loved [5]. Communication and interchange with friends and other senior people especially family members could aid in the development of social connectivity feelings and the expansion of social relationships.

The digital interactions with their family and friends provide a lot of social support that are observed to be especially essential for older persons with mobility issues [6]. This was also evident in their daily actions, like finding quicker ways to maintain their residences and preparing healthier dishes [7]. Despite the challenges of a complicated user interface and an abundance of data, social media platforms such as Twitter, Facebook, Pinterest, Google Hangouts, and Instagram have recently seen greater adoption rates amongst the elderly [8]. Online Social Networks have expanded options for social interaction and collaboration, allowing users to communicate and collaborate with others as part of a continuous social dialogue. Computerized systems must have a better knowledge of the situations in which they offer services or activities, and they must be able to adjust correspondingly. It could be accomplished through context awareness.

In this paper, a 4W framework that offers a general view of the online supporting community model is presented. The framework gives a comprehensive overview of the concepts in the elderly supporting community and serves as a foundation for defining the elderly's needs. The 4Ws mapping data could be used to develop national emergency response plans, as well as to detect discrepancies in supply, human resources, geographic and target group coverage, and technical competence. Participating groups can also utilize it to manage their fund raising and programming efforts. This framework enables us to observe the model's fundamental requirements, review existing ways towards geriatric support, and identify emerging research topics in this sector. It may be applied onto any project under this area and is used for analysis.

The rest of the sections are summarized as follows. Section II explains the recent literature works of supporting frameworks for the elderly people, Section III illustrates the proposed online social community module with components and the tasks performed by each components. Section IV illustrates the application of 4W framework on the proposed online social community model. Section V provides the evaluation of the proposed model through User journey map

followed by its results and finally, section VI concludes the paper.

## II. RELATED WORK

This section gives a background review in the field of using 4W in the social media. Related issues and problems that have been solved in previous works are reported. A context aware system for business-to-government (B2G) information exchange in the container shipping domain was developed in [9] for identifying what environmental components are the significant context, what are the required elements to recognize and adjust to context, and what are the rules for the adapting the system under various circumstances. The highly organized manner in which the elements and criteria are formed from insight into context gives a technique for dealing with the tremendous complexity of the context in this approach along with ambiguity elimination.

Another model of a context aware approach was presented by Hossain et al. [10] for supporting the elderly for entertainment. It covers the entertainment demands of the aged people and allows multiple residents (e.g., caregivers and old adults) to connect multiple media sources in either a formal and informal manner so as to improve the quality of their experience of life in diverse circumstances. The model aids in the development of entertainment systems and services for the aged people, allowing them to more effectively address the issues that arise from their ability to live independently, happily, and actively.

For a persistent Elderly Homecare, Pung et al. [11] developed a Context-Aware Middleware framework for supporting the elderly. It assists through designing and implementing a variety of geriatric home healthcare activities, including location-based emergency response, patient monitoring, unusual daily task detection, persistent accessing of health data, and social networking. This approach has a high level of context query processing efficiency and activity recognition accuracy. However, it confronts challenges in dealing with enormous amounts of data from various sources.

Another platform presented in context aware filed called the OCare Platform to support for caring the persons in independent living facilities. This conceptual, data-driven, cloud-based back-end platform supports people to live independently through providing residents and their informal caretakers with information and knowledge-based services. This system has the potential to offer a realistic working environment and adapt considerably and more quickly [12].

## III. ONLINE SOCIAL COMMUNITY MODEL

In this stage, model components were designed according to the requirement of users. The proposed architecture consists of six core components based on requirements analysis [13]. More detailed description on these components is given in Section 4B. However, the complete system architecture of the proposed model which includes the online social interaction, unmet needs interaction, profile management, recommendation component and unmet needs plan is represented in Fig. 1.

### A. The Concept Groups

The suggested framework's core assumption is an online social community model for elderly Libyans assistance. The broad perspective of the 4W framework is formed by the concept groupings Who, Where, What, and When. The methods that follow to build this framework is similar to that used to build Zachman architecture [14] and Angelov and Geffen models [15]. However, according to Abowd et al. [16], the definition of context is given as, "Any information that can be used to characterize the situation of an entity", where "an entity can be a person, place, or object that is considered relevant to the interaction between a user and an application, including the user and applications themselves".

This definition outlines four distinct kinds of elderly supporting concepts that could be modeled. They are: Where concept (location context); Who concept (Identity context); What concept (Activity context); and When concept (Time context). Similarly, the definition of the online community by Rheingold (1993) which is "[online] Communities are social aggregations that emerge from the Net when enough people carry on those public discussions long enough, with sufficient human feeling, to form Webs of personal relationships in cyberspace" is used to build the 4W framework of the online social community process for elderly Libyans. The next section details how these four concepts can be represented by the process of model components.

Fig. 1. The Online Social Community Model of Elderly Libyans.

TABLE I.        THE TASKS THAT RELATED TO EACH COMPONENTS' FUNCTION

| Code | Task | Descriptions | Component |
|---|---|---|---|
| *Task 1:* | Build your private network community with name (your name care community) | Registering in the community, creating community groups under the name "your name care community" and inviting your family members or friends to this community | Online Social interaction |
| *Task 2:* | Provide a comprehensive assessment of the ability to perform activities of daily living and health status | Evaluating your ability to perform activities of daily living and health status. | Profile Management |
| *Task 3:* | Fulfill your daily unmet need "looking after your home" | Interacting your need "looking after home" with social group network to share interaction requests. | Interaction Unmet Needs |
| *Task 4:* | Generate a plan of your frequently unmet daily needs for this week. | Creating plan of list of your unmet needs for the current week with an optimal balance of work and care duties of your community members. | Unmet needs Plan |
| *Task 5:* | Find a way to get emergency support from group members | Sending an emergency post to a social group members or to a specific recommended member. | Online Social |
| *Task 6:* | Accept any recommendations about your unmet daily need "looking after your home" sent by community group members. | Posting an acceptance on the advice or suggestions about your unmet daily need "looking after your home". | Unmet needs recommendation |
| *Task 7:* | Track your unmet need "looking after your home" and look up activated members who will accept. | Tracking your unmet need "looking after your home" requests and the state of activate group members. | Interaction Unmet Needs |

## B. Corresponding Model Components

The 4W Framework process in the online social community is modelled by representing the model components and applying a set of tasks related to each components' function. However, the tasks represent the components that frame the model as shown in Table I.

## IV. THE 4W ONLINE SOCIAL COMMUNITY FRAMEWORK PROCESS

The 4W online social community framework process is shown in Fig. 2. Each concept is associated with their corresponding components which is represented by the task. The 'what' and 'who' concepts corresponds to all of the seven tasks. The 'What' concept represents the activity contexts that responses the question what is happening in the circumstances;

in the case of model, it represents the activity that is going to be done by elderlies. The 'Who' concept illustrates the identity contexts that responses the question who is the individual, which is elderly Libyans or their community members. The 'Where' concept corresponds the location contexts that responses the question of where the elderly is located or where the task is going to be completed. For instance, tasks such as fulfilling their unmet needs, generating the daily unmet need plans, sending the emergency report and tracking the request with where concept will represent the place that the task starts or completest in it. 'When' concept corresponds to tasks such as building the private network, fulfilling the unmet needs request and tracking the request (represents the time contexts that responses the question when the task defining the circumstances is occurring to record when the task was).

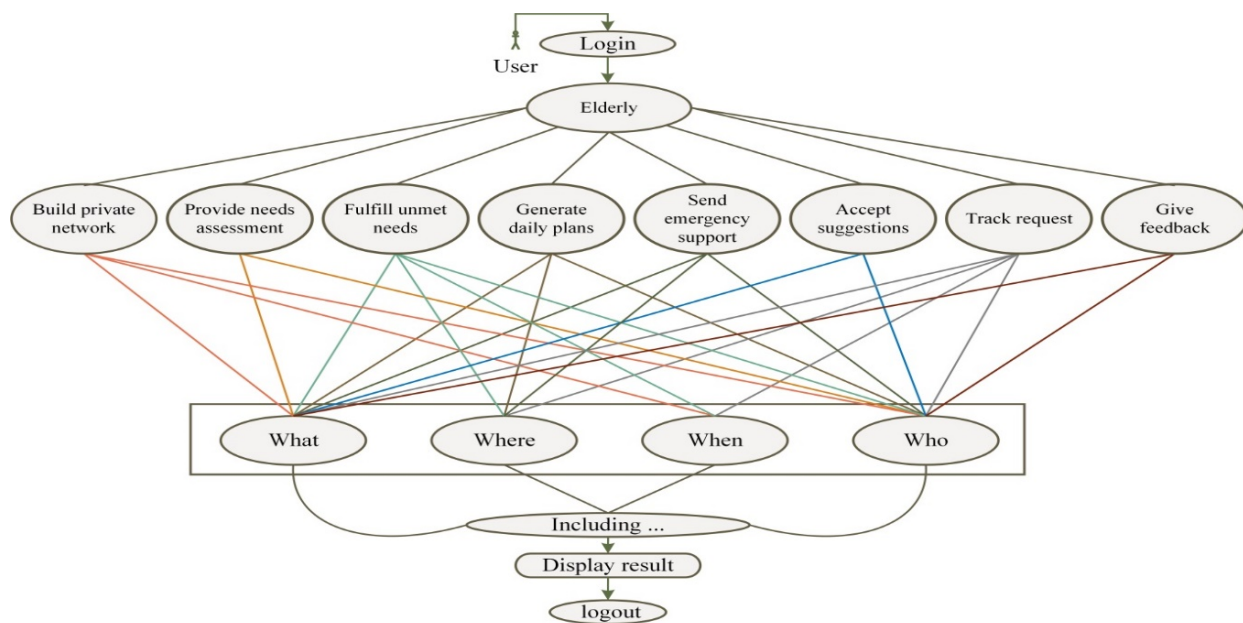

Fig. 2.   The 4W Online Social Community Framework Process.

The online social interaction component is related to the task one and task five. It creates the confidential social network community set up for the elderly as well as the service expert volunteers for helping the elderly Libyans. It also sends an emergency post to social group members or to a specific recommended member in case of seeking emergency support. The profile management component is related to task two. It provides a comprehensive assessment of their ability to perform activities of daily living and their health status. It maintains the elderlies' as well as the caretaker's profile, and thereby it regulates and keeps the elderly profile updated. The unmet needs interaction component is related to task three and task seven. It develops a brief layout of the list of unmet needs and frequent sending of daily need requests, it also keeps trace of the status of the recent unmet needs and the existence of currently active supporting community members, and promotes responding to the elderly's request. The unmet needs plan component is related to task four. It creates a plan of list of unmet needs under every time slot with an optimal balance of work and care duties of the community members. The unmet needs recommendation component is related to task six. It corresponds to the elderly requirements towards the supporting services. It also endorses a suitable group or an individual to assist the elders in satisfying their unmet requirements. It posts an acceptance on the advice or suggestions about elderly Libyans' unmet daily needs.

In this section, the process of 4W online social community framework is elaborated in a detailed manner. The four groups of concepts which are who concept, where concept, what concept and when concept describe with the online social community component representation.

### A. The Who Group of Concepts

The 'Who' concepts describe the actors who participate in a community framework for supporting the elderly people towards fulfilling their unmet needs as it can be seen in Fig. 3. The members in 'who' concept would be a family member, relatives, neighbours, or social supporting community members.

In 4W online social community framework, the 'Who' concept represents many entities based on the task which is performed. In case of building the private network, the 'Who' concept represents the elderly who request for the unmet needs and the private network members who are going to satisfy these needs. Only the group community members who accept to fulfil the elderly needs will represent 'Who' concept. It also represents the member who accepts the elderly person's daily needs plan to satisfy their unmet need request, the member who supports the elderly people when they seek any emergency support. Fig. 3 shows all actors who represent the 'Who' concept in the 4W online social community framework.

### B. The Where Group of Concepts

The 'Where' group of concepts describe the place or location from where the requests arise as shown in Fig. 4. The place could be either from their residence, in private or public place, schools, or markets. It focusses on the location from where the unmet need request arises, the location of the elderly

and the location of their activity in order to generate the unmet needs plan, elderly coordinates to support the elderly in requirement of emergency support. Fig. 4 describes the details of 'Where' concept in the 4W online social community framework.

### C. The What Group of Concepts

The 'What' group of concepts describes what the elderly's request about, what the elderly people exactly need in their request or what are the contents of the daily unmet needs required to be fulfilled. The unmet needs of elderly Libyans come from the geriatric Assessment or the group community member's suggestions based on comprehensive assessment. The nature of those needs is what represents the 'What' concept which includes building community group, needs assessment and unmet needs request, daily plan generation, emergency support, and accepting suggestions. Fig. 5 details the description of 'What' concept in 4W online social community framework.

Fig. 3.    Detailed Who Concept.

Fig. 4.    Detailed Where Concept.
Fig. 5.    Detailed When Concept.

## D.  The When Group of Concepts

The 'when' group of concepts represents the time context that responses the question when the event defining the circumstances is occurring. In 4W online social community framework, the 'when' group represents the duration of the daily needs plan, at which time and date the elderly information are traced, when to generate the unmet daily needs plan. It also focuses on at which time the unmet daily needs are fulfilled and when to provide the comprehensive assessment of the needs. Fig. 6 shows detailed process of 'When' concept in 4W online social community framework.

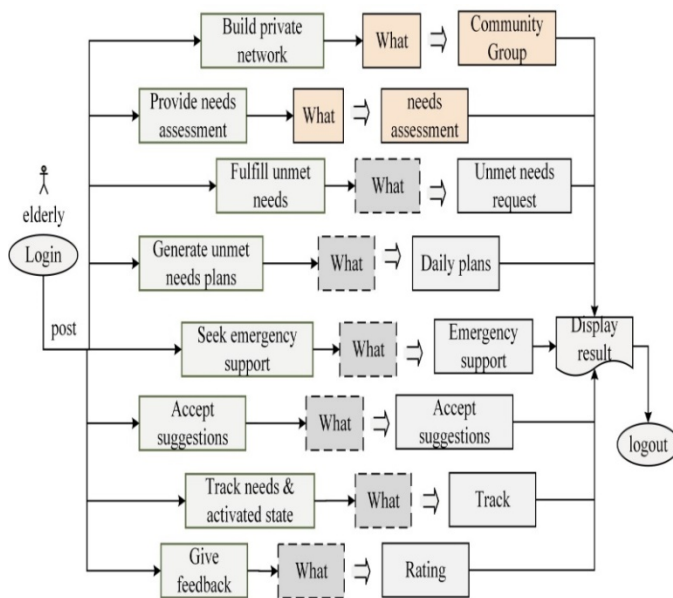

Fig. 6.    Detailed What Concept.

## V.   Evaluation using User Journey Map

In order to visualize the user's experience towards the developed model, the user journey map is developed. User journey mapping was chosen as a method for this analytical study as it gives the understanding of the positive and negative feelings that the user was experiencing while completing their journey. In this section, one user journey map for multiuser was created to understand how users would interact with the prototype. It also reflects the interaction between the user and the interface. This allows for further improvement of the prototype and makes the design better suit the elderly Libyans. The journey maps defined in this section includes four categories as "Pain point", "Action", "Touchpoint", and "Emotion". "Pain points" refers to burdens and obstacles which prevent a user from using a feature. "Action" is how the user interacts with the channel and what actions they undertake. "Touchpoint" refers to places that customers can interact within the channel. "Emotion" refers to how customers feel during each phase of the journey. Table I shows the tasks were assigned for each user when they drew their journey map. However, to empathize with the user experience and understand the issues they are facing, only four personas were considered in this study to draw one journey map.

## A.  User Journey Map Results

The results of applying a journey map based on participants' emotions and actions while they were accomplishing their tasks are discussed below. This highlights the importance of graphic design, attitudinal behaviour, and control and emotional issues in the interface design process for elderly people. Fig. 7 depicts the outcome of the journey map of four elderly people with eight steps based on their tasks. It displays their emotions through each step.

The Four personas are created based on randomly chosen but with made-up identity information such as names, ages, gender, and what they like or dislike with different perspectives. Creating personas allows the researcher to understand user emotions with the interface. Therefore, the final interface would be more efficient and user-friendly.

In general, elderly Libyans in most cases felt comfortable and confident while using the prototype interface because of the overall design and the information layout. Also, they feel more comfortable when the map window is kept at the centre of the user. In contrast, they were disappointed in waiting for group members' acceptance which led to providing some clues to make improvements in the design interface, for instance, notifying the users that they are in a waiting status.

From the user journey map, it is observed that the users feel comfortable and satisfied with the social interaction component of the model as it simplifies the process of interaction and login into the account and inviting their relatives and friends to become members of their group community for fulfilling their unmet needs.
Fig. 7. User Journey Map Outcome.

Researcher: "Are you able to send invitations?"

User: "Yes, I'm trying. I'm attempting to click on the image but I am unable to do so. It's lame. It would be good if it was a button for me because I am a visual person. But for me it is ok, it's clear I can overcome it."

According to the findings, the interface designing should be carefully developed to address consumers' concerns. It's critical to provide a "home" section for elderlies to return to when they feel insecure or misplaced in order to promote a sense of confidence. This establishes the user satisfaction toward the interface of prototype.

Researcher: "So, which one do you prefer?"

User: "I prefer a simple navigation system. I'd go home because everything is there".

Returning to the home page during doing the tasks gives the elderly a sense of safety and security, reassuring them that they are in the correct place. When elderlies couldn't locate what they were doing or searching for, they all opted to return to the main page. It was comfortable for users to return "home."

One of the participants said, "I'd probably go to the main page because it's crucial."

The participants feel very comfortable when they discover what they're accomplishing of tasks on the platform. They wish to use a single working window with lists in order to control window proliferation. It would be more helpful for them if the tool tip pop-ups are provided while the elderly move the pointer towards the key elements of the graphical user interface. Hence, they could get easy access to the task elements of the interface design.

Researcher: "How do you feel mentally, say do the icons of choices in front of you (in the header bar region) make you feel comfortable?"

User: "I feel better instead of searching; I can access many options with this bar."

Researcher: "Where can you usually obtain a list of all available members?"

User: "So maybe back to Home... in the profile of members or friends. I will go to the profile. No... No…, Here… in the member icon on the home page. Why there is no direct link get me here?"

In some cases, the elderly feel quietly disappointed in waiting for group members' acceptance to join and they feel difficulty in inviting the community members to their group. Once they get the response, they feel much happy and excited for the attendance of the supporting community member.

Researcher: "Why are you looking not comfortable?"

User: "Ummm… they have to do something to show we're in a waiting status." Moreover, while creating the list of unmet needs plan, they feel confused of where to slide.

Researcher: "So, what prompted you to return home?"

User: "I have no idea... I just felt it should be a separate part; however, it would've been preferable to keep with unmet demands down the bottom and see if it generates any plans."

Researcher: "How are you feeling right now?"

User: "A little sad."

Researcher: "So, you start from the Home page. Isn't it?"

User: "I'm not sure what they're saying, but there's something."

Also, participants felt unsatisfied to read long text rather visual images. Elderly Libyans respond more quickly to images. One of them expressed the following: "It appears to be in good working order. However, I'm sure there would be more information available on this. I love to work with pictures just because I am a visual person." Besides that, there was no quick access heading bar that allows users to quickly navigate between module components without getting lost.

## VI. DISCUSSION

This designed model includes the reorganization of tasks, a reorganization of data entry windows, and a reorganization of asset groups. The user could also perform the real task of creating the 4W grid using this prototype. The design prototype contains two side panes, left and right pane. The left pane contains the group details and the right pane contains the

details regarding the group members as well as the group recommendations. And, the task pane is available at the centre of the window that switches among the various tabs like recommendations and unmet need plans.

The created website model matched the users' desires and functionality, as per the user task analysis. Users had easy access to the web page and navigation. The majority of users were delighted with the webpage usability characteristics, such as navigation, accessibility, attractiveness and design consistency. The findings demonstrate that the proposed design process efficiently fulfils the webpage accessibility and functionality objectives.

## VII. CONCLUSION

In this paper, the 4W framework of online supporting community model for supporting the elderly towards satisfying their unmet needs is presented. It assists in determining what characteristics of model elements could be upgraded and what new opportunities could be introduced to the supporting community model. From the current design, the participants found that most of the tasks are easy to access and apply. The created platform model matched the users' desires and functionality, as per the user task analysis. Elderlies had easy access to the web page and navigation. The majority of elderly users were delighted with the webpage usability characteristics, such as navigation, accessibility, attractiveness and design consistency. The findings demonstrate that the proposed design process efficiently fulfils the webpage accessibility and functionality objectives of the user.

# Bayesian Network Modelling for Improved Knowledge Management of the Expert Model in the Intelligent Tutoring System

Fatima-Zohra Hibbi, Otman Abdoun, El Khatir Haimoudi

Computer Science Department, Advanced Science and Technologies Laboratory
Polydisciplinary Faculty, Abdelmalek Essaadi University, Larache, Morocco

*Abstract*—The expert module is an essential part of the intelligent tutoring system. This module uses only declarative knowledge, excluding other types of domain knowledge: procedural and conditional. This elimination makes the expert module very delicate. To solve this issue, the authors propose to embed knowledge processing into the expert model. The contribution aims to empower the expert model via the fragmentation of the knowledge process into four categories: Analyzation, Application, Conceptualization, and Experimentation using the Bayesian Network method as an instrument for modelling expert systems in uncertain areas. According to the management of the expert system through a list of criteria, the expert module can suggest the correct type of knowledge and their following status.

*Keywords—Smart tutoring system; expert model; knowledge processing; Bayesian network*

## I. INTRODUCTION

The accompaniment of students is a very important function in a learning situation, and its guarantee promotes motivation, attendance and the smooth running of all learning activities. For this purpose, the researchers tried to integrate techniques of Artificial Intelligence to propose accompanying mechanisms to guarantee the users' assiduity. Several contributions have focused on improving the intelligent tutoring system to make it more efficient, such as the integration of the two tutors: implicit and explicit, or each tutor uses his strategies and toolbox. The choice of one of the tutors is based on the following criteria: learner profile, effective feedback and learning progress data [1]; the latter needs Learning Analytics to collect the traces that learners leave behind and the uses these traces to improve learning [2].

The tutoring system is based during their interventions on the interconnection of these different models and especially the expert model. The knowledge representation in the expert module explores a set of strategies such as schemes, conditions, etc. The orientation of the system is based on the use of the knowledge of the expert module. Some systems use many techniques to formalize the expert module.

The CREAM system is one of the creation devices that offer the user to write specific objectives independently of the subjects. Thus, it uses various terminologies for the acquired skills [17].

However, the classical expert model in the previous intelligent tutoring system handles just declarative knowledge, which means the tutor intervenes in the activities in which the learner needs only definition and examples. This implies a lack of the taxonomy of the knowledge domain. To enhance the learner evaluation the authors [3] proposed a pedagogical solution based on the combination of three bits of knowledge: Declarative, procedural and conditional according to their status.

To enlighten the purpose of this work it would be noteworthy that the work presented in this paper is related to our previous work named: "Knowledge Management in the Expert Model of the Smart Tutoring System". In other words, the objective of the previous work was the management of the knowledge and subdivided into three categories: declarative, procedural and conditional knowledge in the expert model. To confirm this assumption, they investigate the efficiency of the proposed solution presented in the paper above. This article presents the experiments and results of knowledge processing using a Bayesian network technique and shows how the proposed approach can be applied and enhance the learner evaluation. To measure the performance of knowledge processing; they will use metrics, that evaluate the efficiency of each node dynamically in real-time.

The article is organized as follow: the second section describes the problem of the expert model in the smart tutoring system and clarifies the proposed solution; after that, the authors illustrate the construction of the Bayesian network for our model; then, section four details the conditional probability table. Last but not least, the implementation phase is subdivided into three subsections presented as bellow: the Bayesian network program, the results and the evaluation part. Finally, this article will be ended with a conclusion and future works.

## II. RELATED WORKS

### A. The Expert Model of Smart Tutoring System

An intelligent tutoring system (ITS) is a system that provides feedback and helps learners in their learning process such as remediation in a specific field like mathematics [4], or facilitating computer theory [5]. ITS contains four components; the first one is the interface model which can help the learner in a task via a learning environment; the second one is the learner model that has the personal information of the learner, their

preferences and characteristics; then, the instructional model which makes a decision about teaching method via a diagnostic process of the learner model; the last one is the expert model which has the representation of the declarative knowledge [3].

The expert module allows referencing an expert or a domain model. It provides a description of the knowledge or behaviours that represent the expertise in the domain [6]. It is a module where the main information is unrolled and will be taught. The best expert module is the most designed and appropriate [7]. This system must be performed in accordance with the knowledge that is available in the Learner module [8]. The expert module has two main functions [9], [10], [7] to elaborate questions, answers and explanations, and to act as a reference.

Several systems use different tools to model the expert module; among those techniques: the fuzzy cognitive map [11]. Another tool that uses thematic maps is the EON tool, which allows the creation of intelligent tutors oriented towards pedagogy [12] etc. The majority of these tools have a feature of authoring instructional objectives and the lack of the taxonomy of learning inside the expert modules. For that reason, in our previous work, the authors proposed to integrate the implicit and explicit intervention to ITS [2]. This tutor will select the appropriate strategy according to three criteria. This modification is concerned with the instructional model; this later has bidirectional communication with the expert model; this module is a computer representation of declarative knowledge, this knowledge allows the ITS to compare the learner's actions and choices with those of an expert in order to evaluate what he understands and what he does not understand [13], [14]. This module encounters a lot of issues, for that reason the authors propose the solution illustrated in Fig. 1.

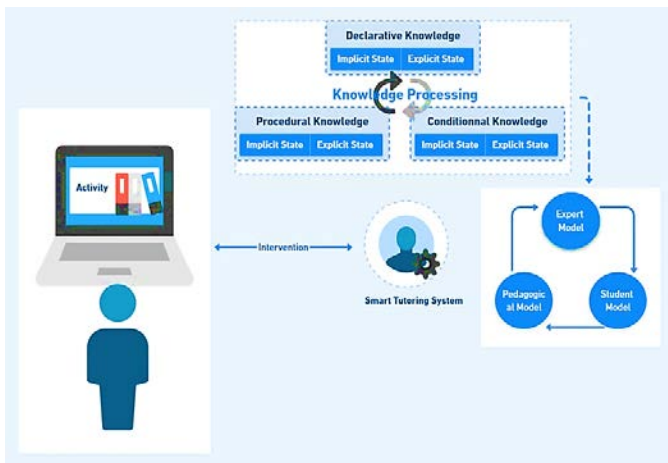

Fig. 1. Knowledge Processing in the Expert Model [3].

This solution combined the three categories of knowledge in the expert model. Declarative: definition of the concepts, procedural: problem-solving ability and conditional knowledge may have an implicit or explicit status, maybe both; and a type of assessment (memorization, administration, Expertise). The modelization of these large numbers of states that have a dispersed representation required the Bayesian network modelling. The choice of Bayesian Network is not arbitrary. This type of network is versatile: they can use the same model

to evaluate, predict, diagnose, or optimize decisions, which helps to make the effort of building the Bayesian network profitable.

Therefore, the graphical representation of a Bayesian network is explicit, intuitive and understandable by a non-specialist, which facilitates both the validation of the model, its eventual evolutions and especially their uses.

### B. The Development of Bayesian Network

Bayesian networks (BNs) are a tool for representing uncertainty using probabilities and robust mathematical foundations. BNs correspond to the probability distributions that can be generated by products of conditional probability distributions [3]. Several models are created based on knowledge representation and reasoning. Probabilistic graphical models, especially the Bayesian networks initiated by Pearl [15], have appeared as tools to describe uncertain knowledge and thoughts based on limited information.

Bayesian networks have been proven successful in modelling any kind of knowledge problem. Thus, Bayesian networks have been applied in numerous diverse fields, including medical diagnostics, information retrieval, and marketing. There are a lot of tools to create efficient Bayesian networks in an easy way like GeNIe [18] and SMILE [19]. Based on the literature, Bayesian Networks have been a positive effect in the student model of the ITS. ANDES is an example of an intelligent tutoring system which used Bayesian networks to conduct a long-term knowledge evaluation, and prediction of learners' behaviors while problem solving [20].

A Bayesian network BN = (G, N) is characterized by

G = (Y, E) directed acyclic graph with a set of vertices associated and random parameters, which is expressed by the following formula:

$$N = P (Y_i — Pa (Y_i)) \qquad (1)$$

With Y= (Y,. . ..,Y_n)

In a real-world application, the modelization of a large number of states that have a dispersed representation is indispensable. For that reason, to generate a classification with a representation that allows modelling with many variables a Bayesian network method is required [16]. The graphical representation of the BN describes the conditional independencies between variables which is easy to figure the joint probability. The Fig. 2 presents the Bayesian Network schema:

Fig. 2. Bayesian Network Schema.

To construct the Bayesian network model for our issue, two essential steps are required: specification of the structure model and specification of variable values.

*1) The specification of the structure model:* To describe the development of the Bayesian network, the authors start by defining the nodes of our model; the model involves an initial node "knowledge category", which is composed of several parent nodes presented as bellow: typeActivity1, typeActivity2 and typeActivity3. Each of these nodes contain child nodes. The links to these nodes are prerequisite relationships:

*a) TypeActivity 1:* The activity is based on a declarative knowledge; this type contains two nodes: Memorization: this activity uses a definition or examples of the concept and status; this is a type of evaluation, it reflects the learner's knowledge; the states of knowledge can be: Implicit: the learner knows what this is meaning, or explicit: the learner knows how to describe it. Fig. 3 presents the node "TypeActivity1" and their child.

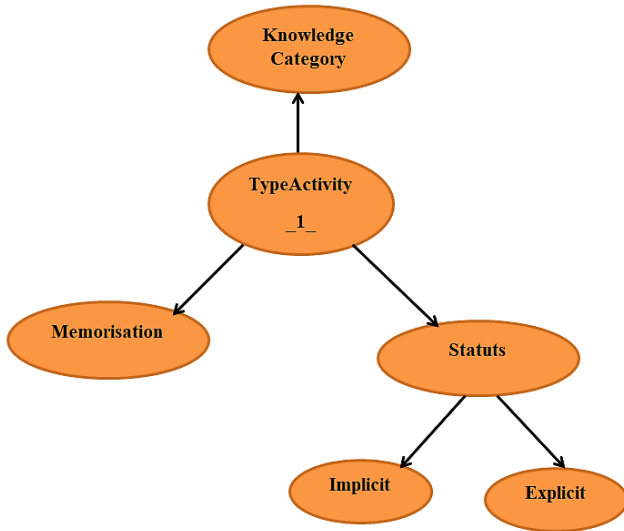

Fig. 3. The Node"TypeActivity1" and the Descendant.

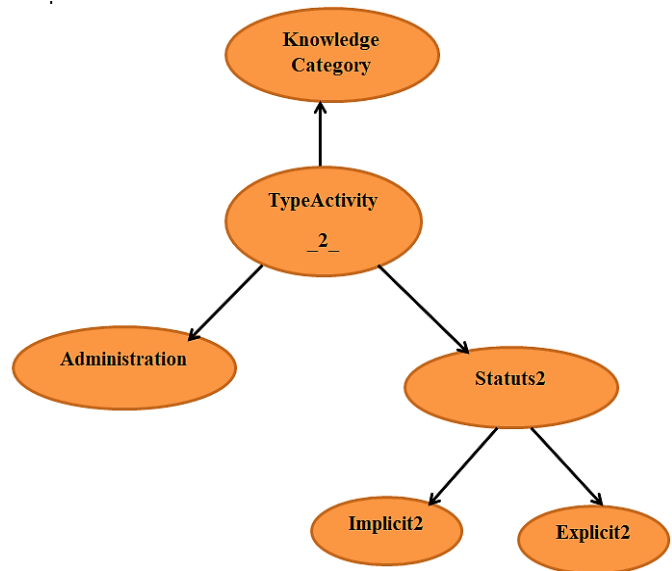
*b) TypeActivity 2:* The activity is based on a procedural knowledge; it is composed of Administration: the activity applies case studies; and the learner tries to figure out how to do the exercise (Explicit status) and how can do it (implicit status). Fig. 4 describes the node "TypeActivity2" and their child: Administration and status (implicit and explicit).


*c) TypeActivity 3:* This type of activity is based on conditional knowledge; it comprises: Expertise exercises. The activity develops the ability to realize a project based on both activities described above: TypeActivity1 and TypeActivity2; and the states of knowledge. The Fig. 5 illustrates the Bayesian network of the "TypeActivity3" as a node and their child.

*2) The specification of variable values:* After presenting the network model, the authors will define the values of the variable. In the construction of Bayesian network, the authors observe that the knowledge category depends of the type of activity. Which make us deduce that is the diagnostic

relationship. The initial node Knowledge Category (KC) comprises three parents: typeActivity1 (TA1), typeActivity2 (TA2) and typeActivity3 (TA3) which are corresponding to three weight: $w_1=0.2$, $w_2=0.3$ and $w_3=0.5$. The conditional probability of KC is calculated using the formula bellow:

$$P(KC|TA1, TA2, TA3)=w_1*h_1+w_2*h_2+w_3*h_3 \qquad (2)$$

With:

$$h_1 = \begin{cases} 1 \text{ if } TA\,1 = KC \\ 0 \text{ } Otherwhise \end{cases}$$

$$h_2 = \begin{cases} 1 \text{ if } TA\,2 = KC \\ 0 \text{ } Otherwhise \end{cases}$$

$$h_3 = \begin{cases} 1 \text{ if } TA\,3 = KC \\ 0 \text{ } Otherwhise \end{cases}$$

Fig. 4. The Node "TypeActivity2" and their Child.

Fig. 5. The Node "TypeActivity3" and their Descendants.

The authors mention that {KC, AT1, AT2, AT3} is a complete set of mutually exclusive variables, whose variable is also random and binary. As a generalization on the formula presented in (3) and (4), it can be said that:

P(X=1|Y1, Y2, ... Yn)= wi*hi, {i=1,…,n}    (3)

P (not X|Y1, Y2… Yn) =1-P(X=1|Y1, Y2, ... Yn)    (4)

The Table I presents the conditional probability of the node "knowledge category".

TABLE I.    THE CONDITIONAL PROBABILITY TABLE OF THE NODE "KNOWLEDGE CATEGORY"

| TA1 | TA2 | TA3 | P(X=1) | P(X=0) =1- P(X=1) |
|-----|-----|-----|--------|-------------------|
| 0 | 0 | 0 | 0,0 | 1,0 |
| 0 | 0 | 1 | 0,5 | 0,5 |
| 0 | 1 | 0 | 0,3 | 0,7 |
| 0 | 1 | 1 | 0,8 | 0,2 |
| 1 | 0 | 0 | 0,2 | 0,8 |
| 1 | 0 | 1 | 0,7 | 0,3 |
| 1 | 1 | 0 | 0,5 | 0,5 |
| 1 | 1 | 1 | 1,0 | 0,0 |

## III. IMPLEMENTATION PHASE

In this section, the authors will describe the environments, present the results and evaluate the efficiency of the proposed solution:

### A. Environments

After the construction of our Bayesian network model, the authors validate the proposed solution using the ANACONDA navigator. Spyder 3.3.6 is a scientific Python development environment and they work with python 3.7 as a programming language. In the phase of coding, they apply the POMEGRANATE package for building probabilistic models. Based on the conditional probability table that they built in the previous section, they initialized the status and activity using Univariate distribution (), which made up of characters and their probabilities. The sum of the probability will be 1.0. The Fig. 6 presents the Parameters of the development environment:

### B. The Results

Fig. 7 illustrates the probability of activity containing conditional knowledge; the result shows us that this activity should have an expertise activity, including the implicit and explicit status.

The probability of an activity containing declarative knowledge is that it should have a memorization activity, including the implicit and explicit status. The results are described in the Fig. 8.

The Fig. 9 presents the probability of activity containing procedural knowledge; the result shows us this activity should have an administration activity including the implicit and explicit status:

Fig. 6.    Parameters of the Development Environment.

Fig. 7.    The Probability to have a Conditional Knowledge.

Fig. 8.    The Probability to have a Declarative Knowledge.

        }
    ],
    "frozen" :false
}nknowledgetprocedural
```

Fig. 9. The Probability to have a Procedural Knowledge.

To summarize the results illustrated in the figures above, the authors can conclude the following points:

To create an activity that can attend the conditional knowledge; a pedagogical sequence must contain an expertise exercise, such as the ability to choose the appropriate method to solve a problem in a case study.

To achieve the declarative knowledge, the activity should have a memorization exercise like the recognition, categorization and differentiation between different objects (implicit status) and schematization, graphic, symbolic, linguistic (Explicit status).

A pedagogical sequence based on procedural knowledge should contain administration exercises in such a way that the learner tries to figure out how to do the exercise (Explicit status) and he can do it (Implicit status).

### C. Evaluation and Discussion

To measure the performance of knowledge processing, the authors used a lot of metrics; the first one is the calculation of the target node and all the evidences using the global confusion matrix (GCM); the obtained results from the GCM helps to know the probability of the correct classification (PCC), after that, they calculated the marginal probability of the correct classification (MPCC), and finally they obtained the marginal improvement (MI), individual PCC (IPCC) and the cost rate.

To evaluate the performance of the Bayesian network, validation of each node is necessary. The Fig. 10 illustrates the node evaluation "Type Activity1" as a target and their two fragments of evidence: "Memorization" and "Status": implicit and explicit.

From the results, the authors find that by adding the evidence nodes in the evaluation of the target node, the percentage probability of correct classifications is rising. By measuring the probability of each node's correct classification, they see how each node contributes separately to the classification. In this evaluation, the "Memorization" node is the biggest contributor. In this evaluation, they find the influence of the node "Memorization" to the target node.

The results reflect the choice of the TypeActivity1 which means that the expert model will concentrate the knowledge on the declarative one; for example: definition and explanation

with the uses of (58, 70%) as an explicit knowledge likes the graphs and schemas; and, (56, 90%) as an implicit knowledge which contains a recognition exercises.

According to the results and the validation of each node of the Bayesian network, the authors were able to handle globally the functioning of the network. According to the management of the expert system through a list of criteria that contains the type of knowledge as well as their status; the expert model can suggest knowledge in the right type as well as the appropriate status. If, for example, the expert system chooses the type of activity1, then suggestions can be demonstrated based on declarative knowledge (memorization) and appropriate status (implicit/explicit).

The Bayesian network modelling helps us to modelize the large number of states that have a dispersed representation. This modelization helps to make a prediction and evaluation of the three categories of knowledge and their child: type of assessment and status.

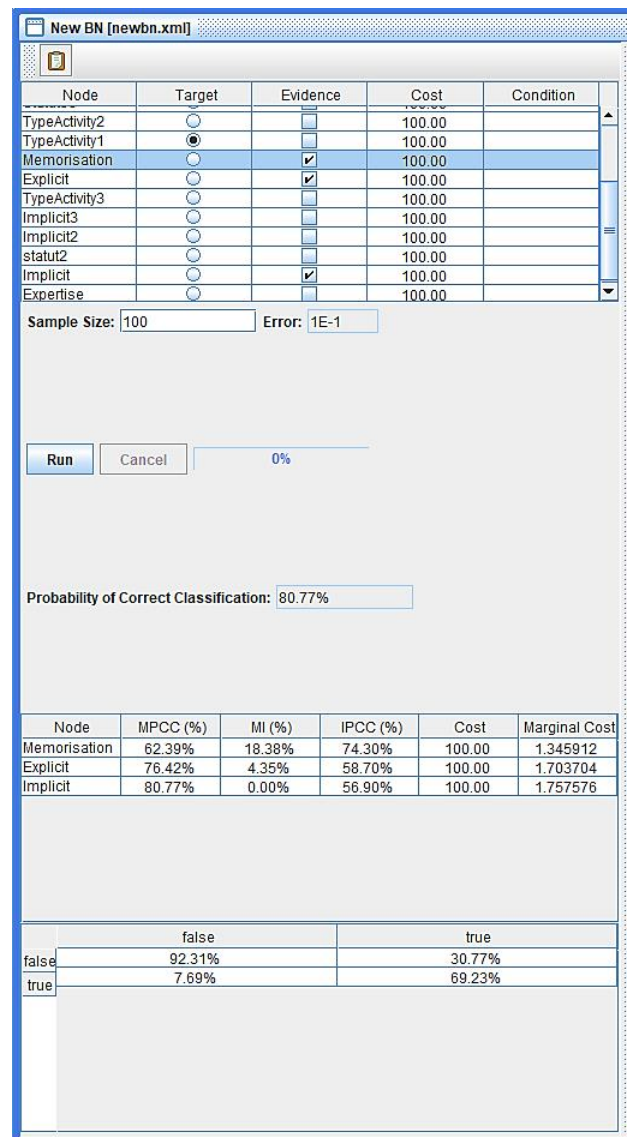

Fig. 10. The Node Evaluation "Type Activity1.

## IV. CONCLUSION

The evaluation part is an essential step in the learning process. To enhance this step in the expert model of intelligent tutoring system, knowledge processing is required. In this paper, the authors have presented the problem of the expert model; after that, they illustrate the construction of the Bayesian network; then, they evaluate the efficiency of the proposed process and the results in the implementation phase. This paper aims to investigate the efficiency of the pedagogical solution presented in their previous research paper via the Bayesian network model. This study analyses the knowledge processing according to the type of activity; this later depends on the knowledge and the status. In future work, we aim to study the process of the selected knowledge, and we will integrate the intelligent tutoring system into the FPL E-learning platform and the different contributions in one solution.

*Abstract*—A digital storytelling tool is one of the interactive technologies that can help youngsters better comprehend Dementia. Dementia makes it difficult for older people to maintain their daily routines. They have difficulties in effectively communicating with those around them. Similarly, children whose grandparents have Dementia will struggle to understand their grandparents' situation. It will also negatively influence children's relationships with their grandparents. Learning through interactive digital storytelling will affect younger people's entertainment experiences, which may help them better comprehend Dementia. As a result, the children's relationships with their grandparents may be strengthened. This study aims to present the framework of digital storytelling in helping young children understand more about Dementia. The framework was developed in a step-by-step procedure that included analyzing and synthesizing current applications and relevant research, constructing the framework, and having it confirmed by experts. Researchers and developers may use the framework as a guideline to build meaningful digital storytelling features.

*Keywords—Digital storytelling; Dementia; interactive learning; entertainment experience*

## I. INTRODUCTION

Dementia is one of the most common public health concerns among the elderly. Most of the research on Dementia treatments focuses on mental health assistance. When a patient is diagnosed with Dementia, it usually affects their family [1]. Children are particularly vulnerable because they lack the necessary information to understand Dementia. Maintaining a relationship with grandparents is difficult for youngsters since they don't know what to say or how to act [2].

Dementia technology intervention has been widely used. Healthcare tracking devices [3], brain training [4] and rehabilitation platforms [5], and predictive analytics and diagnosis [6] are all examples of its applications. Fitbit, Apple Watch, and other personal GPS trackers for the elderly are among the most popular interventions on the market for health tracking gadgets that could be utilized for Dementia treatment. Fitbit is a wearable device that tracks activity, exercise, diet, weight, and sleep to help individuals stay motivated and improve their health. Meanwhile, *BoundaryCare* is a location and health tracking software for Apple's iWatch and iPhone. The apps were created with Dementia in mind, but the apps also may be used to track other cognitive issues, including

Down syndrome and Parkinson's disease. Various devices can be used as personal GPS trackers for the elderly in addition to these. *Mindmate* and *Lumosity* are two other Dementia interventions that can be further considered. These apps are among the various brain training and rehabilitation platforms accessible.

Brain training is one of the most significant parts of improving Dementia symptoms [7]. According to this perspective, the applications are intended to prevent Dementia by training in cognitive processes such as speed, memory, attention, problem-solving, and others. Furthermore, numerous studies in the literature focus on having a mobile application to reduce cognitive impairment among patients [8]. This technological solution aims to improve a person's Dementia status by providing improved treatment support.

Within these five years, the United Kingdom's government, organizations, and communities began an educational information campaign regarding Dementia for the public, focusing on Dementia in family members, for example, the Dementia Friend, the Alzheimer's Association, and the Alzheimer's Disease International. However, the available resources for children are fairly restricted since, at times, children may find it difficult to understand owing to a language barrier that prevents them from grasping the situation. As a result, a more targeted intervention or programme to assist youngsters in understanding Dementia and how to care for their grandparents with Dementia is required. Furthermore, this arrangement will help the children maintain their bond with their grandparents.

It has been discussed who, when, and how to inform children and young people about Dementia. Dementia Friends proposed five key messages about Dementia to help them understand what Dementia is and what a diagnosis means for their relationship: 1) Dementia is not a natural part of ageing, 2) Dementia is caused by diseases of the brain, 3) Dementia is not just about losing your memory, 4) It is possible to live well with Dementia, and 5) There is more to the person than the Dementia. These five stages are the first to learn about Dementia, and an interactive version may also be utilized for youngsters.

Children today are exposed to technology and digital information from an early age. As a result of their early

exposure, they are more comfortable spending time interacting with digital information. The interaction is either for education, entertainment, or a change of lifestyle. Online learning has become the new standard for encouraging self-learning in schools. One of the online learning methodologies, digital storytelling, is regarded as helpful in raising children's motivation [9]. Furthermore, learning using interactive methods such as digital storytelling can aid in developing children's brains [9].

Education and computer application research is now generating a lot of interest in enhancing teaching and learning activities and raising children's productivity. Digital storytelling for Dementia may help youngsters comprehend the situation better [10]. In general, digital storytelling is a narrative style that combines digital pictures, texts, sounds, and other interactive components [11]. Digital tales are typically two to 10 minutes long. They are often saved in digital form and posted to internet sites where they may be viewed with web browsers [12].

Digital storytelling is also defined as short personal stories created with computer software and shared with others to transmit ideas, facts, and views on a wide range of subjects and themes [13]. They're also referred to as picture books [14] and are made up of various digital stories. According to Robin [13], the applications of digital storytelling may be divided into three categories: 1) personal narratives: stories about significant events in one's life; 2) historical documentaries: stories about critical events that help us understand history; and 3) stories that enlighten or instruct the viewer on a particular subject or practise. The application of Dementia to these domains might fall into one of three categories.

As children became more involved in and influenced by digital storytelling material, it is imperative to examine a relevant framework that can guide designers and developers on the appropriate design and development of digital storytelling [13]. Although many academics investigate the design and development of digital stories and picture books, they are mainly focused on specific issues and traits, particularly when developing an interactive tool. There has been minimal research on the appropriate content and design of stories for young children, especially when it comes to Dementia prevention via a digital picture book. There is presently no comprehensive framework that researchers and developers may use as a guide to compare and select relevant parts for digital storybooks. As a result, a comprehensive digital storytelling framework must be developed to create practical guidelines in the future. Therefore, to develop the framework, this paper will address the following:

- To analyze the current implementation of digital storytelling for young children in an online learning environment.

- To identify the essential elements of storytelling to motivate young children's engagement in online learning environments.

- To develop a suitable framework of digital storytelling for young children that can guide designers and developers on the appropriate design and development of digital storytelling tools.

This paper is organized as follows. The research underpinning interactive learning in digital storytelling is presented in Section 2. In addition, the experiences of involvement and amusement in digital storytelling are described. The many tools for implementing digital storytelling are outlined as well. The discussion of approaches to adopting digital storytelling in education is also presented in Section 2. Section 3 offers the development of the framework. The framework validation research is discussed in Section 4, and Section 5 discuss the result obtained from a focus group discussion with experts in the field. Finally, Section 6 concludes with some remarks on the study's significance.

## II. RESEARCH BACKGROUND

### A. Digital Storytelling and Interactive Learning

Digital storytelling is a method widely applied for interactive learning in which it could help to increase students' motivation to learn [13],[15], and it could evoke a sense of entertainment in learning [13]. Digital storytelling can also be viewed as an interactive platform that leverages information visualization to provide fun learning. Interactive learning is a merging technology in traditional education. It provides students with a platform to interact with the content in the learning process. The digital story also plays as a communication tool that conveys information between a teacher and their student based on the interactive story. In this environment, the student's role in the course changes from a passive receiver into an active participant. Interactive learning usually involves social networking. Community on social networks allows students to easily and effortlessly access the learning material, and learn from teachers and other students.

When digital storytelling is used for educational purposes or used for conveying knowledge and ideas, the environment becomes part of an interactive learning platform. Digital storytelling typically transmits stories in the form of a video as it can be readily shared to reach a larger audience [16],[17]. Students and teachers can easily access and share content using social media sites like Facebook and Twitter. Furthermore, students can respond to these digital stories by leaving comments and sharing them. To some extent, they could be able to interact with others when utilizing the provided content. It is believed that the determination to get attention on social media is the kind of reason for the students to get engaged with the digital storybook. Having a good internet connection and tools, on the other hand, is regarded as critical in interactive learning since it determines the ease with which students may gain knowledge both online and outside of class. These technologies function as interactive learning components, substantially altering the engagement between teacher and student.

Apart from that, one of the advantages of digital storytelling is that it can be generated using various media, including video, photos, audio, and music, to build a rich content project. Such inventions may provide viewers with a more profound sense of amusement and excitement when

viewing. As a result, digital storytelling has been applied to various disciplines to reach a wider audience or provide more profound knowledge. Digital storytelling, for example, is used in education to stimulate students' interest in learning and museum tours to enhance the tour experience.

## B. Digital Storytelling in Different Fields

Digital storytelling approaches have become increasingly popular in recent years as the barrier to entry has lowered. Teachers have used it at many school levels to improve students' learning experiences and increase their interest and motivation in the course [18]. Digital storytelling is also used in various domains, such as health care, ageing, and social issues [19].

*1) Digital storytelling in school*: Teachers worldwide have incorporated digital storytelling into their classes to aid in teaching and improve their students' learning experience. Digital storytelling has the potential to stimulate students' interest in learning and boost their drive to learn [15]. Students will benefit from the process of producing a digital story because the goal of a digital story is usually to deliver a message. Students would need to improve their communication abilities to create a digital story. In this way, they learn to arrange their thoughts and create narratives [12]. Creating a digital story might encourage kids to think creatively while improving their cultural literacy [20].

*2) Digital storytelling in museum*: Digital storytelling, as a form of multimedia that combines audio and video, may be more appealing and exciting than traditional oral communication. For example, digital storytelling in a museum tour guide's tour could enhance the tour experience and narrative for guests. Digital stories developed for the museum could serve various functions, like offering advanced information about the exhibition's showpieces or answering visitor queries [21]. For a more engaging and personal tour experience, museums merge digital tales with modern technologies such as smartphone applications, augmented reality, virtual reality, and more.

*3) Digital storytelling in community and non-profit organization*: On the social networking site, digital stories are straightforward and easy to share. As a result, communities and non-profit organizations frequently use it to spread their messages and raise public awareness. For example, a local government-sponsored awareness campaign might simply use and share the stories on social media sites like Facebook, Twitter, and Instagram. Furthermore, digital storytelling can make a complex or abstract subject more understandable for individuals. As a result, it has the potential to attract a more extensive range of people's attention [22].

*4) Digital storytelling in healthcare*: In health care, digital storytelling could be used as an educational tool to assist patients, their families, and caregivers understand their condition. Patients or their families who have gone through a challenging time, difficulties, or trauma due to illness could share their stories and offer advice. This information can be presented as a digital tale. Patients and their families may find

that sharing their tales is a powerful and emotional tool that can help them cope with the pain and challenges they may encounter in the future. It arouses a sense of empathy among caregivers toward their patients indirectly [23]. Hardy & Sumner [10] advocate for patients, family members, and caregivers to create digital tales based on their experiences with physical and mental disorders such as arthritis and Dementia. People who have lived through or experienced a similar event benefited from the digitization of stories.

## C. Engagement and Digital Storytelling

Children are exposed to various stories as they grow up, influencing their behaviour and acceptance of their surroundings. Children appear to be able to process and grasp complex information through narrative and apply it wherever possible [9]. Digital storytelling, enabling youngsters to learn something, has been proved to be an effective strategy in studies [9],[13]. This is because visual signals may assist children in focusing and thus become more engaged with the content. As a result, engagement, engrossment, and absolute immersion have been proposed as three levels of immersion [24].

- Engagement: The term "engagement" refers to both cognitive and emotional states [25],[26]. The interaction encourages the user to use the platform, or at the very least be aware of its existence, and piques the user's interest in digital technology, particularly game theory. Forcing anyone to use the platform, especially young children, is unconstitutional. Rather than forcing them to utilize any digital technology, they should be encouraged to do so. It will have a negative influence, and its monetary value will be lost. Engagement aims to provide a personalized experience through a platform that will attract and spark people's interest [25].

- Engrossment: The user may become highly absorbed and engrossed due to the involvement [24]. A game-created environment can be entered, explored, enjoyed, and defended by users. The player becomes an integral part of the game, and the game immediately impacts their emotions. At this point, players want to keep playing, which allows them to achieve complete immersion [27].

- Total Immersion: The final immersion stage is total immersion [24], which occurs when the user is fully immersed. The most important aspect of total immersion is paying attention. In video games, there are three types of attention: visual, aural, and mental. Combine visual and auditory elements to create an ambience that directs the user's experience [27]. Users must pay close attention to sound and vision, which requires extra effort. Consumers become more engrossed as a result of increased attention and effort.

## D. Digital Storytelling Tools

There are three different types of tools for generating digital stories. 1) Computer-based software programmes.

2) Tools that can be accessed via a web browser. 3) Apps for mobile devices such as smartphones and tablets [12].

- Computer-based Tools: Computer-based tools are software programmes that run on Windows or Mac OS X. They're most commonly used for non-linear editing. The basic functionality of free tools like Windows Movie Maker or iMovie for Mac is necessary to make digital stories. For the construction of digital storytelling, video and audio editing are sufficient. Paid editing applications with greater functionality, such as Adobe Premiere and Final Cut Pro, include transitions, filters, special effects, and more. Globally, computer-based tools have the most users. As a result, many online resources, such as articles, video tutorials, and online courses, explain how to utilize and create.

- Web-based Tools: Web browsers are used to generate these tools. As a result, it is useful for users whose operating systems are continually changing. The utilities are compatible with various operating systems, including Windows, Mac OS X, and Linux. After logging in with a web browser, the data will be synthesized for further processing. WeVideo is the most widely used of these tools. WeVideo, launched in 2011, offers the most functions and is similar to computer-based technologies.

- Applications for iOS or Android: In recent years, many people have switched from PCs to mobile devices as their primary means of work. As a result, professional editing apps for smartphones and tablets are now available. Some, including Adobe Premiere Rush (for iOS and Android) and iMovie for iOS, have grown from computer-based software. These apps are designed for users who are already comfortable with smartphones or tablets and are great for producing digital stories with limited content.

*E. Digital Storytelling as Entertainment Approach*

Digital storytelling is an approach to telling stories through digital technologies. It is considered a fun and entertaining approach when involved with technology. The story will be digitalized and designed with sound, video, or some interactive activities. Also, some are installed with external devices for enhanced learning. Following Hardy & Sumner [10], the storytelling is digitalized in six steps: writing, script, the storyboard, locating multimedia, creating the digital story, and sharing.

The first step is about writing activity. The purpose of this step is to introduce a personal narrative and the main idea for the storytelling. Scripting comes next in step two. It has been refined, and the elements of the narrative story have been defined. Step three is the creation of a storyboard. The storyline for each scene in the storybook will focus on this step. Through a succession of visuals, the storyboard will define the specific aspect and segment of the plot. The next stage is to locate Multimedia, which is the fourth phase. Step four is collecting the materials, which comprise sounds, films, music, graphics, pictures, and images, among other things. Then, in step five, create the digital story. Users will create

their stories using technology or software at this level. Step six is the final step, which is to share. It is critical to share user tales and solicit audience feedback. The digitalizing phases illustrate that when creating a digital tale, the storyline, the fun component, and the entertainment effect were all considered to make the story appealing and impactful to its intended audience.

Learning through entertainment is a valuable method for children because it helps draw their attention and imitate their experiences while learning. Learning and enjoyment are combined in one platform with digital storytelling. Whether digital storytelling is about pleasure, emotion, or suspense, it will interest its readers passively, actively, or enormously [28],[29]. Games, immersive technologies, and artificial intelligence technology can all be used to understand this type of involvement.

- Digital Storytelling in Games: In recent years, many people have switched from PCs to mobile devices as their primary means of work. As a result, professional editing apps for smartphones and tablets have been developed. Some, like Adobe Premiere Rush (for iOS and Android) and iMovie for iOS, arose from computer-based applications. These apps are designed for users who are already comfortable with smartphones or tablets, and they are great for producing digital stories with limited content.

- Digital Storytelling with Immersive Technology: Augmented reality (AR), virtual reality (VR), and mixed reality are examples of immersive technologies (MR). These techniques create a more immersive interaction experience [30], opening more possibilities in content creation, including digital storytelling. Virtual reality (VR) applications for digital storytelling with immersive technologies are the most common. VR is presented via a head-mounted display, allowing users to experience a fully simulated virtual environment. Some forms of digital storytelling will enable the audience to participate. The audience, on the other hand, is primarily passive and consumes the author's substance. In digital storytelling, VR could allow the audience to participate in the environment and provide a direct response to the event [31]. The audience can participate in digital storytelling made in VR. "In the future, you will be the character. The story will happen to you," said Chris Milk, an immersive artist. [32].

- Artificial Intelligence Techniques in Interactive Digital Storytelling: Artificial intelligence (AI) has traditionally been used in video games to enhance digital storytelling. These games give players various options for what the main character does, giving them the feeling of being the story's protagonist. AI would then shape the tale based on the player's decisions. Among the AI approaches are case-based, FSM, genetic algorithms, goal net and fuzzy cognitive mapping, natural language processing, and search algorithms [33].

### III. DEVELOPMENT OF THE PROPOSED CONCEPTUAL FRAMEWORK

#### A. The Framework Development Process

The conceptual framework was developed according to the previous literature review. The research field includes digital storytelling, learning cycle, technology intervention and user engagement. Fig. 1 depicts the four processes involved in developing a framework. The initial stage is to summarise and list the aspects and define the main elements based on the existing literature. According to theories in serious games, interactive technologies, and learning cycles, the second stage is to group the pieces into interactive learning. In this study, the third phase is to build up the elements of digital storytelling. Discussions about technology theories relate to the digital storytelling platform at this point. The framework is built at the last stage.

#### B. List of Elements

Interactive learning and digital storytelling are the two elements of the framework. This section separates the satisfaction of needs in interactive learning and the satisfaction of requirements in digital narrative design. The concept of interactive learning is derived from the theoretical learning cycle and serious gaming, as shown in Table I. Education, engagement, and amusement are three components of interactive learning that are relevant to the primary goal of the research. Each component contains three elements. The first component, education, has three components: empowered learning, problem-based learning, and deep knowledge. The second component is engagement, which has three levels: engagement, engrossment, and ultimate immersion. The third component is entertainment, including passive, active, and immersive forms.

Table II depicts Lambert's digital storytelling concept [12], which includes the seven components of digital storytelling and the establishment of the San Francisco Center for Digital Storytelling. However, the consumers in this study are children who are not suited to complex design. As a result, the five critical factors for launching digital storytelling pique children's interest while also providing an easy-to-use platform in Table II.

#### C. Group Elements of Interactive Learning

Education, engagement, and entertainment are the three components of interactive learning. Educational components are concerned with the learning process; engagement components are concerned with the amount of engagement; and entertainment components are involved with the entertainment experience. The proposed components are based on game theory, learning cycles, and the realm of immersion technologies.

Fig. 1. Framework Development Process

TABLE I. ELEMENT OF INTERACTIVE LEARNING

| Components | Elements | Description |
|---|---|---|
| Education | Empowered Learning | To help the user's motivated to complete tasks. |
| | Problem-Based Learning | It develops problem-solving skills and critical thinking skills. |
| | Deep Understanding | Every decision and action have a meaning, also called meaning as action. |
| Engagement | Engagement | Invite the user to use or know the platform exists and bring the user's interest. |
| | Engrossment | The user becomes deeply involved and becomes engrossed. So, the user's emotions will be affected. |
| | Total Immersion | The Final stage of immersion is total immersion, when the user is fully engaged. |
| Entertainment | Passive Entertainment | It lacks the interaction of the user or viewer. |
| | Active Entertainment | Increases the user's participation and expectations that they have different reactions to respond to different situations. |
| | Immersive Entertainment | Immersive entertainment comes with immersive technology such as Virtual reality (VR) and Augmented Reality (AR). |

TABLE II. LEARNING ELEMENTS OF DIGITAL STORYTELLING

| Elements | Literature |
|---|---|
| Setting | It refers to the physical location, including time, action, place, etc. |
| Characters | The most often-used cartoon or animals as characters. It also can affect the story |
| Plot | It is related to the storyline. |
| Conflict | It brings the challenge of problems that affect the action of the story. |
| Resolution | It is the underlying insight which is the message of the story. |

- Education-Learning Process: Kolb's learning cycle [34] and Gee's ideas for learning games [24] were used to guiding the learning process. These theories look at the deep learning cycle from a user's perspective, allowing them to apply their knowledge to new areas or solve challenging problems. Empowered Learning, Problem-Based Learning, and Deep Learning are the three stages. Empowered Learning, Stage 1: Empowered Learning is the first stage in motivating or encouraging people to use the platform. It is vital at this stage to pique users' interests to finish the work, and as a result, users will continue to use the platform. Stage 2: Problem-Based Learning: During this stage, the user will get experience in solving problems. Stage 3: Deep Understanding: Users must comprehend the meaning of each decision and action to attain deep understanding.

- Education-Engagement Level: The purpose of the engagement level is to assist the user in becoming more engaged. It has been debated in serious game theories as to how to create higher-quality serious games. Gee [24] hypothesized three immersion levels: engagement, engrossment, and ultimate absorption. Stage 1 Engagement: This is the stage in which the user is invited to utilize or become aware of the platform and pique their curiosity. The user begins to devote time, effort, and focus. Stage 2 Engrossment: Following the previous stage, the user becomes more immersed and captivated, which has a direct impact on the user's emotions. Total immersion is the third stage, which describes the circumstance in which the user is completely immersed. Total immersion is the final immersion stage and impacts the user's ideas and feelings. Aside from that, one of the most significant aspects of immersion is paying attention.

- Entertainment – Entertainment Experience: Entertainment Experience has been considered across various platforms, including video, games, and film [29]. Oliver & Bartsch [35] stated that theories on the entertainment experience are divided into three categories: Suspense, Appreciation, and Fun [28],[29]. According to Hall [36], suspense is related to the tension and excitement experiment. Whereby fun refers to enjoyment, appreciation relates to user experience, and suspense refers to the anticipation and excitement experiment. It resembles three cinematic elements: light, serious, and action-oriented [29],[35]. These theories are also similar to the "engagement Level", which has been discussed in the previous section. However, the conceptual framework proposed in this study is for digital interactive learning. Thus, the entertainment experience has been refined within three stages: Passive Entertainment, Active Entertainment and Immersive Entertainment.

*1) Stage 1 passive entertainment*: Passive entertainment lacks the user's or viewer's interaction. It is a type of entertainment produced by others and distributed to others, such as viewing movies or reading a book.

*2) Stage 2 active entertainment*: As the name implies, active entertainment places a premium on your participation and requires you to react and respond to various scenarios. Active entertainment, such as decision-making or character control in video games or interactive digital storytelling, will involve your participation rather than passive entertainment.

*3) Stage 3 immersive entertainment*: Immersive entertainment is a brand-new idea that has emerged as a result of the advent of immersive technology. Virtual reality (VR), which requires the user to interact with a VR headset and VR controller for an immersive experience, is an example of active entertainment with a higher interactive level and immersive simulation.

### D. Relationship between Components

This section discussed the relationship between interactive learning components: 1) Interest links education and entertainment, 2) Immersion links engagement and entertainment, and 3) Interactivity connects education and engagement. We illustrate the interrelationship of these three components in Fig. 2.

*1) Education – entertainment (interest)*: It is already termed in serious games called "Edutainment". However, the best association is "Interest". The more entertained they are by the APP (Games), the more interested the users will be in the learning content conveyed.

*2) Engagement – entertainment (immersion)*: The similarity between "Engagement" and "Entertainment" is in trying to approach the immersion stage, which brings the user totally involved with the platform.

*3) Education – engagement (interactivity)*: Interactivity increases engagement and brings users' attention. Thus, "Interactivity" enhances the learning process to provide an in-depth education system.

### E. A Set of Elements for Digital Storytelling

Digital Storytelling has five elements: Setting, Characters, Plot, Conflict, and resolution. The detail of each component is described in the following Table III.

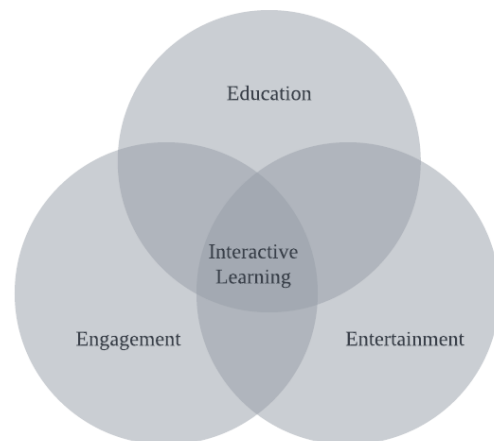

Fig. 2. Framework Development Process.

TABLE III. ELEMENTS FOR DIGITAL STORYTELLING

| Elements | Description |
|---|---|
| Setting | A story's setting refers to the physical location and includes the time, action, place etc. For example, historical stories. |
| Character | It depends on the story. People or animals are most often used as characters. Characters can also affect the story, such as some characters are set up as heroes who have a sense of fair play. |
| Plot | It is related to the storyline. The plot usually begins with a problem and resolves it at the end of the story. |
| Conflict | Most of the story requires conflict, which brings the challenge of problems that affect the action of the story. |
| Resolution | Resolution refers to the underlying insight to find out the "message" of the story. |

*F. Constructing the Framework*

The framework's construction follows the previous part and is divided into three stages, as follows:

Stage 1: The framework is established based on the understanding of interactive learning elements and the components of digital storytelling in constructing a digital storytelling application for promoting Dementia among young children. The framework is established into two sections: interactive learning and digital storytelling.

Stages 2: After establishing the essential component of the framework, the following step is to identify the sub-components for each of the components established for interactive learning – education, engagement, and entertainment. Following the discussion of the education component in Section III(C), the sub-components of the learning process comprise empowered learning, problem-based learning, and deep learning. The sub-components of engagement also discussed in Section III(C) include engagement, engrossment, and total immersion. For the entertainment component, the sub-components contained the entertainment experience, passive entertainment, active entertainment, and immersive entertainment. The relationship between these components was also mentioned in Section III(D). We illustrate this relationship in Fig. 3.

Stage 3: Establishing the connectivity of interactive learning and its requirement for digital storytelling. This study

aims to learn more about how this connectivity has a significant impact on the promotion of Dementia in young children. The digital storytelling element mentioned in Section III(E) is related to technological advancement. The framework of this study is formed by combining the theoretical aspect of interactive learning and the technical part of digital storytelling in Fig. 4.

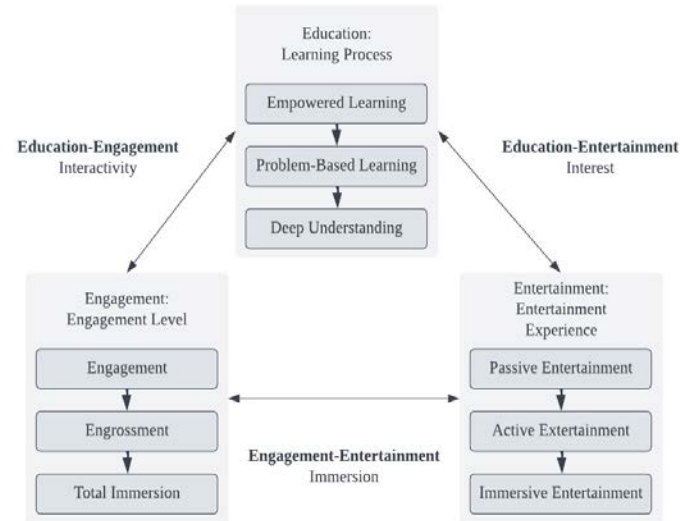

Fig. 3. Component and Sub-Components Relationship Establishment.

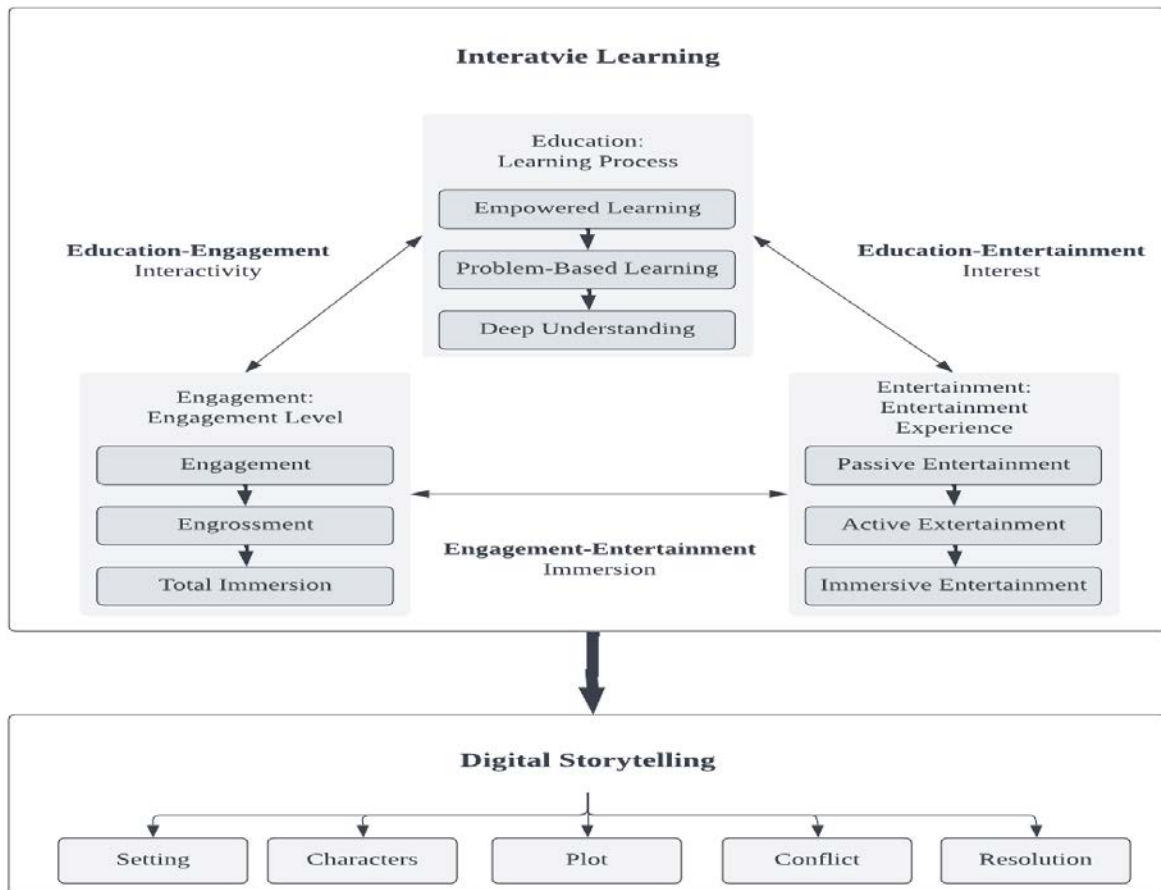

Fig. 4. Digital Storytelling Conceptual Framework.

## IV. FRAMEWORK VALIDATION

Research methods are procedures for collecting and analyzing data. There are various research methods for different types of research. The methodologies used will generally be determined by the research paradigm or how the researcher perceives things related to the study context. In this study, the research method used to validate the framework is through expert review studies. We assumed a framework validation should be conducted in looking into the need to explore and further comprehend the developed conceptual framework. It will uncover the framework limitations or ambiguities that the literature study does not comprehend [37].

### A. Validation Study with Expert Review

The validation study was conducted in the form of an online focus group discussion. The focus group discussion is designed to get collective feedback on the developed framework and plan the future work for developing the AR application. We introduced the framework by explaining the background of the framework, its purpose, the development process, the components, and their relationship at the beginning of the discussion. Then, during the discussion, we asked four questions. The questions are:

- Do you think the framework is comprehensive?

- Do you agree with all the components in the framework?

- Do you find any confusing components in the framework?

- Do you have any comments to improve the framework?

### B. The Participants and Discussion Design

The focus group discussion was participated by six experts. The six experts have decided to follow the minimum of five experts suggested in the heuristics study's guideline for finding average problems [38]. The experts were identified based on their research work and activities as well as their years of experience in user experiences, serious games, and persuasive computing. The demographic of the experts is presented in Table IV. These experts had agreed to participate in the study.

The discussion session was conducted via online meeting. These six experts were first invited via email, asking for their participation and valuable input in the study. When all invited participants consented to participate, all meeting information and survey materials were forwarded to the participants. During the discussion session, experts were briefed beforehand. After the briefing, the session starts with the framework explanation, followed by the question-and-answer session. In the question-and-answer session, the moderator will ask a question, and participants will take turns giving their valuable insight. The online meeting was recorded, lasting about one and a half hours.

TABLE IV. PARTICIPANT DEMOGRAPHIC

| Demographic | No |
|---|---|
| *Gender* | |
| Female | 4 |
| Male | 2 |
| *Age* | |
| 30 - 34 | 1 |
| 35 - 40 | 1 |
| 41 - 45 | 4 |
| *Employment Status* | |
| Academician | 4 |
| Researcher | 2 |
| *Field of Expertise* | |
| User experiences | 2 |
| Serious games | 3 |
| Persuasive Computing | 1 |
| *Years of experience in the field* | |
| 5 - 9 | 3 |
| Ten and Above | 3 |

## V. DISCUSSION

### A. Result and Findings

Based on the discussion, we present the results and analyze them based on the questions during the discussion. The first question gauged the comprehensiveness of the proposed framework. The experts agreed that the components related to interactive learning have a direct effect on the digital storytelling application. Although, some comments are worth to be considered for further improvement. The synchronization of component plot and characters is a noteworthy point. When designing digital storytelling, it is important to ensure that the character's design and implementation are suitable to the story's context. As a result, the impact on interactive learning may be observed more clearly. Two experts discovered that the settings component has little effect on the digital storytelling parts. However, the other experts contended the setting is needed to differentiate the stories and their environment. Thus, the setting component remains in the framework.

The discussion also revolved around the issues of improving the learning outcome. However, it was explained that the issue is not the main objective of the framework. It is part of the learning process that should be considered in future work. Therefore, all experts mutually agreed that based on the given input, the scope of the study, and their expertise in the field, the framework and its constituents are likely to be deemed comprehensive.

The second question concerns consensus on the framework's components. This question was posed as a follow-up to the previous one. The purpose of this question was to ensure that the components were well-considered. After the discussion, the experts generally agreed on all the components. In response to the third question, none of the experts mentioned any concerns that would suggest a problem

with the components. After further explanation, the experts remark on their understanding of the study context.

The discussion for the final topic revolves around remarks and suggestions for further improvement. Apart from what has already been stated, the experts are more interested in the framework's implementation, notably the application design and evaluation strategy. It would be beneficial if the findings were presented in separate sessions.

### B. Refind Framework

According to the expert interviews, the framework was devoid of Dementia-related features. As a result, the Dementia parts were included in the framework as shown in Fig. 5. To make each session more pronounced, the title will be included. Furthermore, significant sections between each framework session may be tightly associated.

Based on the expert interview comments, the following adjustments were made to the proposed model:

- Add framework sections- Information: The five key messages of Dementia friends which involved with 1) Dementia is not a natural part of ageing, 2) Dementia is caused by diseases of the brain, 3) Dementia is not just about losing your memory, 4) It is

possible to live well with Dementia, 5) There is more to the person than the Dementia.

These five fundamental messages are a starting point for understanding Dementia [39]. It is a critical step toward understanding Dementia. The five significant messages were reviewed and turned into a game called Teatime. The game's intended audience is the family of patients in the early stages of Dementia. The game symbolizes a possible Dementia symptom. However, another interactive platform to comprehend Dementia for youngsters will need to be created [39].

- Add a title to each section;

- System: Interactive Learning Setting Platform

- Platform: Digital storytelling Delivery Information: The key message of Dementia friends.

- Links were added to each session;

- System Applied Platform. Use the interactive learning system to apply to the digital storytelling platform.

- Platform Deliver Information. For the user to receive the information to increase their knowledge.

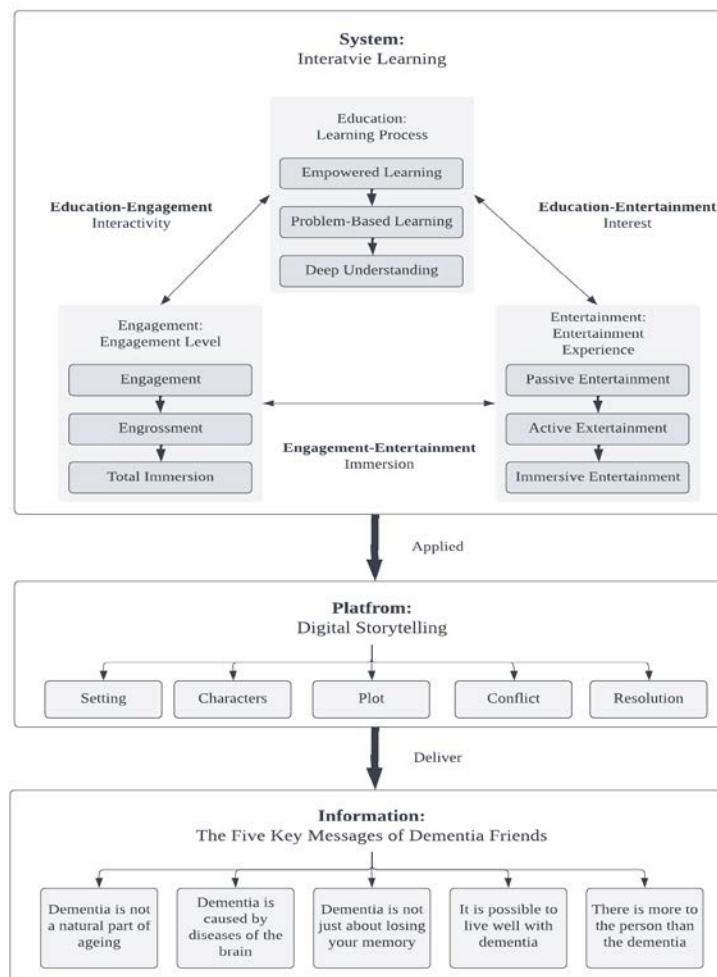

Fig. 5.   Refined Conceptual Framework.

## VI. Conclusion

In general, having a digital storybook can help young children interact with and sustain relationships with their grandparents. This study proposes a framework for a Dementia digital storybook for young children to assist them in comprehending their grandparents' condition. The framework was developed after an examination of applications and a review of the literature. The system featured two key interconnected components: an interactive learning environment and digital storybook elements. The framework's relevant components have been synthesized, and an expert review study has verified it. As a result, while considering the specific application for a Dementia digital storybook, these elements are seen as critical. This study contributes a new guideline for the designer and developer of a Dementia-related application to increase children's comprehension.

A prototype of a Dementia digital storybook for youngsters will be built for future development. This prototype will be evaluated with a range of users, including youngsters and family members with Dementia. The testing findings will eventually be used to prove the framework's validity. Overall, this approach is a useful resource for creating interactive learning aids to understand Dementia better. As part of the current study, children may learn about many long-term diseases (such as [16]) using a digital narrative framework.

The conceptual framework may be expanded with extensive knowledge about Dementia or substituted for various issues, particularly during an informative session. As a result, this research may be broadened to analyze how individuals become more aware of social concerns such as human rights, gender equality, and global warming.

*Abstract*—Storage for large datasets, handling data in different formats and data getting generated with high speed are the major highlights of the Hadoop because of which the Hadoop got invented. Hadoop is the solution for the big data problems as discussed above. In order to give the improved solution (in terms of access efficiency and time) for small sized files, this solution is proposed. A novel approach called VFS-HDFS architecture is designed in which the focus is on optimization of small sized files access problems with significant development compared with the existing solutions i.e. HDFS sequence files, HAR, NHAR. In the proposed work a Virtual file system layer has been added as a wrapper over the top of existing HDFS architecture. However, the research work is carried out without altering the existing HFDS architecture. In this paper drawbacks of existing techniques i.e. Flat File Technique and Table Chain Technique which are implemented in HDFS HAR, NHAR, sequence file is overcome by using Bucket Chain Technique. The files to merge in a single bucket are selected using ensemble classifier which is a combination of different classifiers. Combination of multiple classifiers gives the better accurate results. Using this proposed system, better results are obtained compared with the existing system in terms of access efficiency of small sized files in HDFS.

*Keywords—HDFS; Small sizes files; virtual file system; bucket chain; ensemble classifiers; text classification*

## I. INTRODUCTION

This Hadoop Distributed File System (HDFS) is a core component of Hadoop which works at storage layer of Hadoop. Advantages of HDFS includes varied data sources, availability, scalable, cost effective, low network traffic, ease of use, performance, high throughput, compatibility, fault-tolerant, open source and multiple language support etc. Apart from these multiple advantages, HDFS have limitations too such as handling small files, slow processing speed, support for batch processing, no real time data processing, no Delta Iteration, latency, not easy to use, security etc. Storing and processing of large number of small sized files in HDFS is a major problem. Hadoop Archives provides an efficient way to handle with small files [20].

Hadoop working is best with respect to big data files; small sized files are handled inefficiently in HDFS. NameNode carries the metadata information in memory for the files which are stored in HDFS. Consider a file which is stored in HDFS having size as 1 GB and the NameNode is responsible for storing the information such as filename, offset, length etc. which are split into 1000 fragments and stored all 1000 small files in HDFS. It is mandatory for the NameNode to store metadata information of 1000 small files in memory. This is not efficient way; first it takes up a lot of memory and second soon NameNode will become a bottleneck as it is trying to manage a lot of data [30].

Due to the outbreak of a COVID-19 pandemic, the entire world is now working in online mode. As a result, a massive volume of data has been generated, making it extremely complex to store, analyze and handle. The term big data generally used for this. The generated large volume of data which is in the form of structured or unstructured format. There is an immense need of analyzing and classifying this data in terms of size. HDFS gives the solution for this, which is responsible for handling large files in GBs or TBs in size of unlimited storage. HDFS works closely with the small number of large files. It is inefficient for handling large number of small files. Large number of small sized files consume more memory on the NameNode of the HDFS. Access mechanism of small sized files concept is a major problem in HDFS[8],[9],[10].

*1) Paper organization:* The rest of the paper is organized as follows: Section II gives the related surveys present in the existing literature. Section III provides the discussion on existing solutions on the given problem statement. Section IV describes the proposed work. Section V focusses on experimental set up and results produced. Section VI finally concludes the article.

## II. LITERATURE REVIEW

Xiong et al [1] employed a small file usage pattern to identify candidate files for merging into a single container. Identified gap in this article as and when the HDFS user request pattern changes there is a chance of cache missing.

Zhipeng et. al [4] discussed about merge strategy based hierarchy for improving the small file problem in HDFS, Bing et.al [5] created a novel approach HDFS:TLB MapFile for efficient accessing of small files, Sachin et al [6] discussed about different techniques of dealing with a small files

problem. Authors discussed about Hadoop Archive i.e. achieving technique which binds number of small files into HDFS blocks. Another technique improved HDFS model is index-based i.e. index is built for each small file to reduce the waste caused by them which reduces the burden on the NameNode. EHDFS gives an improved indexing mechanism and prefetching of index information. Lion Jude Tchaye-Kondi et al. [13] encouraged using hash functions to create a perfect file. To get the metadata of a specific file, this approach removes the requirement of parsing the index file. Xun Cai et al. [14] improved the access and storage efficiency of small files. Yanfeng Lyu et al. [15] proposed an efficient merging method that substantially reduces the access time for small files by using caching and prefetching methods. X. Fu et al. [16] proposed a block replica placement technique for effectively processing small files where files are merged as per the pre-determined parameters. Qi Mu et al. [17] advised a method for dealing with small files that is both efficient and effective. T. Wang et al. [18] suggested a method based on the behavior of small files access to build association between the small files. In this article, the concept focusses exclusively on file size. The gap identified in this, file contents have not been checked. If there is a mismatch in the file sizes, then cache will be missed.

## III. EXISTING METHODS

### A. HAR (Hadoop Archives)

HAR files were created to reduce the problem among several files putting a pressure on the memory of name nodes. On the HDFS, a layered system has been installed. The Hadoop archive command is used to create HAR files. It is not more efficient to read through files in a HAR than it is to read across files in Hadoop. Each HAR file access needs the reading of two index files in addition to the data file, which slows down the process [2],[7],[19],[20]. The flat table technique is used to implement the HAR.

Limitations of HAR files:

- Hadoop archive file once created is not updatable i.e. to adding or removing of the file is not possible.

- This archive file will contain a replica of all the original files when '.har' is created and it will take more space as the original files.

### B. NHAR (New HAR)

For NameNode, processing a large number of small files takes more time. In fact, the amount of time it takes to access such data should be minimized. NHAR [2],[7],[11],[12] is a novel solution that relies on Apache Hadoop's HAR. The table chain technique is used to implement NHAR.

### C. Spatiotemporal Small File Merging Strategy

In previous work, Lion Xiong et al. [1] employed a small file usage pattern to identify candidate files for merging into a single container. They employed file access time stamps to analyze usage patterns, then grouped files with sequential time stamps and generated support files for each file group. A single container is used to store a file group with a high support value.

## IV. PROPOSED SYSTEM

In this paper, the proposed technique is implemented by creating a wrapper over existing HDFS architecture without altering the HDFS architecture[5]. The Wrapper contains the Virtual file table which maintains the records of every file category wise like offset, length etc. Using large number of small files with different sizes analyzed the experimental results. Ultimately the time required for accessing files in HDFS is improved.

### A. Bucket Chain Technique

Working methodology of the proposed system is shown in Fig. 1. The root file table contains the list of files category wise, in which the information is gained about the existence of file category. The Bucket or child per category file table contains the metadata of the per category container which holds the metadata as Name, Offset and length of the category. Every child per category file table gives the metadata of the per category container file where the actual contents of the file can receive. Then it can directly access the contents of the actual file as that of reading or getting a file which is working with HDFS.

The advantages of the technique are if a user tries to access the same file repeatedly, the cache only gives the information quickly about the file location reducing the multiple searching and reading overheads.

### B. Methodology

In this method all file's metadata is stored in a single file, this file is called File Table. This file contains linked list of tables, forming a table chain. Another file is used to store actual contents of files; this file is called Container File. One container file is used for each category. All these files are stored on HDFS. File table contains metadata of a file such as filename, offset, and length.

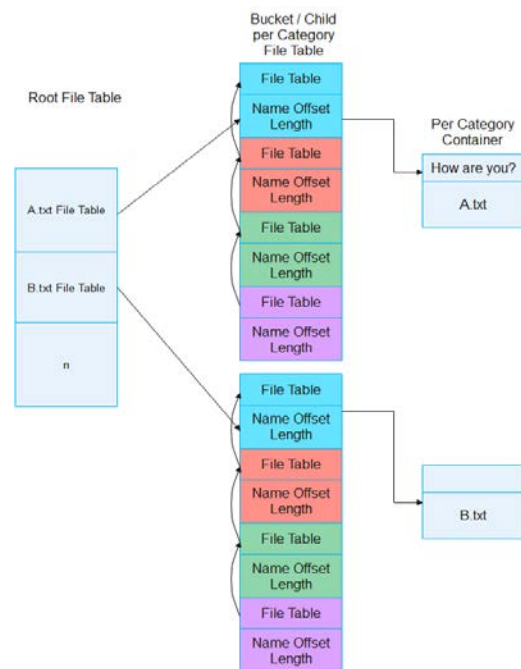

Fig. 1. Bucket Chain Technique for Proposed System (VFS-HDFS).

Before storing every file, it is classified using ensemble classifier to get its category. That file is then stored in container of that category and corresponding file table is also updated.

On startup, the file table for each category is loaded in memory. First the latest file table is located in file table and its contents are added to in-memory file table, then previous file table is located and the process continues until first file table is reached. While doing this, a file's metadata is already found in in-memory file table, then that entry is discarded (as it has become old due to updating or deletion of file).

In every run, a new in-memory file table for each category is created to track new or updated files in that category. At runtime all metadata is created and updated operations are performed on this in-memory file table. Actual contents of the files are appended in container file. On shutdown, the contents of in-memory file tables are appended to file table in HDFS. This creates a chain of buckets, each bucket stores list of file tables which makes it possible to update and delete files.

For reclaiming space used by deleted or updated files, the technique of pruning used. In this technique new copies of file tables are creating while skipping the deleted or updated entries. This will reduce space required for file tables and containers.

Caching is used to reduce time required for reading files in already retrieved blocks. Each cache entry stores tuple of category, file, position, length and its complete block content. This will reduce time at the cost of increased memory requirement.

### C. Algorithm: Bucket Chain

```
globals:
        filenametable
        indexfilemap
        containerfilemap
        filetablemap
        newfiletablemap
        classification_model
        categorylist
function intialize()
        filenamemap=load_filenamemap()
        for cat ∈ categorylist
                indexfile=indexfilemap[cat]
                containerfile=containerfilemap[cat]
                filetable=filetablemap[cat]
        file_index_location=get_last_index(indexfil
        while file_index_location != NULL
        indices=read_index(file_index_location)
                        filetable = filetable ∪ (indices -
(filetable ∩ indices))

        file_index_location=get_prev_index(file_index_location)
```

```
function add_file(filename, content)
        cat = classify(classification_model, content)
        location=append_content(containerfilemap[cat], content)
        add_file_entry(newfiletablemap[cat], filename, location,
len(content))
        add_filenametable(filenametable, filename, cat)
function get_file(filename)
        cat = get_category(filenametable, filename)
        location, length = find_file(newfiletablemap[cat],
filetable[cat], filename)
        data = read_content(containerfilemap[cat], location, length)
        return data
function close()
        for cat ∈ categorylist
                last_index=get_last_index(indexfilemap[cat])
                append_entry_table(indexfilemap[cat],
newfiletable[cat])
                append_prev_index(last_index)
        update_filenametable(filenametable)
```

### D. Advantages of Bucket Chain Technique

*1)* It has separate category wise containers.

*2)* It contains cache memory.

*3)* Pruning is applied to remove unused files in containers to reduce the memory wastage.

*4)* Optimal File Table Size.

*5)* Access time efficiency improved.

### E. Text Classification

It is used to classify the text documents automatically into one or multiple defined categories (Fig. 2). Category of news article from Reuters-21578 Text Categorization dataset [21] is taken into consideration for text classification Text classification consists of main components [23].

*1)* Dataset Preparation.

*2)* Feature Engineering.

*3)* Model Training.

*4)* Improve Performance of text classifier.

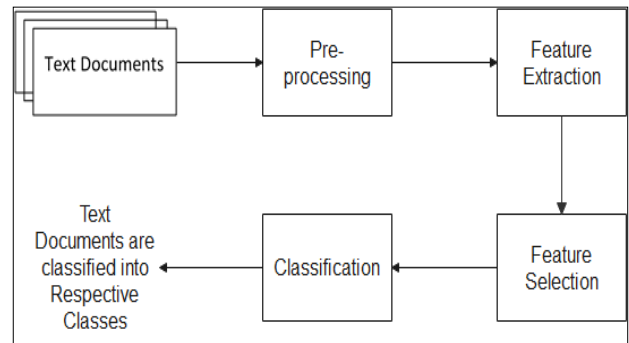

Fig. 2. Text Classification Task.

## F. Datasets Used

Experimentation is done on the Reut2-000.sgm & Reut2-002.sgm files. of Reuters dataset.

Table I gives information about the datasets used.

TABLE I.    DESCRIPTION OF DATASET

| Name of Dataset | Data Types | Default Task | Attribute Type | No. of Instances | No. of Classes | Year |
|---|---|---|---|---|---|---|
| Reuters-21578 Text Categorization Collection | Text | Classification | Categorical | 1000 | 70 | 1997 |

## G. TF-IDF

The technique stands for Term Frequency- Inverse Document Frequency which is used to quantify words from documents; a weight has been assigned to each word which states the significance of each word in the document and its collection. TF-IDF score signifies the relative importance of a keyword or a term in the document and the entire corpus. It is calculated as the logarithm of the number of the documents in the corpus divided by the number of documents where the definite term appears [23].

Formula: $idf(t) = \log(N/df)$

The tf-idf metric is calculated by considering the total number of documents, dividing it by the number of documents that which contain a word and calculating the logarithm.

$$tfidf(t) = tf(t) * idf(t)$$

## H. Classifiers used for Experimentation:

*1) J48 classifiers:* It deals with issues such as numeric attributes, missing values, pruning, predicting error rates, decision tree induction complexity etc[3].

*2) Random forest:* It determines the outcome based on decision tree predictions. It estimates an average of the output of various trees [24].

*3) Naive bayes classifiers:* It is capable of dealing with both discrete and continuous data. It can handle a large number of predictions and data sets [25].

*4) Ensemble classifiers:* For classification purpose the ensemble learning method is used. Fig. 3 describes the architecture of ensemble classifier. These ensembles combine multiple hypotheses to form a better hypothesis. Ensemble learning supports to improve machine learning results as compared to a single model by combining several models. Basic idea is to learn a set of classifiers and to allow them for vote. Combination of Random Forest, Naïve Bayes and J48 classifiers are used for experimentation [26].

Advantages: Motivation behind to use ensemble classifier is to improve the predictive accuracy.

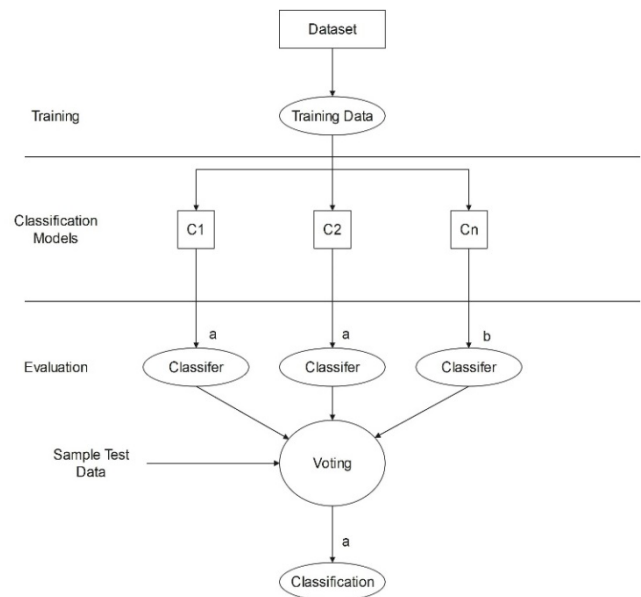

Fig. 3.    Architecture of Ensemble Classifier.

## V.    EXPERIMENTAL SETUP, RESULTS AND ANALYSIS

The proposed system is implemented on top of existing HDFS architecture. The proposed algorithm is experimented on Fedora 32.0 Operating System, Hadoop 3.2.0 and Java 1.8.0 Version. It contains 16 GB of RAM and 500 GB of Hard Disk with i5-5500U CPU @ 2.20GHz processor. Reuters-21578 Text Categorization Collection dataset is used to test the proposed system.

Table II shows the experimental set up used to execute the proposed work.

Table III shows how much memory and time is required to access small sized files in bucket chain algorithm.

TABLE II.    EXPERIMENTAL SETUP

| Sr. No. | Parameters | Description |
|---|---|---|
| 1 | No. of Nodes | Single Node (Acts as both Master & Slave) |
| 2 | Node Configuration | Intel(R) Core(TM) i5-5500U CPU @ 2.20GHz |
| 3 | RAM | 16 GB |
| 4 | Hard Disk | 500GB |
| 5 | Operating System | Fedora 32.0 |
| 6 | Execution Platform | JDK 1.8.0 |
| 7 | Hadoop Version | 3.2.0 |
| 8 | Development Tool | Net Beans 12.0 |
| 9 | Dataset | Reuters containing TEXT files |
| 10 | Number of Files considered | 2138 |
| 11 | File Size Range | Average From 1 KB to 100 KB |
| 12 | No. of Iterations | 1000 |
| 13 | No. of Classes | 70 |

TABLE III.    MEMORY AND TIME REQUIREMENT FOR PROPOSED SYSTEM (VFS-HDFS I.E. BUCKET CHAIN TECHNIQUE)

| Memory & Time Requirement for Proposed Technique (VFS-HDFS i.e. Bucket Chain Algorithm) for 1000 Iterations | | |
|---|---|---|
| Average File Size | Memory (in MB) | Time (in Seconds) |
| 1K | 30.7 | 39 |
| 5K | 31 | 39 |
| 10K | 35.2 | 41 |
| 50K | 40.5 | 46 |
| 100K | 55.2 | 55 |

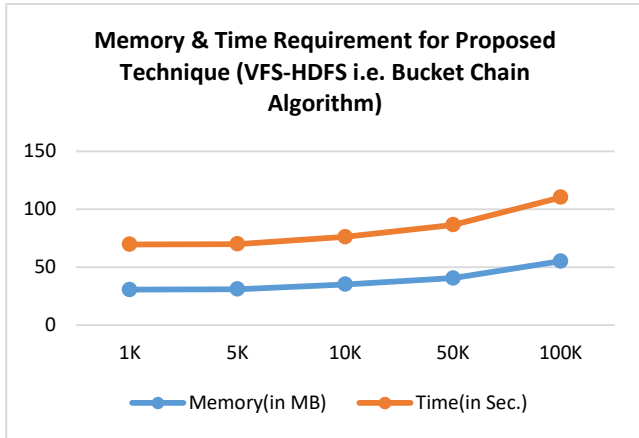

Fig. 4.    Performance with respect to Time and Memory for Proposed Technique (VFS-HDFS, using Bucket Chain Algorithm).

The above graph in Fig. 4 indicates the performance of the proposed technique in terms of time and memory.

Table IV shows the comparative chart of Experimental results of existing technique and proposed Technique VFS-HDFS using Bucket chain algorithm. where the memory requirement is increased due to the cache.

The graph in Fig. 5 shows the comparative chart of experimental results of existing and proposed technique VFS-HDFS using Bucket chain algorithm.

Table V shows the comparative chart of Experimental results of existing technique and proposed technique-VFS-HDFS using Bucket chain algorithm; where small files access time efficiency is increased.

TABLE IV.    COMPARATIVE CHART FOR MEMORY REQUIREMENT FOR EXISTING (HAR & NHAR) AND PROPOSED TECHNIQUE (VFS-HDFS USING BUCKET CHAIN ALGORITHM)

| Memory Requirement for 1000 Iterations | | | |

Classifier Metrics:

Table VI gives the information about different classifiers used and the corresponding experimental results.

Confusion Matrix for a single class:

Confusion matrix is created for class "earn" from reut2-002.sgm file.

TABLE VI.    DIFFERENT CLASSIFIER METRICS ALONG WITH ENSEMBLES

| Parameters | Naïve Bayes | J48 | Random Forest | Ensemble (Naïve Bayes+J48+Random Forest) |
|---|---|---|---|---|
| Total Instances | 962 | 962 | 962 | 962 |
| Correctly Classifies Instances | 684 | 738 | 899 | 922 |
| Incorrectly Classified Instances | 278 | 224 | 63 | 40 |
| Accuracy | 71% | 77% | 93% | 96% |

TABLE VII.    CONFUSION MATRIX

| Total Instances N=962 | Actually Positive | Actually Negative |
|---|---|---|
| Predicted Positive | 131 | 40 |
| Predicted Negative | 0 | 791 |

Table VII shows the confusion matrix [22] of the instances of the earn class.

Fig. 7.    Accuracy of Classification and Predictions.

The above graph in Fig. 7 shows the bubble chart of accuracy of classification and predictions of total 70 classes. X-axis indicates the actual class. Y-axis indicates the predicted class. Instances on 45-degree line are correctly classified instances. Incorrectly identified instances are randomly shown in random positions. Size of bubble indicates number of instances in that position.

## VI. CONCLUSION

In this paper, a novel approach called *VFS-HDFS* architecture is proposed in which exclusive focus is on optimization of the access efficiency of small sized files in HDFS with a significant improvements compared with the existing techniques i.e. flat table (HAR) and table chain (NHAR) technique. A new algorithm is proposed called bucket chain algorithm and the entire work is executed using this algorithm where memory requirement is increased to store the files in cache and time required to access the files from the cache is reduced. The proposed work uses the ensemble classifiers to classify the data sets. It helps to group the similar files in same container. Comparison is made between the experimental results of existing approach-i.e. flat table and table chain techniques and the proposed technique-bucket chain technique. In the proposed system it is observed that time required to access the files is reduced at the cost of memory required to store the files.

Institute for Big Data Analytics and Artificial Intelligence Universiti Teknologi MARA (UiTM) Shah Alam, Selangor, Malaysia

*Abstract*—Machine learning technology has a massive impact on society because it offers solutions to solve many complicated problems like classification, clustering analysis, and predictions, especially during the COVID-19 pandemic. Data distribution in machine learning has been an essential aspect in providing unbiased solutions. From the earliest literatures published on highly imbalanced data until recently, machine learning research has focused mostly on binary classification data problems. Research on highly imbalanced multi-class data is still greatly unexplored when the need for better analysis and predictions in handling Big Data is required. This study focuses on reviews related to the models or techniques in handling highly imbalanced multi-class data, along with their strengths and weaknesses and related domains. Furthermore, the paper uses the statistical method to explore a case study with a severely imbalanced dataset. This article aims to (1) understand the trend of highly imbalanced multi-class data through analysis of related literatures; (2) analyze the previous and current methods of handling highly imbalanced multi-class data; (3) construct a framework of highly imbalanced multi-class data. The chosen highly imbalanced multi-class dataset analysis will also be performed and adapted to the current methods or techniques in machine learning, followed by discussions on open challenges and the future direction of highly imbalanced multi-class data. Finally, for highly imbalanced multi-class data, this paper presents a novel framework. We hope this research can provide insights on the potential development of better methods or techniques to handle and manipulate highly imbalanced multi-class data.

*Keywords*—*Imbalanced data; highly imbalanced data; highly imbalanced multi-class; data strategies*

## I. INTRODUCTION

Every single piece of information in this world is data. The nature of data is that it is not absolutely balanced [1], [2]. It is either slightly imbalanced or highly imbalanced. Highly imbalanced is a situation where the ratio among classes is elevated. For example, 80:20 or 90:10 or 95:5 (majority: minority). While the example of slightly imbalanced is 60:40 or 55:45 or 70:30 (majority: minority). According to Bellinger et al., the imbalance ratio (IR) for highly imbalanced is 1000:1 (majority: minority) [3]. A well-balanced dataset is only possible in a controlled environment in which variables are preset, and data undergoes proper preprocessing.

The advancement of machine learning (ML) facilitates and alleviates problems in data analysis. The Internet of Things (IoT) and big data technology have accelerated the utilization of big data. During the Covid-19 pandemic, ML analysis helps in many ways like in vaccine development in which the cure is

required to restrain the virus spread concisely. With advanced computers, machine learning algorithms can process trillions of data within a short period of time and make accurate predictions, or classification of the problem.

To solve imbalanced data problems, researchers employ three strategies: 1) Data Level or DL 2) Algorithm Level or AL, and 3) Combination Level or CL. DL strategy involves data manipulation activities during the pre-processing phase. Most of the DL strategies involve approaches on data before it enters classifiers. Examples of such methods are undersampling and oversampling and their variants. AL strategy involves classifier-related activities. The main objective of the AL strategy is to apply algorithms or classifiers to manage dataset and handle imbalanced data problems. There are a lot of examples for AL such as Deep Learning variants, and Support Vector Machine (SVM) and their variants. CL strategy is a combination of both DL and AL strategy. This strategy applies to both hybrid and ensemble methods, even though ensemble can also work alone in AL. Ensemble is listed under CL because in most literatures about highly imbalanced data, the ensemble algorithm is combined with some other method(s) to achieve better performance. Some literatures only mention hybrid level, without the ensemble method as part of CL strategy [4], [5]. In some other literature, the ensemble method is mentioned along with DL and AL without the hybrid method [6].

The ensemble method is an interesting area of research. Ensemble algorithms can apply ensemble algorithm to other algorithms, either supervised, semi-supervised or unsupervised (or combination of all) to produce a better algorithm. The hybrid method is also a very interesting method in ML. It combines any method in DL with AL, combines DL method with another DL algorithm(s), or combines AL with another AL method(s). Therefore, this study proposes a new term "Combination Level" for both the hybrid and ensemble methods in highly imbalanced multi-class (HIMC) data. This article then will propose a novel framework for highly imbalanced multi-class data (HIMC). This is crucial so that the structure of the framework and the relevance to future of ML can be explored. It is hoped that this research will pave the road for other researchers to excavate deeper into the nature of HIMC data and various ways to handle it.

This paper is organized into several sections. Section I presents the definition of imbalanced data, highly imbalanced data, multi-class data and highly imbalanced multi-class data. Section II provides the explanations on the research gap, research questions and research objectives. Section III presents the descriptions on the current and previous solutions in

handling imbalanced data, previous solutions in handling multi-class data and previous solutions in handling HIMC data. Section IV provides the descriptions on the prominent validation metrics for HIMC data, data type and dataset behavior along with discussion on the case study dataset. Finally, Section V presents the explanations on the proposed and refined framework of HIMC data and will be followed by Section VI, discussions on open issues. Finally, Section VII provides the conclusion.

### A. Imbalanced Data

Imbalanced data is currently a prominent research topic and acts as a relatively new research interest in machine learning [1], [7]. A circumstance in which the total number of the majority class is significantly greater than the data of the minority class is known as data imbalanced [8]. Most classifiers are designed to work with a balanced dataset in which the majority class is comparable to or equal to the minority class, or the ratio between the two classes is 50:50. A balanced environment is essential to make sure the classifier can perform at the best level of accuracy. Therefore, when unequal data exists, an imbalance data problem transpires [9], [10]. Imbalanced data also occurs because of the existence of minority classes that are lowly represented [11]. It also can happen when the dataset is skewed [12]. Most classifiers in a balanced class are biased toward the majority class [13], [14], [15]. In real life, all real-world data is imbalanced [16], [17]. Real-world data can have a high chance to fall in the category of highly imbalanced data [18]–[20] or slightly imbalanced data [21].

Imbalanced data exists in numerous disciplines for example, wind turbine fault prediction [11], network diagnosis, wireless sensor application [22], acid amino detection [23], medical diagnosis [24], Internet of Things [25], fraud detection [26], and other domains. Many approaches to overcoming the problem have been offered with regard to data imbalanced problem using different solutions from DL to AL and CL strategy, such as those found in [5], [8], [11], [26]–[29].

### B. Highly Imbalanced Data

To deal with the problem of data imbalance, a variety of approaches and methodologies have been proposed. DL and AL strategies focus on ways to reduce biases of classes in a dataset. CL strategy involves an ensemble or a hybrid of several algorithms to achieve the best results. Nevertheless, the problem with imbalance data is far from settled, especially in highly imbalanced data scenarios. The problem with highly imbalanced data is that the ratio is extremely high. The solution that works in slightly imbalanced data might not work in highly imbalanced data. Therefore, highly imbalanced data needs more consideration and investigation. Normal graph distribution does not present in highly imbalanced data as the graph is highly skewed.

In a slightly imbalanced data environment, a conventional method such as Synthetic Minority Over Sampling Technique (SMOTE) can help solve the problem of imbalanced data. Unfortunately, DL method like SMOTE can worsen the classification performance in highly imbalanced data environment. Using randomized methods like Random Undersampling (RUS) is also not effective due to a high

variance created in the IR. To overcome the problem of noisy data and overlapping classes, a new approach for data preprocessing is needed to boost classifiers' performance. A new approach to handle detection and filtering noisy data is needed in the scenario of relabeling classes. The problem can increase the imbalance among classes. It could result in the classifier rebalancing the wrong classes.

A highly imbalanced data problem arises when the IR is too high compared to slightly imbalanced data. For example, the ratio of minority to majority less than 50:1 can be considered slightly imbalanced while imbalance ratio (IR) more than 50:1 can be considered highly imbalanced. According to Triguero et al., IR for highly imbalanced data is 50:1 (majority: minority) [30], [31]. Another well-known IR is 100:1 up to 10000:1 [32]. The same IR (100:1) was suggested by Sharma et al. [33]. Sharma et al. suggest 100:1 as highly imbalanced while 1000:1 was categorized as extreme imbalance [33]. Table I shows benchmark of IR.

TABLE I.     BENCHMARK OF IR

| No. | Reference | IR | Year |
|---|---|---|---|
| 1. | He & Garcia | 100: 1 up 10,000:1 | 2009 |
| 2. | Triguero et al., Leevy et al. | 50:1 | 2015, 2018 |
| 3. | Sharma et al. | >1000:1 | 2018 |
| 4. | Bellinger et al. | 1000:1 | 2019 |

More practical IR was found among bioinformatics and biotechnology domains, and it was 50:1 [30], [31]. In other literatures, highly imbalanced are also known as rare events in which researchers and scholars stated that the minority data that was from 0.1% to less than 10% , can be considered as rare events [34], [35]. In the real-world, IR ranging from 1000:1 up to 5000:1 is possible in fraud detection and medical science [4], [36], [37].

This research has chosen the latest literatures as the benchmark for highly imbalanced data ratio. The latest found in literatures on IR is suggested by Bellinger et al. which is 1000:1 [3]. Therefore, for the purpose of this research, the IR stated by Bellinger et al. will be used. The ratio from Bellinger et al. has also been chosen because the dataset used in this research matches with the stated IR.

### C. Highly Imbalanced Multi-Class (HIMC) Data

Problems in highly imbalanced data originate from problems in slightly imbalanced data, which are alleviated due to the nature of severe IR [3], [33]. Thus, problems in imbalanced multi-class data and highly imbalanced multi-class data can be considered similar in nature, with the difference laying in the IR.

To overcome the HIMC data issue, a new approach for data pre-processing is needed to boost classifiers' performance in HIMC data. Another solution to overcome the problem is by creating synthetic data to move overlapping data to new spaces [38]. Another method is to remove excessive samples and maintain the quality of the data [2], [6] [1], [6].

Relationship among classes is an issue in multi-class data. It is a complicated situation as each group of classes presents

different problems to the data [1], [2], [4], [38], [39]. This problem is elevated in HIMC data, and affects classifiers' performance [40], [41]. Leevy et al. and Rendon et al. suggest that more flexible methods such like the heuristic-based method should be explored to solve multi-class data problems [31], [42]. The HIMC data has multiple skewed classes which reduce classifiers' performance as it is challenging to normalize skewness [31], [43], [44], [45]. Due to skewness, it is also difficult to define borders of the overlap classes [4], [46], [47].

### D. HIMC Data Research Gap

Among the major challenges with highly unbalanced data are the accuracy of classifying highly imbalanced multi-class data, training efficiency for large data, and sensitivity to high imbalance ratio (IR) [48]. In highly imbalanced data, classifiers are prone to a strong bias toward the majority class, which cannot accurately represent the true problem or convey essential information. The minority class were treated as noisy data at the pre-processed level and will cause the loss of crucial information [1], [21]. This creates new challenges to data level strategy in handling biasness [49], [43], [45].

A dataset with multiple target classes is skewed in distribution in imbalanced multi-class data, and this has a substantial effect on classifier performance [38]. HIMC data has multiple skewed classes which significantly reduce classifiers' performance as it is difficult to normalize skewness [31], [43], [44] due to the difficulty to define borders of the overlap classes [4], [47].

At algorithms level, existing classifiers are modified to remove the biases toward the majority classes. One of the methods is the cost-sensitive method. The cost of misclassification for minority samples is higher than for majority samples in the cost-sensitive method. Determining the cost values of trained data is complex since they are dependent on multiple aspects that have trade-off relationships, such as high-dimension, high noise, small sample size, and others [1], [21]. In financial data, biasness causes highly imbalanced distribution [50].

Therefore, based on arguments regarding HIMC data, this research addresses three research questions and three research objectives.

The developed research questions for this study are:

*1)* What is the current trend in handling highly imbalanced multi-class data?

*2)* How to handle highly imbalanced multi-class data?

*3)* How to develop a framework of highly imbalanced multi-class data?

The following objectives are developed based on the research problem:

*1)* To understand the trend of highly imbalanced multi-class data through analysis of all related literatures.

*2)* To analyze the previous and current method of handling highly imbalanced multi-class data.

*3)* To construct a framework handling highly imbalanced multi-class data through research and literature study.

## II. STRATEGIES IN HANDLING IMBALANCED DATA

Based on previous studies on HIMC data, it is imperative to understand these related sub-topics: (1) Strategies in handling imbalanced data; (2) Previous solutions in handling imbalanced data, imbalanced multi-class data and HIMC data; (3) Related method or technique used in solving HIMC data problems.

The same three strategies in handling slightly imbalanced data can be used in handling highly imbalanced multi-class data. The details of these strategies and their methods are put under Appendix 1. There are three types of DL strategies which are oversampling, undersampling and hybrid strategy. AL strategy can be divided further into four methods which are cost-sensitive learning, skewed learning function, sampling-based and other methods. The CL strategy can be divided into two main methods: hybrid and ensemble. The Hybrid method can be divided further into MTD-based, SVM-variants and other hybrid methods. While ensemble method can be divided further into four methods which are integration with data level, integration with cost-sensitive, bagging variants and boost variants.

DL strategy involves data manipulation activities during the pre-processing phase in machine learning. An example of oversampling-related method is Synthetic Minority Oversampling Technique (SMOTE) [51], while an example of undersampling related method is Random Under sampling (RUS) [52]. From the literature review conducted, several literatures related to HIMC data have been found. However, the strategy or method proposed at DL in HIMC data is hardly mentioned. Therefore, this can be a promising area for future research in HIMC data.

AL strategy involves classifier related activities such as Support Vector Machine (SVM) [53], Deep Learning method using Convolutional Neural Network model (CNN) [54], and K-Nearest Neighbor [55]. Convolutional Neural Network (CNN) model was used to predict Chlorophyll-A concentration in Algal Bloom in managing data imbalance and skewness [56], and a Deep Self-Organizing Map (DSOM) was proposed to detect a well-known pre-miRNA protein as compared to a genome's hundreds of thousands of potential sequences [18].

The CL strategy is a combination of both DL and AL strategies, or combination of DL strategy with another DL, and a combination of AL with another AL strategy. In addition, it can also be a combination of ensemble method with AL strategy, or combination of ensemble method with DL strategy, or it can be a combination of both hybrid and ensemble methods [57], [58]–[60]. For example, based on a combination of data rebalancing and Extreme Gradient Boosting (XGBoost), a unique form of malicious synchrophasors detector is developed [61].

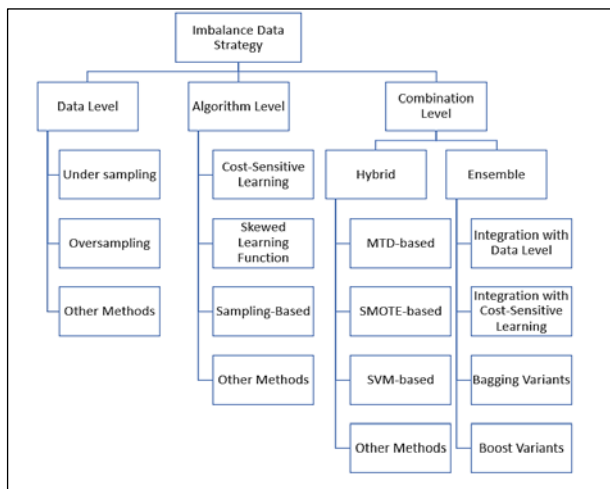
Oversampling and under sampling were combined with SVM in solar flare prediction [7]. Fujiwara et al. proposed a heuristic undersampling and distribution-based sampling with boosting method (HUSDOS-Boost) in handling data problems in health record analysis [44]. The strategies and methods used in handling imbalance data are shown in Fig. 1.


Fig. 1.   List of Strategies in Handling Imbalanced Data.

Fig. 1 shows a list of strategies in handling imbalanced data. Imbalanced data can be divided into three strategies namely DL, AL, and CL strategy. Literatures related to DL and AL can be found in many studies while CL concept is still fresh. In literatures such as Kaur et al. and Johnson and Koshgoftaar, DL and AL have been mentioned along with Hybrid Method (HM). The logic behind this concept is that HM is a combination of both DL and AL [29], [42]. In other literatures such as in Sleeman & Krawczyk, DL and AL have been mentioned along with Ensemble Method (EM), while HM has not been specifically mentioned as their work was more focused on EM [6]. Some might argue on the reason to categorize EM into CL, as EM might also fall into AL strategy.

It is imperative to understand that in recent highly imbalanced data research, EM is usually not working alone and is combined with another method except for performance comparison or proposal of a new framework [62], [63]. In highly imbalanced classification, research of supervised and unsupervised fuzzy measure approaches was conducted by Uriz et al. The authors integrated EM with fuzzy integrals and their synergy with various fuzzy measures [64]. Another study was by Liu et al. where they established a unique framework for imbalance classification that was intended at building a strong ensemble by self-paced harmonizing data hardness by under-sampling, in which a classifier was combined with self-paced EM. [15].

Ghorbani et al. proposed a new hybrid model based on a highly imbalanced dataset to predict early mortality risk in intensive care units (ICU). The authors developed an SVM and SMOTE hybrid strategy (SVM-SMOTE) that included several methods, including a Genetic Algorithm (GA) for feature selection (FS) and Stacking and Boosting (EM) for prediction. SVM-SMOTE was used to tackle imbalanced data problems [65]. Using clustering, weighted scoring, SVM, and EM, Ksieniewicz et al. suggested a hybrid method for managing severely imbalanced data categorization in geometric space [66]. Using a combination of data rebalancing, bagging-based ensemble learning, and the Extreme Gradient Boosting (XGBoost) algorithm, a unique form of malicious synchrophasors detector was developed to address the highly imbalanced data problem. Even if malicious synchrophasors

occur seldom in practice, a detector trained on a highly imbalanced dataset drawn straight from previous operational data is biased toward the majority class. [61]. Tran et al. proposed a combination of K-Segments, under sampling and bagging EM as experimental research to approach extreme imbalanced data classification [64]. From the examples mentioned in this study, EM was combined with other methods to achieve better performance. Appendix 1 until Appendix 4 will entail strategies and methods involved in handling imbalanced data.

## III. Previous Solutions in Handling Highly Imbalanced Multi-Class Data

Ahmadzadeh et al. is one of the most current approaches for extremely unbalanced data that has been proposed [7]. The reviewed literatures discussed solar flare forecasts using under-sampling, over-sampling, and Support Vector Machine (SVM) to handle highly or extremely imbalanced solar flare data. For future development, these works suggested exploring hyperparameter tuning of the proposed method to enhance the model. A multi-class dataset was initially used but then it was converted to binary classification data to make predictions.

Fujiwara et al. published an article in the medical field. In this research, oversampling and undersampling methodologies for highly imbalanced data in health records analysis were presented. When minority samples are too tiny, undersampling and oversampling, or a mix of the two via hybrid and ensemble, did not give satisfactory results. The authors developed HUSDOS-Boost, which stands for Heuristic Under-sampling and Distribution Based Sampling paired with a Boosting ensemble, to cope with the extreme imbalanced and small minority (EISM) problem. When compared to other ensemble approaches, the result was superior. The authors proposed that a hierarchical Bayes model be used to estimate the distribution parameter in future work to improve over-sampling performance [44].

Managing cyber-attacks such as in detecting malicious synchrophasors is very important especially among energy-based companies. Performance of the detectors might be deteriorated severely due to quality of extremely imbalanced data. The authors developed a malicious synchrophasors detector based on data rebalancing, ensemble learning with bagging, and Extreme Gradient Boosting (XGBoost). The proposed method can detect malicious synchrophasors even though only a minimum number of malicious instances were provided [61]. There are several other methods or solutions proposed by different researchers involving different kinds of algorithms or solutions in different kinds of extreme imbalance dataset. Despite all the proposed methods, an extreme or highly imbalance dataset is still a challenging area to explore [44].

### A. Related Method/Technique In Handling Highly Imbalanced Multi-Class Data

This section presents the related methods or techniques that have been used by researchers to handle highly imbalanced multi-class data. In the context of this study, the methods described are ensemble, deep learning, and cost-sensitive method.

*1) Ensemble method:* Research works on highly imbalanced data using ensemble method have become more prevalent since the emergence of Big Data technology [14]. Ensemble method along with hybrid method is steadily gaining attention from researchers around the world. From 2010 to 2021, there are many literatures regarding research works on highly imbalanced data using ensemble method [15], [61], [62], [63], [64] [65], [66], [67], [68]–[74]. The ensemble technique is popular because it combines many algorithm approaches with the ensemble algorithm in machine learning to improve performance [60], [75]–[77]. Compared to a single classifier, the ensemble's total performance was improved by combining several approaches or algorithms. Ensemble modelling is a set of models that work collaboratively to provide a more efficient predictive model. Different modelling techniques, such as Decision Tree (DT) [78]–[82], Neural Networks (NN) [83]–[86], Random Forests (RF) [87], [88]–[91], Support Vector Machines (SVM) [43], [92]–[95] and others can be integrated with ensemble.

Bagging, boosting, and stacking are examples of ensemble techniques that are used to improve the performance of a model or reduce the likelihood of selecting a bad one. There are many literatures on the performance of ensemble method. Among more prevalent methods are Bagging (Bootstrap aggregation) [6], [28] [96]–[99], [100], Stacking (Stacked Generalization) [98], [101], [102], Random Forest (RF) [87], [91], [103], [13], [104]–[109] and Mixtures of Experts [8], [42], [110], [111], [112], [113].

In 1996, Bagging or Bootstrap Aggregating was established as one of the first ensemble approaches. To reduce variance error, this technique trains and picks strong classifiers on subsets of data. Robust performance on outliers, decrease of variance to minimize over-fitting, which requires minimum further parameter adjustment, and the ability to accept high nonlinear interactions are just a few of the advantages. One of the drawbacks of bootstrap aggregation is that the more complicated the model becomes, the less visible and interpretable it becomes [114]–[117].

Boosting is like bagging, but it gives weak classifiers more weight. The weaker classifiers are given additional weight in the following classification phase with each iteration of classifications, increasing their chances of being categorized properly until a stopping point is reached. This can be thought of as course-correcting by re-energizing the data weights that require it. Over-fitting, outlier influence, revision on iteration ending point, and lack of transparency owing to complexity are some of the flaws of this technique, which optimize the cost function. [96], [118]–[120], [121].

Stacking, sometimes known as the least understood ensemble technique, produces ensembles by combining a variety of powerful classifiers. When developing ensemble models, diversity is crucial because it allows stronger learners from various regions to combine their abilities to lower the chance of misclassification. Stacking employs various levels of classification training [98], [102], [122]–[124]. Tier two (2) will use the misclassified regions to adjust the behavior in the

next phase if tier one has feature spaces that are misclassified. The biggest flaw in this form of ensemble is that it lacks transparency when it comes to determining a metadata classifier that adjusts for errors to improve prediction accuracy [59], [125]–[128].

When compared to the implementation in a single classifier, the ensemble's total performance is improved by combining several approaches or algorithms. There is a lot of literature stating about the performance regarding ensemble method [1], [2], [125], [129]–[132].

An effective and popular tool for optimizing ensembles of classifiers is the genetic algorithm (GA), belonging to the family of evolutionary algorithms [133]–[135]. The inspiration to study evolutionary computation (EC) was the imitation of nature in its mechanism of natural selection, inheritance, and functioning. Evolutionary computation is used to demonstrate and unravel complex tasks, primarily for optimization. It is trained based on species, not on an entity, that extends across the lifespan of numerous generations of entities. As a result, generations that are produced progressively meet the conditions of the task, and this would improve the adjustments made to the environment.

It is also worth observing the combination of evolutionary computation with ensemble methods. Examples of such combination can be found in several areas of research like in model-based ensemble [136], micro genetic algorithm, parallel genetic algorithms [137], GA with ensemble method [138], [139], and stacking ensemble [58], [124]. The algorithms mentioned are examples of hybrid and ensemble algorithm that falls into the CL strategy.

Ensemble approaches have been widely applied across several disciplines in the domain of credit scoring and bankruptcy prediction [99], [139], [140], [141] including the latest on personal bankruptcy prediction on imbalanced dataset can be found in several literatures [79], [88], [89], [141], [142].

*2) Extreme Gradient Boosting (XGBoost):* The consequences of noisy data and redundant features, which contributed to the unbalanced data scenario, are mitigated by feature selection methods. In boosting approaches, such as extreme gradient boosting (XGBoost), distributed learning, and multi-core computation, which fully employ the computer's capabilities to speed learning, are possible. As a result, more investigation into boosting is strongly recommended in the highly or extreme imbalanced data research. Chen and Guestrin developed XGBoost which is an advance gradient boosting (GB) [164]. It is a fast, scalable, and efficient algorithm that won Kaggle machine learning competition and was applied in many applications and is used by many corporations.

Base classifiers are known as weak learners. In boosting, models are added concurrently until there is no further change. Boosting is an additive ensemble method that combines new models with existing models to reduce errors. Boosting is a technique for integrating many base classifiers to produce classification accuracy that is considerably better than any single base classifier's performance. A boosted model will

produce a good result even if the base classifiers have a marginally better accuracy than random. XGBoost is an open-source library providing a gradient boosting platform for Python, R, C++, and Java. It employs a gradient-boosting technique to generate a prediction model in the form of an ensemble of weak prediction models, most commonly decision trees.

Gradient boosting (GB), stochastic GB, and regularized GB are the three major types of gradients boosting that XGBoost can perform. The XGBoost approach is flexible in its implementation of distributed and parallel computing and can handle sparse data [143]. It is strong enough to handle hyper parameter fine tweaking and regularization parameter addition. It's been put to the test on large-scale challenges and can handle most regression, classification, and ranking problems, as well as custom objective functions. XGBoost is also portable and compatible, allowing it to run on any operating system. It works with AWS, Azure, and GCE, as well as other distributed cloud platforms.

XGBoost is easily coupled to large-scale cloud data-flow systems like Flink and Spark, which were designed specifically for model performance and computing speed. Model tuning, computational environments, and algorithm enhancement are all available in XGBoost. The algorithm was created with the goal of reducing computation time and allocating memory resources efficiently. XGBoost improves classification accuracy and performs calculations 10 times faster than commercial software. It can prevent over-fitness and dealing with missing values. With learning, XGBoost can figure out the dividing path for the test with incomplete eigenvalues. [60].

*3) Deep learning method:* Research of deep learning in imbalanced data was overwhelming, however research of deep learning in highly imbalanced data still has much room for expansion. The length of the majority data or class is substantially longer than the length of the minority data component in highly imbalanced data settings. To put it another way, the minority data has essentially been ignored by the classifier and most of the time considered as a noisy data [4]. The net gradient, which is responsible for updating the classifier weights, is dominated by the majority data. During early iterations, this reduces the error of the dominant majority quickly, but it often raises the error of the minority group, trapping the algorithm in a slow convergence state. [5].

In the fields of image identification [144], speech recognition [145] and natural language processing [146], [147], deep learning has been widely utilized. However, there have been few studies on the use of deep learning in highly imbalanced data. As the RNN is ideal for time series analysis, one popular application is the deployment of a recurrent neural network (RNN) to investigate network intrusion detection on an imbalanced dataset [148].

Convolutional Neural Network (CNN) is another deep learning model that has been used to forecast bankruptcy. Hosaka et al. took financial statement data from Japanese publicly traded firms and converted the numerical financial ratio data into a grayscale image that was tailored to CNN's

characteristics and could be evaluated directly by CNN. To cope with bankruptcy prediction difficulties, Hosaka suggested a CNN framework, and this model beat comparable conventional solutions, including most of the established machine learning techniques [149]. Mai et al. used layers of neural networks to extract attributes from textual data from over 10000 public corporations in the United States to incorporate deep learning into the prediction of bankruptcy. [150].

It has been revealed that when textual data (e.g., news, public company reports) is combined with classical numerical data (e.g., financial ratio data), deep learning performs better in imbalanced data study using textual disclosures, improving prediction accuracy even more. These intriguing findings open up new avenues for research in the field of bankruptcy prediction on imbalanced datasets, providing new insights and ideas. [151].

*4) Cost-Sensitive learning:* When training a model, cost-sensitive learning considers the costs of prediction errors as well as any additional cost that may be necessary. It is related to classification on datasets that are imbalanced or have skewed class distribution. As a result, a variety of cost-sensitive learning approaches and strategies can be used to solve problems with imbalanced data. [50], [58], [152].

The goal of cost-sensitive learning for imbalanced classification is to assign different costs to different types of misclassification errors, then utilize specific algorithms to compensate for those costs. The concept of a cost matrix facilitates to understand the varied costs of misclassification. A confusion matrix is a list of a model's predictions on classification tasks. It is a table that lists the number of predictions made for each class, separated by the actual class [153].

It is easiest to understand using a classification issue with negative and positive classes, which are commonly labelled with 0 and 1 class labels. Although the meanings of rows and columns can be and often are interchanged with no loss of meaning, the columns in a matrix table indicate the actual class to which the instances belong, and the rows represent the anticipated class. A cell is the number of samples that fulfil the row and column's requirements, and each cell has a unique common name. A confusion matrix for a classification problem is shown in Table II.

The confusion matrix's cost matrix is a matrix that allocates a cost to each cell. The focus of the research on the unbalanced data problem, in relation to the confusion matrix, is on errors, hence 'False Positive' and 'False Negative' will be the primary focal areas. In an imbalanced classification task or a challenge with imbalanced data, the latter is more common than the former.

TABLE II. A CONFUSION MATRIX FOR A CLASSIFICATION TASK

|  | Actual Negative | Actual Positive |
|---|---|---|
| **Predicted Negative** | True Negative (TN) | False Negative (FN) |
| **Predicted Positive** | False Positive (FP) | True Positive (TP) |

## IV. PROMINENT VALIDATION METRICS FOR HIGHLY IMBALANCED MULTI-CLASS DATA

The precision metric, defined as Equation (1), measures the accurately categorized positive class samples.

$$\text{Precision} = \frac{TP}{TP+FP} \tag{1}$$

where TP and FP stand for true-positive and false-positive counts, respectively.

The fraction of accurately identified true positive samples is measured by recall, which is calculated using Equation (2):

$$Recall = \frac{TP}{TP+FN} \tag{2}$$

G-mean and AUC have been designed for class imbalanced problem-measurement. As shown in Equation (3), the F-measure or F-1 score is the harmonic mean of precision and recall:

$$f - measure = \frac{(1+\beta)^2 \; x \; recall \; x \; precision}{\beta \; x \; recall+precision} = \frac{(1+\beta)x\frac{TP}{P}x\frac{TP}{PP}}{\frac{TP}{P}x\;\beta+\frac{TP}{PP}} \tag{3}$$

The geometric mean, or G-mean, is a metric that assesses the balanced performance of a classifier, as shown in Equation (4):

$$G - mean = \sqrt{\frac{TP}{TP+FN} \; x \; \frac{TN}{TN+FP}} \tag{4}$$

The AUC stands for Area under the ROC Curve, which is used to assess the model's performance [21] and can be used to estimate it, as demonstrated in Equation (5):

$$\text{AUC} = \left(\frac{TP}{TP+FN} + \frac{TN}{TN+FP}\right)/2 \tag{5}$$

As a result, the performance evaluators of the classifier employed in most imbalanced data research include F-measure, G-mean, AUC, and Accuracy [1], [154]. However, in a highly imbalanced data situation, accuracy, also known as balanced accuracy, is not a feasible validation metric due to the nature of the classifier, which is bias towards the majority class and ignores the minority class [21], [63], [155].

### A. Related Study on HIMC Data Framework

Before a new framework on highly imbalanced multi-class data can be proposed, related studies on both highly imbalanced binary data and highly imbalanced multi-class data must be discussed thoroughly. This section will present the descriptions and discussions on the differences between highly imbalanced binary data and highly imbalanced multi-class data in terms of literatures, technologies, and domain in real world.

Table III shows literature related to highly imbalanced binary (HIB) data and highly imbalanced multi-class (HIMC) data. Before further explanation on this table is given, a clarification on "Data Mining" domain will be given. It is known as "Data Mining" domain due to the nature of the research which uses multiple different datasets ranging from five datasets to 35 datasets. Each of the datasets are different in terms of discipline and areas of interest such as Abalone, Glasses, Cars, and Credits etc. Therefore, each dataset is a unique domain and thus it is called "Data Mining" domain.

From 2006 to 2021, there were many literatures published about highly imbalanced data. Some of the literatures were on HIB data and the rest were on HIMC data. The related HIB data was from the data mining domain, and this data was grouped based on these algorithms: SR 0-1 LOSS [15], F-BFR [156], T-BFS [157], K-SUB [64], PSU [102], C4.5N [158], DWCE [159], ECSM [72], GP-COACH [160], Fuzzy [161], [162], OSPREY [163], Chi Method, CNN [164], WL-Norm SVM [165], EAIS + Fuzzy [166], GA + Fuzzy [167], US + Ensemble (Data Hardness) [15], Clustering + WS [66], DBE-DCR [73], EUBoost [168], GA-FS-GL [169], GSVM-RU [170], GA-GL+FRBC [171], K-Means + HFS [172], REPMAC k-Means +SVM + DT [173], SwitchingNED [70], SVM-US [174], B-BFS [67].

For the HIMC data, the related domain was the data mining: FMFS [186], DM-UCML [188], WRSEW + RDL [189], aerial imaging: RF-MML [187], bioinformatics: DBNN (DEEP SOM) [18], CNN [56], cyber-attack detection: SAE [190], facial recognition: VFSG [191], fetal aneuploidies: ANN [192], medical: CRF [40], CNN [144], pathology: CNN [193], power synchropasor detection: RXGBOOST [61] and flare forecast: US + OS + SVM [7].

In HIB data, specifically in the data mining domain, there are many published literatures between 2006 and 2021. For data mining domain, several novel methods were developed. For example, Calvert et al. who focused on severely imbalanced big dataset found that C4.5N was by far the best learner in terms of Slow POST attack data. Nevertheless, C4.5 Decision Tree and Chi Algorithm were found to be less effective compared GP-COACH in highly imbalanced dataset [158]. Among the more recent literatures in HIB in data mining domain come from Bringer et al. The authors found that data labeling is difficult in highly imbalanced data environment. Therefore, the authors have proposed OSPREY which is a system to cater data labeling in highly imbalanced data. The system was developed on top of Snorkel framework [163].

The CL is the most popular strategy in HIB data. It can be seen by the number of literatures found especially in the data mining domain. For example, Fernandez et al. studied the behavior of GP-COACH algorithm in highly imbalanced data scenario [160]. Liu et al. developed a novel framework for unbalanced classification that focuses on generating a strong ensemble by self-paced harmonizing data hardness using a mix of under sampling and self-paced ensemble in CL for HIB data [15].

For HIMC data, less literatures were found from 2006 to 2021. Unlike HIB data, there is less research in data mining domains where there is only a single literature at DL [219] and few literatures at AL [18], [56], [40], [190], [144], [187], [121], [191]–[193], and some literature in CL [61], [63], [188], [189], [7].

Domains such imaging [187], bioinformatics [18], [56], cyber-attack [190], facial recognition [191], fetal aneuploidies [192], medical [40], [144] and pathology [193] concentrated on AL strategy while domains such as medical [63], power [61] and solar forecast [7] employed CL strategy. Nonetheless, the only research using DL strategy focused on data mining domain.

TABLE III.      HIGHLY IMBALANCED BINARY DATA VS HIGH IMBALANCED MULTI-CLASS DATA

| Class | Data Level | Domain | Algorithm Level | Domain | Combination Level | Domain |
|---|---|---|---|---|---|---|
| **Binary class** | SR 0-1 LOSS [15], F-BFR [156], T-BFS [157], K-SUB [64], PSU [102] | Data Mining | C4.5N [158], DWCE [159], ECSM [72], GP-COACH [160], Fuzzy [161], [162], OSPREY [163], Chi Method, CNN[164], WL-Norm SVM [165] | Data Mining | EAIS + Fuzzy [166], GA + Fuzzy [167], US + Ensemble (Data Hardness) [15], Clustering + WS [66], DBE-DCR [73], EUBoost [168], GA-FS-GL [169], GSVM-RU [170], GA-GL+FRBC [171], K-Means + HFS [172], REPMAC k-Means +SVM + DT [173], SwitchingNED [70], SVM-US [174], B-BFS [67] | Data Mining |
|  | NRA [175] | Fraud Detection | BERT [19] | Malware Detection | Ensemble + RF [68] | Disease Prediction |
|  | SSFS [176] | Phishing Detection | CNN [177], ECDL [178] | Medical Imaging | DS + ST [179] | Hospital Admission |
|  | BPFs [180], MPRM [181] | Speech Recognition | AL [168] | Social Media | PCA + DA + CNN [145] | Imaging |
|  |  |  | GSVM-BA [182] | Spam Detection | SMOTE-tBPSO-SVM [183] | Malware Detection |
|  |  |  |  |  | Boosting + Sampling [184], SMOTE + RF [185] | Medical |
|  |  |  |  |  | GA + SVM-SMOTE [65] | Mortality Prediction |
|  |  |  |  |  | Ensemble + SMOTE [71] | Sentiment Analysis |
| **Multi-class** | FMFS [186] | Data Mining | RF-MML [187] | Imaging | DM-UCML [188], WRSEW + RDL [189] | Data Mining |
|  |  |  | DBNN (DEEP SOM) [18], CNN [56] | Bioinformatics | ELF [63] | Medical |
|  |  |  | SAE [190] | Cyber Attack | RXGBOOST [61] | Power |
|  |  |  | UCML [121] | Data Mining | US + OS + SVM [7] | Solar Forecast |
|  |  |  | VFSG [191] | Facial Recognition |  |  |
|  |  |  | ANN [192] | Fetal Aneuploidies |  |  |
|  |  |  | CRF [40], CNN [144] | Medical |  |  |
|  |  |  | CNN [193] | Pathology |  |  |

Therefore, it clear that HIB data is more prominent than HIMC data and there is more room for future research to be conducted in highly imbalanced data. HIB data alone dominates the research with 72.7% while HIMC data with only 27.3%.

Table III demonstrates highly imbalanced data categorization based on techniques used. There are four categories of technique that have been used in HIB data and HIMC data research works. They are statistical, semi-supervised, supervised, and unsupervised. This consists of 81.6% from the overall literatures in CL and almost half which is 46.3% from overall literatures in highly imbalanced data.

Combination Level (CL) dominated in terms of number of literatures in both HIB and HIMC data. Supervised type of research in HIB using ensemble were published between 2006 and 2021. In the same technique category (supervised in HIB data), hybrid method is also not less popular with quite several literatures published within the same period while several literatures for unsupervised type of research have been found in binary class data using hybrid technique. Overall, there have been quite satisfying number of literatures published on CL in term of HIB data.

For HIMC data, number of research in ensemble and hybrid was not as many as HIB data, there are only few literatures published between 2006 until 2021 which was literatures in

statistical area using hybrid, and in unsupervised area and other literatures in the area were using ensemble technique. Research in HIMC data area is still quite new.

In terms of feature selection methods in both HIB data and HIMC data, there were several techniques involved in the list of literatures. The technique used was Repetitive Feature Selection, Threshold-based Feature Selection, Binary to Multi-class Feature Selection, Program to Detect Phishing and Feature Maximization for Feature Selection.

The rise of Big Data is one of the most prominent justifications for the adoption of both ensemble and hybrid in all three data techniques (DL, AL, and CL) in both HIB and HIMC data. Big data processing, as well as hybridization and algorithm ensembles have attracted much interest in the research community. Referring to the literatures that have been analyzed, the earliest literature on highly imbalanced data was published in 2006 for HIB data and 2013 for HIMC data respectively, after the emergence of Big Data technology.

## V. PROPOSED NOVEL HIMC DATA FRAMEWORK

This article presents the descriptions on the technologies used and gathered from previous studies and the domains of the literatures published between 2013 and 2021. The literatures were divided further into four categories which were Supervised, Semi-supervised, Unsupervised, and Statistical. In terms of types of algorithms, the publications were segregated based on several groups which were feature selection, artificial neural network, deep learning, case-sensitive learning, ensemble, and hybrid, including two specific algorithms developed for aerial scene imaging and facial expression recognition.

Fig. 2 illustrates the proposed framework of HIMC data. The framework has been developed based on important elements like data category, data behavior, data characteristics, data strategy, model or technique type, and algorithm or model or technique or framework or classifier used in HIMC data research. The HIMC data framework can be used as the underlying basis of highly imbalanced data research both binary data and multi-class data.

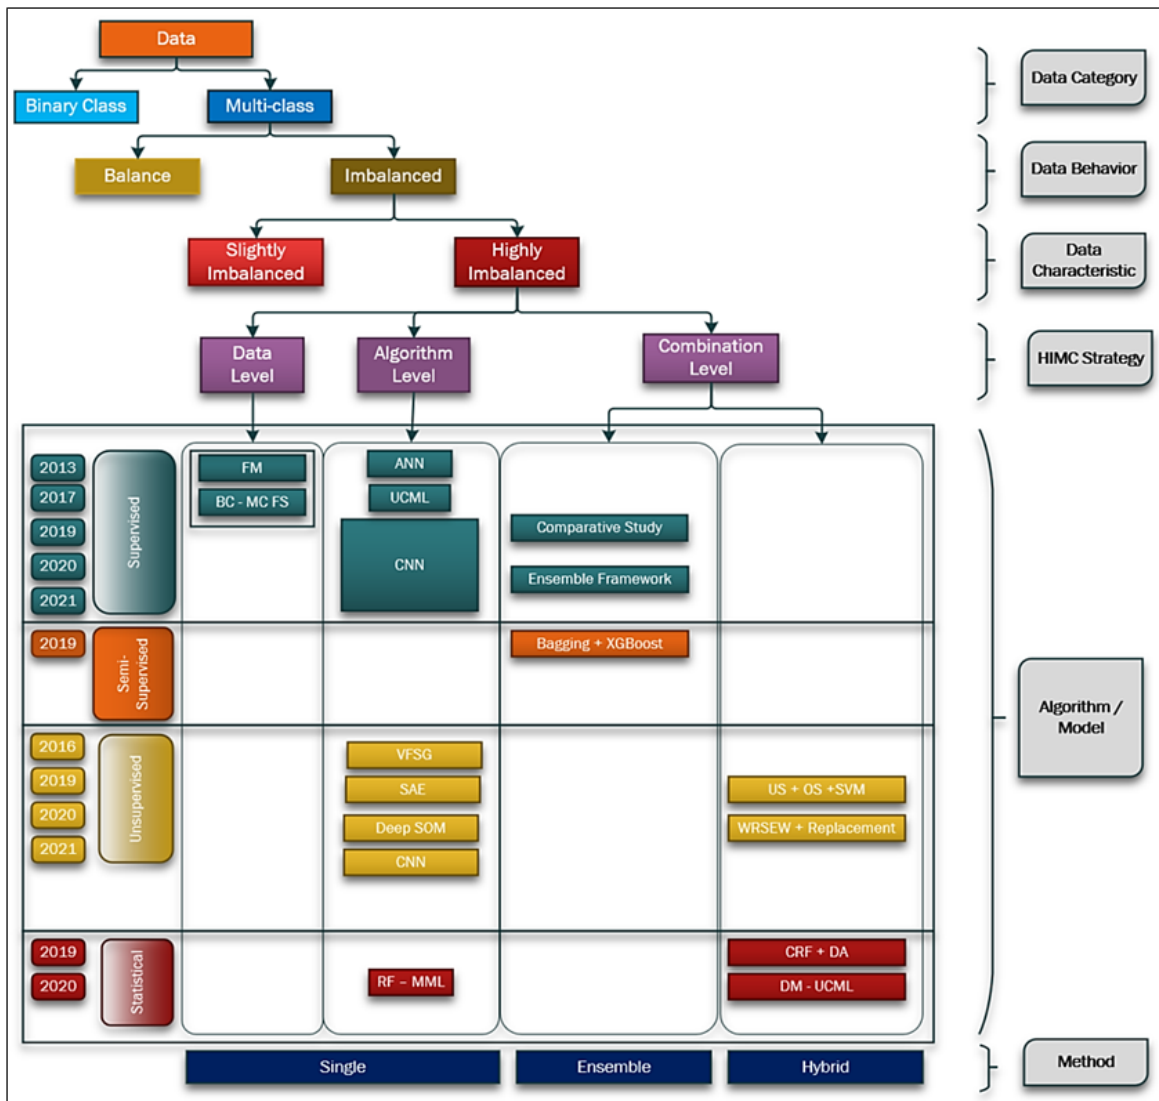

Fig. 2. HIMC Data Framework.

Based on the framework, data can be categorized into binary and multi-class. There are other categories of data such as streamed data and big data, but this research only focuses on these two categories of data. Moreover, both streamed data and big data research are higher-level research when the underlying data categories will come back to multi-class data and binary class data as the base category. Multi-class data can be further divided into balanced and imbalanced data. Balanced data is only present in controlled environment where both majority and minority classes and data are divided to 50-50 percent ratio.

Algorithms or techniques or methods can be divided into different categories which are Supervised, Semi-Supervised, Unsupervised and Statistical. In this framework, year of publication has also been added for easy referencing. Finally, there is technique or model group. It can be categorized into single method, ensemble, and hybrid group. Single method group lists only research works that use a single algorithm or technique or method. Ensemble group is a list of studies that employ ensemble method and hybrid group is a list of research that employ hybrid method. Finally, it is worth mentioning that in this framework, domains for each literature are also stated next to the method used. Multiple domains mean that the referred articles mentioned the use of many benchmarks in many disciplines.

In the framework, highly imbalanced data is further divided into DL, AL, and HM [4], [21]. Since ensemble can work independently or combined with other methods in DL or AL, HM and EM are combined to employ CL strategy. In HIMC data framework, there have been only a couple of literatures related to DL strategy. Using Feature Maximization in Feature Selection, Jean-Charles Lamirel devised a strategy for coping with severely imbalanced textual data grouped into similar classes. [194]. Another study came from Kubler et al. where FS was used to handle problem with how to extend FS from binary classification data to multi-class data [195]. Both literatures used multiple domains in their research.

There are several literatures published between 2016 and 2021 on HIMC data in AL. Domains such as in the study of fetal aneuploidies, medical, application development of facial expression recognition, cyber-attack, aerial scene imaging and bioinformatics. Several articles stated the use of supervised method [56], [144], [121], [192], [196] and others stated the use of unsupervised method [191], [18], [83], [193] and one article mentioned the use of statistical method. All research related in DL and AL employed single method and thus, they were categorized into single method group [187].

CL gained more popularity in recent times. Even though there have been only little literatures related to CL strategy, most of these articles have the best performance benchmark. Two articles mentioned the use of supervised method in medical and malware detection domains [62], [63]. One article mentioned the employment of semi-supervised in power synchrophasors detector domain [61]. Other articles mentioned the use of unsupervised method in rare event of flare forecast and multiple domains [7], [189] and finally the statistical method was used in medical imaging and multiple domains based on several articles [40], [121].

## VI. Discussion

Multi-class data issues are more difficult to solve compared to binary classification data [22]. Most of the articles published recently focus on handling problems in binary classes such as bankruptcy prediction (bankrupt vs. non-bankrupt), computer security (normal activity vs. malicious activity), medical (healthy vs. infected). Because multi-class data can be dissected and handled using binary class methods, many literatures focus on binary class data [21], [31].

Multi-class data have different challenges. If the output for binary classification is binary, multi-class output will be multiplied (more than two targets or results) [1]. Several examples of real-world cases involving highly imbalanced data are like hospital readmission [197], feature pattern of Thoracolumbar spine fracture [87], solar flare forecast [7], modeling of Chlorophyll concentration in Algal Bloom [56], semantic segmentation [198], [199], medical imaging [40], malware detection [19], cyber-physical strike discovery [190] and Bioinformatics [18].

In highly imbalanced multi-class data, a multiple skewed distribution is an issue which affects classifiers' performance as it is difficult to decide the boundaries in highly imbalanced multi-class data. A distance-based algorithm such as Hellinger distance has been used to handle the problem. However, there are issues on overlapping class and noisy data [21], [33], [155]. A good solution for the problem is to combine a method that can minimize overlapping class and reduce noisy data [2], [31], [200]. A promising solution that might handle both problems is by using ensemble methods. This is because this method is capable of rectifying imbalance class and improving weak classifiers [201]. However, ensembles suffer from lack of interpretability and are usually computationally expensive [26].

Problems in highly imbalanced data originate from problems in slightly imbalanced data which are alleviated due to the nature of severe imbalance ratio (IR) [3], [33]. Thus, problems in imbalanced multi-class data and highly imbalanced multi-class data can be considered similar in nature with high IR. In ML, multinomial or multi-class classification is the problem of classifying instances into one of three or more classes [21]. A multi-class classification problem is not as developed as the binary classification problem in imbalanced data [4], [21], [110].

High IR has negative impact toward the minority class and overall performance of data may result in information loss [102], [202]. In multi-class data, performance of each class needs to be focused specifically because each class is distinctive. A classifier might obtain good performance in some classes while unsatisfactory results in other classes [4], [18], [21].

Relationship among classes is another issue in multi-class data. It is a complicated situation because each group of classes presents different problems [4]. Two or more classes might overlap in some group. While other classes might have a normal borderline and considered as normal classes. This problem is elevated in highly imbalanced multi-class data, and it affects classifiers' performance [159], [40].

Leevy et al. and Rendon et al. suggest that heuristic-based and more flexible methods have been less developed to solve multi-class data problems [31], [203]. There are literatures in the analysis of relationships among classes in multi-class data that have produced satisfactory results [155]. However, there is a need to improve on highly imbalanced multi-class data domains as the same method has not produced good results in a highly imbalanced environment.

In multi-class data, class overlapping is an issue because it may happen anywhere within the dataset with different groups of overlap classes. The problem is more complicated in highly imbalanced multi-class data scenarios, as it is hard to define borders of the overlapped classes. The problem will affect the classification or prediction performance of the classifier. The data needed to be properly pre-processed and appropriate sampling procedure be applied [4], [47], [47]. The challenge is to develop solutions that consider the different features within the overlapped classes and at the same time also showing good classification or prediction performance [204].

The presence of noisy data in a dataset can increase the imbalance among classes and eventually could result in the classifier rebalancing the wrong classes [205]. To overcome the issue, a new approach for data cleaning is needed to boost classifier performance in multi-class data [46]. Another way to solve the problem is to create synthetic data, which allows overlapping data to be transferred to other locations. Another method is to remove excessive samples. New approaches should consider removing excessive samples while maintaining the quality of the data [2], [6].

In summary, in highly imbalanced multi-class data, minority classes are treated as noisy data. However, the minority data might have crucial information [1], [21]. Another issue is the misclassification cost between the majority and minority data. The cost-sensitive strategy is a well-known method for dealing with data imbalances. Minority samples, on the other hand, had a higher cost of misclassification than majority samples. [50]. Finally, a highly imbalanced multi-class data has multiple skewed classes which reduces classifier performance as it is difficult to normalize the skewness [26], [31], [44] and difficult to define borders of the overlap classes [4], [46]. Future research in highly imbalanced multi-class data should focus on these issues.

Future direction of HIMC data is clear, that is to have more research focusing on the issues presented in this article. One of the main issues of HIMC was the high IR between data classes. This was because the presence of multiple classes with high IR caused multiple skewed distribution and would affect the minority class as it was ignored by the classifiers because they tended to be biased toward the majority class. Another issue was the overlapping classes. This involved the difficulty to define borders of multiple classes. Finally, the issue on the presence of noisy data especially in big dataset. In this issue, classifiers tended to treat the minority data as noisy data due to the high IR.

## VII. CONCLUSION

Data-related research has evolved as more essential, exciting, and beneficial due to the rapid rise of Big Data. In this research, machine learning algorithms at different levels have been addressed by using different strategies which are DL, AL, and CL to properly manage highly imbalanced multi-class data problems. It has proposed a novel framework for HIMC data in the wake of issues concerning HIMC data. However, due to the dynamism and uniqueness of each dataset and the heterogeneity of data, developing a proper method or technique in handling highly imbalanced multi-class data remains a challenge. As a result, the current state-of-the-art algorithms were found and categorized in four different types in this study: supervised, semi-supervised, unsupervised, and statistical. Finally, the performance of various machine learning techniques used to handle HIMC data is compared in this research. Hence, based on the analysis performed, there is a need for a novel framework of HIMC data to be designed. Finally, open issues, challenges, and future direction of HIMC data have been discussed and presented in this article to pave the road for extended research works in HIMC data to be conducted in the future.

*Abstract*—**Agriculture is one of the most famous case studies in deep learning. Most researchers want to detect different diseases at the early stages of cultivation to save the farmer's economy. The deep learning technique needs more data to develop an accurate system. Researchers generated more synthetic data using basic image operations in traditional approaches, but these approaches are more complicated and expensive. In deep learning and computer vision, the system's accuracy is the crucial component for deciding the system's efficiency. The model's precision is based on the image's size and quality. Getting many images from the real-world environment in medicine and agriculture is difficult. The image augmentation technique helps the system generate more images that can replicate the physical circumstances by performing various operations. It also prevents overfitting, especially when the system has fewer images than required. Few researchers experimented using CNN and simple Generative Adversarial Network (GAN), but these approaches create images with more noise. The proposed research aims to develop more data using a Meta approach. The images are processed using kernel filters. Different geometric transformations are passed as input to the enhanced GANs to reduce the noise and create more fake images using latent points, acting as weights in the neural networks. The proposed system uses random sampling techniques, passes a few processed images to the generator component of GAN, and the system uses a discriminator component to classify the synthetic data created by the Meta-Learning Approach.**

*Keywords—Basic image operations; meta-learning techniques; generator; discriminator; synthetic data; sampling techniques; latent points; kernel filters*

## I. INTRODUCTION

Deep Learning algorithms are famous for solving case studies related to medicine and agriculture. The efficiency of the deep learning model depends on the selection of neural network design. The process of defining the best estimators for a network is coined "Hyper Turning." he system needs more balanced and huge of data to estimate the proper parameters that suit the network. It is highly impossible to collect the real-time images from the farming lands using digital cameras, and the collection of satellite images covers the entire crop. However, it cannot provide individual leaf analysis [19]. So, the agriculture industry needs a system that can generate similar images covering controlled and uncontrolled situations like blur leaf images due to heavy wind effects, half leaf images due to the distance, and others. The generation of similar images is known as "Data Augmentation," and the data is known as "Synthetic Data." The previous researchers created synthetic data using basic image manipulation techniques, GANs or Auto encoders and decoders [10]. The number of images will increase using manipulation techniques like transformation and rotation, but they cannot produce uncontrolled images. Researchers have introduced GANs and encoders over the past few years to create compressed and noisy images so they can handle uncontrolled conditions. However, due to single components of GANs, they produce more noise than required. The proposed system to reduce the number of noisy images and enhance the quality of controlled images introduced a meta-intelligent environment where the architecture is improved by increasing the components of GAN, and these components take the manipulated images rather than the original images from the GAN. The proposed research generates images using simple operations, as discussed below.

### A. Basic Image Operations

Traditionally, to manipulate the images, researchers performed Geometric transformations [18], which involve rotations, flipping, resizing, shifting, zooming, cropping, and noise operations. The system can also perform color space transformations. Images are composed of RGB color conventions but must be converted into grey-scale or other color saturation values for efficient data processing. The essential operations involve a kernel filter [16], extracting the region of interest from the image using convolution neural networks. The image is saved as a two-dimensional matrix, and the filter does a dot product between the inputs and filter layers and then adds the values to get a single value in each location. Edge detection, image sharpening, and blurring operations benefit from kernel filtering. The most recent improvements are the random erasing technique to remove pixels in an image by choosing a rectangular region based on the likelihood determined by aspect and area ratios. The Random Erasing technique is essential for image recognition, object detection, and people re-identification. It can be used on pre-trained models and easily combined with neural networks [13]. The different types of image operations are shown in Fig. 1.
Fig. 1.    Types of basic Image Operations.

*1) Rotation*: Rotation is the most straightforward operation that can be applied to any image to change its orientation. The rotation angle is expressed in degrees, ranging from 0 to 360 clockwise[21].

*2) Flipping*: It is a variation in the rotational operation. The transposition of row and column pixels is accomplished using a flipping operation. Two types of flipping operations can be carried out here. Horizontal and vertical flips may be used, depending on the quality of the images.

*3) Shearing*: Shearing is moving pixels from one location to another, either horizontally or vertically. The image's dimensions remain unchanged. Only a few pixels will be clipped off.

*4) Cropping*: The images generally have a region of interest at different locations. Cropping the image at the required area is the best operation to identify the location. Since the proposed system is a classification model, the model's output should be a subset of the entire image[17].

*5) Zooming*: When a system zooms in, the system can either add new pixel values or interpolate existing ones. If we take the value x as an example, the zoom will perform 1+x and 1-x operations on the image pixels. It aids in the image's standardized sampling.

*6) Brightness or contrast*: This operation can darken or brighten an image. This operation primarily assists the model in training the device in various conditions. The system may use percentages to specify the minimum and maximum values. The image is darkened if the value is less than 1.0 and brightened if the value is more than 1.0.

The below section presents the algorithm in which all the manipulation operations are randomly applied to the dataset's images.

---

**Algorithm:  Basic Image Operations**

Input: Load the tomato dataset from the data repository, T_Data

Output: Retransformed Images

1. for i in len(T_Data):

    Resize_timage←ImageGenerator(T_Data,rescale=1/255).

 2.          train_img_gen←ImageDataGenerator(rotation_range=45, width_shift_range=0.20, height_shift_range=0.25, horizontal_flip= True, zoom_range=0.50)

3. img_gen←train_img_gen.flow_from_directory(directory=path,batch_size=32)

4. for img in img_gen:

    imshow(img)

---

The algorithm will give the individual operations augmented images, as shown in Fig. 2(a), and the combined basic image operations are shown in Fig. 2(b).

Fig. 2(a) represents the individual operation on each image, whereas the proposed system uses the "Data Generator" module to apply different processes on the dataset images. Fig. 2(b) represents five such figures as sample output.

*B. Data Augmentation*

Manually increasing the size of the image dataset is complicated. Neural networks provide different "data augmentation through GAN" [11], as shown in Fig. 3, to simplify the process. The data augmentation can be performed in either online mode or offline mode. This research implements online augmentation techniques since the offline [12] mode involves high memory usage, which is expensive and time-consuming. In online data augmentation, images are transformed randomly in different batches, and the model is trained with more cases in each epoch.

The two design considerations for augmentations are Train-time data augmentation to minimize generalization error and test-time data augmentation to increase predictive accuracy. The most critical operation to perform is resizing. Resizing ensures that all images are the same size. Specific pixel scaling and normalization operations can be carried out.

Rescale          Rotation          Horizontal Shift

Vertical Shift          Horizontal Flip          Zoom

(a)

(b)
Fig. 2.    (a) Individual basic Image Operations on Tomato Leaves, (b) Combined basic Image Operations using Image Data Generator.

Fig. 3.    GAN's Classification.

GAN technique provides adversarial preparation in critical models where Gaussian noise is injected, and images are transformed with worst-case perturbations [15], resulting in incorrect results with high confidence values. It also includes a neural style transferring technique that aids in the creation of new images by blending them, mainly when the model contains text or kinds. It employs two distinct distance roles, one for identifying text differences and the other for identifying style differences. In GANs, the generator takes a fixed-length vector as input and gives a domain-specific sample as output. Discriminator [14] takes the domain's information and generates a binary value depending on the prediction.

The entire paper organizes into five sections, where the introduction discusses the techniques related to image manipulation and data creation operations. The literature review section focuses on the previous researchers' methodologies and their merits and demerits. The literature section and also represents the gaps in the earlier works by analyzing the fallbacks associated with each method. The proposed process initially defines the architectural difference between the existing and proposed techniques. It also presents the layered architecture of the discriminator component and generator component. Finally, it describes the overall process of creating the synthetic data to enhance the size of the data. The result section describes how the accuracy of creating fake and real images in every epoch is computed. It also proves state-of-the-art compared with the other works mentioned in the literature survey. The paper in the last section concludes the piece by justifying the need for intelligent approaches to enhancing data size and presents the future to design an automated system for agriculture [21-24].

## II. LITERATURE REVIEW

### A. Methodologies Implemented using Researchers

[1] Ahmed Ali et al. proposed a framework in which GANs are integrated with CNN to classify mosaic virus in tomato plants. The author increased the dataset size by generating fake images stage by stage. This research's stages are healthy, early, and late infection. Random noise and each stage are passed as discriminators' inputs to generate synthetic samples. In hidden layers, global pooling is applied to create fake images almost nearer to the real images in the training dataset. It generates 512 feature vector dimensions and is passed as input to the discriminator to check its authenticity. If the accuracy rate is low, it loops the entire process for that particular image until it obtains a high accuracy rate. Finally, the model takes these augmented images as input to the neural network and performs multi-classification. CNN uses a 4-layered architecture by taking the standard activation function "ReLu" and standard optimizer "ADAM." This model balanced the dataset by producing an equal number of images in each stage.

In [2], Umit Atila et al. experimented with EfficientNet to eliminate the problems caused by the ImageNet pre-trained Model. The first step to improving efficiency is to perform the uniform scaling operation in all directions along with uniform translations and rotations. The uniform scaling factor is measured by drawing the grid relation between neighboring pixels. The obtained values act as the constraints based on which a neural network is designed to predict the class labels approximately. This research constructed inverted bottleneck layers available in Mobilev2Net to generate the images based on the expansion and contraction techniques. Transfer learning replaces the last layers of the B5 model, with 16 layers of MobileNet and four fully connected layers as a classifier. The disadvantage of this model is that it initialized the learning rate as 0.0001 but obtained an accuracy of 99.97%, which means this model cannot learn the complex relationships among the features.

In [3], Hongxia Deng et al. designed RHAC_GAN using the hidden variable mechanism to increase the dataset size because the collection of small data would not make many effects and would not get better results by using the CNN algorithm. Traditional approaches used image rotation, increased image brightness, and many other factors to solve this problem. Even these cannot help collect extensive data, which results in less accuracy. In the case of agriculture, it needs a large amount of data to identify the disease; however, due to insufficient data collected, even the best method, CNN, cannot give the best results. For the more extensive data collection, they proposed an ACGAN method that takes the generated images and divides them into parts to visualize the disease better. The hidden parameters in this model aim at low-frequency parameters in the image and show it as the disease-affected place.

In [4], Yang Wu et al. implemented an Adversarial VAE encoding mechanism for increasing the number of tomato leaf images in the dataset. Traditional VAE is extended by replacing the single scaling component with a multi-residual member for generating different scaling images in different directions. It is not easy to extract and train the parameters in the model, so the system needs a generalized learning environment and the labels associated with images. In this Model, GAN is integrated with the encoder in stage 1 to create compressed images as a dummy dataset. In stage 2 decoder is attached to reconstruct by creating latent space variables. Usage of the mean pre-processing technique helps the model enhance the dimension from 128 to 256 during the encoding process. The downsampling of neural networks helps the model create a scale block using reduced mean operation.

In [5], Amreen Abbas et al. designed conditional GAN using a transfer learning technique on nine diseases. The model uses a generator of CGAN to create augmented images using three layers. One of the three layers is implemented using an embedded pairing mechanism, consisting of a series of flatten and dropout layers. The advantage of CGAN lies in the fast creation of enhanced images by learning approximately seven lakhs of training parameters, and all the images are labeled from 0 to 9. In the next phase, the augmented images are merged with DenseNet using max pooling and average pooling layer alternately to minimize the number of features in every layer. A fine-tune layer is attached to the pre-trained network, which helps adjust weights optimally and perform the hyper tuning.

In [6], Jashraj Karnik et al. used a new way of classification called YOLOv3. KNN, K-means, and SVM did

the data classification in the olden days. However, with the help of YOLOv3, it would be better and more accessible. They had proposed four ways for the farmers to understand the problem. Pre-processing, data augmentation, classification, and intersection over union have been done. The farmers who lived far away would face a problem identifying the disease.

Moreover, with the help of deep learning and AI, they can only identify the disease in the early stage. All farmers who do not know which plant to have or not and what fertilizers to use were also present in the AI, which would help the farmers increase their growth. YOLOv3 would work in 2 ways: classifying the leaves and the disease. This way, the output would be given to the CNN, identifying the disease. In their proposed AI, they would recognize the disease and help the farmers take the next step that would help them increase their growth.

In [7], Aaditya Prasad et al had implemented a two-step machine learning model for better accuracy for low- and high-fidelity pictures. Here they used UAV images. The two data collectors were used to reduce the imbalance in the high fidelity. One was a data generator, and the other was modeling, and each of these elements had two-step for identification and classification. This model identifies the affected region and captures high-definition images for better understanding and classification. The second phase deals with the technical method for proletarian revolution: synthetic crop images in data generators.

In [8], using MATLAB, Bhattacharya developed a method based on CNN. The rapid investigation and diagnosis of plant illnesses can help manage disease development on various crops, enhancing harvest growth and yield. Apply image analysis and deep learning approaches to automatically discover acceptable features for differentiating the different types of plant disease to make the system efficient. The author introduced the method called convolution neural network architecture. This deep learning technique autonomously categorized three types of wheat leaf disease detection (fungal blight, blasting, and black mark) inside this study [25-28]. They have created a technique for recognizing normal and diseased plants from a batch of 1000 rice plants during the classification stage.

In [9], Guo et al. proposed a method based on RPN integrated with image Segmentation. This work provides a deep learning-based statistical equation for plant disease diagnosis and identification that increases the accuracy, flexibility, and training effectiveness. Its region proposal network is used to identify and locate the affected parts in the plants. So therefore, Chan–Vese (CV) method segments the image to find the illness attribute. Lastly, the separated leaves were fed into a transferring learning model, developed on a dataset containing diseased leaves inside a simplified environment. This prototype is also tested for brown rot, fungal disease, and rust disease. This analysis shows an accuracy of 83.57 percent, which is greater than the best way to minimize the disease impact on food production and promote agriculture's long-term sustainability. As a result, the deep learning methodology suggested in the research has a lot

of potential in smart agriculture, environmental regulation, and agricultural output.

### B. Comparison Analysis

Table I coins all the methodologies presented in the above section with their advantages and limitations to identify the gaps associated with each methodology to solve the problems efficiently.

TABLE I.    COMPARATIVE ANALYSIS OF EXISTING APPROACHES

| S.No | Author Name | Algorithms Used | Merits | Demerits |
|---|---|---|---|---|
| 1 | Ahmed Ali | GANs integrated with CNN | Since the model produces images stage by stage, it can productively increase the size of the dataset. | To increase the accuracy rate for each image, it iterates in loops, which makes the system expensive. |
| 2 | Umit Atila | EfficientNet | Because of the inverted layer architecture, more similar images are generated at a low cost by reducing the generation cycles from k*k to k. | It has hardware limitations because of which it can perform only binary classification. So, plants with multiple diseases cannot be predicted using this model. |
| 3 | Hongxia Deng | RAHC-GAN | Used for a large amount of data. | Have to explore more data to maintain high value and accuracy |
| 4 | Yang Wu | AVE | The architecture with complete dense layers helps the model to train the system with | The model requires a large amount of annotation data to identify the correct labels for each image |
| 5 | Amreen Abbas | CGAN using transfer learning | Usage of fine-tuned layers in DenseNet improves the multi-classification rate without overfitting. | The model needs retraining to work with compressed images efficiently. |

*C. Research Gaps Identified and Solutions to Solve them*

*1)* Most existing systems cannot produce good images using the basic operations because they are costly and cannot simulate real-world conditions.

*2)* Usage of CNN will complicate the model because the direct conversion of the image into a matrix will increase the training time.

*3)* Traditional GANs use the MNIST dataset to regenerate the images. We need to use 2-layered architecture to extract simple 28*28 images, which produce noisy images as fake images.

So, in the proposed research, instead of 3-layered architecture, the model presents a 4-layered Enhanced Cyclic GAN to extract the features from the image and reconstruct it as early as possible. To overcome the problem of the noisy image, the model initially performs pre-processing using kernel filters, and a few images are constructed using the basic image manipulations. These pre-processed and manipulated images are passed as input to Enhanced Cyclic GAN to create the synthetic data. This process is known as the "Meta-Learning Technique," as shown in Fig. 4.

Fig. 4.    Operations in Meta Intelligent Image Augmentation Process.

III.    PROPOSED METHODOLOGY

Using machine learning and deep learning techniques, several Research Scholars and Scientists are constantly working on various plant diseases to improve production quality. These researchers used the PlantVillage dataset [20] to obtain plant images under controlled conditions. The use of computer vision and deep learning techniques have resulted in high-accuracy systems for detecting plant diseases automatically. The images of the dataset are presented in Fig. 5. Image augmentation creates new images in different scenarios using the existing images and applying popular deep learning techniques. The proposed paper discusses the various image augmentation techniques applied to the tomato plant's dataset from the PlantVillage open source. It also suggests the best method to use the data augmentation by comparing the performance evaluation metrics.

*A. Pre-Processing*

The best solution for solving the random and uneven noise is to apply filters to the images. Analyzing the dataset makes it clear that most of the images have salt and pepper noise. The proposed research used a median filter to reduce these noises and obtained the results shown in Fig. 6(b).

In Fig. 6(a), the original image contains more disturbances due to signal fluctuations. The median filter smoothens the images by replacing each pixel with the median of neighboring pixels. The main advantage of the median filter lies in its edge preservation and removing the spikes.

*B. Discriminator*

GAN works as a classifier to distinguish real and fake images. Real images are positive points, and counterfeit images are negative points. The discriminator gets input from training samples and the generator component of the GAN. The working of this component is based on conditional probability; this component calculates the chance for an image authenticity. The discriminator has associated loss functions because the system has accuracy in classifiers. The GAN structure imposes a penalty for misclassification. This component reduces the penalty by adjusting the latent points through the backpropagation technique. The primary focus of the loss function is to analyze the difference between sample distribution among real and fake images. The proposed research designed the layers in the discriminator component, as shown in Fig. 7.

*C. Generator*

It acts as a creative tool to generate fake images to mislead the discriminator in the classification process by maximizing the penalty and taking the feedback from the above component. Creating a random sample image induces noise as input and then converts it into necessary output. In the GAN structure, the training of the generator is the most crucial part, so the noise is converted into vector space. This space should be balanced by reducing one component and increasing another component's performance. During the training process, using the cross-entropy mechanism, GANs use the min-max loss function as shown in equation (1).

| Target Spot | Mosaic Virus |
| Early Blight | Healthy |

Fig. 6.    (a): Original Image, (b): Filtered Image.
Fig. 7.    Layers Design in Discriminator Module.

$MinMax\_CGAN\_Loss =$
$Expected\_Real(\log(Discriminator(X)) +$
$Expected\_Fake(\log(1 - Discriminator(Generator(Y)))- (1)$

Where

Discriminator(X) analyzes the probability associated with the real images.

Generator(Y) analyzes the probability associated with the fake images along with the noise.

The summary evaluation of the layered architecture of the generator component is represented in Fig. 8.

Fig. 8.    Summary Evaluation Report of Generator Component.

### D.  Enhanced Cyclic Generative Adversarial Networks

In practice, GANs act as a tool to generate a fake image by analyzing the sample distribution of the real image. GANs should be designed with the help of two components. One is a generator to take care of modifications in the real images, and the other is a discriminator that focuses on the wrong assumptions made by the model in the identification process. The basic element needed by any GAN to generate fake images is "noise" to generate different variations in images. However, GANs can accept only random noise or probability distribution. In reality, GAN acts as a mapping function between two different dimensional spaces. Designing a good model requires the dimensionality of sample space to map with latent space. Otherwise, the model may lose all the essential properties in the classification process based on the distance. In general, to convert 1D into 2D, the traditional Vanilla GAN tries to analyze the Gaussian distribution among the random samples, but the model fails after a few training epochs. The proposed research defined the latent space dimension as 100, as the traditional GANs cannot support high dimensional conversion, and also, the dataset consists of images of multiple diseases. Hence, the model needs a GAN that can convert one domain to another, which is the basic phenomenon of the consistent cyclic GAN. CGAN consists of two generators and two discriminators, each consisting of 3 layers of CNN in each component, as shown in Fig. 9.

The proposed research modifies the existing 3-layered architecture of GANs into 4-layered architecture (shown in Fig. 10), with a single generator and discriminator, shown in Fig. 10.

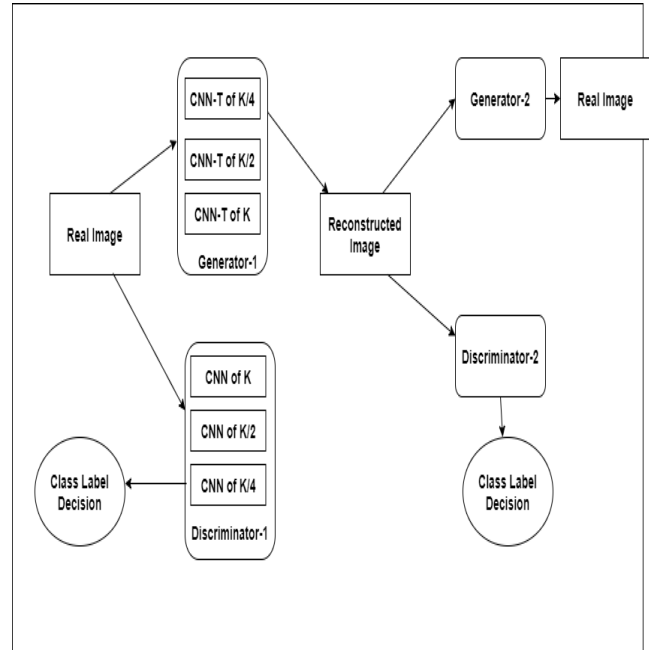

Fig. 9.    Existing Architecture of Cycle GAN.
Fig. 10. Complete MI-Leaf GAN Architecture for the Synthetic Data Creation.

---

**Algorithm for MI-Leaf GAN:**

Input: T_Data←Load the Pre-processed Images of Tomatoes from the repository
Data: Generates more number of augmented images
Begin:
1. Initialize latent_dspace with 100
2. model_discriminator←call enhanced_discriminator()
3. model_generator←call enhanced_generator(latent_dspace)
4. model_enhanced_CGAN←call enhanced_CGAN(model_generator,model_discriminator)
5. Call train_enhanced_model(model_generator, model_discriminator, model_enhanced_CGAN, T_Data[0],latent_dspace)
6. decision←call generate_latent_points()
7. fake_img←model.predict(decision)
8. Plot the images
End

---

**Pseudocode for Enhanced Discriminator using Sequential Network:**
1. Resize the input image to k (where k defines the size as 128)
2. Define four convolution layers of size k/2
3. Define 4 LeakyReLu layers with αn 0.2
4. Add a Flatten layer
5. Add dropout layer to normalize with threshold value as 0.4
6. Add a fully connected layer with sigmoid as an activation function
7. Compile the Model by defining the optimizer, learning rate, loss function, and accuracy

---

**Pseudo code for Training of Enhanced Model**
1. Set up number of batches in each epoch i.e., bperepoch as number of images per number of batches
2. Initialize number_of_epochs as "35000"
 3. a. for i in number_of_epochs:
      b. for j in bperepoch:
        c.                                    img_real, label_real←generate_real_images(T_Data,bperepoch/2)

        d. img_fake, label_fake←generate_fake_images(model_generator,latent_dspace, bperepoch/2)
        e.     d_loss←model_discriminator.train_on_batch(img_real, label_real, img_fake, label_fake)
        f. img_gan←generate_latent_points(latent_dspace,batch_size)
        g. label_gan←np.ones((batch_size,1))
        h. g_loss←model_enhanced_CGAN.train_on_batch(img_gan,label_gan )

---

In binary machine learning algorithms, the class labels will be either 0 or 1, but in GANs, the class labels are assigned as -1, 0, and 1 due to Gaussian distribution. In GANs, the latent space tries to identify the region of interest by performing addition and subtraction operations, i.e., finding the compressed image of the original image by acting as the hidden layer. Each latent space is associated with latent points, which are used to assign random values initially with a discriminator's help. Later, these values are updated through the generator component.

## IV. RESULTS AND DISCUSSION

The Meta Intelligent Leaf GAN designed using a single discriminator and generator with a constant number of neurons in the hidden layers produces the fake images, as shown in Fig. 11. Since the proposed research uses online data augmentation techniques, these are stored in Google drive for further access.

Fig. 12 shows the accuracy produced by the GAN structure at a different number of epochs. The number of epochs is set to 35000, and the model exhibited an output of 400 epochs as a sample. Similarly, the model can also plot the accuracy rate for the fake images.

To train the GAN structure, the model initially defines the latent space with 100 dimensionalities, and then the pre-processed images are passed as input to the GAN. The proposed model computes the loss functions for both components. Fig. 13 presents a sample output for a single iteration with the corresponding accuracy of real and fake images.

Fig. 11. Synthetic Images Created using MI-GAN.
Fig. 12. Accuracy for Generating Real Images at Different Epochs.

Fig. 13. Loss Function Computation for GAN.

To date, many researchers worked on different GAN structures. Most of the problems faced are either due to noise or complexity of the design rather than random noise. The first traditional GAN was developed for the MNIST dataset. For 28*28 images, they have used two generators and discriminators with three layers each. Similarly, Table II represents the other mechanisms with the corresponding accuracy and proves that the proposed model has achieved good accuracy and simple architecture.

From Table II, the GAN approach has crossed approximately 90% out of the traditional CNN and GAN. So the proposed system enhanced the GAN technique using meta intelligent concept and reached 99.29%, which is approximately a 2.29% improvement from previous approaches. Accuracy alone cannot be stated as state of the art. So in Table III, the model presents other metrics of learning approaches.

TABLE II. ACCURACY ANALYSIS BETWEEN EXISTING AND PROPOSED GAN

| Reference Number | Algorithm | Accuracy |
|---|---|---|
| [1] | CNN Integrated GAN | 97 |
| [3] | Feature Fusion | 78.80 |
| [5] | CNN | 97.1 |
| [7] | RPN for Image Segmentation and GAN | 83.5 |
| [9] | RAHC-GAN | 93.28 |
| Proposed Work | MI-GAN | 99.29 |

TABLE III. EVALUATION METRICS

| Algorithm | Accuracy | Precision | Recall | F1-Score |
|---|---|---|---|---|
| CNN Integrated GAN | 97 | 90 | 85 | 87 |
| Feature Fusion | 78.8 | 73 | 76 | 74.5 |
| CNN | 97.1 | 90 | 85 | 88 |
| RPN for Image Segmentation and GAN | 83.5 | 80 | 80 | 80 |
| RAHC-GAN | 93.28 | 85.1 | 89 | 87 |
| MI-GAN | 99.29 | 96 | 98 | 97 |

The visualization graph of the Table III analysis is presented in Fig. 14, where the X-axis represents the algorithm's name and the Y-axis represents the measurement scale. The proposed system has performed accurately in all metrics. So, the state-of-the-art for the proposed system is achieved.

Fig. 14. Metrics Evaluation Analysis.

## V. CONCLUSION

It is complicated to label every image from the live capturing. It is difficult to predict the type of disease using unsupervised algorithms like clustering. So, the model should develop a classification system where data labeling is mandatory. In a real-time environment, the conditions are uncontrolled. The method may face problems like labeling disease datasets, addressing the data imbalances, and overfitting because of the size of diagnostic clues, which are smaller than in the real-world scenario. The system also suffers from overfitting because it takes many computations to select and apply possible geometric transformations. Designing a GAN structure for high dimensionality images is challenging because the standard MNIST uses three-layered architecture for simple 28*28 size images. If the size increases, the number of layers get increased, and the model becomes complicated. So, by designing a good policy schema, like Meta Intelligent Leaf GAN, the auto augmentation process can efficiently improve the accuracy where the enhanced GAN model uses an integrated filter. The MI Leaf GAN modules generate more training data because the system addresses the overfitting problem that occurs due to basic image operations. Fig. 13 shows that accuracy is more accurate for the proposed research in generating fake images and successfully fooling the discriminator after performing more epochs. Even though the size of the images is vast, the model considered is more significant than standard GAN; it was designed only in four layers to complete the task.

CUFE, Cairo, Egypt

*Abstract*—This work is concerned with the Path Planning Algorithms (PPA), which hold an important place in Robotics navigation. Navigation has become indispensable to most modern inventions. Mobile robots have to move to a relevant task point in order to achieve the tasks assigned to them. The actions, which are planned in a structure, may restrict the task duration and even in some situations, the mission tends to be accomplished. This paper aims to study and compare six commonly used informed and uninformed algorithms. Three different maps have been created with gradually increasing difficulty levels related to a number of obstacles in the tested maps. The paper provides a detailed comparison between the algorithms under investigation of several parameters such as: Total steps, straight steps, rotation steps, and search time. The promised results were obtained when the proposed algorithms were applied to a case study.

*Keywords—Mobile robots; informed algorithm; uninformed algorithm; path planning*

## I. INTRODUCTION

Mobile robots [1] are getting more important in daily life as a result of their increasing role in making human's life easier. According to this point of view, it is obvious that Mobile Robots will be an indispensable part of future life [2]. To make Mobile Robots able to perform an assigned task, they have to know their locations [3], how to navigate [4] within their environment [5] and how to comprehend what the world around them looks like in order to choose the optimal path [6] from the start to the end point in order to reach the target. The path selection depends on the selected criteria to evaluate the path (ex: travel time, number of visited nodes, etc.).The optimal route [7] can be obtained by a variety of methods like the graph theory [8], probabilistic or heuristic [9] based optimization methods [10]. At every point in the grid map representing the working area of the robot, the selected algorithm assigns a direction for the robot out of the possible four directions: Right, Left, Up, and Down. In this paper six different algorithms have been studied, categorized as Informed [11] and Uninformed types [12], a differentiation between them in characteristics is applied, how the algorithm itself works, how the steps of work are correctly applied, and finally, there were three different maps that graduate in their difficulty related to a number of obstacles [13] to test those algorithms, testing six different types of path planning algorithms with three different maps was a challenging work that has been done successfully.

The key objectives of the research are the following:

*1)* Single mobile robot represents as one node mass.

*2)* Start and End from Fixed node. Easy, Medium, Hard Map depend on the number of obstacles.

*3)* Modified informed algorithms and adjusted all algorithms to make the Mobile Robot pass in four dimensions; now no longer in eight directions to ensure that modified algorithms move with less rotation and short pass.

*4)* Compared all algorithms with each other and get results.

This paper is organized as follows: Section II briefly views the general optimal path problems definitions and the methods, which are executed and discussed in this study. Section III presents the Simulation and the results. Section IV presents the conclusion and the future work.

## II. PATH PLANNING PROBLEM AND ALGORITHMS

### A. Path Planning Problem

First, the path planning is traditionally divided into two categories: local [14], and global [15]. The local is used in an unknown environment while the global is a prior knowledge of the work environment. In this classification, path or route planning [16] is defined as a problem in which an agent moves from a start to an endpoint by avoiding the obstacles in order to reach the target with minimum cost. The starting and the endpoints could be the same (loop closure) or even different. It is preferably desired to have the shortest distance [17] between the start/endpoints. However, the definition of the optimal path can be changeable in some situations. For example, if the tasks are successively assigned to the robots, the elapsed time to calculate the optimal path also matters. When the computation time is too long to obtain the optimal path, it will be difficult to provide the task continuity. According to this reason, the most suitable algorithm has to be chosen according to the desired optimal criterion.

Fig. 1 to 8 demonstrates the different types of the environments as following:

*1)* Creating a grid map environment for all experiments.

*2)* Fixed dimensions for the grid map shall be (30*40).

*3)* Making sure to start and end from a fixed node.

*4)* Categorizing different Maps depending on a number of obstacles to: Easy, Medium, and Hard Maps.

*5)* Making modifications and adjustments for the informed algorithms by making them work in four dimensions rather than eight directions.

*6)* Choosing a single mobile robot to represent only one node mass.

Fig. 7.   Hard Map.

Fig. 8.   Single Mobile Robot.

## B. Path Planning Algorithm

Optimal path planning algorithm can be classified to informed or uninformed (blind) one. Table I summarizes the algorithms which will be discussed in this paper.

*1) Informed algorithms:* Informed Algorithms are the algorithms that can be applied if complete information about the working area is available.

TABLE I. INFORMED AND UN-INFORMED ALGORITHMS

| Informed | Un-Informed |
|---|---|
| 1-Dijkstra [18] | 4-Best First Algorithm [19] |
| 2-A star search [20] | 5-Breadth First Search [21] |
| 3-Bidirectional A Star [22] | 6-Depth First Search [23] |

Several algorithms are related to informed algorithms. In this paper, the most common algorithms were selected, which are Dijkstra, A star, and Bidirectional A star.

*a) Dijkstra's Algorithm:* Dijkstra algorithm is one of the oldest algorithms used in path planning. It was published by Dijkstra in 1959. However, it is still being widely used in several applications [24], [25] [26]. The problem which is handled by Dijkstra Algorithm is represented as follows: when given a graph and a source vertex in that graph, it's obligatory to find the shortest paths from the source to all vertices in the given graph.

The algorithm can be summarized by using the following flowchart:

---

**Algorithm 1: Dijkstra's Algorithm**

**Initialization**:
 **for** every vertex X in Graph:
 *Dst*[X] = infinity // initial distance from source to vertex X is set to infinite
 *previous*[X] = undefined // Previous node in optimal path from source
 *Dst* [source]:= 0 // Distance from source to source
 D: = the set of all nodes in Graph // all nodes in the graph are unoptimized - thus are in D

**Main Loop**
 **While** D is not empty
 S = node in D with shortest distance from source
 Remove S from D
 **for** each neighbor X of S such that X □D
alt = *Dst*[*S*] + distance between (*S, X*)
**if** *alt < Dst*[*X*] then
*Dst*[*X*] = *alt*
*previous*[*X*]:= *S*
**End while**

---

The algorithm outputs an array indicating the best previous node (previous) for every node and another array stores the best distance from the source to every node in the graph (dist).

*b) A star search (A\* or A-star or A\* search):* A search method [27][28][29] based on a heuristic function, h (n), where n refer to a node n. Every node is associated an estimation h(n) of a route's cost from n to a goal node, while h(n) is equivalent to the actual distance (cost) from n to the goal node.

The other part of this function is g(n), that represents the cost of the path from the beginning node to node n, and f(n), which shows the estimated cost of the path that is being obtained which moves via n to reach to the goal node. f (n) is defined as the total of g (n) with h (n), as in shown Equation:

$$f(n) = g(n) + h(n) \tag{1}$$

Two lists are mentioned in following flowchart:

---

**Algorithm 2: A Star Algorithm**

**Initialization:**
 Let open list have only the starting node
 Let closed list empty

**Main Loop**
 **While** (the destination node has not been reached):
 consider the node with the lowest f score in the open list
 **If** (this node is destination node):
 we are finished.
 **Else If**: put the current node in the closed list and look at all of its neighbors.
 **For** (each neighbor of the current node):
 **If** (neighbor has lower g value than current and is in the closed list).
 replace the neighbor with the new, lower, g value
 current node is now the neighbor's parent
 **Else If** (current g value is lower and this neighbor is in the open list).
 replace the neighbor with the new, lower, g value
 change the neighbor's parent to current node
 **Else If** this neighbor is not in both lists:
 add it to the open list and set its g .
**End while.**

---

The algorithm outputs an array indicating the best path related to the lowest cost 'g value' for every node and an array stores the best distance from the source to every node in the graph (closed list).

*c) Bidirectional A Star Algorithm:* The bidirectional search algorithm combines two separate searches. The search that is performed from both the origin and destination simultaneously, and when these two searches meet, then the shortest path can be obtained.

Next are the steps and pseudocode to show how bidirectional A star search works:

- Search forward from the start point.

- Search backward from the goal point.

- Using "fF", "gF" ,"hF" to indicate f, g, and h-costs in the forward search.

- Also using "fB","gB","hB" similarly in the backward search.

| **Algorithm 3: Bidirectional A Star Algorithm** |
|---|
| **Initialization:** <br> Open F and Open B <br> store states generated in the forward and back ward directions, Finally, g min F, g min B, f min F and f min B <br><br> denote the minimal g- and f-values in OpenF and OpenB <br> **d (x, y)** denotes the shortest distance between **x** and **y**. **Front-to-end** algorithms use two heuristic functions. **Main Loop** <br> The **forward heuristic**, **hF** , is forward admissible <br><br> **If** f hF (u) ≤ d (u, goal) <br> **For** all u in G and is forward consistent <br><br> **If** f hF (u) ≤ d (u, u') + hF (u') <br> **For** all u and u' in G. <br> The backward heuristic, hB, is backward admissible <br><br> **If** f hB(v) ≤ d (start, v) <br> **For** all v in G and is backward consistent <br><br> **If** f hB(v) ≤ d (v', v) + hB (v') <br> **For** all v and v' in G. <br> final f = d (start, goal) is the cost of an optimal solution. <br> **End** |

After this implementation, some modifications in informed algorithms are needed to improve path length to make them more optimum and straight as possible.

The huge problem in informed algorithms which is related to the cost function search is that they cannot find the least rotation steps in many paths with the same path length. In this paper, informed algorithms are improved by adding the rotation cost estimation method based on a moving direction. Assuming that the node n coordinate is $(x_n, y_n)$, then the previous node coordinate is $(x_{n-1}, y_{n-1})$, and the coordinates of the next node is $(x_{n+1}, y_{n+1})$. Then the rotation evaluation function of node n is k (n).

$$f (n) = g (n) + h (n) + K(n) \tag{2}$$

*2) Uninformed algorithms:* Blind search is another name for uninformed search formulas. The search algorithm generates the search tree without relying on any domain knowledge, which is a brute force in nature. Uninformed Algorithms lack background information on how to approach the goal or destination that must be reached.

Best First Algorithm "BFS" stands for Best First Search, it's an evaluation function that measures distance to the goal, the general approach of this search algorithm is that the node is selected for expansion based on an evaluation function f(n).

It combines the advantages of both DFS and BFS in a single method; in DFS not all combining branches have to be expanded; on the other hand, the BFS are not trapped on dead-end paths. Combining the two to follow a single path at some time, but switching between paths whenever there is some competing path looks more promising than the current one.

*a) Best first search algorithm:* At every step of the BFS [30] search process, The most promising nodes are selected that have been generated thus far, applying some appropriate heuristic function to each of them, and then making an expansion to the chosen node by using the specified rules to generate its successors, which is known as an OR-graph, because each of its branches representing an alternative problem-solving path, and storing the nodes in the to Visit Nodes data structure using a queue.

| **Algorithm4: Best First Search Algorithm** |
|---|
| **Initialization**: <br>     open list containing the start state. <br>     CLOSED list empty. <br>     BEST =start state. <br>     lets s= arg max e(x). <br>     (get the state from OPEN with the highest evaluation) <br>     remover S from OPEN and add to CLOSED <br>     **if** e(S)>=e(BEST), <br>     then BEST =S <br>  **Main Loop** <br>     **for** each child t of s that is not in the OPEN or CLOSESD list, evaluate and add to OPEN <br>     **if** BEST changed in the last set of expansions <br>     goto step four <br>     Return BEST |

*b) Breadth first search:* There are different ways to traverse graphs, this algorithm means by graph traversal visiting every vertex and edge exactly one time in a well-defined order, as using a certain graph algorithm, each vertex of the graph must be visited one time exactly, and the order in which the vertices are visited are so important as it may depends on the algorithm or the problem that is needed to be solved.

Next are steps and pseudo code explaining BFS methodology.

First step: move horizontally then visit all the nodes of the present layer.

Second step: Move to the following layer

| **Algorithm 5:Breadth First Search** |
|---|
| **Initialization** <br>     Set all nodes to "not visited"; <br>     q = new Queue (); <br>     q. enqueue (initial node); <br> **Main Loop** <br>     **While** (q ≠ empty) <br>     **do**{ x = q. dequeue (); <br>     **If** (x has not been visited) <br>     {visited[x] = true; // Visit node x <br>     **for** (every edge (x, y) // we are using all edges <br>     **If** (y has not been visited) <br>     q. enqueue(y); // Use the edge (x, y) <br> **End While** |

*c) Depth first search:* DFS stands for Depth First Search, it is an algorithm for traversing or searching a tree or graph data structure, it uses a stack data structure for implementation. In DFS, one starts at the root and explores as far as possible along each branch before backtracking. Nest are steps and pseudocode explaining DFS methodology.

- Initializing nodes with status =1(ready data).

- Put starting node in the stack and change status to status=2(waiting state).

- Loop: repeat the next two steps until stack gets empty or algorithm reaches goal node.

- Remove front node N from stack, process them and change the status of N to status=3(processed stat).

- Add all the neighbors of N to the stack and change status to status=2(waiting status).

| Algorithm 6:Depth First Search |
|---|
| **Initialization**:<br>　　procedure DFS-iterative (G, v) is<br>　　let S be a stack<br>　　S.push (v) |
| **Main Loop**<br>　　**While** S is not empty do<br>　　v = S.pop()<br>　　**If** v is not labeled as discovered then<br>　　label v as discovered<br>　　**For** all edges from v to w in G.adjacent Edges (v)<br>　　**do** S.push(w)<br>**End while** |

## III. SIMULATION AND RESULTS

To demonstrate the benefits of the modification for the algorithms in terms of search speed, visited nodes, number of rotations, path selection, and path length, Three separate experimental locations have been created, basic and modified algorithms are compared then comparing those algorithms with uninformed ones, The experiments aim to establish a starting point and a target point environment.

Fig. 9(a) to 11(b) shows the difference between Basic and Modified Dijkstra is in three different maps.

### A. Dijkstra Algorithm

In this environment, it shows the search methods and gives a comparison between the two algorithms (Dijkstra algorithm and modified Dijkstra algorithm) in three environments.

Fig. 9(a) to 11(b) shows the difference between Basic and Modified Dijkstra in three different maps.

Also, Tables II to IV compare Basic and Modified Dijkstra in total steps, straight steps, rotation steps, visited nodes, and search time on three different maps.

### 1) Dijkstra and modified Dijkstra algorithm in Easy Map.

(a)       (b)
Fig. 9. (a) Modified Dijkstra for Easy Map (b) Basic for Easy Map.

TABLE II. COMPARISON BETWEEN BASIC AND MODIFIED DIJKSTRA ALGORITHM IN EASY MAP

| Algorithm | Total Steps | Straight Steps | Rotation Steps | Visited nodes | Search time |
|---|---|---|---|---|---|
| Basic Dijkstra | 56 | 47 | 9 | 986 | 4.9 |
| Modified Dijkstra | 56 | 50 | 6 | 1010 | 5.3 |

### 2) Dijkstra algorithm in Medium Map

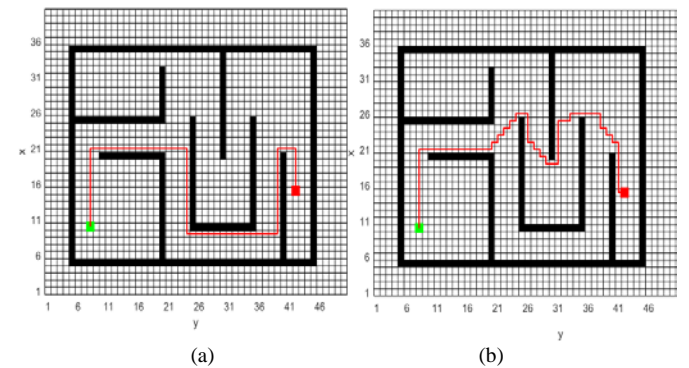
(a)       (b)


Fig. 10. (a) Modified Dijkstra for Medium Map (b) Basic Dijkstra for Medium Map.

TABLE III. COMPARISON BETWEEN BASIC AND MODIFIED DIJKSTRA ALGORITHM IN MEDIUM MAP

| Algorithm | Total Steps | Straight Steps | Rotation Steps | Visited nodes | Search time |
|---|---|---|---|---|---|
| Basic Dijkstra | 76 | 45 | 31 | 974 | 4.29 |
| Modified Dijkstra | 76 | 70 | 6 | 976 | 4.32 |

### 3) Dijkstra Algorithm in Hard Map.

Fig. 11. (a) Modified Dijkstra for Hard Map (b) Basic Dijkstra for Hard Map.

TABLE IV.    COMPARISON BETWEEN BASIC AND MODIFIED DIJKSTRA ALGORITHM IN HARD MAP

| Algorithm | Total Steps | Straight Steps | Rotation Steps | Visited nodes | Search time |
|---|---|---|---|---|---|
| Basic Dijkstra | 112 | 73 | 39 | 812 | 3.95 |
| Modified Dijkstra | 112 | 97 | 15 | 814 | 3.96 |

As shown in the Fig. 9(a) to 11(b) and Tables II to IV, both of the Dijkstra algorithm and the improved Dijkstra algorithm can search for symmetric paths of the same length, but the search path of the improved Dijkstra algorithm has more straight length, the path trajectory is different, and the number of rotation points in the paths are also different. It is obvious that the improved Dijkstra algorithm search straighter than the Dijkstra algorithm by equal to 3 steps in easy map, 25 steps in medium map and 19 steps in hard map.

### B. A Star Algorithm

In this environment, Fig. 12(a) to 14(b) shows the difference between basic and modified A Star in three different maps.

In addition, Tables V to VII gives a comparison between the two algorithms in total steps, straight steps, rotation steps, visited nodes, and search time on three different maps.

### 1) A Star Algorithm in Easy Map

Fig. 12. (a) Modified a Star for Easy Map, (b) Basic a Star for Easy Map

TABLE V.    COMPARISON BETWEEN BASIC AND MODIFIED A STAR ALGORITHM IN EASY MAP

| Algorithm | Total Steps | Straight Steps | Rotation Steps | Visited nodes | Search time |
|---|---|---|---|---|---|
| Basic A Star | 56 | 47 | 9 | 569 | 2.96 |
| Modified A Star | 56 | 49 | 7 | 726 | 3.15 |

### 2) A Star Algorithm in Medium Map.

Fig. 13. (a) Modified a Star for Medium Map, (b) Basic a Star for Medium Map.

TABLE VI.    COMPARISON BETWEEN BASIC AND MODIFIED A STAR ALGORITHM IN MEDIUM MAP

| Algorithm | Total Steps | Straight Steps | Rotation Steps | Visited nodes | Search time |
|---|---|---|---|---|---|
| Basic A Star | 76 | 61 | 15 | 758 | 3.19 |
| Modified A Star | 76 | 69 | 7 | 768 | 3.21 |

### 3) A Star Algorithm in Hard Map

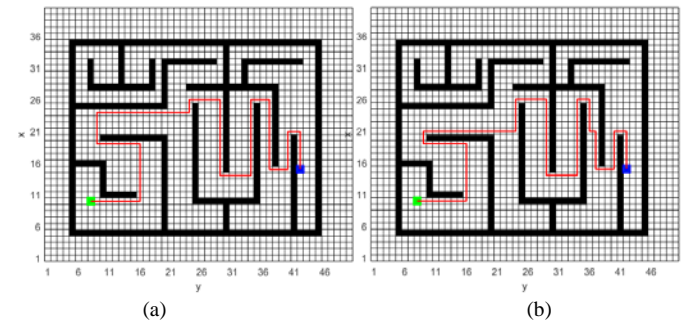

Fig. 14. (a) Modified a Star for Hard Map, (b) Basic a Star for Hard Map.

TABLE VII.    COMPARISON BETWEEN BASIC AND MODIFIED A STAR ALGORITHM IN HARD MAP

| Algorithm | Total Steps | Straight Steps | Rotation Steps | Visited nodes | Search time |
|---|---|---|---|---|---|
| Basic A Star | 112 | 95 | 17 | 679 | 2.96 |
| Modified A Star | 112 | 97 | 15 | 698 | 2.97 |

As shown in above Fig. 12(a) to 14(b) and Tables V to VII, both A Star algorithm and the improved A Star algorithm can search for symmetric paths of the same length, but the search path of the improved A Star Algorithm has more straight length, the path trajectory is different, and the number of rotation points in the paths are also different. And it is obvious that the improved A Star Algorithm search straighter than A Star Algorithm by equal to 3 steps in easy map, 8 steps in medium map and 2 steps in hard map.

### C. Bidirectional a Star

In this environment, Fig. 15(a) to 17(b) shows the difference between Basic and modified Bidirectional A Star in three different maps.

In addition, Tables VIII to X give a comparison between the two algorithms in total steps, straight steps, rotation steps, visited nodes, and search time on three different maps.

#### 1) Bidirectional A Star algorithm in Easy Map:

(a)                                    (b)
Fig. 15. (a) Modified Bidirectional a Star for Easy Map (b) Basic Bidirectional a Star for Easy Map.

TABLE VIII. COMPARISON BETWEEN BASIC AND MODIFIED BIDIRECTIONAL A STAR ALGORITHM IN EASY MAP

| Algorithm | Total Steps | Straight Steps | Rotation Steps | Visited nodes | Search time |
|---|---|---|---|---|---|
| Basic Bidirectional A Star | 56 | 48 | 8 | 437 | 1.32 |
| Modified Bidirectional A Star | 56 | 49 | 7 | 462 | 1.57 |

#### 2) Bidirectional A Star Algorithm in Medium Map

(a)                                    (b)
Fig. 16. (a) Modified Bidirectional a Star for Medium Map, (b) Basic Bidirectional a Star for Medium Map.

TABLE IX. COMPARISON BETWEEN BASIC AND MODIFIED BIDIRECTIONAL A STAR ALGORITHM IN MEDIUM MAP

| Algorithm | Total Steps | Straight Steps | Rotation Steps | Visited nodes | Search time |
|---|---|---|---|---|---|
| Basic Bidirectional A Star | 76 | 68 | 8 | 651 | 2.71 |
| Modified Bidirectional A Star | 76 | 69 | 7 | 659 | 2.73 |

#### 3) Bidirectional A Star Algorithm in Hard Map.

(a)                                    (b)
Fig. 17. (a) Modified Bidirectional a Star for Hard Map (b) Basic Bidirectional a Star for Hard Map.

TABLE X. COMPARISON BETWEEN BASIC AND MODIFIED BIDIRECTIONAL A STAR ALGORITHM IN HARD MAP

| Algorithm | Total Steps | Straight Steps | Rotation Steps | Visited nodes | Search time |
|---|---|---|---|---|---|
| Basic Bidirectional A Star | 112 | 97 | 15 | 747 | 3.16 |
| Modified Bidirectional A Star | 112 | 97 | 15 | 756 | 3.19 |

As shown in Fig. 15(a) to 17(b) and Tables VIII to X, it can be seen that both the Bidirectional A Star algorithm and the improved Bidirectional A Star algorithm can search for symmetric paths of the same length, but the search path of the improved Bidirectional A Star algorithm has more straight length, the path trajectory is different, and the number of rotation points in the paths are also different. In addition, it is obvious that the improved Bidirectional A Star algorithm search straighter than Bidirectional A Star algorithm can reach to one-step in easy map one-steps in medium map and the same steps in hard map.

### D. Best First Search Algorithm

*1) Best first search algorithm in easy map:* The three different maps of BFS are demonstrated in three figures [Fig. 18(a) to 18(c)].

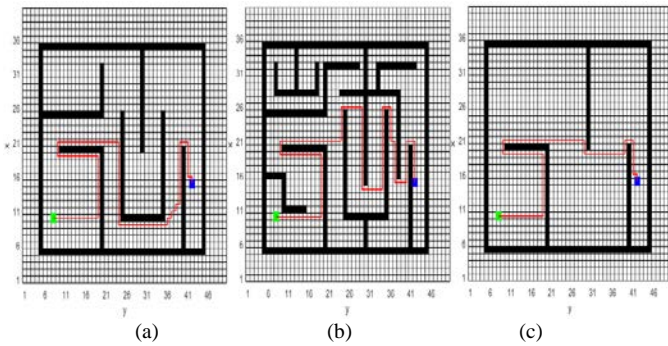
(a)                          (b)                          (c)


Fig. 18. (a) BFS Easy Map, (b) BFS Medium Map, (c) BFS Hard Map.

Tables XI gives the result of BFS in total steps, straight steps, rotation steps, visited nodes, and search time on three different maps.

TABLE XI.    RESULTS OF BFS IN EASY, MEDIUM AND HARD MAP

| Algorithm | Path Length | Straight Steps | Rotation Steps | Visited nodes | Search time |
|---|---|---|---|---|---|
| BFS Easy Map | 76 | 65 | 11 | 462 | 1.54 |
| BFS Medium Map | 96 | 78 | 17 | 659 | 2.75 |
| BFS Hard Map | 118 | 101 | 17 | 756 | 3.17 |

### E. Breadth First Search

*1) Breadth first algorithm in easy map:* The three different maps of BFS is demonstrated in three Fig. 19(a) to 19(c).

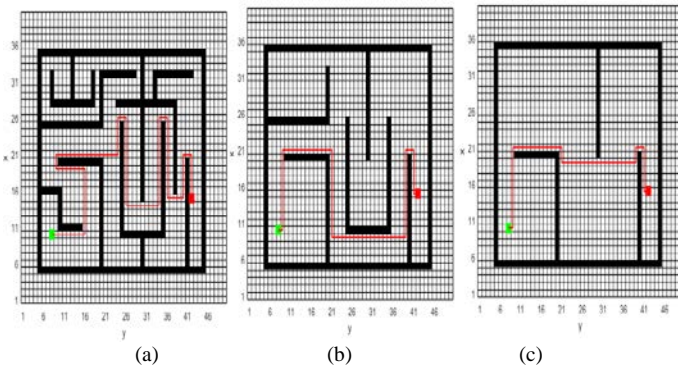
(a)                          (b)                          (c)


Fig. 19. (a) BFS Easy Map, (b) BFS Medium Map, (c) BFS Hard Map.

The Table XII gives the result of BRFS in total steps, straight steps, rotation steps, visited nodes, and search time on three different maps.

TABLE XII.    RESULTS OF BRFS IN EASY, MEDIUM AND HARD MAP

| Algorithm | Total Steps | Straight Steps | Rotation Steps | Visited nodes | Search time |
|---|---|---|---|---|---|
| BRFS Easy Map | 56 | 48 | 8 | 678 | 2.95 |
| BRFS Medium Map | 76 | 68 | 8 | 673 | 2.97 |
| BRFS Hard Map | 112 | 97 | 15 | 805 | 3.81 |

### F. Depth First Search

*1) Depth First algorithm in Easy Map:* The three different maps of DFS is demonstrated in three figures below [Fig. 20(a)-(c)].

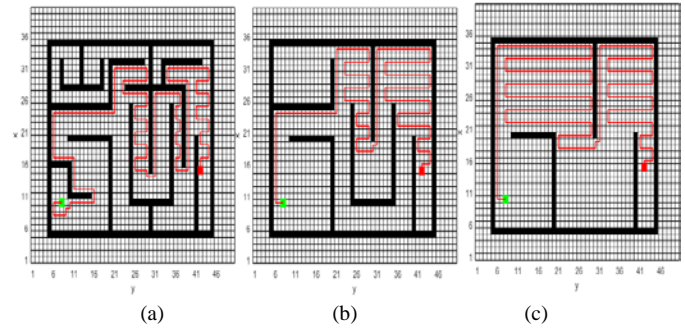
(a)                          (b)                          (c)


Fig. 20. (a) DFS Easy Map, (b) DFS Medium Map, (c) DFS Hard Map.

The Table XIII gives the result of DFS in total steps, straight steps, rotation steps, visited nodes, and search time on three different maps.

TABLE XIII.    RESULTS OF DFS IN EASY, MEDIUM AND HARD MAP

| Algorithm | Total Steps | Straight Steps | Rotation Steps | Visited nodes | Search time |
|---|---|---|---|---|---|
| DFS Easy Map | 332 | 289 | 41 | 625 | 2.68 |
| DFS Medium Map | 220 | 177 | 43 | 526 | 2.61 |
| DFS Hard Map | 224 | 159 | 65 | 526 | 2.35 |

*2) Comparison between modified informed algorithm and informed algorithms:* In all informed and modified informed algorithms path length are equal in all maps, but trajectory path and straight length in selected path is improved as shown in Table XIV.

TABLE XIV.    COMPARISON OF STRAIGHT LENGTH IN UNINFORMED ALGORITHMS

| Algorithm | Easy Map straight Length | Medium Map Path Length | Hard Map Path Length |
|---|---|---|---|
| BFS | 65 /76 | 78/96 | 101/118 |
| BRFS | 48/56 | 68/76 | 97/112 |
| DFS | 289/332 | 177/220 | 159/224 |

### G. These Experiments Show us Best Uninformed Algorithm in all Maps is BRFS

*1) Comparison between modified informed algorithm and informed algorithms:* In Table XV all informed and modified informed algorithms path length are equal in all maps, but trajectory path and straight length in selected path is improved, in easy map path equal 56 steps, in medium map 76 steps, in hard map 112 steps.

TABLE XV.   COMPARISON OF STRAIGHT LENGTH IN MODIFIED INFORMED AND INFORMED ALGORITHMS

| Algorithm | Easy Map straight Length | Medium Map straight Length | Hard Map straight Length |
|---|---|---|---|
| Dijkstra | 47 /56 | 45/76 | 73/112 |
| Mod Dijkstra | 50/56 | 70/76 | 97/112 |
| A star | 47/56 | 61/76 | 95/112 |
| Mod A star | 49/56 | 69/76 | 97/112 |
| Bidirectional A star | 48/56 | 68/76 | 97/112 |
| Mod Bidirectional A star | 49/56 | 69/76 | 97/112 |

Table XV shows us that:

- Dijkstra algorithm is improved by more than 5% in Easy Map, more than 32% in medium Map, more than 19% in Hard Map.

- A Star Algorithm is improved by more than 3% in Easy Map, more than 10% in medium Map, more than 1% in Hard Map.

- Bidirectional A Star Algorithm is improved by more than 1% in Easy Map, more than 2% in medium Map.

- Modified Dijkstra has higher effect in results more than other two algorithms.

*2) Comparison between modified informed algorithm and uninformed algorithms:* According to informed and uninformed algorithms experiment data as shown in Table XVI, the obtained path trajectories are not the same for all algorithms, which indicates that the Modified Dijkstra algorithm has Minimum straight length path in all maps, in other side modified A Star, modified Bidirectional A Star have same straight length easy and medium map, also all of three modified informed algorithms have Minimum straight length path Comparing the search time easy, medium and hard map informed and uninformed search.

TABLE XVI.   COMPARISON BETWEEN MODIFIED INFORMED AND UNINFORMED ALGORITHMS

| Algorithm | Visited nodes | | | Search time in second | | |
|---|---|---|---|---|---|---|
| | Easy | Medium | Hard | Easy | Medium | Hard |
| Mod Dijkstra | 1010 | 976 | 814 | 5.3 | 4.32 | 3.96 |
| Mod A star | 726 | 768 | 698 | 3.15 | 3.21 | 2.97 |
| Mod Bidirectional A star | 462 | 659 | 756 | 1.57 | 2.73 | 3.19 |
| BFS | 462 | 659 | 756 | 1.54 | 2.75 | 3.17 |
| BRFS | 678 | 673 | 805 | 2.95 | 2.97 | 3.81 |
| DFS | 625 | 526 | 526 | 2.68 | 2.61 | 2.35 |

## IV.   DISCUSSION

To demonstrate the Benefits of the modified algorithms in terms of search speed, number of rotation, path selection and path length, three separate experimental locations have been created. The experiments establish a starting point and target point environment. Dijkstra algorithm improved by more than 5% in Easy Map, more than 32% in medium Map, more than 19% in Hard Map.

A Star Algorithm improved by more than 3% in Easy Map, more than 10% in medium Map, more than 1% in Hard Map.

Bidirectional A Star Algorithm is improved by more than 1% in Easy Map, more than 2% in medium Map.

Modified Dijkstra has better results over the other two algorithms.

## V.   CONCLUSION

The purpose of this paper is to modify and adjust informed search algorithms and compare pure informed algorithms and uninformed algorithms to find the shortest path between the start and the goal on designed maps of various obstacles' quality. Additionally, to enhance the identification of the shortest path for each algorithmic search with less rotation within the path and to simulate its performance in the designed maps, it can be noticed from the results that algorithms that have high visited nodes have more optimums than algorithms with low visited nodes. Search time is directly proportional to the number of visited nodes. Finally, heuristic search algorithms are more flexible than blind search algorithms.

Future work will involve the proposed algorithms that are compatible with Artificial Intelligence to make high-response and more features to keep up with the modern technology requirements.

# Modified Gradient Algorithm based Noise Subspace Estimation with Full Rank Update for Blind CSI Estimator in OFDM Systems

Saravanan Subramanian, Govind R. Kadambi

Faculty of Engineering and Technology
Ramaiah University of Applied Sciences
Bangalore, India

*Abstract*—**This paper presents a modified Gradient-based method to directly compute the noise subspace iteratively from the received Orthogonal Frequency Division Multiplexing (OFDM) symbols to estimate Channel State Information (CSI). By invoking the matrix inversion lemma which is extensively used in Recursive Least Square (RLS) algorithms, the proposed computationally efficient method enables direct computation of noise subspace using the inverse of the autocorrelation matrix of the received OFDM symbols. In the case of a vector input, the modified Gradient algorithm uses rank one update to calculate noise subspace recursively. For an input in the matrix form, the modified Gradient algorithm uses a full rank update. The validity, efficacy, and accuracy of the proposed modified Gradient algorithm have been substantiated through a relative comparison of the results with the conventional Singular Value Decomposition (SVD) algorithm, which is in wide use in the estimation of the subspaces. The simulation results obtained through the modified Gradient algorithm show a satisfactory correlation with the results of SVD, even though the computational complexity involved in modified Gradient is relatively less. Apart from the results encompassing various power levels of the multipath channel, this paper also discusses the adaptive tracking of CSI and presents a comparative study.**

## I. INTRODUCTION

Radio systems based on Orthogonal Frequency Division Multiplexing (OFDM) are increasingly being adopted by many wireless communication standards [1]. With the ability of OFDM systems to effectively handle impairments of wireless channels, communication engineers and system designers can use standards for broadband digital data communication standards such as IEEE 802.11 [a, b, j, n], IEEE 802.15.3a, etc. OFDM is adopted as the waveform in IEEE 802.16 [d, e], IEEE 802.120, digital video broadcasting, digital audio broadcasting and cellular [3G, 4G]. Additionally, in high-speed wireless data communication using OFDM waveforms, the effects of multipath and the delayed spread of channels have a significant impact on data throughput. Figure 1 describes a typical OFDM transmitter and Receiver operating in a multipath wireless channel. For efficient operation and

throughput of the OFDM system, it is important to estimate the multipath wireless channel (Channel State Information) at the receiver end.

In summary, accurate estimation of Carrier Frequency Offset (CFO) and CSI is essential for ensuring the satisfactory performance of the OFDM system. The attainment of time synchronization between OFDM symbols is assumed to be present. The emphasis of this paper is on CSI which deals with the estimation of the multipath wireless channel. Instead of conventional SVD, this paper presents a computationally efficient modified gradient algorithm to estimate the noise subspace directly (Instead of signal subspace first and then through it, the noise subspace). The noise subspace is then utilized for the estimation of CSI.

This paper is structured as follows. Section II presents the review of CSI estimation techniques. Section III presents the OFDM system model. Section IV deals with the second-order statistics and the blind CSI estimation process of the subspace. Section V discusses the proposed modified Gradient based noise subspace. Section VI presents the formulation for the estimation of CSI using the proposed modified gradient algorithm. Section VII analyses the performance of modified Gradient based CSI estimator, to substantiate its efficacy and ability in improving the estimation accuracy of CSI. Section VIII presents the conclusions of the paper.

## II. RELATED WORK

This section presents a comprehensive review of research studies pertaining to OFDM in general and estimation of CSI in particular.

The authors in [2] propose an Integrated OFDM (I-OFDM) system to meet the BER performance of Enhanced Long-Term Assessment (LTE-A). For the pilot-aided CSI estimation

technique, pilot arrangement of comb type as well as convolution (Channel) encoder with best-known bounds of Coding Bounds are used. "Maximum A Posteriori (MAP)" decoder for the convolution encoder is at the receiver. The evaluation of BER performance was through convolution codes of Recursive systematic and non-systematic nature. The proposed I-OFDM showed significant improvement in the system performance combining traditional IM and multiple-mode IM in [3]. To achieve the varied diversity order and spectral efficiency required next-generation wireless communication networks, CIM techniques (subcarrier-wise and subblock-wise) are presented.

To achieve higher data bandwidth in such systems, it is of greater importance to estimate the CSI, the transfer function of the wireless channel. Author in [4] addresses the clustering strategy for heterogeneous wireless sensor networks. The clustered heads are chosen based on the CSI, the nodes' residual energy, and the network's average energy. Author proposes periodic transmission of a data packet containing the information about the energy dissipation of the wireless sensor nodes using Bluetooth low energy, ZigBee, and ANT protocols for the appropriate choice for the protocol selection.

The authors in [5] propose the OFDM/OFDMA system's improved performance by introducing closed-loop rotate modulation schemes involving BPSK, QPSK, and QAM. The method utilizes the feedback of the complex-valued CSI. The rotate modulation serves the role of channel equalizer and does not need the guard interval insertion. With BPSK and QPSK, the proposed method does not degrade BER performance with feedback delay. However, with QAM, the feedback delay degrades BER performance.

The authors of [6] discuss the potential demands and challenges of the emerging 6G wireless communication network. The authors address system capacity requirements, data rate, latency, enhanced security, and the improved quality of service of 6G relative to 5G. The paper also dwells on the potential applications of mm-wave, terahertz communications, and massive MIMO systems in 6G.

This paper [7] addresses the issue of Pilot contamination in a massive MIMO system. The authors proposed a scheme for reducing pilot contamination by combining time-shifting protocol, the directional pilot scheme, and a greedy algorithm-based pilot allocation scheme for channel estimation. The simulation results show the significantly enhanced performance of a massive MIMO system with the proposed combinatorial scheme compared to the individual constituents of the combination.

The receiver improves the overall bandwidth efficiency of the system by detecting CSI accurately and efficiently. CSI acquisition is generally performed using pilot or non-pilot techniques. To estimate CSI, pilot-based techniques typically use significant bandwidth to train the channel estimator at the receiver and send the training sequence. Paper [7] addresses the issue of pilot contamination in large-scale MIMO systems. The authors proposed a scheme to reduce pilot contamination by combining a time-shift protocol, a directional pilot scheme, and a pilot allocation scheme based on a greedy channel estimation algorithm. The simulation results show that the performance of

large MIMO systems using the proposed combination scheme has improved significantly.

For non-pilot assisted methods, CSI estimation requires statistical information about the data received. In addition, non-pilot assistive techniques (often referred to as blind techniques) are more bandwidth efficient because they do not require a unique training sequence.

The authors in [8,9] proposed pilot aided technique for channel estimation. The authors investigated the performance of block type and comb type pilot insertion technique in estimation of the channel. Comb time pilot insertion scheme is found to be more appropriate to track time varying channel. The technique involves the pilot insertion on the estimation. The frequency domain interpolations are carried in case of the block type pilot insertions and time domain interpolation is carried in case of the comb type pilot insertions.

In [10], the authors presented the pilot aided technique for channel estimation in OFDM. The performance of two pilot based estimators performance is evaluated at different SNRs. Bayesian based Minimum Mean Square Estimator (MMSE) performs better at low SNR when compared to the Maximum Likelihood (ML) estimator. Both MMS and Bayesian estimators require a prior information about the channel statistics. The estimator requires more number of pilot tones as compared to the Channel Impulse Response (CIR) length.

Linear Redundancy Precoding (LRP) uses either cyclic prefixes (CPs) or zero pads (ZPs) in OFDM systems [11, 12]. LRP is one of the categories of blind techniques for estimating the CSI of OFDM systems. The estimation accuracy of the LRP technique depends on the CP / ZP length of the OFDM symbol. The second category of blinding techniques relies on the subspace of the secondary statistics of the received sample to estimate the CSI of the OFDM system. The performance of the subspace-based method depends heavily on the accuracy in estimating the autocorrelation matrix of the received sample. This paper focuses on a subspace-based approach with improved stability in CSI numerical estimation and improved channel bandwidth efficiency.

In [12] and [13], the underlying method for estimating CSI is based on the singular vector of the covariance matrix. CSI estimation requires a noise subspace of the autocorrelation matrix. Computing the required noise subspace with traditional algorithms such as SVD requires extensive computation. A zero padded OFDM system is explored in [14] for CSI estimation based on subspace.

Numerical methods for calculating noise subspaces are not as common as signal subspace estimators. In addition, most algorithms for estimation [15] that combine signal and noise subspaces are available with high complexity. The estimation algorithm exists exclusively for the signal subspace, but there seems to be no algorithm dedicated to the noise subspace.

This paper presents a Gradient [16] based method for iteratively calculating noise subspaces from received OFDM symbols. The method proposed in this paper directly calculates the noise subspace required to estimate the CSI. In the proposed method, the calculation of the noise subspace requires the inverse of the autocorrelation matrix of the

received OFDM symbols. In addition, this paper employs the matrix inversion lemma, which is very commonly used in recursive least squares algorithms (RLS) [17], to overcome the high computational cost of direct inversion of autocorrelation matrices.

Also, the noise subspace of the autocorrelation matrix is just the signal subspace of the inverse autocorrelation and is calculated using the numerically stable Gradient algorithm. In this paper, the modified Gradient refers to fitting the inverse matrix to compute the inverse of the autocorrelation matrix and using the numerically stable Gradient algorithm to estimate the noise subspace. This paper also shows two schemes of modified gradient based on whether the underlying input to the modified Gradient algorithm is a vector or a matrix. For vector inputs, the modified Gradient recursively calculates the noise subspace using rank one updates. On the other hand, modified Gradient algorithm recursively computes the noise subspace using a full-rank update if the input is in the form of a matrix. Without loss of generality, this paper assumes channel matrix to be a full-rank Hankel matrix.

The emphasis of this paper is on CSI which deals with estimation of multipath wireless channel. Instead of conventional direct SVD, this paper presents a computationally efficient modified gradient algorithm to estimate the noise subspace directly. The noise subspace is then utilized for the estimation of CSI. The application of the new algorithm has been substantiated in the estimation of CFO using MUSIC algorithm [18], which also requires the noise subspace. This paper extends the utility of the modified gradient algorithm for the estimation of CSI. It is envisaged that the modified gradient algorithm proposed by the authors [18] is new way of estimating CFO and CSI, since modified Gradient algorithm is computationally efficient compared to the conventional direct SVD[19].

### III. OFDM System Model

In this section, the basic OFDM symbol is formed by N carriers. The basic OFDM symbol is followed by L zeros. Where $L \geq L_H$ (length of channel impulse response). In this document, the zero-pad OFDM system eliminates ISI. Equation (1) represents the nth received OFDM symbol $Y_n$ after full time synchronization.

$$Y_n = HF^H x_n + w_n \tag{1}$$

$Y_n$ is $n^{th}$ Received OFDM symbol with L zero padding of size (N+L) x 1

$H$ is channel convolution matrix of size N+L x N.

$F^H$ is the orthonormal IIFT matrix.

$x_n$ is $n^{th}$ i.i.d unit norm data vector of size N x 1.

$w_n$ is i.i.d additive white Gaussian noise of variance $\sigma^2$.

$$H = \begin{bmatrix} h(0) & 0 & \cdots & 0 \\ \vdots & h(0) & \ddots & \vdots \\ h(L_H) & \vdots & \ddots & 0 \\ 0 & h(L_H) & \ddots & h(0) \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & h(L_H) \end{bmatrix}$$

H is a full-rank non-negative Toeplitz channel convolution matrix. The element of matrix H is the normalized channel impulse response of length $L_H$. The channel is assumed to be time-invariant and frequency-selective over the symbol period. To overcome the effects of ISI, the length of the selected ZP will be $L \geq L_H$. The CSI estimate assumes carrier frequency offset (CFO) cancellation introduced by the Doppler or local oscillator of the received OFDM symbol $Y_n$.

### IV. Blind CSI Estimation

The blind CSI estimation algorithm in this document uses the noise subspace calculated from the quadratic statistics of the received OFDM symbols [14]. The quadratic statistics (autocorrelation) of the received OFDM symbols contain only the information about the transmitted OFDM symbols and the convoluted channels. However, due to the orthonormal nature of the inverse Fast Fourier Transform (IFFT) and the nature of the independent identical distribution and unit norm of the transmitted data $X_n$, the autocorrelation matrix can be used to estimate the CSI [14].

$$R_n = E\{Y_n Y_n^H\} \tag{2}$$

$$R_n = HH^H + \sigma_{noise}^2 I_{N+L} \tag{3}$$

Where $R_n$ is the autocorrelation matrix and E is the expected value operator. The matrix $HH^H$ is the Hermitian positive semi-finite matrix, $I_{N+L}$ is the identity matrix, and $\sigma^2_{noise}$ is the noise power of the channel. The size of the resulting autocorrelation matrix $R_n$ is N+L x N+L. The identity matrix can diagonalize the resulting $R_n$ by applying the spectral theorem. SVD is used to diagonalize $R_n$.

$$R_n = U \sum V^H \tag{4}$$

$$U = [U_{signal} U_{nosie}] \tag{5}$$

$$V^H = [U_{signal} U_{noise}]^H \tag{6}$$

$$\sum = \begin{bmatrix} \Delta + \sigma_{noise}^2 I_N & 0 \\ 0 & \sigma_{nosie}^2 I_L \end{bmatrix} \tag{7}$$

The orthonormal matrices U and $V^H$ contain subspace components of signal and noise subspaces. $U_{signal}$ corresponds to the signal subspace of dimension N+L x N of the autocorrelation matrix $R_n$, and $U_{noise}$ corresponds to the noise subspace of dimension N+L x L. $\Delta$ is a diagonal matrix with diagonal elements representing the signal power of each N-subcarrier. Equation (1) shows that the received OFDM symbol $Y_n$ is basically in the signal space across the channel convolution matrix H. A linear combination of the channel convolution matrix H multiplied by $F^H x_n$ yields the received OFDM symbol $Y_n$. The channel convolution matrix H is a Toeplitz matrix of size N+L x N, so there are N non-identical columns and the rank is N. This indicates that the rank of the

main subspace (signal subspace) of this matrix H is N, and the rank of that subspace (noise subspace) is L.

$$U_{noise}^H \times U_{siganl} = 0 \tag{8}$$

Equation (8) states that the U$_{signal}$ and U$_{noise}$ are orthogonal subspaces. Each vector in the noise space is orthogonal to the entire signal space U$_{signal}$. Similarly, each vector in the signal space is orthogonal to the total noise space U$_{noise}$. This special property is used to estimate the channel impulse response h$_n$. Since the columns of the channel convolution matrix H span the entire signal space, the received OFDM symbol Y$_n$ is also in the signal space across H . Therefore, this space is also orthogonal to any vector in the noise space Unoise calculated from the SVD on the autocorrelation matrix R$_n$.

$$U_{noise}^H \times H = 0 \tag{9}$$

$$u^H = [u_1 \quad u_2 \quad \cdot \quad \cdot \quad u_{N+L}] \tag{10}$$

$$u^H \times H = 0 \tag{11}$$

if u$^H$ in Equation (10) is a vector of length N+L in the noise subspace, it is also an orthogonal complement of the channel convolution matrix H by equation (11). From Equation (11) to Equation (12) rewritten by the Toeplitz structure of the channel convolution matrix H. Where V is a Henkel matrix of size L+1 x N formed using the elements of u, which is the noise vector of the noise subspace U$_{noise}$. The cost function for estimating CSI includes the complex conjugate of equation (12).

$$h^H \times V = 0 \tag{12}$$

$$(h^H \times V) \times (h^H \times V)^H \tag{13}$$

$$h^H V V^H h = 0 \tag{14}$$

By using all the noise vectors in the noise subspace U$_{noise}$, Equation (14) is rewritten as the cost function of Equation (16) to estimate the CSI.

$$W = \sum_{i=0}^{L} V_i V_i^H \tag{15}$$

$$h^H W h = 0 \tag{16}$$

V$_i$ is a Hankel matrix formed from the individual noise vector elements of the noise subspace U$_{noise}$. Equation (16) means that the vector h, which is a small singular vector of W, can minimize the cost function. This small normalized singular vector is an estimate of CSI with phase ambiguity. Each complex element, when scaled, is a small singular vector that is also the solution to the cost function defined in Equation (16).

V$_i$ is the Henkel matrix formed by using the elements of the individual noise vectors of the noise subspace U$_{noise}$. Equation (16) implies that the vector h, a minor singular vector of W, can minimize the cost function. This minor singular vector normalized is the estimate of CSI with a phase ambiguity. Any complex element, when scaled, a minor singular vector, is also a solution to the cost function defined by Equation (16). This phase ambiguity is attributed to the above.

Considering the process of CSI estimation from the reception of OFDM symbol Y$_n$ to the solution of equation (16), the calculation of equations (4) and (16) uses a computationally intensive algorithm (SVD) in two steps. Analysis of the steps involved in the CSI estimation shows that noise space is more important in the CSI estimation. In fact, of the results of Equations (4) and (16), the noise vector from each calculation is used in the subsequent process of the CSI estimation method. However, the computational cost of the $O((N+L)^3)$ SVD method makes this estimation method a non-viable option for real-time implementations. In the next section, this paper proposes a new algorithm for efficiently estimating the noise vectors in Equation (4) (using rank-one updates) and equation (16) (using full-rank updates). The proposed algorithm has computational advantages over existing algorithms such as SVD.

## V. MODIFIED GRADIENT ALGORITHM

Let x(t) be a column vector in complex vector space $C^n$ observed at instant t. In time domain spectral analysis, it is a vector of n consecutive samples of summation of r non coherent complex sinusoids corrupted by additive complex Gaussian noise n(t) with variance $\sigma^2$.

$$x(t) = \sum_{k=1}^{r} s_k \, a(w_k) + n(t) \tag{17}$$

$$x(t) = As(t) + n(t) \tag{18}$$

Where $A = [a(w_1) \, a(w_2) \dots a(w_r)]$ is the deterministic matrix of size n x r. $a(w_p) = [1 \, e^{jw_p} \, e^{j2w_p} \, \dots \, e^{j(n-1)w_p}]^T$ is the frequency vector and $S(t) = [s_1 \, s_2 \dots s_r]$ is the random source vector. The correlation matrix $R$ is formed from the snapshot vector x(t).

$$R = E[x(t) \, x^H(t)] = AC_s A^H + I\sigma^2 \tag{19}$$

Where $C_s = E[S(t)S^H(t)]$, I denotes the identity matrix and E stands for expectation. Taking Eigen decomposition of Equation (5).

$$R = U\Sigma U^H \tag{20}$$

$$U = [U_s U_n] \tag{21}$$

$U_s$ contains the signal space vectors and $U_n$ has the noise space vector. The first r vectors in U (Equation (21)) form the signal subspace vector alias column subspace vectors. The remaining (n-r) vectors form the noise subspace vectors alias left Null subspace vector. Similarly, $\sum$ (Equation (20)) is the diagonal matrix containing the Eigen values corresponding to the signal and noise subspace respectively. It is important to note that both the matrices A and $U_s$ span the same column space alias the signal subspace. The $U_s$ signal subspace vectors and $U_n$ noise subspace vectors are orthogonal and they complement each other. The above-mentioned properties are exploited in high resolution spectral estimation technique using MUSIC [20] and ESPIRIT algorithms [21].

It is clear that the matrices A and $U_s$ span the same column space alias the signal subspace. This enables to build a cost function to estimate the signal subspace. Let y(t) be a vector in the column space of the $U_s{}^H$ . Then,

$$y(t) = U_s{}^H x(t) \tag{22}$$

$$x(t) = U_s \, y(t) \tag{23}$$

$$x(t) = U_s U_s^H x(t) \qquad (24)$$

Superscript H denotes the Hermitian transpose. For convenience $U_s$ and $U_s^H$ are rewritten as $W$ and $W^H$ respectively. The scalar cost function can be arrived as

$$J(W) = E\|x(t) - WW^H x(t)\|^2 \qquad (25)$$

$J(W)$ has global minimum only at when the columns of W span the signal space of A.

Global minimum of Equation (25) can be found recursively using the Gradient Descent method [16]. As a first step, the gradient of the unconstrained cost function with respect to W is derived.

$$\nabla J = [-2R + RWW^H + WW^H R]W \qquad (26)$$

The update on the subspace can be written as

$$W(t) = W(t-1) + [2R(t) - R(t)W(t-1)W^H(t-1) - W(t-1)W^H(t-1)R(t)]W(t-1) \qquad (27)$$

The above Equation (27) converges to the signal subspace of the correlation matrix $R(t)$. This implies that the conventional Gradient algorithm facilitates the computation of signal subspace only. One has to compute the noise subspace after computing the signal subspace. The proposed modified Gradient algorithm is aimed for the direct computation of noise subspace instead of first computing the signal subspace and then computing the noise subspace from the knowledge of auto correlation matrix. To obtain the noise subspace, R(t) in Equation (27) is to be replaced with $R_{inv}(t)$, where $R_{inv}(t)$ is the inverse of correlation matrix $R(t)$. With this modification, Equation (27) can be rewritten as shown in Equation (28).

$$W(t) = W(t-1) + [2R_{inv}(t) - R_{inv}(t)W(t-1)W^H(t-1) - W(t-1)W^H(t-1)R_{inv}(t)]W(t-1) \qquad (28)$$

Equation (28) is the modified Gradient Method for the noise subspace estimation. The computational complexity of Equation (28) is comparatively less when compared to the batch based SVD or EVD techniques [19] which is of the order of $O(n^3)$ operations.

## VI. MODIFIED GRADIENT IN CSI ESTIMATION

This section presents a unique method for calculating the noise vector of $R_n$, the autocorrelation matrix by altering the current Gradient method [16]. The Gradient-based subspace estimation method is a member of the iterative power-based subspace estimation algorithm class. These categories of algorithms estimate and track signal vectors more effectively than the noise vector of the subject matrix. In addition, the iterative power-based approach predicts the greatest vector in the signal space. Typically, signal subspace vectors are computed prior to noise subspace estimation. The noise subspace created by inverting $R_n$, the autocorrelation matrix eliminates the need to compute the noise subspace following the signal subspace. Taking into account the inversion of the subjected $R_n$ matrix, the same power-based technique will be more effective at directly estimating and tracking the noise space vector or minor vectors.

The inverse of the autocorrelation matrix $R_n$ is calculated in the proposed modified Gradient, $X_n$, by utilizing the underlying received OFDM symbol $Y_n$. This is carried out in a recursive fashion. The classic matrix inversion lemma is used in the recursive least square estimation techniques, and it is utilized by the modified Gradient. The underlying matrix that will be employed in tracking the noise vectors in Equations (4) and (16) of interest for estimating the CSI will be the inverted version of $X_n$, which will have a dimension of N+L x N+L. During the process of estimating the CSI, this modified Gradient method will be used to calculate and keep track of the noise vectors. In terms of the amount of computing power required, a technique of this iterative nature is quite effective. The comparative performance of blind CSI estimation using the proposed modified Gradient algorithm and SVD based approach will be described later in section VI with a random complex channel. The focus of this section is on the performance of blind CSI estimation using modified Gradient method.

This paper describes the procedure for computing the noise subspace vectors specified in Equation (4) and (16) using the modified Gradient approach. A pseudocode for the CSI estimation is also presented. Estimation of CSI begins with the OFDM signals that were successfully received. $X_n$ denotes the $n^{th}$ estimate of the inverse of the autocorrelation matrix, $R_n$.

A brief explanation of pseudo-code is presented here in order to estimate the noise subspace vectors making use of modified Gradient, with rank one update being performed by the underlying OFDM signal $Y_n$. As shown in the Equation (31), the rank-one update of the inverse autocorrelation matrix $X_n$ is computed using $Y_n$, the received OFDM signal.

Initialize

$$V_{nosie}(0) = [I]_{N+L \ X \ L}$$

$$X(0) = [I]_{N+L \ X \ N+L}$$

Where N is the number of carriers and L is the zero-padding length. $V_{nosie}(0)$ is the initial noise subspace matrix of $X_n^H$, and X(0) is the initial inverse of $R_n$.

For n = 1,2,3... ,

$$KalGain \ A(n) = X(n-1)Y(n) \qquad (29)$$

$$Gamma \ A(n) = \frac{1-\lambda}{\lambda + (1-\lambda)Y^H(n)KalGainA(n)} \qquad (30)$$

$$X(n) = \frac{1}{\lambda}(X(n-1) - GammaA(n)KalGainA(n)KalGainA^H(n)) \qquad (31)$$

$$V_{nosie}(n) = V_{nosie}(n-1) + [2X(n) - X(n)V_{nosie}(n-1)V_{nosie}^H(n-1) - V_{nosie}(n-1)V_{nosie}^H(n-1)X(n)]V_{nosie}(n-1) \qquad (32)$$

End

$\lambda$ is the forgetting factor between 0 and 1.

$V_{nosie}$, which has the noise vectors corresponding to the noise subspace vector of Equation (10). The $L_{noise}$ vectors

from $V_{nosie}$ construct the Henkel matrix V needed to compute W, as shown in Equation (15). The smallest singular vector of W is obtained using the procedure listed below.

A summary of pseudo code for estimating the noise vectors using the modified Gradient method is presented with full-rank updating of W, which is computed from the $V_{nosie}$ as described in the Equation (15).

Initialize

$$Q(0) = \begin{bmatrix} I \\ 0 \end{bmatrix}_{N+L \, X \, L}$$

$$W_{inv}(0) = [I]_{LXL}$$

*for n* = 1,2,3…

$$KalGainB(n) = W_{inv}(n-1)W(n) \qquad (33)$$

$$GammaB(n) = \frac{1-\lambda}{\lambda+(1-\lambda)\det(W^H(n)KalGainB(n))} \qquad (34)$$

$$W_{inv}(n) =$$

$$\frac{1}{\lambda}(W_{inv}(n-1) - GammaB(n)KalGainB(n)KalGainB^H(n)) \qquad (35)$$

$$Q(n) = Q(n-1) + [2W_{inv}(n) - W_{inv}(n)Q(n-1)Q^H(n-1) - Q(n-1)Q^H(n-1)W_{inv}(n)]Q(n-1) \qquad (36)$$

End

Q in Equation (36) contains noise subspace vectors of $W_{inv}$ of Equation (35). The first singular vector is the estimate of the channel's impulse response. The impulse response estimate is normalized to get the estimate of CSI. The estimated normalized impulse response will have a phase ambiguity and is resolved with the help of a single pilot carrier.

The Gradient class of subspace estimation algorithms typically exhibit a complexity of $O((N+L)L)$ with the additional complexity of $O((N+L)^2)$ for inversion of matrix using matrix inversion lemma of Equation (31). In general, computational complexity in the estimation of noise spaces through the proposed modified Gradient scheme is $O((N+L)^2+(N+L)L))$, instead of $O((N+L)^3)$ operations of the conventional SVD based methods. This in turn implies a reduction in computational complexity of modified Gradient method. Table I presents the comparison of computational complexity between the direct SVD and modified Gradient algorithms in computing the noise subspace with rank one update. As shown in Table I, the computational complexity of modified Gradient is comparatively less than the direct SVD based algorithms for various values of N and L.

TABLE I. COMPARISON OF COMPUTATIONAL COMPLEXITY OF DIRECT SVD AND MODIFIED GRADIENT IN ESTIMATION NOISE SUBSPACE WITH RANK ONE UPDATE

| SI. No | N | L | SVD | Modified Gradient |
|---|---|---|---|---|
| 1 | 128 | 8 | $O(136^3)$ | $O(26.955^3)$ |
| 2 | 256 | 16 | $O(272^3)$ | $O(42.788^3)$ |
| 3 | 512 | 32 | $O(544^3)$ | $O(67.921^3)$ |

## VII. PERFORMANCE ANALYSIS

This section presents the results of the simulation to establish the ability modified Gradient based CSI estimation algorithm using the directly computed noise subspace. The simulation model assumes the reception of the OFDM symbol with 128 carriers and zero-padded to the extent of $1/4^{th}$ of the OFDM symbol. Out of 128 carriers, one carrier is a reference carrier to resolve the issue of phase ambiguity. The simulation of the Rayleigh channel model mimicking the outdoor channel is through 16 tap FIR filter. The subcarriers of the OFDM use the modulation scheme of the QPSK constellation. The simulation is with 1500 OFDM symbols. The changes in the Rayleigh channel model are induced to occur at the time instances of $500^{th}$ and $1000^{th}$ OFDM symbols. The Channel Impulse Response, which is nothing but CSI, is estimated and is tracked using a subspace-based technique at various power levels. The estimate of CSI is compared with a response of modelled ideal Rayleigh channel. Direct SVD and proposed modified Gradient techniques are adopted to estimate the noise subspace. Noise subspace, in turn, is used to estimate the CSI. Fig. 2 to Fig. 4 present the comparative performance and analysis of CSI estimates obtained through modified Gradient, Direct SVD, and the ideal channel response.

Fig. 2 to Fig. 4 illustrate the comparative estimation performance of the modified Gradient and direct SVD-based noise subspace estimators in the estimation of CSI of the OFDM system. In the simulation studies presented in this paper, 400 OFDM symbols are utilized to reconstruct the autocorrelation matrix which is required for noise subspace estimation. The results of Fig. 2 correspond to the power level (SNR) of the wireless channel at 10 dB. The ideal Rayleigh channel shown in Fig. 2, is the reference for comparison and has been modeled through 16 tap FIR filter. Fig. 2 depicts the estimation of the Rayleigh channel state (at SNR of 10 dB) at the $400^{th}$ OFDM symbol. While Fig. 2(a) depicts the amplitude response of the CSI estimation, the corresponding phase response is shown in Fig. 2(b). There is an excellent agreement between the results obtained through the modified Gradient and direct SVD-based blind CSI estimators. The results of Fig. 2(b) reveal a fixed offset between the results of modified Gradient and Direct SVD relative to the ideal Rayleigh channel. The referred fixed offset in the phase of estimated CSI is attributed to the phase ambiguity (which is already explained while discussing Equation (16)). This phase ambiguity is resolved or negated using a single reference subcarrier.

Similarly, Fig. 3(a) and Fig. 3(b) depict the amplitude and the phase of the CSI estimation (SNR of 20 dB) at the $400^{th}$ OFDM symbol. At increased power level of the channel (SNR), the correlation between the CSI estimation by the blind CSI estimators and the ideal channel improves.

The analogous results at SNR of 30 dB are shown in Figures 4a and 4b. The results on amplitude response of CSI estimation shown in Figure 4a show perfect agreement among the blind CSI estimators and ideal channel. It is pertinent to note that modified Gradient requires relatively lesser computational effort compared to direct SVD.

Fig. 5 depicts the channel tracking performance of the proposed modified Gradient algorithm with direct SVD at SNR

of 10 dB. It also illustrates the Relative Error Norm performance of the proposed modified Gradient and direct SVD-based blind CSI estimators. Whenever there is a change in the state of the Rayleigh channel, the blind CSI estimator takes around 100 OFDM symbols for attaining the steady state. Post 100 symbols, the Relative Error Norm falls to around -6 dB at 1000th and 1500th OFDM symbols.

Fig. 2. (a) Amplitude Response: CSI Estimation for Rayleigh Channel at 400th OFDM Symbol (SNR of 10 dB), (b) Phase Response: CSI Estimation for Rayleigh Channel at 400th OFDM Symbol (SNR of 10 dB).

Fig. 3. (a) Amplitude Response: CSI Estimation for Rayleigh Channel at 400th OFDM Symbol (SNR of 20 dB), (b) Phase Response: CSI Estimation for Rayleigh Channel at 400th OFDM Symbol (SNR of 20 dB)

Fig. 4. (a) Amplitude Response: CSI Estimation for Rayleigh Channel at 400th OFDM Symbol (SNR of 30 dB), (b) Phase Response: CSI Estimation for Rayleigh Channel at 400th OFDM Symbol (SNR of 30 dB)

Fig. 5. CSI Tracking of Rayleigh Channel at SNR of 10 dB.

Similarly at the higher SNR value of 20 dB (Fig. 6), the Relative Error Norm shows decreasing trend (as low as -16 dB).

Fig. 6. CSI Tracking of Rayleigh Channel at SNR of 20 dB.

The results of Fig. 7 reveal that for a channel power level (SNR of 30 dB), the Relative Error Norm is as low as -22 dB. As the power level increases, the difference in the Relative Error Norm continuously decreases leading to very good agreement between the results of direct SVD and the modified Gradient method. This substantiates the ability of modified Gradient algorithms to accurately estimate the CSI of the wireless multipath channel at a lower computational cost.

Fig. 8 presents the comparison of the Mean Square Estimate (MSE) of CSI estimation performed through Modified Gradient algorithm and with that of Cramer Rao Lower Bound (CRLB). The subspace-based techniques which are blind in nature are formulated to perform the estimation of CSI without the knowledge of complete information. The proposed modified Gradient algorithm compares favorably with CRLB at high SNR. At SNR of about 15 dB and above, the modified Gradient algorithm requires about 2 to 3 dB additional power gain to attain the limits of CRLB. Indeed, it is

exhibiting a good performance in spite of complete blind operation.

Fig. 7. CSI Tracking of Rayleigh Channel at SNR of 30 dB.

Figure 8: CRLB Comparison.

## VIII. CONCLUSION

This paper presents a modified Gradient based method to directly compute the noise subspace iteratively from the received OFDM symbols to estimate CSI. The proposed method enables direct computation of noise subspace using the inverse of the autocorrelation matrix of the received OFDM symbols. This paper adopts a matrix inversion lemma to overcome the heavy computational efforts in the direct inversion of an autocorrelation matrix. This paper also introduced two schemes of modified Gradient based on whether the underlying input to the algorithm is a vector or matrix. In the case of a vector input, the modified Gradient algorithm uses rank one update to calculate noise subspace recursively. For the matrix input, modified Gradient algorithm uses full rank update. The validity, efficacy and the accuracy of the proposed modified Gradient algorithm have been substantiated through a relative comparison of the results with the conventional SVD algorithm, which is in wide use in

estimation of the subspaces. The results of performance analysis obtained through modified Gradient algorithm show satisfactory correlation with the results of SVD, even though the computational complexity involved in modified Gradient method is relatively less. This enables to adopt the noise subspace-based CSI estimation in realistic scenario of OFDM system. The reduced computation complexity in the estimation of the noise subspace estimation by the proposed modified Gradient can be of potential utility for the use of a subspace-based technique in the estimation of CSI for coherent demodulation in OFDM systems. Through simulation studies, this paper also has illustrated the ability of the blind CSI estimator in tracking the changes in the wireless channel state at various time instants.

The focus of this paper is on CSI estimation assuming the presence of perfect carrier frequency synchronization. However, the joint CSI and CFO estimation without the assumption of perfect carrier frequency synchronization will be of practical relevance from the performance perspective of the OFDM system. The joint CFO-CSI estimators based on the noise subspace technique is a topic of research interest of the authors.

# COVID-19: Challenges and Opportunities in the Online University Education

Irena Valova, Tsvetelina Mladenova

Department of Computer Systems and Technologies
University of Ruse, Ruse, 7017
Bulgaria

*Abstract*—**The COVID-19 pandemic had a very severe impact on the education both in schools and in universities. In the span of several weeks, educators around the world had to transform completely the teaching method and students had to adapt to the new form of learning. The following article reviews the opinions of university students based on three different studies – one before the pandemic and the distance learning, one in the middle of it and one in the end of the distance learning. The goal is to see how students' thinking and perceptions of online learning has changed over the last three years as a result of different conditions.**

*Keywords—e-Learning; online learning; students' attitude to e-learning; pandemic outbreak; COVID-19*

## I. INTRODUCTION

Undoubtedly, in the last two years, the COVID-19 pandemic has been decisive in the lives of people around the world and has greatly changed their habits and daily lives. The education sector is one of the key sectors that have borne much of the burden of this pandemic. Hospitals, doctors and medical staff were invariably under the greatest strain, as they met directly with the illness. In addition, the COVID-19 pandemic had a very severe impact on education. The Government closed schools and universities to prevent the spread of the infection. This closure was not expected by anyone and was unprecedented, so both students and teachers were not at all prepared for it. Within two weeks, the teaching had to be transferred entirely to the electronic environment, online. These conditions forced the teachers to prepare their lectures and teaching materials in a completely new way. Students should look at e-learning not as a supplement to the standard learning, but as the main and only way. Since this has never happened to neither lecturers, nor students before - both sides faced many challenges and overcame many problems together.

## II. STATE AND RELEVANCE OF THE PROBLEM

Before the spring of 2020, e-learning was seen as an object of research and an opportunity to complement standard education in schools and universities, but since that spring online learning was introduced as a means of ensuring continuing education. The pros and cons of online learning and the comparison of the results of standard and online learning or standard and blended learning [3, 4, 5] are mainly examined before the pandemic, while online learning is the only option after the pandemic and research is addressed mainly to its refinement or improvement [6, 7, 8]. Online learning is a convenient form of distance learning that has developed since

2000. Initially, to provide access to teaching materials and training for students who are far from the place of the school or university, for those who are professionally engaged and cannot afford to attend standard university courses. This form of learning gives access to training and materials to a wide range of people, regardless of their age and previous experience or profession [1]. In addition, education is generally expensive and offering online courses at a lower cost makes them much more accessible to a wider range of learners. Anyone who has access to the Internet and an interest in a field has access to materials from top universities and can study and develop for free or at a relatively low cost [2]. Last but not least, the advantage of online courses is that they are available at a time convenient for the learner. They can watch, listen to or read them as many times as they want.

In order for online learning to be successful, the environment or the learning management system (LMS) that will be used plays a very important role. Before 2020, most of the courses were offered on popular platforms for sharing audio and video materials, the universities themselves used LMS systems [11, 12, 13] or teachers supplemented the systems and communication with students using social networks [9, 10, 13]. After the announcement of the 2020 pandemic and the transition to full online learning, it was necessary to improve and adapt LMS systems to the new conditions very quickly. It was no longer enough for students to have access to structured materials - lectures, exercises, homework, as the LMS had to allow direct communication in real time and the opportunity for direct conversations and meetings [14, 15]. An analysis of the impact of the pandemic on the development of this type of system is described in [16]. Before the pandemic, our university used LMS, which was more of a file management system (file manager) with materials for students in various disciplines in PDF or PPT formats. Therefore, the university management had to make a choice promptly and decide to introduce another system, with more opportunities and, above all, the possibility of synchronous online learning.

## III. STUDY, METHOD, PARTICIPANTS, CONDITIONS AND DURATION OF THE RESEARCH

With the help of Google Forms, we collected the opinions of the students from the department of Computer systems and technologies in the University of Ruse, Bulgaria, regarding their opinion about online learning. Three studies have been conducted - one before the pandemic [18], the second one at

the beginning of the pandemic [17] and the third one recently at the end of the distance learning. Our goal was to see how students' thinking and perceptions of online learning has changed over the last three years as a result of different conditions.

A few months before the COVID-19 pandemic, without even suspecting it, we wanted to see what the students thought about the materials provided by the lecturer. How, in what form and whether there is a need to have access to them, do they think it makes sense to combine traditional with online learning. This questionnaire was completed by 201 participants in the study. It was distributed publicly and filled not only by our current students, but also by former ones, with the idea to see different points of view.

At the beginning of the COVID-19 period (the first online semester for them), we tried to assess students' attitudes and sense of learning during the pandemic. Number of students participated were 109, average age being 22 years. For some of the participants in the survey, this was the only semester online, and for others - this is the second semester of learning and they had no real experience in normal university education.

Our latest study involved 75 students with an average age of 22, mostly men. They studied 4 semesters online, they were also online at the beginning of the current semester and have been in-person for several weeks now. Some of them have been entirely online since the beginning of their university studies and have no experience with standard academic lecturing at the university. Some of these students (about 50%) also participated in the first study.

In Bulgaria, schools were one of the first and very quick to return to normal education, starting with the youngest. Universities had the opportunity to decide what form of education to use independently and at our university we had 2 trials in 2-3 weeks for in-person lecturing and education but came back to online again. We hope that the return to the normal form of study this semester will last at least until its end, if not permanently.

After the two surveys, we wanted to see what the students thought and what their experience of those two years was after almost entirely online education.

## IV. Results Analysis

After the experience gained in online teaching, we can say that due to the compulsory online training the various IT technologies are widely used in the teaching itself, as well as that this teaching has been the engine for active development of these technologies in the last two years.

Advantages of online learning: Students have the opportunity to study and learn the material at their own pace, thus encouraging engagement, independent thinking and working on problems. There were no problems with technology and information technologies in general, because they are studying such courses, but there were those who did not have good internet connection or suitable devices, for example.

In the meantime, lecturers and students had to face some challenges:

- They had to quickly learn to use different LMS systems with the possibility of online connection in real time with the students.

- In a short time, they had to adapt their materials so that they can be used online. And all this without any special training before that.

- It is inevitably a big challenge to face the use of new technologies and various digital devices.

- Uncertainties about students' readiness for learning, social isolation and participation in online classes.

- The need to develop materials in an attractive and appropriate form.

- Developing and using training strategies tailored to the new conditions.

- The transition from face to face to online learning is related to overcoming communication barriers for both parties.

- Measures and methods for overcoming the lack of interest in both sides of the learning process.

- Ways to organize and conduct online exams and presentation of diploma projects.

At first glance, it may be considered that when teaching is in the field of computer systems and technologies, online teaching is not so complicated. There are indeed courses that may be more appropriate and productive for online rather than standard teaching, but there are many courses that are very difficult to adapt for online use - for example, those that require specific hardware, laboratory facilities or equipment.

Before COVID-19, students said that they found classes in the form of exercises and workshops the most useful for them. They are the most difficult to conduct online if they involve any specialized equipment. For courses related to programming and using a popular, unlicensed environment, conducting it online may be even more useful for the students. In these courses, they are forced to install and configure the various software environments needed to conduct practical exercises in the learning process on their own, under the supervision and assistance of the teacher remotely. Some students said that this was one of the very useful aspects of the teaching, because if they were taught in-person, most of them do not install the used environments at all and do nothing at home. 52% of the respondents said that they had installed all the software products that were necessary for their teaching and 72% performed all the tasks set by the lecturers.

During the long period of online learning, the university improved their chosen platform and the hardware resources, while the lecturers got used to it and did not have a need for the university's LMS at all. The students themselves (73.3%) think that the platform used for online learning is the main issue during teaching (Fig. 1).
Fig. 1.   What are the Main Issues during the Online Learning According to the Students.

Although 89% of students used a computer to participate in lectures and 93% to participate in exercises, there were still students using mobile phones at the end of the pandemic. This means that these students practically only attended, but did not fully participate in the classes. 40% of respondents said that they kept notes, 17.3% that they used specialized recording software (which is not regulated and allowed because teachers are not informed about it) and almost 35% did not need notes because the teachers provided the necessary materials and presentations. 52% attended all the lectures, 28% attended 75% of the lectures and unfortunately there are still students - 13.3% who attended the classes online only because the teachers said it is mandatory to attend and checked attendance. Graphic representation of the attendance of online classes for all respondents, as well as depending on the number of semesters in which they studied online, is shown in Fig. 2.

Given that the surveyed students are studying Computer Science, the use of mobile devices for classes makes virtually no sense. It is assumed that in order to actively participate in the teaching, they must use different programming environments or software products for various engineering research, which is not possible to have on their phones or tablets. Despite the presence of such students who are still using mobile devices, 52% answered that during the exercises they had software installed to perform the tasks and 72% tried to do everything assigned to them by the teacher. However, there are still those who have just joined the online classroom and did not stay in front of the device, did not listen or did not participate in the classes and 19% who have only listened and watched and done nothing. Although a small percentage, this means that about 20% of students have trained as a computer engineer for 4 semesters, but have not tried to program or solve their own tasks. They do not even participate in discussions during the classes.

Fig. 2.   Graphic Representation of the Attendance of Online Classes Depending on the Number of Semesters in which they Studied Online.

What do students think about their lecturers? Only 9.3% of students think that very few lecturers have provided materials, 40% thinks most teachers have had and have provided materials and 50.7% say that all teachers have provided their materials. The differences probably come from the different courses, as in the first 2 semesters of their education they study only basic and general courses: mathematics, physics, foreign languages, etc. which are not so suitable for providing materials and online learning. From the third semester onwards, they are taught mainly by the specialized department and the courses are more appropriate for online teaching. 56% answered that by studying online they were able to learn and understand the material better because they were provided with materials by the teacher and the teachers themselves spent more time and attention and answered additional questions and organized online consultations if necessary.

Students are almost equally divided in their assessment of workload during online learning. 53.4% of all participants think that it is not burdensome for them since 34.7% of them think that they can just start their online classroom and do other things while 18.7% definitely do not find this form of training stressful and work loading.

For the other half of the participants, this form of training was more stressful since for 33% of them it was more difficult due to the lack or limitation of social contacts with other students. For 21% the workload felt hard due to longer duration, and for 16% it was stressful because they had to work alone, while in face to face education they work in teams and they are not active during classes.

Unlike the traditional way of teaching, where students use laboratories and computer rooms with installed software environments and applications with no commitment to install and configure, online teaching requires additional commitments from the students to install and configure everything on their computers. The students themselves shared that for some of them these were the first encounters with this type of problem. Although the lecturers helped, this process was long and complicated for some students, and some did not manage to cope, mostly due to lack of interest on their part. This moment of online training was burdensome for lecturers as well, because they had to prepare a step-by-step description of the installation itself, and some of them had to find and replace their prepared materials for another environment that is free and does not require licenses. Unfortunately, we did not have opportunities for remote access to the university resources for each of the students. Despite the difficulties for both parties, this part of the learning process and the opportunity for everyone to work independently on their own computer (in traditional learning we do not provide a separate computer for each student, usually 2 students are working together on one computer) were very useful. The students were able to try to solve their tasks on their own, to share their screen with the teacher and others and to get quick and adequate answers to their questions. They saw that they could do much more on their own than they expected, and that made them more confident and more willing to work. 25.3% believe that they have learned more online than they would have learned in-person, for 54.7% this way of learning was quite acceptable given the circumstances, 9.3% cannot judge. Unfortunately,

there are those who think that they have not learned anything more and even that was a complete waste of time. For 65.3%, online learning has helped them become more confident and independent in solving various practical tasks, and 34.7% do not think that there has been an impact.

The answers to the question about the understanding of the taught material, shown in Fig. 3, are optimistic. It can be seen that for 56% of the respondents the assimilation and understanding of the material was easier, because they had materials provided by the teachers and the latter spent more time for additional explanations of the material or to discuss with students' various problems. 19% answered that they spent a lot more effort and time and thanks to this they were able to understand and learn the material. A quarter of them failed to understand and master the material taught and believe that the teachers did not devote the necessary time and effort or that the problems with LMS did not allow them to cope.

As can be seen from the graph in Fig. 4, the best part of the online teaching according to the students was that they were provided with all the materials and did not have to take notes, write or look for specific books or materials to prepare for classes or for the exam. It is impressive as well that according to 44% the good thing about online learning were the easy exams.

During the pandemic, not only teaching but also exams had to be conducted online. We had written rules of procedure for online exams, most teachers tried to adapt to the conditions and took advantage of the opportunities provided by Google to create online tests, but there were some that remained on the classic type of exams with writing on selected topics. The system used was quite limited and did not provide opportunities to conduct tests or exams online, so we had to look for other options. Students are generally satisfied with the online exams, but unfortunately admit that they have used unregulated materials to take the exam easily (have copied from their colleagues or from the Internet, used pre-prepared materials or used someone else's help, which is not allowed, according to the rules). 26.7% did not take advantage of the situation, 24% used unregulated materials for all exams, and the rest for at least one or several exams. Fig. 5 shows how many of the exams students have taken using unregulated materials, according to the number of semesters taught online (2, 3, 4 or 5).

An interesting fact is that students prefer to take exams in the form of an online test (85%). They don't like exams that involve writing on some questions and solving problems (Fig. 6).

50.7% said that during the online teaching they lacked communication with other students, 42.7% missed on the environment and conditions of study at the university, and 26.7% missed on direct communication with lecturers and professors. For communication with each other they mostly used social networks, such as Facebook - messenger and Facebook groups and Discord. It is noteworthy that information about the learning process and related messages

were received not only through their university e-mail addresses (86.7% indicated this option) but also from social networks, mainly Facebook pages (56%) and groups in various courses (82,7%).

Fig. 3. Were you Able to Understand the Material Taught Better?

Fig. 4. What was the Best thing about Online Learning?

Fig. 5. How Often and Whether Students use Unregulated materials during the Online Exams.

Fig. 6. Preferable Exam Type According to the Students' Answers.

During the first few months of the pandemic most lecturers were using Facebook groups to organize their online teaching. This method proved quite useful for communication with the students, instead of exchanging emails. One of the reasons for this is that in our university, we do not store information about which students are taking each course and no record of their university email address. Even now, when we have gone back to in-person teaching, the Facebook groups are still used to exchange information and for discussions.

Communication between the students has been a useful channel of information (75%), as well as communication with the lecturers (55%) (Fig. 7). It is worth noting that despite the online teaching, a positive tendency was that some students would take a leadership role and mediate the information between lecturers and students and aid the teaching process. These leaders, typically one or two, were responsible for collecting the materials and messages from the different courses, reminding and organizing their fellow students and quite often to motivate them to be more active in the teaching process.

During the COVID-19 pandemic, although isolated in their homes, students kept in touch with each other (Fig. 8). Messenger was cited as the most popular means of communication (96%), followed by Discord. Young people prefer online communications to telephone calls.

Fig. 7. How and from Where the Students Received Information about the Learning Process?

Fig. 8. How you Communicated with each other during Online Learning.

The number of students has significantly dropped in the last two years while the teaching has been almost entirely completed remotely. Each year there are 70-75 new students on average, while at the moment the students are: 1st year - 37, 2nd year - 36, 3rd year - 22 and 4th year - 34. The drop in students is most noticeable in third year and this is due to the fact that these students have only had 1 semester of in-person teaching, did not expect that the teaching would transform to online learning when they enrolled and after 1 semester in university they were not at all used to the different method of teaching compared to high school. They were the most affected by the sudden change in teaching. However, undeniably there has never been such a drop in student numbers within our department. Unfortunately, we are unable to speak directly to the students and we do not have clear information why they chose to drop out. It can only be speculated that these students were forced to go back to their hometowns and families due to the pandemic and were not interested in finishing their education. When asked if they would continue their education if the teaching was entirely online, 86.7% say they would definitely continue or would continue as part-time students. The responses are positive since only 8% would not want to continue their education online, but expect and would go back if the teaching was in-person (Fig. 9).

Fig. 9. Would you Continue your Education if you were Online Again?

## V. CONCLUSIONS

Despite all the negatives of social isolation due to COVID-19 measures and restrictions, there are some positive moments from online education during the last 5 semesters.

Students have become more confident and independent, they have to and manage to solve problems and tasks of the learning process, which in normal conditions in standard education do not arise before them - installing and configuring software environments and products and working independently with them.

Teachers and professors (for the most part) have prepared and provided students with much more materials and resources in the courses they teach. They also manage to spend more time consulting and discussing with students, albeit online.

Students feel much freer to ask questions and discuss learning materials. They admit that online exams are easier, they use unregulated materials and they have even started to prefer online forms of exams. They recommended in the survey that even under normal conditions, lectures and exams should be held online.

Perhaps with a more developed online LMS than the one used by our university, it would be more convenient for lecturers to give online lectures. At the moment, this is not appropriate, because you never know who is actually in class and whether the lecturer is not "teaching to themselves". In all cases, online learning is much more stressful, time consuming and difficult for lecturers (especially for those who have not had prepared materials in an appropriate form for online learning).

# Multi-modal Brain MR Image Registration using A Novel Local Binary Descriptor based on Statistical Approach

Thuvanan Borvornvitchotikarn

Center for Information Technology and Communication Services
University of Phayao, Phayao, Thailand

*Abstract*—**Medical image registration (MIR) has played an important role in medical image processing during the last decade. Its main objective is to integrate information inherent in two images, from different scanning sources, of the same object for guiding medical treatments such as diagnostic, surgery and therapy. A challenging task of MIR arises from the complex relationships of image intensities between the two images. Its performance is primarily depending on a chosen similarity measure technique. In this work, a statistical local binary descriptor (SLBD) is proposed as novel local descriptor of similarity measure, which is simple for computation and can handle Multi-modal registration more effectively. The proposed SLBD employs two statistical values, i.e., the mean and the standard deviation, of all intensities within the image patch for its computation. Finally, these experimental results have shown that SLBD outperforms other descriptors in terms of registration accuracy. In addition, SLBD has demonstrated that SLBD is robust to different modalities.**

*Keywords—Local binary descriptor; multi-modal image registration; statistical approach; medical image registration; similarity measure*

## I. INTRODUCTION

Nowadays, medical imaging techniques (MIT) have been continuously improved, and this leads to the advancement in computer-aided surgery and radiotherapy (CAS). In general, in the procedure of CAS, medical practitioners need to utilize medical images produced from different scanning protocols [1] to perform their works. The medical images from different sources can provide different kinds of information for them. For instance, an MRI image provides functional information whereas anatomical information is from an X-Ray image. Multi-modal image registration (MIR) is the process of finding an optimal amalgamation of both corresponding anatomical and/ or functional structures of the two images [2]. Therefore, MIR can help medical practitioners to perform more effective diagnosis of a disease. Basically, MIR has three main components: 1) the similarity measure used to evaluate the similarity between images that are to be registered, 2) the transformation model deforming the moving image to the fixed image, 3) the optimization method determining the optimal parameter for the transformation to achieve the best similarity [3]. Applications of MIR in medical image processing have faces more challenges due to the complex relationships of intensities between multi-modal

images. One major challenge task is how to improve the similarity measure between the two multi-modal medical images in order to achieve more accurate and efficient registration [4, 5].

In the last decade, Mutual information (MI) is an important concept relevant to several theorems of information theory and most widely studied as similarity measures. Particularly, it has been extensively and successfully used to measure the intensity relationships in image processing [6] [7]. During the last decade, many researchers have enhanced the accuracy of image registration based on MI, such as Tsallis and Renyi's entropies [8], Jensen- Renyi's entropy [9], hybrid EMPCA-Scott approach [10], and self-similarity $\alpha$-MI (SeSaMI) [11]. However, the notion of MI alone still has a well-known drawback, i.e., it ignores spatial information [12]. For medical image registration, spatial information is important because it provides the medical information. Therefore, many researchers have enhanced MI to handle spatial information, such as second-order MI (SMI) [13], Regional MI (RMI) [14], PCA Regional MI (PRMI) [15], Conditional MI (CMI) [16]. However, Heinrich et al. [17] have noticed that these approaches are still difficult to find an accurate correspondence between different modality images. Therefore, they proposed a method, called MIND, based on neighbourhood information. MIND uses the sum of squared differences (SSD) to estimate the similarity of two images. It has higher accuracy than several methods. However, MIND is highly subject to the central patch. This limitation affects the noise robustness [18]. Hence, they introduced a so-called self-similarity context (SSC) to improve the noise robustness of MIND. SSC avoids the central patch and uses pairs of patches within six-neighbourhood [18].

Local binary pattern (LBP) is one of the most effective and well-known approaches used in texture classification [19]. Trichet and Bremond [20] introduced a novel pedestrian detection technique by using a 12-valued filter representation based on LBP. It can improve filtering performance, which leads to a sharper feature. Hong et al. [21] proposed the LBP-Top for facial expression recognition to reduce the demand of loops and the computational cost. Weber Local binary pattern (WLBP) was presented by Liu et al [22]. It is a combination of Weber local descriptor and LBP and is robust to many challenges. The non-local mean local binary descriptor (NLM-LBD) was presented in [23]. By taking advantage of structural information, he NLM-LBD can improve the NLM method in

terms of both computation time and quality for real-time denoising applications. DRLBP [24] was an enhancement of LBP for rotation robustness. These approaches have high computation speeds for registration, but some structural information may be lost.

Recently, Jiang et al. [25] proposed miLBP descriptor that can improve robustness to noise, intensity and non-uniformity of medical image processing. Its performance is better than recent methods such as SeSaMI [11], CoCoMI [26], and SSC [18]. In addition, Lu et al. [27] introduced a registration technique by combining local features and geometric invariants. Shen et al. [28] enhanced MI with a hybrid optimization technique based on Powell's method and cuckoo search. Yonghong et al. [29] applied an improved particle swarm optimization (PSO) to an image registration algorithm based on MI. The value of MI of the registered image is calculated and is used in the fitness function of PSO. Bai et al. [30] presented Multi-modal CT rigid MIR with regional weighted mutual information (RWMI), which is robust to large rotation and translation. However, RWMI is sensitive to registration with very small overlap and small intensity variance. Furthermore, Borvornvitchotikarn and Kurutach [31] have improved miLBP, which combines miLBP and DRLBP. This method achieves the best results for registration with rotational transformations. The other work of authors also enhanced the miLBP, which adopts the mean and standard deviation of the image patch for adaptive threshold and uses the sorting operation for sorting the pixels within image patch. Therefore, it could provide terms of robustness in modality-independent and rotation-invariant descriptor (miRID) [32]. Yang et al. [33] have proposed MIR based on image segmentation and symmetric self-similarity. This method uses BCFCM to segment multi-modal medical images and extracts target regions in medical images.

However, due to limitations of existing approaches, the spatial information may be lost from the computation of those descriptors. Hence, the key reason for the proposed SLBD approach is that it makes the multi-modal image similarity measure remain the spatial information of the regions of interest.

The contributions of this work are summarized as follows:

- This work points out and proposes a novel approach to measure the similarity or dissimilarity between the intensities of pixels in the regions of interest on multi-modal medical images. The proposed similarity measure is suitable to handle the complexity of intensity relationships between two modalities of images more effectively. In addition, it can avoid the weakness of the traditional LBD, where image artefacts within the central patch directly affect its performance. Moreover, this method still retains the structural information potentially, which can estimate a direct patch-to-patch mapping between image multi-modality. This proposed approach will be called SLBD (for statistical local binary descriptor) and will be described in detail in Section III.

- The proposed similarity measure is a complementary method to previous LBD-based methods such as miLBP and miRID.

This paper is organized as follows. Section II presents the background. Section III describes the proposed method. The experimentations and results present in Section IV. The discussions and conclusion will be discussed in Sections V and VI, respectively.

## II. BACKGROUND CONCEPTS

### A. Image Registration

MIR is a process of transforming a moving image to optimally align with a fixed or target image. Its goal is to maximize the similarity or minimize the dissimilarity between the two registered images. To accomplish the task, MIR needs to have three main components: a similarity metric, a transformation model, and an optimization model. The similarity metric is a measure of how well the two images match. The transformation model is used to transform the moving image to match the fixed image. The optimization model is to find a variation of parameters in the transformation model to maximize the matching criteria [34]. To formally formulate the notion, registration $T'$ of a moving image $I_m$ and a fixed image $I_f$ is defined by (1),

$$T' = \arg \min_T D\left(I_f, T(I_m)\right) \tag{1}$$

where $D\left(I_f, T(I_m)\right)$ is a dissimilarity measure which determines the degree of alignment between $I_f$ and $T(I_m)$ and $T$ denotes a deformable transformation. In (1), $T'$ is to find the optimal transformation $T$ that provides the minimum value of $D$ [12].

### B. Similarity Measure based on Local Binary Pattern

The standard LBP was introduced by Ojala et al. [35]. It is a simple principle of the texture classification. For the patch size of 3 x 3, the binary result gives 8-bit integer codes. The LBP operator can be defined as follows:

$$LBP = \sum_{n=1}^{N} s(g_n - g_c) \cdot 2^{n-1}, with \tag{2}$$

$$s(x) = \begin{cases} 1, x \geq Th \\ 0, x < Th \end{cases} \tag{3}$$

where $n$ is the position of a neighbouring pixel, $N$ denotes the number of the neighbouring pixels, $g_n$ is the intensity of the neighbouring pixel at the position $n$, $g_c$ is the intensity of the central pixel, and $Th$ is the threshold value. In the area of medical image analysis, LBP-based similarity metrics, such as miLBP [25] and Hybrid LBP (HLBP) [36], could provide higher accuracy in registration results. HLBP can cope well with the variation of the local intensity on the 4D CT lung registration, which includes a median binary pattern and a generalised central-symmetric LBP. The miLBP is another LBP-based method which can provide the highest accuracy on the registration of CT-MR images with different modalities from Brainweb [37] and RIRE [38] datasets. Moreover, miLBP adopts the technique of the adaptive threshold using the standard deviation δ of the intensity values of the

neighbouring pixels. The miLBP is defined by (4), (5) [25]. The concept of miLBP can be illustrated in Fig. 1.

$$miLBP = \sum_{n=1}^{N} s(|g_n - g_c|).2^{n-1}, \text{ with} \quad (4)$$

$$s(|g_n - g_c|) = \begin{cases} 1, |g_n - g_c| > \delta \\ 0, |g_n - g_c| \le \delta \end{cases} \quad (5)$$

Fig. 1. Illustration of the miLBP Performed on Image Pixels (here: δ =13).

miRID [32] has the potential to increase the stability of medical image registration to rotation variations. Instead of utilizing the intensity of the center pixel, miRID uses the mean of all intensity values inside the patch to achieve this. In addition, the sorting procedure is conducted on intensity values within the patch to make miRID stable against rotational deformations. The miRID is defined by (5), (6).

$$miRID_I^P = \mathbb{T}_{i=1}^{P} s(Sort|g_i - M|), \text{ with} \quad (5)$$

$$s(|g_i - M|) = \begin{cases} 1, |g_i - M| > \delta \\ 0, |g_i - M| \le \delta \end{cases} \quad (6)$$

where $\mathbb{T}_{i=1}^{P}$ represents the bitcount operation, which counts the number of bits having the value of 1. $|g_i - M|$ denotes the absolute difference of the intensity difference between $g_i$ and $M$. $M$ represents the mean of intensity of all pixels. $Sort$ operation indicates the descending order operation. $P$ denotes the number of the pixels in the patch and $\delta$ represents the standard deviation of all pixels.

## III. PROPOSED METHOD

This section will present a novel local binary descriptor, which enhances the technique of LBP. This descriptor can prominently handle the complexity of intensity relationships between different modalities. Both LBP and miLBP methods estimate the similarity value based on the use of the central pixel. However, image artifacts within the central patch can affect the performance of the descriptors. Therefore, this method needs to avoid the use of the central pixel in computing the intensity relationships in a descriptor that is to register multi-modal images. To accomplish that, the proposed method adopts the mean m and the standard deviation δ of all intensity values within the patch as the threshold values instead of using the intensity of the central pixel. Evaluating the similarity between two images is formally defined by (7) - (11). The overview of the proposed SLBD is illustrated in Fig. 2.

This work will define the binary pattern $SLBD_I^P$ of the intensities within the region of interest as follows:

$$SLBD_I^P = C_{i=1}^{P} s(g_i), \text{ with} \quad (7)$$

$$s(g_i) = \begin{cases} 1, \lambda_{lower} \le g_i \le \lambda_{upper} \\ 0, \text{otherwise} \end{cases} \quad (8)$$

Fig. 2. Overview of the SLBD Concept.

where:

$SLBD_I^P$ is the binary pattern of pixels' intensities within the interesting region of image $I$.

$C_{i=1}^{P}$ is the bitwise concatenation operation, where:

$P$ represents the total number of pixels within the image patch.

$i, 1 \le i \le P$, is a pixel location in the patch ;

$s(g_i)$ is a binary value assigned to the pixel $i$ based upon the intensity value $g_i$ against the boundary values $(m - \delta)$ and $(m + \delta)$;

$m$ denotes the mean value of the intensities of all pixels within the patch, as defined in (9):

$$m = \frac{1}{P}\sum_{i=1}^{P} g_i \quad (9)$$

δ denotes the standard deviation of the intensity values of all pixels within the patch, as defined by (10):

$$\delta = \sqrt{\frac{1}{P-1}\sum_{i}^{P}(g_i - m)^2} \quad (10)$$

$\lambda_{lower}$ and $\lambda_{upper}$ are the threshold values defined as follows:

$\lambda_{lower} = (m - \delta)$;

$\lambda_{upper} = (m + \delta)$;

In this proposed approach, it is assumed that the moving image $I_m$ and the fixed image $I_f$ are of the same size $G$. Then, the dissimilarity measure $A_{(I_f, T_{I_m; \mu})}$ between the two images can be evaluated by (11). The value of $A_{(I_f, T_{I_m; \mu})}$ is within a range of [0,1].

$$A_{(I_f, T_{I_m; \mu})} = \frac{1}{G} bitC \left\{ C_{i=1}^{G} SLBD_{I_f} \oplus C_{i=1}^{G} SLBD_{T_{I_m; \mu}} \right\} \quad (11)$$

where:

$SLBD_{I_f}$ and $SLBD_{T_{I_m; \mu}}$ are the binary patterns of image $I_m$ and image $I_f$.

$\oplus$ denotes Hamming distance operation.

$G$ is the image size.

$T_{I_m; \mu}$ represents a transformation with respect to transformation parameters $\mu$.

The $bitC$ function is bit count operation which counts the number of bits having the value of 1.

For solving (1), this experiment will find the optimal transformation using a gradient descent optimization method. where $\nabla A_{(I_f, T_{I_m; \mu})}$ is derivative of the cost function $A_{(I_f, T_{I_m; \mu})}$ with respect to the non-rigid transformation parameter $\mu$ in (12). The optimization of the cost function is shown in (13). where $\phi_{k+1}$ is the next position, $\phi_k$ denotes the current position and $s_k$ represents the step size.

$$\nabla A_{(I_f, T_{I_m; \mu})} = \frac{\partial A_{(I_f, T_{I_m; \mu})}}{\partial \mu} \tag{12}$$

$$\phi_{k+1} = \phi_k - s_k \nabla A_{(I_f, T_{I_m; \mu})} \tag{13}$$

Fig. 3 shows the block diagram illustrating the proposed registration model. Formulas for evaluating the values of some components can be found in (7) - (13). Specifically, the *SLBD* is used to represent the binary pattern of the original fixed image and the transformed moving images. The dissimilarity value between *SLBD* of $I_f$ and *SLBD* of $T_{I_m; \mu}$ is calculated by $A_{(I_f, T_{I_m; \mu})}$ as defined by (10). To find the optimal transformations, *SLBD* minimizes the dissimilarity values with $A_{(I_f, T_{I_m; \mu})}$.

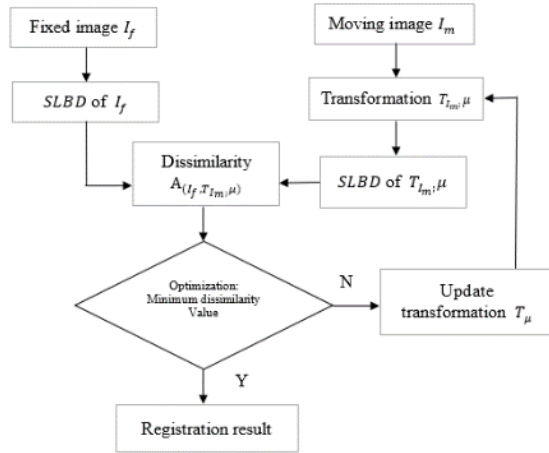

Fig. 3. Block Diagram of the Registration Model.

## IV. EXPERIMENTATION AND RESULTS

The previous section has presented SLBD as a local similarity descriptor for measuring the dissimilarity of the image patches in MIR. Its advantages are simplicity of computation and effectiveness in dealing with different modalities. This section will investigate the performance, in terms of registration accuracy, of the proposed algorithm in comparison with other approaches: MI [38], SSC [18], miLBP [25], RWMI [30], and miRID [32]. This experiments were configured the image patch size as follows: for the MI and RWMI methods, the image patch with the size of 7 x 7 pixels and 64 bins was used. For the SSC, miLBP, miRID, and SLBD methods, an image patch with the size of 3 x 3 pixels was chosen. More details for parameter setting on SSC, miLBP methods can be found in their original works [18] and [25], respectively. These methods were quantitatively assessed

by the mean target registration error (mTRE) [17] and tested on a computer with an Intel® Core™ i7-7700 CPU 3.60 GHz and RAM memory 16.0 GB. SLBD is implemented as a local similarity descriptor into non-rigid image registration, which uses Free-form deformation (FFD) with three hierarchical levels of B-spline central point [39].

This experiment carries out registrations of T1-T2, T1-PD, and T2-PD modalities from the BrainWeb dataset [37]. The voxel values are defined at a 1mm. and an image size of 181 x 217 x 181 voxels with 3% noise and 40 % intensity non-uniformity. As the moving images, the 2D 15th slice of a T1-weighted image is shown in both Fig. 4(a) and Fig. 5(a) and the 2D 15th slice of T2-weighted image in Fig. 6(a). In the first experiment, they were rotated within the range of -20°. Fig. 4(b) shows the corresponding T2-weighted image and Fig. 5(b) and Fig. 6(b) show the corresponding PD-weighted images, as the fixed images. The checkerboard images of the registered images using SLBD are shown in Fig. 4(c), Fig. 5(c), and Fig. 6(c). The transformations of these registrations are shown in Fig. 4(d), Fig. 5(d), and Fig. 6(d).

TABLE I.        RESULTS OF MULTI-MODAL NON-RIGID IMAGE REGISTRATION
WITH BRAINWEB DATASET

| Methods | Modalities | | | mTRE. |
|---------|-------|-------|-------|-------|
|         | T1- T2 | T1-PD | T2-PD |       |
| MI [38] | 2.63 | 2.88 | 3.01 | 2.84 |
| SSC [18] | 2.46 | 2.27 | 2.47 | 2.40 |
| miLBP [25] | 2.44 | 2.45 | 2.35 | 2.41 |
| RWMI [30] | 2.48 | 2.49 | 2.51 | 2.49 |
| miRID [32] | 2.35 | 2.37 | 2.43 | 2.38 |
| SLBD | **2.12** | **2.23** | **2.11** | **2.15** |

Table I shows the performance evaluation of T1-T2, T1-PD, and T2-PD registrations in terms of the target registration error (TRE.). It is obvious that the registration errors of SLBD are the lowest, especially in the cases of T1-T2, and T2-PD. SLBD could achieve the best overall registration accuracy (mTRE=2.15). They are a significant improvement compared to miRID (2.38), SSC (2.40), miLBP(2.41), RWMI (2.49), and MI (2.84), respectively. To illustrate the cases, Fig. 4 to 6 show the visual results of the SLBD method experimenting on the T1, T2, and PD-weighted MR images. These resulting images estimated by SLBD are more like the fixed images.

## V.  DISCUSSIONS

Generally, white matter appears as a bright grey in both T1 and PD and a dark grey in T2. Cerebro-spinal fluid appears as a dark grey in T1, a light grey in T2, and a grey in PD. These are the challenges in the non-rigid image registration with different MR modalities. However, in this experimentation on the registrations of T1-T2, T1-PD, and T2-PD using various approaches, it has been found that the proposed method, SLBD, has the least errors. In comparison, the miLBP [25], RSSD [31], and miRID [32] have the high speeds of MIR and also have the robustness of modality-independent. The miRID [32] could perform the best performance in MIR both rigid and non-rigid registration. However, those descriptors may lose the structural information due to their calculation. For example, miLBP represents the 8-pixels within the image patch to the single value of 0-255 ranked by multiple $2^{n-1}$ and miRID uses the sorting operation for sorting the pixels in the image patch. The computation of both miLBP and miRID may be possible to lose the spatial information of the regions of interest in the computation of both miLBP and miRID. Unlike, miLBP, RSSD, and miRID, SLBD was easily represented by the pixels within the image patch by an adaptive threshold. Another advantage is that SLBD can maintain the spatial information appropriately. The binary pattern results of SLBD can be estimated by the similarity with the patch-to-patch mapping of the corresponding regions.

## VI.  CONCLUSION

This paper has presented a novel similarity descriptor, called SLBD, based on a simple statistical concept. It is an enhancement of the local binary descriptor for multi-modal image registration. This experimentation shows that proposed approach outperforms others in terms of accuracy of multi-modal medical image registration. In addition, the proposed method is simpler in its computation. In future work, SLBD will implement as the loss function of deep convolutional neural networks for estimating the similarity between the ground truth and the prediction.

# Core Elements Impacting Cloud Adoption in the Government of Saudi Arabia

Norah Alrebdi, Nabeel Khan
Department of Information Technology
College of Computer, Qassim University, Buraydah, Saudi Arabia

*Abstract*—**The Kingdom of Saudi Arabia is taking rapid steps towards digital transformation in the field of government services. Cloud computing adoption may be the next step that supports this digital transformation to providing many features and reducing costs. Therefore, this paper will present multiple factors that may make it difficult to move to the cloud by conducting several interviews and questionnaires with government sector workers, those with technical experience, and that too to take caution and develop suitable solutions in advance. This paper also presents some recommendations and suggestions useful to consider when adopting the cloud in the public sector.**

*Keywords—Cloud computing; e-governance; cloud computing adoption; smart government; Saudi Arabia vision 2030*

## I. INTRODUCTION

Based on trends of using technology, a basis in all government transactions within the Kingdom of Saudi Arabia (KSA) and in solidarity with the 2030 vision for digital transformation, several technologies should be considered and used in several fields. Cloud computing is one of the foremost necessary technical revolutions due to the advantages it offers. Therefore, the cloud is one of the technologies that the Kingdom attached great importance during this vision [1]. The World Bank defines e-government as "the use by government agencies of information technologies (such as Wide Area Networks, the Internet, and mobile computing) that have the ability to transform relations with citizens, businesses, and other arms of government" [2]. While cloud computing is defined by the National Institute of Standards and Technology as" a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction" [3]. The resources vary according to their type. They may be an Infrastructure, platform, or software[4]. While deployment models of cloud vary rely upon the goals. It might be a Public, Private, Hybrid, or Community cloud [5]. Cloud computing provides several features relating to performance, availability, and reducing costs [6,7]. Therefore, the government of Saudi Arabia confirmed cloud computing's value, so it worked to develop some procedures for providing government services as a cloud service [8]. On the other hand, cloud computing in the government sector correlated with specific considerations. This research would address some factors influencing cloud computing implementation in government organizations based on prior literature review [9,10]. This research aims to assist

decision makers in implementing cloud computing in government organizations and make them aware of the essential concerns to put in place the necessary measures to protect their organizations.

## II. LITERATURE REVIEW

This section will discuss related works that discussed the factors affecting cloud adoption in government institutions in Saudi Arabia. By studying the previous literature, Alanezi in [11] conducts several discussions with IT employees in different organizations in different fields, for instance, the health field, finance field, education field, etc., in Saudi Arabia. They examine some expected effect factors when embracing cloud computing in their public or private organization. These discussions covered two aspects: negative and positive factors. The study shows four negative factors: Security and privacy challenges, government rules, lack of experience, and control loss. While the positive aspects contain three factors: the low cost, enhance performance, and the potential of scalability and flexibility, as shown in Table I.

Al-Ruithe et al. in [12] put forward several risks that may prevent the government sector from moving to the cloud. These risks are related to many technical, security, legal, and other aspects. Likert scale was used to measure these factors' effect on adopting cloud in public organizations based on 206 public sector workers' answers. The Table II illustrates these concerns and the average measure of responses. The findings indicate that Privacy issues and Trust issues represent the biggest fear of cloud adoption.

In [8] author proposed a framework of critical security elements using the triangulation method to validate results. The triangulation method contains three steps. First, review a previous literate review to collect the elements considered as critical security elements. Second is to organize interviews with IT professionals to review the data collected in the first step, besides suggesting new elements from experts. The final step is for conducting a survey using a close-end questionnaire to assure effective operation of framework. This framework dealt with three aspects: security risk elements, Social elements, and expected security advantages, as illustrated in Table III. Security risk elements contain interface security risks, threats of sharing the same sources, steal some accounts or services, malicious insiders, violating rules and regulations, the possession of data, data protection, data Spread, and client-side encryption error. The social elements contain confidence, security, and privacy. While the expected security advantages aspect contains scalability, take benefit of the advanced

security tools in the cloud market, a system of sophisticated security, standardized security interfaces, cloud security checking, check the implementation of Service Level Agreement (SLAs), and resource concentration [13].

TABLE I. POSITIVE AND NEGATIVE FACTORS OF ADOPTING CLOUD COMPUTING

| S.No | Factors Affecting Cloud Computing Adoption | |
|---|---|---|
| | *Negative* | *Positive* |
| 1. | Security and Privacy | Low cost |
| 2. | Government Rules | Enhance Performance |
| 3. | Lack of Experience | Ability of Scalability and flexibility |
| 4. | Loss of Control | |

TABLE II. SAUDI ARABIAN PUBLIC SECTOR CONCERNS ABOUT CLOUD COMPUTING

| S.No. | Risks with Statistical Ratio | |
|---|---|---|
| | *Risk* | *Statistical Ratio* |
| 1. | Unsatisfactory Financial Benefit | 3.47 |
| 2. | Unripe Cloud Computing | 3.76 |
| 3. | Unknown Data Storage place | 3.91 |
| 4. | Lack of Functionalities | 3.69 |
| 5. | Lack of Performance | 3.71 |
| 6. | Loss of Control | 4.04 |
| 7. | Data Governance Failure | 4.03 |
| 8. | Proprietary lock in | 3.67 |
| 9. | Dangerous Availability | 3.8 |
| 10. | Integration problems | 3.7 |
| 11. | Trust problems | 4.1 |
| 12. | Privacy Problems | 4.15 |

| 15. | Security Problems | 4.07 |

TABLE III. FRAMEWORK OF CRITICAL SECURITY ELEMENTS

| S.No. | Framework Elements Based on Security Aspects | | |
|---|---|---|---|
| | *Security Threats Elements* | *Social Elements* | *Expected Security Advantage* |
| 1. | Interface Security Risk | Security | Scalability. |
| 2. | Threats of Sharing the Same Services | Confidence | Advanced Security tools in the cloud Market. |
| 3. | Steal some accounts or services. | Privacy | System of Sophisticated Security. |
| 4. | Malicious Insider | | Security Interfaces Unified |
| 5. | Violating rules and regulations. | | Cloud Security Checking. |
| 6. | Possesions of Data | | Checking the Implementation of SLAs |
| 7. | Data Incorporation and Service | | Resource Concentration |
| 8. | Data Spread | | |
| 9. | Client Side Encryption Error | | |

## III. PROBLEM STATEMENT

With the growth of electronic services of Saudi Arabian government, it has become crucial to adopt cloud computing technology to make it robust and secured. Due to immense benefits offered by cloud computing, such as low cost and scalability, its necessary to guide ever emerging public sector. On the other hand, the implementation of cloud computing may bring some concerns and risks. Therefore, this paper aims to summarize the concerns that government institutions in the Kingdom of Saudi Arabia may face when adopting the cloud by reviewing previous literature to try controlling it and finding precautionary measures to avoid.

## IV. RESULTS AND DISCUSSION

### A. Research Method

This research incorporated quantitative research method to list factors that are important in Saudi Arabian public sector. It involves two steps; the first step was used by applying systematic literature review method which involved searching for the literature on this topic by using several approved search engines for papers such as Google Scholar and some popular databases such as ScienceDirect. In this research, authors used some keywords to help find papers related to the topic, such as: "cloud adoption," "public sector in Saudi Arabia," "affect factors," in addition to several other keywords. The research focused on papers published from 2017 to the present day of 2022. In the second step of this paper, we conducted a detailed review and analysis of the factors mentioned in the literature related to cloud adoption in the Saudi Arabian public sector. This paper introduces some of the concerns mentioned in previous literature to help researchers and government organization officials find solutions to overcome cloud adoption issues.

### B. Results

Cloud usage in the public sector leads to the elimination of tremendous costs and adding several advantages. However, its adoption may pose some risks, making decision-makers hesitant about adopting it in their institutions. This study reviewed three research papers that discussed the factors affecting the implementation of cloud computing in the Saudi Arabian public sector. One of the papers mentioned in this research identifies factors affecting the public and private sectors. We noticed some similarities in the factors extracted, which may signify that there are common factors between the two sectors, so this research may help officials in the private sector also in the decision to adopt the cloud. Table IV shows general information on these papers. This review revealed that cloud and data security are the most important concerns affecting cloud adoption, in addition to the loss of control and data governance.

### C. Recommendations

This section recommends solutions suggested by some researchers. In [14], its stated that Saudi government has expedite the process of restructuring and transforming the e governance strategy ensuring; cost reduction, improvement in services, time saving, increase in effectiveness and efficiency across all government organizations. "YASSER" platform has already been developed ensuring overall control of all

procedures, activities and all other issues related to implementation of effective e-governance. Moreover, the kingdom has recently taken a forward step to facilitate its adoption across government bodies by establishing committee to develop the necessary regulations for the cloud paradigm. Based on the findings in this research a comprehensive cloud system is recommended as shown in Fig. 1.

TABLE IV.     LITERATURE REVIEW COMPARISON

| Framework Elements Based on Security Aspects | | | | | |
|---|---|---|---|---|---|
| *Research Reference* | *Approach type* | *Sample Size* | *Year* | *Discuss Risk factors* | *Discuss Benefit factors* |
|  | Quantitave Study | 55 Universities | 2021 | Yes | Yes |
| [9] | Qualitative Study | 32 Interviews | 2018 | Yes | Yes |
| [10] | Empirical Study (Quantitative) | 206 Questionaries | 2018 | Yes | No |
| [8] | Mixed: Qualitative and Quantitative | 12 Interviews and 32 Questionnaires | 2017 | Yes | Yes |

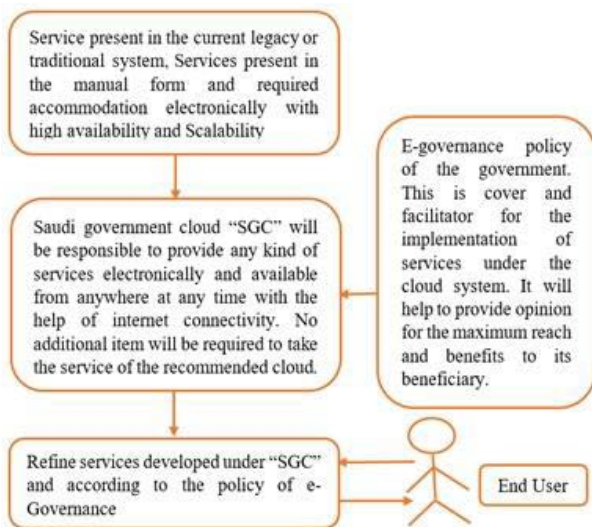

Fig. 1.    Recommended Cloud System.

In this research authors proposed to plan for an umbrella Saudi Government Cloud i.e., "SGC". A number of teams to be formed aiming to work specially in the reformation of cloud and e-governance resulting in implementation of SGC. These teams should have members from the government organizations to facilitate the process of investigating technical and financial feasibility of the system. Once the system is ready, it should be included under SGC with classification based on services and policies of e-governance.

Alannsary and Hausawi in [15] proposed a solution using cloud computing in the public organizations of Saudi Arabia. This solution is to launch a national cloud center headed by a Communication and Information Technology Commission (NCC). NCC will take responsibility for the cloud services of infrastructures and platforms. Besides the solutions and maintenance of the cloud services of software, this solution helps to decrease cost and IT resources. In contrast, SaaS's control, rules, and management will be the prerogative of each government agency. As for solutions that will provide by NCC, they propose two methods, either by studying the solutions that agencies are currently using and converting them into SaaS solutions. While the other is developing solutions they are needed from scratch, which may reduce time and cost.

In 2019, the same authors in [16] presented the previous proposal in detail and considered all parties contributing to developing and protecting this system. They proposed to create an Intelligent Government Cloud (IGC) powered by the National Center. This cloud provides services of all types to government agencies besides accountable for maintenance and verification work. The paper proposes that Riyadh be the headquarters of the IGC, with the establishment of several physical centers throughout the Kingdom to act as backup sites. The author suggests that the centers be part of Saudi universities due to many specialists who may contribute to this work's development. All government institutions must follow the Ministry of Finance regulations and the Ministry of Civil Service. IGC will provide any software solutions currently used in government organizations to a SaaS solution, which will contribute to reducing the costs paid by making them usable by any party separately. This proposal is consistent with the concern of the Kingdom in cybersecurity. Several organizations established interested in this field: The National Authority for Cyber-Security, the Saudi Federation for Cyber Security and Programming, the National Center for Information Security Technology, and the National Cyber-Security Center. Having these organizations may help implement the solution safely and accurately in compliance with government procedures and regulations.

In [17, 18], Al-Ruithe and Benkhelifa suggested a research paradigm focused on nine factors in the public organization of Saudi Arabia as helpful factors for the effective adoption of cloud data governance. These factors contribute to managing data, determining the requirements for data management, knowledge of the required functions of the data governance team, and align cloud data with other data in the organization. In addition to the ability to integrate cloud data governance functions with the cloud computing context adopted by the data-owning organization, development of the necessary contracts between the cloud consumer and the provider, the deployment of the system and the capacity to manage it in real-time, the attempt to sustain the data management program for a long period of time, the monitoring of the implementation method to ensure its correctness. Each factor contains some items that are defined from literature reviews and questionnaires. 28 hypotheses were brought up that fall under two types of hypotheses that are associative and causal. It was evaluated using Structural Equation Modelling (SEM). The results of hypothesis testing demonstrated that the model was adequate.

## V. CONCLUSION

Due to the tremendous interest exhibited by Saudi Arabia in providing government services electronically, the next step

for Saudi's government sector should be in adopting the cloud. For this reason, this paper discusses several previous research that discussed concerns related to cloud adoption in the government sector. This research provides a thorough overview of the risks that can arise when adopting a cloud to prepare for it and create innovative solutions before it crashes into failure. This review illustrates that the security element occupies a large proportion of concerns. Besides this, loss of control and data governance is potentially severe concerns.

As future work, we look forward to making a case study for one of the government organizations that adopted the cloud and investigating the amount of reduced costs after adopting it. As well as understanding the consequences and difficulties they faced at present and how they overcome them.

*Abstract*—This paper focuses on the development of a tribrid control strategy for leader-follower flocking of multi-agents in octagonal polygonal formation. The tribrid approach encompasses Reinforcement Learning (RL), centralized and de-centralized control strategies. While the RL for multi-agent polygonal formation addresses the issues of scalability, the centralized strategy maintains the inter-agent distance in the formation and the decentralized strategy reduces the consensus (in position and velocity) error. Unlike the previous studies focusing only on the predefined trajectory, this paper deals with the leader-follower scenario through a decentralized tribrid control strategy. Two cases on initial positions of multi-agents dealt in this paper include the octagonal pattern from RL and the agents randomly distributed in spatial environment. The tribrid control strategy is aimed at simultaneous formation and flocking, and its stability in a shorter response time. The convergence of flocking error to zero in 3s substantiates the validity of the proposed control strategy and is faster than previous control methods. Implicit use of centralized scheme in decentralized control strategy facilitates retention of formation structure of the initial configuration. The average position error of agents with the leader is within the position band in 3s and thus it confirms the maintenance of formation during flocking.

*Keywords*—*Simultaneous; flocking; polygonal formation; decentralized; hybrid; adaptive; control strategy; simulation*

## NOMENCLATURE

| | |
|---|---|
| $r_{ox}$ & $r_{oy}$ | Position of leader along x and y axes respectively |
| $V_{ox}$ & $V_{oy}$ | Velocity of leader along x and y axes respectively |
| $A_l$ | System matrix of leader dynamics |
| $r_{ix}$ & $r_{iy}$ | Position of $i^{th}$ agent along x and y axes respectively |
| $V_{ix}$ & $V_{iy}$ | Velocity of $i^{th}$ agent along x and y axes respectively |

## I. INTRODUCTION

The connectivity among mobile agents imposes a challenge for coordination and communication among agents, during flocking. The multi-agents interact with each other using the communication strategy and achieve formation and flocking configuration. This communication strategy encompasses a challenge for the MAS, having both homogeneous and heterogeneous agents. The challenges include interactions with the environment, and the use of various sensors for communication between the homogeneous and heterogeneous agents [1]. For the ease of operation during flocking and formation configuration by multi-agents, either homogeneous or heterogeneous multi-agents are considered. The consideration is due to the mismatch in the communication frequency [2] and may lead to diverging behaviour. The collective operation of communication and control strategies is required to establish coordination among agents. These strategies also enable to obtain cohesion in formation and flocking configurations of MAS.

Many formation and flocking control strategies have been proposed. For example, leader-follower, behavioural and virtual structure [3] for preserving formation among agents. The formation of agents can include a specific pattern: triangle [4, 5], rectangle [6] and ellipse [7]. These patterns are achieved with agent's control reference to the virtual leader trajectory tracking configuration [8]. The agent's position changes dynamically based on the velocity at which the agents are travelling. The agent's position is controlled such that no agents collide with each other to preserve the formation and achieve the stability. The control of agents [9] depends on the dynamics of each agent and the rotational transformation matrix (to transfer the agent's position from the body reference frame to the global frame).

The cyclic pursuit control strategy [10] is suitable to achieve polygonal shape. This control strategy uses a centralized control station for controlling the angle and distance of each agent. The centroid of the polygon is referred to as the virtual leader and controls the position of each agent. If there is non-availability of the virtual leader due to some destruction in the environment, then the centralized control strategy fails. Thus, the formation and stability of the MAS will not be achieved.

The centralized control strategy is also used in trajectory tracking application to control the agents from a single control station. It is challenging with the expansion of several agents and can increase the computation time with energy consumption [1]. The distributed and decentralized control strategies will overcome the disadvantages of the centralized control strategy. However, to operate simultaneous polygon formation and leader-follower flocking of multi-agents, the solitary control strategy is not useful. In this paper, the tribrid approach of a centralized and decentralized control strategy with Reinforcement Learning (RL) is proposed to perform analysis of simultaneous polygon formation and leader-follower flocking of multi-agents.

In the proposed tribrid control strategy, the polygon obtained using RL [11] is utilized along with the transformation technique (centralized control technique) to maintain the formation. The decentralized control strategy is used along with the centralized strategy for simultaneous pattern formation and leader-follower flocking of multi-agents. The proposed tribrid control strategy maintains the initial formation configuration and achieves time-varying flocking configuration at a quicker response time. The rest of this paper is organized as follows. In Section II, the review on centralized and decentralized control strategies are discussed. In Section III, the MAS model and proposed tribrid control strategy are discussed for communication and control of multi-agents, followed by consensus topology. Section V presents the simulation results and analysis for tribrid control strategy. Section VI provides conclusions.

## II. LITERATURE REVIEW

The trajectory tracking and formation of multi-agents are research topics of significant importance in MAS. The application of flocking in polygon contour is required in coverage control of multi-agent surveillance systems [12, 13]. The centralized, decentralized and distributed control strategies are used in the formation and flocking configurations of MAS [4, 14, 15]. The centralized control strategy in [9] uses a control strategy to control all agents based on the availability of information of agents as a whole. The control law is designed for decentralized or distributed control strategy based on the neighbourhood information of agents in MAS.

The decentralized control strategy is preferred over centralized control strategy (cyclic pursuit strategy) [5,10] for achieving the flexibility in changing the polygonal formation [9,14,16]. The decentralized control strategy is required to make agents in pattern follow the leader's trajectory for a multi-agent dynamical system with time-varying velocity [15,17]. The distributed control strategy is used for the agents in hexagon to flock along the pre-defined trajectory [8]. The pre-defined trajectory is addressed only for the constant velocity profile. And also, the analysis is not performed for the pattern of agents in leader-follower scenario. The bearing control approach in [18] uses positive gains to obtain formation maneuvering or flocking in a pattern. However, this decentralized bearing control approach has converged flocking

error to zero in 20s (larger settling time). The desired bearing angle between the agents is required for formation maneuvering. Any communication failure in maintaining the bearing angle can affect the MAS stability [19, 20]. The switching of formations maneuvering may not be useful for time-varying trajectory [21]. The novelty of this proposed paper is to overcome the disadvantages of bearing angle control approach and use tribrid of centralized and decentralized control strategies to achieve time-varying formation maneuvering with lesser settling time.

## III. MULTI-AGENT DYNAMICS AND CONTROL

In this paper, we will consider double integrator system for leader and multi-agent dynamics. The leader dynamics depends on its own states, given by:

$$\dot{r}_{ox} = V_{ox} \tag{1}$$

$$\dot{r}_{oy} = V_{oy} \tag{2}$$

$$\dot{V}_{ox} = g_{11}V_{ox} + g_{12}V_{oy} \tag{3}$$

$$\dot{V}_{oy} = g_{21}V_{ox} + g_{22}V_{oy} \tag{4}$$

where, $r_{ox}$ and $r_{oy}$ represent position of leader along $x$ and $y$ axes respectively. $V_{ox}$ and $V_{oy}$ represents velocity of leader along $x$ and $y$ axes respectively. $A_l = \begin{bmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{bmatrix}$ is the system matrix of the leader.

The agent dynamics depends on its own state and control input of neighbour states, position consensus terms and velocity consensus terms, given by:

$$\dot{r}_{ix} = V_{ix}$$
$$\dot{r}_{iy} = V_{iy} \tag{5}$$

where $r_{ix}$ and $r_{iy}$ are $x$ and $y$ position vector components of the $i^{th}$ agent. $V_{ix}$ and $V_{iy}$ are $x$ and $y$ velocity vector components of the $i^{th}$ agent. i = {1,2,3,….,8}

The velocity vector components of $i^{th}$ agent uses an additional term of control input to perform flocking in leader-follower scenario.

$$\dot{V}_{ix} = g_{11}V_{ix} + g_{12}V_{iy} + u_{ix} \tag{6}$$

$$\dot{V}_{iy} = g_{21}V_{ox} + g_{22}V_{oy} + u_{iy} \tag{7}$$

where $u_{ix}$ and $u_{iy}$ are $x$ and $y$ control input vector components of the $i^{th}$ agent.

The distributed control and communication network consisting of eight agents is represented using undirected graph $G$ in Fig. 1.

In the Fig. 1, A represents agent, u represents control input to the agent and C represents centralized control station. The decentralized control inputs {u1, u2,..., u8} to the agents {A1, A2,…., A8} are used for flocking in the leader-follower configuration.
Fig. 1. Proposed Control Configuration for Agents in Octagonal Formation.

A graph, $G$ is defined as: $G = (v, E)$, where $v$ is the set of vertices, $v = \{ A1, A2, A3, \ldots\ldots, A8 \}$ and $E$ is the edges, $E = v \times v$, i.e., a pair of vertices in a given spatial environment. Each vertex represents the identity of an agent in the graph. The connection between two agents is bi-directional, represented using the adjacency matrix. The adjacency matrix definition is given in (8).

$$a_{ij} = \begin{cases} 1 \ if \ two \ agents \ are \ connected \\ \quad 0 \ otherwise \end{cases} \qquad (8)$$

The neighbors of $i^{th}$ agent are given in (9).

$$N_i^t = \left\{ j : \left\| r_j(t) - r_i(t) \right\| \leq C_s, j \in v, j \neq i \right\} \qquad (9)$$

where $C_s$ indicates the spatial communication range, $r_i$ is the position of $i^{th}$ agent and $r_j$ is the neighbour position of $i^{th}$ agent. The neighbours of the agent are determined for the inter-agents positions lying within the spatial communication range. Apart from the communication strategy to connect the agents, control strategy is required to achieve flocking (trajectory tracking) and formation configuration of MAS.

The centralized control strategy is used in trajectory tracking application to control the agents from a single control station. It is challenging with the expansion of several agents and can increase the computation time with energy consumption [1]. The distributed and decentralized control strategies will overcome the disadvantages of the centralized control strategy. However, to operate simultaneous polygon formation and leader-follower flocking of multi-agents, the solitary control strategy is not useful. In this paper, the tribrid approach of a Reinforcement Learning (RL), centralized and decentralized control strategy is proposed to perform analysis of simultaneous polygon formation and leader-follower flocking of multi-agents.

The octagonal formation obtained using a RL technique [15] is maintained using a centralized (transformation technique) control strategy and then is integrated with a decentralized control strategy to obtain a leader-follower flocking configuration of multi-agents. In this proposed control strategy, the agent's position in the polygon is computed using RL and updated with initial position while tracing the leader's trajectory (5). The initial position of formation is computed using (10).

$$\dot{r}_i = R(\emptyset)(r_{i+1} - r_i)$$

where

$$R(\emptyset) = \begin{bmatrix} \cos \emptyset & \sin \emptyset \\ -\sin \emptyset & \cos \emptyset \end{bmatrix}$$

and $\emptyset$ is the rotation angle along z-axis, given by: $0 < \emptyset < \frac{\pi}{N}$, $N$ is the number of agents.

The rotation angle, $\emptyset$ is adjusted to maintain the desired distance between positions of agents. It is given by:

$$\emptyset = \frac{\pi}{N} + g(100 - d)$$

Here 100 is the desired distance and $g = 0.014706$ is the value of gain obtained by trial and error to adjust inter-agent distance $(d)$ between the agents. The distance, $d$ between agents is calculated using,

$$d_{ij} = \| r_i - r_j \|$$

The decentralized control inputs ($u_{ix}$ and $u_{iy}$) of $i^{th}$ agent for (6) and (7) is described in (11) and (12), respectively.

$$u_{ix} = -d_{11}h_{11}(r_{ix} - r_{ox}) - d_{11}h_{12}(r_{iy} - r_{oy}) - d_{11}h_{11}(V_{ix} - V_{ox}) - d_{11}h_{12}(V_{iy} - V_{oy}) + \sum_{j \in n_i} g_{ij}( \| r_j - r_i \|) \left( a - b \, e^{-\frac{\left\| r_{ij}^2 \right\|}{\check{c}}} \right) (r_{jx} - r_{ix}) + \sum_{j \in n_i} a_{ij}( \| r_j - r_i \|)(V_{jx} - V_{ix}) \qquad (10)$$

$$u_{iy} = -d_{21}h_{11}(r_{ix} - r_{ox}) - d_{21}h_{12}(r_{iy} - r_{oy}) - d_{21}h_{11}(V_{ix} - V_{ox}) - d_{21}h_{12}(V_{iy} - V_{oy}) + \sum_{j \in N_i} a_{ij}( \| r_j - r_i \|) \left( a - b \, e^{-\frac{\left\| r_{ij}^2 \right\|}{\check{c}}} \right) (r_{jy} - r_{iy}) + \sum_{j \in N_i} a_{ij}( \| r_j - r_i \|)(V_{jy} - V_{iy}) \qquad (11)$$

where $i = 1, 2, \ldots\ldots, N = 8$, $r_{ix}$ and $r_{iy}$ are positions of agent along $x$ and $y$ component respectively. $V_{ix}$ and $V_{iy}$ are velocities of leader along $x$ and $y$ axes respectively. $a_{ij}$ is the adjacency matrix. $H = [h_{11} \ h_{12}] = [0 \ 1]$, 8 agents can observe the second (y component) position of leader. $D = [d_{21}; d_{22}] = [0 \ 1]$, 8 agents can observe the second (y component) velocity of leader. $a = 1, b = 20, \check{c} = 0.2$ are constants [17].

## IV. Consensus Topology in Leader-follower Flocking Configuration

The MAS consisting of $N$ agents should ensure position and velocity consensus among the agents during flocking and formation of multi-agents. Suppose the network of multi-agents in polygon is connected, the control input ($u_{ix}$ and $u_{iy}$) ensure semi-global consensus in formation and flocking. For the global consensus of multi-agents, the conditions below are required to be satisfied.

276 | P a g e

Position Consensus

- For any position of $i^{th}$ agent in the bounded set, i.e., $r_i \subset \Re^n$, position of leader, $r_o \subset \Re^n$, there is an $\mathcal{E}^*$ such that, for each $\mathcal{E} \in (0, \mathcal{E}^*)$,

$$\lim_{t \to \infty} ||\frac{1}{N} r_i(t) - r_o(t)|| = \mathcal{E}^*,$$

$i = \{1,2,3, \dots, N; N = 19\}$

where $\mathcal{E}$ represents small value in $r^*$

- For any position of $i^{th}$ agent in the bounded set, i.e., $r_i \subset \Re^n$, neighboring agent, $r_j \subset \Re^n$, there is an $r^*$ such that, for each $r \in (0, r^*)$,

$$\lim_{t \to \infty} ||r_i(t) - r_j(t)|| = r^*,$$

$i = \{1,2,3, \dots, N = 19\}$

where $r^*$ is in the band of $[0,10] \times [0, 10]$

Velocity Consensus

The velocity of $i^{th}$ agent is in the bounded set, i.e., $V_i \subset \Re^n$, velocity of leader, $V_o \subset \Re^n$

$$\lim_{t \to \infty} ||V_i(t) - V_o(t)|| = 0,$$

$i = \{1,2,3, \dots, N; N = 19\}$

The above position and velocity consensus terms are substantiated using simulation results of flocking behaviour of multi-agents.

## V. Simulation Analysis of Tribrid Control Strategy for Simultaneous Polygonal Formation and Flocking of MAS

The analysis is performed for two cases of initial position of agents: polygon pattern (in Fig. 2, obtained using Reinforcement Learning (RL), [11]) and randomly distributed in the environment (in Fig. 3). The velocity is chosen randomly in the range ($[0, 2] \times [0, 2]$) (in Fig. 4).

The spatial communication or interaction range is 2 and the connectivity is established among all agents with the leader. The cyclic pursuit and the adaptive control strategies are used to achieve synchronization of octagonal formation and tracing the leader's trajectory.

### A. Formation Control using Cyclic Pursuit Strategy

In this paper, the cyclic pursuit strategy (centralized control strategy) is preferred over decentralized control strategy for achieving the flexibility in changing the polygonal formation [15]. The formation of a polygon is described by deviated cyclic pursuit in $\Re^2$ by maintaining the desired distance between positions of agents. In a deviated cyclic pursuit strategy, the rotation angle (in (10)) is adjusted to maintain the desired distance between the agents. The inter-agent distance between the neighbours has converged to maintain a constant value of 100 and is shown in Fig. 5.

Fig. 2. Initial Position in Octagonal Formation.

Fig. 3. Random Initial Position of Eight Agents and the Leader.

Fig. 4. Initial Velocity of Eight Agents and Leader.

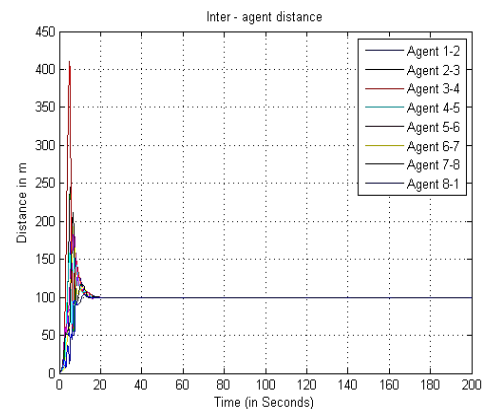

Fig. 5. Inter-agent Distance for All Agents.

The angle is increased to maintain the distance between the agents. Also, a constant multiplying gain factor is adjusted to maintain a constant inter-agent distance between the agents. In Fig. 5, it is observed that, initial transient period is around $9s$ to achieve the steady-state behaviour.

Apart from maintaining the distance, it is also necessary to check whether the formation is maintained. To check that the formation is maintained, all agents should agree to the same point during flocking. This agreement is captured by averaging the positions of agents in $x$ and $y$ axes. The simulation substantiates that all agents have agreed on the position pursuit of interest (shown in Fig. 6) in $20s$. It can be observed that, all agents collectively agree on the same point, $(50, -50)$ i.e., the pursuit point of interest. The rotation angle in (10) is adjusted to maintain the inter-agent distance and angle from the centroid of eight agents. The maintenance of inter-agent distance, angle from the centroid and consensus agreement among agents during the flocking validates the pattern in polygon.

### B. Flocking of Agents in Polygon using Adaptive Strategy

The flocking behaviour is obtained by integrating the agent's dynamics with the adaptive controller. The position of agents is updated using the cyclic pursuit strategy (discussed in Section 4A.). The communication or interaction range is 2 and the connectivity is established among all agents with the leader. The cyclic pursuit and the adaptive control strategies are used to achieve synchronization of octagonal formation and tracing the leader's trajectory. The analysis of simultaneous formation and flocking is discussed in two cases:

- The octagonal formation is developed using Q-learning, where the eight agents learn independently in $x$ and $y$ frames. The agents are subjected to follow the leader's trajectory after the octagonal contour is formed. The initial position of the agent is the same as the vertices of the octagon pattern (in Fig. 2) and the velocity is chosen randomly in the range $[0, 2] \times [0, 2]$ (in Fig. 4).

The flocking error is analyzed to match the velocity of agents with the leader and achieve one of the flocking attributes: alignment [21]. The variation in the relative velocity of agents with the leader results in flocking error in leader-follower configuration of MAS. The relative velocity of agents with the leader is shown in Fig. 7. It is observed that the agents in polygon formation follow the leader's trajectory in $1.5s$ (settling time) along x and y axes [shown in Fig. 7(a) and Fig. 7(b)]. The transient time for both axes is around 1s at 0.2 amplitude. This infers that the agents are flocking quickly at less peak amplitude value. The distributed control strategy is used for the agents in hexagon to flock along the pre-defined trajectory [8]. The flocking of the hexagon pattern converges to zero at $5s$ using the distributed control strategy [8]. The proposed strategy is useful to achieve convergence of flocking error to zero, faster than in [8] and is suitable for any polygonal configuration. The cycle change is observed every $20s$ and follows the trajectory of the leader.

Fig. 6. Consensus Agreement for All Agents.

The robustness of MAS is achieved by maintaining average position error of agents with the leader as minimal as possible (band of $[-1, 1] \times [-1, 1]$). The robustness of flocking behaviour is analyzed to stay close to nearby agents and avoid the collision. The agents are informed to establish a connection with the leader after updating the position using the cyclic pursuit strategy. The connection indicates that the agents are tracing the leader's trajectory, as shown in Fig. 8.

(a) Relative Velocity of Agents with Leader Along x-axis.

(b) Relative Velocity of Agents with Leader Along y-axis.

Fig. 7. Velocity Consensus of Multi-Agents for the Case 1.
Fig. 8. Trajectory Tracking by Agents in a Closer View using Tribrid Control Strategy for the Case 1.

Because the agents are following the leader's trajectory, the relative velocity of agents with the leaders is converging to zero. Since the agent's velocity is closely observable with that of the leader, the average position error of the agents with the leader is decreased to a minimum constant value of $-0.45$ in $x$ axis and $-0.02$ in y axis in $20s$.

The average position error in $\Re^2$, is shown in Fig. 9(a) and Fig. 9(b), respectively. The error is within the position band and the settling time is, $20s$ as the formation should also be maintained during flocking.

(a) Average Position Error of Agents with Leader Along x-axis.

(b) Average Position Error of Agents with Leader Along y-axis.

Fig. 9. Position Consensus of Multi-Agents for the Case 1.

The octagon formation should be maintained while tracking the leader's trajectory. It is analyzed by using the agent's position at various time and distance between the agents. The distance is maintained at a constant value between $0.19$ and $1.18$ in $20s$, as shown in Fig. 10.

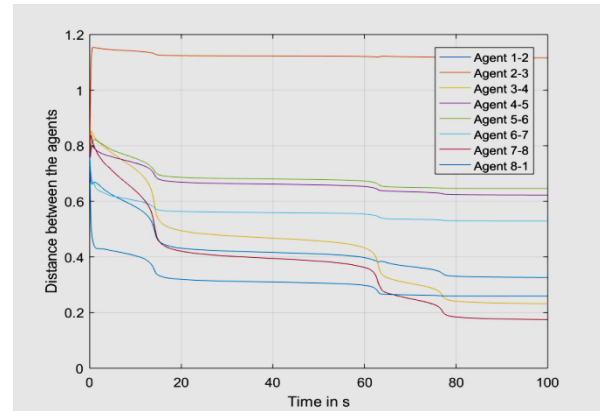

Fig. 10. Inter-agent Distance in Tribrid Strategy for the Case 1.

The structure of the formation is maintained in initial octagonal pattern as shown in Fig. 11. During flocking, the switching in position affects the initial octagonal pattern, as observed in every iteration. The octagonal pattern is achieved in $20s$ (at the iteration $t = 200$). It is observed that in every iteration, two agents are little away from the remaining six agents. It is also inferred in Fig. 11 that inter-agent distance, 2-3, 4-5 and 5-6 are high compared with the other inter-agent distances.

Fig. 11. Formation using Tribrid Control Strategy for the Case 1.

- The agents distributed randomly in space are subjected to follow the leader's trajectory. The initial position of the agent is distributed randomly in the space (in Fig. 3) and the velocity is chosen randomly in the range $[0, 2] \times [0, 2]$ (in Fig. 4).

The variation in the relative velocity of agents with the leader results in flocking error in leader-follower configuration of MAS. The relative velocity of agents with the leader is shown in Fig. 12(a) and Fig. 12(b). It is observed that the agents in octagonal formation follow the leader's trajectory by observing the value of the leader's velocity in $20s$. The

cycle change is observed every $60s$ and follows the trajectory of the leader. However, in $3s$, the agents follow the trajectory of the leader with the flocking error of $0.2m/s$.

The robustness of MAS is achieved by maintaining average position error of agents with the leader as minimal as possible (band of $[0,10] \times [0,10]$). The robustness of flocking behaviour is analyzed for an agent to stay close to nearby agents and avoid the collision. The agents are informed to establish a connection with the leader after updating the position using the cyclic pursuit strategy. The connection indicates that the agents are tracing the leader's trajectory, as shown in Fig. 13.

The agents' velocity is closely observable with that of the leader's velocity. Hence, the average position error of the agents with the leader has decreased to a minimum constant value of $-0.065$ in $x$ axis and $-0.6$ in $y$ axis in $20s$. The average position error in $\Re^2$ along x- and y axes is shown in Fig. 14(a) and Fig. 14(b), respectively.

The formation should be maintained while tracking the leader's trajectory. It is analyzed by using the agent's position at various time and distance between the agents. The distance is maintained at a constant value between $1.5$ and $9$ in $80s$, as shown in Fig. 15.

Fig. 13. Trajectory Tracking by Agents in a Closer View using Tribrid Control Strategy for the Case 2.

(a) Average Position Error of Agents with Leader Along x-axis.

(b) Average Position Error of Agents with Leader Along y-axis.

Fig. 14. Position Consensus of Multi-Agents for the Case 2.

(a) Relative Velocity of Agents with Leader Along x-axis for Random Configuration.

(b) Relative Velocity of Agents with Leader Along y-axis for Random Configuration.

Fig. 12. Velocity Consensus of Multi-Agents for the Case 2.

The structure of the formation is maintained with the initial pattern as shown in Fig. 16. During flocking, the switching in position affects the initial pattern, as observed in every iteration. The initial pattern is achieved in $20s$ (at the iteration $t = 200$). It is observed that in any iteration, the configuration is the same as the initial pattern.
Fig. 15. Inter-agent Distance in Tribrid Strategy for the Case 2.

Fig. 16. Formation using Tribrid Control Strategy for the Case 2.

The distributed control strategy is used for proper communication and coordination among agents and avoids a collision while flocking in a pre-defined trajectory [8] and in the leader-follower scenario [17]. The analysis does not focus on simultaneous polygon formation and flocking in the leader-follower scenario. The proposed tribrid control strategy is discussed under two cases: the octagonal pattern from RL and agents distributed in the spatial environment are chosen as the initial position of agents. The comparative analysis for the two cases is given in Table I and Table II.

TABLE I. COMPARATIVE ANALYSIS OF FLOCKING AND FORMATION BEHAVIOUR IN TRIBRID CONTROL STRATEGY

| Flocking Configuration | | | | | |
|---|---|---|---|---|---|
| Cases | Relative Velocity of Agents with the Leader in m/s | | Average Position Error of Agents in m | | |
| | Transient Time in s | Settling Time in s | x- coordinate | y - coordinate | Settling Time in s |
| Case 1 | 0.2 | 1.5 | -0.45 | -0.02 | 1.5 |
| Case 2 | 1 | 20 | -0.065 | -0.6 | 20 |

TABLE II. COMPARITIVE ANALYSIS OF FORMATION BEHAVIOUR IN TRIBRID CONTROL STRATEGY

| Formation Configuration | | |
|---|---|---|
| Cases | Inter-agent Distance Range | Formation Structure |
| Case 1 | 0.19-1.18 | Same as initial position |
| Case 2 | 1.5-9 | Same as initial position |

The flocking error of eight agents in the polygon pattern has converged to zero at $1.5s$ for the Case 1 and $20s$ for the Case 2. The distributed control strategy is used for the agents in hexagon pattern to flock along the pre-defined trajectory [8]. The flocking of the pattern converges to zero in $5s$ using the distributed control strategy [8]. Thus, the proposed strategy enables the system to converge faster. The details of comparison of various configurations of flocking at time-varying velocity are described in Table III. As can be observed in Table III, the earlier studies [8,19,22] did consider configurations which have dimensions smaller than octagon configuration to flock at time-varying velocity. In this paper which considers octagonal contour for flocking, the convergence of flocking error to zero has been achieved faster than the existing studies [8, 19, 22].

TABLE III. COMPARITIVE ANALYSIS OF VARIOUS CONTOUR CONFIGURATION FLOCKING AT TIME-VARYING VELOCITY

| | | Flocking Error |
|---|---|---|
| Sl. No. | Contour configurations flocking at time- varying velocity | Settling Time in s |
| 1 | Octagonal contour flocking at time-varying velocity (Proposed Tribrid Control Strategy for Case 1) | 1.5 |
| 2 | Square contour flocking at time – varying velocity [22] | 5 |
| 3 | Formation tracking control [19] | 2 |
| 4 | Hexagonal contour flocking at time – varying velocity [8] | 5 |

The settling time is high ($20s$) for the Case 2, compared to Case 1. If the agents are randomly distributed in an environment, then the centroid of agents cannot be maintained with the leader's position. It results in a larger average position error, as observed in Table I. Also it results in larger inter-agent distance range, as observed in Table II. The advantage of the tribrid approach is that the formation structure will remain the same as the initial configuration.

## VI. CONCLUSIONS

In this paper, the simulation model of flocking uses the tribrid control strategy for demonstration of two cases: multi-agents distributed randomly in the environment and multi-agents in polygonal formation (obtained from Reinforcement Learning (RL)). The initial positions of multi-agents are varied with the variation of gain value in the cyclic pursuit strategy to maintain the distance between the agents at a constant value. Also, the cyclic pursuit strategy is applied to the multi-agent dynamics to achieve consensus among the agents and to maintain the formation. The analysis of simultaneous formation and flocking is discussed in two cases:

- The agents form polygonal formation using Q-learning and are integrated with cyclic pursuit strategy to maintain the octagonal formation.

- The agents in a randomly distributed environment use cyclic pursuit strategy to achieve and maintain the octagonal formation.

In both the cases, the inter-agent distance and cyclic pursuit interest are achieved in $20s$. The positions of agents are updated using the cyclic pursuit strategy before performing flocking. The flocking error of eight agents in the polygon pattern has converged to zero at $1.5s$ in first case and at $20s$ in the second case, with the proposed tribrid control strategy. The average position error of agents with the leader has increased by 4% for the second case, compared with the first case. In both the cases, the agents in the octagonal polygon configuration follow the leader's trajectory in $0.2s$. To conclude, the proposed tribrid control strategy enables the flocking error of multi-agents to converge faster and is suitable for closed contour configuration of multi-agents. The advantage of the tribrid approach is the facilitation of the retention of formation structure of the initial configuration. The proposed approach has the assumption that all the agents are always connected during flocking and formation. The disconnection leads to diverging behavior of flocking and formation configuration of multi-agents. Hence an analysis for the scenario of loss of connectivity during simultaneous polygonal formation and leader-follower flocking of multi-agents can be of significant importance from both research and system perspectives.

# Merged Dataset Creation Method Between Thermal Infrared and Microwave Radiometers Onboard Satellites

Kohei Arai

Saga University, Saga City, Japan

*Abstract*—**Merged dataset creation method between Thermal Infrared (TIR) and Microwave Scanning Radiometer (MSR) onboard remote sensing satellites is proposed. One of the key issues here is the relation between thermal and microwave emissions from the same observation target in particular, Sea Surface Temperature (SST). An example of Tropical Rainfall Measuring Mission (TRMM) satellite based TIR and MSR, Visible Infrared Scanner (VIRS) and TRMM Microwave Imager (TMI) is shown in this paper. SST is estimated, independently, with VIRS or TMI. A method for interpolation of multi-sensor satellite images based on Multi-Resolution Analysis (MRA) is also proposed. The experimental results with TMI/SST image and VIRS/SST image show that Root Mean Square (RMS) error ranges from 0.87 to 0.91-degree C.**

*Keywords—Wavelets; VIRS/SST; TMI/SST; MRA; Daubechies; TRMM; TIR; MSR*

## I. INTRODUCTION

In order to increase observation chances of SST, both of TIR radiometer data and microwave radiometer data are desirable to use with consideration of the difference of radiative transfer processes and interactions between electronic magnetic waves and the sea surfaces. Also, a merged dataset between TIR and microwave radiometer data is also desirable together with a combined SST dataset derived from the TIR and microwave radiometer data.

In general, spatial resolution of TIR is better than that of MSR. TIR data can be acquired in a clear weather condition only. On the other hand, MSR data can be acquired in a cloudy condition as well as rainy condition. If these data can be merged, then fine resolution of microwave and thermal emission of data can be available to use. Also, it becomes possible to increase observation frequency.

Merged dataset creation method between TIR and microwave radiometers onboard remote sensing satellites is proposed. One of the key issues here is the relation between TIR and microwave emissions from the same observation target in particular, SST.

As an example of applying wavelet analysis (expansion, transformation, etc.) to the processing analysis of earth observation satellite images, a method of superimposing multiple visible images after wavelet transform [1], superimposing multiple Synthetic Aperture Radar: SAR images with different off-nadir angles [2], a method of

applying the wavelet transform to the pattern of annual fluctuation of the sea surface temperature estimated from satellite data and extracting its characteristics [3], and applying the wavelet transform to the extraction of the surface roughness of sea ice. There are methods [4], methods [5] for extracting spatial features from images extracted from soil moisture, etc. [6].

By the way, in November 1997, the TRMM (Tropical Rainfall Measuring Mission) satellite [Solar Asynchronous Orbit] was launched. The Sea Surface Temperature (SST) is estimated independently by the sensor TMI (TRMM Microwave Imager) and the sensor VIRS (Visible Infrared Scanner) mounted on the TRMM satellite [7]. In this paper, the relationship between SST (TMI / SST) estimated from TMI observation data and SST (VIRS / SST) estimated from VIRS observation data is examined using multi-resolution analysis. That is, the relationship between the actual observation satellite data questions of different types of sensors.

The proposed method considers Multi-Resolution Analysis (MRA). The Daubechies basis (orthonormal basis) is used as the mother wavelet when performing multi-resolution analysis.

The next section describes the related research works in particular SST estimation methodology then the proposed method of merged dataset is created between TIR and microwave radiometer data and theoretical background of fundamentals of wavelet analysis. After that experimental method and results are described followed by conclusion with some discussions.

## II. RELATED RESEARCH WORKS

As for the SST estimation method, there are the following related research works.

SST estimation of the pixels partially contaminated with cloud is conducted [8]. A merged dataset for obtaining cloud free Infrared (IR) data and a cloud cover estimation within a pixel for SST retrieval is defined [9]. SST estimation with Advanced Earth Observing Satellite (ADEOS) / Ocean Color and Temperature Scanner (OCTS) data is conducted [10].

Cross validation of OCTS Global Area Coverage (GAC) SST with Multi-Channel SST (MCSST) is conducted [11]. On the other hand, antenna pattern correction and SST estimation algorithms for Advanced Microwave Scanning Radiometer: AMSR is made [12].

SST estimation method with linearized inversion of radiative transfer code for ADEOS/OCTS is proposed [13]. SST estimation accuracy assessment for ASTER/TIR is conducted and also an effectiveness of 8.3μm water vapor absorption band for SST retrieval is investigated [14].

SST estimation with microwave radiometers by means of simulated annealing based on an ocean surface model is conducted [15] together with SST retrieval with microwave radiometer data based on simulated annealing [16].

Estimation of SST, wind speed and water vapor with microwave radiometer data based on simulated annealing is attempted [17] together with estimation of SST, wind speed and water vapor with microwave radiometer data based on simulated annealing [18].

Estimation method of SST with Moderate resolution of Imaging Spectrometer: MODIS data in particular utilizing Band 29 for reducing water vapor influence on SST retrievals is proposed [19]. Nonlinear optimization-based SST estimation methods with remote sensing satellite based Microwave Scanning Radiometer: MSR data are proposed [20].

Comparative study on sea surface temperature estimation with thermal infrared radiometer data among conventional MCSST, split window and conjugate gradient-based methods is conducted [21]. Effectiveness of Noise Equivalent delta Temperature: NEdT and Band 10 (8.3 um) of The Advanced Spaceborne Thermal Emission and Reflection Radiometer: ASTER/ Thermal Infrared Radiometer: TIR on Skin SST: SSST estimation is estimated [22].

Band combination selection method for SST estimation with satellite data is proposed [23]. Artificial Intelligence: AI and remote sensing satellite big data analysis is overviewed [24].

On the other hand, there are the following related research works on the microwave remote sensing.

Data fusion between microwave and thermal infrared radiometer data and its application to skin sea surface temperature, wind speed and salinity retrievals are proposed [25]. Comparative study of optimization methods for estimation of Sea Surface Temperature (SST) and Ocean Wind (OW) with Microwave Radiometer data is conducted [26]. Also, method for rainfall rate estimation with satellite-based microwave radiometer data is proposed [27]. Meanwhile, ice concentration estimation method with satellite-based microwave radiometer by means of inversion theory is proposed [28].

## III. PROPOSED METHOD WITH THEORETICAL BACKGROUND

### A. Proposed Method

Merged dataset creation method proposed here is to utilize both of TIR and microwave radiometer data together. Therefore, the relation between TIR and microwave radiometer data is a key issue here. Moreover, missing data are another issue. TIR radiometer data does not work in a cloudy condition and rainy condition. Furthermore, spatial resolutions are different between TIR and microwave radiometers. Therefore, some treatments of the missing data as well as spatial

resolution difference are needed to use both radiometer data together. In order to take into account the missing data and spatial resolution difference, wavelet Multi-Resolution Analysis (MRA) is featured.

### B. Theoretical Background on Wavelet Analysis

Multi-Resolution Analysis (MRA) needs Mother wavelet and is based on Discrete Wavelet Transform: DWT. As a mother wavelet is defined as follows:

The function $\phi$ that satisfies the two-scale relationship as follows:

$$\phi(x) = \sum_{k \in Z} p_k \phi(2x - k) \tag{1}$$

This is called the scaling function.

The sequence $\{p_k \, / \, k \in Z\}$ is called a two-scale sequence, and the scaling function $\phi$ is determined by the sequence $\{p_k \, / \, \kappa \in Z\}$. The mother wavelet $\psi$ is determined by equation (2).

$$\psi(x) = \sum_{k \in Z} q_k \, \phi(2x - k) \tag{2}$$

Also, Discrete Wavelet Transform: DWT is defined as follows:

The transformation of the discrete wavelet of the function $f(x)$ by mother wavelet $\psi(x)$ is also given by (3), and its inverse transformation is given by (4).

$$d_k^{(j)} = 2^j \int_{-\infty}^{\infty} \overline{\psi(2^j x - k)} f(x) dx \tag{3}$$

$$f(x) \sim \sum_j \sum_k d_k^{(j)} \psi(2^j x - k) \tag{4}$$

## IV. NUMERICAL EXPERIMENT

### A. Outline of Experiment

The data used this time are SST estimated images from November 1998 to September 2000 estimated by sensor TMI and sensor VIRS, respectively. Fig. 1(a) shows an example of SST (VIRS / SST) estimated from VIRS observation data, and Fig. 1(b) shows an example of SST (TMI/SST) estimated from TMI observation data.

(a) VIRS.

(b) TMI.

Fig. 1. Examples of SST Images Estimated with VIRS or TMI.

From Fig. 1, it can be seen that the spatial resolution of the VIRS observation data and the TMI observation data are different. The image size of VIRS / SST is 1024 x 512, and the image size of TMI / SST is 512 x 256. The spatial resolution of VIRS observation data is about twice the spatial resolution of TMI observation data.

In this experiment, wavelet decomposition is performed on the VIRS / SST image, and the relationship between the result (LL component) and the TMI / SST image is examined. In addition, consider the impact of differences in support length. By the way, the target VIRS / SST and TMI / SST each include missing data due to the influence of the atmosphere, sensor characteristics, satellite orbit characteristics, and the like. In this experiment, the land data is regarded as missing data. Therefore, the multi-resolution analysis is performed in consideration of the missing data. That is:

*1)* Data of points where TMI / SST is not missing.

*2)* All VIRS / SST for generating data corresponding to the points where TMI / SST is not missing by using wavelet decomposition have been observed.

Consider using data that satisfies the two conditions of the data in the region (not missing) [problem of support length during wavelet decomposition]. The above two conditions are called considerable conditions.

First, Z (sup, i, j, t) def is defined as follows:

$$\vartheta(sup, i, j, t) = 1 \; or \; 0 \tag{5}$$

1: Satisfy the conditions for consideration.

0: Does not meet the considerable conditions.

Then, evaluation is performed using the following.

$$J1(sup) = \sqrt{\frac{\sum_{t=1}^{22} \sum_{(i,j)} (\vartheta(sup,i,j,t) \varepsilon_1(i,j,t)}{N}} \tag{6}$$

$$\varepsilon_1(i,j,t) = (G(i,j,t) - H(i,j,t))^2 \tag{7}$$

However, sup represents the support length of the mother wavelet, t represents the time, [i, represents the position, and (i, j, t) represents the TMI / SST, and σ (i, j, t)]. Represents the LL component when VIRS / SST is wavelet-decomposed. Further, N represents the number of Z (sup, i, j, t) = 1.

### B. Experimental Results

Table I shows the value of J1 (sup) when the support length sup is changed and the number of data N that satisfies the conditions that can be considered for each support length.

TABLE I.    THE ERROR J1(SUP) AND NUMBER OF OBSERVED DATA N FOR THE SUPPORT LENGTH SUP

| SUP | J1(SUP) | N |
|---|---|---|
| 2 | 25.63 | 2559974 |
| 4 | 25.644 | 2537353 |
| 6 | 25.652 | 2506378 |
| 8 | 25.659 | 2471573 |
| 16 | 25.676 | 2331352 |
| 20 | 25.681 | 2264613 |

Fig. 2 shows the relationship between the LL component and TMI / SST when the VIRS / SST is wavelet-decomposed when the support length sup is changed [under the conditions that can be considered].

(a) sup=2.

(b) sup=4.

(c) sup=6.
(d) sup=8.

(g) sup = 20.

Fig. 2.   Relationship between TMI / SST Data and the Estimated SST through MRA.

(e) sup=12.
The horizontal axis shows TMI / SST, and the vertical axis shows the LL component when VIRS / SST are wave-resolved. Also, physical properties of the ocean surface in thermal emission and microwave emission are different each other so that these effects have to be clarified. For instance, penetration depth of the ocean surface is different between thermal and microwave electric magnetic wave. The divergence shown in the Fig. 2 is caused by the different physical properties of the ocean between thermal and microwave electric magnetic wave.

Table II shows the results of regression analysis on the scatter plots at each support length in Fig. 2, that is, the unknown regression coefficient (a, b) was obtained using the following:

$$J2(sup) = \sqrt{\frac{\sum_{t=1}^{22} \sum_{(i,j)} (\vartheta(sup,i,j,t)\varepsilon_2(i,j,t)}{N}} \quad (8)$$

$$\varepsilon_2(i,j,t) = (G(i,j,t) - H(i,j,t))^2 \quad (9)$$

TABLE II.     REGRESSION COEFFICIENTS OF SST ESTIMATION AND THE ERROR J2(SUP) , FOR THE SUPPORT LENGTH SUP

| SUP | A | B | J2(SUP) | N |
|---|---|---|---|---|
| 2 | 1.948 | 0.873 | 0.87 | 2559974 |
| 4 | 1.947 | 0.927 | 0.873 | 2537353 |
| 6 | 1.944 | 0.997 | 0.873 | 2506378 |
| 8 | 1.942 | 1.07 | 0.875 | 241573 |
| 12 | 1.937 | 1.219 | 0.883 | 2400801 |
| 16 | 1.932 | 1.363 | 0.895 | 2331352 |
| 20 | 1.927 | 1.505 | 0.909 | 2264613 |

(f) sup=16.

## V.   CONCLUSION

Merged dataset creation method between Thermal Infrared (TIR) and Microwave radiometers onboard remote sensing satellites is proposed. One of the key issues here is the relation

between TIR and microwave emissions from the same observation target in particular, Sea Surface Temperature (SST). An example of Tropical Rainfall Measuring Mission (TRMM) satellite based TIR and microwave radiometers, Visible Infrared Scanner (VIRS) and TRMM Microwave Imager (TMI) is shown in this paper. SST is estimated, independently, with VIRS or TMI. A method for interpolation of multi-sensor satellite images based on Multi-Resolution Analysis (MRA) is also proposed.

In this paper, the relationship between the actual observation satellite data questions of different types of sensors including missing data was examined using multiple resolution analysis. From Table I, when examining the relationship between different types of sensors and data questions using multiple resolution analysis, it was confirmed that the shorter the support length, the better the error J1 (sup). From Table II, the regression error J2 (It was confirmed that sup) was 0.87 to 0.91 [C].

## VI. FUTURE WORKS

In the future, the author will continue to validate of the proposed method with a variety of TIR and microwave radiometer data. Improvement of observation frequency by the proposed method is another issue. Also, physical properties of the ocean surface in thermal emission and microwave emission are different each other so that these effects have to be clarified. For instance, penetration depth of the ocean surface is different between thermal and microwave electric magnetic wave.

AUTHORS' PROFILE

Kohei Arai, He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January, 1979 to March, 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science on April 1990. He was a councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA since 1998. He also is Vice Chairman of the Science Commission "A" of ICSU/COSPAR since 2008 then he is now award committee member of ICSU/COSPAR. He wrote 55 books and published 620 journal papers as well as 450 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Mister of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. http://teagis.ip.is.saga-u.ac.jp/index.html.

# A Hybrid RNN based Deep Learning Approach for Text Classification

Pramod Sunagar, Anita Kanavalli

Department of Computer Science and Engineering

M S Ramaiah Institute of Technology (Affiliated to VTU)

Bangalore, India

*Abstract*—**Despite the fact that text classification has grown in relevance over the last decade, there are a plethora of approaches that have been created to meet the difficulties related with text classification. To handle the complexities involved in the text classification process, the focus has shifted away from traditional machine learning methods and toward neural networks. In this work the traditional RNN model is embedded with different layers to test the accuracy of the text classification. The work involves the implementation of RNN+LSTM+GRU model. This model is compared with RCNN+LSTM and RNN+GRU. The model is trained by using the GloVe dataset. The accuracy and recall are obtained from the models is assessed. The F1 score is used to compare the performance of both models. The hybrid RNN model has three LSTM layers and two GRU layers, whereas the RCNN model contains four convolution layers and four LSTM levels, and the RNN model contains four GRU layers. The weighted average for the hybrid RNN model is found to be 0.74, RCNN+LSTM is 0.69 and RNN+GRU is 0.77. RNN+LSTM+GRU model shows moderate accuracy in the initial epochs but slowly the accuracy increases as and when the epochs are increased.**

## I. INTRODUCTION

Text classification has posed a necessity in the current generation, which is precisely due to the fact that the data being handled is increasing in volume at an alarming rate [1]. This can be attributed to the increase in the number of end-users, thereby necessitating effective data handling. Effective handling also involves uploading and retrieval of data at least possible time. The data being uploaded and retrieved may be in the context of many real-time applications like web applications, banking servers, scientific literature, or digital libraries of documents. Some of the applications also involve data filtering [2] and organization, where voluminous data is sorted and categorized as per the relevance [3]. Also, apart from data organization, opinion mining is an application of utmost importance. Therefore, efforts have been put-forth to extend the classified data for opinion mining [4]. Lastly, e-mail classification is also an application of great significance, where text classification is used to identify spam e-mails [5-7]. The applications, as mentioned earlier, also include challenges that are to be addressed critically and with utmost precision.

Researchers have made few significant efforts toward addressing real-world problems in the recent past [8-14]. Most of the applications concentrate on Natural Language Processing (NLP) and text analytics, with enormous efforts to efficiently handle the data. The extension of efforts also aims at text classification more effectively and intricately. In general, post receipt of the raw data, text classification can be executed stage-wise, viz. feature extraction, reduction of dimensions of the data, selection of the classifier, and finally, the metrics that facilitate quantifying the accuracy of classification. Although many models have been implemented to improve the text classifications, still there are lot of challenges persists. The proposed model tries to improve the text classification by creating a hybrid models and utilizes the advantages of RNN, LSTM and GRU models. Transfer learning is a strategy that involves developing a model for one problem and then utilizing it to train another related problem [37]. Using transfer learning the accuracy of the text classification tasks can be improved [38].

## II. RELATED WORKS

The authors have used a BBC news text categorization structure in this work and implemented ML algorithms like logistic regression, KNN algorithms [15] and random forest. These methods are evaluated using measures such as accuracy, precision, F1-score, confusion matrix, and support. The logistic regression algorithm has better accuracy than other algorithms in classifying the text in the given dataset. In this work, the authors have performed a comparative analysis of deep learning models on Arabic text for the single and multi-label text classification [16]. Authors have demonstrated that the pre-processing stage is not required when using the suggested models. The word2vec embedding method is included to enhance the accuracy of the deep learning models. In this work, the authors have projected a model which utilizes a convolutional layer, Bi-LSTM, and attention mechanism to understand the semantics and improve the text classification accuracy [17]. The authors have analyzed the traditional deep learning models and proved that the proposed model has the highest accuracy over others. The feature extraction methods and developing classifiers are significant for the text classification techniques. In this work, the authors have highlighted the improved word embeddings with machine learning models for automatic document classification jobs [18]. The authors have used the word embedding techniques such as word2vec, Glove, and fastText. The authors have used the freely available dataset and implemented algorithms such as SVM, XGBoost, and CNN to use hierarchical and flat measures. The fastText embedding technique has proved to

improve the classification accuracy of the text. The authors have investigated the hierarchical multi-label text classification task [19]. Since the documents are stored in a hierarchical structure, the classification task becomes tough. The authors have proposed a new framework called Hierarchical Attention-based Recurrent Neural Network (HARNN) for categorizing documents into the appropriate labels by integrating texts and the hierarchical category structure.

The authors examined text categorization techniques based on machine learning [20]. AG's News Topic Classification Dataset, which comprises 120000 training and 7600 testing samples, was used in this case. Support vector machine, Rocchio, bagging, boosting, naive bayes, and KNN are examples of commonly used machine learning algorithms that are implemented and assessed using accuracy, precision, F1 score, and recall. According to the authors, the SVM technique outperformed all other algorithms tested for this job. The authors classified tweets regarding Covid-19 pandemic using DL techniques [21]. They have investigated three traditional deep learning algorithms, CNN, RNN, and RCNN, and two hybrid algorithms, RNN+LSTM and RNN+Bi-LSTM with Attention. When coupled with GloVe and Word2Vec, the RNN+Bi-LSTM with Attention mechanism correctly classified tweets. The time taken to train and predict the accurate labels is more for RNN+LSTM when compared to other deep learning models.

The authors provide a different feature selection approach called Multivariate Relative Discrimination Criterion (MRDC) in this study to minimize dimensionality and feature space in order to enhance text classification performance [22]. The suggested technique focuses on reducing duplicate features by employing the notions of minimal redundancy and maximal relevancy. The suggested approach considers document frequency for each word while assessing its usefulness for that purpose. The suggested technique picks the characteristics with the highest relevance and considers the redundancy between them using a correlation metric. The authors discussed a deep learning strategy called HDLTex, which integrates various deep learning algorithms to create hierarchical classifications [23].

The authors' proposed architecture uses a mix of RNN at the top level and DNN or CNN at the bottom level to classify articles more accurately than standard SVM or Naive Bayes. The deep learning models were optimized using RMSProp and Adam to improve accuracy. The DNN has eight hidden layers. RNN was built using LSTM and GRU, and CNN with eight hidden layers. The authors have presented a comprehensive overview of the 150 classifiers introduced in recent years to accomplish this study's text categorization problems [24]. The work comprises 40 widely used datasets for text categorization. To improve the precision of text categorization, the authors proposed combining transformers and pre-trained language models with deep learning techniques. The work also establishes the grouping of 150 DL models into ten broad categories: feed-forward networks, CNN-based models, RNN-based models, Graph neural networks, hybrid models, etc.

## III. METHODOLOGY

Based on earlier efforts, it is clear that every neural network architecture has shortcomings, which can be addressed by combining other architectures to compensate for the deficiencies. Therefore, embedding layers of other architectures to the existing neural network model and their contribution to the model's performance has been studied in the present work. For example, the Long Short Term Memory (LSTM) layer [25-27] (Fig. 1) has the ability to remember long-distance relations when compared to Gated Recurrent Unit (GRU) [28-29] (Fig. 2).

Fig. 1. Long Short Term Memory Units.

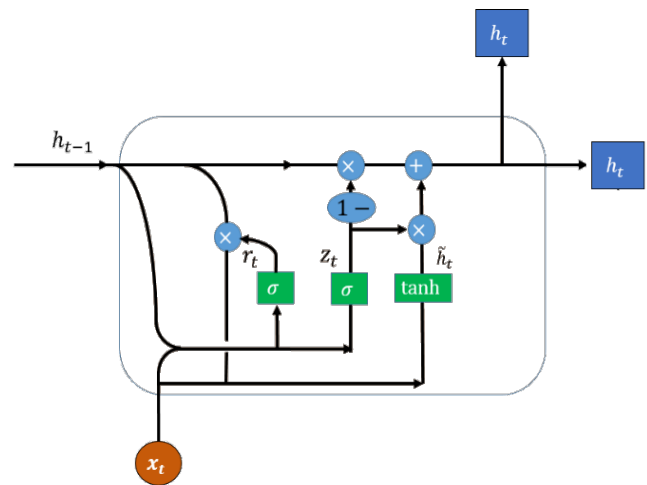

Fig. 2. Gated Recurrent Units.

The sigmoid function is used in both LSTM and GRU units, whereas the hyperbolic activation function in the output layer facilitates data retrieval even after a considerable amount of time. On the other hand, GRU is easy to train compared to LSTM, with a lesser number of data and a better performance than LSTMs. This motivates researchers to embed GRUs against LSTM when retrieval is not of great significance.

Three models are considered for the present study namely Recurrent Neural Network (RNN) [30-31] with GRU unit, RNN with LSTM as well as GRU units and Region-Based Convolutional Neural Network (RCNN) with LSTM layer. A conventional RCNN [32] model is modified by adding four LSTM layers along with the convolutional layers as indicated in Fig. 3, the performance of which is compared with two models comprising a typical RNN model with four GRU layers (Fig. 4) and RNN model with 3 LSTM layers and 2 GRU layers (Fig. 5). The LSTM layer used in RCNN and RNN architectures is a forgotten gate type and an input and output gate, as shown in Fig. 1.

The output gate layer is the most significant layer that enables long-term dependencies handling. The forget gate layer assigns a value based on the input vector of the current cell, the output vector of the previous and the previous cell state. This is also indicative that the forget layer carries out the decision of allowing the value to the input layer. The sigmoid neural function with a point-wise multiplication operator is used to generate values in the LSTM's forget gate layer. The Input gate layer is responsible for two tasks. The entering vector data is first updated using a sigmoid activation function, and the value created by the sigmoid activation function is then compared to the hyperbolic activation function. The new values obtained as a result of the comparison are combined with the prior cell state. The Output Gate Layer compares the input vector generated by the sigmoid activation function to the updated cell state generated by the hyperbolic activation function.

Whereas, irrespective of LSTM, a fully gated GRU comprises only two gates, viz. forget gate layer and an input gate. Though GRU is around half a decade old, it is preferred in specific, precise circumstances because they need a considerably smaller dataset and time for training the model. It can be observed that LSTM has a separate update gate and forget gate, rendering it more sophisticated. Therefore, the complexity of the LSTM paves the way for the usage of GRU, wherein the control on the model embedded with GRU units is better. Based on the earlier observations, three models are considered with LSTM, GRU, and LSTM-GRU units embedded, respectively, and their performances are evaluated. The training of the models is facilitated by the GloVE dataset [14], which can effectively capture syntactic and semantic representations of the words. The shortcoming of GloVE [33] is its inability to capture out-of-vocabulary words, which demands a considerable corpus to train the model, thereby eventually increasing the memory requirement. Though GloVE is similar to Word2Vec [34-35] in its operation, the weights associated with frequent word pairs will not pre-occupy the training process. The merits mentioned above support the usage of the GloVE dataset for training the models considered for the study.

Fig. 3. RCNN Model with LSTM Layers.

Fig. 4. RNN Model with GRU Layers.

Fig. 5. RNN Model with LSTM and GRU Layers.

## IV. EVALUATION

The evaluation of the models is carried out with the help of two parameters, viz. precision, and recall. Precision is the ratio of true prediction to a total number of predictions (Equation 1), while recall is the ratio of true positive to the sum of true positive and false negative. Though precision highlights the accuracy of the model, recall indicates sensitivity. An increase in precision reduces the number of false positives, increasing false negatives. Therefore increase in false negative decreases the recall value. It is undoubtedly a balance between precision and recall, which renders a valuable model for a given application as they demonstrate an inverse behavior. The cumulative effect of precision and recall are captured using the F1 score, which can be obtained by evaluating the area under the precision and recall curve plotted for both models. F1 score is the harmonic mean calculated from precision and recall values (eq. 3), which forms a significant metric to evaluate the performance of the models.

$$Precision\ (P) = \frac{True\ Positive}{True\ Positive + False\ Positive} \qquad (1)$$

$$Recall\ (R) = \frac{True\ Positive}{True\ Positive + False\ Negative} \qquad (2)$$

$$F_1 = 2\left[\frac{P\ X\ R}{P + R}\right] \qquad (3)$$

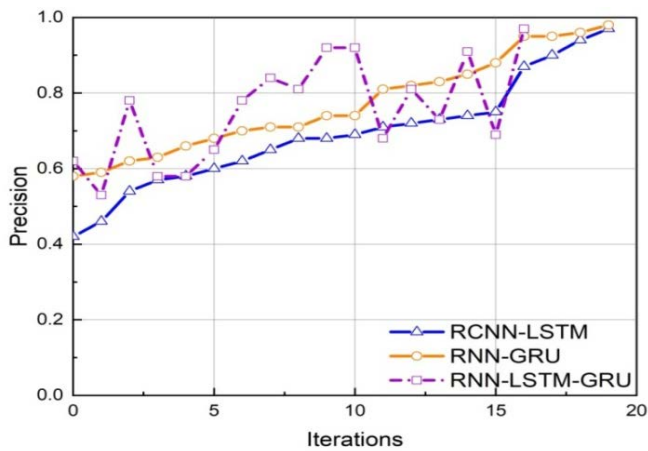

Fig. 6.    Comparison of Precision for RCNN-LSTM, RNN-GRU, and RNN-LSTM-GRU Models.

The results are plotted for the precision and recall as shown in Fig. 6 and Fig. 7, respectively. It is observed that the RNN model consistently outperforms the RCNN model. After the 18th iteration, hybrid RNN and RCNN provide almost the same precision and recall values. Hybrid RNN is embedded with GRU layers that can be trained for a lesser number of data and for a lesser time to generate a greater accuracy, as indicated in Fig. 6 and Fig. 7.

The recall precision curve is of great significance for assessing the performance of the RCNN-LSTM, RNN-GRU and RNN-LSTM-GRU model as shown in the Fig. 8, 9 and 10. The results obtained are plotted, for which the polynomial curve is fitted by using the least-squares method. The area under the curve (AUC) [36] indicates the F1 score for each model, thereby depicting the optimum blend of precision and recall of the model. The RCNN-LSTM model occupies a

larger area when compared to RNN-GRU and RNN-LSTM-GRU models, indicating a more extensive range of recall-precision values.

Fig. 7.    Comparison of Recall for RCNN-LSTM, RNN-GRU, and RNN-LSTM-GRU Models.

Fig. 8.    Variation of Precision with Recall for RCNN-LSTM Model.

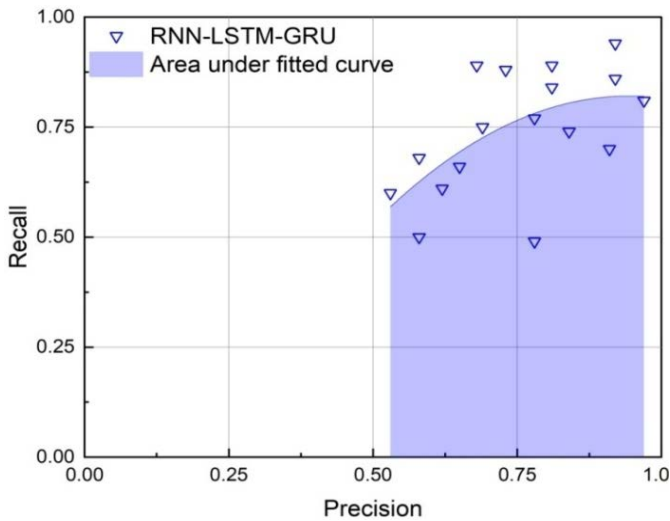
Fig. 9.    Variation of Precision with Recall for RNN-GRU Model.


Fig. 10. Variation of Precision with Recall for RNN-LSTM-GRU Model.

Fig. 12. Variation of Loss in values for RCNN-LSTM, RNN-GRU, and RNN-LSTM-GRU Models.

Fig. 11. Comparison of Accuracy for RCNN-LSTM, RNN-GRU, and RNN-LSTM-GRU Models.

Fig. 13. Comparison of Precision-Recall for RCNN-LSTM, RNN-GRU, and RNN-LSTM-GRU Models.

The comparison can be more clearly observed in Fig. 13, and the corresponding variations in the F1 score are indicated in Fig. 14. The average F1 score for RCNN-LSTM, RNN-GRU, and RNN-LSTM-GRU models are indicated in Table I. It can be observed that the RNN-GRU model outperforms RCNN and RNN-LSTM-GRU model by a margin of 10% and 4%, respectively. Since the GRU layers embedded in the RNN model require lesser time and smaller datasets for training, the F1 curve of the RNN model consistently dominates over RCNN and RNN-LSTM-GRU models. RNN-GRU model is embedded with the GRU layer, which cannot handle long-term dependencies. When long-term dependencies are of great significance, as is the case in text classification, RNN-LSTM-GRU is preferred the most, which carries the merits of both LSTM and GRU layers. RCNN has LSTM layers, which are capable of handling long-term dependencies; they take more significant time and more extensive data to get trained, which renders RNN-LSTM-GRU more suitable for text classification.

Also, Fig. 11 and Fig. 12 indicate the variation of accuracy with the normalized time. It can be observed that the RNN-GRU model and RNN-LSTM-GRU model perform almost the same after a normalized time of 0.75s. The accuracy of both the models is nearly the same, which is indicative that the RNN-LSTM-GRU can replace the RNN-GRU model to enable the retrieval of long-term dependencies. The difference in slopes over the initial normalized time from 0 to 0.6s is because of the presence of the LSTM layer in the RNN-LSTM-GRU model, which requires more time for training, while the GRU layer compensates for the initial delay by matching the slope when trained beyond a normalized time of 0.75s.

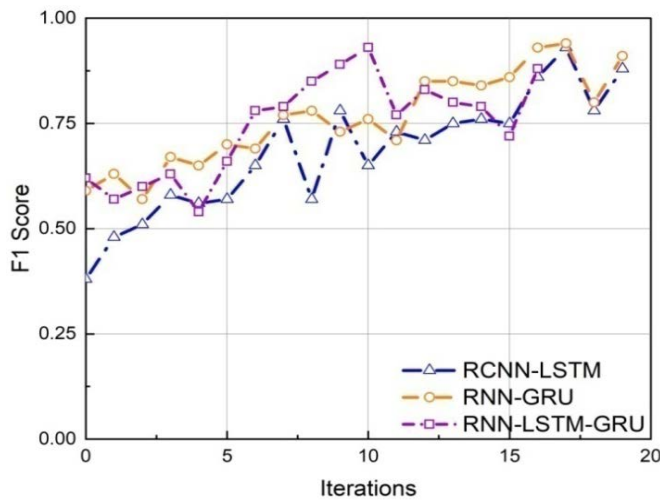
The area under the precision-recall curve gives the F1 score (Fig. 13). The variation of the F1 score for all three models is depicted in Fig. 14. Though the fluctuation of RNN-LSTM-GRU is considerably significant compared to RNN-GRU and RCNN-LSTM, the average F1 value is more significant than RCNN-LSTM and marginally less than RNN-GRU. The values are listed in Table I.


Fig. 14. Variation of F1 Score with Epoch for RCNN-LSTM, RNN-GRU, and RNN-LSTM-GRU Models.

TABLE I.    COMPARISON OF PRECISION, RECALL, AND F1 SCORE

| Model | Average Precision | Average Recall | F1 Score |
|---|---|---|---|
| **RCNN-LSTM** | 0.691 | 0.6825 | 0.682 |
| **RNN-GRU** | 0.7695 | 0.7615 | 0.7615 |
| **RNN-LSTM-GRU** | 0.7395 | 0.7163 | 0.7226 |

## V.    CONCLUSION

The present comprehensive study intends to address three text classification strategies by modifying the models and evaluating the performances in connect with precision and sensitivity. It is observed that the model selection for a given application is a trade-off among the variables such as time, dataset, and handling of the long-term dependencies, which define a suitable model for the application. Hence, RCNN with more accurate when compared to RNN with an ability to remember the dependencies, whereas RNN embedded with GRU has a shorter learning time which a smaller volume of the dataset can train. The average F1 score of RNN (4 layer model) is 0.77, whereas, for RCNN (8 layer model), the average F1 score is 0.69, which is around 10% less than RNN.

# Deep Learning Approach for Masked Face Identification

Maad Shatnawi, Nahla Almenhali, Mitha Alhammadi, Khawla Alhanaee

Department of Electrical Engineering Technology, Higher Colleges of Technology, Abu Dhabi, UAE

*Abstract*—Covid-19 is a global health emergency and a major concern in the industrial and residential sectors. It has the ability to spread leading to health problems or death. Wearing a mask in public locations and busy areas is the most effective COVID-19 prevention measure. Face recognition provides an accurate method that overcomes uncertainties such as false prediction, high cost, and time consumption, as it is understood that the primary identification for every human being is his face. As a result, masked face identification is required to solve the issue of recognizing individuals with masks in several applications such as door access systems and smart attendance systems. This paper offers an important and intelligent method to solve this issue. We propose deep transfer learning approach for masked face human identification. We created a dataset of masked-face images and examined six convolutional neural network (CNN) models on this dataset. All models show great performance in terms of very high face recognition accuracy and short training time.

*Keywords*—*Masked face human identification; face recognition; deep transfer learning; convolutional neural networks*

## I. INTRODUCTION

Covid-19 is a global pandemic that began in the year 2020 and has triggered a global health crisis and impacted a wide range of businesses, including education, aviation, health care, tourism, luxury shopping, religion, and so on. It had a significant impact on people's daily lives as well. Wearing a face mask in public areas, according to the World Health Organization (WHO), is one of the most effective preventative measures to stop the spread of disease and save lives [1]. Furthermore, several public service providers restrict customers to utilize their services while wearing facemasks that meet specific standards. However, due to the face mask covering the majority of the crucial facial characteristics, such as the nose and mouth, conventional face recognition systems used for security have proven ineffective in the current circumstance making it exceedingly challenging to identify the person [2].

The unlocking techniques based on passwords or fingerprints are risky since the COVID-19 virus can be transmitted through contact. Without touching, face recognition makes it considerably safer, but when wearing a mask, existing face recognition technologies become unreliable. To address the current challenges, it is essential to enhance the current face recognition techniques, which primarily rely on all facial feature points, so that identity verification may still be carried out with reliability even when faces are only partially revealed. [3]These systems recognize people identities without the need to take off the mask which can be used in hospitals, offices, educational institutes,

construction sites, manufacturing plants, airports, and in many other places. Masked-face recognition can also be used in attendance systems in schools, offices, and other working places.

Extensive studies enable the establishment of new datasets or masked face recognition. These studies significantly contribute since datasets of masked faces are correspondingly few and make it difficult to train suggested algorithms. There are several machine learning and deep learning techniques used to identify a face mask, some of which are based on enhanced pre-trained and existing models that all perform effectively [4].

Machine learning is a rapidly growing field of computational intelligence that seeks to emulate human learning from their environment. Computer vision, image recognition, speech recognition, natural language processing, and bioinformatics are some domains of machine learning. It is currently a primary competence of computer scientists. It includes computationally intensive methods, and is already widely utilized in the social sciences, marketing, systems engineering, and applied sciences. The degree of complexity of these systems can vary, and they may comprise multiple phases of complex human-machine interactions and decision making, which would naturally draw machine learning algorithms to enhance and automate various procedures. Numerous systems' efficiency and safety may be increased if machine learning algorithms had the potential to generalize from their current context and learn new tasks [5].

Deep learning is a type of machine learning that mimics the human brain's data processing to detect objects, recognize speech, translate languages, and make decisions. It is learning from both labeled and unlabeled data without the need for human interaction. Deep learning's capacity to handle large amounts of information makes it extremely powerful when dealing with unstructured data [6]. Deep learning has been effectively used to handle a broad variety of issues in the fields of image identification and natural language processing. It is based on neural network architectures with several layers of processing units [7].

Transfer learning is a type of machine learning in which a model is designed for one task and then utilized as the starting point for another task to be modified. People's ability to logically use previously acquired knowledge to solve new issues more quickly or effectively is what drives the study of transfer learning. Transfer learning is particularly beneficial in science as most real-world problems involve big amount of labeled data, demanding complicated models. Transfer learning can be used by developers to combine multiple applications

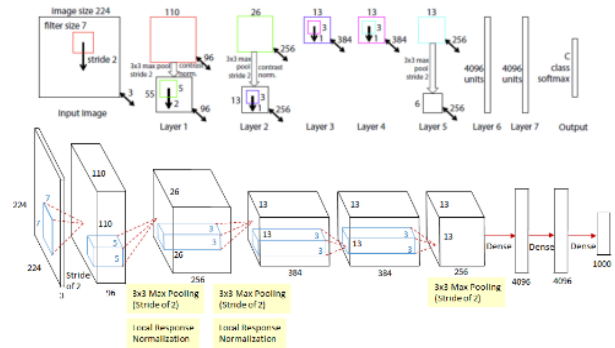
into one. Developers can also train new models for difficult applications quickly. It's also a useful tool for improving the accuracy of computer vision models [8].

This paper proposes a deep transfer learning approach for masked face recognition. We trained and tuned six convolutional neural network (CNN) models based on a masked face dataset.

## II. PRE-TRAINED NETWORKS

Pre-trained networks have various characteristics that are important to consider when choosing a network to perform a certain task. The most important performance measure of a network is accuracy, computational time, and memory size. Choosing a network is usually alternated between these functions. In this work, we have examined six pre-trained convolutional neural network models which are briefly explained in this section.

### A. SqueezeNet

SqueezeNet is an eighteen-layer deep convolutional neural network that can classify images into 1000 different classes. The network has learned sophisticated function representations for a wide spectrum of pictures. The goal of utilizing SqueezeNet is to create a smaller neural network with fewer datasets that can be more readily integrated into computer memory and transmitted across a computer network [9]. SqueezeNet architecture is illustrated in Fig. 1.


### B. GoogleNet

GoogleNet has twenty two layers with twenty seven levels dedicated to pooling. There are a total of nine initiation modules layered in a linear fashion. It also employs eleven convolution filters. The parallel network architecture significantly contributes to minimize computational time and memory requirements. GoogleNet architecture is illustrated in Fig. 2.

### C. AlexNet

AlexNet is one of the most widely used neural network designs nowadays. It's been used to train and classify millions of object images. The network input is 227×227×3 RGB images. AlexNet solves the over-fitting issue by using dropout layers. AlexNet architecture is illustrated in Fig. 3.
### D. ResNet-50

ResNet-50 is a 50-layer deep convolutional neural network that has been trained on over a million of images. The network has been pre-trained to classify images into 1000 different classes. The network input is 224×224×3 RGB images [10]. The network architecture is illustrated in Fig. 4.

### E. VGG-16

VGG-16 is one of the very deep convolutional networks for large-scale image recognition. In ImageNet, a dataset with over 14 million pictures divided into 1000 classes, VGG-16 model achieves 92.7% classification accuracy. The network input is 224×224×3 RGB images [11]. The network architecture is illustrated in Fig. 5.

Fig. 1. SqueezeNet Architecture.

Fig. 2. GoogleNet Architecture.

Fig. 3. AlexNet Architecture.

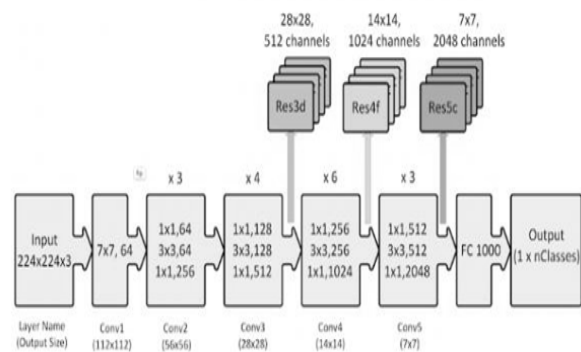


Fig. 4. ResNet-50 Architecture.
Fig. 5.    VGG-16 Net Architecture.

### F. MobileNet-V2

MobileNet-V2 was one of the first initiatives to create CNN architectures that could be readily implemented in mobile apps. Depth-wise separable convolutions, which are illustrated here, are one of the key advances. A separable convolution divides a single convolution kernel into two. Instead of a 3x3 kernel, we get a 3×1 and a 1×3 kernel, for example. It scales the image's input size from 224 to 128 pixels. You can train your MobileNet-V2 on 224×224 pictures and then use it on 128×128 images since it utilizes global average pooling instead of flattening [12]. The network architecture is illustrated in Fig. 6.

Fig. 6.    MobileNet-V2 Architecture.

## III. Current Approaches

The current face mask detection approaches are summarized and discussed in this section.

Cabani et al. [13] presented a dataset of correctly and incorrectly masked face images. Each set has 49 randomly sampled images, with 70,000 high-quality images in PNG and 1024 ×1024 resolution. The masked Face-Net dataset contained 139,646 images with 49% of correctly masked faces and 51% of incorrectly masked faces.

Mingjie et al. [14] proposed a Retina Face Mask method that uses transfer learning. The proposed method is a one-stage detector that combines a feature pyramid network with several feature maps to fuse high-level semantic information with a unique context attention module to focus on identifying face masks. The dataset has been split into a train, validation, and test set with 4906, 1226, and 1839 images individually; each

experiment operates 250 epochs. The Advantage of the method MobileNet-V2 backbone shows that transfer learning can increase the detection performance by 3 to 4% in face and mask detection results. Also, feature extraction ability is enhanced by utilizing pre-trained weights.

Loey et al. [15] presented a hybrid model with deep transfer learning and classical machine learning for face mask detection. The machine learning approach uses decision trees and Support Vector Machines (SVM) to classify face masks. Three face masked datasets have been selected for investigation. The decision trees classifier achieved 96% of validation accuracy. The SVM classifier achieved 98% of validation accuracy with the least time consumed in the training process.

Chavda et al. [16] presents a CNN-based architecture for detecting instances of incorrect use of face masks. The system uses transfer learning technique with three nets which are MobileNetV2, DenseNet121, and NASNet. The system classifies images into three classes: correct face mask covering, incorrect face mask covering and no face mask. The dataset is used from a pre-trained model in Kaggle for quick generalization and stable detection. The results and accuracy percentage of each net are: MobileNetV2 is 99.12%, DenseNet121 is 99.40%, NASNet is 99.13%. The advantages are high accuracy while having using less training data, the inference time is significantly shorter, and the system can be integrated with an image or video capturing device. On the other hand, the disadvantages are having a motion blur, dynamic focus and frame transition may face in video feed analysis.

Hariri [17] presents a masked face recognition technique based on occlusion removal and deep learning-based features. The system utilizes three pre-trained deep Convolutional Neural Networks (CNNs) to extract deep features from the resulting regions which are: VGG-16, AlexNet, and ResNet-50. This system is using two datasets which are, Masked Face Recognition Dataset (RMFRD), and Simulated Masked Face Recognition Dataset (SMFRD) that are from an open source [17]. The advantages are that the system obtained high accuracy compared to other face recognizers due to the best features extracted from the last convolutional layers of the pre-trained models, and the high efficiency. Recognition performance on RMFRD dataset obtained 91.3% accuracy, and SMFRD dataset is 88.9%.

Nagrath et al. [18] presented a method that uses deep learning, TensorFlow, Keras, and OpenCV to detect face masks. The SSDMNV2 method employs the Single Shot Multibox Detector as a face detector and the MobilenetV2 architecture as a framework for the classifier. The dataset used in this method is from Kaggle's Medical Mask Dataset (678 images) and the dataset available at PyImageSearch (1,376 images; wearing masks 690 pictures, and without wearing a mask, 686 pictures). The advantages are that SSDMNV2 is very lightweight and can even be used in embedded devices, it is useful method for real-time mask detection, and it achieved a high accuracy score of 92% which indicated a well-trained model.

Aswal et al. [19] presented two techniques that are used to recognize and identify masked faces. Using a single camera: A two-step process with a pre-trained one-stage feature pyramid detector network RetinaFace for localizing masked faces and VGGFace2 that generates facial feature vectors for efficient mask face verification; and (ii) a single-step pre-trained YOLO-face/trained YOLOv3 model on the set of known individuals. The dataset consists of 17 videos of individuals wearing face masks nearby. The dataset contains variations in orientation, scale, occlusions, illumination, and appearance. On their dataset, experimental results show that RetinaFace and VGGFace2 deliver state-of-the-art results in 1:1 face mask verification, with 92.7% overall performance, 98.1% face detection, and 94.5% face verification accuracy, respectively. The advantage of using transfer learning on YOLOv3 pre-trained the dataset is that the training process requires fewer images per class. And the YOLOv3 is a more advanced version of YOLO, Darknet-53, with shortcut connections for better GPU utilization, efficient evaluation, and faster performance. In comparison, the YOLO-face is to increases face detection performance at a fast detection speed.

Ding et al. [20] constructed two datasets created for masked faces recognition (MFR) for masked faces verification (MFV), which contains 400 pairs of 200 identities for verification, and masked faces identification (MFI), which contains 4,916 images of 669 identities for identification. A latent part detection (LPD) method is also developed for locating the latent facial part that is robust to mask wear. Extensive tests on the MFV, MFI and synthetic masked LFW data show that the LPD model outperforms alternative approaches. They use the LPD network, which has a level of accuracy of 94.34 %. There are two major drawbacks, when using these approaches to solve the MFR problem directly. First, the PFR techniques need the use of pre-defined partial face images as inputs, which are difficult to identify or define semantically in masked faces. Second, the PRF techniques disregard global signals such as chin contours in masked face images.

Most of the current approaches aims to detect whether an individual is wearing a face mask or not or to detect if the mask is worn in a correct way or not. There are few masked-face human identification approaches. This work proposes a deep transfer learning approach for masked face recognition that outperform existing approaches in terms of identification accuracy.

## IV. METHOD

### A. Dataset

We collected a dataset of 400 RGB images for ten human masked faces. Each individual class includes 30 images for the training and validation, and 10 images for the testing. Examples of the masked face data are illustrated in Fig. 7. The image sizes are in the range of 1.5 and 4 MB. We resized the images to match the required input dimensions of each of the six networks. SqueezeNet and AlexNet use $227 \times 227$ pixels, while GoogleNet, VGG16, and ResNet-50 use $224 \times 224$ pixels. However, MobileNet-V2 uses an input size of 128 to 224 pixels.

Data augmentation is a technique used in machine learning to expand the quantity of data by introducing slightly modified copies of available image data or newly created artificial data from real data. It functions as a preprocessing step and aids in the training of a machine learning model in order to reduce overfitting. Geometric transformation, flipping, color altering, cropping, rotation, noise injection, and random erasure are all examples of data augmentation techniques. We used data augmentation in our trained networks by acquiring many photos from various perspectives, surroundings and conditions, orientation, position, and brightness. The objective for this is to ensure that the output contains accurate predictions. We also applied several geometric transformations to the existing images to generate synthetic images. These transformations are random rotation in the range of -90° and +90° and random scaling in the range of 1 and 2.

### B. CNN Model Training and Validation

We trained and evaluated six pre-trained CNN models which are SqueezeNet, GoogleNet, AlexNet, ResNet-50, VGG-16, and MobileNet-V2. The training was performed using a single CPU. The validation was done in a 10-iteration process to ensure that the system is trained well without overfitting.

SqeezeNet training takes 33 minutes and 46 seconds. The network achieved a validation accuracy of 97.78% as illustrated in Fig. 8. GoogleNet training takes 46 minutes and 59 seconds and achieved a validation accuracy of 100% as illustrated in Fig. 9.

Fig. 11. ResNet-50 Training and Validation.

AlexNet training takes 38 minutes and 37 seconds and achieved a validation accuracy of 100% as illustrated in Fig. 10. Training the ResNet-50 network takes 115 minutes and 20 seconds and achieved a validation accuracy of 100% as illustrated in Fig. 11. Training the VGG-16 network takes 148 minutes and 50 seconds and achieved a validation accuracy of 100% as illustrated in Fig. 12. Training the MobileNet-V2 training takes 62 minutes and 20 seconds. The network achieved a validation accuracy of 100% as illustrated in Fig. 13.

50 as it achieved validation accuracy of 100% but in a long training time of 115 mins 20 sec. The fifth network is VGG-16 that has achieved high validation accuracy of 100% but in a very long training time. The lowest network performance was observed is in SqueezeNet because it provides the lowest validation accuracy among the six networks, but it took a very good training time, which is 33 minutes and 46 seconds.

### C. CNN Model Testing

The six CNN models were tested on unseen images from each of the ten classes; we tested the system on ten images for each class, the models output the predicted label and the confidence level of each prediction. Fig. 14 illustrates samples of testing results of each of the six models on three unseen images. All the six models have successfully identified all the images correctly with very high confidence level indicating that the six models achieve 100% recognition rate. The overall testing results are summarized in Table II. In the presence of the mask, the suggested method enhances the generalization of the face recognition process.

Fig. 12. VGG-16 Training and Validation.

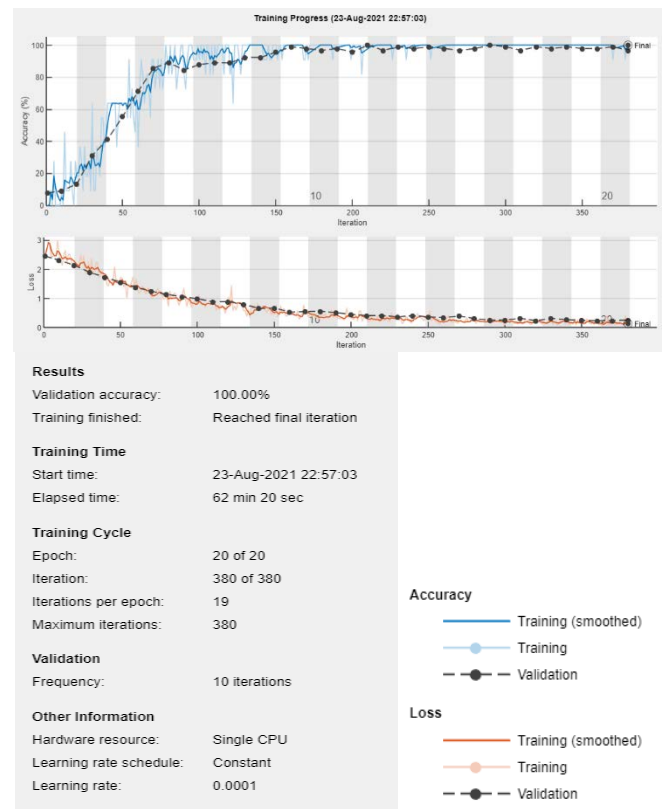

Fig. 13. MobileNet-V2 Training and Validation.

The training performance of the six CNN is summarized in Table I. According to the results, most of the nets achieved a very high accuracy, but when the training time is considered, AlexNet has the shortest training time. GoogleNet is the second-best model which achieved an accuracy of 100% with a reasonable training time of 46 mins 59 sec. However, MobileNet-V2 is the third-best model which achieved a validation accuracy of 100% with a good training time which is 62 mins 20 sec. Moreover, the fourth-best network is ResNet-

TABLE I. COMPARISON OF CNN TRAINING PERFORMANCE

| Model | Learning rate | Epochs | Validation Accuracy | Elapsed Time | Hardware Resource | Max. iterations |
|---|---|---|---|---|---|---|

## V. CONCLUSION

We propose a deep transfer learning approach for masked face recognition. We were able to find an appropriate pre-trained network models and utilize them as a starting point for fine-tuning and developing a deep neural network for a new image classification job using our training masked face data. We successfully utilized transfer learning to speed up training and increase the deep learning model's performance. We examined six convolutional neural network (CNN) models on this dataset. All models show great performance in terms of very high face recognition rate and short training time. The models are SqueezeNet, GoogleNet, AlexNet, ResNet-50, VGG-16, and MobileNet-V2.

These six models achieved validation accuracy between 97.8% and 100%. When tested on unseen data, all the models were able to identify all masked faces correctly with very high confidence level indicating that the six models achieve 100% recognition rate. The proposed approach is critical because it detects a person faster than the human eye, it is more accurate, and provides complete security. In the presence of the mask, the suggested method enhances the generalization of the face recognition process. The proposed approach can be applied in smart access systems and intelligent attendance systems in schools, hospitals, and various industries. The work can be expanded by evaluating more CNN models and by including more human masked-face image data.

The research opens up exciting new areas for study. The suggested method is not restricted to mask detection only and can be incorporated into any high-resolution video surveillance systems. A face mask may be used with the model to recognize facial landmarks for biometric applications. In future work, we anticipate being able to create our own network and provide it with the tools it needs to be well-trained to suggest a more extensive work.

*Abstract*—**Mobile Adhoc Network (MANET) is a fast deployable wireless mobile network with minimal infrastructure requirements. In these networks, autonomous nodes may function as routers. Due to the mobility of MANET nodes, the network's topology is dynamic. Recent scientific emphasis has been placed on MANET security. Few MANET attacks have been discussed in the existing literature. Wired networks provide more security choices than wireless networks. Most routing protocols fail in a MANET with a malicious node. This research focuses on S-DSR, a novel hybrid secure routing system that guarantees the delivery and performance of packets across network nodes. This protocol leverages neighbor trust information to choose the most secure route for file transfer. This protocol is used by OMNET++. It offers a higher delivery rate and lower delay than AODV, AOMDV, and other similar protocols. MANETs, or mobile ad-hoc networks, will be used in the future communication protocols of industrial wireless networks. These protocols will decentralise the connection of smart devices. Due to the unidimensional nature of digital data, it is impossible to apply encryption methods indirectly. These publications are digital. To strengthen the privacy of e-healthcare MANETs, a safe, lightweight keyframe extraction technique is required. The purpose of this project is to develop a secure protocol for MANET wireless networks. This study proposes the use of chaotic cryptography to enhance the security of MANET Wireless networks. Using Modified Self-Adaptive Sailfish Optimization (MSA-SFO), it is possible to construct vital maps in a chaotic setting. This method produces secure key pairs.**

*Keywords—MANET; sail fish optimization; energy; routing protocol*

## I. INTRODUCTION

One of the most often used kinds of independent wireless technology for communication with mobile nodes is called a MANET. Mobile ad hoc networks (MANETs) rely on mobile nodes to perform dual roles as end systems and routers for the network's packet transmissions [1]. Due to the fact that wireless communication is used, it is much simpler to reestablish the connection, and moreover, nodes might be designed to be mobile. Given the nature of the nodes, which is that they are movable, it is not required that a permanent network structure be used for communication. MANET, on the other hand, does not make use of base stations, which might be helpful in a number of different networking configurations. Due to the number of users using the MANET for diverse purposes, such as military and emergency operations, it is

crucial that the platform be safeguarded from unwanted users. This is due to the fact that the network's popularity has made it hard for illegal users to connect to it.

There are several uses for mobile ad hoc networks (MANETs), such as between special events, communications in places where radio infrastructure does not exist, catastrophes, and military surgery. MANET's flexibility and dynamic topology make it vulnerable to a variety of attacks, including eavesdropping, routing, and the modification of applications. The quality of services has been surpassed by MANET's security problems (QoS). So, the best way to ensure MANET's security is to use intrusion tracking, which modifies the system to notice any other vulnerability. Anti-intrusion detection is vital to providing safeguards and serves as an additional layer of security against unauthorized entry. In the presence and absence of a selective packet dropping attack, this solution was put to the test against the best-known practices [1].

Ad hoc network (MANET) is a grouping of nodes that communicate without the intervention of a central administrator in an infrastructure-free environment. The nodes in these networks are more dependent on each other to perform basic network activities. Secure routing is difficult to establish because of the shortage of resources. A system must be in place to deter misbehavior and preserve the network's synergy in order to assure safe routing. At each node, a partly distributed dynamic model is used to enhance the overall network's security and privacy. During route creation, additional information about network misbehavior is provided across the nodes as a precautionary step to maintain safe routing. In the real world, a node may engage in many forms of misbehavior at various points in time. To cope with nodes that show different levels of misbehavior, it offers a dynamic decision-making method. The model's ability to cope with misbehaving nodes has been shown in a series of simulations [2].

Unlike traditional networks, mobile ad-hoc networks (MANETs) are self-contained and do not rely on centralized access. MANET's rapid and flexible networking style allows it to be used in a broad range of situations. However, the network's constantly shifting architecture and open communication channels provide security risks. Active-routing authentication (AAS) was suggested in this work using the properties of active routing protocols. In order to prove the

AAS's effectiveness against selective forwarding, fake routing, byzantine, and spoofing attacks, we used BAN logic to examine the potential of hostile nodes mixing in a MANET [3][4].

The research problem and contribution of this research is to design a brand-new heuristic algorithm known as MSA-SFO by enhancing the already existing SFO algorithm's capacity for self-adaptation. This study was done with the intention of preserving users' privacy inside MANETs. This speeds up the process of convergence and decrease the likelihood of being stuck in a local minimum.

Paper organization is as follows:

The section outlines the format of this paper: The work that is connected to Optimal Energy Routing Protocol is shown in Section 2. This part also provides an explanation of the fundamental Routing Protocol for MANET techniques that were used throughout this research. The planned MSA-SFO-Modified Self Adaptive Sail Fish Optimization is described in Section 3, which reflects its current state. The analysis and discussion of the obtained data are presented in Section 4. Our results are summarised in Section 5, which also includes a discussion of the work that will be done in the future.

## II. RELATED WORK

Despite extensive deployment, the AOVDV routing scheme remains vulnerable to blackhole attacks. Lu and his team developed the SAODV protocol, a secure mechanism for routing networks, to overcome this problem. Due to the nature of a blackhole assault, which requires the cooperation of two nodes, it cannot be defended against using conventional protection measures. The BP-AODV protocol was created to solve this concern. It combines the features of the original AOVDV protocol with the BP-AODV to provide a secure and efficient routing system. A study of the BP-AODV protocol found that it can effectively repel a blackhole assault, regardless of whether it is launched by a forwarding node or a malicious actor. It also shows that BP-AODV may avoid a blackhole attack even if it happens throughout the whole routing procedure.

One of the most difficult and significant routing security concerns in VANETs and self-driving and connected cars is the detection of Black Hole attacks (ACVs). Cyber-physical paths may be hacked by malicious vehicles or nodes, converting a safe route into a less secure and dependable one. To avoid a neighboring node, malevolent nodes snatch data packets that may include emergency alerts and discard them instead [5]. When using MANETs, the nodes are on the move at all times. Macro-area networks (MANETs) have unique issues due to their inherent vulnerability to several types of security assaults and their inability to maintain secure operations while protecting their resources and providing safe routing among nodes. It is critical, therefore, to provide a reliable secure routing protocol to guard against anonymous attacks on nodes. Selfishness problems may now be studied, formulated, and solved using game theory. Malicious activity in networks is seldom detected using this technique. Instead, it focuses on the nodes' strategic and logical conduct. The dynamic Bayesian signaling game was utilized to examine the strategy profile of

normal and malicious nodes in our research. In this game, specific tactics for each node were also disclosed. Combining player payoffs and tactics to achieve perfect Bayesian equilibrium (PBE) serves as a popular solution for signaling games dealing with partial knowledge. For both ordinary and malicious nodes, the use of PBE techniques is private information. In order to avoid being detected, legitimate nodes should cooperate with routing and keep their payoffs up-to-date, whereas malevolent nodes take calculated risks to avoid being detected. The reputation mechanism encourages improved collaboration between nodes by reducing the utility of malevolent nodes. [6] Bayes rule-based belief updating systems are used by regular nodes to continually assess their neighbors.

Since the beginning of the previous decade, MANET has been a major research focus. As the Internet-of-of-Things (IoT) expands into urban areas, this sort of networking paradigm is becoming more widely accepted as an essential component of the IoT's impending urban applications. Existing routing techniques in traditional MANETs cannot be used with IoT because of a considerable hurdle. The MANET-based application linked to the IoT platform may be exposed to security threats as a result of this routing mismatch. In order to enable real-time streaming applications, the mobile nodes in this study must communicate multimedia signals. Understanding the attacker's unexpected behavior is one of the most important aspects of safeguarding data. Attackers' sophistication is examined in the present research. To perform fatal assaults, they know one other's identities and collaborate, which is seldom represented in current security modeling data. This study utilizes the modeling capabilities of game theory to represent the multiple-collusion attacker situation. Modeling strategies of regular/malicious nodes as well as employing an optimization technique utilizing innovative auxiliary information to build the best strategies are some of its contributions. Malicious nodes may now be accurately predicted by each normal node, thanks to the new model's enhanced capacity to do exact computations. Game theory's baseline method is outperformed by the suggested mathematical model in MATLAB simulations [7].

Intelligent Transportation Systems may benefit from the use of Vehicular Ad-hoc Networks (VANET), which are a subset of Mobile Ad-hoc Networks (MANET) (ITS). Due to quick topological changes, high mobility, and frequent link disconnections, routing in these networks is a difficult issue. Because of this, establishing an effective routing system that meets the time constraints and minimizes the amount of overhead is a challenge. VANETs must also be capable of identifying malevolent vehicles. Using Unmanned Aerial Vehicles (UAVs) may be a useful tool in dealing with these constraints. UAVs in VANETs may be used to aid in the identification of potentially harmful vehicles by operating in ad hoc mode and collaborating with the vehicles. There are two unique modes of routing data in the VRU routing protocol: (1) sending packets of data between vehicles using UAVs, and (2) routing packets of data between UAVs. Using the NS-2.35 simulator on Linux Ubuntu 12.04, the performance of VRU routing components in an urban setting is evaluated. VANET MobiSim, a generator of mobility, and MobiSim, a UAV

motion generator, are both used in the generation of vehicle movements. Comparatively, the performance study shows that the VRU protocol may increase the delivery and detection rates by 16 and 7 per cent, respectively, over existing routing protocols. End-to-end latency and overhead are both reduced by 40% using the VRU protocol [8].

Nodes in a mobile network self-organize into mobile ad hoc networks (MANETs), which develop a dynamic network architecture to link them. Before reaching its final node, data in a MANET must travel via a series of intermediate nodes. To keep malicious nodes from gaining access to this data, we need to have some kind of protection in place. Routing security has been addressed in a variety of ways in the literature, each of which addresses a distinct component of security [9].

Multipath routing, as compared to the conventional single-path routing, is often employed in wireless networks to increase their fault tolerance. The GAHC algorithm is a mix of the Hill-Climbing and Genetic Algorithms that takes into consideration all of the variables that influence route selection. In addition, an enhanced C-means algorithm was created to apply this method [10]. A computation is conducted based on the value of the nodes that fulfill the trust threshold for a certain route. The cluster heads then route their networks through other routes. The ideal route for their applications is then determined by analyzing these routes. MSA-SFO is a multi-path routing scheme with a maximum throughput of 0.85 bits per second and a 90 percent detection rate. Additionally, its packet delivery rate is 89 percent. To evaluate its performance, selective packet dropping was used [11].

Mobile ad hoc networks are well suited for emergency communications and rural locations lacking radio infrastructure. They may also be used for emergency communications. Nonetheless, owing to the network's changeable topologies, security is its most susceptible point. Due to the nature of the MANET's security challenges, it is advised that network managers monitor and identify possible attacks on a frequent basis, prior to them becoming severe. This may prevent them from influencing the performance of the system. The ability of a mobile node to forward packets is one of the most crucial aspects that might impact its performance [12]. This research intends to build a trust-based multi-path routing algorithm for usage in MANETs. The selected cluster heads based on the suggested method are next examined to find the appropriate application path. After calculating the trust levels of the nodes, the ideal path for the applications was determined. The cluster heads then route their networks using multi-hop routing. This approach calculates the ideal path based on several performance-affecting criteria.

Multiple Sub-Silo Order (MSA-SFO) is a multi-path routing technique that greatly outperforms previous algorithms. It may also lower network energy usage by around 80 percent. Due to its adaptability and portability, the mobile ad hoc network (MANET) is gaining popularity. Although security procedures have been implemented to secure the networks, they do not protect the communication channels. To provide total security, it is necessary to create both the communication

and routing protocols. The implementation of security procedures developed for wireless and wired networks may be particularly costly on MANETs due to their restricted network resources. This research attempts to create a secure architecture that can guarantee total network security. SUPERMAN, a proposed security framework, was evaluated against three distinct security protocols: IPsec, SAODV, and SOLSR. The simulation results demonstrated that the SUPERMAN architecture is optimal for wireless communication security. Due to the nature of the mobile ad-hoc network, a significant portion of its nodes are susceptible to assault. These nodes offer access to the network by unauthorized persons and organizations. In order to preserve the network's functioning, network administrators must routinely monitor and identify possible risks. The study provides a safe approach for selecting neighbors that combines machine learning and conventional routing techniques. By combining these strategies, it may be feasible to construct safe and dependable routes to a target. By observing the behavior of the nodes at changing connection levels, this technique may be implemented [13].

Various measures, such as the packet delivery ratio and the throughput, are used while evaluating the performance of a suggested method. The research demonstrates via experimental analysis that the suggested technique can perform consistently. Due to the nature of mobile ad hoc networks, it is becoming more challenging to create and maintain end-to-end infrastructure in specific places. As a consequence, DTN networks are becoming increasingly prevalent in these regions. DTNs are appropriate for high-latency applications, but they should also be considered for maritime networks. Due to the characteristics of the maritime environment, DTN networks are also addressed while addressing security issues. In order to provide tactical signals, for instance, the article demonstrates how to employ a DTN to address perimeter security issues. This study suggests utilizing the discriminant analysis to enhance the security of DTN connections. NDN is a future Internet architecture that permits the efficient delivery of the material as opposed to the standard data carriers. With its diverse forwarding techniques, NDN-based wireless networks are able to maintain safe and dependable communication. The two primary kinds of packets that NDN networks send back and forth are INTEREST and DATA. This study examines the strategies and issues found during the implementation of NDN-based networks such as MANETs, VANETs, WSNs, and WMNs [14].

## III. Proposed MSA-SFO-Modified Self Adaptive Sail fish Optimization

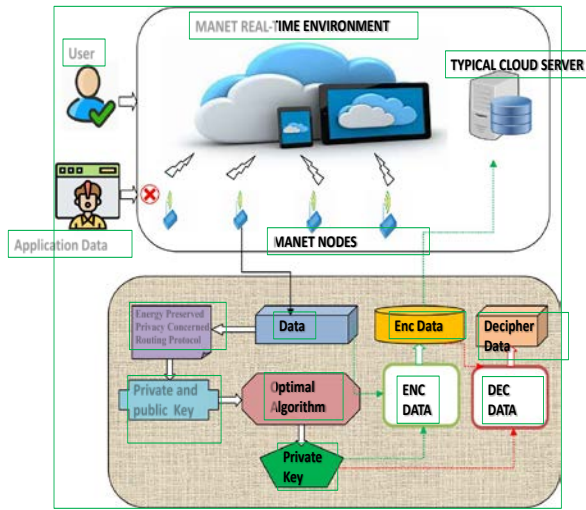
The mobile networks serve as the terminal service in the wireless MANET, which allows for communication between the different wireless network devices. This communication has completely transformed the digital age. Because of its widespread use across a wide variety of sectors and employees, it is essential to provide a protected setting for the communication process at all times. The computing platform at the network's edge is often targeted in MANET, which is designed for wireless networks. This has the effect of reducing the platform's popularity in crucial services.


Fig. 1.    Perspective on the Proposed MSA-SFO Architecture.

After the detailed analysis of the parallel and recent research outcomes, in this section of the work, the problem is formulated using the mathematical model.

In order for a network to have a long-life span, the cluster head must be replaced on a regular basis to ensure the security and the proposed architecture shown in Fig. 1.

At every moment, T(CH) signifies the cluster head determining function, which yields the cluster head instance g is a collection of groups. Any cluster has a total number of nodes known as N.

For the above lemma to hold, it must be shown (Eq. 1) that a cluster of nodes (Eq. 2) exists in the complete network, where the number of non-dead or active nodes is not zero.

$$\forall g \subset G \qquad (1)$$

And,

$$\varnothing(g) \neq NULL \qquad (2)$$

Also,

$$\forall n \subset N \qquad (3)$$

Consequently, Eq. 4 and 5 so that the newly picked cluster head may avoid being comparable to the previous one.

$$\forall n(t) \subset N' \qquad (4)$$

And,

$$N \notin N' \text{ and } N' \notin N \qquad (5)$$

If the R(k) represents the proportion of cluster heads in the N that are still available, then (Eq. 6) represents the percentage of cluster heads in the N that are still accessible.

$$1 - R(k)[\text{k} . \text{mod} \frac{1}{R(k)}] \qquad (6)$$

As a result, we can write the cluster dead decision function as follows:

$$T(CH) = \frac{R(k)}{1 - R(k)[\text{k} . \text{mod} \frac{1}{R(k)}]} \qquad (7)$$

The energy consumption is evenly distributed throughout the cluster's many components. In Eq. 5, the rationale for avoiding repeating clusters in subsequent eras is made evident.

The suggested algorithm for the control of energy consumption in clusters is presented in the following section:

Step (1). MSA-SFO serves as the foundation for the suggested approach. Before installing the cluster, the list of active nodes is compiled.

Step (2). After choosing it from the list of active nodes, the node's energy status is calculated. The node's status will be presented in the subsequent phase.

Step (3). For the time being, the cluster head will be chosen based on the weight function, which includes the amount of available energy and the number of non-repeating nodes. Cluster heads are referred to as CH.

Step (4). This data will be stored in the routing table RTab using the settings listed below in Step 4 of the installation process.

Step (5). After that the closest neighbour node will be determined, and the process will be repeated from steps 1 through 4.

Step (6). After deciding on a route, the data is sent. If the network topology changes, go back to step 1 to 5 and repeat the process.

It may have a larger delay than other algorithms, but it will be more secure and energy-conscious than others.

Further, based on the Proposed MSA-SFO algorithm, the obtained results are discussed in the next section of the work.

A Stepwise Procedure for the Protection of Privacy When Utilizing the Modified Self-Adaptive Sailfish Optimization (MSA-SFO) Algorithm

In order to provide a concise explanation of the technique for the suggested privacy preservation in the MANET environment, the following is provided:

*1) Data collecting* the first thing that has to be done in order to complete this procedure is to acquire the necessary data set from the MANET environment. Text messages are used to carry out communication amongst the various mobile devices that are part of a MANET. These mobile devices serve as the edge platform for the MANET. These text messages include vital information, and the privacy settings ensure that it will not be disclosed to unauthorized parties. The subsequent step is to compose the basic text. The text message is generated using the cluster's acquired data. The raw data contains a number of different characters and strings. To guarantee the appropriate formatting of the text message, each character is converted into a 16-digit number.

*2) If a 16-character-long text message* is deemed to be covered by the privacy policy. To convert it to a simple text, each letter is converted to a binary value of 16 bits. This number is subsequently converted into the text's length. After the plain text has been generated, the ideal key must be generated. This procedure is performed to enhance privacy protection. The key is then sent to the hybrid chaotic map that processes the text. Using the suggested approach, the fundamental parameters of the map are adjusted, and the optimum key is then generated.

*3) The encryption* of a data file occurs immediately after the generation of the key. This phase entails utilising the binary plain text as the encryption's foundation. The result of the encryption is stored on the cloud, and only the owner has access to it. The process of producing ciphertext is referred to as the binary extension-or operation.

*4) The decoding procedure* is executed to extract the file's data. The key and the binary representation of the encryption are then subjected to a kind of XOR to guarantee the integrity of the original data.

## IV. RESULTS AND DISCUSSIONS

The obtained results are highly satisfactory and are furnished in this section of the work.

The simulation results with 30 notes are formulated here (Table I).

Further, in the next section of this work, the research conclusion is furnished.

The performance of the suggested MSA-SFO, as well as the performance of the comparison heuristic models is stated by the measurements. Tables II, III, IV, V, and VI exhibit the statistical performance of the suggested MSA-SFO as well as the comparing methodologies for different character lengths, including 20, 40, 60, 80, and 100 correspondingly. And the results are visualized graphically shown in Fig. 3, 4, 5, 6 and 7.

In comparison to the PSO, GWO, and SFO, the MSA-SFO framework has achieved the highest values. Additionally, it is 48 percent greater than the average performance. In terms of plot count, the proposed structure is likewise 90% better than the simple parameters. In addition, it has been 60 percent better than the GWO and 50 percent better than the WOA.

## V.   CONCLUSION

MSA-SFO (Modified Self Adaptive Sail Fish Optimization) is a cluster-based routing method designed to increase the energy efficiency of current MANET routing algorithms. This research focuses on examining the different denial criteria of current algorithms. he researches compared the proposed system's performance to that of the current systems. Then, a performance study was conducted on the various systems, including the DSDV, DLSR, and FSR. It was discovered that the suggested strategy is more consistent and energy-efficient. The suggested algorithm, which has a 50 percent improvement in power awareness, serves as the foundation for a new algorithm designed to enhance the energy efficiency of current algorithms. In addition, a privacy preservation model was created to improve the security of MANET Wireless networks. The development of the suggested method has been significantly enhanced by the incorporation of the multi-state adaptive scheduling optimization approach (SFO). Utilizing this method, optimum key pairs were generated for the chaotic map. Messages were then encrypted and decrypted using the suggested technique. The development of the suggested method has been substantially enhanced by

the use of the multi-state adaptive scheduling optimization approach (SFO). Utilizing this method, optimum key pairs were generated for the chaotic map. It has also increased the degree to which text messages may be secured from prying eyes. To verify that the suggested algorithm can safeguard the privacy of sensitive data, the investigators altered the length of the text messages. The suggested method has acquired the highest performance values, which are much greater than those of the PSO, GWO, and SFO. It is also much superior than the maximum character count for text messages, which is 100. In terms of performance, the suggested method has enhanced its values by around 90 percent. According to the results, the suggested algorithm MSA-SFO provides more security for MANET Wireless networks than alternative models. It also provides a high degree of security. Implementation of the suggested technique on a large number of nodes will increase the scope of this investigation.

*Abstract*—Today, kidney medical imaging has become the backbone for health professionals in diagnosing kidney disease and determining its severity. Physicians commonly use Computerized Tomography (CT) and Magnetic Resonance Imaging (MRI) scan models to obtain kidney disease information. The significance and impact of kidney tumor analysis drew researchers to semantic segmentation of kidney tumors. Traditional image processing methodologies, in general, require more computational power and manual assistance to analyze kidney medical images for tumor segmentation. Deep Learning advances are enabling less computational and automated models for kidney medical image analysis and tumor lineation. Blobs (regions of interest) detection from medical images is gaining popularity in kidney disease diagnosis and is used widely in detecting tumors, glomeruli, and cell nuclei, among other things. Kidney Tumor segmentation is challenging compared to other segmentation models due to morphological diversity, object overlapping, intensity variance, and integrated noise. In this paper, It have proposed a kidney tumor semantic segmentation model based on CU-Net and Mask R-CNN to extract kidney tumor information from abdominal MR images. Initially, It trained the Custom U-Net architecture on abdominal MR images with kidney masks for kidney image segmentation. The Mask R-CNN model is then used to lineate tumors from kidney images. Experiments on abdominal MR images using Python image processing libraries revealed that the proposed deep learning architecture segmented the kidney images and lined up the tumors with high accuracy.

*Keywords*—*Kidney tumor (Blob) detection; custom U-Net; mask R-CNN; semantic segmentation; deep learning; medical image processing*

## I. INTRODUCTION

Medical imaging provides high resolution and coverage for the visualization of specific body organs. X-Ray, CT, MRI, and PET-CT scans are some frequently used medical imaging [1] technologies. In general, physicians will manually analyze the content of medical images to identify disease information. Image processing [2] and deep learning technologies [3] have been providing disease diagnosis models for over a decade, removing human errors in disease prediction. Deep learning for medical image analysis has attracted researchers and medical analysts because it requires less human intervention in data labeling and depth processing models than traditional image processing methods. Diseased

regions (biomarkers) in a medical image differ in properties (i.e., the contrast in brightness) from their neighbor pixels and appear as blobs in nature. These biomarkers or blobs are the regions of interest (ROI) in medical image diagnosis, and they must get identified, segmented, classified, and labeled to predict disease. Image analysis models based on deep learning will assist in detecting biomarkers in medical images and provide spatial information such as location, shape, scale, inertia, and convexity. The Blob (or image ROI) detection [4] allows disease diagnosis in many instances of the medical image diagnosis such as brain tumors, kidney glomeruli, eye retina, breast lesions, and cell nuclei detection, among others. Medical image biomarkers detection models are becoming prominent applications for physicians in disease conformation, staging, and treatment planning.

Due to the importance of biomarkers detection in medical image analysis, many former researchers were focused on this topic and proposed various deep learning models for medical image blobs detection. Although many scholars have worked on medical image diagnosis, some prominent literature aided us in selecting the objectives and designing the proposed system using deep learning technologies. Parvathi et al. [5] integrated deep learning and image processing algorithms to execute the blob detection and classification operations on kidney 3D MRI images. They used the ECLAHE and IMBKM models to segment the blobs from the input images and later the deep learning IMBKM and EDCNN classifiers to classify the blobs into the selected disease categories. Xu et al. [6] created a hybrid model that used a deep U-Net model and hessian analysis to detect small blobs in 3D MRI images for kidney glomeruli detection. They designed a superset of blobs using the hessian analysis to distinguish the real-convex blobs from the noisy ones. Their custom deep learning model UH-Net integrated the hessian superset information and the U-Net pre-training knowledge to find the glomeruli through small blobs detection from the 3D kidney MRI images. Peng et al. [7] proposed a multi-scale blob detection model for automated stem cell segmentation from the underlying microscopic image set. The cell boundaries are delineated with high accuracy using blob and centerline detection.

In the literature survey, it went through many research articles as part of the medical image disease prediction and identified some research gaps, which are as follows: Because

of the morphological diversity, segmenting the kidney object from the multi-organ medical image using shape and location information yields less accuracy. The traditional semantic segmentation approach, which may detect object categories in medical images, is insufficient because the medical image contains many instances of the same object type. Therefore, the instances must be categorized as it will.

Since kidney cancer became a major cause of kidney failure in people, our primary research goal was to detect kidney tumors from MRI images. To achieve this goal, it planned to segment the kidney objects from the MR first, and the lineation of the tumors from the kidneys is later. Image processing models (such as SIFT [8] and SURF [9]) and deep learning models (such as DNNs [10], CNNs [11], and Res-Net [12], among others) are the two different technologies used to segment the kidneys from CT images. Although each model has its pros and cons for kidney segmentation, it is interested in deep learning models because they are computationally cheaper and allow for high-level automation of the segmentation process. Unlike commonly performed object segmentation from images, kidney segmentation is a unique and challenging task, as shown in Fig. 1, because diseased kidneys segmentation has issues due to morphological diversity, object overlapping, intensity variance, and integrated noise.

Kidney tumor segmentation from MR images is a two-step process that includes kidney object (with tumor) segmentation and tumor object lineation. To accomplish the kidney tumor segmentation task and address segmentation issues (research gaps), in this paper, it proposed an efficient and optimal kidney tumor segmentation architecture using the custom U-Net and Mask R-CNN [13] deep learning models. The custom U-Net model is used first for kidney segmentation, and the Mask R-CNN model is used to lineate tumors from the segmented kidney images. The custom U-Net model is used first for kidney segmentation, and the Mask R-CNN model is used to lineate tumors from the segmented kidney images. To demonstrate the efficiency of the proposed kidney tumor segmentation model, a set of MR images collected from the TCGA-KIRC dataset and a python prototype is implemented to conduct the experiments.

## II. RELATED WORK

In this section, it will discuss the Key technologies that have been used in our kidney tumor semantic segmentation processes like CNNs [14], U-Net [15] and Mask R-CNN [13].

### A. CNNs

Recent advances in high-speed internet and mobile technology have resulted in a digital multimedia world with tons of images and videos. Computer vision is an emerging future domain, which is responsible for video and image manipulation as needed. Extracting useful information from an image is a complicated task because that needs to process a high volume of pixels. For over a decade, multi-layered deep learning models have made image processing easier than traditional methods. Because of their high accuracy and fully connected layers, Convolutional Neural Networks (CNNs) have proven to be the dominant deep learning model among the various deep learning models. As a descendant of Artificial Neural Networks (ANNs) [16], CNNs [14] will automatically train the feature maps from pixel arrays and identify the receptive fields through backpropagation using Key methods like convolution, pooling, and fully connected networks (FCN) [17].

*1) Convolution:* In general, the image is a collection of pixels, and these pixels will get converted into the respective intensity (RGB and grayscale) values for representation in a binary matrix model, which is feasible for manipulations. To manipulate the images with less computational overhead, they should be resized to a small size (down sampling) while retaining their receptive field (context) information. Convolution [18] is an affine transformation model in which the selected kernel matrix (filter) elements are iteratively multiplied against the input image matrix elements to generate the small-sized output convolved matrix. Fig. 2(a) represents the convolutional model with an input image (5x5x1) and the kernel (3x3x1) with a stride value of 2, and also the output convolved image (3x3x1). When it comes to the 3D images with RGB values, three color channels map with three different kernels for computations, and the final summation value is added with the bias to generate the convolved output image.

Fig. 2. Input Image Convolution and Pooling Model.

*2) Pooling:* In CNN, the convolution is followed it by a pooling [19] process, which mimics the behavior of the convolution process to reduce the convolved image spatial size at a high rate. Using either the max or average pooling method reduces computational overhead while learning and regulates over-fit issues. In Fig. 2(b), the average pooling method with a 2x2 filter and stride value of 2 is applied on a convolved image (4x4x1) to generate a pooled feature map (2x2x1). Like the convolution process, the pooling does not support the zero-padding at input feature map borders.

*3) FCN:* The FCN [17] is a feed-forward neural network model for multilayer perceptron that enables the backpropagation to learn the key features for classification across the epochs. The high-level features generated by the final convolution/pooling process are encoded using a single (flattened) vector and fed into the FCN. The FCN calculates the loss-entropy value for decision-making against classification uncertainty to reduce false positives in classification.

## B. U-Net

Ronneberger [15] designed U-Net, as it knows deep convolutional network architecture, for the semantic segmentation of objects from images, with high speed and precision. Extraction of the ROI is frequently required task in biomedical images, particularly for organ segmentation, objects localization. An efficient deep learning-based semantic segmentation model, such as U-Net, is required to achieve this ROI extraction. Compared to other CNN architectures [20], the U-Net is the most adaptive for medical image segmentation because of additional benefits such as pixel-level segmentation, limited training data, end-to-end training, pixel padding support, de-convolutions, and elastic deformation.

The two sections of the U-Net architecture are the contracting path (encoder part) and the symmetric expanding path (decoder part). The encoder part of U-Net, like convolutional networks, is continuous with convolutions and pooling methods to make the context more precise and sharper. This encoder reduces the dimensionality of the input feature without losing context, allowing the process to complete with less computation. The encoder performs the 3x3 convolutions iteratively till the pivot point. And after each convolution process, the batch normalization and the activation function [21] (Rectified Linear Unit (ReLU)) are applied with pooling strides for down-sampling, which helps in the précised context making. In contrast, the U-Net has a decoder part with a transposed convolution mechanism on the other side, making the U-Net an end-to-end FCN model. The encoder output is up-sampled [22] by the decoder using convolutions, batch normalizations, and ReLU activations. The decoder is intended to return the output with precise localization using the up-sampling process and transposed convolution.

## C. Mask R-CNN

As part of their research on AI, the Facebook AI Research Team (FAIR) introduced the instance segmentation framework called Mask R-CNN [10] as an extension to the Faster R-CNN [23] by adding the ROI segmentation masks. Compared to the other models, the Mask R-CNN is fast, simple, flexible, and accurate in instance segmentation is proven by the COCO - 2016 challenge. Mask R-CNN can segment the multiple instances precisely from the images, using image localization, object detection, and segmentation methods. Mask R-CNN architecture was designed by joining the Faster R-CNN with FCN model [24] for instance segmentation process.

Initially, a set of input images with different class objects are selected for instance segmentation. Deep CNN architectures [20] with convolution and pooling operations will extract the ROI bounding boxes from the input images. Unlike the Region-based CNN model, the Mask R-CNN had the ROI alignment phase, in which the exact spatial ROI volumes are identified from input images based on the input masks, using the pixel to the pixel alignment process. Mask R-CNN evaluates the ROIs from ROI-Pool and in parallel performs the target object detection to overcome the performance issues. Mask R-CNN evaluates the ROIs from ROI-Pool and in parallel performs the target object detection to overcome the performance issues. The bounding boxes are scaled using the Intersection over Union (IoU) metrics [25] after completing the ROI alignment process, and misinterpretations get eliminated using the feature matching threshold value. At this point, various class masks are applied to the coarse-grained bounding boxes to find the fine-grained segmentation. Finally, these fine-grained segmentations are precisely lineated and masked.

## III. KIDNEY TUMORS SEGMENTATION ARCHITECTURE USING CU-NET AND MASK R-CNN MODELS

In recent times, kidney tumor diagnosis from the medical images becomes a focusable research area due to its impact and importance in disease diagnosis and staging. The contribution of tumor detection is invaluable in cancer disease staging and treatment (especially in targeted therapy) planning. Researchers are interested in medical image analysis using deep learning models over traditional image processing techniques to reduce the computational (i.e., hardware) difficulties [26] in medical image processing. It is discussed in Section I that the kidney tumor diagnosis from MRI images faces several issues since this process differs slightly from the regular object segmentation and lineation process. To address the issues involved with the kidney tumor semantic segmentation process, It designed an efficient and optimal deep learning architecture (shown in Fig. 4) using the Custom U-Net [10] and Mask R-CNN models for kidney image segmentation and the tumor instance lineation from medical MR images. Kidney tumors can be segmented [27] from the medical MR images in two phases: Kidney(s) segmentation from MR images and tumors boundary lineation from kidney images.

## A. Kidney Segmentation Phase

The process of extracting kidney images (with tumors) from MR scan images is known as kidney segmentation [28]. Later these extracted kidney images are used for tumor detection and its boundary lineation. For this, it selected a set of abdominal MR images and their associated ground truth values (masks) as a training dataset (shown in Fig. 3) for the experimental analysis. However, extracting the kidney context from the MR images is a complex process due to several reasons. Because of the cancer disease [29], the shape of the kidneys is inconsistent in nature and different from one other, which will make the network's training process difficult. Because the MR scan images are collected from different MR scanners, the intensity of the input images varies, which is incompatible with many deep learning networks. In addition to kidneys and other organs, noisy data is often present in MR scan images, making the object detection process more complex.

*1) Custom U-Net:* To solve these challenges in the kidney extraction process, it used the custom U-Net [10] model, a trained convolutional neural network that is suited for medical image segmentation. U-Net model [15] was selected over the other CNNs [21] because the U-Net supports the classification at pixel level and is suitable for the multi-class instance labeling if required. Due to the systematic hurdles [30] involved in data collection and processing, obtaining a dataset with tons of images and masks is impossible related to medical images. U-Net is a light-tight model because it can train efficient models with limited training datasets. Unlike trained nets [20] such as LeNet-5 and Dense DNN, the U-Net is free from dense layers and thus accepts input data with intensity variance.

It designed a custom U-Net model with additional features by extending the traditional U-Net to support kidney object segmentation with high accuracy. Our custom U-Net model is designed with a validation set to ensure test accuracy. By adjusting the hyper-parameters at validation time, the custom U-Net tunes the deep model to achieve high accuracy in test results. CU-Net was enhanced with data augmentation techniques such as image flips and others to double the size of the input dataset to generalize the training model. Dropout regularization functions it added to CU-Net during the training phase after each max-pooling operation to randomly replace neurons (pixels) with zero values and train the model with alternative neural networks to minimize overfitting.

Fig. 3. An Abdominal MR Image (356 x 356) with Kidney Tumor (Left) and its Ground Truth Image for Training (Right).

*2) Dataset model:* A set of total $'n'$ MR scan abdomen images $\underline{I} = \{I_1, I_2, I_3 \ldots I_n\}$ containing multiple organs with dimensions $D = [d_1, d_2]$, pixels $P = (p_1, p_2)$, are presented in a binary matrix model $M = [m_p \; x \; m_q]$. In our dataset, an image $I_1$ is having the greyscale pixel $(i_1(P))$ with its pixel value is represented as $0 \leq i_1(P) \leq 255$. Mask image set Ḿ is a set of total $'n'$ masks with information about kidneys with tumors segmentation, and it maps with their original MR images for training. The mask image set $Ḿ = \{M_1, M_2, M_3 \ldots M_n\}$ along with its label information $L$ is presented as $M_k = \{(M_k, L) \in I_k \; \& \; L = 1\}$.

*3) Training Custom U-Net:* Once the data is defined and available in hand, the next immediate step in Custom U-Net is the data preparation. It classifies the data into a training set $\underline{I}_\alpha$, validation set $\underline{I}_\beta$, and test set $\underline{I}_\gamma$. It used the validation set $\underline{I}_\beta$ in the training phase to assess the model accuracy and to detect the overfitting problems [31] at the training phase itself. After partitioning the data set into train and test sets, a custom U-Net model with a contracting path and an expensive path was designed. The U-Net model is symmetric, with four layers of processing at each path. The 2D_convolution, max pooling, and dropout functions are implemented in the contracting path, whereas the transpose convolution, concatenate, and dropout functions are implemented in the expensive path, as shown in Algorithm 1. In U-Net, the contracting path's four layers are executed first, with convolution, max pooling, and dropout functions, and the results are passed to the next layer in the path. The convolution function increases the context of the input image $\underline{I}_{in}$, which helps in target feature extraction, using the neurons $(z)$, kernel $(k_{m*n})$, stride $(s_{m*n})$, activation function $\varphi$, an array of 4 channels $\mu = [1, 2, 4, 16]$, and padding $p$ elements.

Down sampling [22] is a spatial dimensionality reduction method that reduces image height and width to make the image computationally feasible. After executing the convolution process twice, the resulted image volume is given as input to the max-pooling function to reduce the dimensionality of the image without losing the context. The ideal pool size $(e_{m*n})$ is selected and evaluated against the convolved image $C_i$ to create the max pooled image $Q_i$. After max pooling, dropout functions with a frequency rate $(f_{rate})$ (0.0 - 1.0) are executed during the training phase. This function randomly sets the input pixels to zero, which helps to prevent values from dropping during the training phase and keeps the model from overfitting. This step completes a layer of the contracting path, and it will take four repeats to complete the entire contracting path. Soon after the contracting path completes, the convolution process will be repeated twice with the double neurons $(\mu)$ of the contracting path's last layer to build the connection $(C_m)$ it has two paths.

Like the contracting path, the expensive path had four layers with transposed convolution, concatenation, dropout, and convolution functions but executed in backward direction. The Con2DTrans function performs the de-convolution process to reverse the convolution processes using the specified stride $s_{m*n}$, kernel $k_{m*n}$, and other attributes. The

de-convolved image $D_i$ is concatenated with its counterpart convolution image $C_i$ to increase the dimensions. Dropout function can by the convolutions restores the image with equal dimensions of its counterpart contracting path layer. The same process will be repeated four times to conclude the expensive path execution. Finally, the single neuron and the 1x1 kernel-based convolution process will be executed to return the output image $I_{out}$ with sharpened target context. In this manner, our proposed custom U-Net model is trained against the input image set to obtain the segmentation knowledge, which helps in validation and testing operations.

---

**Algorithm-1: Custom U-Net Model Algorithm**

**Input:** $I_{in}, k, s, p, z, \varphi, e_{m*n}$
**Output:** $I_{out}$
**Method:**
$cn_1, cn_2, cn_3, cn_4, \mu = [v_1, v_2, v_3, v_4]$
*// contracting path*
for i=1 to 4 do
$C_i = con2D( (z * \mu [i-1]), k_{m*n}, \varphi, p)( I_{in})$
$C_i = con2D( (z * \mu [i-1]), k_{m*n}, \varphi, p,)(C_i)$
$cn_i = I_{in}$
$Q_i = Max\_Pool(e_{m*n}, C_i)$
$Q_i = D\_Out(f_{rate})(Q_i)$
$I_{in} = Q_i$
end // for
*// connected layers*
$C_m = con2D( (z * \mu [3] * 2), k_{m*n}, \varphi, p)( I_{in})$
$C_m = con2D( (z * \mu [3] * 2), k_{m*n}, \varphi, p)( C_m)$
$\mu = [v_4, v_3, v_2, v_1]$
*// expensive path*
for i=4 to 1 do
$D_i = con2DTrans( (z * \mu_{i-1}), k_{m*n}, s_{m*n}, \varphi, p)( C_m)$
$D_i = concat(D_i, C_i)$
$D_i = D\_Out(f_{rate})(D_i)$
$D_i = con2D( (z * \mu [i-1]), k_{m*n}, \varphi, p)( D_i)$
$D_i = con2D( (z * \mu [i-1]), k_{m*n}, \varphi, p,)(D_i)$
$C_m = D_i$
end //for
$I_{out} = con2D( 1, k_{1*1}, \varphi, p,)(cn_1)$
return $I_{out}$

---

Regular classification models treat the validation set as an optional activity because it consumes more time for validations. But in our custom U-Net segmentation process, it generated the validation set $I_\beta$ to monitor the model performance and hyper parameters tuning [32] according to the requirements. After the training process designed a segmentation model $\omega$, the validation set $I_\beta$ assesses the model performance at the training phase itself and fine-tunes the parameters through the backpropagation method if required. At the test phase, these fine-tuned models will assure the précised ROI segmentation. Due to the complexity involved in pixel-level processing, the medical image training may encounter the overfitting [31] problem, which arises when the trained segmentation model performance is specific and bounded to the training dataset only. In this case the trained model yields the best results on training data $I_\alpha$ but it fails to segment the test data $I_\gamma$. To overcome this over fitting issue in segmentation, it customized the U-Net to compare the trained model segmentation accuracy on both the training and validation datasets. The precision difference between both

datasets will be compared against the over-fit threshold($\delta$) to confirm the overfit or the difference in performance $\mathbb{D}$ is shown below.

$$\mathbb{D} = \frac{1}{k} \sum_{i=1}^{k} \omega(I_\alpha) - \omega(I_\beta) \ \{ if \ \mathbb{D} \geq \delta \ than \ overfit \}$$

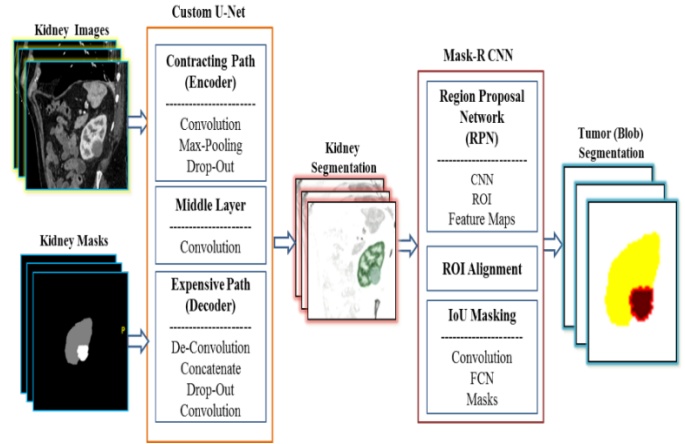

Fig. 4. Kidney Tumor Blob Instance Segmentation Architecture using CU-Net and Mask R-CNN Models.

*B. Tumor Segmentation and Boundary Lineation*

Because the kidney images (including tumors) it used to train the Custom U-Net based kidney segmentation model (shown in Fig. 4), the trained U-Net model returns segmented kidney images with tumors as a result. The tumor instances from the kidney images should be lineated and masked to find the tumor instance boundaries. Some prominent solutions include threshold-based segmentation, edge detection segmentation, feature clustering, bounding box, and ROI extraction. Among them, it selected Mask R-CNN [13], a fast, simple, and generalized ROI-based segmentation model for the target tumor object selection and precise segmentation (lineation) process. Stones, glomeruli, and tumors, etc. may appear as blobs in kidney imaging. Mask R-CNN detects a variety of blob objects on existing kidney images using the bounding boxes, and then the target tumors are identified using the shaded masks.

Convolution is used to extract feature maps from kidneys with tumor instances, and the Region Proposal Network (RPN) [23] is applied to the feature maps to generate bounding boxes for the target tumor blob. Based on the ROI volume, the bounding boxes are selected for further processing. ROI volume is evaluated using the Intersection over Union (IoU) approach, which compares the bounding boxes with the ground truth labels for ROI presence estimation. FCN has been used to detect the blob structures and mask them with the selected bounding boxes. Compared to the other segmentation models, this Mask R-CNN is lighter, faster, and reliable for pixel-level semantic segmentation.

IV. EXPERIMENTAL ANALYSIS

To conduct the experiments on the proposed kidney tumor semantic segmentation architecture with CU-Net and Mask R-CNN models, it collected a set of 30 kidney MR images from

the TCGA-KIRC dataset [33]. Images with 360x360 pixels and their corresponding masks (shown in Fig. 2) are extracted from these MR images for training and testing. The proposed Custom U-Net and Mask R-CNN based tumor segmentation architecture was implemented using the Keras-2.4.3 python interfaces on the TensorFlow-2.3.0 platform.

First, the MR image dataset is preprocessed and partitioned into train and test datasets, as explained in Section III. Train dataset images are transformed into two-dimensional binary arrays using the pixel data transformation methods for further processing. The images are now resized to 320x320 pixels for process compatibility with the custom U-net model. The contracting path and expensive path of the CU-Net are designed using convolutional and max-pooling methods respectively from the Kera's library. The proposed Custom U-Net model with the input layer and output layer uses the binary cross-entropy [34] as loss function and Adam's optimizer [35] for accuracy calculation with the prediction results. The dataset was augmented using image flips and other techniques to generate a set of synthetic data images derived from the core MR images. This step will increase the training data size by 2x more than the actual size to handle the overfitting issue in the classification process. Along with the data augmentation techniques, early stopping feature is also introduced to stop the training process at the appropriate time to avoid the over fit and under fit issues in training. To regularize the learning rate across multi epochs the learning rate reducing techniques also applied with CU-Net model. By specifying the epochs and the batch sizes for training process, the CU-Net model is trained on MR images to generate the efficient model for kidney image detection and segmentation.

The kidney segmentation binaries obtained from the Custom U-Net have been used as input to the Mask R-CNN model, which extracts tumor data. Mask R-CNN extracts objects from input images using bounding boxes and aligns the extracted objects using ROI information. Soon after the object localization using the bounding boxes alignment process, Mask R-CNN starts the pixels level comparison using the FCN to lineate the objects with specified shade masks. In Fig. 5, the kidney tumor segmentation results are shown along with the input images, masks, CU-Net kidney segments, and Mask R-CNN tumor lineation.

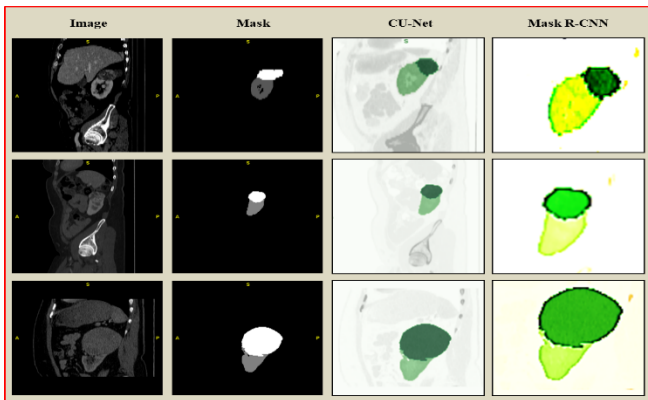

Fig. 5. Kidney Tumor Segmentation Results from the Experiments on Custom U-Net and Mask R-CNN Model.

Finally, the proposed model results have been evaluated using the loss and accuracy metrics from the prediction results on the test dataset. It adjusted the training and validation dataset proportions to test the accuracy and IoU metrics, and the results from the proposed architecture with CU-Net and Mask R-CNN are shown in Table I.

TABLE I. KIDNEY TUMOR SEGMENTATION ACCURACY AND IOU RESULTS

| Data Partition | IOU | Accuracy |
|---|---|---|
| TD-70% and VD-6% | 0.875 | 0.912 |
| TD-75% and VD-8% | 0.913 | 0.941 |
| TD-65% and VD-15% | 0.849 | 0.877 |
| TD-60% and VD-20% | 0.831 | 0.819 |

Fig. 6 depicts the generated validation results accuracy and loss value across multiple epochs for the proposed Custom U-Net model. The experimental results show that the proposed Custom U-Net and Mask R-CNN model is optimal, and it efficiently lineated blobs like kidney tumors with high lineation precision and segmentation accuracy.

Fig. 6. Proposed Segmentation Model Results Accuracy and Loss Values across the Epochs.

## V. DISCUSSION

For starters, this model allows for the use of global location and context at the same time. Second, it works with fewer training samples and outperforms other segmentation algorithms. Mask R-CNN outperforms all existing single-model entries on every task. Faster R-CNN is extremely efficient, with only a minor overhead added. Mask R-CNN can be easily adapted to other tasks.

## VI. CONCLUSION

In this paper, it proposed the kidney tumor segmentation architecture with Custom U-Net and Mask R-CNN models. U-Net model is customized to overcome the kidney object segmentation issues like morphological diversity, object overlapping, intensity variance, and training overfit. Mask R-CNN is chosen to accurately lineate the tumor boundaries and segment (mask) the instances. The proposed architecture is used to train a set of MR scan images of kidney cancer, and the results are presented with the metrics IoU and accuracy. The experiments yielded high accuracy and IoU in kidney tumor segmentation and masking.

# GonioPi: Towards Developing a Scalable, Versatile, Reliable and Accurate Handheld-Wearable Digital Goniometer

Thomas Jonathan R. Garcia, Dhong Fhel K. Gom-os

Center for Research in Intelligent Systems, Department of Computer Science
University of the Philippines Cebu, Cebu, Philippines

*Abstract*—Range of Motion (ROM) Testing is an important physical examination performed in physical therapy used in assessing the ROM of a patient's joint. The most commonly used instrument for ROM Testing is the universal goniometer. The most common cause for unreliable and inaccurate joint angle ROM measurements is measurement errors. Multiple studies have been done to mitigate measurement errors in clinical goniometry by designing and developing wearable digital goniometers using sensor technology. This study aims to design and develop a handheld-wearable digital goniometer called the GonioPi that is versatile, scalable, reliable and accurate when using the MPU-6050 IMU sensor and Raspberry Pi Pico as the main components. The results showed that the GonioPi is versatile and scalable as it is able to support multiple ROM Tests using multiple different positions on people with varying heights, weights, and BMI categories. The results also showed that the GonioPi is reliable and accurate as it was able to record joint angle ROM measurements of less than 5 degrees and 10 degrees which are the accepted standard values for reliability and accuracy, respectively.

*Keywords—Range of Motion (ROM); goniometer; physical therapy; goniometry; wearable; sensors; MPU-6050; Raspberry Pi Pico*

## I. INTRODUCTION

Range of Motion (ROM) Testing is one of the important physical examinations performed in physical therapy and rehabilitative sciences. ROM Testing can be used to identify a patient's underlying conditions to help with diagnosis and rehabilitative treatment.

A goniometer is the most used instrument for ROM Testing. It is used to measure the angle of a patient's ROM at a joint. Goniometers have different types that vary in shape and size depending on which joint is being tested. The most used goniometer are the short arm and long arm universal goniometers. These universal goniometers are still analog which lead to the most common complication in clinical goniometry – measurement errors. Errors in measurement can be caused by systematic errors such as improper technique, improper use of the instrument, the instrument being used, or visual estimation when an instrument is not available. These measurement errors result in unreliable and inaccurate joint angle ROM measurements. A universal goniometer is considered reliable, its mean joint angle ROM measurement should be < 5 degrees [1, 2]. Moreover, it was shown that

universal goniometers have a minimum significant difference of 10 to 14 degrees which is considered unreliable and inaccurate when used to measure joint angle ROM [3].

To mitigate measurement errors in clinical goniometry, wearable digital goniometers using sensor technology has been designed and developed by some [4, 5]. Wearable devices using sensor technology in physical therapy and rehabilitative science have shown high reliability and accuracy when used for the application of clinical goniometry. However, gaps in the research can be seen with other factors of the devices such as versatility, scalability, and cost-efficiency.

Previous attempts to develop wearable digital goniometers using sensor technology are neither versatile nor scalable. These studies only considered some of the 34 different ROM tests [6] such as wrist flexion and extension, forearm supination and pronation, radial deviation, and ulnar deviation [7, 8]; elbow joint [9 ,10]; hip flexion [11]; and knee flexion and extension [12]. There is no study which attempted to develop a scalable and versatile digital goniometer - one that can support all possible ROM tests in multiple different positions on people with varying heights, weights, and BMI categories.

Developing a scalable and versatile, not just an accurate and reliable, digital goniometer is important in the field of clinical goniometry [13]. Such an instrument will provide a dependable single device to users without the need to use multiple different instruments to perform different ROM tests. This reduces cost and eliminates the need to train in multiple different instruments.

Therefore, this research aims to design and develop a versatile and scalable handheld-wearable digital goniometer with the use of affordable components that is at the same time accurate and reliable in terms of joint angle ROM measurements when performing ROM Testing. The device is referred here as GonioPi – a portmanteau of the word's goniometer and Raspberry Pi, the microcontroller used to develop the device.

## II. REVIEW OF RELATED LITERATURE

### A. Physical Therapy and Clinical Goniometry

Physical therapy and rehabilitative science is a field of medicine that focuses on the care of patients with medical conditions related to movement and health. Patient care in this

field is done by physical therapists by providing services that prevent or limit dysfunction.

The concepts of kinesiology and goniometry are important in the field of physical therapy and rehabilitative science as they focus on the study of human motion and joint angle measurements [6, 14]. Moreover, both these concepts are important in identifying and assessing medical conditions related to muscle performance and neurological function [14].

Clinical kinesiology and goniometry involve range of motion which is a technique used to examine the angle created at a joint to assess the need for physical rehabilitation [15, 16]. This is done through different types of range of motion tests such as flexion, extension, abduction, adduction, and rotation among others. Reliable and accurate range of motion tests are needed in diagnosing, assessing, evaluating, and tracking of a patient's physical rehabilitation progress.

### B. Range of Motion Instruments

A patient's range of motion can be assessed with the use of different range of motion instruments with the universal goniometer being the most used. Other instruments include the gravity-dependent goniometer (inclinometer), electrogoniometer, and visual estimation [14]. Although these manual instruments (universal goniometer, inclinometer, and visual estimation) are inexpensive, the common issue shared by these instruments are their susceptibility to systematic errors which lead to measurement errors. Electrogoniometers on the other hand, provide better accuracy and reliability as they use electronic components. However, this instrument is often used for the purposes of research rather than in the clinical setting because it is expensive.

### C. Wearable Devices using Sensor Technology for Clinical Goniometry

The emerging trend of wearable electronics has extended into the field of medicine with fitness trackers like the Fitbit being the most sold product in the commercial market. Wearable devices are categorized as electronic devices that can be worn, embedded, or implanted in a person's body or clothing. In healthcare, specifically, wearable devices should perform a specific medical function [17]. Wearable devices that monitor biochemical measurements, blood oxygen saturation, blood pressure, cardiac activity, and respiration are currently used in the clinical settings [18].

Wearable devices along with other technologies such as video games and consoles, virtual and augmented realities, exoskeletons, and robots have influenced the medical specialty of physical therapy and rehabilitative science. Over the past decade multiple studies focusing on wearable devices using sensor technology in physical therapy and rehabilitative science have been published [13]. The most used types of sensors in these studies were flex sensors, inertial measurement unit (IMU) sensors, hall-effect sensors, magnetometers, and e-textile and stitched sensors [5]. The studies presented that all these types of sensors have high accuracy and reliability when used for clinical goniometry. However, it is important to consider the advantages and disadvantages of these sensors with regards to other factors such as versatility, scalability, and cost-efficiency.

### D. Applications of the MPU-6050 IMU Sensor for Clinical Goniometry

Based on the acquired information from the related literature of wearable devices using sensor technology, it was clear that IMU sensors were the most suitable type of sensor for the design and development of a digital goniometer since they were not limited in versatility, and they had high reliability and accuracy. Thus, the MPU-6050 IMU sensor was chosen as the specific IMU sensor for this research.

The MPU-6050 IMU sensor has multiple applications for both non-medical and medical purposes. The MPU-6050 IMU sensor is used widely across different fields for different purposes utilizing the sensor's 6 degrees of freedom (DOF) with its 3-axis accelerometer and 3-axis gyroscope.

Focusing specifically on the applications of the MPU-6050 IMU sensor for clinical goniometry, related literature has explored the sensor's use in devices that measure the joint angle ROM of the fingers, wrist, forearm, elbow, hip, and knee mostly focusing on the motions of flexion and extension. A data glove for finger joint measurement using three MPU-6050 IMU sensors coupled with two 2.2-inch flex sensors connected to an Arduino microcontroller with all the components sewn onto a cloth glove was used for finger joint flexion – the results showed that the use of MPU-6050 IMU sensor for the device was highly accurate as it recorded low percentage of error ranging from 0.81% to 5.41% [19]. This study only considered fingers, wrist, forearm, elbow, hip, and knee and mostly focused on the motions of flexion and extension. It can be said that the developed device is not versatile. It also did not mention testing for different body sizes, so its scalability is not proven.

Two related studies using the MPU-6050 IMU sensor on a wearable device focused on the ROM Tests of wrist flexion and extension, forearm supination and pronation, radial deviation, and ulnar deviation – the results of both studies were considered reliable since all the ROM Tests recorded joint angle ROM measurements with a standard deviation of < 5 degrees [7, 8]. Similarly, these two developed devices, although found to be reliable, are not versatile. There was also no mention in the studies if the devices were tested for scalability as only one or two test subjects were able to test them.

Another two related studies used the MPU-6050 IMU sensor on wearable devices for the elbow joint [9 ,10]. The first study focused on the ROM Tests of elbow flexion and extension as well as forearm supination and pronation while the second study only focused on the ROM Tests of elbow flexion and extension. The wearable devices of both studies were also considered reliable as they were also able to record average standard deviations for joint angle ROM measurements of < 5 degrees. Both studies also did not consider versatility and scalability, although the devices are found to be reliable.

A study that focused on measuring pelvic retroversion during hip flexion used two MPU-6050 IMU sensors connected an Arduino microcontroller that were attached to elastic Velcro-like straps recorded an average angle of 7.30

degrees which is considered reliable for pelvic retroversion – with this result the researchers concluded that the MPU-6050 IMU sensor was considered reliable when performing the ROM Test of hip flexion [11]. The device, however, cannot be considered versatile or scalable. Although 12 testers tested the device, the BMI categories of the testers were not known.

Finally, a custom physical activity and knee angle measurement sensor system for patients with neuromuscular disorders and gait abnormalities was developed using two MPU-6050 IMU sensors and an 8-bit RISC microprocessor attached to a knee sleeve [12]. The wearable device was used to perform knee joint angle measurements for the ROM Tests of knee flexion and extension and the results were considered reliable as the recorded data showed a standard deviation of < 5 degrees when compared to ground truth data recorded from an electromechanical goniometer. The study did not consider versatility and scalability.

Overall, the MPU-6050 IMU sensor is highly reliable and accurate in measuring joint angle ROM for the application of clinical goniometry. However, it can also be seen with the related literature that the developed wearable devices were limited in versatility and scalability since they generally conform to only some joints or body segments.

## III. METHODOLOGY

The methodology includes the design, development, testing, and evaluation of the GonioPi and its Assisted Mode feature. The design and development of the GonioPi focuses on achieving high reliability and accuracy as well as satisfying the factors and requirements of versatility and scalability.

### A. Design and Development of the GonioPi

The design of the GonioPi is comprised of three parts – the digital goniometer, the acrylic case, and the wearable attachable container.

The digital goniometer is the main component of the GonioPi. It is the instrument that allows users to perform ROM Tests and measure joint angle ROM. To satisfy the factors and requirements of versatility and scalability, the design of the GonioPi's digital goniometer considered components that would allow the MPU-6050 IMU sensor to measure reliable and accurate joint angle ROM measurements. Moreover, these components would have also been of a small and compact form factor. Therefore, the components of the GonioPi's digital goniometer were composed of the Raspberry Pi Pico microcontroller, MPU-6050 IMU sensor, Waveshare Dual GPIO Expander, Waveshare 1.14" LCD Display, DIYMORE 18650 Battery Shield V8, and two 18650 Li-ion rechargeable batteries.

The GonioPi's acrylic case also aimed to satisfy the factors and requirements of versatility and scalability when the GonioPi is used for both its handheld and wearable configuration. Considering that the components of the GonioPi's digital goniometer were chosen since they satisfied the factors and requirements of versatility and scalability, then the goal was to create a case design in which its dimensions were enough to enclose the assembled digital goniometer while maintaining the versatility and scalability of the device.

Furthermore, it was taken into consideration that the components of the GonioPi's digital goniometer, especially the MPU-6050 IMU sensor, should be visible to the user in order to avoid errors in placement when positioning the GonioPi on a specific joint or body segment. Thus, the GonioPi's acrylic case was made with 3mm acrylic sheets precisely cut using a CNC machine. The dimensions of the GonioPi with its acrylic case are 7.16cm (length), 6.30cm (width), and 11.20cm (height). Fig. 1 shows the GonioPi with its assembled digital goniometer enclosed in the acrylic case.

The GonioPi's wearable attachable container still aimed in satisfying the factors and requirements of versatility and scalability.

Considering that the GonioPi's digital goniometer enclosed in its acrylic should have already satisfied the factors and requirements of versatility and scalability, then the goal was to create a wearable design that would maintain the versatility and scalability of the device. Thus, the GonioPi's wearable attachable container had a pouch-like design made of synthetic fabric, specifically spandex lined with fusible interfacing, with an adjustable buckle strap. The adjustable buckle strap of the GonioPi's wearable attachable container has a length of 133cm which allowed it to fit from the waist and chest body segments all the way down to the wrist joint. Fig. 2 shows the GonioPi inside its wearable attachable container.

Fig. 1.    GonioPi with Assembled Digital Goniometer in the Acrylic Case.

Fig. 2.    GonioPi's Wearable Attachable Container.

Finally, dual-axis tilt calculation was used to calculate and output the tilt angle measured by the MPU-6050 IMU sensor. Dual-axis tilt calculation was done by solving for the ratio of the inverse sine of the x-axis and inverse cosine of the y-axis [20]. Equation (1) shows the formula for dual-axis tilt calculation. Equation (2) shows the formula to solve for the angle (theta) using dual-axis tilt calculation. With this implementation, the GonioPi was able to output angle measurements from 0 degrees to 180 degrees when it is tilted either clockwise or counterclockwise on the x-axis or z-axis.

$$\frac{A_{X,OUT}}{A_{Y,OUT}} = \frac{1\,g \times \sin(\theta)}{1\,g \times \cos(\theta)} = \tan(\theta) \tag{1}$$

$$\theta = \tan^{-1}\left(\frac{A_{X,OUT}}{A_{Y,OUT}}\right) \tag{2}$$

### B. Assisted Mode Feature

The Assisted Mode feature of the GonioPi has the main functionality of outputting responsive feedback to the user when the GonioPi is used to measure joint angle ROM. The feature uses the factors of age and gender to give the user feedback if the joint angle ROM measured is BELOW NORMAL, NORMAL, or ABOVE NORMAL.

The Assisted Mode feature was implemented using a finite state machine which utilized a nested switch case algorithm. The factors of age sex, type of joint, type of motion, and normal range of motion are used to assess the measured joint angle ROM.

### C. Initial Device Testing

The initial device testing of the GonioPi was performed independently by the researchers with the aid of a test subject to identify the supported ROM Tests of the GonioPi. This was done using both the handheld and wearable configurations. Since the researchers are not professionals in the field of physical therapy, a criterion stating that a ROM Test was considered initially supported by GonioPi if the device was able to output a joint angle ROM with a minus 5-degree threshold from the maximum value of the full ROM of a specific joint. Fig. 3 shows the researchers performing the initial device testing on a test subject.

### D. Final Device Testing

The final device testing of the GonioPi consisted of confirming which ROM Tests were supported by the GonioPi using both the handheld and wearable configurations, reliability and accuracy testing, and an evaluation of the GonioPi and its Assisted Mode feature. The final device testing of the GonioPi was performed by eight medical professionals, specifically physical therapy interns, grouped into four pairs. Fig. 4 shows the final device testing of the GonioPi performed by the testers.

### E. Final Device Testing for Confirmed Supported ROM Tests

The final device testing for confirmed supported ROM Test was done by making the testers use the GonioPi to perform a specific ROM Test on their partner. The testers were then asked to record if whether a specific ROM Test was either supported or unsupported by the GonioPi. Considering that the testers were professionals in the field of physical therapy, the decision of labeling whether a specific ROM Test was

considered supported or unsupported by the GonioPi was purely based on the tester's assessment of the device when using it in both its handheld and wearable configurations respectively.

The results recorded by the medical professionals were then collected and tallied. A specific ROM Test was then confirmed to be supported by the GonioPi if 60% or five out of eight testers labeled it as supported, otherwise it was confirmed to be unsupported by the GonioPi.

### F. Final Device Testing for Reliability and Accuracy

The final device testing for reliability and accuracy of the GonioPi was limited to the ROM Tests of flexion and extension for the shoulder, elbow, hip, and knee. The GonioPi's reliability and accuracy were evaluated using the statistical methods of standard deviation and significant difference, respectively.

Fig. 3. Initial Device Testing of the GonioPi.

Fig. 4. Final Device Testing of the GonioPi.

It is important to note that the ROM Tests of shoulder and elbow flexion and extension were performed using the in sitting position, the ROM Test of hip flexion was done using the supine position, and the ROM Tests of hip extension as well as knee flexion and extension were done using the prone position.

The testers measured the joint angle ROM of each ROM Test being tested for reliability five times on their partner. Once the data was gathered and collected, the standard deviation for a specific ROM Test of each test subject was computed by the researchers. This was done for both the handheld and wearable configuration. The average standard deviation for each ROM Test was then computed by the researchers using the values of the individual standard deviation for a specific ROM Test of each test subject.

An average joint angle ROM measurement of <= 5 degrees must have been achieved by the GonioPi for it to be considered reliable when performing a specific ROM Test, otherwise it was considered unreliable.

The accuracy of the GonioPi was evaluated using significant difference. A Bland Altman plot using 1.96 multiplied by the standard deviation generates a 95% confidence interval for evaluating a ROM Test [3]. Thus, the GonioPi's accuracy for each ROM Test was solved by multiplying 1.96 with the values of the average standard deviation of each ROM Test collected from the GonioPi's reliability testing.

An average joint angle ROM measurement of <= 10 degrees must have been achieved by the GonioPi for it to be considered accurate when performing a specific ROM Test, otherwise it was considered inaccurate.

### G. *Versatility and Scalability of the GonioPi*

Versatility is the ability of a device to perform multiple ROM Tests on different joints using different types of motions and scalability is the ability of a device to handle different body sizes [13].

The versatility and scalability of the GonioPi were evaluated based on the results of the GonioPi's final device testing for the confirmed supported ROM Tests. Versatility of the GonioPi was evaluated based on the number of ROM Tests supported by the GonioPi – specifically considering how many out of the 11 joints and 15 motions were supported by the GonioPi using its handheld and wearable configurations, respectively. Scalability of the GonioPi was also evaluated based on the number of ROM Tests supported by the GonioPi – specifically considering the varying heights, weights, and BMI categories of the test subjects.

### H. *Evaluation of the GonioPi and the Assisted Mode Feature*

Both the GonioPi and its Assisted Mode feature were evaluated through a survey with a series of qualitative questions. The GonioPi was evaluated based on its perceived usefulness, perceived ease of use, emotions, attitudes, and comfort. The Assisted Mode feature was evaluated based on its importance, usefulness, helpfulness, and design.

## IV. RESULTS AND DISCUSSION

The results and discussion include a general overview of the results for initial device testing as well as the evaluation of the GonioPi and its Assisted Mode feature. Meanwhile, detailed results of the final device testing for the confirmed ROM Tests of the GonioPi and device reliability and accuracy testing are presented.

### A. *Results of the Initial Device Testing*

The initial device testing of the GonioPi showed promising results for both the handheld and wearable configurations. Majority of the ROM Tests for both configurations were considered initially supported by the GonioPi using multiple different positions based on the set criterion. Specifically, the handheld configuration supported 30 out of 34 ROM Tests and the wearable configuration supported 21 out of 34 ROM Tests. With these promising results, it was evident that final device testing with medical professionals had to be performed to confirm the supported ROM Tests of the GonioPi.

### B. *Results of the Final Device Testing of the GonioPi for Confirmed Supported ROM Tests*

The results for the final device testing of the GonioPi for the confirmed supported ROM Tests of the GonioPi showed that using its handheld configuration, the GonioPi supports 34 out of 34 ROM Tests using multiple different positions such as supine, prone, in sitting, and standing. Notably, all 34 ROM Tests were unanimously confirmed to be supported by the testers.

Furthermore, using its wearable configuration, the GonioPi supports 18 out of 34 ROM Tests using multiple different positions such as supine, prone, in sitting, and standing. The other 16 ROM Tests were confirmed by the testers to be unsupported by the GonioPi when used as a wearable device. Out of the 16 ROM Tests confirmed to be unsupported by the testers, 8 of which consists of the wrist and ankle joints – these were the ROM Tests of wrist flexion, wrist extension, ulnar deviation, radial deviation, ankle dorsiflexion, ankle plantarflexion, ankle inversion, and ankle eversion. These ROM Tests were considered unsupported by the testers because the GonioPi's size was too bulky when attached to these joints which did not allow the testers to properly position the device to perform these ROM Tests. Moreover, the testers stated that the bulkiness of the GonioPi also impeded the movement of the joint when attached to the test subject. Four ROM Tests, specifically cervical extension, cervical lateral flexion, trunk flexion, and trunk extension were considered unsupported by the testers because the GonioPi could not output joint angle ROM measurements that were satisfactory for the testers to consider them supported. Moreover, the testers stated that due to the bulkiness and weight of the GonioPi, testing these ROM Tests using the wearable configuration was greatly affected by gravity. The GonioPi in in its attachable container would sag which affected the joint angle ROM measurement being outputted by the GonioPi. Also, for the ROM Tests of trunk flexion and extension the testers stated that they could not position the GonioPi using its attachable container properly on the test subject's body. Finally, the last 4 ROM Tests, specifically forearm supination, forearm pronation, hip abduction, and hip adduction – these

ROM Tests were considered unsupported by the testers because the GonioPi's sensor does not work and could not output a proper joint angle ROM measurement when attached to the body segment or joint of these ROM Tests as the sensor was oriented on the y-axis. The GonioPi's dual-axis tilt calculation implementation only allows for it to output angle measurements when the sensor is oriented on its x-axis or z-axis.

Table I shows a summary of all the confirmed supported and unsupported ROM Tests of the GonioPi both using its handheld and wearable configurations.

TABLE I.    SUMMARY OF THE CONFIRMED SUPPORTED ROM TESTS FOR HANDHELD AND WEARABLE CONFIGURATIONS

| GonioPi Final Device Testing Results | | |
|---|---|---|
| **Range of Motion Test** | **Handheld** | **Wearable** |
| 1.   Cervical Flexion | (8/8) Supported | (7/8) Supported |
| 2.   Cervical Extension | (8/8) Supported | (1/8) Unsupported |

| 34.  Ankle Eversion | (8/8) Supported | (0/8) Unsupported |

## C. Results of the Final Device Testing for Reliability and Accuracy

The results of the final device testing for reliability presented that the GonioPi using the handheld configuration is reliable for 6 out of the 8 ROM Tests that were evaluated. Specifically, the ROM Tests of shoulder flexion, shoulder extension, elbow flexion, hip extension, knee flexion, and knee extension. The GonioPi was considered reliable in performing these ROM Tests because their individual average standard deviations when using the GonioPi in its handheld configuration was <= 5 degrees. As for the ROM Tests considered as unreliable, specifically elbow extension and hip flexion – they were considered unreliable because their individual standard deviations were > 5 degrees. However, it is important to note that for the ROM Test of elbow extension the average standard deviation was only greater by 0.13 degrees and for the ROM Test of hip flexion the average standard deviation was only greater by 0.41 degrees.

Moreover, using the wearable configuration, the GonioPi is reliable for 5 out of 8 ROM Tests that were evaluated. Specifically, the ROM Tests of shoulder extension, elbow flexion, elbow extension, hip flexion, and knee extension. The GonioPi was considered reliable in performing these ROM Tests because their individual average standard deviations when using the GonioPi in its handheld configuration was <= 5 degrees. As for the ROM Tests considered as unreliable, specifically shoulder flexion, hip extension, and knee flexion – they were considered unreliable because their individual standard deviations were > 5 degrees. However, it is important to note that for the ROM Test of shoulder flexion the average standard deviation was only greater by 0.91 degrees. Furthermore, for the ROM Test of hip extension the average standard deviation was only greater by 0.47 degrees and for the ROM Test of knee flexion the average standard deviation was only greater by 0.35 degrees.

Table II shows a summary of the results for the GonioPi's reliability testing.

Considering the accuracy testing of the GonioPi for the 8 ROM Tests being evaluated was dependent of the average standard deviation values for the GonioPi's reliability testing, it was expected that the results would be consistent in the sense that the ROM Tests considered reliable were also accurate and the ROM Tests considered unreliable were also inaccurate.

Therefore, for the handheld configuration the 6 ROM Tests of shoulder flexion, shoulder extension, elbow flexion, hip extension, knee flexion, and knee extension the GonioPi was accurate in performing these ROM Tests because their individual significant differences were <= 10 degrees. As for the 2 ROM Tests of elbow extension and hip flexion, the GonioPi was inaccurate in performing these ROM Tests because their individual significant differences were > 10 degrees. However, it is still important to note that the significant difference for the ROM Test of elbow extension was only greater by 0.05 degrees and for the ROM Test of hip flexion the significant difference was only greater by 0.60 degrees.

TABLE II.　SUMMARY OF THE AVERAGE STANDARD DEVIATIONS FOR RELAIBLITY TESTING USING THE HANDHELD AND WEARABLE CONFIGURATIONS

| GonioPi Reliability Testing Results for Handheld Configuration | | |
|---|---|---|
| Range of Motion Test | Average Standard Deviation | Remarks |
| Shoulder Flexion | 4.01° | Reliable |
| Shoulder Extension | 3.64° | Reliable |
| Elbow Flexion | 4.42° | Reliable |
| Elbow Extension | 5.13° | Unreliable |
| Hip Flexion | 5.41° | Unreliable |
| Hip Extension | 4.61° | Reliable |
| Knee Flexion | 4.06° | Reliable |
| Knee Extension | 4.87° | Reliable |
| GonioPi Reliability Testing Results for Wearable Configuration | | |
| Range of Motion Test | Average Standard Deviation | Remarks |
| Shoulder Flexion | 5.91° | Unreliable |
| Shoulder Extension | 4.18° | Reliable |
| Elbow Flexion | 3.74° | Reliable |
| Elbow Extension | 4.36° | Reliable |
| Hip Flexion | 4.17° | Reliable |
| Hip Extension | 5.47° | Unreliable |
| Knee Flexion | 5.35° | Unreliable |
| Knee Extension | 4.85° | Reliable |

TABLE III.　SUMMARY OF THE SIGNIFICANT DIFFERENCE FOR ACCURACY TESTING USING THE HANDHELD AND WEARABLE CONFIGURATIONS

| GonioPi Accuracy Testing Results for Handheld Configuration | | |
|---|---|---|
| Range of Motion Test | Average Significant Difference | Remarks |
| Shoulder Flexion | 7.86° | Accurate |
| Shoulder Extension | 7.13° | Accurate |
| Elbow Flexion | 8.66° | Accurate |
| Elbow Extension | 10.05° | Inaccurate |
| Hip Flexion | 10.60° | Inaccurate |
| Hip Extension | 9.04° | Accurate |
| Knee Flexion | 7.96° | Accurate |
| Knee Extension | 9.55° | Accurate |
| GonioPi Accuracy Testing Results for Wearable Configuration | | |
| Range of Motion Test | Average Significant Difference | Remarks |
| Shoulder Flexion | 11.58° | Inaccurate |
| Shoulder Extension | 8.19° | Accurate |
| Elbow Flexion | 7.33° | Accurate |
| Elbow Extension | 8.55° | Accurate |
| Hip Flexion | 8.17° | Accurate |
| Hip Extension | 10.72° | Inaccurate |
| Knee Flexion | 10.49° | Inaccurate |
| Knee Extension | 9.51° | Accurate |

Moreover, for the wearable configuration, the 5 ROM Tests of shoulder extension, elbow flexion, elbow extension, hip flexion, and knee extension the GonioPi was accurate in performing these ROM Tests because their individual significant differences were <= 10 degrees. As for the 3 ROM Tests of shoulder flexion, hip extension, and knee flexion, the GonioPi was inaccurate in performing these ROM Tests because their individual significant differences were > 10 degrees. However, it is also still important to note that for the ROM Test of shoulder flexion the significant difference was only greater by 1.58 degrees. Furthermore, for the ROM Test of hip extension, the significant difference was only greater by 0.72 degrees. Finally, for the ROM Test of knee flexion, the significant difference was only greater by 0.49 degrees.

Table III shows the summary of the results for the GonioPi's accuracy testing.

There is no consistency with the ROM Tests considered as unreliable and inaccurate when comparing the results for both the handheld and wearable configurations. Thus, retesting these ROM Tests for reliability using the GonioPi or an improved version of the device should be considered in a future study.

Overall, it can be said that the GonioPi can be considered as reliable and accurate for the 8 ROM Tests evaluated for reliability and accuracy since most of them were considered reliable and accurate and those considered unreliable and inaccurate were only a few decimal points greater than accepted standard values of 5 degrees and 10 degrees respectively.

*D. Results for the Versatility and Scalability of the GonioPi*

In terms of versatility, considering that 34 out of 34 ROM Tests are supported by the GonioPi using its handheld configuration and out of those 34 supported ROM Tests 11 out of 11 joints and 15 out of 15 motions are supported, then it can be said that the GonioPi is versatile when used as a handheld digital goniometer.

Furthermore, still in terms of versatility, considering that 18 out of 34 ROM Tests (52%) are supported by the GonioPi using its wearable configuration and out of those 18 supported ROM Tests, 6 out of 11 joints (54%) and 8 out of 15 motions (53%) are supported then it can be said that the GonioPi is relatively versatile when used as a wearable digital goniometer. The GonioPi's issue with versatility using its wearable configuration is due to its bulky size and improper sensor orientation when attached to a specific unsupported joint. The issue of the GonioPi's bulky size can be resolved by making the design of the GonioPi smaller and more compact. The issue of improper sensor orientation can be resolved by using triple-axis tilt calculation for solving the joint angle ROM measurement rather than the current implementation which uses dual-axis tilt calculation.

In terms of scalability, considering that the GonioPi using both its handheld and wearable configurations was tested on test subjects of varying heights, weights, and BMIs – specifically, five (5) normal, (2) overweight, and (2) obese then it can be said that the GonioPi is scalable as both a handheld and wearable digital goniometer. However, a future study can be performed to include the underweight BMI category to

better establish the GonioPi's scalability. Moreover, the GonioPi using its handheld configuration can be used to perform ROM Tests for both large and small joints of the body while the GonioPi using its wearable configuration can be used to perform ROM Tests for mostly large joints on the body. Both configurations, however, do not allow for ROM Tests for the finger joint. Finally, it is important to note that the GonioPi's wearable attachable container design can conform to all joints of the body except for the fingers.

*E. Results of the Evaluation of the GonioPi and Assisted Mode Feature*

The results of the survey for the evaluation of the GonioPi presented that majority of the testers found the GonioPi to be useful, easy to use, likeable, and comfortable when used as a digital goniometer by medical professionals for both its handheld and wearable configurations. Majority of the positive feedback from the testers regarding the GonioPi highlighted its efficiency, convenience, and ease of use. A tester also mentioned that it is a nice and useful innovation. Moreover, the testers mentioned that the GonioPi helps them in their profession by allowing them to get ROM measurements faster and easier. When it comes to the negative feedback of the GonioPi, the testers highlighted its size being too bulky. Moreover, the testers also stated that its wearable configuration limits some motions and that because of its weight it is greatly influenced by gravity. The testers also mentioned that the sensor is quite sensitive and picks up some unnecessary motions. A tester also mentioned that the GonioPi has a lack of visual markers such as a fulcrum and arm like the universal goniometer. Finally, as for the wearable attachable container's design, they found it a bit loose, and the adjustable buckle strap a hassle to adjust. The testers stated that the GonioPi can be improved by decreasing its size – making it less bulky and more compact. Moreover, adding visual markers such as an indicator of a fulcrum and an arm on the acrylic case could help getting joint angle ROM measurements easier in the sense that it decreases user error of overcompensating or undercompensating the tilt of the device. One tester mentioned that a bigger switch and buttons would be beneficial for them. Finally, as for the wearable attachable container, the testers suggested that the strap should be thinner and smoother while the attachable container should be more secure.

The results for the survey of the Assisted Mode feature of the GonioPi presented that majority of the testers found the Assisted Mode feature to be important, useful, helpful, and user friendly which increases the usability and relevance of the GonioPi. Moreover, the feature also makes the GonioPi a better device overall. Majority of the positive feedback from the testers regarding the Assisted Mode feature of the GonioPi highlighted how it makes it easier for a user to determine whether or not the joint angle ROM measurement of a patient is within normal range or not. Moreover, the testers mentioned that it is helpful in aiding physical therapists determine the state of a patient's ROM. Lastly, a tester stated that it is useful and effective especially for "newbies". When it comes to the negative feedback from the testers regarding the Assisted Mode feature of the GonioPi, the testers highlighted how the feature only has limited motions and joints. A couple of testers stated that the feature may be at risk for inaccuracy due to

human error when using the GonioPi. Lastly, a tester stated that the feature has no indication of the normal values of each joint. The testers stated that the GonioPi's Assisted Mode feature can be improved by adding more options of joints and motions to be tested. Moreover, a tester stated that adding the normal values of each joint for a user's awareness and knowledge can be helpful. Finally, a tester also stated that a warning message requesting the tester to immobilize patient's joint being tested may help in decreasing human errors that may lead to measurement errors in the joint angle ROM measurement.

*F. Limitations of the Final Device Testing*

It should be noted that the method for the final device testing of the GonioPi for confirmed supported ROM Tests was done by making each tester perform 9 ROM Tests using different positions on their partner while the other pairs observed and gave their remarks based on their observation of the ROM Test being performed. This means that all testers have not tested each ROM tests using the device. This may have effects on the collected data as actually using the device for measurement may give a different result compared with just observing.

In addition, the testers in the final device testing are physical therapy interns. While it is assumed that they have sufficient knowledge in clinical goniometry, it might provide different results if the test was carried out by experienced physical therapists.

Looking at the results for reliability of the GonioPi for both the handheld and wearable configurations, there is no consistency with the ROM Tests considered as unreliable. Moreover, comparing the individual data collected from the test subjects, the first two pairs of testers-test subjects (testers 1, 2, 3, and 4) had higher values of individual standard deviations for the different ROM Tests compared to the next two pairs of testers-test subjects (testers 3, 4, 5, and 6). The possibility of these differences in results may have been caused by tester-test subject/patient fatigue as manifested by the testers themselves during testing. Considering that the first two pairs of testers-test subjects extended their testing time during the first day, it raises the possibility that by the time they were collecting the data for reliability testing they were already tired and could not properly and consistently perform the different ROM Tests being evaluated. Compared to the next two pairs of testers-test subjects who performed the data gathering for the reliability testing during the second day of testing – they were able to perform the different ROM Tests more consistently as they were not affected by fatigue from an entire day of testing.

## V. FUTURE WORKS AND RECOMMENDATIONS

The current size of the GonioPi is too bulky. An improvement that can be made to resolve this issue would be to look for and use smaller and more compact components to reduce the overall size of the GonioPi. The researchers suggest future works consider using the Pimoroni LiPo SHIM for Pico power supply. It is a small and compact power supply that can be powered by a LiPo/Li-Ion battery and soldered onto the back of the Rapsberry Pi Pico microcontroller. Using this component as a substitute power supply of the battery shield

V8 would reduce the thickness of the GonioPi by about 2.70cm which would result to an overall thickness of 3.60cm for the next version of the GonioPi.

A reduction in the overall size and weight of the GonioPi would allow the attachable container to be more secure since it will be affected less by gravity due to the reduced weight of the GonioPi. Moreover, as for the adjustable straps of the wearable attachable container, an improvement can be made by reducing its thickness and changing the adjustable buckle strap to an adjustable belt strap and lock as suggested by one of the testers.

For the GonioPi to support more ROM Tests using its wearable configuration as well as improving its reliability and accuracy, it is suggested that future works pursue on implementing a triple-axis tilt calculation for measuring joint angle ROM. Implementing a triple-axis tilt calculation would allow the GonioPi to calculate and measure joint angle ROM measurements when the sensor is oriented on the y-axis. Moreover, implementing a triple-axis tilt calculation would also slightly improve the sensor's reliability and accuracy.

It is also suggested that future studies perform testing that include a participant with BMI categories of underweight and higher classes of obesity. This would mean that the scalability of the device can be evaluated for much smaller and larger participants, respectively.

An improvement can also be made by implementing a sampling window. Implementing a sampling window would allow the sensor to output stable data to the Raspberry Pi Pico microcontroller before outputting it on the display. This would mean that the joint angle ROM measurement outputted on the display won't update every second with the slightest movement but rather it will stabilize first and output an average value of a chosen number of samples.

It is also recommended to add a straight edge ruler component at the back of the acrylic case design of the GonioPi as suggested by a tester in order for them to know that they are neither undercompensating nor overcompensating the tilt of the device when performing a ROM Test. Moreover, another tester suggested that a visual marker be added to midsection of the top of the acrylic case design to act as visual marker for rotation, and deviation motions of joints.

An improvement can also be made in the Assisted Mode Feature by adding more joints and motions as the testers considered the current implementation of the feature important, useful, and helpful.

A retest of the eight (8) ROM Tests evaluated in this research should be conducted to make the results of the handheld configuration testing consistent with the wearable configuration testing. The researchers also suggest that the testing for device reliability and accuracy should be performed independently from any other device testing to avoid tester-test subject/patient fatigue.

The researchers suggest the use of other sensors such as the ADXL335 3-axis Accelerometer Module, ADXL345 Accelerometer Module, BNO055 9-DOF IMU sensor, and MPU-9250 9-Axis IMU sensor. The researchers also recommend exploring the use of the accelerometers of modern smartphones for the application of clinical goniometry, like existing apps such as PhysioMaster.

## VI. Conclusion

In conclusion, the design and development of the GonioPi has shown that a versatile, scalable, reliable, and accurate digital goniometer can be made using the MPU-6050 IMU sensor along with the components of the Raspberry Pi Pico microcontroller, Waveshare Dual GPIO Expander, Waveshare 1.14" LCD Display, 18650 Battery Shield V8, and two (2) 18650 Li-ion rechargeable batteries enclosed in an acrylic case with a wearable design of a pouch like attachable container with adjustable buckle straps.

In terms of versatility and scalability, the GonioPi has shown that it is versatile and scalable as it supports 34 ROM Tests of 11 different joints using 15 different motions, and 18 ROM Tests of 6 different joints using 8 different motions in multiple different positions using both the handheld and wearable configurations respectively for people of varying heights, weights, and BMIs. Improvements can be made for the wearable configuration to support more ROM Tests by using triple-axis tilt calculation and reducing the size of the GonioPi by substituting its power supply component.

In terms of reliability and accuracy, the GonioPi has shown high reliability and accuracy as it was reliable and accurate for majority of the ROM Tests of flexion and extension for the shoulder, elbow, hip, and knee joints for both the handheld and wearable configurations as its joint angle ROM measurements of $< 5°$ for device reliability, and joint angle ROM measurements of $< 10°$ for device accuracy. Improvements can be made for the GonioPi's reliability and accuracy by adding visual markers to the device in order to minimize user error when using the GonioPi.

Finally, regarding the Assisted Mode feature of the GonioPi – the feature has proven to be important, useful, and helpful with the feedback of the testers who also requested for more joints and motions to be added to the feature as an improvement.

*Abstract*—Breast Cancer is reckoned amongst the most common cause of morbidity and mortality among women, adversely affecting female population irrespective of age. The poor survival rate reported in invasive carcinoma cases demands the identification of early developmental stage key markers. MicroRNAs are contributing a critical role in gene regulation potential markers. Over 2000 miRNAs have been identified and considered to offer a unique opportunity for early detection of diseases. In this study, a gene-miRNA-TF interaction network was constructed from the differentially expressed genes obtained from the invasive lobular and invasive ductal carcinoma samples. The network consists of experimentally validated miRNAs and transcription factors were identified for the target genes, followed by thermodynamics studies to identify the binding free energy between mRNA-miRNA. Our analysis identified miRNA; hsa-miR-28-5p binds with MAD2L1 with unexpectedly high binding free energy equivalent to -92.54kcal/mol and also makes canonical triplex with hsa-miR-203a, which acts as a catalyst to initialize the MAD2L1 regulation. For the identified regulatory elements, we proposed a mathematical model and feed-forward loops that may serve in understanding the regulatory mechanisms in breast cancer pathogenesis and progression.

*Keywords*—*Breast cancer; invasive lobular carcinoma; invasive ductal carcinoma; biomarkers; MicroRNA; transcription factors; feed forward loops*

## I. INTRODUCTION

Breast cancer is the major type of cancer affecting female population in both developed and developing countries. Breast carcinoma can be classified into ductal carcinoma in situ (DCIS) and lobular carcinoma in situ (LCIS). In the initial stages of breast cancer (i.e., DCIS), the abnormal cells are restricted to the lining of breast ducts, which may lead to invasive cancer if not treated, "In situ" type tumor is confined to the epithelial layer, where it leads to DCIS and LCIS [1]. When the tumor cells burst out from the tissues, these can be Invasive Ductal Carcinoma (IDC) and Invasive Lobular Carcinoma (ILC). IDC accounts for almost 80% of the diagnoses of breast cancer cases, while ILC is composed of another 5%-15% [2].

Most breast cancers begin as asymptomatic lump or tumor that originates from either glandular tissue of breast i.e. lobules or in the ducts that connect these lobules. Molecular subtypes of cancer have been identified by biomarkers including hormones (Estrogen (E), progesterone (P)), and receptors (ER, PR, HER1 and HER2). In 2019, almost 62,930 and 268,600 new cases of DCIS and IDC were reported respectively in United States. Breast cancer is associated with mutations in genes like BRCA1/2, p53, ATM, and CHD1. Nearly 5-10% of breast cancers are linked to the inheritance of gene mutations, mostly BRCA1/2 mutations. Women with BRCA1/2 mutations have a 45-65% higher chance of developing breast cancer [3]. Non-genetic risk factors include first-degree family history, race and ethnicity, lifestyle, exposure to radiation, alcoholism, obesity, and hormone replacement therapies. Few reports suggest that metabolism, particularly fatty acid oxidative metabolism plays a significant role in cancer progression by reprogramming their signaling pathways [4,5].

MADL21 gene is known as mitotic arrest deficient 2 like 1 or mitotic spindle assembly checkpoint protein MAD2. Aliases of MAD2L1 include or HSMAD2 and MAD2. MADL21 plays an essential role in supervising cell cycle regulation, G1/S checkpoint, cell growth and death, Oocyte meiosis and progesterone-mediated oocyte maturation [6]. Studies have reported that chromosomal instability due to aberrant expression of MAD2L1 may promote tumorigenesis, where upregulation of MAD2L1 has been reported in breast, lung, liver and stomach cancer [7,8,9].

MicroRNAs (miRNAs) are small, 18-22 nucleotide long, non-coding RNA molecules. They are the key players in RNA interference pathways causing silencing of their associated target genes. miRNAs regulate the expression of 30-50% of genes and target various elements of signaling pathways and cellular networks. Recent studies have established their role as oncogenes or anti-oncogenes in regulating multiple cellular pathways involved in breast cancer pathogenesis. Therefore, miRNA may aid in developing new methods for cancer diagnostics and therapy.

## II. RELATED WORK

The expression profile of miRNAs differs in normal and tumor tissues. miRNA profiling has identified that miR-99a was dysregulated in breast cancer tissues as compared to normal tissue [10]. Furthermore, numerous studies have reported that miRNAs are dysregulated at various stages of breast cancer [11]. Therefore, they have been used to identify characteristic miRNA signatures in human breast cancers. To decipher and analyze the differential changes of oncogenes

and tumor suppressor genes, transcriptome analysis with the help of microarray expression-based studies would help in the identification of novel markers associated with the cancer progression [12].

The role of miR-28-3p is well established in different cancer types including breast cancer, colorectal cancer, B-cell lymphoma, glioma and renal cell carcinoma. Liang Ma et al. identified the inhibition property of miR-28-3p by regulating WSB2 in breast cancer [13], while in other cancer it has been found to target TRPM7, Rap1b and cyclin D1 [14, 15]. However, the potential role of miR-28-3p targeting MAD2L1 is not yet reported in breast cancer.

## III. MATERIALS AND METHOD

### A. Mining of Differentially Expressed Genes

In the present study, breast cancer dataset GSE36295 was retrieved from Gene Expression Omnibus database of NCBI and analyzed to identify DEGs. The dataset encompasses 50 Saudi Arabian subjects with 5 control samples, 5 ILC (Invasive Lobular Carcinoma samples), 34 IDC (Invasive Ductal Carcinoma) and the remaining 6 samples were poorly differentiated (not included in the study). Expression profiling was conducted on Human Gene 1.0 ST GeneChip arrays (Affymetrix) testing platform. In order to calculate and analyze the DEGs between Control vs. ILC and Control vs. IDC samples, we have used Bioconductor packages in R namely affy, limma and other packages included in our customized pipeline. To calculate FDR and p-values, Benjamin and Hochberg (FDR) and t-test methods were utilized respectively [16]. A volcano plot and heatmap were constructed, which represent the distribution of p-value and fold change of DEGs using R.

### B. Gene-Gene Interaction Network (GGIN) Analysis for Hub Nodes and Target Genes Identification

GeneMANIA [17] and Search Tool for Retrieval of Interacting Genes/Proteins (STRING) [18] were utilized to develop GGIN. The parameters used for network generation were; all prediction sources enabled medium confidence score≥0.40 and no interactors in the first and second shell. The final GGIN was downloaded in .txt format for visualization and analysis in Cytoscape 3.7.1 using CytoHubba [19]. In this study, identified hub genes were further subjected to the Oncoprint module in cBioPortal and the hub genes with the relative frequency of mutation and copy number variants < 1 were selected as target genes.

### C. Enrichment Analysis of Target Genes and Functional Annotation

Erichr [20] identified the enriched terms in a given gene list and web-based gene set analysis toolkit (WebGestalt) [21] is a data mining system. It has four modules that aid in examining gene sets for Gene Ontology terms, metabolic and signaling pathways, tissue expression and chromosome distribution. The target genes were subjected to enriched pathways and biological process enrichment analysis through Enrichr and WebGestalt, respectively.

### D. Identification of Validated miRNA for Target Genes

miRTarBase provides comprehensive data on experimentally validated miRNA and target interactions [22]. It consists of more than 13,404 validated miRNA and target interactions. In our study, the genes with a lesser frequency of mutations were subjected to regulatory analysis to identify the novel targets for validated miRNA. Furthermore, Regulatory Network Repository (RegNetwork) consisting of the integration of five-types of transcriptional and post-transcriptional regulatory relationships for mice and humans, was used to identify the experimentally validated Transcription Factors.

### E. Thermodynamics Estimation of Gene-miRNA Interactions and miRNA-mRNA Duplex Binding Site Prediction

miRmap is an open-source software library that ranks potential targets on the basis of repression strength. It combines evolutionary, probabilistic, thermodynamics and sequence-based features [23]. It uses four approaches to examine feature correlations using experimental data from transcriptomics, proteomics and immunopurification studies. For binding site and thermodynamics estimation, the identified target gene-miRNA duplex was subjected to miRmap web.

### F. miRNA Triplex, ODE and mRNA Regulation using Feed Forward Loop

TriplexRNA is a web resource that incorporates methods for triplex structure analysis, miRNA target prediction, simulation and c. The triplex formation of target genes obtained miRNA was examined through TriplexRNA [24]. An Ordinary Differential Equation (ODE) was proposed to explain the alteration of miRNA and Transcriptional Factors (rate of change) concerning the target gene in initiating the regulatory pathogenesis of the disease. The MAD2L1 regulatory mechanism was further explained with Feed Forward Loop.

## IV. RESULTS AND DISCUSSION

### A. Identification of differentially Expressed Genes

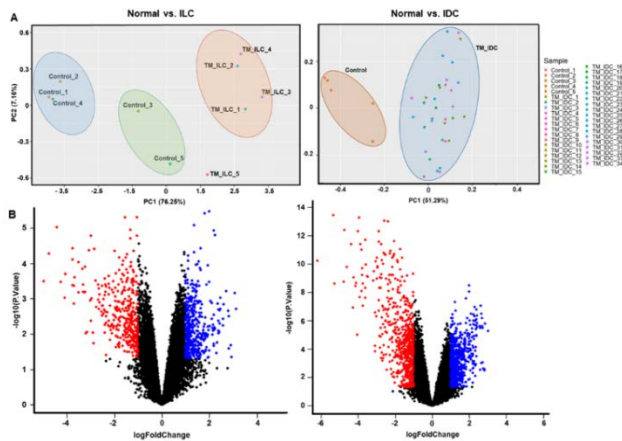
The microarray expression dataset GSE36295 was obtained from GEO and was analyzed in R using bioconductor packages. The dataset comprised of 5 control, 5 ILC, and 34 IDC tissue samples of female breast cancer patients. The principal components analysis revealed the relatedness between samples of each category (Fig. 1A). The dataset was normalized using RMA normalization approach and DEGs were identified using the threshold of |logFC|≥1 and a Benjamini & Hochberg adjusted p-value cut-off of 0.05 (Fig. 1B). The principal components analysis plots clearly classify the distinct expression of genes in Control and Cancerous samples (IDC and ILC). Each cluster represents the sample with same feature within it and differentiates from the samples in other clusters. Thus, differentiating the gene expression in normal breast to the gene expression in breast cancer samples. 1509 DEGs were identified that were further used for network construction.


Fig. 1.   (A). Principal Components Analysis of IDC and ILC Samples with Normal Samples. (B). Volcano Plots for DEGs where Red Dots and Blue Dots Represent up and Downregulated Genes Respectively.

## B. The Structure of GGIN and Identification of Target Genes and Enrichment Analysis

From GeneMANIA studies, the DEGs were found to have a well-established role in the pathogenesis of cancer based on co-expression, co-localization, and pathways. The GGIN obtained from STRING consisted of 1509 nodes and 21993 edges, with average local clustering coefficient of 0.381 and average node degree of 29. CytoHubba plugin of Cytoscape 3.7.1 identified central elements of the GGIN. Hubs are nodes with maximum interactions and occupy a central position in the interaction networks. Maximum Clique Centrality measure identified the hub genes including BUB1B, CDCA8, CDK1, TOP2A, NUSAP1, MAD2L1, SPAG5, KIF2C, ASPM, CCNB2 (Fig. 2A). In cBioPortal, we examined genetic alterations in the top ten hub genes and identified that for CDCA8, CDK1, NUSAP1, TOP2A, MAD2L1 and CCNB2 the frequency of mutations and copy number variants were less than one. Since these genes showed the least genetic alterations, therefore, were selected as target genes for further study. The enrichment analysis of target genes revealed that they were associated with metabolic processes of amino acids, lipids, drugs and nucleoside bisphosphates (Fig. 2B). Furthermore, they were enriched in Progesterone mediated Oocyte mutation; Cell Cycle; p53 signaling and cellular senescence pathways (Fig. 2C). The identified biological processes and signaling pathways have a well-established role in cancer pathogenesis.

## C. Identification of Validated miRNAs and Transcriptions Factors for Target Genes

The regulatory elements of the gene i.e. validated miRNAs and Transcription Factors were obtained from miRtarBase and RegNetwork (Table I). The interactions between gene-miRNA in and the interactions between gene-miRNA-cooperative miRNA in forming a triplex were given in Table II. The experimentally validated miRNAs and Transcription Factors (Table I) were identified for the target genes MAD2L1 and CDK1; for other target genes, no validated regulators were found.

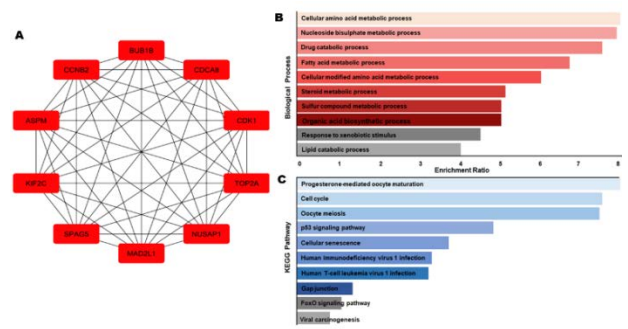

Fig. 2.   (A) Top 10 Hub Genes of GGIN as Identified from CytoHubb. Functional Enrichment Analysis of Target Genes (B) Biological Processes (C) Signaling Pathways.

TABLE I.        VALIDATED MIRNAS FOR CDK1 AND MAD2L1

| Gene | Regulatory Elements | |
| --- | --- | --- |
| | *Transcription Factor* | *miRNA* |
| MAD2L1 | E2F4, ESR2 MYB, MYC | hsa-miR-28-5p hsa-miR-192-5p |
| CDK1 | RB1, SP1, ATF1, E2F1, E2F4, ETS2, MYB, MYC | hsa-miR-31-5p hsa-miR-663a hsa-miR-24-3p hsa-miR-302a-3p |

## D. Seed Pairing and Construction of Gene Regulatory Network

In case of seed pairing CDK1-hsa-miR-31-5p form a complementarily pairing with a binding free energy of -34.33 Kcal/mol (Table II) and with triplex formation, CDK1-hsa-miR-31-5p-hsa-miR-543 forms a canonical triplex to initiate the process of regulation. Similarly, MAD2L1-hsa-miR-28-5p-hsa-miR-203 forms a canonical triplex. The interaction between the genes: CDK1, miRNAs: hsa-miR-28-5p, hsa-miR-31-5p and transcription factors (TFs): RB1, SP1, ATF1, E2F1, E2F4, ETS2, MYB and MYC is given in Fig. 3.

Fig. 3.   Network Representing Regulation of CDK1 and MAD2L1 by miRNAs and TFs, where the Target Genes are represented in Red Color and Regulatory Elements in Blue Color.

TABLE II.    INTERACTION OF GENE-MIRNA (SEED PAIRING) AND GENE-MIRNA-COOPERATIVE MIRNA (TRIPLEX)

| Gene | Regulatory Element (miRNA) | Binding Free Energy (Kcal/mol) | Triplex Form-ation (cooperative miRNA) | Binding Free Enery of Triplex (Kcal/mol) | Nature of Complementarily (Self/Duplex/Triplex) |
|---|---|---|---|---|---|
| MAD2L1 | hsa-miR-28-5p | -92.58 | hsa-miR-203 | -28.86 | Canonical Triplex |
| CDK1 | hsa-miR-31-5p | -34.33 | hsa-miR-543 | -33.36 | Canonical Triplex |
| | | | hsa-miR-181a | -32.96 | miRNA Self Complementarily |
| | | | hsa-miR-181b | -31.96 | Canonical Triplex |
| | | | hsa-miR-181c | -31.76 | miRNA Self Complementarily |
| | | | hsa-miR-146a | -31.16 | Canonical Triplex |
| | | | hsa-miR-146b | -31.16 | Canonical Triplex |
| | | | hsa-miR-494 | -30.76 | miRNA Self Complementarily |
| | | | hsa-miR-181d | -30.56 | target self complementarity |
| | | | hsa-miR-329 | -29.26 | miRNA self-complementarity |
| | | | hsa-miR-362-3p | -28.16 | miRNA self-complementarity |

*E. Analysis of miRNA-Mediated Mechanisms of Translation Repression and Gene Regulation via Transcription Factors*

The gene MAD2L1 was regulated by transcription factors E2F4, ESR2, MYB and MYC and repressed by hsa-miR-192-5p and hsa-miR-28-5p. Similarly, the regulation of the gene CDK1 is a combination of activation by transcription factors RB1, SP1, ATF1, E2F1, E2F4, ETS2, MYB and repression by miRNAs hsa-miR-31-5p, hsa-miR-63a, hsa-miR-24-3p and hsa-miR-302a-3p. However, it was observed that the binding free energy of MAD2L1-hsa-miR-28-5p is less than CDK1-hsa-miR-31-5p (Table II). Therefore, the stability of MAD2L1-hsa-miR-28-5p was more than CDK1-hsa-miR-31-5p. Therefore, MAD2L1-hsa-miR-28-5p was taken forward for further understanding its role in driving the regulatory pathogenesis of Invasive Ductal and Invasive Lobular Breast Carcinoma.

*F. Analytical Modeling of Gene Regulation to Understand the Regulatory Pathogenesis of Breast Cancer*

In the mathematical modeling of the miRNA mediated transcriptional regulatory network which was associated with the pathogenesis of breast cancer, the involved factors are (i) gene: MAD2L1, miRNA: hsa-miR-28-5p, hsa-miR-203 and TFs: E2F4, ESR2, MYB and MYC. Hence, the regulatory pathogenesis of Breast cancer is initiated by the regulation of the gene: MAD2L1, activated by the TFs: E2F4, ESR2, MYB and MYC and repressed by the miRNAs: miRNA: hsa-miR-28-5p with the cooperation of hsa-miR-203. Since the cooperative miRNA, hsa-miR-203 act as a catalyst in driving the pathogenesis, the core miRNA hsa-miR-28-5p is preferred in the modeling and the ordinary differential equation of the mathematical model that initiates the regulatory pathogenesis in Breast Cancer is illustrated as:

[d (MAD2L1) / dt = k (Synthesis of E2F4, ESR2, MYB and MYC) + MAD2L1 + k (Up-regulation of E2F4, ESR2, MYB and MYC) (hsa-miR-28-5p) - k (Degradation of E2F4, ESR2, MYB and MYC) (E2F4, ESR2, MYB and MYC)] where k represents the rate of synthesis/degradation of TFs.

Additionally, the mRNA binding sites of the corresponding miRNA hsa-miR-28-5p and hsa-miR-203a of breast cancer-associated gene MAD2L1 were obtained by gene-miRNA mapping pair. The binding sites are shown in Fig. 4. We found that hsa-miR-28-5p has one binding site on MAD2L1 while ha-miR-203a has two binding sites on MAD2L1. For hsa-miR-192-5p, there was no binding site found on MAD2L1.

*G. mRNA-miRNA-TF Regulatory Analysis through Feed-Forward Loops*

Although no specific protocol has been studied for the mechanism of miRNAs, comparative studies have identified that genes regulated by miRNAs might have considerable contribution in cellular processes [25]. The available experimental shreds of evidence justify the regulation of genes due to miRNA through translational repression with or without mRNA decay. However, the variation in these contributions over time remains undefined which is also went unnoticed in case of TFs [26]. Therefore, we design a transcription network utilizing one of the most significant motifs i.e. Feed Forward Loop (FFL) motif [27]. In this study, the FFL is composed of a transcription factor (E2F4, ESR2, MYB, MYC) which regulates other or the miRNA (hsa-miR-28-5p), then TFs and miRNA both bind at the regulatory region of the target gene (MAD2L1) and jointly modulate its transcription rate. This FFL collectively has three transcription interactions, which could be either activation or repression. A recent computational analysis demonstrated that FFL, containing TF and miRNAs, are overrepresented in gene regulatory networks, assuming that they confer useful regulatory opportunities [28].

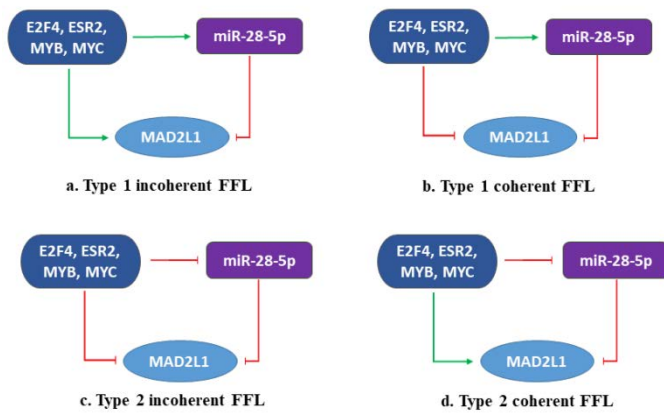
Fig. 4.   Target Binding Site of miRNA (A) hsa-miR-28-5p and (B) hsa-miR-203a with MALD21.


Fig. 5. The Incoherent and Coherent Feed forward Loops between the Target Gene and its Regulatory Factors is Represented; where Arrows (Green) Indicate Activation, the T-bars Indicate Repression. The Dark Blue Shape with Circular Ends Represent Transcription Factors.

The FFL has two possible structure configurations in both coherent and incoherent FFL specified as type 1 or 2 coherent FFLs and type 1 or 2 incoherent FFLs respectively as shown in Fig. 5(a, b, c, d) where miR-28-5p is miRNA and MAD2L1 is the target protein. In 5(a) represents Type 1 incoherent FFL where TF activates both target mRNA and miRNA synthesis. 5(b) Type 1 coherent FFL, miRNA and TF represses target mRNA but activates miRNA synthesis. 5(c) Type 2 incoherent FFL, TF represses both target mRNA and miRNA synthesis. 5(d) Type 2 coherent FFL, TF activates target mRNA and represses miRNA synthesis. Additionally, we emphasize that this study is carried out utilizing secondary data repositories which encompass a limited number of genes/miRNAs; hence these may provide bounded results. In this study, we performed a comprehensive analysis using various bioinformatics approaches to understand the molecular interaction between genes and miRNA and their involvement in the pathogenesis of breast cancer. The findings from this study strongly suggest that hsa-miR-28-5p might play a critical role by regulating MAD2L1 which subsequently inhibits cell cycle and p53 signaling pathway in breast cancer patients. The potential role of hsa-miR-28-5p mediating breast cancer pathogenesis on binding with MAD2L1 gene may act as a significant therapeutic target for the diagnosed subjects.

## V. CONCLUSION

The systematic analysis for identification of target genes majorly contributing in the primary stage of development of invasive breast carcinoma, MAD2L1 was found to have experimentally validated miRNA and transcription factor targets from multiple databases. The regulation of MAD2L1 is a combination of activation by transcription factors E2F4, ESR2, MYB and MYC and repression by hsa-miR-28-5p and hsa-miR-192-5p. In case of seed pairing, MAD2L1-hsa-miR-28-5p forms a complementarily pairing with a binding free energy of -92.58 Kcal/mol and a canonical triplex MAD2L1-hsa-miR-28-5p-hsa-miR-203. Since, the binding free energy of MAD2L1-hsa-miR-28-5p seed pairing is 3-folds lesser than CDK1, the stability of MAD2L1-hsa-miR-28-5p will be much greater than CDK1-hsa-miR-31-5p. Therefore, the mRNA-miRNA-TF complex MAD2L1 - hsa-miR-28-5p and

associated transcription factors: E2F4, ESR2, MYB and MYC might play a vital target in driving the regulatory pathogenesis of breast cancer. The regulatory pathogenesis of breast cancer is initiated by the regulation of the gene: MAD2L1, which is activated by the TFs: E2F4, ESR2, MYB and MYC and repressed by the miRNA: hsa-miR-28-5p with the cooperation of miRNA: hsa-miR-203. Since the cooperative miRNA hsa-miR-203 act as a catalyst in driving the pathogenesis, the mathematical model that initiates the regulatory pathogenesis in Breast Cancer is illustrated as:

[d(MAD2L1)/dt = k(Synthesis of E2F4, ESR2, MYB and MYC ) + MAD2L1 + k(Up regulation of E2F4, ESR2, MYB and MYC )( hsa-miR-28-5p) – k(Degradation of E2F4, ESR2, MYB and MYC ) ( E2F4, ESR2, MYB and MYC)].

Additionally, the type 1 and type 2 coherent and incoherent feed-forward loops help to determine the regulatory mechanism of TFs and miRNA associated with MAD2L1, which further need invitro validation to determine the exact conditional mechanism of these regulators in breast cancer pathogenesis.

Since limited studies have been focused on the regulatory role of MAD2L1 associated miRNAs and their impact on tumor progression in breast cancer, this study will help in understanding the pathogenesis of MAD2L1 regulation in estimating the cascade of processes associated with breast cancer initiation and progression throughout invasive ductal carcinoma and invasive lobular carcinoma. The constructed model requires simulation with experimentally determined values in a larger time scale.

*Abstract*—This study used opinion mining theory and the potentials of artificial intelligence to explore the opinions, sentiments, and attitudes of customers expressed on Twitter regarding the services provided by the Saudi telecommunications companies during the COVID-19 crisis. A corpus of 12,458 Twitter posts was constructed covering the period 2020–2021. For data analysis, the study adopted a discourse-based mining approach, combining vector space classification (VSC) and collocation analysis. The results indicate that most users had negative attitudes and sentiments regarding the performance of the telecommunications companies during the pandemic, as reflected in both the lexical semantic properties and discoursal and thematic features of their Twitter posts. The study of collocates and the discoursal properties of the data was useful in attaining a deeper understanding of the users' responses and attitudes to the performance of the telecommunications companies during the COVID-19 pandemic. It was not possible for text clustering based on the "bag of words" model alone to address the discoursal features in the corpus. Opinion mining applications, especially in Arabic, thus need to integrate discourse approaches to gain a better understanding of people's opinions and attitudes regarding given issues.

*Keywords—Artificial intelligence; collocate analysis; COVID-19; discourse; opinion mining; vector space clustering*

## I. INTRODUCTION

In recent years, millions of users all over the world have been using social media platforms and networks in an unprecedented manner as channels for expressing their views and commenting on different issues [1, 2]. In many ways, these platforms and networks have gained such legitimacy that they have become an integral part of modern life. In the face of the increasing influence of social media networks in modern societies, institutions and organizations have begun to explore people's attitudes and responses to their policies and decisions as reflected on social media networks [2, 3].

Social media networks are used extensively to express trends and ideas within society due to their potential to offer a dialogue based on equality between the individual, the elite, and the masses; thus, the elite is no longer playing its former role in shaping and mobilizing public opinion [4, 5]. Social networks have transformed and changed from being just a means of communication between individuals and groups, or even conveying the news or commenting on it, to a means of addressing various issues and provoking reactions based on the tremendous ability to spread messages. Indeed, sometimes news is transmitted from social networking sites (Facebook, Twitter) to newspapers, satellite programs, and official media, increasing the impact and spread of these sites [6]. Modern technologies and the information revolution have provided ease of broadcasting to all at low cost, resulting in the emergence of many actors. Indeed, anyone, even those lacking knowledge, competence, and qualifications in the relevant field, can express points of view and prejudices through social media, transmitting and using images, videos, and publications [7, 8]. In this regard, in recent years there has been increasing interest among academics, politicians, and marketing agencies in the ways social media networks and platforms can be used to measure public opinion in an approach known as opinion mining [9, 10].

However, in Arab countries, including Saudi Arabia, the potential of opinion mining has not yet been fully exploited in relation to social media content. The failure to consider people's responses and sentiments concerning given issues can lead to serious problems and challenges for organizations and institutions. Thus, this study seeks to propose a reliable model of opinion mining that takes into consideration the discoursal properties of social media language, as well as the unique linguistic features of Arabic. It does so through an empirical analysis exploring and identifying the opinions, sentiments, and attitudes of Saudis regarding the services provided by telecommunications companies during the COVID-19 pandemic expressed on Twitter. The study sets out to answer two major questions: What were Saudis' opinions of and responses to telecommunications services during the COVID-19 lockdown? How can discourse-based approaches be integrated in data mining studies to offer a reliable conceptual analysis of people's opinions and sentiments as expressed on social media networks and platforms? To address the research questions, the study employed a corpus of 12,458 Twitter posts covering the period 2019–2021. The rationale is that Twitter is one of the most popular social media networks in Saudi Arabia and it was the most preferred venue for Saudis to express their views during the COVID-19 lockdown.

## A. Background

During the COVID-19 pandemic, there was an urgent need for reliable and effective telecommunications services that could address the increasing demand for non-traditional methods of connecting people and ensuring businesses and government agencies performed properly. The three telecommunications companies operating in the Kingdom of Saudi Arabia (STC, Mobily, and Zain) announced different initiatives to improve their performance and increase their ability to address the needs of their users and institutions throughout the Kingdom. These initiatives included incentive packages for students, internet coverage in remote areas, and free internet access for the social distancing application "Tawakalna". The telecommunications companies announced their commitment to meeting business and private demands, whether in terms of aiding the fight against the epidemic or facilitating the work of economic sectors and supporting citizens.

In education, for instance, the telecommunications companies released an initiative whereby students were given free access to the "Your Lesson" educational platform administered by the Ministry of Education. This was meant to enable students to learn remotely with the shift from face-to-face education to distance learning. Through this initiative, the telecommunications companies intended to provide support for the local community and fulfill their social responsibilities under the exceptional circumstances suddenly being experienced in the Kingdom and globally. The initiative was also a continuation of the telecommunications companies' support for the education sector in the Kingdom, given the recognition of its importance in policy and the right of all to receive an education. The "Your Lesson" platform was launched by the Ministry of Education when it suspending in-person teaching hours and switched to distance learning at the beginning of the pandemic. More than two million students enrolled in government schools, their parents, and all those in charge of the educational process could browse the platform for free, with no effect on their data usage or allowances provided by their cellular lines or home internet subscriptions.

During the COVID-19 pandemic, the Saudi Communications and Information Technology Commission (CITC) was keen to issue a set of decisions that would contribute to ensuring the safety of citizens and residents in the Kingdom, and it launched many initiatives to enable the communications and information technology sector to perform its role in facing the pandemic. The CITC developed an action plan that would assure the performance of its tasks and mitigate the effects of the pandemic. The measures included cooperation with the competent official authorities in the country to approve the import, customs release, and field inspection of shipments of communications devices, equipment, and spare parts. The extraordinary circumstances at the time highlighted the importance of the telecommunications sector and its role in empowering other sectors through the capabilities it provides. These include facilitating links between ministries, companies, institutions, and even individuals.

Despite the policies and initiatives adopted by the CITC, telecommunications companies faced a series of complex challenges during the COVID-19 pandemic in maintaining business sustainability and continuing to serve customers who were confined to their homes in lockdown. Moreover, they had to address the pressures of hugely increased consumption as demand for internet access on mobile networks exceeded all expectations. Not only did many employees start working remotely, but also the rates of data consumption related to entertainment increased among people unable to leave their homes.

## B. Theoretical Framework

Opinion mining is a field of research in natural language processing (NLP) that includes data mining, text mining, and internet mining [11]. Research in this field extends beyond computer science to business management and sociology due to its importance for business and society [11]. Its significance has become increasingly evident with the development of social media platforms such as Twitter and Facebook [12, 13]. Opinion mining is the process of analyzing data from different perspectives and discovering anomalies, patterns, and correlations in data sets that are insightful and useful for predicting outcomes that can help users make informed decisions [14, 15]. Opinion mining refers to the use of NLP, computational linguistics, and textual analysis to reveal positive, negative, or neutral sentiments and attitudes toward given issues or products through the extraction of useful patterns from textual data, and the categorization and interpretation of data using certain analytic techniques [16, 17].

The underlying principle of opinion mining is that people tend to have biased opinions, so the aim is to build a system that analyzes individuals' feelings and opinions on certain topics and to identify what they want from a product, service, or event [18]. Data analysis is thus the process of inferring, measuring, or understanding people's opinions of a product, service, or brand in the marketplace. People express their opinions by texting images, sending personal messages, and commenting, increasingly on social media networks, such as Twitter and Facebook. Companies and governments can use the data produced by social media companies to measure opinions on a particular topic or product. In this process, opinion mining can be exploited to interpret the nuances of customer reviews, financial news reports, social media, etc. [19]. Artificial intelligence has played a key role in almost all opinion mining applications [20, 21], with algorithms specifically designed for the analysis of people's opinions on social media sites.

## II. LITERATURE REVIEW

In recent years, both research and industry have paid special attention to the huge amounts of data available on the internet [22, 23]. The sources of data can be user or customer ratings of specific products, posts, comments, tweets, news articles, and various types of information on web pages. With the advent of social media, people started talking more openly about their experiences with products and services online through blogs, social media stories, reviews, recommendations, reports, hashtags, comments, direct messages, news articles, and so on [24]. Such online interactions leave a digital fingerprint of an individual's

expression of the experience. Hence there arose a need to adopt NLP approaches to organize what is circulated on social media sites, and to treat it in a short time with the least effort and cost [25, 26].

From a business point of view, opinion mining has proved useful for businesses and organizations. By analyzing users' opinions through surveys or their interactions (posts or comments about a particular product) on social media sites, companies can respond to their customers' needs, and improve their services and products to suit those needs [14, 27]. The underlying principle is that by drawing on a wide range of opinions and expressions, businesses and brands can accurately capture the voice of their target audience, understand market dynamics, and even identify their market position among end users [28]. Pazos-Rangel et al. argue that opinion mining not only helps companies and businesses understand the current context of a particular topic, but also enables them to predict the future, as well as using the information contained in the texts to calculate positive/negative feedback, which is an important indicator in decision-making processes [29]. Liu considers that adopting opinion mining and sentiment analysis techniques can aid companies, enterprises, and governments in the difficult process of making sound decisions by providing information on people's opinions and experiences of the products, services, or policies concerned [14].

In business, opinion mining has been widely used in marketing, customer services, and other areas to increase revenue, improve spending, target new customers, provide the best customer service, and address customer needs through analysis of the opinions, sentiments, and attitudes of users and customers related to services and products. Bal et al. assert that opinion mining has become one of the critical success factors for the growth and survival of organizations in an era of unprecedented global competitiveness [30].

According to Zvarevashe and Olugbara, there are many examples of the successful use of opinion mining to improve the quality of products and services. Manufacturers use opinions about a product or service as a reaction to make decisions aimed at improving quality [31]. Opinion mining and sentiment analysis are used to analyze the opinions of consumers or online customers to determine the advantages and disadvantages of a product or service, and this process saves the money that would previously have been spent on gathering information by other means.

Opinion mining has been closely associated with marketing research [32, 33]. This is one of the fields that uses sentiment analysis techniques to analyze consumer trends in relation to certain products or services, and it is also used to determine the success of an advertising campaign and study "what an individual needs from products or services that are not available in the market"; thus, it is highly significant and if used in the right way economically, it will be of great benefit to businesses [34-36].

Various opinion mining methodologies and techniques have been developed based on different models, including polarity, automatic detection, and aspect-based approaches. In the polarity model, sentiments and attitudes are automatically

identified and categorized (positive, negative, neutral). In some cases that require high accuracy, the classes of polarity are expanded, encompassing very positive, positive, neutral, negative, and very negative [17, 37].

In the emotion detection model, the goal is to identify emotions, such as happiness, fear, anger, etc. Dictionaries tend to be used in this approach (listing words with their corresponding emotions), but automatic learning algorithms can also be employed [17]. Here it is worth noting that when using dictionaries, the problem of the relation between different emotions and words arises, in particular that people can express their emotions in different ways [38].

In aspect-based opinion mining applications, the goal is to extract both the entity described in the text (in this case, attributes or components of a product or service) and the sentiment expressed toward such entities [39]. According to Moghaddam, the premise is that extracted aspects and estimated ratings clearly provide detailed information for users to make decisions and for suppliers to monitor their consumers. [40].

Despite the popularity of these methodologies and models, one major problem remains. Put simply, they do not consider the context of the texts because this adds to the complexity of the models and increases the time and cost of processing [41]. This study addresses the gap in the literature by proposing an integrated opinion mining model that takes into account the contextual aspects and features of the texts under investigation.

### III. METHODS, DATA AND PROCEDURES

To explore and identify the opinions, sentiments, evaluations, and attitudes of Saudis regarding telecommunications services during COVID-19 pandemic, this study is based on a corpus of 12,458 Twitter posts over the period 2020–2021. The rationale is that Twitter is one of the most popular social media networks in Saudi Arabia. Furthermore, Twitter was the most preferred venue for Saudis to express their views and sentiments during the COVID-19 lockdown. The study is confined to tweets written in Arabic. The data include posts in both Modern Standard Arabic (MSA) and Saudi spoken Arabic. The latter is not usually considered in NLP applications in Arabic as it has typically been considered a lower variety than MSA. With the emergence of social media networks, however, colloquial and spoken dialects of Arabic have become highly prevalent. It is thus appropriate to include all the Arabic varieties in Saudi Arabia to undertake a thorough classification of Saudis' responses.

Different methodologies are used for opinion mining, including rule-based methodologies and methodologies based on machine learning techniques. In rule-based methodologies, determining polarity and identifying the sentiments and attitudes of the users are based on manually defining a set of rules in which lexicons of groups of words and expressions with corresponding feelings are predefined [42]. Two strings are usually created that directly identify polarity. Positive words can include good, great, and reliable. Negative words may include bad, failed, and unreliable. The words expressing

positive feelings and the words expressing negative feelings are then counted and calculated. If the number of positive words exceeds the number of negative words, the result is a positive feeling, and vice versa; in the event of equality, the result is neutral [43].

In machine learning methodologies, no hand-written rules are developed. The premise is that opinion mining is first a clustering issue. Thus, machine learning algorithms are used for data clustering, based on no prior assumptions about the data [44]. Text clustering is the process of automatically grouping natural language texts according to an analysis of their informational content using machine learning algorithms [45]. Clustering is one of several computational systems for carrying out data mining tasks. Document clustering has proved successful in many important operations for data mining, including NLP, feature extraction, annotation, and summarization.

Text clustering underwent considerable development in the 1990s when it emerged as a subtask of information retrieval (IR) applications. The hallmark of that development was a dramatic improvement in the effectiveness of text clustering systems. The last two decades have witnessed an unprecedented revolution in the rise of mechanized solutions for organizing the vast quantity of unstructured digital documents and of powerful tools for turning an unstructured repository into a structured one [46]. The main bulk of clustering systems or approaches can best be described under the heading vector semantics (VS) or vector space clustering (VSC). Semantic structure is essential for clustering applications. The underlying principle of VSC is that it measures or computes semantic similarity between the documents to be clustered [47].

For the purposes of this study, VSC was conducted based on the lexical semantic properties of the linguistic content of the tweets. VSC is one of the most appropriate classification methods for opinion mining applications [48-50]. The steps are described in the following sub-sections.

### A. Text Preprocessing

Texts are first chopped into a list of tokens representing them. This is usually done in a straightforward way, removing punctuation and non-alphabetic characters and all extraneous material. This has the effect of converting texts into what is called a "bag of words," in which context and word order are not considered.

### B. Removing Function Words

One of the main challenges with text clustering applications is the difficulty of extracting the semantics of natural language texts. This is usually due to the occurrence of irrelevant terms within documents. In text clustering, function words are classified as irrelevant. Thus, text clustering is typically based on what can be called keyword indexing. This is the selection of only index terms, or what are traditionally called content words, within documents. The main assumption in removing function or grammatical words is that they do not carry lexical significance, so it is essential to remove them. Function words are described as "noisy" and are not considered in the analysis. Hence, they are best described as

irrelevant features. The retention of such irrelevant variables or features is useless and even misleading in clustering applications.

### C. Stemming

After removing the function words, stemming is carried out. Stemming can broadly be defined as the process of conflating semantically equivalent word variants into the same root by removing derivational and inflectional affixes [51]. The basic concept of stemming is that words with the same stem or root referring to the same concept must be grouped under the same form. Stemmers are thus designed to conflate together all and only those pairs of words that are semantically equivalent and share the same stem [52]. The premise is that word endings do not have essential meanings in themselves and thus their removal is useful in text clustering applications. Conflating words that have the same root into a single term improves the performance of clustering systems by reducing the size and complexity of the data in the system [45].

Various stemmers have been developed in English. These have been concerned particularly with suffixes, i.e., derivational and inflectional endings attached to words. As noted by Stageberg, derivational suffixes affect the part of speech (act, active, activate, activation) and they can be piled up [53]. That is, it is possible to add more than one suffix to one word. Inflectional suffixes, in contrast, do not change the part of speech, but indicate a grammatical function or change within the word (play $\rightarrow$ plays, cat $\rightarrow$ cats, big $\rightarrow$ bigger). Inflectional suffixes cannot pile up, the only exception being the plural followed by the possessive. The attachment of derivational and inflectional morphemes typically leads to an increase in word variant forms. According to Stageberg, derivational morphology is one of the most means of creating new words. From an IR viewpoint, this is a problem since the increase in word variant forms leads to complexity in the data in the system. As a result, word variant forms affect the effectiveness of IR systems and it is necessary to employ stemming algorithms that can reduce the size and complexity of the corpus by conflating semantically related variant forms in a common term.

English stemmers are not appropriate for Arabic due to the morphological and linguistic differences in the languages. Arabic has its own unique morphological system that is completely different from English. For the purposes of the study, the light-based stemmer (Light10) was used.

### D. Data Representation

For data representation, a matrix is built including all the lexical types of the posts. A data matrix is simply a quantitative data table that summarizes the frequencies of each word within the documents, where the documents are the rows and the words or lexical types are the columns. A collection of 500 documents can be all represented in just one matrix. The matrix includes all the lexical types in the corpus after removing the function words and carrying out stemming. The lexical frequency is weighted. A matrix of this kind is called a row vector matrix and can be represented as Xij, where i represent rows and j represents columns. Thus, the data matrix Xij is a representation of rows (tweets in this case), and columns (lexical types).

One problem with such a matrix is variation in document length. Posts in Twitter tend to vary in length, some being long and others very short. Variation in document length can have serious consequences for the reliability of classification applications. If not addressed, there will be a negative influence, since the classification will be based on the length of documents not the lexical properties [47]. All documents need to contribute significantly and equally to the distance in VSC, so that the distances are equitable. Otherwise, the differences between very long documents will dominate the distance calculation. One way of addressing this problem is to compensate the short texts for length through a process called normalization of text length [54]. Cosine normalization is used for this purpose. In this process, all row vectors of the matrix are transformed to have unit length and are made to lie on a hypersphere of radius 1 around the origin so that all vectors are equal in length. Accordingly, variation in the lengths of documents, and correspondingly of the vectors that represent them, are no longer a factor [55]. This has the effect of representing the variables equally in the matrix.

In this study, having carried out the normalization of text length, it was clear that high dimensionality was another problem that could have a negative impact on the reliability and validity of document classification. High dimensionality of the data is challenging for automatic classification systems as it is difficult to classify documents based on their lexical semantic properties when the number of dimensions is staggeringly high [56, 57]. In the face of this problem, term frequency-inverse document frequency (TF-IDF) can be used so that the classification is based on only and all the most distinctive features or variables. In our case, the datasets were reduced to the highest 200 TF-IDF variables thought to be the most distinctive features in the corpus, as shown in Fig. 1.

Then, the posts were clustered using Euclidean distance methods to identify and explore the responses of Saudis to the services of the telecommunications companies during the pandemic. Euclidean geometry is concerned with modelling the world as it is experienced. It describes the physical world in any finite number of dimensions using a distance formula [58]. Euclidean geometry has been used virtually unchanged for 2,000 years to understand physical reality. It used to be seen as a perfect model for logical reasoning. Despite its deficiencies, Euclidean geometry is still used in a range of disciplines, including the analysis of textual data.

Fig. 1. Term Weighting using TF-IDF.

To overcome the limitation of machine learning algorithms in the classification process, discourse analysis methods were finally incorporated in the analysis and categorization of the data. The hypothesis here is that context is essential for understanding the polarity within the data and users' attitudes and sentiments. Failure to consider the context can result in misinterpretation of users' views.

## IV. ANALYSIS AND DISCUSSION

In this study, the data matrix was first hierarchically analyzed using Euclidean distance with four clustering methods (single linkage, complete linkage, average linkage, and increase in the sum of squares), then using squared Euclidean distance with the same clustering methods. Finally, the clustering structures were compared to determine the extent to which they agreed on the data structure.

The results showed no significant difference between the Euclidean and squared Euclidean measures. For all the hierarchical cluster analyses, optimizing both functions produced almost the same order of the proximity matrix and tree. However, the Ward clustering method worked better with Euclidean distance than with squared Euclidean distance as it gave clearer results, and the groups or classes were more clearly defined. It was also apparent that all four methods agreed on the main clusters in their clustering of the matrix rows but disagreed on the detailed structure.

Single linkage clustering was not very useful in identifying meaningful clusters for this study because of the "chaining effect" feature that characterizes it. The problem with such clustering is that the texts are chained together in a way that obscures any structure beyond sequentiality. Likewise, complete linkage was not appropriate. The two complete clustering structures were uneven, producing a large number of small-membership clusters and sometimes producing a small number of large-membership clusters.

Although average linkage clustering is considered the default method in agglomerative hierarchical clustering since it overcomes the problems associated with single and complete linkages, it was not ideal in this case because of the overwhelming tendency toward left branching. One more problem with average linkage is that some classes or groups are too small to be considered distinct classes, whereas some other classes are too large to express the dataset consistently.

Thus, Ward linkage clustering (or what is usually referred to as the sum of squares) with the Euclidean distance measure seemed to be the most appropriate because it achieved the clearest partitioning of the matrix rows. Ward clustering served the purpose of the analysis, namely to discover useful associations and meaningful groups in the dataset, and thus obtain a clearer picture of the responses of the users. The study was not only concerned with identifying the yes/no or approve/disapprove dichotomy. Rather, it sought to gain a deeper understanding of the data corpus. Using the sum of squares, it was easy to identify the number of clusters (2). The matrix rows were assigned into two clearly identified classes or clusters, as shown in Fig. 2.
Fig. 2.   Identification of the Number of Clusters.

Next, principal components analysis (PCA) was carried out. The comparisons showed a great deal of agreement in all clustering structures, supporting the validity of the results. The clustering structure most agreed on was Ward clustering with the Euclidean distance measure. The matrix rows of this structure are assigned into two groups, A and B.

### A. Centroid Comparison

To measure the distance between the two clusters, centroid analysis was used, such that numerical differences between Group A and Group B specify the numerical difference between the vectors of A and B for each of the 200 variables. Based on the centroid comparison results, it is possible to determine which variables are most and least characteristic of each group, and which most differentiate them. There is too much detail here for convenient interpretation. Attention can be restricted to a smaller number of higher variance variables at the top of the tables, shown in Table I.

TABLE I.   CENTROID COMPARISON

| Variable index | Centroid 1 frequency Group A | Centroid 2 frequency Group B | Difference |
|---|---|---|---|
| 48 | 2.44595E009 | 0.000 | 2.44595E009 |

Based on the centroid comparison, it is clear that there are significant differences between the members of each cluster or group. A comparison of the most distinctive variables in each group reveals that the texts in Group A tend to express approval of the telecommunications and internet services, as indicated by words like good, better, free, useful, and initiative, shown in Table II.

TABLE II.   DISTINCTIVE LEXICAL FEATURES OF GROUP A

| Group A | | |
|---|---|---|
| Arabic words | Transliteration | English translation |
| جيد | Jyid | good |
| أفضل | Afdil | better |
| مجاني | Majaani | free |
| مفيدة | Mufida | useful |
| مبادرة | Mubadara | initiative |
| إضافية | Iidafiatan | additional |
| سماح | Samah | allowance |
| يمكن | Yumkin | enable |
| حلوة | Hulwa | cool |
| معقول | Maequl | reasonable |
| كويس | Kuays | well/fine |

Group B, in contrast, reflects the disapproval of the users of the services provided by the companies, as indicated by words such as poor, worst, disconnected, and complaint, shown in Table III.

TABLE III.    DISTINCTIVE LEXICAL FEATURES OF GROUP B

| Group B | | |
|---|---|---|
| **Arabic words** | **Transliteration** | **English Translation** |
| أسوأ | 'aswa | the worst |
| سيئة | Sayiya | poor |
| عدم | Eadam | Non |
| شكوي | Shakwi | complaint |
| فصل | Fasl | disconnect |
| مفيش | Mufish | Nothing |
| بايظ | Bayiz | Down/not working |
| لعنة | Laena | Curse |
| فاشل | Fashil | loser/failure |
| مو | Mw | not |
| لا | La | no |
| هدر | Hadr | waste |
| غلا | Ghlana | expensive |

Concerning the number of the tweets in each group, it is clear that most users had negative attitudes toward the services provided by the telecommunications services during the COVID-19 pandemic. The first group includes 31% of the tweets in the corpus, while the second group includes 69%. Referring to the lexical centroids, it can be claimed that the attitudes of Saudis to the services provided by the telecommunications companies during the pandemic were largely negative. Although the statistical findings of the study give broad indications about the attitudes and sentiments of the users on this issue, it is important here to look at the discourse features of the corpus to obtain a broader and more in-depth knowledge about the data. This is shown in the collocation analysis below.

*B. Collocates*

This section seeks to explore the distinctive discourse features of the two groups assigned through cluster analysis. For this purpose, three key words, MOBILY, ZAIN, and STC, were selected denoting the three telecommunications companies operating in Saudi Arabia. These are shown in Table IV.

TABLE IV.    FREQUENCY OF KEY WORDS

| KEY WORD | | | FREQUENCY |
|---|---|---|---|
| Mobily | موبايلي | MOBILY | 1486 |
| zain | زين | ZAIN | 1369 |
| stc | إس تي سي | STC | 1199 |

A frequency analysis of the three key words using the KWIC concordance analysis was then carried out with the two groups, A and B, to explore the discoursal and thematic features of each group.

In Group A, the three key words were associated with concepts such as shopping apps, working from home, facilitating virtual interactions, health information, access to services, social distancing, tracing apps, social connectedness, connectivity solutions, education services, and education providers, as shown in Table V.

For Group 2, the three key words MOBILY, ZAIN, and STC appeared to be associated with key concepts including service suspension, weak infrastructure, reduced network performance, congestion in mobile networks, high cost, uneconomical, high-priced, connection problems, threatened with disconnection, frustrating handling of individual complaints, remote areas, missing classes, disadvantaged neighborhoods, digital divide, poor coverage, and poor customer service. A frequency analysis of these collocates is shown in Table VI.

Based on the collocation analysis, it can be suggested that most users had negative attitudes concerning the performance of the three telecommunications companies during the pandemic. They were not happy with the high costs of the services and packages, or the connection problems that had negative implications for their commitment to classes. Many of them expressed their dissatisfaction with the companies' handling of their complaints. Others were concerned with the poor infrastructure in remote areas and disadvantaged neighborhoods. In contrast, a minority of users had positive attitudes. Referring to their tweets, they expressed their satisfaction with the services in terms of disseminating information on health, facilitating social distancing, and supporting distance learning through education platforms, and working from home. They were also happy with the initiatives and free internet services provided by the companies during the pandemic.

TABLE V.    COLLOCATES IN GROUP 1

| | **Collocates** | **Frequency** |
|---|---|---|
| تسهيل التواصل | facilitating virtual interactions | 865 |
| معلومات صحية | health information | 775 |
| الوصول إلي الخدمات | access to services | 692 |
| توافر الخدمات | availability of services | 692 |
| التواصل الاجتماعي | social connectedness | 544 |
| سرعة عالية | high speed | 356 |
| التباعد الاجتماعي | social distance | 344 |
| حلول الإتصال | connectivity solutions | 311 |
| الخدمات التعليمية | education services | 289 |
| المؤسسات التعليمية | education providers | 257 |
| التعليم الجامعي | university education | 249 |
| تطبيقات التسوق | shopping apps | 199 |
| العمل من المنزل | working from home | 185 |
| منصات التعليم | Education platforms | 167 |

TABLE VI.    COLLOCATES IN GROUP 2

| | Collocates | Frequency |
|---|---|---|
| فصل الخدمة | service suspension | 1968 |
| بنية تحتية ضعيفة | weak infrastructure | 1885 |
| انخفاض أداء الشبكة | reduced network performance | 1779 |
| الضغط علي شبكات المحمول | congestion in mobile networks | 1766 |
| مكلفة | Costly | 1693 |
| تكلفة عالية | high-cost | 1655 |
| غير اقتصادي | Uneconomical | 1588 |
| غالي | high-priced | 1579 |
| مشاكل الإتصال | connection problems | 1344 |
| مهددة بانقطاع وفصل الخدمات | threatened with disconnection | 1288 |
| التعامل المحبط مع شكاوي العملاء | frustrating handing of individual complaints | 1262 |
| مناطق نائية | remote areas | 1223 |
| الغياب عن المحاضرات | missing classes | 1175 |
| الأحياء المحرومة | disadvantaged neighborhoods | 1134 |
| تغطية سيئة | poor coverage | 988 |
| خدمة العملاء السيئة | poor customer service | 967 |

It can thus be argued that the study of collocates and discoursal properties of the data was useful in attaining a deeper understanding of the users' responses and attitudes to the performance of the telecommunications companies during the COVID-19 pandemic. It was not possible for text clustering based on the "bag of words" model alone to address the discourse features in the corpus. Opinion mining applications, especially in Arabic, thus need to integrate discourse approaches to gain a better understanding of people's opinions and attitudes regarding given issues. Arabic is one of the most widely used languages on the internet, but it has not received sufficient attention in such applications compared to other languages, particularly English. The reason for this is that it has a complex linguistic structure and its own linguistic nature, and the availability of linguistic resources on Arabic is limited mainly to dictionaries and grammar. This is one of the challenges facing researchers working in Arabic. The proposed method addresses some of the linguistic challenges in opinion mining applications in Arabic.

## V.  CONCLUSION

This study has addressed the issue of using the potential of artificial intelligence to explore the sentiments and attitudes of customers concerning the performance of the Saudi telecommunications companies during the COVID-19 pandemic. It is clear that most users had negative attitudes. The study has offered an integrated approach that combines VSC and discourse analysis tools to address the limitations traditionally associated with opinion mining applications. The integration of discourse analysis tools was useful in attaining a deeper understanding of the users' responses and attitudes. Although this study was limited to the performance of telecommunications companies in Saudi Arabia during the COVID-19 pandemic, the proposed method can be usefully applied in other opinion mining applications, especially in

Arabic, which poses many challenges for researchers due to its unique linguistic features and lack of linguistic resources. Such issues tend to have negative implications for NLP applications in Arabic, including opinion mining.

# Building Footprint Extraction in Dense Area from LiDAR Data using Mask R-CNN

Sayed A. Mohamed*, Amira S. Mahmoud, Marwa S. Moustafa, Ashraf K. Helmy, Ayman H. Nasr

Data Reception, Analysis and Receiving Station Division, National Authority for Remote
Sensing and Space Science, Cairo, Egypt

*Abstract*—**Building footprint extraction is an essential process for various geospatial applications. The city management is entrusted with eliminating slums, which are increasing in rural areas. Compared with more traditional methods, several recent research investigations have revealed that creating footprints in dense areas is challenging and has a limited supply. Deep learning algorithms provide a significant improvement in the accuracy of the automated building footprint extraction using remote sensing data. The mask R-CNN object detection framework used to effectively extract building in dense areas sometimes fails to provide an adequate building boundary result due to urban edge intersections and unstructured buildings. Thus, we introduced a modified workflow to train ensemble of the mask R-CNN using two backbones ResNet (34, 101). Furthermore, the results were stacked to fine-grain the structure of building boundaries. The proposed workflow includes data preprocessing and deep learning, for instance, segmentation was introduced and applied to a light detecting and ranging (LiDAR) point cloud in a dense rural area. The outperformance of the proposed method produced better-regularized polygons that obtained results with an overall accuracy of 94.63%.**

*Keywords—Deep learning; object detection; mask R-CNN; point cloud; light detecting and ranging (LiDAR)*

## I. INTRODUCTION

The identification and extraction of urban footprint has become an important research topic and tool in city planning, transportation planning, urban simulation, 3D city modelling, and building change detection [1-3]. Automatic building footprint extraction is needed to meet the rising demand for precise city building outlines. LiDAR data creates digital terrain and surface models [4]. Despite the benefits of using LiDAR to extract vegetation, essential infrastructure, and hydrography, building footprint extraction is desired for estimating population, energy demand, and quality of life [5].Several techniques have been introduced to extract building footprints using optical sensors. These techniques include image-based, LiDAR-based, and data fusion-based [6]. For instance, Image-based technique use spectral properties. Spectral ambiguities and shadow occlusions can lead to inaccurate building footprints. [7]. Nemours approaches used LiDAR intensity, echo, and geometric attributes, but fusing LiDAR and high-resolution images improves performance and robustness.

Deep learning uses multilayer neural networks in many applications [8, 9] such as: object detection [10], image classification, image denoising [11], medical image segmentation [12], image super-resolution [13-15], and depth

prediction in stereo and monocular images [16]. Recently, several researches have investigated deep learning algorithms to improve building footprint extraction [17-19] either using CNN or a fully convolutional neural network.

CNN-based object detectors are single and two-stage. Fast R-CNN, faster R-CNN [20], and mask R-CNN are widely identified as two-stage detectors. Fast R-CNN doesn't allow end-to-end training since it uses a selective search to extract region proposals, which reduces the performance. Faster R-CNN replaces Region Proposal Network (RPN) selections, allowing end-to-end training. However, multiscale and small objects are a challenge. Despite their high inference speed [21], YOLO [22], YOLOV2, YOLOV3, and Single Shot Detector SSD [23] are single-stage networks with low detection accuracy in dense and tiny objects. Building footprint extraction requires accuracy; hence a two-stage neural network is used.

Mask R-CNN combines object detection and segmentation to improve overall accuracy and detect small and multiscale objects. But the detection speed is hardly real-time.

Class imbalance is an issue in remote sensing. This occurs when one or more classes are underrepresented in a dataset [7]. Traditional learning algorithms assume a balanced training set, which leads to a bias toward the majority classes. Consequently, the built model predicts poorly since all objects are in the dominating class regardless of the feature vector value [24]. The majority class classification bias is worse for high-dimensional data when variables exceed samples. The problem of skewed class distribution caused by uneven data was ignored. Class imbalance techniques are divided into data and algorithmic techniques. Data level approaches include data sampling, random over sampling, random under sampling, and a hybrid between them and feature selection. Algorithmic approaches are cost-sensitive and hybrid/ensemble. these approaches perform better.

In imbalanced datasets, ensemble classifiers improve single classifiers by merging them. Ensemble learning algorithms improve imbalanced data classification more than data sampling strategies. Due to precision-focused ensemble construction methods, the minority class is unrecognized. Developing ensemble learning algorithms must address class imbalances. Several approaches using ensemble learning and imbalanced learning have been reported [4]. Integrating ensemble-based techniques into an imbalanced dataset reduces overfitting and improves classification accuracy.

---

*Corresponding Author.

This paper used an ensemble of mask R-CNNs to effectively extract the building footprint using the LiDAR dataset in dense rural areas. The dense area in Maghagha city contains a skew distribution between structure and unstructured buildings. Datasets of GIS buildings were integrated with the collected LiDAR dataset to improve the building extraction results. The main contributions are summarized as follows:

- The mask R-CNN framework was used to effectively extract building footprints in dense areas.

- Different core mask R-CNN networks were adopted to benefit from transfer learning and different strategies (data augmentation and postprocessing).

- Class imbalance was handled in building types using a weighted voting ensemble approach.

The remainder of this work is structured as follows: Section 2 provides relevant work and a summary of point cloud classification methods. Section 3 introduces the proposed LiDAR building footprint extraction method from the point cloud. Section 4 summaries the results of several tests done to evaluate the efficiency of the proposed LiDAR classification method on real data for Maghagha area. Section 5 concluded the findings.

## II. RELATED WORK

LiDAR is an effective remote sensing technology for precisely describing terrain geometry. Thus, it is a viable solution for mapping dense urban areas to support infrastructural reconstruction, maintenance, and visibility. LiDAR technology provides very precise spatial resolution and height information [25]. Many studies have outlined the benefits of applying LiDAR data in characterizing urban structures [26, 27]. LiDAR point cloud data segmentation for automatic building extraction improves building detection and surface extraction in urban scenes [28]. A point feature based on normal vector variance is presented to extract buildings from LiDAR point cloud data by merging point- and grid-based features [29]. Building footprints using LiDAR data were needed to build a dataset for the open data portal and evaluate the minimal acceptable criteria for accurate building extraction [30]. Airborne laser scanning is a good choice in urban planning because of its capacity to determine building height, mobility, and rapid data acquisition [19, 31].

Morphology utilizes a filtering window to create an identical output image. A morphological operation compares a point's value to its neighbors. Dilation and erosion are morphological procedures that extend or diminish structures. Dilation adds border points, but erosion subtracts. The image structure dictates how many points are added or removed. The structuring element is a set of coordinates that determines the performance [1, 32].

Recently, machine learning algorithms in LiDAR have been generalized. Insufficient, complicated structure and large size limit the machine learning performance. In [4], The authors presented an effective method for combining point cloud and optical data. The method extracted points and super voxel features. The TraAdaboost algorithm with multi classes was utilised to improve LiDAR-based point cloud classification. The results demonstrated the improved classification performance compared with nonregistered LiDAR points. In [5] Integrated spectral signatures from diverse sensors into LiDAR point cloud classification utilizing multiple feature spaces using machine learning algorithms.

Furthermore, several efforts were conducted [1, 4, 5] to assess LiDAR data in building footprint extraction, varying between semiautomatic to automatic. Extracting a building footprint can be divided into three phases: isolating nonground points, segmenting building points, and extracting the building outline from the building footprint segmentation, as shown in Fig. 1.

Fig. 1. Typical Building Footprint Extraction from LiDAR Data.

Different levels of filters, such as morphological filters [5, 24, 33], progressive densification [34], surface-based filters [35], and segmentation-based filtering [36], can be applied in the isolation of nonground points phase. These filtering methods work well on flat ground but poorly on undulating terrain [37]. Another common approach was to employ a nonhierarchical classification to separate land-use types. Here, point cloud intensity was used to improve classification. However, roadways and parking lots have the same intensity values as building rooftops; including them does not improve results [38].

In the segmentation phase, trees, utilities, buildings, etc. are used as nonground points. A traditional method for separating these objects uses thresholds on a digital surface model (DSM) or a normalized DSM (difference between Digital Terrain Models DTM and DSM) [39]. This isn't always successful, as trees and buildings are often comparable heights and close together [40]. Other approaches for separating trees from building points include morphological filters, texture analysis, and plane fitting [41], and hierarchical object-oriented classification [42]. Notably, the acuracy depends on study area complexity [43]. SSD is considered simple compared with other approaches that use object proposals. SSD encapsulated proposal creation and feature resampling in a single network to simplify training [23]. Mask R-CNN can distinguish the adjacent objects and extract the outline of an object [44]. Finally, an extraction technique to construct a polygon or footprint from noisy and irregular boundaries is required. Examples of most common approaches include the least squares technique [45], nonlinear least squares [46], angle histogram of boundary points [47], weighted line segmentation [5], and invariant parameters using known roof types [48]. The quality of the building footprint depends on the various factors as point density, geometry, and building density [48]. In a fully convolutional network, a Spatial Residual Inception module termed (SRI-Net) was proposed to collect and combine multiscale multilevel features. SRI-Net can detect large buildings easily while preserving global and local details [49]. Due to land-cover changes and delayed geospatial data updates, some building annotations may be missing in the ground truth building mask., thereby leading to confusion in

CNN. To address this issue, the building footprints extraction problem was formulated as a long-tailed classification. Then, a three-term joint loss function was proposed: 1) logit adjusted cross-entropy, 2) weighted dice loss, and 3) boundary alignment loss. The obtained results indicate that the proposed loss function preserves the fine-grained structure of building boundaries, effectively discriminates between building and background pixels, and increases F1-scores [50].

## III. PROPOSED METHOD

An ensemble method for building footprint extraction was introduced that combines two mask R-CNNs working in tandem, followed by a postprocessing phase to enhance building footprint prediction. Two backbone architectures were adopted ResNet (101, 34). The input layer accepts images of dimensions $256 \times 256$ and $128 \times 128$ pixels, respectively. Furthermore, different augmentation approaches were adopted to enhance the results. Fig. 2 shows a graphical representation of the proposed approach.

The mask R-CNN is a versatile model used in different fields [21] and comprises two phases: region proposals generation and classification [51]. This paper adopted the mask R-CNN as the benchmark model for detecting the footprints of rural buildings in dense areas. In the following subsection, data preparation, training, and detection phases were discussed in detail.

### A. Data Preparation

Six-stage workflow in extracting the building footprint was adopted a. In the first stage, DSM for the study area was generated a using LiDAR ENVI software. To automatically define the building footprint, only points designated as buildings was filtered. The deep learning framework for the ArcGIS Pro software was incorporated in the preparation and labeling of the second stage. Thus, 150 sample buildings were chosen to serve as training data for the proposed neural network ensemble using "Label Object for Deep Learning." In the third stage, to contain image chips and labels, the sample data were converted into training data using the "Export Training data for Deep Learning" tool. In the fourth stage, two mask R-CNN ResNet backbones (34, 101) were trained and generated models for each of them. In the fifth stage, the "Detecting Objects using Deep Learning" tool was used for testing and data inferencing. Finally, the regularization of the building footprint use was done in the sixth stage by simply removing artifacts and correcting distortions in the building footprint polygons generated using "Feature Extraction."

### B. Backbone Initialization

Image patches of size ($256 \times 256$ and $128 \times 128$) were fed to ResNet-101 and ResNet-34 backbones in mask R-CNN, respectively to extract features. Table I shows a detailed description of both backbones. The residual family converges faster and achieves better training results compared with the shallow network. The image patches were fed to the backbone architecture to extract feature maps using transfer learning. These feature maps served as input for the next layer, after which the RPN was applied. This forecasts whether an object is present in that region. Here the regions obtained from RPN, which the model predicts, contain some objects and take various shapes. Hence, a pooling layer was applied to make the shape of all regions uniform. Next, these regions were fed to a fully connected network to forecast class labels and bounding boxes.

Fig. 2. Workflow of Mask R-CNN Ensemble Learning by using Two different Backbones Resnet 101 and 34.

## C. The Ensemble Voting Schema

Dense urban in the Maghagha study area is considered a mix of structured and unstructured building units. However, the skew class distribution between most of the unstructured and structured buildings introduced a bias in favor of the majority class. To address this problem, a hard-weighted voting scheme of the selected models was set ranging from 0 to 1. For each roof type, each model has a class likelihood score. The scores were multiplied by the CNN weights. Then, the products for the weighting step were summed. The weights were chosen at random using the Bayesian optimization process. Finally, the output class was decided using the maximum probability index. With default parameter settings, the Bayesian optimization method was run 100 times. The weighted voting is given in Eq (1).

$$\text{weighted voting} = w_1 * \text{Model}_1 + \cdots. + w_n * \text{Model}_n \qquad (1)$$

where n denotes the number of models and $w_1$ and $Model_1$ represent the weight and probability score of the selected Mask R-CNN model, respectively. Two models are considered in this work (n=2).

TABLE I. RSNET-34 AND 101 ARCHITECTURES

| Layer name | Output size | ResNet-34 | ResNet-101 |

## IV. EXPERIMENTAL RESULTS

### A. Dataset

Maghagha city is located in the north of El-Minya Governorate, Egypt. It is positioned between longitudes (30° 30′: 31° E), and latitudes (28° 30′: 29° N), as shown in Fig. 3, and covers an area of approximately 2,700 km2 [52]. Trimble® AX60, a high-performance, adaptable, and fully integrated airborne LiDAR solution designed to fulfill most aerial survey needs were utilized. The AX60 is a complete system that provides optimum quality, operational flexibility and efficiency, and in-service reliability [53]. The dataset was acquired using an Airborne Beechcraft B200. Furthermore, another dataset of high-resolution optical data, Nikon IC65+ and 2D-RGB imagery, from the same aircraft with sensors being rigidly fixed to the same platform used. Table II shows the parameters of the system used. The collected dataset study area comprises 10 LAS files, each approximately 2.2 km in

width and 18.5 km in length. Additionally, we collected 580 TIF RGB images measuring 1.6 km in length and 1.2 km in width. Because of limited computation power, one LAS file was used to generate DSM and Digital Elevation Model DEM for the data object segmentation process. As a sample training set, only two roof types were considered: structured and unstructured, as shown in Fig. 4.

### B. Evaluation Matrics

The proposed building footprint extraction workflow performance was evaluated using the overall accuracy (OA), precision, recall, and F-score. The precision computed by Eq. (2) shows the average of images that are correctly identified to the total number of structured and unstructured buildings that are correctly and non-correctly identified with the reference input.

$$\text{Precision (P)} = \frac{T_p}{T_p + F_p} \qquad (2)$$

where $T_p$ and $F_p$ represent the true and false positives, respectively.

TABLE II. THE PARAMETERS OF THE USED SYSTEM

| Trimble® AX60 System | |
|---|---|
| **LiDAR point clouds** | |
| Sensor model | Trimble AC IQ180 |
| Laser wavelength | Near-infrared |
| Laser pulse repetition rate (PRR) | 100–400 kHz |
| Scanning mechanism | Rotating polygon mirror |
| Scan frequency (max.) | 200 Hz |
| Operating flight altitude | 50–4700 m (164–15,500 ft) AGL |
| Range measurement accuracy | 2 cm |
| Intensity capture | 16-bit dynamic range for each echo |
| | |
| Digital aerial camera | |
| Model | Nikon IC 65+ |
| Array size | 80 MP |
| Channels | Three (RGB) |
| Shutter type | Electronically controlled leaf shutter |
| Ground sample distance | >5 cm |
| Calibration | Geometrically and radiometrically |

Fig. 3. Location Map of the Study Area (Maghagha, El-Minya Governorate, Egypt).

(a)

(b)
Fig. 4. Samples of Training Set Roofs, Structured and Nonstructured Covered (a) Point Clouds and (b) Very High-resolution RGB Image.

Recall, Eq. (3) defines the average number of structured and nonstructured buildings that are correctly identified of the total number of buildings that are correctly and non-correctly identified.

$$\text{Recall (R)} = \frac{T_p}{T_p + F_N} \qquad (3)$$

where $F_N$ represents the false negative.

F-score is defined in Eq. (4). If the obtained value is 1, the object detection is best and is worst when at 0.

$$\text{F-score} = \frac{2PR}{P+R} \qquad (4)$$

Finally, OA represents the ratio of correctly identified structured and nonstructured buildings to the total number of buildings.

### C. Experimental Setup

The suggested building footprint detection model was tested using datasets from Maghagha areas. The chosen dataset contains a mix of urban variety, including both structured and unstructured roofs. Various roofing materials, shapes, widths, and heights were used on the buildings. The LiDAR data used were collected on March 25, 2015. The system had a 30° scanning angle and a ±15° camera angle. The LiDAR data have an average point density of 7 points/m2 and a point spacing of 0.38 m. Overall, the minimum and maximum elevations of the operating area were 46.83 and 90.5 m, respectively. In the working area, DSM varied from 47.15 to 104.87 m. The raw LiDAR point clouds were used to create two separate products: DEM and DSM. Furthermore, the laser

scanning equipment also captured RGB images along with the point clouds. The orthophotos collected had a spatial resolution of 20 cm.

DSM was created using Inverse Distance Weighting IDW interpolation with a spatial resolution of 0.05 m. Meanwhile, DEM was created using the multiscale curvature classification filtering algorithm in ArcGIS (MCC) [20]. This solution has several advantages, including a built-in function in ArcGIS software that simplifies the deployment and allows integration into an automated processing workflow. With a mini-batch size of 2, the models were trained with 20 epochs and a learning rate of 0.0001. All tests were run on an Intel (R) Core i7 3.40 GHz processor with an NVIDIA GeForce GTX 1080-Ti GPU. These parameters were chosen based on their experimentally high accuracy. Because of the limited computational resources, optimizing the training algorithm settings may enhance performance even further.

### D. Results and Discussion

Experiments were conducted in several regions with varying numbers of buildings and roof shapes to demonstrate the detection accuracy of the framework. Fig. 5 shows the visual results. Despite the discontinuous and unclear borders in the DSM pictures, the suggested approach reliably identifies building footprints from highly populated locations. Furthermore, by overcoming the obstacles of location, form, and size, the mask R-CNN approach precisely partitioned the building footprints.

Fig. 6 shows another visual result for building footprints. From the results, the proposed method can accurately localize and segment building footprints under several settings, due to the extraction of a representative set of features by ResNet-34 and the segmentation capabilities of Mask R-CNN. Thus, the localization and segmentation ability may be slightly reduced for samples with large changes in size, particularly in dense regions. Fig. 7 shows a snapshot of results obtained from ResNet101, ResNet 34, and the proposed ensemble. One can observe the outperformance of the proposed ensemble results compared with the other two backbone architectures.

The proposed approach can precisely identify varied shapes of the building footprint with an average accuracy of 0.9463 on the dataset. Furthermore, by overcoming the differences in position, size, and shape, the suggested method can precisely segment regular and nonregular roofs. Evaluation measures (OA, precision, recall, and F-score) were applied to better understand the performance of proposed strategy. Table III shows the outcomes of the proposed approach. The results obtained show average overall accuracy, precision, recall, and F-score of 94.63%, 82%, 97.60%, and 88.46%, respectively.

TABLE III. OBTAINED ACCURACY, PRECISION, RECALL, AND F1- SCORE OF DIFFERENT BACKBONE COMPARED WITH THE PROPOSED

|  | OA | Precision | Recall | F-score |
|---|---|---|---|---|
| **ResNet34** | 81% | 32.6% | 33.18% | 31.4% |
| **ResNet101** | 88.75% | 72.19% | 70.6% | 71.4% |
| **Proposed ensemble** | 94.63% | 82% | 97.60% | 88.46% |

## V. CONCLUSION

Buildings are fundamental for urban planning and are essential in the development of a city. The extraction of precise building footprints from remote sensing data has been a topic of consideration. Recently, it has received much attention. Building data are useful in many geospatial applications, including urban planning, risk assessment, 3D city modeling, environmental sciences, and natural disaster damage assessment. Satellite photographs, aerial shots, radar scans, and laser scanning data can all be used to determine the footprint of a building. LiDAR provides a precise and efficient method of getting elevation data, which can be used to extract ground objects such as buildings. The ability to collect high-density point clouds quicker, great vertical precision, and low cost are all advantages of LiDAR over traditional photogrammetry. However, accurate extraction of buildings in urban dense areas with imprecise boundaries is difficult due to the presence of nearby objects. This paper proposed a building footprint extraction model tested using the LiDAR dataset. The study was chosen because the dense rural areas have a mix of urban elements, including both structured and unstructured roofs. Conclusively, the trained building footprint extraction model can detect all structured and unstructured buildings in the LiDAR data. The detected buildings could be saved as a feature layer and used for various data products to derive business value.

*Abstract*—The advancement of hardware and deep learning technologies has made it possible to apply these technologies to a variety of fields. A deep learning architecture, the Convolutional Neural Network (CNN), revolutionized the field of computer vision. One of the most popular applications of computer vision is in sports. There are different types of events in cricket, which makes it a complex game. This task introduces a new dataset called SNWOLF for detecting Umpire postures and categorizing events in cricket match. The proposed dataset will be a preliminary help, it was assessed in system development for the automatic generation of highlights from cricket sport. When it comes to cricket, the umpire has the authority to make crucial decisions about on-field incidents. The referee signals important incidents with hand signals and gestures that are one-of-a-kind. Based on detecting the referee's stance from the cricket video referee action frame, it identifies most frequently used events classification: SIX, NO BALL, WIDE, OUT, LEG BYE, and FOUR. The proposed method utilizes Convolutional Neural Networks (CNNs) architecture to extract features and classify identified frames into Umpire postures of six event classes. Here created a completely new dataset of 1040 images of Umpire Action Images containing these six events. Our method train CNNs classifier on 80% images of SNWOLF dataset and tested on 20% of remaining images. Our approach achieves an average overall accuracy of 98.20% and converges on very low cross-entropy losses. The proposed system is a influential answer for generation of cricket sport highlights.

*Keywords—Cricket match; computer vision; deep learning; SNWOLF dataset; umpire recognition; umpire action images; CNN; event classification*

## I. Introduction

The emerging areas like Artificial intelligence (AI) and machine learning (ML) are transforming modern society. An important subset of machine learning is deep learning, which can be employed to recognize images and speech. Deep learning is rapidly being applied in sports for a variety of applications, due to the advancements in computer vision. The use of AI is ubiquitous, from helping executives match in the decision-making process to helping athletes train on physical aspects. In the last few years, advances in TV channel transmission and CCTV technology have made it possible to exploit vast volumes of data and vision in the computer

research for sporting activities is growing. CNN is a highly efficient deep learning feature extractor and classifier for detecting various details and patterns in images. Time related physical movements of the fingers, hands, arms, head, face, or torso that are expressive and significant aimed at assigning meaningful information or interacting with the environment.

In recent years, gestures have become widely used by humans to interact with computers and machines and most everyday devices such as televisions, smart phones, and car dashboards can now be controlled with simple hand gestures. Gestures of cricket sports helps the umpire to take decision, gesture recognition for event recognition, development of assistive devices for the hearing impaired, sign language recognition, patient emotional medicine that allows very young children to interact with computers. It is also used in many areas such as gesturing [1] condition or stress level, lie detection, driver attention / fatigue monitoring, etc.

Incorporating gesture recognition technology into the sport makes game play fairer and more proficient. Gestures made by sports people show what meaningful information can be derived. Gestures are intended by those who move parts of their body in a predefined way to help with specific highlights, video context labeling, and more importantly, decision making and automatic extraction of highlights. Cricket is an important sport in many countries, the second most popular sport in Asia, the fourth most popular in Europe and the second most popular sport in the world [2]. However, since the 19th century, the same old manual method has been used to update the scoreboard. This puts a lot of strain on the scoreboard. The manner of viewing the rating has modified loads in time, however the simple rating updating manner remains the equal and achieved with the aid of using a person. Therefore, in the 21st century, there is an urgent need for automated systems in this area. Automated systems are replacing many of the tedious manual tasks performed by humans five or ten years ago. Therefore, there is an urgent need to develop such a fully functional automation system. Using state-of-the-art equipment and machine learning algorithms, one can improve the accuracy of decisions and provide perfect results that are evasive to the naked eye. This has led to the design of a system that recognizes cricket referee gestures in real time. In

*Corresponding Author.

addition, the reason for choosing cricket is that there are not enough technical applications to make cricket more impartial and accurate. Therefore, cricket has become an interesting topic for deep learning researchers doing computer vision-based research to identify and recognize the referee's various postures to extract the highlights of the cricket match.

In this work there is no existing record of cricket referee behavioral gestures. Created and named own dataset-"SNWOLF"- to train and evaluate the performance of the proposed method. The dataset includes 1040 umpire actions images and proposed a method which uses SNWOLF dataset for identifying the umpire event postures from umpire action images and classified into six event classes for Highlights Extraction using CNNs. Initially the Convolutional neural network classifier was pre-trained on 80% Umpire Action Event images, like SIX, NOBALL, WIDE, OUT, LEG BYE and FOUR, from SNWOLF dataset and remaining 20% Umpire Action images are tested. Our method can be noted as novel approach for state-of-the art techniques.

SNWOLF Dataset: SNWOLF is collections of Umpire Action images. We use this dataset to train CNN machine learning and computer vision algorithm. SNWOLF dataset has 1040 Umpire Action colored images. It has Six classes, and they are an SIX, NO BALL, WIDE, OUT, LEG BYE, FOUR. The images are of size 32x32 pixels. The dataset consists of 832 training and 208 testing examples. It is a database for people who want to try learning techniques and pattern recognition methods on real-world data while spending minimal efforts on preprocessing and formatting. We will use this database in our experiment.

## II. RELATED WORKS

In the area of cricket activity detection, some work is being done using computer vision. For ball-by-ball cricket video classification, Dixi et al. [3] compared three separate CNN architectures. To classify each ball into distinct results, they used the VGG16-CNN framework, which had already been pre-trained for transfer learning. In a game of cricket, Batra et al. [4] suggested an automated multifaceted perceptual approach for detecting balls thrown. To extract the highlight event of the cricket match, Harry Al. [5] employed the intensity projection profile of the referee. Hari et al. [5] used the referee's intensity projection profile to extract the highlight event of the match of cricket. To recognize foot crossings, Chowdhury et al. [6] recommended using video processing technologies. Lazarescu et al. [7] categorized cricket footage in broad terms based on camera movement metrics. The batsman's motion vector was employed to detect cricket shots by Karmaker et al. [8]. Semwaletal et al. [9] used saliency and optical flow to emphasize static and dynamic cues from cricket video, and then used CNN to extract feature representations for these cues. Finally, they adopted a Support Vector Machine (SVM) [10] to categories' cricket shots premised on those characteristic representations.

There exists limited work for classification of cricket sports images to detect cricket events. It has been noticed that an approach, based on Convolutional neural networks, provides the most precise detection. Very few explorations have been conducted by experts in the of cricket event

detection. However, none of them have attempted to recognize Events – like SIX,NOBALL,WIDE,OUT,LEG BYE,FOUR - using deep learning(CNN) method. Our findings may be the basis for future research on cricket video summarization and query-oriented highlight extraction.

All the current vision systems mainly rely on deep learning approach [11] which is a part of machine learning[12] attracted many researchers and the results of applying to this technique in many fields [13], [14], [15] are becoming more encouraging. L. Y. Deng and Y. Liu [16] provides event feature manipulations at multiple levels and correctly detects interested events, video indexing with merge for what user preferences. Aravind Ravi et al.[17] used pre-trained VGG19 and Inception V3 networks for feature extraction and highest classification results are obtained using linear SVM.Rabia A. Minhas et al.[19] proposed an effective shot classification method based on AlexNet Convolutional Neural Networks (AlexNet CNN) for field sports videos and achieves the maximum accuracy of 94.07%. In [20-22] provides large scale image Net for visual recognition, umpire-signals for different activities and scene classification for video summarization. Karen Simonyan et al.[23] suggested an evaluation of networks of increasing depth using an architecture with very small (3x3) convolution filters. In deep learning, a machine models learns to perform independently, the classification tasks from images, text, or sound with almost accurate results as compared to past. The models get trained by huge labeled data templates and neural network structure with many layers.

Table I shows the Research Gaps in this. So we have carried out the work considering the current scenario of digitization of cricket sports video. In this paper umpire gestures are recognized and classified for highlights generation, video summary creation and further work is query based event retrieval from the cricket sports video at global level.

Contributions of the proposed work:

- In this work a novel deep learning framework has been designed to recognize Umpire Action Image such as SIX, NOBALL, WIDE, OUT, LEGBYE, FOUR etc which can be used for Cricket Video Highlight Summarization. It consists of 14 layers of Convolution, pooling, flattening and fully connected layer.

- A designed dataset consisting of 1040 Umpire Action Images of events like SIX, NOBALL, WIDE, OUT, LEGBYE, FOUR has been built to train and evaluate the model.

- This work mainly concentrates on calculating Feature map for each Umpire Action Image and classify it among six Umpire Event Classes- SIX, NOBALL, WIDE, OUT, LEGBYE, FOUR etc. Hence CNN has been applied to reach the acceptable accuracy of the model.

- Rigorous experimentation has been carried out to tune the model and the relationship between model accuracy and parameters is presented. 80% dataset images used for huge training set and remaining for testing to achieve model accuracy of 96.48%.

TABLE I.    IDENTIFICATION OF RESEARCH GAPS AND LIMITATIONS FROM EXISTING MODEL

| Sl.No. | Author | Algorithm | Merits | Research Gaps | Accuracy |
|---|---|---|---|---|---|
|  | Kalpit Dixit et al.[3] | Single Frame Based architecture using softmax probabilities | Softmax function translates these raw scores into softmax scores which helps for classification | The model can be extended to more general problem of commentary generation | 80% |
| 2 | N. Batra et al.[4] | Trajectory Approximation Algorithm | Detection of no-ball and wide ball making accurate decisions | Technique could be extended to check for faults, order of service in doubles and aces. | 85% |
| 3 | M.Lazarescu et al.[7] | Incremental learning Algorithm | Camera motion parameters define the trajectory of the ball. | straight drive shot was unable to accurately classify the shot | 77% |
| 4 | Md Nafee Al Islam et al.[18] | CNN model with transfer learning | Model classifies Cricket bowlers based on bowling actions | Extend our work and include bowlers from all the cricket playing nations. | 93% |
| 5 | Shahid Karim et al.[24] | Inverted residual network architecture | SSD method quickly and accurately recognize the multi-gesture hands in video | Design more advanced CNN network to improve the accuracy of gesture recognition. | 90% |

## III. PROPOSED MODEL FOR CLASSIFYING UMPIRE ACTION FRAMES

### A. SNWOLF Dataset

The existing image dataset for event classification of the umpire action frame could not be found. Work accumulated pictures of Umpire completing a variety of tasks actions related to types of events as an example: "SIX", "NO BALL", "OUT", "LEG BYE", "FOUR" and "WIDE". There are six types of data in the dataset. To train and test the model, we had to create our own dataset called "SNWOLF". Each class is made up of 174 images, and each of the six classes provides a total of 1040 images. Fig. 2 depicts some of the photographs from the dataset for each of the six types of events. From the dataset, we trained the model with 832 images and remaining 208 images were used as a validation set to achieve test accuracy.

Fig. 1.    System Architecture for Cricket Event Classification.

Fig. 2.    An Example of a SNWOLF Dataset showing an Image of a Referee for Actions such as: "Six", "No Ball", "Wide", "Out", "Leg Bye" and "Four".

Fig. 1 shows the proposed model is a deep learning based model which makes use of convolution neural networks. There are two phases, one is training phase and another is testing phase. During training, the model is trained on 80% of SNWOLF dataset images and knowledge base is created to test remaining Umpire Action Images for classification among six classes of events. The CNN and its layers are explained in Section subsequent sections.

### B. Convolution Neural Network

CNNs (Convolutional Neural Networks) [11, 12] are a deep learning architecture that is being used to classify images [13]. Yann Le Cunetal. [14] first, introduced the idea of a Convolutional neural network that can be trained by back propagation. Jing Yu, Hang Li, Shou-Lin Yin, and Shahid Karim [24] offer a deep learning method for recognizing dynamic gestures in Human-Computer Interfaces using Transfer learning and to recognize different gestures quickly and effectively but the accuracy improvement is required in gesture recognition. Convolutional neural network's design became well-known with researchers that specialize in deep learning, with the introduction of LeNet5 in [15] and demonstrated outstanding performance in handwriting recognition and our proposed framework of Convolutional Neural Network is as shown in Fig. 3.

Fig. 3.   Framework of Convolutional Neural Networks.

Convolutional Neural Network has four layers. They are convolution, pooling, flattening and fully connected layer. We assume a gray scale or RGB image 'I' represented by size n1 * n2 denoted by function given in Eq. (1).

$$I:\{1,\dots,n_1\} *\{1,\dots,n_2\}\rightarrow W\epsilon R, (i,j)7\rightarrow I_{i,j} \tag{1}$$

Given the filter $K\epsilon R^{2h_1+1*2h_2+I}$, the discrete convolution of the image I with filter K is given by Eq. (2)

$$I\times K = \sum_{u=-h1}^{h1} \sum_{v=-h2}^{h2} K_{u,v}I_{r+u,s+v} \tag{2}$$

Where the filter K is given by Eq. (3).

$$K = \begin{matrix} K_{-h1,-h2} & \dots & K_{-h1,h2} \\ \dots & K_{0,0} & \dots \\ K_{h1,-h2} & \dots & K_{h1,h2} \end{matrix} \tag{3}$$

A filter which is most familiar for smoothing is the discrete Gaussian filter $K_{G(\sigma)}$ which is given by Eq. (4).

$$K_{G(\sigma)} = \frac{1}{\sqrt{2\pi\sigma^2}} exp2^{\frac{r^2+s^2}{2\sigma^2}} \tag{4}$$

Convolution Layer: The small window with width and height spatially convolves through the input volume and dot products are computed between the entries of the filter during the forward pass. Assume layer l be a Convolutional layer. The input to this layer constitutes m1 (I-1) feature maps from the preceding layer with m2 (I-1) *m3 (I-1) size. When I=1, image I is a input consisting of one or more mediums. This is how raw images are fed as input to the convolution neural network. The output from the layer l constitutes m1 (l) feature maps m2 (l) *m3 (l) sized Eq. (5) is used to compute the feature map (i[th]) of layer l.

$$Y^l_i =B_i^{(l)} +\sum 1 \, ^{m}_1 \, ^{(i-1)}_{j-1} \, K_{i,j}^{(l)} *Y_j^{(l-1)} \tag{5}$$

Where, B is a bias and K is the filter of size 2h1+l*2h2+l coupling the jth activation map in layer(l-1) with the ith activation map in layer l. m2 (l) and m3 (l) are determined by border influences. If layer l is not linear, m1(l) activation maps are the inputs to it and m1(l) = m1(I-1)activation maps are the outputs, each of size m2(l) *m2(l)along with m3(l) *m3(I-1),given by Eq.(6).

$$Y^{(1)}_i =f( Y_i^{(l-1)}) \tag{6}$$

Pooling layer: Pooling is nothing but a down-sampling with non-linearity. The output of pooling is maximum value of such sub-region and reduces size of representation, memory, computation in network and controls the over fitting.

Flattening Layer: Flatten our pooled feature map into a column and insert the data into Artificial Neural Network.

Fully Connected Layer: It takes the output from several convolution and max pooling layers and performs affine transformation with matrix multiplication and bias offset to compute its activations. The output of this layer is calculated using Eq. (7).

$$Y_i^{(l)} = f (Z_i^{(l)}) \tag{7}$$

## C. Model Implementation

The provided training data set was being used to train the CNN model. Initially the image features are extracted from each umpire action training images and model creates feature map- knowledge base - for testing. If the image in the frame was categorized as being one of the six classifications as : SIX, NO BALL, WIDE, OUT, LEG BYE or FOUR, then the processed frame is accumulated in one of the six classes and further used for generating the Event video summary of Cricket Sport. Algorithm 1 depicts the way in which the model is created for the purpose.

---

**Algorithm 1 : Proposed work Model**

---

**Input**: Upload dataset- SNWOLF-consisting of 80% images for training purpose

**Output**: trained CNN model

**Begin**

**Step1**: Data Pre-processing

      **Step2**: Input Layer

      This step reshapes the image into 3*32*32 pixels

**Step3**: Convolution and Pooling layers

      P=32

For i = 1 to 4 do

      1.Add six convolution layer with P feature maps of size 3*3 and a rectifier activation function. Also dropout layer at 20% in between these six layers

      2.    Add 2*2 is the greatest pool layer size and stride 3

      3.    P=P*2

  End

**Step4**: Flatten Layer

      It is going to flatten our pooled feature map into a column. Set dropout layer at units and a 20%

**Step5**: Dense layer:

      Create a 512-unit completely linked layer with a rectifier activation function.

      Also set dropout layer at 20%

**Step6**: layer output

      With 50 units and a softmax activation mechanism, create a fully connected output layer.

**Step7:** logic layer

      The final step is the prediction.

**End**

---

## IV. Results and Evaluation of SNWOLF Dataset

After the model has been trained, we tried to achieve almost 100% performance using the validity set. Fig. 4 displays the accuracy of instruction and verification progressively improves with the range maximum iteration. Our system was able to achieve an exactness of 98.2% which demonstrates classification ability on the practice set. Fig. 5

depicts the model's confusion matrix after being put through its paces with the test set. A matrix of uncertainty was used to measure the Accuracy, Precision and Recall of each class. The model's macro was then used to determine the F1 score average of the fit rate score and the recall score. Table I provides a summary of the model evaluation.

Table II shows the summary result of the classification assessment of the model on the practice set (SNWOLF).

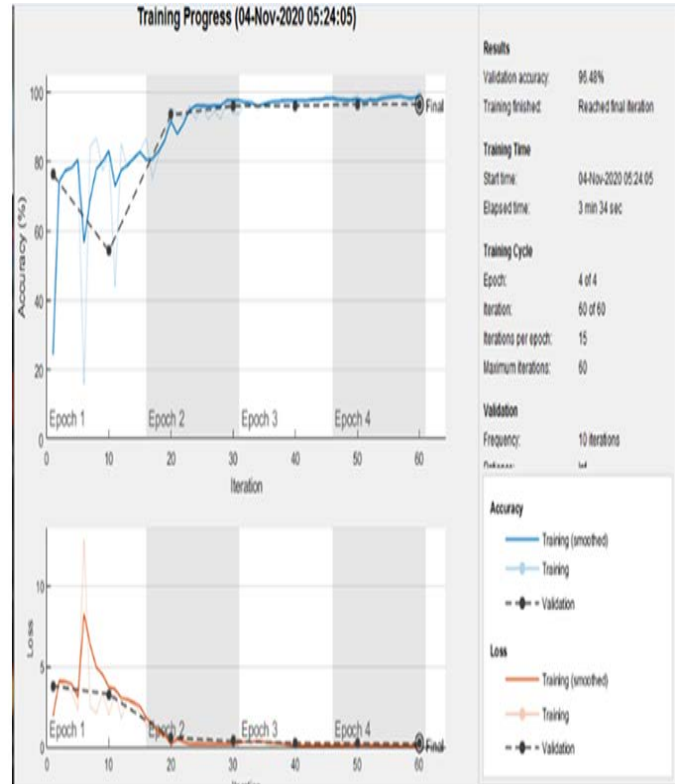

Fig. 4. Training and Validation Accuracy.

TABLE II.    Summary Result of the Classification Assessment of the Model on the Practice set –SNWOLF

| Event Name | Accuracy for individual event | Error rate for individual Event | Precision | Recall | F1 score | Accuracy |
|---|---|---|---|---|---|---|
| 1.Action.No Ball | 83.3 % | 16.7% | 83 | 52 | 92% | 98.20% |
| 2.Action.Wide | 98.5% | 1.5% | 97 | 96 | | |
| 3.Action.Out | 97.9% | 2.1% | 97 | 99 | | |
| 4.Action.Four | 98.7% | 1.3% | 98 | 100 | | |
| 5.Action.Six | 100% | 0% | 100 | 100 | | |
| 6.Action.Leg Bye | 98.2% | 1.8% | 100 | 91 | | |

## Results of CNN Classification

Fig. 5.   Confusion Matrix.

## V.   CONCLUSION AND FUTURE WORK

A CNN deep feature model is proposed in this research that can identify and classify six unique cricket EVENTS (SIX, NO BALL, WIDE, OUT, LEG-BY, FOUR) based on the Umpire Action Frame of the dataset. Using SNWOLF as a dataset, we trained the model on 80% of the images to identify and classify six events related to a cricket match between the two countries. Our model, shown in Fig. 6, test set was 98.2% accurate and the Fl score was 92.0%, which worked very well. The sample outputs of six classes Gestures are shown in Fig. 7. We intend to broaden our scope of study in the future to cover all forms of cricket competition country events where different types of cricket matches are played.

Fig. 6.   Classification Model Evaluation Results on Accuracy, Error, Precision, Recall, F1 Score and Accuracy.

Fig. 7.   Sample Images of Output Classes Six, No Ball, Wide, Out, Leg Bye and Four Events.

We intend to broaden our scope of study in the future for detection of other events, like Ball Catch, Baler Detection, Boundary, Third Umpire Decision, etc. will be suggested. Further covering all forms of cricket competition country events where different types of cricket matches are played. In this work open problems identified for future work are Text Tagging for events detected and Audio Annotation with Commentary.

*Abstract*—Genetic Algorithm (GA) has been proven to be easy in falling into local optimal value due to its fixed crossover probability and mutation probability, while Adaptive Genetic Algorithm (AGA) has strong global search capability because the two probabilities adjust adaptively. There are two categories of AGA according to the different adjustment methods for crossover and mutation probabilities: probabilistic linear adjustment AGA and probabilistic non-linear adjustment AGA. AGA with linear adjustment of probability values cannot solve the problems of local optimal value and premature convergence. The nonlinear adaptive probability adjustment strategy can avoid premature convergence, poor stability and slow convergence speed. The typical AGA with nonlinear adjustment of probabilities are compared and analyzed through benchmark functions. The optimization performance of typical AGA algorithms is compared and analyzed by 10 benchmark functions. Compared with traditional GA and other AGA algorithms, AGA with crossover and mutation probabilities adjusted nonlinearly at both ends of the average fitness value has higher computational stability and is easy to find the global optimal solution, which provides ideas for the application of adaptive genetic algorithm.

*Keywords—Adaptive genetic algorithm; genetic algorithm; nonlinear adjustment; probability*

## I. INTRODUCTION

Genetic Algorithm (GA) was first put forwarded by Professor Holland [1]. GA is a highly parallel random search algorithm developed from natural selection and evolution mechanism in biology, providing a solution to complex optimization problems. It has the characteristics of fast search speed, simple process and the flexibility is strong [2]. However, the optimization results easily fall into local optimal values due to its fixed crossover probability and mutation probability [3-4].

For this reason, many researchers put forward an improved method of GA to enhance its global search ability. Generally speaking, there are three categories of these improvements [5]:

The first category is a hybrid optimization algorithm based on GA [6-8]. Combining GA with other optimization algorithms to improve the performance is meaningful for solving different types of optimization problems. However, because different methods are relatively independent, their improvement work can only be carried out in their respective fields.

The second category is to improve the crossover operator [9] or mutation operator [10] in GA, which improves the optimization performance of GA to some extent, but the improvement is not significant [11].

The third category is Adaptive Genetic Algorithm (AGA) [11-14], which adaptively adjusts crossover probability ($P_c$) and mutation probability ($P_m$). Because the $P_c$ and $P_m$ adapted to the population are used in each evolutionary generation, instead of the fixed probability value, the adaptive ability of GA can be greatly improved, and the algorithm can converge to the global optimal solution more easily. Moreover, this improved method has wide application range and strong universality [5].

AGA was first proposed by Srinivas et al. [15]. In AGA algorithm proposed by Srinivas et al., when the fitness value of an individual is equal to the maximum fitness value of the individual in this generation, the values of $P_c$ and $P_m$ will be zero, which will lead to premature optimization calculation. For this reason, many scholars have put forward improved methods for AGA. Several different versions of improved AGA have been found. There are two categories of improved AGA methods: linear adjustment and nonlinear adjustment according to the different adjustment methods of crossover and mutation probabilities. This paper focuses on AGA algorithm for nonlinear adjustment of probability.

## II. ADAPTIVE GENETIC ALGORITHM

The adaptive ability of genetic algorithm should be reflected in that individuals in the population automatically discover the characteristics and rules of the environment according to the changes of the environment. The most obvious environmental feature is the individual's adaptability to the environment, and the most obvious evolutionary law is the relationship between the individual's fitness value and the average fitness value of all individuals in the population and the minimum fitness value and the maximum fitness value in the population.

In evolution, individuals don't remember which generation they evolved into, only whether they improved their ability to adapt to their environment. If there are improvements, then a better evolutionary pattern will be found, and as much as possible this pattern will be preserved in the algorithm design. Otherwise, the model is likely to become obsolete by nature.

The main difference between GA and AGA is the choice of $P_c$ and $P_m$ values. In GA, these two probabilities are randomly determined or based on insufficient prior knowledge reference, while AGA depends on the state of population in the evolution process to select the optimal value. The optimization process of AGA is in Fig. 1.

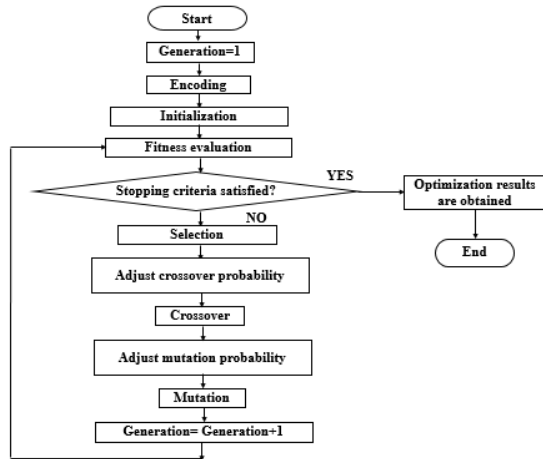

Fig. 1.    The Flowchart for AGA.

## III.    Literature Review about Nonlinear Adjustment AGA

There are two categories of AGA according to the different adjustment methods for $P_c$ and $P_m$: probabilistic linear adjustment AGA [16-18] and probabilistic nonlinear adjustment AGA [19-22]. AGA with linear adjustment of probability values cannot solve the problems of local optimal value and premature problem [19-22]. The nonlinear adaptive probability adjustment strategy can avoid premature problem, poor stability and slow convergence speed. According to whether the probability is adjusted at two branches of the average fitness value, the AGA with nonlinear adjustment can be divided into three types: one end is fixed and the other end is nonlinear adjustment (taking the average fitness value as the cutoff point) [18-19]; linear adjustment at one end and nonlinear adjustment at the other [21-22]; nonlinear adjustment at two ends.

### A.    One Branch is Fixed and the Other is Adjusted Nonlinearly [19-22]

*1) Nonlinear adjustment of probability value by exponential function[19]:* Equation (1) and equation (2) give the adjustment formulas of $P_c$ and $P_m$ through exponential function [19] in solving the minimum optimization problem, respectively. This AGA is labeled as AGA-1.

$$P_c = \begin{cases} P_{c\max} - (P_{c\max} - P_{c\min})\exp\left(1 - \dfrac{f_{avg} - f_{\min}}{f_{avg} - f}\right), f' \le f_{avg} \\ P_{c\max}, f' > f_{avg} \end{cases} \tag{1}$$

$$P_m = \begin{cases} P_{m\max} - (P_{m\max} - P_{m\min})\exp\left(1 - \dfrac{f_{avg} - f_{\min}}{f_{avg} - f}\right), f \le f_{avg} \\ P_{m\max}, f > f_{avg} \end{cases} \tag{2}$$

where $f_{\max}$, $f_{\min}$ and $f_{avg}$ represent the maximum, minimum and average fitness values, respectively; $f'$ is the larger fitness value of the selected individuals participating in crossover for $P_c$ [18], and $f$ is the fitness value of selected individual participating in mutation for $P_m$ [18], and $P_{\max} > P_{\min} \in (0,1)$. If $f' = f_{avg}$ or $f = f_{avg}$, $P_c = 0.01$ and $P_m = 0.001$.

*2) Nonlinear adjustment of probability value by sigmoid function[20]:* The adjustment formulas of $P_c$ and $P_m$ through sigmoid function (A=9.903438) [20] in solving the minimum optimization problem are given in Equation (3) and Equation (4), respectively. This AGA is labeled as AGA-2.

$$P_c = \begin{cases} \dfrac{(P_{c\max} - P_{c\min})}{1 + \exp\left(A\dfrac{2(f_{avg} - f')}{f_{avg} - f_{\min}} - 1\right)} + P_{c\min}, f' \le f_{avg} \\ P_{c\max}, f' > f_{avg} \end{cases} \tag{3}$$

$$P_m = \begin{cases} \dfrac{(P_{m\max} - P_{m\min})}{1 + \exp\left(A\dfrac{2(f_{avg} - f)}{f_{avg} - f_{\min}} - 1\right)} + P_{m\min}, f \le f_{avg} \\ P_{m\max}, f > f_{avg} \end{cases} \tag{4}$$

Fig. 2 shows the adaptive curves of $P_c$ and $P_m$ for AGA-1 and AGA-2. $P_c$ and $P_m$ will adjust nonlinearly according to the fitness of individuals between $f_{avg}$ and $f_{\min}$.

(a) Pc.

(b) Pm.

Fig. 2.    Adaptive $P_c$ and $P_m$ of AGA-1 and AGA-2.

## B. One Branch is Linear and the other is Nonlinear (Mark as AGA-3) [22]

Although AGA-1 and AGA-2 can avoid the local optimization and the premature convergence problem to some extent due to the adoption of a nonlinear adjustment strategy on one branch, it may still lead to the algorithm to fall into local optimum solution easily when the individuals' fitness value are larger than average fitness value and $P_c$ and $P_m$ are both fixed. For this reason, Wang [21] proposed the following improved adjustment strategy as shown in equation (5) and equation (6).

$$P_c = \begin{cases} P_{c3} + (P_{c2} - P_{c3})\exp\left(\dfrac{10(f' - f_{avg})}{f_{avg} - f_{min}}\right), f' \leq f_{avg} \\ P_{c2} - \dfrac{(P_{c1} - P_{c2})(f_{avg} - f')}{f_{max} - f_{avg}}, f' > f_{avg} \end{cases}$$

(5)

$$P_m = \begin{cases} P_{m3} + (P_{m2} - P_{m3})\exp\left(\dfrac{10(f - f_{avg})}{f_{avg} - f_{min}}\right), f \leq f_{avg} \\ P_{m2} - \dfrac{(P_{m1} - P_{m2})(f_{avg} - f)}{f_{max} - f_{avg}}, f > f_{avg} \end{cases}$$

(6)

Adjustment curves of $P_c$ and $P_m$ for AGA-3 are in Fig. 3.

(a) Pc.

(b) Pm.
Fig. 3. Adaptive $P_c$ and $P_m$ of AGA-3.

## C. Two Branches are Nonlinear (Mark as AGA-4) [22]

The values of $P_c$ and $P_m$ are adjusted adaptively and nonlinearly at both branches by sigmoid function [22]:

$$P_c = \begin{cases} P_{c3} + \dfrac{(P_{c2} - P_{c3})}{1 + \exp\left(A\dfrac{2(f_{avg} - f')}{f_{avg} - f_{min} - 1}\right)}, f_{min} < f' \leq f_{avg} \\ P_{c2} + \dfrac{(P_{c1} - P_{c2})}{1 + \exp\left(A\dfrac{\left(\dfrac{f_{avg} + f_{max}}{2} - f'\right)}{(f' - f_{avg})(f_{max} - f')}\right)}, f_{avg} < f' < \dfrac{f_{avg} + f_{max}}{2} \\ P_{c2} + \dfrac{(P_{c1} - P_{c2})}{1 + \exp\left(A\left(1 - \dfrac{2(f' - f_{avg})}{f_{max} - f_{avg}}\right)\right)}, \dfrac{f_{avg} + f_{max}}{2} < f' \leq f_{max} \end{cases}$$

(7)

[22]

$$P_m = \begin{cases} P_{m3} + \dfrac{(P_{m2} - P_{m3})}{1 + \exp\left(A\dfrac{2(f_{avg} - f)}{f_{avg} - f_{min} - 1}\right)}, f_{min} < f \leq f_{avg} \\ P_{m2} + \dfrac{(P_{m1} - P_{m2})}{1 + \exp\left(A\dfrac{\left(\dfrac{f_{avg} + f_{max}}{2} - f\right)}{(f' - f_{avg})(f_{max} - f)}\right)}, f_{avg} < f < \dfrac{f_{avg} + f_{max}}{2} \\ P_{m2} + \dfrac{(P_{m1} - P_{m2})}{1 + \exp\left(A\left(1 - \dfrac{2(f - f_{avg})}{f_{max} - f_{avg}}\right)\right)}, \dfrac{f_{avg} + f_{max}}{2} < f \leq f_{max} \end{cases}$$

(8) [22]

Adjustment curves of $P_c$ and $P_m$ for AGA-4 are presented in Fig. 4.

## IV. ANALYZE ALGORITHM PERFORMANCE BY BENCHMARK FUNCTION

The performance of the above four AGAs for minimum optimization problems is examined in this section. In order to analyze the results, basic GA is used as a benchmark for comparison. Ten standard benchmark functions commonly

used in literatures are selected for numerical simulation analysis.

### A. Parameters Setting of Algorithm

GA and the above four AGAs have the same parameters except $P_c$ and $P_m$. All parameters are exhibited in Table I.

TABLE I.    PARAMETERS OF GA AND AGAS

| Parameters | Value | Parameters | Value |
|---|---|---|---|
| Population(P) | 50 | $P_{cmax}$ for AGA-1 and AGA-2 | 0.75 |
| Generation(G) | 500 | $P_{cmin}$ for AGA-1 and AGA-2 | 0.3 |
| $P_c$ for GA | 0.85 | $P_{m1}$ for AGA-3 and AGA-4 | 0.1 |
| $P_m$ for GA | 0.01 | $P_{m2}$ for AGA-3 and AGA-4 | 0.05 |
| $P_{c1}$ for AGA-3 and AGA-4 | 0.9 | $P_{m3}$ for AGA-3 and AGA-4 | 0.01 |
| $P_{c2}$ for AGA-3 and AGA-4 | 0.6 | $P_{mmax}$ for AGA-1 and AGA-2 | 0.075 |
| $P_{c3}$ for AGA-3 and AGA-4 | 0.3 | $P_{mmin}$ for AGA-1 and AGA-2 | 0.01 |

### B. Benchmark Function

Ten benchmark functions [23] are used here to evaluate the performance of AGA. Their expressions, search ranges and global optimum values are listed in Table II. $f_1$–$f_5$ are multi-modal functions, and $f_6$–$f_{10}$ are singlemodal functions. GOV stands for global optimum value, and D stands for dimensions in Table II.

### C. Numerical Results

The numerical results are presented in Table III and IV. Table III gives the average optimum value of 20 calculations using basic GA and the four different AGAs, and Table IV provides the standard deviations.

The results in Table III show that the optimized values obtained by AGA-4 are the smallest among the five algorithms, showing the advantage of AGA-4 in solving the minimum optimization problem. It can be seen from Table IV that the standard deviation values of AGA-4 in the 20 calculations are also the smallest, which indicates the stability and the optimization consistency. Numerical results demonstrated that the adaptive probability of nonlinearly tuning $P_c$ and $P_m$ can avoid the problems of premature maturation and slow convergence, as well as poor stability of AGA-4.

TABLE II.    BENCHMARK FUNCTION

| Objective function | Search range | GOV[1] | D[2] |
|---|---|---|---|
| $f_1(x) = \sum_{i=1}^{D} \frac{x_i^2}{4000} - \prod_{i=1}^{D} \cos(\frac{x_i}{\sqrt{i}}) + 1$ | [-600,600] | 0 | 10 |
| $f_2(x) = -20\exp\left(-0.2\sqrt{\frac{1}{D}\sum_{i=1}^{D} x_i^2}\right) - \exp\left(\frac{1}{D}\sum_{i=1}^{D} \cos(2\pi x_i)\right) + 20 + e$ | [-32.768, 32.768] | 0 | 10 |
| $f_3(x) = 418.9829D - \sum_{i=1}^{D} x_i \sin\left(\sqrt{|x_i|}\right)$ | [-500,500] | 0 | 10 |
| $f_4(x) = \left(\sum_{i=1}^{5} i\cos((i+1)x_1+i)\right)\left(\sum_{i=1}^{5} i\cos((i+1)x_2+i)\right)$ | [-10,10] | -186.731 | 2 |
| $f_5(x) = -0.0001\left(\left|\sin(x_1)\sin(x_2)\exp\left(\left|100-\frac{\sqrt{x_1^2+x_2^2}}{\pi}\right|\right)\right|+1\right)^{0.1}$ | [-10,10] | -2.0626 | 2 |
| $f_6(x) = \sum_{i=1}^{D-1}\left[100\left(x_{i+1}-x_i^2\right)^2 + \left(x_i-1\right)^2\right]$ | [-2.048, 2.048] | 0 | 10 |
| $f_7(x) = (x_i-1)^2 + \sum_{i=2}^{D} i\left(2x_i^2 - x_{i-1}\right)^2$ | [-10,10] | 0 | 10 |
| $f_8(x) = \sum_{i=1}^{D} ix_i^2$ | [-10,10] | 0 | 10 |

## D. Discussion

In order to improve the comparative analysis of different AGAs, the probability adjustment curves of different AGAs are drawn in Fig. 5. Fig. 5 exhibit that the curves of $P_c$ and $P_m$ in AGA-3 become steeper when $f_{avg}$ and $f_{min}$ are closer to each other. As a result, the probabilities of these individuals are greatly different each other even if there is little difference in individual fitness values. Thus, most individuals only have lower $P_c$ and $P_m$, causing the evolution to stagnate. In order to avoid the occurrence of the above situation, firstly, the adaptive adjustment curves of $P_c$ and $P_m$ should be changed slowly at $f_{avg}$ so as to greatly enhance $P_c$ and $P_m$ of individuals with fitness closer to $f_{avg}$ . Secondly, to ensure that better individuals in contemporary population still have a certain crossover and mutation probabilities, the adaptive adjustment curve at $f_{min}$ should be smoothed. Although AGA-1's adaptive adjustment curve is relatively smooth in the near area $f_{avg}$, it retains a large probability value in the near area $f_{min}$, which is not conducive to the retention of dominant individuals in the late stage of evolution. However, in AGA-2, the $P_c$ and $P_m$ vary slowly in the near area $f_{avg}$, and $P_c$ and $P_m$ values close to $f_{avg}$ are significantly improved. At the same time, since the patterns of nearby $f_{min}$ individuals are preserved as much as possible, their values are low but greater than zero, which explains why the algorithm tries to get out of local convergence.

On the other hand, the results of AGA-2 are obviously better than AGA-1 and AGA-3, which indicates that a good nonlinear adjustment curve can greatly improve the performance of AGA. However, to some extent, it is easy for AGA to fall into the local optimal solution because AGA-2 adopts a fixed probability value between $f_{avg}$ and $f_{max}$. AGA-4

makes the $P_c$ and $P_m$ curves change nonlinear slowly through nonlinear adjustment, and makes the curves smooth at any point. When the individual population is in a comparable state, AGA-4 pulls apart most individuals near $f_{avg}$, thus promoting the process of evolution. It is of positive significance to eliminate local convergence and prevent the algorithm from falling into stagnation.

(a) $P_c$

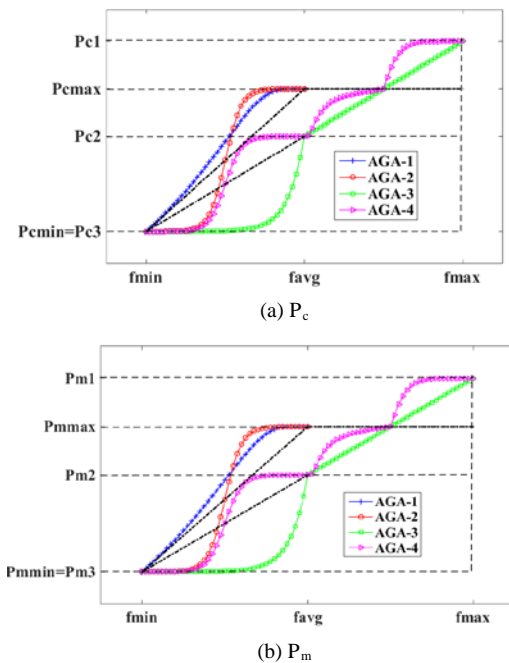
(b) $P_m$


Fig. 5.    Adaptive $P_c$ and $P_m$ of AGA-1, AGA-2, AGA-3 and AGA-4.

## V. CONCLUSION

AGA algorithms with nonlinear adjustment of $P_c$ and $P_m$ are systematically summarized, and the optimization performance of typical AGA algorithms is compared and

analyzed by 10 benchmark functions. The optimization calculation results of benchmark functions show the superiority of AGA-4 which has crossover probability and mutation probability that are nonlinear adjusted at both ends of $f_{avg}$.

Compared with traditional GA and other AGA algorithms, AGA-4 has higher computational stability and it's easy to find the global optimal solution.

In the future, we will study the crossover operator and mutation operator of AGA in order to further improve the performance of the optimization algorithm.

*Abstract*—The automated guided vehicles dispatching is one of the important operations in containers terminal because it affects the loading/unloading process. This operation has become faster and more complex until the automation advent. Although this evolution, the environment has become dynamic and uncertain. This paper aims to propose an improved particle swarm approach for solving the bi-objective problem of automated guided vehicles dispatching and routing in a dynamic environment of containers terminal. The objectives are to minimize the total travel distance of all automated guided vehicles and maximize the workload balance between them. The application of particle swarm algorithm in its basic form, shows a premature convergence. To ameliorate this convergence, the authors proposed the application of a method to escape the worst particles from the local optimum. The new Hybrid Guided Particle Swarm approach consists of hybridization between Dijkstra algorithms and a Guided Particle Swarm Algorithm. The routing problem is solved with Dijkstra algorithm and the dispatching problem with guided particle swarm approach. As a first step, this approach has been applied in a static environment where the dispatching parameters and the routing parameters are fixed in advance. The second step consists of applying this approach in a dynamic environment where the number of containers associated with each automated guided vehicles can change, the shortest path and the container locations can also change during the algorithm execution. The numeric results in a static environment show a good Hybrid Guided Particle Swarm performance with a faster and more stable convergence, which surpasses previous approaches such as Hybrid Genetic Approach and the efficiency of its extension approach Dynamic Hybrid Guided Particle Swarm in a dynamic environment.

## I. INTRODUCTION

The productivity of maritime transportation has significantly advanced with the advent of automation. Automated container terminals have become crucial intermediaries between the marine and land transportation systems. As the number of ships entering and exiting daily from terminals has greatly increased, the number of containers loaded by ships has become very large [1]. Following this revolution, many maritime ports worldwide have established automated equipment to manage the increase in container traffic. They also installed an automated control system to achieve an optimal performance. The equipment in ACT is classified into three principal types: quayside equipment, quay cranes (QCs) used to load or unload containers from or to the ship; landside equipment, yard cranes (YCs) employed for container loading or unloading in the yard storage depots; and intermediate zone equipment, automated guided vehicles (AGVs) used to transport containers from the two sides of the port. An AGV is a mobile robot that follows markers or wires on the floor or uses vision, magnets, or lasers for navigation. It is extensively employed in industry to transport goods from an origin location to a target location [2, 3, 4]. AGVs are widely used in manufacturing, medicine, and logistics industries. Although this equipment has accelerated the ACT operations, any working failure of any one of them may cause a late or partial blockage or global blockage of the whole system in the ACT. The most critical goal of an automated container terminal is to increase productivity by minimizing the berthing duration of ships. This objective can be accomplished by finishing the main ship loading/unloading operation at its scheduled time because any lateness can affect the synchronization of the entire system. This operation includes four types of sub-operations: (1) loading/unloading containers from/to the ship, (2) AGV dispatching and routing, and (3) loading/unloading containers to the yard storage zone. The container loading/unloading process began after ship berthing. The containers are unloaded from the ship by the quay cranes and are then transported by the AGVs to the landside of the port. They are then unloaded by yard cranes and stocked in the corresponding yard storage zone. Conversely, the ship-loading operation begins by assigning containers to AGVs for transfer to the quayside to be loaded by the quay cranes to the ship. These loading and unloading operations have become faster with the advent of container terminal automation and a high number of equipment in the port [5]. Nevertheless, with this important evolution of the container terminal, the risk of breakdown of any element in the system increases. This failure can have some consequences, such as the lateness of the loading/unloading operation; therefore, the berthing duration of the ship increases, which will indirectly disturb the productivity of the port. The latency of the ship berthing duration may cause the unavailability of container terminal equipment, which will delay the loading/unloading operation of all ships after this disruption. This paper studies the problem of AGVs dispatching in a static and dynamic environment of containers terminal. In the first step, the authors investigate to solve the static problem. They choose to optimize the total travel distance of all AGVs and the workload balance between them. By studying these two

criteria; the total travel distance depends on AGV's path and the balance workload depends on AGV's autonomy. The first criteria were optimized by using an exact algorithm to search the shortest path for each AGV and the second criteria were optimized by maximizing the autonomy of each AGV. The workload balance makes the AGVs system more robust because the AGV working more tasks than other AGVs will lose its autonomy early. Because the AGV's autonomy is limited to its battery energy, the breakdown of AGVs can be frequent with absence of workload balance. In a static environment, this problem parameters are fixed in advance; the number of road network nodes, and the number of AGVs, and the number of containers. However, the real situation in maritime ports in completely different because the number of equipment is big, so the possibility of breakdown of any equipment is also big. A breakdown of any equipment can make a delay in the corresponding sub-process which can affect the loading /unloading operation. A new ship arriving to the port may haven't the necessary equipment of its unloading/loading operation available. An extension of the proposed approach in the first step, was developed to solve the problem of dispatching AGVs to containers in a dynamic environment. The remainder of this paper is organized as follows: the second Section presents a literature review of this problem. The problem description and mathematical formulation are presented in the third Section. In the fourth Section, we present the proposed approaches in a static environment. In the fifth section, the authors propose an extension of the proposed approach for the dynamic environment. The numerical study results are cited in the sixth section, and finally, a discussion of the results and conclusions is given in the seventh section.

## II. Literature Review

### A. Related Work

In ACTs, the operations can be grouped into two classes of processes: loading and unloading. The loading process consists of transferring containers from the yard location area to AGVs via yard cranes to be transported to the ship to be loaded by the quay cranes. The unloading process involves unloading containers from the ship using quay cranes, and transportation by AGVs to the corresponding storage locations in the yard. Many studies have focused on ACT operations. Most studies were concerned with global loading and unloading operations. They proposed simultaneous scheduling systems including QCs, AGVs, and YCs. Despite the importance of dispatching containers to AGVs and AGV routing in the unwinding of loading and unloading processes, few studies have independently focused on this problem. Several literature reviews were developed [7, 8, 9, 10] studying yard and quay side operations, examining independently studied problems, as well as combined problems. They also revised the literature on yard crane scheduling, transport vehicle dispatching and scheduling, quay crane assignment and scheduling problems for the yard, vehicle routing and traffic control, and storage location and space planning problems. [11] considered the global ACT system and proposed an integrated scheduling model for handling equipment coordination and AGV routing. The optimization goal was to minimize the makespan of the global

process. The authors developed a Congestion Prevention Rule-based bi-level genetic algorithm (CPR-BGA) to solve the proposed model. [12] proposed a new method for optimizing the ASC and AGV scheduling and a collaborative AGV and ASC scheduling model in automatic terminal. The proposed model is designed based on a genetic algorithm (GA) and aims to minimize the AGV waiting time and ASC running time. The dispatching problem of AGVs to containers was studied by [6], where the AGVs scheduling was assimilated as a process of allocating AGVs to tasks, considering the cost and time of operations. The objectives chosen were makespan maximization and minimization of the number of AGVs, while considering the battery charge of the AGVs. A fuzzy GA, PSO optimization algorithm, and a hybrid GA-PSO were developed to optimize the proposed model. [13] proposed an approach named the modified memetic particle swarm optimization (MMPSO) algorithm based on PSO integrated with the memetic algorithm (MA). This approach is applied to generate the initial feasible solutions for scheduling multi-load AGVs to minimize travel and waiting time in manufacture system (FMS). [14] studied the problem of work transport organization and control. They proposed an approach based on a non-changeable path during travel and a fuzzy logic to order the set of stations requesting transport services. GA is applied to stations sequence optimization. [15] studied the problem of resource optimization in AGV-served FMS. They proposed a scheduling model integrating machines and AGVs. The objective function is the makespan of jobs from raw material storage to finished parts storage. [16] consider the problem of dispatching multiple-load AGVs in an FMS. A PDER rule based on pickup-or-delivery-in-route is proposed to address the task determination problem, which indicates whether the next task of an AGV partially loaded should be picking up a new job or dropping off a carried load. A workload-balancing (WLB) algorithm was developed to address the pickup-dispatching problem that determines which job should be assigned to an AGV. [17] investigated the multiple-AGV path planning. The authors proposes a GA approach with two innovations; a three-exchange crossover heuristic operators, used to produce better offspring and a double-path constraint for minimizing the total path distance of all AGVs and the single path distances of each AGV. [18] studied the autonomous driving system that uses dynamic path planning to avoid static and moving obstacles. To determine the optimal path, acceleration, and vehicle speed, the proposed method generated a set of path candidates. The optimum path selection is based on the total cost of static safety, comfortability, and dynamic safety, with the identification of acceleration and speed. [19] proposed a Q-learning method to find the AGVs shortest-time routes. To improve the selecting action policy for this method, the authors developed an improved anisotropic Q-learning routing algorithm with vehicle-waiting-time estimation. The performance of these methods was tested based on simulations. [20] considered the dynamic scheduling process to solve the AGV scheduling and planning problems. The authors proposes a two stage mixed integer model for AGVs cost transportation optimization with lay time constraint. They developed an approach based on heuristic, and DIK algorithm, and Q-learning algorithm for solving the proposed model. A strategy for avoidance conflict of AGVs

was also proposed. [21] investigated the dynamic AGVs scheduling problem with AGVs and machines having specific speed. They proposed a biological intelligent approach (BIA) inspired by hormone regulation in endocrine system. The objectives were to minimize the makespan and maximize the shop floor work efficiency. To solve this problem in a static environment, many approaches have been proposed, and metaheuristics perform well for this type of problem [6]. The PSO algorithm is one of the best algorithms cited in the literature, although the disadvantage of its premature convergence. To the authors' best knowledge, the problem of dispatching containers to AGVs in container terminals has been studied in general, in an integrated manner with other dispatching problems, such as the dispatching of quay cranes and yard cranes. The weakness of the combination of this problem of dispatching with the other problems of dispatching in container terminals in the same system management can propagate any disruption from one phase to the following phase. For example, if there is a problem in quay crane dispatching, it will propagate to AGV dispatching. So, the resolution becomes more complex. The study of this problem separately can easily detect any disruption and facilitate its resolution. Many studies investigate the problem of AGV dispatching and routing in a static environment, but this approach is different of the real situation inn container terminals so its application will not be efficient. A scarce number of researchers are interested in this problem in a dynamic environment. All the previous studies don't combine the two criteria of travel distance and workload balance, although the combination of these two criteria can be more attached and applicable to the real situation. The hybridization of particle swarm with Dijkstra algorithm make a good guide to PSO approach to find the best solution and the re-initialization of worst particles parameters help these particles to avoid from local optimum. The PSO approach has the advantage of the fast convergence in comparison with genetic algorithm. In this paper, the authors propose a guided hybrid particle swarm algorithm (GHPSO) to solve this problem in a static environment. Because the accurate situation in the container terminal is not static, they propose an extension of this approach to apply in the dynamic environment.

*B. Particle Swarm Optimisation*

A particle swarm is a metaheuristic algorithm presented in 1995 by Kennedy and Eberhart, and it was developed under the inspiration of the behavior laws of bird blocks, fish scrolls, and human communities. To achieve the optimum solution, PSO starts from a group of random groups of solutions and then repeatedly searches. It has proven to be a highly efficient optimization algorithm in numerous studies and experiments [22]. As a metaheuristic, PSO does not guarantee that the optimal solution is obtained. The basic particle swarm optimization is described as follows:

Assuming $N$ is the number of particles, the $i^{th}$ particle position $i = (1,2, ...., N)$ in dimension space $d$ can be denoted as $X_i = [x_{i,1}, x_{i,2}, ...., x_{i,d}]$, its velocity is defined as the moving distance between the particles in each iteration, and is denoted as $V = [v_{i,1}, v_{i,2}, ..., v_{i,d}]$.

The objective function consists of determining the optimal position of the particle, and the local optimal particle position $P_{best}$ in the $t^{th}$ iteration is denoted as $P_i = [p_{i,1}, p_{i,2}, ..., p_{i,d}]$. The global optimal position gbest in the $t^{th}$ iteration is denoted as $P_g = [p_{g,1}, p_{g,2}, ..., p_{g,d}]$. In the $(t + 1)^{th}$ iteration, the flight velocity $V_{i,j}(t + 1)$ of the $i^{th}$ particle in the $j$ dimensional space, $j = (1,2, ..., d)$, and its position $X_{i,j}(t + 1)$ can be derived from the following equations:

$$V_{i,j}(t + 1) = W * V_{i,j}(t) + C_1 * R_1 * [P_{i,j} - X_{i,j}(t)] + C_2 * R_2 * [P_{g,j} - X_{i,j}(t)] \qquad (1)$$

$$X_{i,j}(t + 1) = X_{i,j}(t) + V_{i,j}(t + 1), \ j = 1,2, ..., d \qquad (2)$$

$W$ is the inertia coefficient; $C1$ and $C2$ are the cognitive coefficient and social learning coefficient, $R1$ and $R2$ denote random numbers between 0 and 1; $P_{i,j}$ is the local optimal particle position of the $i^{th}$ particle in the $j$ dimension space, $P_{g,j}$ is the global optimal particle position of the $i^{th}$ particle in the $j$ dimension space. PSO achieves its optimum solution by starting from a group of random solutions and then repeatedly searching [23, 24, 25, 26]. PSO has a good level of particle convergence because of the fast transmission of information among the particles. For this reason, swarm diversity decreases very quickly after the iterations and can lead to a suboptimal solution. This evolution process can trap in a local optimum or premature convergence.

Many variants of the PSO algorithm have been proposed to solve the diversity loss problem. The problem of decreasing diversity can be attributed to several factors. The population diversity of PSO is an important feature that demonstrates the exploration or exploitation ability of the algorithm. It is a technique used to determine the degree of convergence or divergence of PSO in the search process. As example, ARPSO is a method used to control the degree of diversity. It consists of an algorithm called ARPSO, which tests if the diversity is above the predefined threshold $d_{low}$, then particles attract each other, and if it is below $d_{low}$, then the particles repel each other until they meet the required high diversity $d_{high}$. LOD is also a method for local optima detectors; it consists of computing the number of iterations in which the neighbor does not improve, that is, if the fitness value (FV) of the best particle remains unchanged for a specific number of iterations, the particle optimization sub-process is trapped in a local optimum [27, 28, 29, 30, 31, 32]. To increase the diversity of swarms, several methods have been cited in the literature as particle re-initialization and particle mutation. Inspired from the idea of LOD, the authors apply this method to escape the worst particles from the local optimum.

*C. Scheduling/ Rescheduling System*

The goal of this system is to plan the production of a collection of jobs assigned to multiple machines given the production environment specifications. The scheduling problem has been demonstrated in the literature as a non-polynomial (NP-hard) [33]. In a multi-AGV system, n containers are available: $\{C_1, C_2, C_3, ..... C_n\}$ to be transferred by k AGVs $\{V_1, V_2, V_3, ..... V_k\}$, and the main objective is to determine the optimal schedule for n containers to be transported by the system. Each AGV can transfer only one

container within a specific time interval. According to literature the selection of AGV can be based on one of the following methods: [34, 35]

- Longest travel distance
- Shortest travel distance
- Random
- Minimum AGV queue size

In its standard form, the scheduling problem can be described as a set of known tasks assigned to a set of available machines, considering the technological limitations of the system. This class of approach is called static scheduling. In this scheduling type, the tasks to be assigned and system parameters are known in advance and are invariant in time [36, 37, 38]. Multiple events, such as new task arrivals, machine breakdowns, task priority changes, and preventive machines, can affect the system in real situations. These changes in circumstances result from a dynamic environment that necessitates task reassignment. Rescheduling is defined as the process of updating existing production scheduling to react to any event. The literature explains three different strategies [39]. The Predictive-reactive strategy consists of providing an initial predictive schedule and changing it to reply to the disturbances that appear within the system. The proactive (or robust) strategy based on developing a schedule that absorbs any disturbances that may occur in the system. The dynamic strategy does not provide an initial schedule, but the assignment is performed dynamically. The authors choose the proactive rescheduling because the proposed approach was applied for static environment in first step, then it was extended for dynamic environment in second step.

### III. PROBLEM FORMULATION

Assume a set of containers $C = \{C_1, C_2, C_3, \ldots C_m\}$ stored in different locations $L = \{L_1, L_2, L_3, \ldots L_n\}$ at the port. These containers must be transferred to unloading locations to be transported by trucks and trains to clients, or inversely to a charging location to be loaded on a ship. A set of AGVs, $V = \{V_1, V_2, V_3, \ldots V_k\}$ should/will be available for transporting containers. The problem consists of assigning this set of containers to a set of AGVs and planning the path to each AGV. This problem can be decomposed into two sub-problems: A dispatching problem of AGVs to containers and a routing problem of AGVs. Many factors intervene in this optimization problem, such as distance traveled by AGVs, stability of the road network in the port, availability of AGVs, and utilization ratio of AGVs. For these reasons, the problem is considered as multi-objective problem. The authors choose to optimize the AGVs total travel distance and the balancing workload of AGVs. The AGVs dispatching and routing system can be assimilated to a scheduling system where a job is equivalent to the task of transferring the container from its origin location to its target location and the machine is equivalent to the AGV. In a static environment, the initial scheduling is sufficient for carrying a set of containers from their initial locations to their target locations. However, with the appearance of port automation, the number of pieces of equipment has become very

important, and many events can appear and change the system situation. For example, new arrival of containers, changes in container priorities, breakdown of any equipment or AGV, AGV battery changes, and AGV preventive maintenance lead to system disruption. This change in the port situation requires system rescheduling. To develop an efficient scheduling system, it is necessary to study this problem in a dynamic environment. In first step, the authors study the problem of AGVs dispatching and routing in a static environment. In the second step they consider the cases of new containers arrival, the breakdown of AGVs, and the disruption of the road network in the port and proposed an extension of the first approach for resolving the problem in the dynamic environment.

### A. Mathematic Model in a Static Environment

$C = \{C_1, C_2, C_3, \ldots C_m\}$: Set of containers.

$L = \{L_1, L_2, L_3, \ldots L_n\}$ : Set of container locations (nodes).

$V = \{V_1, V_2, V_3, \ldots V_k\}$ : Set of vehicles (AGV).

$d_{ij}$ : Distance between nodes i and j

$S$ : Speed of AGV

$t_{ijk}$ : Travel time of vehicle $V_k$ from node i to node j

$[tb_i, te_i]$ : Time window of node i

$tb_i$ : Beginning time of task in node i

$te_i$ : Ending time of task in node i

$td_i$ : Departure time from node i

$ta_i$ : Arrival time at node i

$tw_i$ : Waiting time at node i

$S$ : Speed of AGV

$q_{ik}$ : Load of AGV

$Twt_k$ : Total work time of vehicle $V_k$

$X_{ijk}$ : Decision variable $\begin{cases} 1 \ if \ the \ vehicle \ V_k \ is \ busy \\ 0 \ otherwise \end{cases}$ (3)

The objective function is an aggregation of two sub-functions to be optimized: The function F1 for the total travel distance of all AGVs and the function F2 for the balance of AGVs workload.

$$F = \alpha * F_1 + \beta * F_2 \tag{4}$$

The objective function value depends on two coefficients α and β associated respectively to F1 and F2 which values are fixed by a domain specialist.

$$F \equiv \begin{cases} F_1 = \sum_{i \in N} \sum_{j \in N} \sum_{k \in V} X_{ijk} * \frac{d_{ijk}}{S} \\ F_2 = \sqrt{\left(\frac{1}{k} - \frac{1}{k^3}\right) * \left(\sum_{k \in V} Twt_k^2 - 2 * \prod_{k \in V} Twt_k\right)} \end{cases} \tag{5}$$

$$\sum_{i \in N} \sum_{k \in V} X_{ijk} = 1, \forall \ j \in N \tag{6}$$

$$\sum_{i \in N} X_{i0k} = 1, \forall k \in V \tag{7}$$

$$\sum_{j \in N} X_{0ik} = 1, \forall k \in V \tag{8}$$

$$\sum_{i \in N} X_{ijk} - \sum_{i \in N} X_{jik} = 0, \forall k \in V, \forall j \in N \tag{9}$$

$$Q_k = \sum_{i \in N} \sum_{j \in N} q_{ijk} = 1, \forall k \in V \tag{10}$$

$$X_{ijk} = 1 \rightarrow tb_i \le ta_i < te_i, \forall i \in N, \forall j \in N, \forall k \in V \tag{11}$$

$$X_{ijk} = 1 \rightarrow tb_i \le td_i < te_i, \forall i \in N, \forall j \in N, \forall k \in V \tag{12}$$

$$X_{ijk} = 1 \rightarrow ta_i - t_{ijk} + Tw_i \le_i tb_i, \forall i \in N, \forall j \in N, \forall k \in V \tag{13}$$

$$X_{ijk} = 1 \rightarrow td_i - t_{ijk} + Tw_i \le_i te_i, \forall i \in N, \forall j \in N, \forall k \in V \tag{14}$$

(6) The transport cost from node $i$ to node $j$ is equal to 1.

(7) and (8): the possibility of moving from node zero to any other node.

(9): bi-directionality of each edge.

(10): AGV load equals 1

(11): The AGV must arrive at node $i$ within the arrival time window.

(12): The container must be moved within the departure time window of the node.

(13) and (14): The AGV must arrive before the beginning of the node time window, and must move before the end of the node time window.

## B. Dynamic Environment Parameters

In containers terminal, the real situation is dynamic and uncertain. Any equipment such as quay crane, truck, AGV, road can breakdown at any moment of time. A lateness of the loading/unloading operation for the corresponding ship can appear. This tardiness will propagate for all the ships coming after. Three cases was investigated in this study:

*a) New Arrival Containers*: This case can change the number of containers. Assume $C'$ the set of containers of the new arriving ship. For the current process, the total number of containers to be loaded/unloaded will be $C_T = C \cup C'$. Each AGV will have an extra number of containers to transfer.

$C = \{C_1, C_2, C_3, \dots . C_m\}$ : set of containers for current ship

$C' = \{C'_1, C'_2, C'_3, \dots . C'_n\}$ : set of containers for new ship

$C_T = \{C_1, C_2, C_3, \dots . C_m, C'_1, C'_2, C'_3, \dots . C'_n\}$ : Total set of containers to be loaded/unloaded

*b) Road Network Disturbance*: This case appear when there is a breakdown in some nodes of road network. Assume L1 and L2 are unavailable, all the paths containing these two nodes will be modified. Assume $L = \{L_1, L_2, L_3, \dots . L_n\}$, the initial set of nodes, the new set of nodes will be $L' = L \backslash \{L_1, L_2\}$. As consequence the AGV will travel a path other than the shortest path proposed initially.

*c) AGVs Breakdown*: If an AGV is unavailable, the set of containers corresponding to this AGV will be assigned to other AGVs. Assume $V = \{V_1, V_2, V_3, \dots . V_k\}$, if $V_1$ and $V_3$ are unavailable, the new set of available AGVs will be $V' = V \backslash \{V_1, V_3\}$. This event will have an effect on the workload balance of AGVs.

## IV. PROPOSED APPROACHES

To increase the diversity of swarms, several methods have been cited in the literature as particle re-initialization and particle mutation. The main of particle re-initialization method is to increase the possibility of "jumping out" of local optima and to maintain the ability of the algorithm to find the "good enough" solution. After several iterations, some particles were selected to reinitialize their position and velocity. The number of chosen particles can be either constant or fuzzy. Three methods to select particles: 1) The random selection consists of selecting randomly a set particles to reinitialize its position and velocity. This method can obtain great exploration ability owing to the possibility that all particles have the chance to be reinitialized. 2) The elitist selection based on choosing a set of the best particles, having the best fitness value, to reinitialize its position and velocity. When the population diversity decreases, most particles have the best fitness values. When these elitists are reinitialized, the exploration ability of the algorithm increases but the good particles can be lost. 3) The worst particle selection consists of choosing a set of the worst particles to reinitialize its position and velocity. This idea can increase the ability of the algorithm to explore space and find the "good enough" solution by ameliorating bad particles. The particle mutation method is based on applying the mutation feature of GA to change one or more features of a particle to achieve better particles quality. This is a common method for increasing the population diversity. It can improve exploration abilities, which can be applied to different elements of a particle swarm.

The authors propose a new hybrid PSO approach called HPSO based on a heuristic and PSO algorithm. This approach did not show a clear convergence. It presents a very quick convergence which risks premature convergence. To improve the approach results, the authors propose a second approach guided particle swarm called GPSO. It consists of guiding the HPSO approach in the routing problem by choosing the shortest path for each AGV by applying the Dijkstra algorithm. This approach presents acceptable convergence. In comparing its results with previous results, it appears acceptable, but it's necessary to verify the problem of premature convergence. A third approach is proposed, named GHPSO, which combines the ameliorations of the two previous approaches (Fig. 1).

## A. Hybrid Particle Swarm Approach (HPSO)

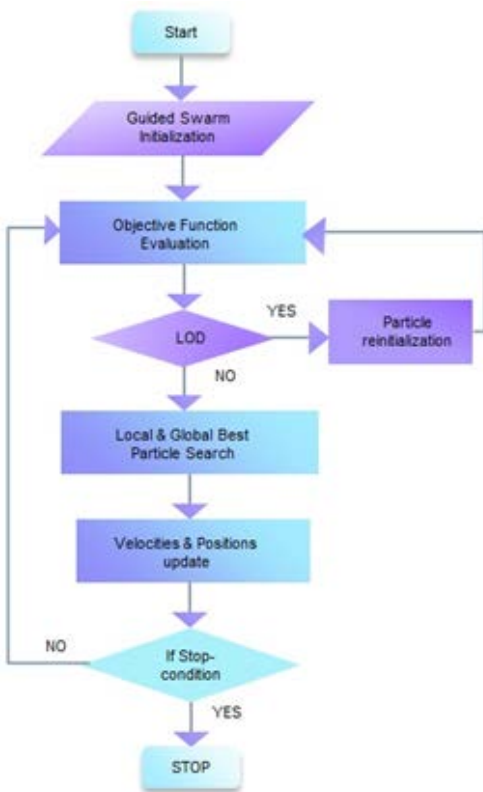
This approach is a hybridization between a heuristic, the Dijkstra algorithm, and the particle swarm algorithm; it is called the HPSO approach. It uses a heuristic based on assigning each container to the nearest AGV.


Fig. 1.   GHPSO Flowchart.

The AGV travels the shortest distance to arrive at a container location. The shortest path problem is solved using the Dijkstra algorithm, and the optimal solution is determined by applying the PSO algorithm through a fixed number of iterations. The HPSO algorithm is as follows (Fig. 2).

**Algorithm1: HPSO**
**Results:** GBest
Iterations = 1;
**Guided_Swarm_Initialization( );**
**While (Iterations <= Nb_iterations)**
  {
  Objective_Function_Evaluation( );
  Best_Positions_Search( );
  Particles_Updates( );
  Iteration = Iteration + 1;
  }
**End Algo**
 **Procedure1: Guided_Swarm_Initialization()**
 Sort_List_Containers( );
 **While (List_Containers # ф)**
 {
   Assign_container_AGV( );
   Choose_shortest_path( );
 }
 **End proc**

Fig. 2.   HPSO Algorithm.

## B. Guided Hybrid particle Swarm Approach (GHPSO)

The HPSO approach and the GPSO approach show a fast convergence which risks the premature convergence. To surpass this deficiency, the authors propose to study the diversity of PSO population. The population diversity was computed to prevent premature convergence. They choose to control the activity of particles to detect which particles were responsible for the diversity of population loss. LOD (local optimum detector) for each particle to determine whether the particle is inactive for an important number of iterations. The authors selected a threshold value for the number of iterations.

After detecting these particles, they re-initialize the positions and velocities for all particles to jump out of the local optimum.

## C. Robustness of the GHPSO in a Dynamic Environment

In a dynamic container terminal environment, any disturbance can cause an increase in the number of containers in depots or Quays, because the waiting time for loading or unloading increases. The number of AGVs in the port is fixed but may decrease due to any breakdown (Fig. 3).

**Algorithm2: GHPSO**
Results: GBest
Iterations = 1;
Guided_Swarm_Initialization( );
**While (Iterations <= Nb_iterations)**
{

  **While (List_Particles # ф)**
    if (LOD(Particle) == true)
    {

      Particle_reinitialization( );
      Go to **EV**;
    }
   else
    {
      Best_Positions_Search( );
      Particles_Updates( );
    }
  Iteration = Iteration + 1;
}
 **Procedure2: LOD(Particle, limit_repetition)**
 **if** (nb_repetition_Particle == limit_repetition)
 {
  nb_repetition_Particle = 0;
  return true;
 }
 else
 {
  nb_repetition_Particle = nb_repetition_Particle + 1;
  return false;
 }
 **End proc**

Fig. 3.   GHPSO Algorithm.

**End proc**

The authors propose an extension of the GHPSO approach for a dynamic environment, dynamic guided hybrid particle swarm called DGHPSO approach, which studies three disturbance cases:

*a) Arrival of New Containers*: To solve the problem of new container arrivals, DGHPSO proposes to add the new containers to the AGVs queues during the Algorithm execution. The number of containers associated to each AGV will increase. An $AGV_i$ can begin the dispatching process with n containers and finishes it with n+m containers. The solution will be optimized after completing the iterations.

*b) AGV Breakdown*: The DGHPSO approach proposes a new distribution of containers associated with a broken AGV for other AGVs. The number of containers for the available AGVs increases. New dispatching was proposed and optimized after completing the iterations.

*c) Network Road Disruption*: The unavailability of any node in the road network affects the set of paths proposed for the AGVs. This disturbance can cause inaccessibility of any path. AGVs must stop the transfer of the associated container. The DGHPSO approach proposes a new path to travel, then the solution will be optimized.

## V. EXPERIMENTAL STUDIES

The application of these approaches was performed with a computer having 8 GOs of RAM and a processor speed of 2.4 GHz. The proposed approaches were implemented with a swarm population of 50 particles, the number of AGVs is 4 and the number of containers is 20. The PSO parameter values chosen after several tests were C1=2, C2=2, Wmin=0.4, and Wmax=0.9. R1 and R2 were randomly chosen such that $R_1 + R2 = 1$. The threshold value chosen after several tests was 5. After several numeric tests, the genetic algorithm parameters chosen are as follows: 70% of the population was selected for crossing over and 10% for mutation.

Numerical tests were applied to two previous versions of the GA approach [40] and four new versions of the PSO approach.

Fig. 4 shows a comparative graph between the two previous genetic algorithm approaches: genetic algorithm (GA) and hybrid genetic algorithm (HGA: GA + Dijkstra). The initial solutions of the two approaches are very different. This demonstrates the importance of hybridization with the Dijkstra algorithm in the second approach. The convergence of the GA with an optimum solution value is 2.51, but it is not significant because of the random paths chosen for the AGVs. The HGA graph shows good convergence with an optimum solution value of 1.5 because the paths are optimized using the Dijkstra algorithm.

Fig. 5 presents a comparative graph of the PSO approaches. The basic PSO algorithm (PSO curve in blue) shows quick convergence from the first iterations with an optimum solution value of 2.6, and it becomes almost stable at 2.5.

Fig. 4. GA Approaches Comparison.

Fig. 5. PSO Approaches Comparison.

The hybridization with Dijkstra's algorithm and the insertion of a heuristic for choosing the nearest AGV with the standard PSO (HPSO curve in green) considerably improves the optimum solution value from 2.5 to 1.7, but the convergence is again not very remarkable. It is clear that the population diversity quickly decreases. The guided particle swarm approach GPSO (PSO+ re-initialization: curve in light green) shows a slight improvement in the solution value. Its value decreases from 1.7 to 1.4, and the convergence appeared significant. The last curve represents the GHPSO model. Its solution value is 0.7, which is the optimum among all proposed approaches. This convergence becomes significant in comparison with previous approaches. It is clear that the problem of a faster decrease in population diversity is solved by the insertion of LOD and the re-initialization of particles.

To determine the best approach, the authors performed a final comparison between the best GA and PSO approaches, as shown in Fig. 6. The graphs show good convergence of the PSO approach in comparison with the previous GA approach.

A comparison of the running times computed for each approach is shown in Fig. 7. The GHPSO presented an acceptable running time of 19.510-3 s in comparison with other proposed approaches.
Fig. 6.   GA and PSO Aproaches Comparison.

Fig. 7.   Running Time Comparison.

Fig. 8.   New Containers Arrival.

Fig. 9.   AGV Breakdown

Fig. 10.  Unavailable Path.

The numerical results show the good performance of the GHPSO as the best PSO approach in a static environment. This approach also surpasses the performance of GA. This deduction encourages the authors to apply this approach in a dynamic environment, where the number of containers, AGVs, and nodes in the road network are not fixed.

Fig. 8 shows the approach convergence after the insertion of new containers. The authors propose the insertion of 20 containers at 50 iterations. It is clear that the approach begins by improving the initial solution to determine the optimum solution. The initial solution objective function value is 3, and at iteration 50, it becomes 1. When new containers were inserted, the solution value increased to 1.65. Subsequently, it was again in decreasing order to find the best solution. It reached notable convergence at almost 120 iterations with an optimum solution value of 0.6. This result demonstrates the robustness of the GHPSO approach in determining the optimum solution in the case of new container arrivals.

Fig. 9 presents the numerical results of an AGV breakdown at iteration 100, when the guided hybrid particle swarm approach (GHPSO) begins to converge. The solution value increases again because of the distance traveled by each AGV, but after 140 iterations, it converges again with a solution value of 1.25, which was greater than the initial optimum solution value due to increasing of workload of each AGV. These results demonstrate the GHPSO approach efficiency in reaching the optimum solution.

Fig. 10 shows the numerical results when some paths become unavailable. The solution value increased again and then decreased to converge to a solution value of 1.2, which was greater than the optimum solution before path breakdown due to unavailability of shortest path.

## VI.  CONCLUSION AND PERSPECTIVES

In this study, the problem of dispatching containers to AGVs in a container terminal in static and dynamic

environments was investigated using an improved PSO algorithm. A new guided PSO approach named GHPSO was proposed for optimizing the total travel distance and balancing the workload between AGVs. The first idea was to combine heuristic and Dijkstra with the PSO algorithm to obtain the optimum solution. The numerical results show an acceptable solution, but the convergence is not significant because an important number of particles cannot ameliorate their best local solution. The idea was to apply the insertion of the LOD parameter and reinitialize the particles to achieve good results. The convergence became significant for the GPSO, and the best optimum solution value was obtained using the GHPSO. This work showed a very good GHPSO performance compared to other approaches, although the running time was acceptable. The proposed approach was tested in a dynamic environment (DGHPSO), where the number of containers, number of AGVs, and network road nodes were not fixed. To demonstrate the robustness of this approach, the authors proposed an extension to study the arrival of new containers during approach execution. The numerical results show good convergence for the approach. In addition, for the two AGV breakdown and node breakdown cases, the proposed approach shows good convergence. This approach shows good robustness in static and dynamic environments for finding the optimum solution within a reasonable running time. In future work, the authors will study the efficiency of this approach for the multi-objective problem with the AGV energy constraint and its effect on task allocation in a static and uncertain environment.

*Abstract*—Address Resolution Protocol (ARP) Poisoning attack is considered as one of the most devastating attacks in a network context. As a result of its stateless nature and lack of authentication, this protocol suffers from many spoofing attacks in which attackers poison the cache of hosts on the network. By sending spoofed ARP requests and replies. This paper proposes an approach for detecting and mitigating ARP poisoning. This approach includes three modules: Module 1 for giving permission for first time and to store information in the database. There a security measure using MD5 hash is used. Module 2 is for avoiding internal ARP. Module 3 is for detecting whether a MAC has two IPs or an IP has two MACs. The architecture includes a database that gives a great facility and support for storing ARP table information. As ARP table entries generally expire after a short amount of time. To ensure changes in the network are accounted for. Experiments were conducted on real life network environment using Ettercap to check the functionality of the proposed mechanism. The results of experiments show that the proposed approach was able to detect and mitigate ARP poisoning. Especially, whether a MAC has two IPs or an IP has two MACs.*

*Keywords—Address Resolution Protocol (ARP); ARP detecting; ARP mitigation; ARP spoofing*

## I. INTRODUCTION

The security of the network is becoming a major concern for network managers and engineers. Traditional networks are vulnerable to a variety of security flaws and assaults. In order to identify the attacks or infections, anti-virus software or an intrusion detection system (IDS) might be used. Inconsistency in communications between hosts, on the other hand, exacerbates security concerns. Security techniques that can be effectively used in network innovation are in short supply.

The fundamental reason for such assaults is a breakdown in communication between security innovation engineers and network designers [1]. A programmer will concentrate on the communication channel, collect data, decode it, and re-insert a copy message. The most important aspects to consider while constructing a secure network are confidentiality and integrity. The variety of attacks, on the other hand, continues to grow with the passage of time [2].

Address Resolution Protocol (ARP) is a mechanism for mapping Internet Protocol (IP) addresses to Media Access Control (MAC) addresses that is widely used. ARP, on the other hand, has a number of flaws. For example, there is no

built-in way for a receiving node to verify the sender of a packet [3]. The ARP process excludes any authentication or integrity verification and is unconcerned whether the packet originates from a legitimate source. Any packet that has its fields filled from the allowed set of values is right.

As a result, ARP is a stateless protocol. The nodes can send ARP answers without receiving an ARP request first. Attackers use these weaknesses in ARP to carry out the ARP Cache Poisoning attack. This attack is carried out in traditional networks by poisoning a host's cache through introducing bogus or spoofed IP to MAC address mappings into the victim's ARP cache table.

The detection and mitigation of ARP Poisoning attacks are critical. Because attackers can use this attack to launch other attacks as Denial of Service (DoS), Distributed Denial of Service (DDoS) and Man-In-The-Middle (MITM) attacks. Attackers can use ARPs to communicate with the system they want to attack since they allow links between networks using IP and MAC addresses. ARP Spoofing leads to simply intercepting or dropping and not forwarding the target's packets.

The paper is organized as follows: Section II presents the related work. Section III introduces the proposed ARP approach. Testing and recorded results are shown in Section IV. Section V has the conclusion and future work.

## II. RELATED WORK

The research publications relevant to ARP attack detection and prevention will be presented in this section. A framework has been introduced in [4] to detect any rogue user in the network attempting to impersonate another user. The framework included a built-in security measures to prevent attacks on the framework itself and to prevent having a single point of failure. The framework also used robust security mechanisms including RSA. This initializes the random time intervals to prevent other devices from sending client messages. AES encryption has been used for all subsequent messages.

Authors in [5] have examined the conditions for conducting a Man in the middle (MITM) attack in networks using the Address Resolution Protocol (ARP). In addition to, methods for detecting and preventing such attacks. They presented an implementation of an ARP spoofing attack using Python and

*Corresponding Author.

C# (scapy) languages. They have provided Man-in-the-middle attacks examples such as DHCP spoofing and ICMP redirection. While authors in [6] proposed a detection algorithm that looks for differences between the real MAC Address and the response MAC Address of the ARP Packet sniffed. In addition to, a prevention algorithm for ARP Poisoning attacks using static entries in ARP table. The implementation for both algorithms has been done using Python Programming language using scapy library.

A survey study for the theory of ARP spoofing attacks and the various existing techniques proposed to defend ARP against them was presented in [7]. The study has shown that for best security measures, both detection and prevention systems should be implemented in the network with consideration to minimize the cryptography processes. They also recommended the four security requirements to develop a mechanism approach to detect/prevent ARP spoofing attacks shown in Fig. 1.

Fig. 1.    ARP Detection and Prevention Requirements.

The description of ARP and how it works was discussed in [8]. The topic of ARP Spoofing and its many attacks then has been discussed. Finally, it compared several detection and mitigation approaches, as well as their benefits and drawbacks, in order to combat ARP attacks.

In [9], the authors offered three methods for detecting and preventing ARP spoofing. These methods may have few flaws or disadvantages. Within a LAN, these strategies are simple to implement. Method 1 is the most effective, Method 2 necessitates the creation of a new protocol, and Method 3 is costly and time-consuming owing to software or server deployment. Depending on the needs of the business, any of these strategies can be used.

The authors in [10], looked at various tools and strategies for detecting and preventing Address Resolution Protocol Spoofing attacks. To learn more about how a host maintains the address resolution protocol cache table with a spoofed or false media access control, MAC cache table, the ARP spoof tool was used to send a spoofed Address Resolution Protocol reply packet to a host in a local area network. Lastly, they compared the detection and prevention tools and approaches against the Address Resolution Protocol Spoofing assault in terms of their efficiency in detecting and preventing the attack as well as system performance requirements.

The ARP spoofing attack in traditional networks was investigated in [11]. They first performed ARP spoofing in an SDN network and discovered that the threat of an ARP attack is still present and has a significant impact on the network. They suggested a unique protection method for ARP spoofing based on the OpenFlow platform. The mechanism was given a theoretical analysis, and it was implemented as a module of the POX controller. On the OpenFlow platform and related SDN platforms, this significantly decreased the security danger of ARP spoofing.

A detailed survey on various solutions to mitigate ARP Cache Poisoning attack in SDN was carried out in [12]. Flow graph-based solutions, traffic pattern-based solutions, and IP-MAC Address Bindings-based solutions were all characterized in this survey. All of these solutions were assessed rigorously in terms of their functioning principles, benefits, and drawbacks. Another key element of this study was the ability to compare different systems based on numerous performance measures, such as attack Detection time, ARP response time, delay calculation at the controller, and so on.

Thus, all the pervious related works solutions considered ARP cache table in switch for either detecting or mitigating ARP poisoning. Without resolving the problem in which, the ARP cache table may be destroyed. If the switch is restarted or if an administrator action is performed.

## III.    PROPOSED ARP APPROACH

The proposed ARP approach in this paper consisted of three modules that will effectively detect and mitigate ARP cache poisoning in real life network. The proposed approach overview is shown in Fig. 2. Module 1 is responsible for initialization of eligible new user. Where information will be stored in the database; in addition, checking information of eligible users before going to module 2. Detecting and mitigating internal ARP will be occurred in module 2. While external ARP detection and mitigation will be in module 3. Where intruder is either an IP with two MACs or a MAC has two IPs.

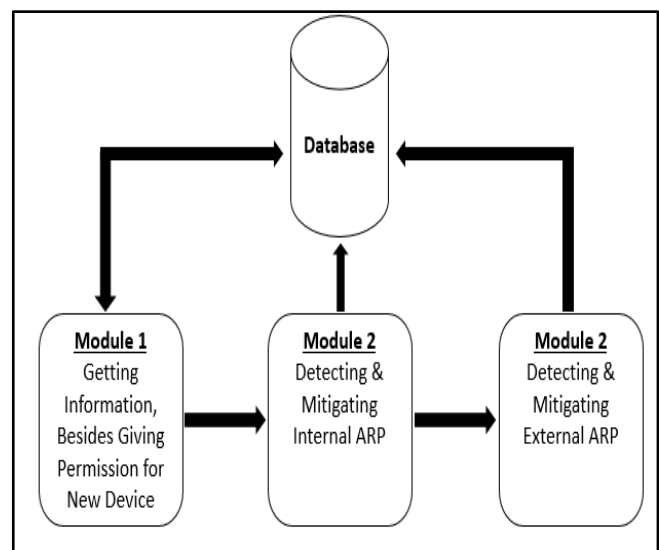

Fig. 2.    Proposed Approach Overview.

The database was added to check and compare ARP table content. As the typical timeout for ARP cache is from 10 to 20 minutes [13] [14] [15], thus this made the cache to be cleared automatically. In addition to, the ARP cache table may be deleted due to switch restarting or an admin action. The database was designed to store the following ARP information:

- IP Address.
- MAC Address.
- Hash for IP + MAC.
- Port Number.
- Time.
- Date.
- Switch IP.

The database facilitates the detection of whether a MAC has two IPs or an IP has two MACs.

*A. Module 1*

Fig. 3 represented the flowchart for module 1. Module 1 was designed for getting and checking device data in database to decide whether forwarding device packets or not. In case which data was found, and then move to module 2. While if not found, an admin has to decide whether to give permission for that device to join network or to block device. In addition module 1 included adding a device that first time asks to join network. After assigning IP to joined device MAC, the proposed approach pop up a message showing this IP with its MAC.

If yes the following information will be stored in the database <IP, MAC, Hash for IP + MAC, Port Number, Time, Date, Switch IP> (first-give-permission) this scenario repeated each new device joined. The hash for IP and MAC has been done using MD5. A 128-bit fingerprint is generated by encoding a string of arbitrary length into an MD5 hash. The MD5 algorithm will always provide the same 128-bit hash value when encoding the same string. When storing sensitive data in databases like MySQL, MD5 hashes are typically utilized with smaller strings [16].

*B. Module 2*

To avoid internal ARP, module 2 was proposed as in Fig. 4. After checking device data in the database, Module 2 has to check IP and mac stored in switch ARP table. If found, the hash for that IP and MAC would be compared with the stored in the database. If the comparison result was match then, forward packet otherwise go to module 3. While if the hash for IP and MAC was not found in switch ARP table. Check for hash of IP and MAC in the database. If found, switch ARP table will be updated, then return to the start of module 2. If not found, move to module 3.

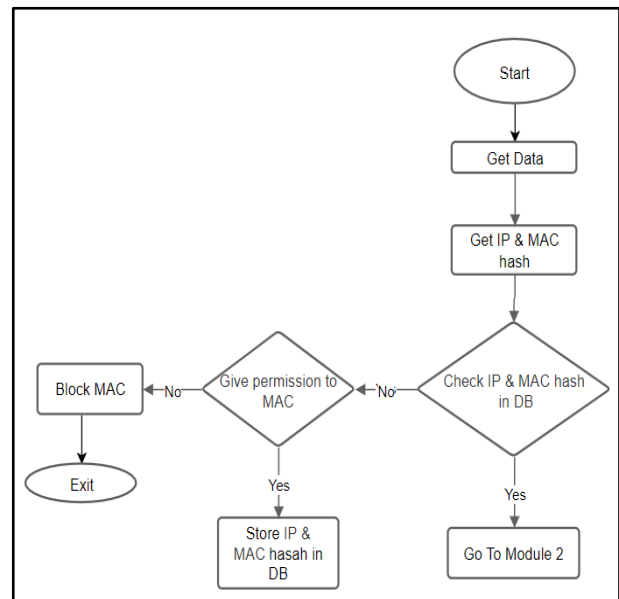

Fig. 3. Module 1 Flowchart.

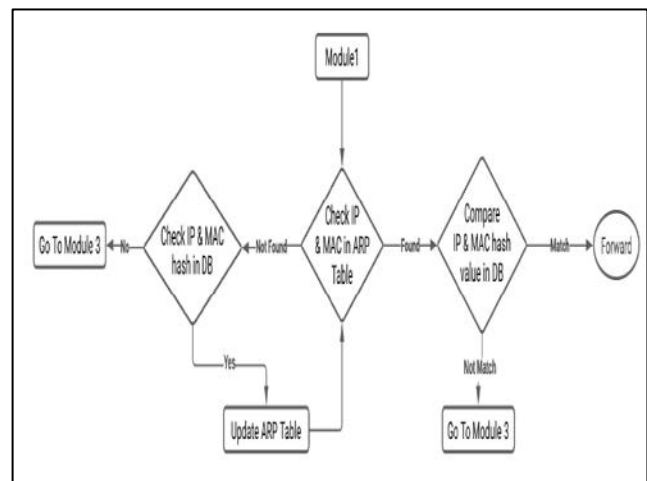

Fig. 4. Module 2 Flowchart.

*C. Module 3*

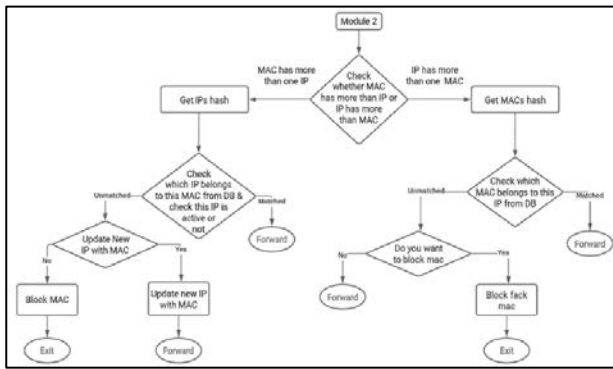
Module 3 as shown in Fig. 5, was designed to detect whether a MAC has two IPs or an IP has two MACs. In case of an IP has more than one MAC. The module will retrieve all MAC hashes from the database. Then it will check which MAC belongs to that IP from the database. The packet will be forwarded if MAC belongs to that IP was matched in the database. Otherwise an admin has to decide either to block MAC or to forward packet. The second case is in which a MAC has two IPs. All IPs hashes will be retrieved from the database. Checking which IP belongs to that MAC hash in the database. Besides checking which IP is active. If the result is matched and active then forward the packet. If not matched the admin has to choose either to update the database with new IP, or to block this MAC.


Fig. 5.   Module 3 Flowchart.

## IV.   TESTING AND RESULTS

This section will illustrate environment setup for the proposed approach. Besides presenting test cases and results, the proposed approach architecture is shown in Fig. 6. In which, two eligible devices were connected. The attacker (intruder) was trying to control the switch that was synchronized with database.

Fig. 6.   Proposed Approach Architecture.

### A. Environment Setup

The following tools and libraries are required to build up the environment for the suggested approach:

- VMWare Workstation Pro [17]: is a hosted hypervisor that works with x64 versions of Windows and Linux. Users can create Virtual Machines on a single device with VMWare Workstation Pro. The Virtual Machines can then be used with the physical machine at the same time.

- Kali Linux [18]: Kali Linux is a Debian-based Linux distribution operating system designed for digital forensics and penetration testing.

- Scapy [19]: is a computer network packet manipulation tool. Using scapy, packets can be faked, decoded, sent over the wire, captured, and Requests and responses can be matched.

- Netmiko [20]: is a multi-vendor library that makes it easier for Paramiko to connect to network devices via SSH.

- Ettercap [21]: can deconstruct various protocols (even encrypted ones) both actively and passively, and it has a lot of features for network and host investigation.

One kali Linux virtual machine was created to work as attacker using Ettercap.

- MySQL Database [22]: gives consumers the flexibility, scalability, and availability they need to handle the database problems of next-generation web, cloud, and communications services. The database was connected with the proposed approach using mysql.connector.

- Python [23]: Python is a general-purpose programming language with a high level of abstraction. Its design philosophy priorities code readability and makes extensive use of indentation.

### B. Phase 1 "Initialization" Testing and Results

In this phase, module 1 checked the database to either allow or deny connecting a new node. Fig. 7 represented that the database was empty. In addition, the proposed approach popped up a message for adding new node. Fig. 8 presented the database after storing a new device information in which, MAC [00:0c:29:dd:29:c8] with IP [172.19.15.18] was successfully added.

### C. Phase 2 "Authentication" Testing and Results

Besides matching between the database and the ARP table for authenticating IP and MAC, Phase 2 included checking for IP and MAC in the ARP table or not, which was happened in module 2. Check for IP with its MAC in ARP table. If it is found in the ARP table then the hashed value for IP and MAC is compared with the database.

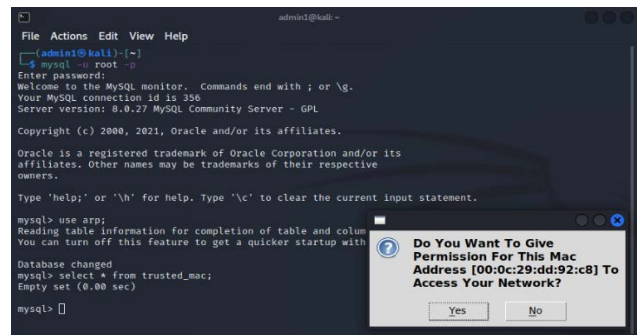

Fig. 7.   Empty Database.

Fig. 8.   Adding New Device in the Database.
Fig. 9. Check for MAC with IP in Both ARP Table and Database.

The proposed approach popped up a message for MAC [00:0c:29:dd:29:c8] with IP [172.19.15.18] in case of matching and founding in both ARP table and the database as in Fig. 9. If not matched go to module 3.

Fig. 10 shows the case in which MAC [50:65:f3:5d:01:fd] with IP [172.19.13.200] was not found in ARP table. The proposed approach would check for stored MAC and IP hashes in the database. If not found then, it would move to module 3. While in case of found, the proposed approach would update the ARP table automatically in Fig. 11.

Fig. 10. ARP Table before Update.

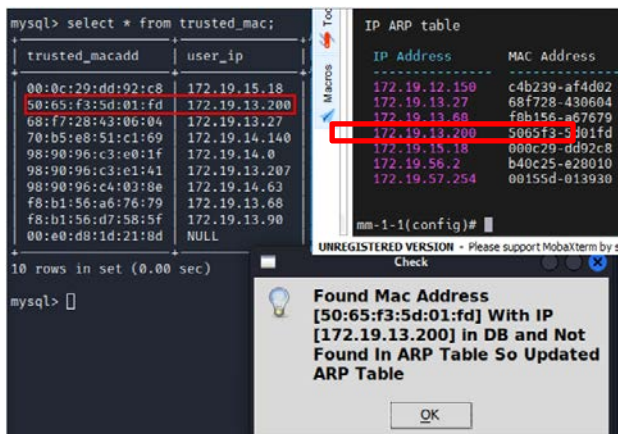

Fig. 11. ARP Table after Updating.

### D. Phase 3 "Poisoning Detection & Classi-fication" Testing and Results

Module 3 where classification and detection of whether an IP has two MACs or a MAC has two IPs, was tested in this phase. The first case included testing of a MAC has more than one IP. All IPs hashes was retrieved from the database. Then, the original IP belonged to this MAC was checked in the database as in Fig. 12. Where the ARP table showed MAC

[f8:b1:56:a6:76:79] with IP [172.19.12.201] and [172.19.13.68]. While the database showed that IP for MAC [f8:b1:56:a6:76:79] was [172.19.13.68]. The packet of the active and original IP would be forwarded and the other IP would be released. While if not active the admin has to decide either to update the database with new IP or to block the MAC as in Fig. 13.

Fig. 12. Check for Original IP.

The second case was for one IP with more than one MAC. The original MAC was checked from the database after getting all MACs hashes. The packet of the matched one was forwarded. But if not matched, the proposed approach popped up a message alerting that ARP poisoning was happened as in Fig. 14. Where IP [172.19.13.207] has original MAC [98:90:96:c3:e1:41] and fake MAC [00:0c:29:dd:92:c8]. Thus, the admin has to decide either to block fake MAC or not.

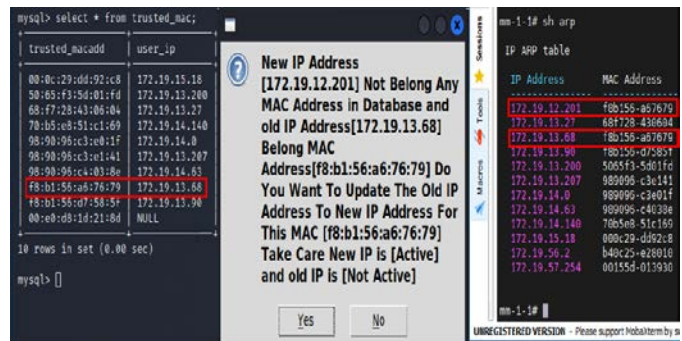

Fig. 13. Update IP or Block MAC.

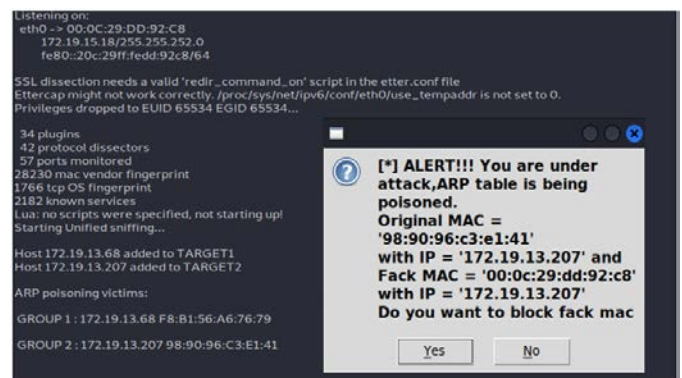

Fig. 14. IP with Two MACs.

## V. CONCLUSION AND FUTURE WORK

This research proposed a new approach for detecting and mitigating ARP poisoning attack. The database was added to the proposed approach architecture for storing information from switch. Avoiding missing the data as typical timeout for ARP cache is from 10 to 20 minutes. Furthermore, the ARP cache table may be deleted due to switch restarting or an admin action. The proposed approach has included three modules. The first one was for getting data and storing it in the database. Besides giving permission for new joining device, the second one was for checking IP and MAC in both ARP table and comparing them with the stored records in the database.

The comparison has been done for hashing of IPs and MACs that were stored in the database. The used function for hashing IP and MAC was MD5 function. The third module was to detect either a MAC has more IPs or an IP has more MACs. Where a successful detection for both cases has been done and presented in testing and results shown in Fig. 12, 13 and 14. The ARP poisoning attack was generated using Ettercap.

For future work, the proposed approach may be applied for detecting ARP poisoning in Software Defined Network (SDN). The proposed approach may also apply for other attacks as Man-In-The-Middle (MITM) attack.

# Cross-Layer based TCP Performance Enhancement in IoT Networks

Sultana Parween, Syed Zeeshan Hussain

Department. of Computer Science
Jamia Millia Islamia
New Delhi, India

*Abstract*—Transmission Control Protocol (TCP) used multiple paths for performing transmission of data simultaneously to improve its performance. However, previous TCP protocols in Internet of Things (IoT) networks experienced difficulty to transmit a greater number of subflows. To overcome the above issues, we introduced cross-layer framework to perform efficient packet scheduling and congestion control for increasing the performance of TCP in IoT networks. Initially, the proposed IoT network is constructed based on grid topology using Manhattan distance which improves the scalability and flexibility of the network. After network construction, packet scheduling is performed by considering numerous parameters such as bandwidth, delay, buffer rate, etc., using fitness based proportional fair (FPF) scheduling algorithm and selecting best subflow to reduce the transmission delay. The scheduled subflow is sent over an optimal path to improve the throughput and goodput. After packet scheduling, congestion control in TCP is performed using cooperative constraint approximation $3^+$ (CoCoA3$^+$-TCP) algorithm in which three stages are employed namely congestion detection, fast retransmission, and recovery. The congestion detection in TCP-IoT environment is performed by considering several parameters in which cat and mouse-based optimization (CMO) is utilized to adaptively estimate retransmission timeout (RTO) for reducing the delay and improving the convergence during retransmission. Fast retransmission and recovery are performed to improve the network performance by adjusting the congestion window size thereby avoiding congestion. The simulation of cross-layer approach is carried out using network simulator (NS-3.26) and the simulation results show that the proposed work outperforms high TCP performance in terms of throughput, goodput, packet loss, and transmission delay, jitter, and congestion window size.

*Keywords—Internet of things (IoT); transmission control protocol (TCP); cross-layer approach; packet scheduling; congestion control; fast retransmission; recovery*

## I. INTRODUCTION

In recent days, Internet of Things (IoT) is an emerging technology that provides connectivity between various heterogeneous devices to send data through the network. Various sensor nodes act as IoT devices that are interconnected and it is applied for various applications such as health care, home automation, environmental monitoring, transportation, and management of infrastructure [1], etc. Several IoT protocols are used for performing data transmission between heterogeneous IoT devices such as AMQP (advanced message queuing protocol), MQTT (message queuing telemetry transport) and CoAP (constrained

application protocol), HTTP (HyperText Transfer Protocol), and XMPP (Extensible Messaging and Presence Protocol). These protocols are provided effective communication among IoT devices that are used in applications such as embedded systems and industrial 4.0 [2]. However, various challenges are present in IoT data transmission between sensor nodes due to their individual transmission rate which leads to high network congestion [3]. To overcome such challenges Transmission Control Protocol (TCP) which is a transport layer protocol is introduced for efficient data transmission because it transmits huge amount of data traffic globally and is constrained to handle network blockage by reducing the congestion in the IoT environment and also enhances the quality of service (QoS) [4], [5]. This protocol provides effective data transmission with better performance in terms of load, connectivity, reliability, low latency, and speed when compared with user datagram protocol (UDP) [6], [7].

However, several challenges are present in TCP protocol which affects the data transmission by fixed round trip time (RTT) and retransmission timeout (RTO), transmission delay, high buffer rate, bandwidth consumption, etc. that leads to high data congestion. The challenges in TCP affect the performance of the network [8], [9]. Several approaches are introduced to control the congestion occurred in TCP by implementing CoCoA, CoCoA$^+$ , etc. algorithm [10] for classifying weak RTT. However, these algorithms are suffered from severe issues in affecting the network performance, so there would be an improvement in those algorithms must be needed and perform exponential backoff by estimating RTT and RTO however, the frequent retransmission in the network leads to congestion in the network [11]. Congestion control is performed by adjusting the size of congestion window (CWND) after successful recovery. The precise changes in congestion window with respect to the available bandwidth improve the throughput. Some of the works focused on adjusting the congestion window size by considering only limited assumptions. However, the precise analytical justification was not provided which affects the reliability [12]. Retransmission is performed if RTO is expired. After duplicate acknowledges, retransmission is performed. Several works need high retransmission attempts for better recovery [13]. Packet scheduling is performed to avoid congestion by selecting optimal paths and sub-flows [14]. Queue scheduling and path scheduling are also performed for congestion avoidance [15]. Several challenges are present in packet scheduling such as high consumption of bandwidth, high transmission delay, and degradation of throughput which

affects the efficiency of congestion control [16]. However, efficient packet scheduling with congestion control is still in demand.

### A. Motivation and Objectives

In this study, the transmission control protocol for cross-layer approach in IoT is designed for improving the performance of the network. This research also addresses the problems of high bandwidth consumption, high packet loss, high transmission latency, and low throughput to enhance TCP performance. The performance of TCP is affected by high packet loss, throughput degradation, high transmission latency, and bandwidth consumption. The existing works address these problems but, still, it does not provide a proper solution for TCP performance improvement. We are motivated by the major problems of this research which are listed below:

- Inappropriate Congestion Control: The existing works perform congestion control by considering RTT and RTO information; however, they did not estimate based on the current network status which leads to high packet loss and transmission delay. In addition, the count of duplicate acknowledgement (DACK) also affects the process of fast retransmission and fast recovery which degrades the throughput and Goodput.

- High Bandwidth Consumption: The existing work utilizes fixed RTO for congestion control mechanism which consumes high bandwidth when the packet transmission is completed before RTO expired; the completed packets need to wait until the RTO gets over. Further, the existing path selection methods consume high bandwidth as the initial data was sent over multiple paths in the network to find the optimal path.

- Inefficient Scheduling: In scheduling, most of the works only consider limited parameters (RTT, loss rate, and bandwidth) for packet scheduling and optimal path selection which provides inefficient scheduling which increases high jitter and packet loss. In addition, existing random subflow selection achieves high packet loss due to no consideration of completion time.

The above major gaps in the existing works motivated us to provide an effective objective in TCP. The major objective of this research is to reduce packet loss, and transmission latency and increase throughput and Goodput by performing packet scheduling and congestion control using cross-layer approach [17]. The other sub-objective of this research is listed as follows,

- To reduce jitter and transmission latency by performing efficient packet scheduling by considering several metrics such as transmission rate, queue length, completion time, etc. which improves the performance of congestion control.

- To increase the performance of TCP by performing cross layer-based congestion control in which the RTO is estimated by considering the current status of the network which increases the performance of congestion control.

- To increase the performance of fast retransmission and fast recovery by reducing the count of DACK that reduces transmission latency during data transmission.

### B. Research Contribution

The proposed CoCoA3+-TCP approach introduced cross-layer framework to improve the performance of TCP in IoT environment. The major contributions of this research are sorted as follows,

- Firstly, network construction is performed based on grid topology to increase the flexibility and scalability of the network which leads to high communication efficiency with low transmission delay.

- Secondly, packet scheduling is performed by implementing fitness based proportional fair (FPF) scheduling algorithm and selecting of best subflows and optimal path to reduce the jitter and transmission delay efficiently.

- Finally, congestion control in TCP is performed using CoCoA3+-TCP algorithm by congestion detection and avoidance, fast retransmission, and recovery to improve the throughput and goodput which reduces the packet loss.

The performance of the proposed CoCoA3+-TCP method is evaluated by considering several performance metrics to illustrate the performance of TCP such as throughput, goodput, packet loss, transmission delay, jitter, and congestion window size.

### C. Paper Organization

The rest of the paper is organized as follows, Section II provides the existing works and its research gaps, section III emphasizes some specific problems in this field, and corresponding solutions are also provided. Section IV illustrates the proposed work with detailed explanation, relevant diagrams, equations, and pseudocodes. Section V explains the experimental analysis which consists of simulation setup, comparative analysis, and summary of the research are provided. Section VI tells about the conclusion and possible future direction of the proposed method.

## II. LITERATURE SURVEY

This section represents the literature survey of the previous approaches to increase the performance of TCP in terms of packet scheduling and congestion control. In addition, the research gaps in the previous methods are also described in this section.

### A. Packet Scheduling Schemes

This sub-section describes the related works which were proposed for performing packet scheduling to increase the performance of TCP.

Authors in [18], proposed novel congestion control method for multipath TCP. The proposed work performed congestion control and scheduling for improving the performance of TCP.

This research used explicit congestion notification method for detection of shared bottleneck, which includes two processes such as subflow monitoring noticing the segment of TCP and estimating the congestion degree, and verification of shared bottleneck. Based on the shared bottleneck, congestion control is performed. Then packet scheduling is performed by considering fastest subflow, which is arranged based on RTT. Finally, simulation result shows that the proposed work achieved better performance in terms of throughput and detection accuracy. For subflow scheduling, this research only considers RTT which is not enough for optimal subflow scheduling leading to inefficient scheduling, therefore it degrades the performance of multipath TCP.

In [19], authors proposed an efficient packet scheduling method for improving the performance of multipath TCP. The proposed scheduling algorithm computes the number of packets is sent for every path. For that, optimal path is selected by considering buffer rate and completion time, and RTT. In addition, congestion control is performed based on the size of congestion window. For every path selection, congestion window size is evaluated and updated. The experimental results demonstrate that the proposed work achieved superior performance compare to existing approaches. Here, optimal path is selected by considering limited parameters which are not enough for selecting optimal path; hence it leads to degradation of throughput and Goodput.

Authors proposed coupled bottleneck bandwidth and round-trip propagation time (BBR) for improving the performance of multipath TCP by performing congestion control in [20]. The proposed work includes two phases such as congestion control and adaptive scheduling. Initially, coupled BBR evaluates the bandwidth for allocating the sending rate for every subflow for performing congestion control. Then scheduler selects the optimal path by considering the RTT and bandwidth to increase reliability and robustness. Here, packets are scheduled using pre-scheduling algorithm. The experimental result shows that the proposed work achieved better performance in terms of throughput and Goodput. Here, packet scheduling is performed by using pre-scheduling algorithm. However, it considers only limited parameters for scheduling which is not enough for optimal scheduling, in addition, random subflow based scheduling is performed which leads to high transmission latency and low throughput.

Authors proposed an approach to perform congestion control based on cross-layer in the wireless sensor network using fuzzy sliding method for controlling the modes [21]. Initially, signal to noise ratio (SNR) was applied to the channel in the TCP model with cross-layer-based congestion control in the middle of MAC layer, and transmission layer. Then integrating the sliding-mode control with fuzzy control for designing the Fuzzy-Sliding Mode Controller (FSMC) manages the buffer queue length in the congested nodes adaptively. Finally, NS-2.35 was used to perform simulation for comparing the proposed approach with several state-of-the-art methods in terms of packet loss, throughput, convergence, and delay. Here congestion control was performed using FSMC. However, lack of considering the priority of packets leads to high packet loss.

In [22], authors proposed an approach to perform congestion control and scheduling in the wireless network dynamically for reducing the delay. Initially, scheduling of selected data flow was performed to minimize the end-to-end delay using virtual rate scheduling algorithm which modifies the scheduling scheme. Flow control was performed based on windows to reduce the buffer overflow. In scheduling, each slot is decoupled into various mini-slots for low complexity. In addition, the congestion control was effectively performed by separating the mini-slots into numerous micro slots. Adjustment of virtual rate was performed to identify the priority of every flow link.

Authors proposed multi-path scheduling and congestion control by implementing deep reinforcement learning approach [23]. Initially, packet scheduling and congestion control framework was proposed by implementing deep Q learning (DQL) for the multipath TCP. The DQL technique was used to perform congestion control and scheduling optimally by the intelligent agents based on experience using policy gradients. Dynamic scheduling and congestion control were performed across all network paths by integrating the DQL with policy gradients. Recurrent neural network and long-short term memory algorithm were used to learn the behavior of paths and adjusts the scheduling and congestion control appropriately. Finally, experimental analysis was performed by comparing the performance of this approach with existing multipath TCP algorithms.

### B. Congestion Control Schemes

This sub-section describes the related works which were proposed for controlling the congestion to increase the performance of TCP.

A dynamic congestion window algorithm for IoT environment was proposed by the authors in [24]. The main objective of this research is to minimize the delay and maximize the packet delivery ratio. In this research, congestion window size is dynamically changed based on the transmission rate, and bandwidth. The congestion window is adjusted only when the paths need to transmit the data. The simulation results demonstrate that the proposed work achieved superior performance in terms of packet delivery ratio, delay, and throughput. Here, the congestion window is adjusted based on the transmission rate and bandwidth which is not enough for congestion control due to lack of significant parameters such as RTO, RTT, and queue status, hence it leads to poor congestion.

A novel congestion control algorithm to improve the performance of improved multipath TCP was proposed in [25]. The main aim of this research is to reduce the delay and increase the throughput. The proposed work includes four processes such as startup, drain, probe bandwidth, and probe RTT which estimate the size of the congestion window considering pacing rate, congestion window, and send quantum. In this way, congestion control is performed for improving the performance of multipath TCP. The simulation result shows that proposed work achieved better performance in terms of throughput compared to existing approaches.

A novel method to improve the performance of TCP was proposed in [26] by considering queue size, retransmission, medium access control (MAC) overhead, and node energy. Here, the contention window is adjusted based on residual energy, queue size, slot time, and congestion window. Scheduling is done by estimating backoff time in a dynamic manner which improves the performance of TCP. The experimental result shows that the proposed work achieved better performance in terms of throughput, overhead, and energy consumption.

The congestion control mechanism for multipath TCP based on the flow control of the data was proposed by the authors in [27]. The proposed congestion control algorithm includes two main goals; first one is enhancing the throughput compared to single-path TCP. Second one is collecting the subflows by shared bottleneck. The bottleneck detection is performed based on RTT, packet loss, and congestion notification. For that purpose, this research proposed three filters such as RTT filter, congestion notification filter, and packet loss filter. Based on these filters the proposed work performed congestion control for multipath TCP. The simulation result shows that the proposed work achieved better performance in terms of detection accuracy and latency. Here, congestion window is adjusted based on three parameters that perform well, but the values are not considered based on the current network status, hence it leads to performance degradation of multipath TCP.

Authors in [28], proposed a congestion control method to improve the performance of TCP. The proposed work used window-based congestion control for resolving the limitations of the TCP in wireless networks. Here, congestion control is performed by considering queue level, sending rate, and flow utilization rate. This research includes three processes such as congestion window growth, congestion control, and recovery. In which the window growth is estimated based on threshold value (i.e., maximum window size). Congestion control is performed by considering two-level notifications. Finally, stability of the throughput is estimated based on transmission rate, and utility rate. The simulation shows that the proposed work achieved superior performance in terms of throughput, end-to-end delay, and Goodput. Authors proposed an approach to perform multipath scheduling of packets for controlling the network congestion concerning buffer acknowledgment in [29]. This method consists of two major entities a multi-path-packet scheduler (MPS), and a multi-path-congestion controller (MCC) in which the MPS was used to schedule the path based on three delay probabilities such as transmission delay and In-Out delay, and congestion delay. The MCC was used to manage the congestion control by considering the transmission control rate with respect to buffer availability, and packet delivery rate for increasing the throughput with low packet loss. Finally, simulation was performed to prove the performance of this approach in terms of buffer utilization, and throughput. Here, path scheduling was performed to reduce the transmission delay. However, lack of considering the data priority leads to high data loss.

The related works from [18 to 23] represents the packet scheduling schemes of the state-of-the art works whereas, the works [24 to 29] describes the congestion control schemes of the previous approaches. These methods have several limitations which are described at the end of each previous method. These limitations pave the way for the proposed CoCoA3$^+$-TCP method.

## III. PROBLEM STATEMENT

The retransmission-based effective TCP congestion control method for IoT was introduced in [30]. Bottle-neck bandwidth round trip propagation time improves the fairness of RTT for congestion control was introduced in [31]. The major problems employed in this research are,

- Authors performed RTT estimation to calculate RTO for exponential backoff to improve congestion control of TCP. However, fixed RTO increases the waiting time of packets which leads to high latency and bandwidth consumption.

- Authors considered only queue status and delivery rate for adjusting CWND to perform congestion control. However, these parameters are not enough to perform effective congestion control leading to high jitter and low Goodput.

- Authors performed retransmission after obtaining three duplicate ACKs for reducing packet delivery failure. However, it increases the total delay of transmission which degrades the performance of TCP.

The packet scheduling and congestion control framework based on BBR to enhance the fairness of multipath TCP wireless networks was introduced in [32]. The major problems employed in this research are:

- Authors considered RTT to adjust the CWND for the improvement of congestion control. However, lack of considering RTO that leads to degradation of throughput.

- Two or more subflows share the same bottleneck set simultaneously for congestion control. However, these subflows are selected randomly without considering buffer rate and data size which leads to high transmission delay and packet loss.

- Several parameters such as bottleneck bandwidth, RTT, loss rate, and subflows are considered for packet scheduling. However, these parameters are not enough for optimal scheduling of packets which leads to high transmission delay.

The cross-layer congestion control framework for IoT environment was introduced in [33]. The major problems employed in this research are:

- Authors selected paths by considering only path bandwidth for congestion avoidance. However, single parameter is not enough to select the optimal path that leads to high jitter and packet loss.

- The proposed congestion control policy is used for performing fast retransmission based on adaptive data rate with respect to the path. However, lack of

considering RTO leads to high bandwidth consumption and high retransmission delay.

### A. Research Solutions

To overcome the above problems faced by the existing works, the proposed work initially constructed the network as grid topology based on Manhattan distance which increases the flexibility and scalability of the network. After that, efficient packet scheduling is performed to reduce the latency during transmission and jitter using fitness based proportional fair scheduling algorithm which calculates the fitness value for every scheduling slot. The subflow and optimal path selection is done after packet scheduling to improve the throughput. The congestion control is performed to improve the performance using CoCoA3$^+$-TCP Algorithm that consists of three sub-processes namely congestion detection and avoidance, fast retransmission, and fast recovery. Here, congestion is detected by several metrics in that RTO is adaptively estimated using CMO algorithm. After congestion is detected fast transmission and fast recovery are performed by reducing the count of duplicate acknowledgment which reduces the transmission latency during data transmission. The overall proposed work improves the throughput, and goodput, and reduces the jitter and transmission latency in the TCP IoT environment.

## IV. PROPOSED WORK

This section provides the research methodology of the proposed cross-layer CoCoA3$^+$-TCP. The proposed work mainly focuses on improving the performance of the TCP using the cross-layer approach in an IoT environment. The performance of TCP is affected by high packet loss, Round Trip Time (RTT), and maximum segment size which lead to high latency and low throughput. The proposed work uses cross-layer design which allows the interaction between the data link layer and transport layer to transfer the information. Fig. 1 denotes the overall architecture of the proposed work in which cross-layer approaches among two layers is depicted.

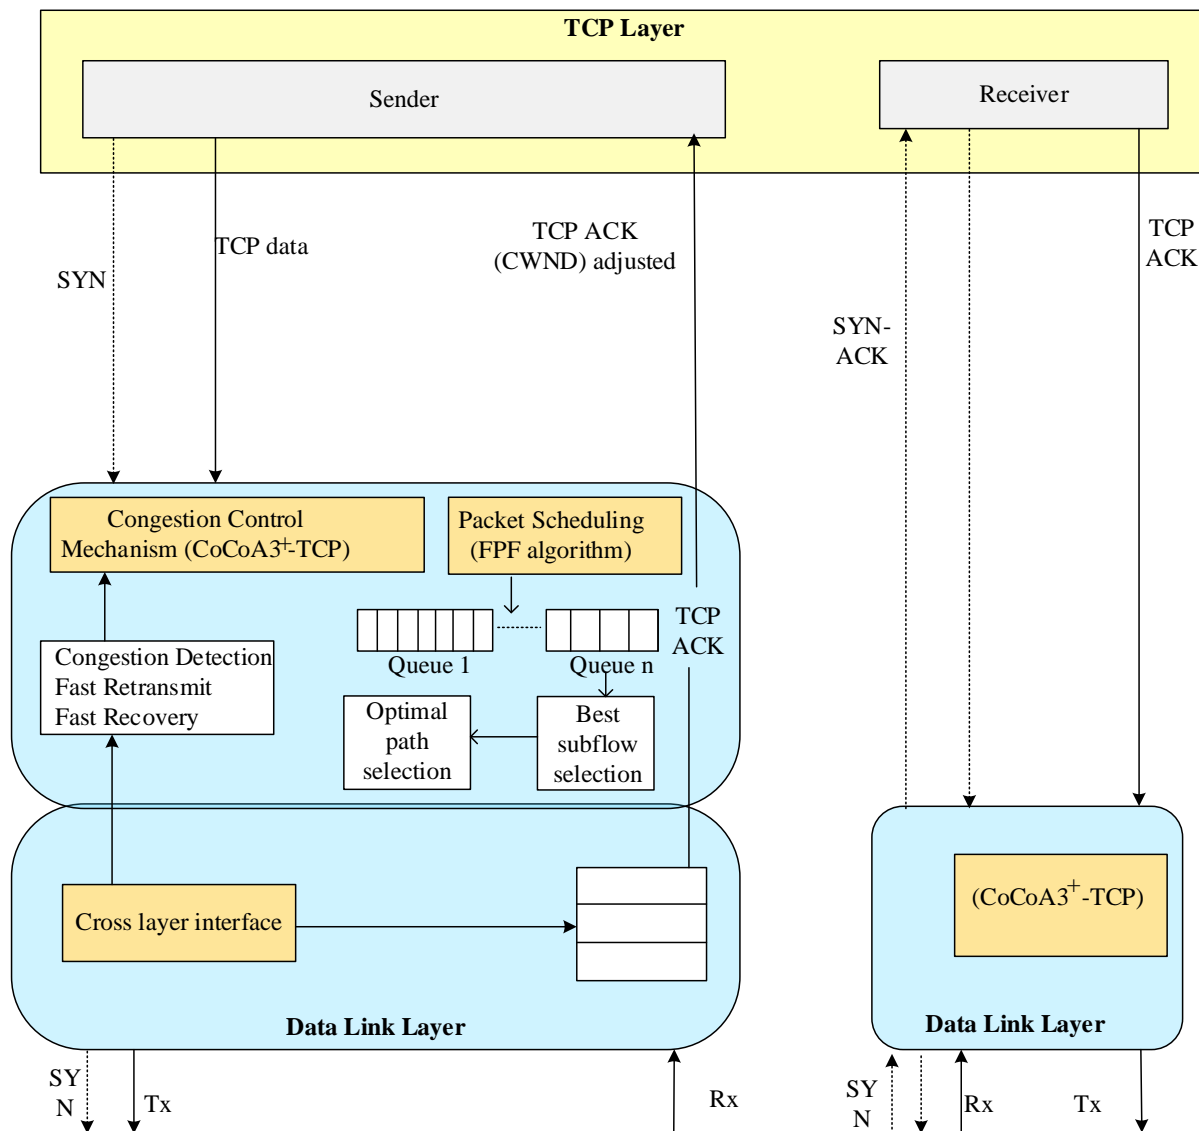

Fig. 1. CoCoA3$^+$-TCP Architecture.

Initially, the network is constructed by Manhattan distance-based grid topology which is a simpler grid topology that increases the flexibility and scalability of the network. The nodes are arranged in grid size of order $10 \times 10$. The proposed work assumes that the nodes in the network have stable range of communication range and that there are no crashes among the IoT nodes. Each node can communicate with each other, which are in the range of their respective communication. The range of transmission is constrained so that there is immediate communication among the nodes is established. Let $(C^{n_i}, D^{n_i})$ be the coordinates of node $n_i$, hence the distance $(Dis)$ among the node $n_i$ and node $n_j$ can be formulated as.

$$Dis_{n_i, n_j} = |C^{n_i} - C^{n_j}| + |D^{n_i} - D^{n_j}| \qquad (1)$$

The above equation denotes the arrangement of IoT nodes in the environment in $10 \times 10$ by Manhattan distance measure. This research improves the TCP performance by providing two processes which are listed as follows,

- Efficient Packet Scheduling
- TCP Congestion Control

*A. Efficient Packet Scheduling*

The main aim of packet scheduling is to reduce the jitter and transmission latency and improve the Goodput and throughput. Here, packets are scheduled and transmitted to the receiver which reduces transmission delay and congestion. For packet scheduling, we proposed FPF by considering bandwidth, energy $(En)$, delay $(dl)$, transmission rate $(TXr)$, queue length $(Ql)$, buffer rate $(BR)$, completion time $(cti)$ and data size $(dz)$which can be formulated as,

$$P^{\blacksquare} = arg \max_p \left( \frac{SR_{k,b}}{(W-1)T_k + \sum_{b=1}^{B} I_{k,b} SR_{k,b}} \right) \qquad (2)$$

Where, $P^{\blacksquare}$ denotes the important value of each user which is used for effective packet scheduling, $SR_{k,b}$ rate of service for the $k^{th}$ user at $b^{th}$ time index based on the above-mentioned packet scheduling metrics, $T_k$ indicates the $k - th$ user throughput, $W$ is the window size, $I_{k,b}$ denotes the indicator variable which indicates the, when $I_{k,b} = 1$ the $k - th$ user packet is scheduled at $b - th$ time index else 0. The $T_k$ can be formulated as.

$$T_k(t+1) = \begin{cases} \left(1 - \frac{1}{w}\right) T_{k,b}(t) + \frac{1}{w} A_k(t), V = P^{\blacksquare} \\ \left(1 - \frac{1}{w}\right) T_{k,b}(t), \quad V \neq P^{\blacksquare} \end{cases} \qquad (3)$$

Where, $T_k$ denotes the past throughput that is dispensed to users in the previous transmission time interval. $T_k(t+1)$ denotes the current throughput which is calculated based on the $T_k$. $V$ denotes the index of the user packets, $A_k$ indicates the user throughput in current transmission time interval. Based on the importance value of each user fitness value is calculated. Here, fitness value is used to enhance long-term fairness and throughput in every scheduling slot which can be formulated as,

$$Fit(U) = \begin{cases} \max_{SR}(En, TXr, Ql) \\ \min_{SR}(dl, cti, dz, BR) \end{cases} \qquad (4)$$

The above equation denotes the fitness value of each user packet. The user packets are scheduled based on the above-mentioned equation.

After completed packet scheduling best subflow is selected for scheduling which reduces the transmission delay during data transmission. The best subflow is selected based on the priority and fitness values of the user packets. The user packet with highest $Fit(U)$ are given more priority which can be formulated as

$$SF = \begin{cases} \uparrow \ Fit(U), \ SF_1 \\ \quad \vdots \\ \downarrow \ Fit(U), \ SF_n \end{cases} \qquad (5)$$

From the above equation, the $\uparrow Fit(U)$ indicates the user packet with higher fitness value who is given more priority and selected as first subflow while $\downarrow Fit(U)$ denotes the user packet with lower fitness value who is given less priority and selected as $n - th$ subflow. Finally, optimal path is selected from multiple paths for sending scheduled subflows. For optimal path selection, we consider congestion rate, transmission delay, and high throughput. Finally, TCP performances are improved by sending the scheduled subflow through optimal path. Fig. 2 represents the efficient packet scheduling, sub scheduling, and optimal path selection of the proposed work.

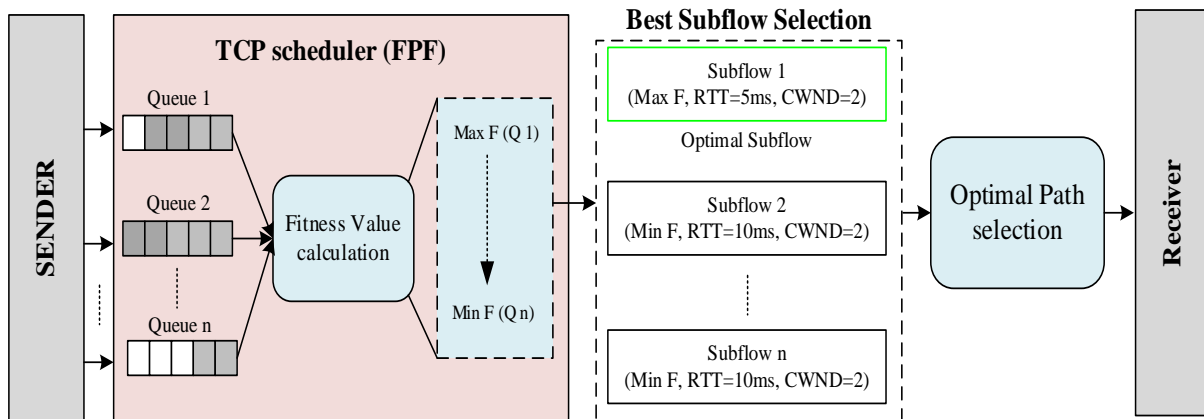

Fig. 2.    FPF based Efficient Packet Scheduling.

*B. TCP Congestion Control*

In general, the network has congestion due to many packets being sent by the senders at a particular time, which affects the performance in terms of throughput, and packet delivery rate in TCP. To improve the performance of TCP, we need to avoid congestion in the network. The proposed congestion control CoCoA3$^+$-TCP Algorithm includes three sub-processes such as congestion detection and avoidance, fast retransmission, and fast recovery.

Initially, congestion is detected by considering RTT, Retransmission Timeout (RTO), transmission rate, delay, bandwidth, delivery rate, and queue status.

*1) Round trip time (RTT):* The amount of time taken for data to reach its destination and return the acknowledgment is known as RTT. The RTT can be formulated as,

$$RTT = 2 \times Pd \tag{6}$$

Where $Pd$ denotes the propagation delay. The good protocol must have less $Pd$ thereby having less RTT.

*2) Transmission rate (TXr):* The $TXr$ is defined as the amount of data transmitted in a specific channel over a unit of time. In TCP the $TXr$ is dependent on the size of the window which can be formulated as,

$$W = \frac{trf_t}{speed} \tag{7}$$

Where $W$ is window size, generally $TXr$ depends on $W$ in TCP, $trf_t$ indicates the time of transfer, and $speed$ denotes the speed of transfer, respectively.

*3) Delay (dl):* The delay is defined as the amount of time taken for data to transmit from source to destination. Generally, unit of delay depends on the time is taken nature of data. The delay must be less for a good communication protocol.

*4) Bandwidth (BW):* The $BW$ is defined as the capacity of the network to withstand with high amount of data over a medium of transmission. The $BW$ can be formulated as,

$$BW = \frac{W}{RTT} \tag{8}$$

Where $W$ denotes the size of the window, and $RTT$ denotes the round-trip time.

*5) Delivery rate (DR):* The amount of data packet delivered to the destination in a period is known as $DR$. Generally, a good TCP must have high $DR$.

*6) Queue status (QS):* The $QS$ is defined based on the queue length. Higher the Queue length greater the congestion rate. The $QS$ can be formulated as,

$$Ql = (1 - W) \times Ql + W \times Q_{sam} \tag{9}$$

Where, $W$ is the window size, $Q_{sam}$ is the sample queue that denotes the actual queue length of the packet arrival.

Here, the RTO value is estimated dynamically rather than fixed as a static value based on the current status of the environment. Then overall RTO value is estimated which is optimally calculated by CMO which is presented in CoCoA3$^+$-TCP. The CMO algorithm is a nature-inspired algorithm that mimics cat and mouse behaviours. This algorithm consists of two phases namely missing acknowledgment modelling and packet retransmission modelling. The population of packets in the TCP-IoT network is determined as,

$$R = \begin{bmatrix} R_1 \\ \vdots \\ R_i \\ \vdots \\ R_n \end{bmatrix}_{n \times m} = \begin{bmatrix} R_{1,1} & \cdots & R_{1,d} & \cdots & R_{1,m} \\ \vdots & & \vdots & & \vdots \\ R_{i,1} & & R_{i,d} & & R_{i,m} \\ \vdots & & \vdots & & \vdots \\ R_{n,1} & & R_{n,d} & & R_{n,m} \end{bmatrix}_{n \times m} \tag{10}$$

From the above equation, $R$ denotes the packets population matrix, $R_i$ denotes the exploration agent $(i - th)$, $n$ indicates the number of packets transmitted in the network, and the problem variable is denoted as $m$. In the network, each transmitted packet must be objective function which can be formulated as,

$$OF = \begin{bmatrix} OF_1 \\ \vdots \\ OF_i \\ \vdots \\ OF_n \end{bmatrix}_{n \times 1} \tag{11}$$

Where, $OF$ is the objective function vector, and $OF_i$ is the exploration agent objective function. From the above $OF$ values the best and worst transmitted packets are selected that can be formulated as,

$$OF_{alt} = \begin{bmatrix} OF_1^{alt} & Mini(OF) \\ \vdots & \vdots \\ OF_n^{alt} & Maxi(OF) \end{bmatrix}_{n \times 1} \tag{12}$$

From the above equation, $OF_{alt}$ denotes the altered transmitted packet objective function based on equation (11). The transmitted packet with minimum objective function is considered as the best member else worst member. The overall packet population matrix consists of two groups namely missing acknowledgment packets and retransmitted packets. From that, the population of missing acknowledgment packets and retransmitted packets can be formulated as follows:

$$Mi(R) = \begin{bmatrix} Mi(R)_1 = R_1^{alt} \\ \vdots \\ Mi(R)_i = R_i^{alt} \\ \vdots \\ Mi(R)_{nR} = R_{nR}^{alt} \end{bmatrix}_{nR \times m} =$$

$$\begin{bmatrix} R_{1,1}^{alt} & \cdots & R_{1,d}^{alt} & \cdots & R_{1,m}^{alt} \\ \vdots & & \vdots & & \vdots \\ R_{i,1}^{alt} & & R_{i,d}^{alt} & & R_{i,m}^{alt} \\ \vdots & & \vdots & & \vdots \\ R_{nR,1}^{alt} & & R_{nR,d}^{alt} & & R_{nR,m}^{alt} \end{bmatrix}_{nR \times m} \tag{13}$$

$$rt(R) = \begin{bmatrix} rt(R)_1 = R_{nR+1}^{alt} \\ \vdots \\ rt(R)_j = R_{nr+j}^{alt} \\ \vdots \\ rt(R)_{nrt} = R_{nR+nrt}^{alt} \end{bmatrix}_{nrt \times m} =$$

$$\begin{bmatrix} R_{nR+1,1}^{alt} & \cdots & R_{nR+1,d}^{alt} & \cdots & R_{nR+1,m}^{alt} \\ \vdots & & \vdots & & \vdots \\ R_{nR+j,1}^{alt} & & R_{nR+j,d}^{alt} & & R_{nR+j,m}^{alt} \\ \vdots & & \vdots & & \vdots \\ R_{nR+nrt,1}^{alt} & & R_{nR+nrt,d}^{alt} & & R_{nR+nrt,m}^{alt} \end{bmatrix}_{nrt \times m} \quad (14)$$

From the above equations (13) and (14), $Mi(R)$ denotes the missing acknowledge packets and $rt(R)$ denotes the retransmitted packets respectively. Therefore, in first phase, the missing acknowledgment packets are found by,

$$Mi(R)_i = \begin{cases} Mi(R)_i^{new}, |OF_i^{Mi(R),new} < OF_i^{Mi(R)} \\ Mi(R), else \end{cases} \quad (15)$$

Where, $Mi(R)_i^{new}$ is missing acknowledgment based on current network status, and $OF_i^{Mi(R),new}$ denotes the objective of missing acknowledgment. In second phase, the retransmitted packet is found by,

$$rt(R)_j = \begin{cases} rt(R)_i^{new}, |OF_i^{rt(R),new} < OF_i^{rt(R)} \\ rt(R), else \end{cases} \quad (16)$$

Where, $rt(R)_i^{new}$ new retransmitted packets based on current network status, and $OF_i^{rt(R),new}$ denote the objective function of new retransmitted packets. From the equation (15) and (16), the RTO is adaptively determined by,

$$RTO = Mi(R)_i^{new} - rt(R)_i^{new} \quad (17)$$

The pseudocode for adaptive RTO estimation based on cat and mouse optimization algorithm is given below:

---

**Pseudocode**

**Adaptive RTO selection ()**

**Start** CMO

   Initialize $R$ using (10)

   Set exploration agents (n) and iterations (T)

   Compute $OF$ using (11)

   Alter the $OF$ using (12)

   Set the $Mi(R)$ population using (13)

   Set the $rt(R)$ population using (14)

   **Stage 1: Missing ACK stage**

     **For** i=1: nR;

       Find the missing acknowledged packets using (15)

     **End**

   **Stage 2: packet retransmission modelling**

     **For** j=1: nrt;

       Find retransmitted packets using (16)

     **End**

   Calculate RTO using (17)

**End**

---

Due to congestion, the network has high packet loss; hence we need to perform fast retransmission and fast recovery. The basic goal of fast retransmission is to minimize the count of duplicate acknowledgment (DACK) which reduces the transmission latency during data transmission. The steps involved in fast retransmission are:

- Step 1: Sender sent some packets to the receiver, and receiver receives the packets and gives acknowledgment.

- Step 2: If correct acknowledgment, the sender sends another packet. Else, sender sends acknowledge message along with lost packets to sender.

- Step 3: Along with lost packets, sender continuously sends another packet which leads to two DACK.

- Step 4: After getting two DACK, the sender retransmits the missing packets (i.e., Fast recovery) without exceeding RTO based on the current network status which is evaluated by RTT for every packet given in equation (6).

The proposed algorithm adjusts the congestion window size that reduces the delay which is illustrated in Fig. 3. The current network status is determined based on RTT. If the RTT increases beyond network limit then there is congestion in the network, and when RTT gets decreased there is no congestion, at that time size of congestion window must be increased to avoid the congestion further.

Fig. 3. CWND Adjustment for Fast Retransmission and Recovery.

## V. Experimental Results

In this section, the proposed CoCoA3$^+$-TCP is experimented with and validated. This section is further subdivided into four sub-sections such as simulation setup, application scenario comparative analysis, and research summary.

### A. Simulation Setup

This sub-section describes the simulation of the proposed work. Initially, the network is constructed as grid topology based on Manhattan distance for improving the scalability of the network. This work utilizes the system with hardware configuration of random-access memory (RAM) 8GB, hard disk 256GB, and processor of Intel(R) Core (TM) i5-3210M CPU @ 2.50GHz; the software configuration of network simulator with version 3.26, and operating system of Ubuntu Linux 18.04. Table I denotes the various simulation parameters used for simulating the proposed model. Fig. 4 represents the simulation grid topology of the proposed CoCoA3$^+$-TCP.

The above figure represents the simulation grid topology of the proposed CoCoA3$^+$-TCP. The proposed work constructs the grid as size of $10 \times 10$ using Manhattan distance which is flexible and mitigates the scalability issues. By this grid topology construction, the proposed work achieves high transmission efficiency, high throughput and less delay during packet scheduling and congestion control, respectively.

TABLE I. SIMULATION CONFIGURATION

| Simulation Parameter | Values |
|---|---|
| Network Simulator | NS-3.26 |
| Routing Protocol | AODV |
| Type of Traffic | TCP |
| Area of Simulation | 1500m × 1500m |
| No. of IoT nodes | 100 |
| No. of Base station | 1 |
| Size of the window | $2^8$ |
| Size of the packet | 2000 bytes |
| Size of the Queue | 30 packets |
| Placement of IoT node | Grid topology |
| Topology Size | 10 × 10 |
| Time for Total Simulation | 300ms |

Fig. 4. Simulation Grid Topology of CoCoA3$^+$-TCP.

### B. Application Scenario

The proposed TCP-IoT model can be adopted in medical environment (i.e. patient monitoring system). The medical environment consists of numerous patients and each patient are equipped with IoT sensors (i.e. heart beat sensor, blood pressure sensor, etc.). The improper counter measure in the medical environment leads to severe threats to the patients. To take correct medical counter measure at correct time period, the sensed data are optimally report to the doctors. For that we propose, reliable TCP-IP congestion control fast and reliable mechanism in which every sensor data is forwarded to the server where it performs scheduling using FPF algorithm based on several metrics such as bandwidth, delay, buffer rate, etc. The scheduled data are selected best sub flow using CoCoA3$^+$-TCP algorithm. The proposed work can be applied in the medical environment for patient monitoring reduces the latency, and congestion issues.

### C. Comparative Analysis

In this sub-section, the comparative analysis is performed for the proposed CoCoA3$^+$-TCP method with several previous approaches such as ICC-TCP (28), and BC-CPS (30) methods for evaluating the performance of these methods. Various performance metrics are considered in terms of throughput, goodput, packet loss, transmission delay, jitter, and congestion window size respectively to evaluate the performance of the proposed CoCoA3$^+$-TCP method and other previous works.

*1) Impact of throughput*: This metric is used to evaluate the total number of data packets received ($\beta$) at a certain period ($\mathfrak{t}$) by the receiver. Throughput ($\varsigma$) is denoted in terms of bits per second. The formulation of this metric is described as follows,

$$\varsigma = \frac{\beta}{\mathfrak{t}} \tag{18}$$

Fig. 5 illustrates the comparison of throughput between the proposed CoCoA3$^+$-TCP method with several previous methods such as ICC-TCP, and BC-CPS methods with respect to the packet size. A network with high throughput achieves better communication between the source and destination. Throughput increases with increasing the packet size.

Fig. 5. Throughput Vs. Packet Size.

In the existing BC-CPS approach, congestion control and packet scheduling are statically performed with poor RTO measurement, and retransmission was performed after several ACK which increases the latency that leads to low throughput. In the proposed CoCoA3$^+$-TCP method, adaptive RTO estimation is performed and retransmission of packets is performed after receiving two DACK which reduces the latency that increases the throughput of the proposed CoCoA3$^+$-TCP method. The comparative results show that the proposed CoCoA3$^+$-TCP method achieves high throughput (12-20 Mbps) when compared with ICC-TCP (6-14 Mbps) method and BC-CPS (4-11 Mbps) method.

Similarly, Fig. 6 shows the comparison of throughput with respect to simulation time. From this figure, it is clearly shown that the proposed CoCoA3$^+$-TCP method achieves high throughput of 20 Mbps for the packet size of 2100 bytes which is 6 Mbps higher than the ICC-TCP method and 9 Mbps higher than BC-CPS method.

*2) Impact of goodput*: It is one of the important metrics which is the other form of throughput in the application level to evaluate the performance of the proposed algorithm for performing accurate and efficient communication, especially during huge data transmission. Goodput (ß) is formulated by the ratio between the amount of particular data (ų) to the time taken for reaching the receiver (ɧ) which is expressed as follows:

$$ß = \frac{ų}{ɧ} \qquad (19)$$

Fig. 7 represents the goodput comparison for the proposed CoCoA3$^+$-TCP method and several previous works in terms of packet size. A network with low transmission delay achieves high goodput which increases the communication efficiency. The goodput increases with respect to increase of packet size. In the existing BC-CPS method, lack of considering the RTO when evaluating the RTT for the communication increases the latency which reduces the performance of the TCP by attaining low goodput.

In the proposed CoCoA3$^+$-TCP method, the RTO is estimated based on current status of the network which increases the TCP performance by achieving high goodput. From the graphical results, it is proved that the proposed CoCoA3$^+$-TCP method achieves high goodput when compared with state-of-the-art methods. The proposed CoCoA3$^+$-TCP attains high goodput of 800 Kbps at 2100 bytes. The difference of goodput between the proposed CoCoA3$^+$-TCP method and the ICC-TCP method is 120 Kbps, and 200 Kbps for the BC-CPS method.

Similarly, Fig. 8 represents the comparison of goodput to the simulation time. The comparative results show that the proposed CoCoA3$^+$-TCP method achieves high goodput of 800 Kbps which is 140 Kbps higher than ICC-TCP method and 200 Kbps higher than BC-CPS method at 300ms.

*3) Impact of packet loss:* It is used in the network to evaluate communication reliability. Packet loss is defined as the ratio of the number of data packets that are not received to the total amount of packets which is formulated as follows:

$$ ⋔ = \frac{ⱦ}{∂} \qquad (20)$$

Fig. 6. Throughput Vs. Simulation Time.

Fig. 7. Goodput Vs. Packet Size.

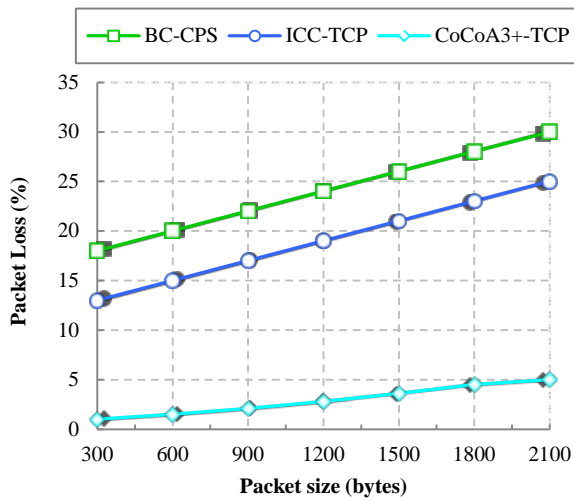
Fig. 8. Goodput Vs. Simulation Time.


Fig. 9. Packet Loss Vs. Packet Size.

Fig. 10. Transmission Delay Vs. Packet Size.

Where ⋔ shows the packet loss, ⳨ represents the non-received data packets and ∂ denotes the total amount of packets. Fig. 9 shows the comparison of packet loss between the proposed CoCoA3$^+$-TCP method and several previous approaches. A network with low packet loss reduces the number of retransmissions which decreases the network congestion. The packet loss increases with increase in packet size. In the ICC-TCP methods, the congestion control is performed by evaluating the RTT without considering the present network status that increases the DACK which leads to high packet loss. In the proposed method, congestion control is performed by adaptively implementing CoCoA3$^+$-TCP algorithm. In addition, the congestion window is increased by one when more than two DACK reduces the packet loss.

The comparative results illustrate that the proposed CoCoA3$^+$-TCP method achieves low packet loss when compared with other previous methods. The proposed CoCoA3$^+$-TCP method achieves low packet loss of about 5% for 2100 bytes of packet size which is 20% lower than ICC-TCP method, and 25% lower than BC-CPS method. Table II describes the packet loss variation of the proposed CoCoA3$^+$-TCP method and other existing approaches.

*4) Impact of transmission delay:* Transmission delay (ǰ) represents the amount of additional time taken by the proposed CoCoA3$^+$-TCP method to transmit the packets from the source to the destination. It is formulated by the difference between the actual packet received time (ɵ) and the expected time (ζ) which is expressed as follows:

$$ ǰ = ɵ - ζ \tag{21} $$

TABLE II. NUMERICAL ANALYSIS OF PACKET LOSS

| Methods | Packet Size |
|---|---|
| BC-CPS | $24.3 \pm 0.5$ |
| ICC-TCP | $19.5 \pm 0.4$ |
| CoCoA3$^+$-TCP | $2.92 \pm 0.1$ |

Fig. 10 illustrates the comparison of transmission delay for the proposed CoCoA3$^+$-TCP method and other existing methods in terms of packet size. A network with low transmission delay increases the throughput as well as goodput. The transmission delay increases with increasing the packet size. In the BC-CPS method, random selection of subflows is performed with insufficient parameters such as RTT, loss rate, etc., for data transmission which increases the transmission delay and also leads to high packet loss. In the proposed CoCoA3$^+$-TCP work, Optimal selection of subflows is performed by considering buffer rate, queue length, etc. which improves the fairness for long term that reduces the transmission delay when compared with other previous methods. From this figure, it is clearly shown that the proposed CoCoA3$^+$-TCP method achieves low transmission delay of about 20ms for 2100 bytes of packet size which is 30ms faster than ICC-TCP method and 50ms faster than BC-CPS method.

Similarly, Fig. 11 shows the comparison of transmission delay with respect to simulation time between the proposed CoCoA3$^+$-TCP method and existing methods. The results show that the proposed CoCoA3$^+$-TCP method achieves low transmission delay of about 20ms for 300ms of simulation time which is 28ms faster than ICC-TCP method and 48ms faster than BC-CPS method.

Fig. 11. Transmission Delay Vs. Simulation Time.

*5) Impact of jitter:* This metric is used to evaluate the difference between the transmitting time and receiving time. The formulation of jitter is defined as the time variation between the current and previous data packets which is expressed as follows:

$$\lambda = \xi - \varkappa \tag{22}$$

Where $\lambda$ denotes the jitter, $\xi$ represents the current packet receiving time, $\varkappa$ shows the previous packet receiving time.

Fig. 12 shows the comparison of jitter between the proposed CoCoA3$^+$-TCP method and several state-of-the-art approaches in terms of packet size. A network with low jitter increases the performance of TCP. The jitter increases with increasing the packet size. In the ICC-TCP method, DACK was not considered during retransmission which increases the latency of data recovery that leads to high jitter. In addition, lack of considering RTO in the BC-CPS method during congestion control also increases the jitter.

In the proposed CoCoA3$^+$-TCP method, fast data recovery is performed by considering the DACK more than two and reducing the congestion window to half of the present status of congestion window with respect to RTT and RTO is considered based on the network's current status that reduces the jitter effectively when compared with other previous works. The graphical results illustrate that the proposed CoCoA3$^+$-TCP method achieves low jitter of about 15ms for 2100 bytes of packet size. Whereas, the ICC-TCP and BC-CPS methods achieve jitter of about 50ms and 60ms for the same packet size which is 35ms and 45ms greater than the proposed CoCoA3$^+$-TCP method.

Similarly, Fig. 13 illustrates the comparison of jitter between the proposed CoCoA3$^+$-TCP method and other previous methods with respect to simulation time. The results show that the proposed CoCoA3$^+$-TCP method achieves low jitter of about 15ms which is 32ms faster than ICC-TCP method and 43ms faster than BC-CPS method.

Fig. 13. Jitter Vs. Simulation Time.

*6) Impact of congestion window size:* This metric is used to evaluate the number of data packets transmitted from the source to the destination without any traffic. A network with large congestion window size increases the throughput of the network. Whenever DACK occurs, the size of the congestion window decreases to half of its size to perform fast retransmission and recovery.

Fig. 14 represents the comparison of congestion window size for the proposed CoCoA3$^+$-TCP method and other existing methods with respect to simulation time. The size of the congestion window increases when normal data transmission and decreases when retransmission occurs with increasing simulation time. In the state-of-the-art approaches, the size of the congestion window is randomly changed to send the data packets with lack of considering the RTO which increases the congestion that leads to high complexity in congestion control.

Fig. 12. Jitter Vs. Packet Size.

Fig. 14. Congestion Window Size Vs. Simulation Time.

In the proposed CoCoA3+-TCP method, the congestion window is adaptively changed, i.e. whenever the DACK increased, the congestion window is increased by one. For faster data recovery, the congestion window is reduced by half with respect to RTT which reduces the congestion and increases the control of congestion. In addition, estimation of dynamic RTO is performed based on the network's current status which also reduces the retransmission of packets. The comparative results illustrate that the proposed CoCoA3+-TCP method achieves better congestion window size when compared with other previous methods.

The proposed CoCoA3+-TCP method attains high congestion window size of about 27 which is 4 larger than ICC-TCP method and 6 larger than the BC-CPS method. When retransmission occurs, the size of the congestion window decreases by about 13 which is 5 lower than BC-CPS method and 3 lower than ICC-TCP method. Table III illustrates the changes in congestion window size between the proposed CoCoA3+-TCP method and several previous works.

TABLE III.     NUMERICAL ANALYSIS OF CONGESTION WINDOW SIZE

| Methods | Simulation Time |
|---|---|
| BC-CPS | $19.3 \pm 0.5$ |
| ICC-TCP | $20.5 \pm 0.3$ |
| CoCoA3+-TCP | $21.5 \pm 0.1$ |

### D. Research Summary

This sub-section summarizes the overall performance of the proposed CoCoA3+-TCP method in terms of throughput, goodput, packet loss, transmission delay, jitter, and congestion window size respectively from Fig. 5 to 14. The major highlights of the proposed CoCoA3+-TCP method are described in this sub-section. Fitness based Proportional Fair (FPF) scheduling algorithm is proposed for performing efficient packet scheduling which improves throughput and Goodput by reducing the transmission delay and jitter. The CoCoA3+-TCP algorithm is proposed for improving congestion control and avoidance with CMO by considering multiple parameters such as delay, transmission rate, RTT, RTO, and bandwidth. DACK count is minimized by performing fast retransmission and recovery which retransmits the packets before the threshold of RTO depending upon the current network status. Table IV represents the ablation study between the existing and proposed approaches which consists of the average values of the corresponding performance metrics. From this table, it is proved that the proposed CoCoA3+-TCP method achieved high TCP performance when compared with other existing works.

TABLE IV.     NUMERICAL ANALYSIS OF PROPOSED AND EXISTING METHODS

| Performance Metrics | | BC-CPS | ICC-TCP | CoCoA3+-TCP |
|---|---|---|---|---|
| Throughput (Mbps) | Packet Size (bytes) | $7.14 \pm 0.5$ | $9.58 \pm 0.3$ | $15.57 \pm 0.1$ |
| | Simulation Time (ms) | $7.15 \pm 0.4$ | $9.5 \pm 0.2$ | $15.5 \pm 0.1$ |
| Goodput (Kbps) | Packet Size (bytes) | $547.14 \pm 0.5$ | $650.20 \pm 0.4$ | $748.57 \pm 0.1$ |
| | Simulation Time (ms) | $550.20 \pm 0.4$ | $610.15 \pm 0.3$ | $750.18 \pm 0.1$ |
| Transmission Delay (ms) | Packet Size (bytes) | $61.85 \pm 0.4$ | $41.23 \pm 0.2$ | $9.42 \pm 0.1$ |
| | Simulation Time (ms) | $61.5 \pm 0.5$ | $43.25 \pm 0.4$ | $10.91 \pm 0.1$ |
| Jitter (ms) | Packet Size (bytes) | $51.5 \pm 0.5$ | $41.85 \pm 0.2$ | $9.3 \pm 0.1$ |
| | Simulation Time (ms) | $53.5 \pm 0.4$ | $42.83 \pm 0.3$ | $9.83 \pm 0.1$ |

### VI. CONCLUSION AND FUTURE WORK

The cross-layer approach is proposed in this research to perform efficient packet scheduling and congestion control for improving the TCP performance in IoT networks. Initially, network construction is performed which improves the flexibility and scalability of the network. After network construction, packet scheduling is performed by considering numerous parameters using FPF scheduling algorithm, and best subflow is selected which reduces the transmission delay and jitter. Optimal path selection is performed by considering several parameters to increase the throughput and goodput. The congestion control in TCP is performed by proposing CoCoA3+-TCP algorithm which consists of three sub-stages such as congestion control, fast retransmission, and fast recovery to reduce the transmission delay and improve the network performance. Fast retransmission is achieved by estimating the RTO dynamically using a cat and mouse based optimization (CMO) algorithm and fast recovery is performed by reducing the congestion window. The simulation is performed by network simulator (NS-3.26) and the results illustrate that the proposed CoCoA3+-TCP method achieved high performance of TCP in IoT network when compared with other previous works.

In future, this research will be improved by providing security for TCP protocol in IoT environment with low complexity that reduces the transmission delay. In addition, the security increases the throughput and goodput with low retransmission.

*Abstract*—**Currently, software complexity and size has been steadily growing, while the variety of testing has also been increased as well. The quality of software testing must be improved to meet deadlines and reduce development testing costs. Testing software manually is time consuming, while automation saves time and money as well as increasing test coverage and accuracy. Over the last several years, many approaches to automate test case creation have been proposed. Model-based testing (MBT) is a test design technique that supports the automation of software testing processes by generating test artefacts based on a system model that represents the system under test's (SUT) behavioral aspects. The optimization technique for automatically generating test cases using Sena TLS-Parser is discussed in this paper. Sena TLS-Parser is developed as a Plug-in Tool to generate test cases automatically and reduce the time spent manually creating test cases. The process of generating test cases automatically by Sena TLS-Parser is be presented through several case studies. Experimental results on six publicly available java applications show that the proposed framework for Sena TLS-Parser outperforms other automated test case generation frameworks. Sena TLS-Parser has been shown to solve the problem of software testers manually creating test cases, while able to complete optimization in a shorter period of time.**

*Keywords*—*Software testing; schema parser; software under test (SUT); model based testing (MBT); java applications*

## I. INTRODUCTION

Before a software can be released to consumers, it needs to pass the software testing phase. Software testing covers the aspect of testing the software to meet its functional requirements as well as discovering errors before the software is released. Two main factors are usually used to determine whether tests will show failures: test inputs and test oracles [1]. A statement in JUnit test is an example of a test oracle. Software testing is important not only for the software company, but also for consumers. Many consumers are currently worried about how software companies ensure software quality, the mechanisms used to do so, and so on. Although the types, frequency and activities of tests vary from program to program, most of the common activities used in

each test cycle are: requirements testing, test planning, writing test cases, test execution, testing feedback and defect testing.

The development of test cases is a difficult aspect of software testing [2]. Creating test cases manually is time consuming. Creating test cases manually should address the aspects of the test objective. Therefore, creating test cases automatically is more efficient and consumes less time. The techniques for automated test case generation aim to efficiently identify a limited number of cases that satisfy an adequacy criterion, reducing the cost and resulting in more effective software product testing. One of the well-known techniques for software testing is Model-based testing (MBT). MBT is a testing technique that creates test cases automatically from models derived from existing application artifacts [3]. MBT is a promising approach for automatic testing to increase testing performance and effectiveness [4]. MBT can perform and complete test tasks in a more cost-effective and reliable manner than conventional test methods. A description of the MBT method is presented in [5]. This paper addresses the problem of manually creating test cases that consume more time. By introducing Sena TLSParser, test cases can be automatically created and generated. Sena TLS Parser can reduce time in generating test cases manually.

The next section will discuss related works followed by details of the proposed Sena TLS-Parser Framework. Subsequently, the implementation of Sena TLS-Parser is discussed followed by the comparison of the proposed framework with other frameworks.

## II. RELATED WORK

With the development of model-based engineering technology [6], MBT has attracted more and more interest in research. In the past few years, several MBT tools have been developed to support MBT activities [7]. Li et al. [4] proposed and applied a set of test case generation criteria, as well as surveying new methods that have not been used in previous research or have not been analyzed using test case generation criteria. From 2000 to 2018, a review study on requirement-based test case generation was presented in [8]. The study was

conducted to gain information in the areas of requirements-based test case generation and future studies. In addition, authors in [9] present a systematic mapping study (SMS) by analyzing 87 studies in this field. They discovered that the majority of the studies were devoted to test generation activities. Utting et al. [10] presented model-based research literature over the last ten years including MBT methodology and the industry's current level of MBT adoption. The Unified Modeling Language (UML) is a diagrammatical modeling language that enables developers to identify, visualize, create, analyze and document system features. It is the most popular and widely accepted language in the software industry, to the point that its spread and popularity may have reached a point where it is impossible to imagine a software working without it. There are many UML diagrams used for this purpose such as class diagram, use case diagram, activity diagram and others. One of these diagrams, the UML activity diagram is used to describe behavior while modeling the sequence of activities in the system. It is closely related to use case diagram, which shows the sequence of steps the system performs in order to carry out a use case. By using it, any software process is simplified and improved by identifying complex use cases. Therefore, many research works concentrate on generating test cases from UML [11 - 16].

Many researchers have created a variety of tools for test case generation, but the features of these tools vary greatly. This makes it difficult for the user to identify the right tool for the testing process. TCG, an open-source LoTuS modelling tool plugin was developed by Muniz et al. [17] to generate test cases. EvoSuite [18, 19] is a tool that generates test suites automatically for Java programs with high code coverage and assertions. EvoSuite employs a number of innovative techniques that result in increased structural coverage and efficient assertion selection based on seeded defects, both of which are important features that other Java tools are lacking. Another tool called EPiT was developed by Ibrahim et al. [20], which is shown to be effective in generating test cases automatically. With the increase in Android mobile devices, there is growing interest in automated testing for Android applications. GUI testing is one of the most used techniques for detecting errors in mobile applications and for testing app functionality and usability. Salihu et al. [21] proposed AMOGA which is an alternative model-based testing approach for mobile apps. Their proposed method uses a combination of the UI element's event list and each event to dynamically exercise event ordering at run time. Another tool called APE is presented by Gu et al. [22] for Android apps testing. PLATOOL [23] is another tool that has been proven effective in creating useful functional tests to deal with events involved in mobile applications during the automatic testing phase. More details about various software testing techniques applied for testing mobile applications are shown in [24].

The Synchronized Depth First Search (SDFS) introduced by Pinkal and Niggemann [25] to automate test case generation is proven to efficiently execute testing with less effort and time compared to other techniques. Based on research, it is possible to generate test cases automatically using Timed Synchonizable I/O Automation. Genetic algorithms have been used successfully in software testing. Mishra et al. [26, 27]

shows how genetic algorithms are used for software testing in generating random test cases. Du et al. [28] presents a combination of genetic algorithms with mutation testing to increase coverage and mutation score within test cases. To assess output in terms of generating test cases, the proposed algorithm by Wang and Liu [29] shows that it is capable of achieving both high performance and low time cost in the automated generation of software test cases.

One significant approach is the generation of test cases from UML models. Shin and Lim [30] propose an approach in reducing time and resources required for testing embedded software. Ma and Provost [31] suggest a testing process that ensures that a system's nominal behavior is fully covered while still allowing for the consideration of defective behavior. Elqortobi et al. [32] describe the components of an automated Modified Condition/Decision Coverage MC/DC Test Generation Tool (TGT) for avionics software test sequence generation. Their method incorporates three coverage parameters to increase the performance and error detection capacity of the derived tests. The criteria are selected to satisfy the industrial needs for avionics software certification.

## III. SENA TLS-PARSER

Sena TLS-Parser consists of four main steps. Fig. 1 shows the flowchart for Sena TLS-Parser.

Based on Fig. 1, Sena TLS-Parser can be used to generate test cases automatically in Eclipse Integrated Development Environment (IDE). The source code is the input for Sena TLS-Parser. The schema parser will read the source codes line by line. The token will be used to detect classes and methods using code smell. The algorithm for code smell is discussed in [33]. MBT is used for generating the test cases. The algorithm for generating the test cases is discussed in [20]. However, for the time being, Sena TLS-Parser can only generate test cases for Java applications only. The output for Sena TLS-Parser is the generated test cases as shown in Fig. 2.

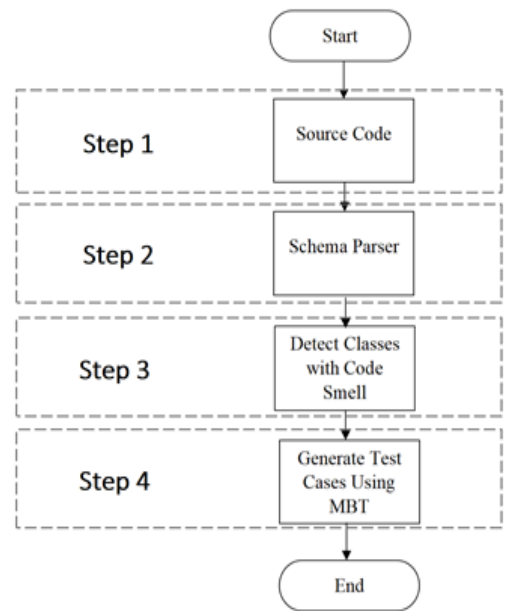

Fig. 1.   The Flowchart for Sena TLS-Parser.

```

Fig. 2.   Test Cases Generated from Sena TLS-Parser.

## IV. IMPLEMENTATION OF SENA TLS-PARSER

The tool is executed in four steps and this section discusses the steps. The first step is importing the java project to an Eclipse environment as a Plug-in Tool. Fig. 3 shows an example of how Sena TLS-Parser is imported as a Plug-in Tool. By clicking the in-help tab menu, Sena TLS-Parser can be installed as a new software option in Eclipse environment. Sena TLS-Parser will then analyze the codes by right clicking the project and selecting the SenaTLSParser-2.0 as shown in Fig. 4.

Based on Table II, Sena TLS-Parser successfully generated test cases automatically for each application. The duration also depends on the line of code (LOC) for the application. If the LOC is smaller, less time is taken to generate the test cases; for example the Calculator application. If, however, the LOC is much bigger, more time is required to generate the test cases. However, the generation of the test cases also depends on the complexity of the algorithm and the number of methods the application has; for example the Elevator application.

Fig. 3.   Installation of Sena TLS-Parser as a Plug-in Tool.

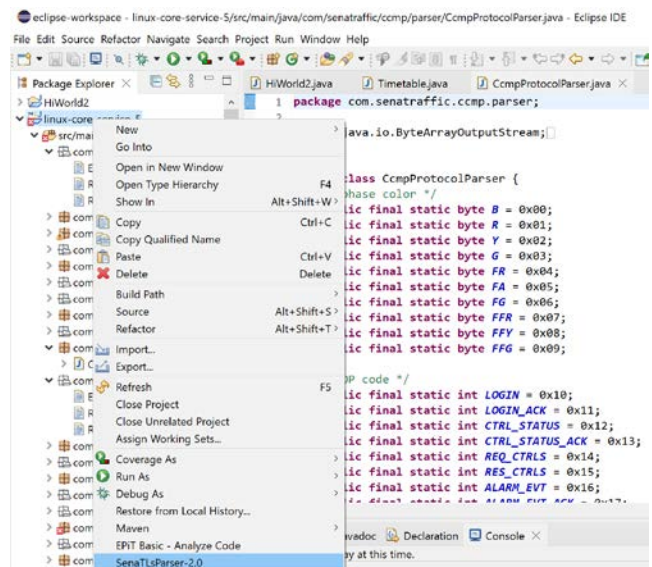

Fig. 4.   Sena TLS-Parser as a Plug-in Tool.

Fig. 4 shows the second step for selecting Sena TLS-Parser to analyze source code. The third step is for Sena TLS-Parser to begin analyzing and detecting all of the classes in the source code. The class will be detected by the parser node by node. Sena TLS-Parser then identifies a method within each node. Sena TLS-Parser will save all detected method classes in a variable. Finally, for the fourth step, test cases are generated based on the identified attributes. When Sena TLS-Parser has finished analyzing the source codes, a success popup menu will appear. Fig. 5 shows the popup menu appearing, which indicates the time used to analyze the source code.

Fig. 5.   Time Taken to Generate Test Cases from Sena TLS-Parser.

After the code analysis process is complete, the results will be shown in the Sena TLS-Parser console. The console contains all project information such as project name, test cases created for each class, and the time and date of when the test was conducted. Fig. 2 shows the Sena TLS-Parser console.

## V. RESULTS AND DISCUSSION

Case studies are used for testing the performance of Sena TLS-Parser. The case studies are completed by testing Java applications only by developing test cases for each case study to evaluate performance in execution time. For the case studies, performance evaluation regarding Java applications is tested using Eclipse IDE Version 4.5. The six case studies were selected and downloaded from GitHub website [34]. The six case studies are Calculator [35], ATM Machine [36], BlackJack [37], Traffic Light Simulation [38], Airline Reservation [39] and Elevator [40]. Table I describes the case studies used in this paper by providing a summary of the number of classes for each application and a description for each case study.

TABLE I.        THE CASE STUDIES

| Application | Number classes | Description |
|---|---|---|
| Calculator [35] | 1 | The application contains mathematical methods like add, subtract, multiply, divide methods. |
| ATM Machine [36] | 5 | The application has financial transactions such as cash deposits, withdrawals and transfer funds. |
| BlackJack [37] | 5 | Simple Blackjack implemented in Java. Creates a random deck of cards, or takes in a file with a list of cards, and plays a round. Prints the winner and the resulting hands of the player and the dealer. |
| Traffic Light Simulation [38] | 5 | A traffic light has three lenses, green, orange and red mounted in a panel. Simulates a set of traffic lights (N, S), (E, W) at an intersection. |
| Airline Reservation [39] | 7 | Provide online ticket and seat booking for national and international flights as well as flight departure information. |
| Elevator [40] | 9 | A small Java project to simulate the evolution of an elevator. |

The source codes from all applications are uploaded in Eclipse environment. Subsequently, Sena TLSParser is used as a Plug-in Tool to generate test cases for each application listed in Table I. The results for each case study are shown in Table II. Sena TLSParser shows the duration taken to analyze the source code and generate test cases based on the number of classes detected in the LOC for each application. The results show that the Calculator application is the fastest with 1ms. Meanwhile, the slowest is the ATM Machine application, which is 89ms. The comparison is based on the time required to generate test cases using Sena TLS-Parser.

Based on Table II, Sena TLS-Parser successfully generated test cases automatically for each application. The duration taken also depends on the LOC for each application. If the LOC is smaller, less time is required to generate the test cases; for example the Calculator application. If, however, the LOC is much bigger, more time is required to generate the test cases. However, the generation of the test cases will also depend on the complexity of the algorithm and the number of methods in the application; for example the Elevator application.

TABLE II.        THE RESULTS USING SENA TLS-PARSER

| APPLICATION | Number classes | LOC | Duration Time (ms) |
|---|---|---|---|
| Calculator | 1 | 63 | 1 |
| ATM Machine | 5 | 635 | 89 |
| BlackJack | 5 | 458 | 51 |
| Traffic Light Simulation | 5 | 185 | 46 |
| Airline Reservation | 7 | 154 | 15 |
| Elevator | 9 | 1150 | 75 |

Testing the software manually requires effort and is time consuming. Automation saves time and money while also increasing test coverage and accuracy, which is beneficial to both developers and testers. Choosing the right automation framework is critical to assist with various types of testing such

as unit, functional, and regression testing. For comparison purposes, three automated testing frameworks are reviewed compared to the proposed framework, Sena TLS-Parser. These frameworks are JUnit [41], TestNG [42] and Epit [20], which are widely used in the generation of test cases.

### A. Junit Testing Framework

JUnit [41] is a well-known Java unit testing framework. It is easy to understand, simple to integrate, and best of all, it is open-sourced. For writing test cases, JUnit employs annotations and assertions. It includes a test-runner for identifying and running all test methods in a project. The JUnit process is done through setting fixed states for objects and running tests by using Fixtures, Test suites, Test runners and JUnit classes are the main features offered by JUnit. The work of these Fixtures aims to provide a good environment for the conduct and implementation of the test. Test suites are a collection of unit test cases that are compiled together. Before testing a code, annotations are used in order to run the test suite. Test runners are used to carry out test cases while JUnit classes are used for testing and writing JUnits, with assert, test case, and test result.

### B. TestNG Framework

Cédric Beust created TestNG [42], an open-source test automation framework inspired by JUnit and NUnit for the Java language. The goal of TestNG's design is to provide more powerful and easy-to-use functionalities for a broad range of test categories such as unit, functional, end-to-end, integration, and so on. TestNG's advanced and useful features make it a more robust framework than its competitors. In this framework, the executing of the methods is determined by a set of codes called annotations. Using these annotations demonstrates the usage of Java language new features in a real-world production environment.

### C. EPiT Plug-in

EPiT [20] was created to reduce the time spent manually generating test cases by utilizing code smell technique for automated test case generation. EPiT begins by reading the code line by line before applying code smell technique to detect all classes in the Java application. Following that the tool determines the method's name, input parameter, and return type and stores them in variables for use in generating test cases. EPiT has demonstrated its ability to optimize automated test case generation using the code smell technique in a short period of time and with high efficiency.

### D. Comparisons of Results

Each framework is used to test the generation of test cases for the case studies. Table III presents the result comparison of the test cases generation framework for each case study based on execution time.

A JUnit test is a method in a class that is only used for testing. This is known as a Test class. To indicate that a method is a test method, @Test annotation is used. This function executes the code being tested. An assert method is used which is provided by Junit.

TestNG covers all categories of tests such as unit, functional, and integration testing. In this research, TestNG has

been integrated with eclipse to generate the test report and execute multiple test cases in parallel. TestNG uses various Annotations for test cases generation, such as @BeforeSuite, @AfterSuite, @BeforeTest, and @AfterTest. Annotations in TestNG are lines of code that can control how the method below them will be executed. Annotations are preceded by "@" symbol.

TABLE III. THE RESULTS FOR DIFFERENT FRAMEWORKS

| Application | JUnit | TestNG | EPiT | Sena TLS-Parser |
|---|---|---|---|---|
| Calculator | 32 | 9 | 8 | 1 |
| Airline Reservation | 96 | 57 | 59 | 15 |
| Traffic Light Simulation | 4201 | 4101 | 91 | 46 |
| BlackJack | 93 | 60 | 111 | 51 |
| ATM Machine | 179 | 76 | 94 | 89 |
| Elevator | 339 | 67 | 95 | 75 |

The comparison between the testing frameworks has been done based on duration required to generate test cases for each application. The results demonstrate the effectiveness of the proposed tool (Sena TLS-Parser) in automatically and quickly producing test cases. Oshin et al. [43] compared JUnit framework with TestNG framework. Based on Table III, TestNG gives better results as compared with JUnit. The results shown are consistent with the comparison done by [43]. The results show that the Calculator application is the fastest with 32ms for JUnit, 9ms for TestNG, 8ms for EPiT and 1ms using Sena TLS-Parser. For Calculator application, Sena TLS-

Parser gives the best result compared to JUnit, TestNG and EPiT. Meanwhile, for the Traffic Light simulation, both JUnit and TestNG have more execution time as compared to EPiT and Sena TLS-Parser. Sena TLS-Parser is an automation testing tool dedicated for Sena Traffic Light System (TLS) with MBT embedded in its algorithm. Therefore, the results show it has better performance. Meanwhile, EPiT with its technique for code smell [33] improved the generation of test cases compared to the JUnit and TestNG frameworks.

For more clarification, Fig. 6 shows the graph for the applications and duration time for each of the frameworks. It is noticeable that the time taken by each framework to generate test cases depends on the complexity of the algorithm and the number of methods of the application. For example, the traffic light simulation application has more complexity for the algorithm as compared with the Elevator application. Therefore, it takes a lot of time to generate test cases using JUnit and TestNG frameworks. Comparing with EPiT and Sena TLS-Parser, traffic light simulation application takes less time than Elevator application in generating test cases. In addition, the line of codes for the ATM Machine application is less than the Elevator application, however it takes more time using EPiT framework when applying code smell algorithm for the purpose of reducing the redundancy of test cases generation.

To summarize, there are numerous factors that contribute to inconsistent results, including project code complexity, CPU usage, and memory usage. Despite inconsistencies in the results, the results of the case studies demonstrated that Sena TLS-Parser is faster than conventional manually generated test cases and other testing frameworks.

Fig. 6. Comparison of Results from different Frameworks.

## VI. CONCLUSION AND FUTURE WORK

During the software testing process, automatic test data generation is critical. Unit-level testing is more successful because test cases cover all the essential paths of the software being tested. The process of creating test cases automatically by Sena TLS-Parser in an Eclipse setting was discussed in this paper. Based on the results presented in this paper, it is shown that Sena TLS-Parser has successfully generated test cases automatically and has a faster response time than traditional manual testing as well as JUnit testing and TestNG. Also, using the MBT technique to create test cases is a very powerful way to do so. For future work related to this research, Sena TLS-Parser framework can be extended to work with other programming languages such as C and C++. Adding other features would also be an interesting direction for future work using Sena TLS-Parser. Sena TLS-Parser can also be generalized to cover mobile applications for software testing. A convertor can be used to convert the source codes of mobile application in ".apk" format into source codes of java programming in ".java" format. By having the convertor, Sena TLSParser will also be able to generate test cases for mobile applications.

*Abstract*—In the world of social media, the amount of textual data is increasing exponentially on the internet, and a large portion of it expresses subjective opinions. Sentiment Analysis (SA) also named as Opinion mining, which is used to automatically identify and extract the subjective sentiments from text. In recent years, the research on sentiment analysis started taking off because of a huge of amount of data is available on the social media like twitter, machine learning algorithms popularity is increased in IR (Information Retrieval) and NLP (Natural Language Processing). In this work, we proposed three phase systems for sentiment classification in twitter tweets task of SemEval competition. The task is predicting the sentiment like negative, positive or neutral of a twitter tweets by analyzing the whole tweet. The first system used Artificial Bee Colony (ABC) optimization technique is used with Bag-of-words (BoW) technique in association with Naive Bayes (NB) and k-Nearest Neighbor (kNN) classification techniques with combination of various categories of features in identifying the sentiment for a given twitter tweet. The second system used to preserve the context a Rider Feedback Artificial Tree Optimization-enabled Deep Recurrent neural networks (RFATO-enabled Deep RNN) is developed for the efficient classification of sentiments into various grades. Further to improve the accuracy of classification on n-valued scale Adaptive Rider Feedback Artificial Tree (Adaptive RiFArT)-based Deep Neuro fuzzy network is devised for efficient sentiment grade classification. Finally, this research work proposed a Fuzzy-Rule Based Deep Sentiment Extraction (FBDSE) Algorithm with Deep Sentiment Score computation. Accuracy measure is considered to test the proposed systems performance. It was observed that the fuzzy-rule based system achieved good accuracy compared with machine learning and deep learning based approaches.

## I. INTRODUCTION

Nowadays, online social media platforms like Twitter or Face book provide a valuable framework for individuals to share and discuss ideas and opinions regarding various topics including health related issues. Within the past decade these kinds of platforms have spread globally and witnessed a rapid growth in the number of users reaching people from various demographic groups, ethnicity and occupations. Twitter is a social media platform that was used by millions of active users to share their opinion, sentiments and their thoughts on any issue. In this platform, the users are interacted through

messages which are called tweets. The estimation of the organizers of the twitter is around 500 million tweets are forwarded in every day. These tweet messages are restricted in size which can contain at most 140 characters. Twitter allow for an exhaustive aggregation and analysis of user generated content which facilitates monitoring of public opinions and sentiment over time towards certain topics of interest. Keeping track of these developments can be crucial for health professionals in order to understand and address the public opinion and behavior with regard to health related topics.

Due to the importance of sentiment analysis to business, the interest has shifted from computer science to management, economics and to the whole society. Nowadays, almost all of the big companies and organizations are having a sort of voice of the customer channel such as emails or call centers and a mean to analyze it. This will help organizations to reshape their services and re-engineer their business processes into the best practice ones. Recently, business has realized the important role that voice of the customer plays in their organizations. The need to have classification systems that are able to handle their feedback data efficiently is emerged. Sentiment analysis is considered as branch of social information where retrieved text is intended to be classified into many classes depending on the detected emotions [1].

Sentiment analysis is the science of extracting, studying and investigating people's sentiments, experience and point of view that documented into a piece of text called, *review*. This extracted information could express general feelings of the authors or extracting sentiments regarding entities such as service, or a product [2]. In computer science, it is about modeling a system that classifies the polarity of a given review. Sentiment analysis model trying to classify reviews into labeled polarities like negative or positive and some adding neutral class [3]. The significant definition for an opinion is a quadruple of four components (G, S, H, T). G is sentiment target, also known as entity or aspect such as camera, product or service under review. S is the sentiment with respect to a target. Opinion's holder is representing by H, whereas T is the time that the opinion was given in. Analyzing the sentiment of given input could be done on three different levels. In the literature, document level sentiment analysis is investigated when calculating the sentiment of the total document, having that the document is about single entity. Another level of a scope is the sentiment level when each sentence is analyzed and given a polarity [3]. In this level, it is assumed that the review consists of several opinionated

targets, aspects or entities and their polarities. Finally, aspect level sentiment analysis, where the sentiment is determined on the aspects of an entity. Sentiment analysis has many end-user applications such as monitoring news and social media to look for biased opinions, monitor attitudes towards political candidates or controversial topics during an election, or keeping track of company reputation and consumer response. Sentiment analysis can also be useful for researchers in other fields such as political science and media studies by providing a quantitative method of analyzing public opinion. The internet is growing by the minute and most of the content is in the form of unstructured text. A lot of this data, like blogs, social media and product reviews, are subjective and opinionated. Market analysis is one of the most prominent use cases of SA. Companies used sentiment analysis to keep track of customer relationships, company reputation, consumer response to products and more. Another use of SA is intelligence, where governments can monitor and flag potential threats to national security. There are also many political uses like identifying ideological shifts on social media or identifying which topics engage the public. SA is also used to analyze twitter for public opinion on some topic analysing the plot of fiction, tracking how emotions change throughout the story.

Many of sentiment analysis systems focus on a single language, typically English. However, as the Internet spreads around the world, users are leaving comments in a variety of their native languages. Sentiment analysis in a single language increases the possibility of missing sensitive details in texts written in other languages. Multi-lingual sentiment classification techniques were developed to evaluate data in multiple languages [10]. Sentiment classification frameworks and techniques for various languages are being developed as a result of this. The majority of research in sentiment classification based on the usage of machine learning techniques, unsupervised and supervised. The supervised methods used machine learning algorithms to train with labeled sentiment data and to determine the sentiment of unlabeled test documents. A machine learning method is used in the training phase to learn a prediction model, which is then utilized in the testing or prediction phase to classify documents that the model has never seen before. Feature engineering is likely the most important of these components for classification. People express their negative feelings in sarcastic text by using positive words. Because of this, sarcasm can easily fool sentiment analysis models unless they are specifically designed to account for its possibility. English is considered Majority of the digital platforms and articles are using.

Traditional approaches take the input text, process it and find the sentiment classifications like positive and/or negative based on users one-dimensional reviews. But, these are failed to look into multidimensional perspective of the users review like sarcastic reviews. So, there is very much need for the approaches which are capable to understand the user's multidimensional perspective in giving the reviews.

In this work, machine learning based approaches are used for sentiment analysis at the initial phases. Deep leaning based architectures are developed in the next phases to tokenize the input as word embeddings for the sentiment analysis task. Finally, this research demonstrates the fuzzy rule based approaches to compute the degree of sentiment using polarity and deep sentiment score. This study is experimented on SemEval competition sentiment classification dataset contains small micro-blog twitter messages.

This work is structured in six sections. The Section 2 explains the existing work of the sentiment analysis. The dataset details and evaluation measures are presented in Section 3. The machine learning based approach described in Section 4 with experiment results. The Section 5 explains the deep neural architectures and experimental results for sentiment classification. Section 6 concludes this work.

## II. RELATED WORK

The automated process of splitting and categorizing units of texts into separate, specified categories, also known as classes, is referred to as text categorization. Text classification can be used to extract a text's topic, but it can also be used to classify sentiment. Sentiment classification, often known as sentiment analysis, is the process of determining whether a text is negative, positive, or neutral. NLP methods are used to systematically analyze and evaluate the sentiment expressed in text and assign it to a sentiment class.

Topic classification, i.e. determining whether a text is about politics or sports, is usually done using machine-learning approaches. Pang et al. (2002) adopted [1] these machine-learning methods and regarded positive or negative sentiment as topics of their own. With this approach they managed to achieve performances hovering around 80% when analyzing movie reviews. However, the experiments conducted only contained reviews that were considered positive or negative. Agarwal et al. conducted [4] the accuracy of sentiment analysis on Tweets using a Support Vector Machine (SVM) was around 60% depending on the features employed. They also pre-processed the Tweets by replacing acronyms with full meanings and emoticons with their emotional states. When doing binary classification, the proposed method achieved an accuracy of roughly 75% when omitting the neutral class and just having positive or negative classes.

Bhayani et al. conducted [5] experiments that utilized distant supervision on data extracted from Twitter. Distant supervision relates to gathering and labelling training data automatically. They worked on the notion that any Tweet with a positive emoticon likewise has positive emotion, and any Tweet with a negative emoticon has negative sentiment. They could construct an annotated classifier training set without hand-labeling data using these assumptions. They regarded emoticons to be noise; therefore they removed them from the data set. Given the importance of emoticons in expressing moods and their widespread use in sentiment analysis, a feasible upgrade to this approach would be to appropriately integrate emoticons and their emotional connotations.

Edilson Anselmo et al., explained [6] a multi-view ensemble approach for the task of SA also specifically named as Message Polarity Classification in SemEval-2017 challenge. In this ensemble approach, different types of

features are used to train every base classifier. The first base classifier is Linear SVM which uses bag-of-words model as a feature space. The second base classifier is another Linear SVM which uses the averaging of word embeddings of tweets. The third base classifier is Logistic Regressor where in the tweets are represented as averaging of weighted word embeddings. In the first classifier, the tweets are represented with the TF-IDF (Term Frequency and Inverse Document Frequency) weights of bag-of-words. In the third classifier the word embeddings weight is represented with TF-IDF measure. In case of F1-score and recall, their proposed system got an 18th rank and 20[th] respectively among 38 participants in the competition.

Tzu-Hsuan Yang et al., implemented [7] a system for SA task in twitter dataset. This system is a combination of two deep neural networks based models such as LSTM Recurrent Neural Network and convolution neural network (CNN) through interpolation. These models take the input as distributional words representations of tweets as vectors and the output is the sentiment of a tweet. They observed that the word embeddings performance is good in RNN for computing Recall and accuracy when compared with one-hot vectors. They identified that LSTM model performance is good for predicting all classes but the RNN fails to predict the negative class. They also observed that the performance of LSTM is good on neutral and positive classes and the performance of CNN is good on negative class compared with LSTM. The proposed system obtained an average F1 score of 0.587, average recall rate of 0.618 and the accuracy of 0.618 for sentiment analysis task of SemEval 2017 Competition.

Recently, the implementation of SA in twitter using neural networks become one of the state of the art techniques because they took less number of features when compared with traditional techniques. Yichun Yin et al., proposed [8] an effective and simple ensemble method to boost the performance of neural network models. They collected the several sets of word embeddings which are constructed by using skip-gram model or released publicly or learned from different corpus. They assume that the usage of these embeddings increases the performances and generalizations of neural network models. They identified different types of neural networks like RNN, CNN, LSTM and GRU for implementing their method, but they used RCNN [9] in their method. The aim of RCNN is to capture non-consecutive and longer range patterns in a weighted manner by using adaptive gated decay and non-consecutive convolution. The proposed method achieved 1[st] rank in Accuracy and 5[th] rank in average recall in the SemEval 2017 sentiment analysis competition.

Traditional techniques used a different type of hand crafted features such as semantic, surface-form and sentiment lexicons for sentiment classification of twitter [10]. The performance of these techniques mainly depends on the quality work of feature construction and developing a popular system for these features. Moreover, the one-hot representation of these features proposes the sparsity problem in the representation and the semantic information also not captured in the representation. To overcome this problem, Tang et al. induced [11] real-valued, sentiment-specific and low-dimensional embedding features for sentiment classification of twitter which encode the combination of sentiments and semantics of words. They identified that the hand-crafted features and embedding features achieved similar results.

AbeedSarker et al., presented [12] a system by combining the dense and sparse vector representations of words and clusters are used for generalized words representations for supervised text classification. The neural networks are trained by using the dense vectors which are represented with word embeddings in a large unlabeled dataset to predict the neighboring words. The sequences of word n-grams (n range is 1-3) are used for generating the sparse vectors. The Support Vector Machines (SVMs) with an RBF kernel is used for classification of a text segment by concatenating the different vector representations. This system is specifically proposed for non-experts of machine learning and natural language processing and doesn't require any manual tuning of weights or parameters. The system generates the classification model by automatically optimizing the relevant hyper-parameters and producing the training vectors for SVM classifier from a given training dataset. This system is evaluated on the sentiment analysis task of SemEval 2017 English dataset. The proposed system achieved F1-score of 0.632, accuracy of 0.646 and average recall of 0.637.

Raphael Troncy et al., proposed [13] a SentiME++ system which is an ensemble approach for the SA task of SemEval 2017 competition. The aim of this system is to classify the English tweets based on the type of sentiment like negative, positive or neutral sentiments they have. SentiME++ merge the predictions of five popular sentiment classifiers such as NRC-Canada [10], GU-MLT-LT [14], KLUE [14], TeamX [15] and Stanford Sentiment System (subsystem of the Stanford NLP Core toolkit). In SentiME++ approach, a bootstrap sampling (a uniform random sampling with replacement) technique is used to produce four different training sets from the initial training set T. These training sets are used to train the four sub classifiers separately. SentiME++ trains four classifiers separately and fifth classifier Stanford Sentiment System is not trained with training data. The outputs of five classifiers are represented as a feature vector and this is directed to stack supervised learner. This system produced a F1-score of 0.613 for sentiment classification and obtained 12[th] rank in the competition.

Chukwuyem Onyibe explained [16] a supervised system which uses lexical features (Uni-grams, Tweet length, Tweet length binned, Bi-grams, SentiStrength, Removed URL, Stop words) and optimized Conditional Random Fields to predict the tweet sentiment. We used CRF++which is implemented with the primary machine learning component as Conditional Random Fields (CRF). They were inspired by the work of Yang et al. (2007) who used CRFs to identify the sentiment in web blogs by giving training at sentence level and classifying at the document level by considering the sequences of sentences. In their work, they optimized the parameters of CRF++ as well as lexical features for the task of sentiment classification in twitter of SemEval 2017. The combination of SentiStrength and unigrams performed well to obtain good results. They obtained good results for sentiment classification when the parameters of CRF are f value 1, c value 8.5 and

features are uni-grams. The proposed system achieved an average F1-score of 0.54226, average recall of 0.59024 and accuracy of 0.61519.

Mohammed Jabreel et al., proposed [17] a system named as SiTAKA for SemEval 2017 twitter SA task for both Arabic and English languages tweets. In this system, the tweets are represented with a set of novel features which includes the information generated by five lexicons (NRC hashtags lexicon [10], General Inquirer [T8], TSLex [18], Hu-Liu opinion lexicon (HL) [19] and SenticNet [20]) and a bag of negated words. It was observed that the combination of these features with some basic features (syntactic, basic text, lexicon, Word Embeddings and cluster) increases the performance of the classification. The SVM classifier is used to identify the sentiment of tweets. The proposed system achieved 2[nd] rank in Arabic and 8[th] rank English language tweets.

SymeonSymeonid is proposed [21] an approach based on a Majority Vote scheme and combined the classical linguistic resources such as sentiment lexicon features and bag-of-words with supervised machine learning methods for sentiment classification task. The usage of lexicons and bag-of-words representation has a predefined sentiment for each uni-gram and bi-gram. We used different types of classifiers such as Ridge, Logistic Regression, Stochastic Gradient Descent, Nearest Centroid, Bernoulli Naive Bayes, Linear SVC, Passive-Aggressive for testing the performance of the proposed approach. It was observed that among the set of all three combination classifiers one set of classifiers such as the Nearest Centroid, the Stochastic Gradient Descent (SGD) and Bernoulli Naive Bayes achieved best results. They also identified that Nearest Centroid is a weak classifier when alone but it gives best contribution when combined with other two classifiers.

Sentiment classification is one of the major issues of NLP and become more popular among many research fields. Typically, sentiment classification predicts the sentiment of a text into various discrete classes like negative, positive or neutral. Ming Wang et al., explained [22] a deep learning system to classify 2-polarity, 3-polarity and 5-polarity in tweets by combining SVM with GRU. In their system, first they used pre-trained word embeddings to train a gated recurrent neural network, and then they extracted features from GRU layer and forwarded these features to SVM to perform quantification and classification sub-tasks. Joosung Yoon et al., proposed [23] a sentiment analyzer for sentiment classification to predict the sentiment at document level of English tweets for SemEval 2017 competition. This method is based on lexicon integrated CNNs with attention (LCA). The proposed method achieved an average recall of 58.9%, an average F1-score of 55.2% and an accuracy of 61.4% for the task of sentiment classification.

MickaelRouvier et al., explained [24] a system which is an ensemble model of Deep Neural Networks (DNN) such as RNN-LSTM and CNN. We used four different types of pre-trained embeddings such as three different sentiment embeddings and one lexical embedding on large datasets to initialize the input representation of DNN. These models can capture word level information only. We injected some sentence level features like Emoticons, Elongated units, Lexicons, All-caps and Punctuation into the system. They used a score-level fusion approach to combine the ensemble of DNNs. The proposed system got 2[nd] rank at SemEval 2017 competition and achieved an average recall of 67.6%. It was identified that the CNN model obtained best results for sentiment classification when compared with RNN-LSTM models. Haowei Zhang et al., proposed [25] a multichannel model named as CNN-LSTM to predict the sentiment of English language twitter tweets and this model is a combination of two parts such as multi-channel LSTM and CNN. Unlike a CNN, a multi-channel strategy is applied in the proposed model to extract different scales of active local n-gram features and various filters of different length are used in this strategy. Then LSTM is used to compose the information sequentially. In the classification process, they considered both long distance dependencies across tweets and local information within tweets by combining both CNN and LSTM. This multi-channel approach achieved an accuracy of 0.640 for sentiment classification.

AmitAjitDeshmane et al., proposed [26] a system for SemEval 2017 twitter sentiment analysis task. The system is an ensemble of three different deep learning architectures. The first architecture used CNNto perform the text classification. The second architecture implemented with gated RNN. In third subsystem, the opinion lexicons are integrated directly with CNN architecture. The proposed ensemble system obtained a macro-averaged recall of 64.3%. It was observed that the first architecture is crucial to improve the results of sentiment classification. Iv´an Castro et al., proposed [27] a system for SemEval-2017 twitter sentiment analysis task. In this system, they studied about how the relationships among sense n-grams and sentiment polarities like negative, neutral or positive are contributed to this task. They also tested the effect of removing a large set of char n-grams features reported in previous works. Based on these observations, they explore a SentiWordNet as a polarity lexicon and constructed a SVM system. The proposed system got 10[th] rank in the competition and achieved an F1-score of 0.624.

Yunxiao Zhouet al., reported [28] a system for SA in twitter task of SemEval-2017 competition. They investigated various traditional Natural Language Processing (NLP) features (Word RF n-grams, POS tag, Negation), domain specific features (All-caps, Bag-of-Hashtags, Elongated, Emoticon, Punctuation) and word embedding features (GoogleW2V, GloVe, sentiment word vector (SWV), sentiment-specific word embedding (SSWE)) alongwith supervised machine learning techniques ((SVM), AdaBoost, Logistic Regression (LR) and SGD) to address this task.

## III. PROPOSED FUZZY-RULE BASED SYSTEM AND METHODOLOGY

In this section an automated framework for deep sentiment extraction is proposed with the components described in (Fig. 1).

Initially, the framework will accept the reviews from any dataset and then text processing steps like stemming and stop word removal are performed. The process of feature selection is carried out as second step for the process using novel

machine learning methods, which is elaborated in this work. Pre-processed data is given as input in the feature extraction stage, where extraction of significant features, namely spam words-based features, SentiWordNet features, emoticon-based features and TF-IDF features takes place for decreasing the processing of data. Further, the key phrases from the review text are extracted using feature fusion methods. This section elaborates the procedure of identification of parameter µ based on decision tree. At first, review data is trained for finding the parameter after that, rule is induced and categorized. Feature fused output is taken as input for classification of sentiment grade. Here, a classifier named Deep learning network is used to perform the classification of the sentiment grade. Moreover, deep learning network is trained based on devised Adaptive RFATO technique. This proposed Adaptive RFATO algorithm is devised by combining ROA [29] and FAT scheme [30] with adaptive concept.

On the other hand, ROA involves four riders, namely follower, bypass rider, attacker and overtake racing besides others for reaching destination. Finally, fuzzy rule based approaches are used to analyze the degree of sentiment using polarity and to extract the opinion. The combination of ROA and FAT scheme, named as RFATO technique offers best solution to solve optimization issues. However, this method consumes more computational time. Hence, this research included the adaptive mechanism with RFATO method for obtaining less computational time.

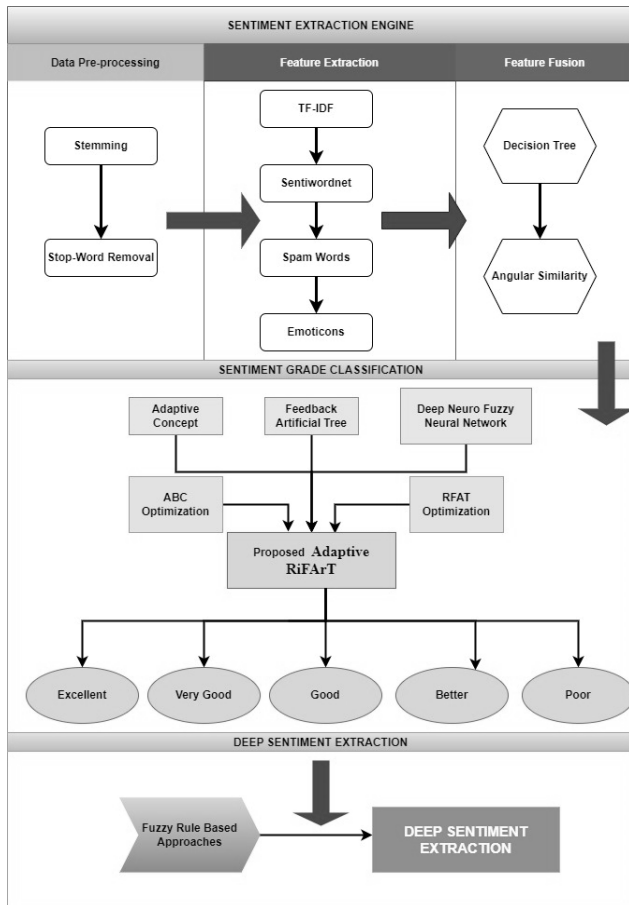

Fig. 1.    Proposed Frameworks for Deep Sentiment Extraction.

## A. Gated Recurrent Units (GRU) for Sentiment Analysis

By using the gating mechanism the gradient stays high for long time-steps and thus overcome the problem of vanishing gradient. Despite its effectiveness, the complexity found in the gating mechanism make the architecture expensive to execute and hard to analyze. As a result, many variations have been proposed but Gated Recurrent Unit (GRU) introduced by [32] is one of the strongest competitors to LSTM. Compared to LSTM, it is much simpler and faster and needs fewer gates to calculate. In sentiment classification task, RNN based layer could be used to generate sentence hidden representation and then, this representation could be used as input to the classification function to find a polarity of a given tweet [33, 34].

For the proposed models, GRU layer is used rather than LSTM as its GRU works better in this experiment as the validation loss on the dataset was lesser and it was faster also. Compared with standard RNN, GRU cell uses two gates to handle the flow of the data, $z_t$ to represent update gate and $r_t$ to represent reset gate. $z_t$ determines the amount of previous information to keep while $r_t$ determines the methodology of combining the old memory with the new input. The entire internal memory is output without an additional activation. At each step, each word-distributed representation is given as an input word $x_i$, the current cell state $c_t$ and hidden state $h_t$ can be updated with the previous cell state $c_{t-1}$ and previous hidden state $h_{t-1}$. The equations (1) (2) (3) and (4) are used to compute the $z_t$, $r_t$, $c_t$ and $h_t$ respectively.

$$z_t = \sigma\left(x_t U_z + h_{t-1} W_z\right) \tag{1}$$

$$r_t = \sigma\left(x_t U_r + h_{t-1} W_r\right) \tag{2}$$

$$c_t = tanh\left(x_t U_z + Wc(h_t - 1 \odot r_t)\right) \tag{3}$$

$$h_t = (1 - z_t \odot c_t + z_t \odot h_t - 1) \tag{4}$$

The output of this layer is the hidden representation of the given tweet that is going to be fed into the attention layer to highlight the most informative words and to generate the final tweet representation.

## B. Attention Layer for Sentiment Orientation

The attention mechanism is used to amplify the most informative words in a given tweet with higher weights inspired by [31]. The attention layer is placed after GRU layer to point out the most influence words to the tweet meaning and then the specific word representations are combined to form a vector representation for tweets. To generate the final tweet representation, the attention layer uses the following mathematical formulas.

Using each hidden state $h_t$ and dot product with its weights is producing the hidden representation $u_t$. The equation (5) is used to compute $u_t$.

$$u_t = \tanh\left(h_t w_t + b_t\right) \tag{5}$$

The un-normalized hidden representation of the current word $u_t$ is passed to softmax function to get the normalized importance weight $\alpha_t$. The '$\alpha_t$' is computed using equation (6).

$$\alpha_t = \frac{\exp(u_t)}{\sum_{i=1}^{T} \exp(u_i)} \tag{6}$$

Where, T is count of time-steps in the input, $w_t$ and $b_t$ are the weights of attention layer which are optimized during training to allocate more weights to the most important words of a sentence. Finally, the high level vector representation of a tweet $S$ is produced based on the weights by using weighted sum of the word annotations. The S is computed using equation (7).

$$S = \sum_{i=1}^{T} h_{it}\alpha_{it} \tag{7}$$

To classify the tweets into the sentiment labels, the final vector representation of tweet is fed into fully connected Sigmoid logistic regression layer. It produces an output in the range between 0 and 1 by using the probability distributions of all sentiment classes.

This result into a semantic orientation of the word or the phrase using the Point_wise Mutual Information:

$$SO(S) = PMI(S, Excellent) - PMI(S, poor) \tag{8}$$

Here,

SO(S), denotes the semantic orientation of the phrase.

PMI (S, Excellent), denotes the PMI for the phrase with positive sentiment.

PMI (S, poor), denotes the PMI for the phrase with negative sentiment.

## IV. PROPOSED MODEL FOR SENTIMENT EXTRATION

This section elaborates on the proposed mathematical model for the deep sentiment extraction process. Firstly, the generic set of positive and negative words accumulated in two different classes. The words are collected based on the popular vocabulary of the most commonly used phrases for consumer product review systems.

$$[P] = \langle Good, Excellent, Amazing, Incredible, Great, .....\rangle \tag{9}$$

and

$$[N] = \langle Bad, Poor, Terrible, .....\rangle \tag{10}$$

Here, the Positive and Negative reference words are represented by the sets P and N.

$$SO(S) = PMI(S, [P]) - PMI(S, [N]) \tag{11}$$

Further, only the phrases or the words are considered with the highest correlation as $SO(S)_{>1}$

Finally, perform the iterative classification of the phrases in the review or feedback for identifying the sentiment score and calculate the total score based on the weighted calculation of rating and text feedback, the mathematical model is

converted into the workable algorithm as discussed in Algorithm-1.

---

**Algorithm-1: Fuzzy-Rule Based Deep Sentiment Extraction (FBDSE)**

---

Step -1. Create collection of positive and negative word sets

Step -2. Accept the list of products and analyse

    A. For each product

    B. Break the sentences into phrases

        i. For each zone

            a. Calculate the correlation score

            b. if the score is higher than 1

                • Then consider the phrase

            c. else

                • Reject the phrase from the set

            d. Repeat for minimal set

    C. Consider the Compound score- Deep Sentiment can be measured by Compound Score and it lies between -1 to +1

    D. Calculate the Deep Sentiment Score = rating *0.8 + text score * 0.2

    E. Deep Sentiment score >= 0.5= Positive (P) neutral if 0 <Deep Sentiment score < 0.5= Neutral(Nu)
       negative if -1 >= Deep Sentiment score<=-0 = Negative(N)

---

## V. DATASET CHARACTERISTICS AND EVALUATION MEASURES

In this work, the experiment conducted on the dataset provided by the organizers of SemEval competition task of twitter sentiment analysis at tweet level. This dataset is a combination of the twitter datasets and the characteristics of a dataset are specified in the Table I.

In the training dataset, the number of tweets in neutral class is more compared to other two classes. The dataset is not balanced which means the three classes contain varying number of tweets. The researchers of sentiment analysis used various measures such as F1-Score, recall, precision and accuracy for evaluating the machine learning techniques. In this work, accuracy is used to test the efficiency of the machine learning techniques. Accuracy is the ratio of the number of test tweets are correctly classified their sentiment and the number of test tweets considered in the experiment. Precision and recall metrics are highly recommended especially if the dataset is unbalance. Precision measures the probability that a positive prediction is really positive. Recall measures the efficiency of a model to find all positive reviews in a dataset. Here, the detailed classifications of sentiment types based on given user ratings are shown in Table II.

TABLE I. THE DATASET CHARACTERISTICS

| Dataset | Total | Positive | Negative | Neutral |
|---|---|---|---|---|
| SemEval train | 47831 | 18377 | 7442 | 22012 |
| SemEval dev | 5653 | 2412 | 1056 | 2185 |
| SemEval test | 12284 | 2375 | 3972 | 5937 |

TABLE II.        USER RATINGS AND SENTIMENT TYPE MAPPING

| User Rating (Given) | Sentiment Type |
|---|---|
| -2 | Poor |
| -1 | Better |
| 0 | Good |
| 1 | Very Good |
| 2 | Excellent |

The following Table III consists of sample of tweets classified into different feature types rated in between -2 and 2.

TABLE III.        EXTRACTION OF SENTIMENT FEATURES AND TYPES

| Company Name | Total tweets | Poor (-2) | Better (-1) | Good (0) | Very Good (1) | Excellent (2) |
|---|---|---|---|---|---|---|
| Microsoft | 100 | 12 | 34 | 20 | 31 | 3 |
| Amazon | 100 | 6 | 12 | 12 | 55 | 15 |
| Bentley | 100 | 1 | 2 | 32 | 62 | 3 |
| David Cameron | 100 | 7 | 31 | 37 | 24 | 1 |
| Donald trump | 100 | 2 | 42 | 40 | 15 | 1 |
| Google | 100 | 0 | 8 | 59 | 33 | 0 |
| Harry Potter | 100 | 2 | 0 | 18 | 64 | 16 |
| i-phone | 100 | 0 | 5 | 30 | 56 | 9 |
| Jurassic World | 100 | 0 | 5 | 11 | 62 | 22 |
| Madonna | 100 | 0 | 2 | 21 | 73 | 4 |

User sentiment score have been calculated as three categories Negative(N), Positive(P) and Neutral (Nu) following table (Table IV) consists of sample of tweets classified into different feature types rated in between -2 and 2.

Next, Deep sentiment score discussed in the proposed approach for the above mentioned three sentiment types is calculated and shown in Table V.

Next, the comparison between the extracted user sentiment score and deep sentiment score have been composed and the observations are shown in Table VI.

TABLE IV.        USER SENTIMENT SCORE

| Company Name | Negative(N) | Neutral(Nu) | Positive(P) |
|---|---|---|---|
| Microsoft | 0.46 | 0.2 | 0.34 |
| Amazon | 0.18 | 0.12 | 0.7 |
| Bentley | 0.03 | 0.32 | 0.65 |
| David Cameron | 0.38 | 0.37 | 0.25 |
| Donald Trump | 0.44 | 0.4 | 0.16 |
| Google | 0.08 | 0.59 | 0.33 |
| Harry Potter | 0.02 | 0.18 | 0.8 |
| i-phone | 0.05 | 0.3 | 0.65 |
| Jurassic World | 0.05 | 0.11 | 0.84 |
| Madonna | 0.02 | 0.21 | 0.77 |

TABLE V.        DEEP SENTIMENT SCORE

| Company Name | Negative | Neutral | Positive |
|---|---|---|---|
| Microsoft | 0.092 | 0.04 | 0.068 |
| Amazon | 0.036 | 0.024 | 0.14 |
| Bentley | 0.006 | 0.064 | 0.13 |
| DavidCameron | 0.076 | 0.074 | 0.05 |
| Donald Trump | 0.088 | 0.08 | 0.032 |
| Google | 0.016 | 0.118 | 0.066 |
| Harry Potter | 0.004 | 0.036 | 0.16 |
| i-phone | 0.01 | 0.06 | 0.13 |
| Jurassic World | 0.01 | 0.022 | 0.168 |
| Madonna | 0.004 | 0.042 | 0.154 |

TABLE VI.        COMPARISON OF EXTRACTED USER AND DEEP SENTIMENT SCORE

| Company Name | Negative(N) | | Neutral(Nu) | | Positive(P) | |
|---|---|---|---|---|---|---|
| | USER | DEEP | USER | DEEP | USER | DEEP |
| Microsoft | 0.46 | 0.092 | 0.2 | 0.04 | 0.34 | 0.068 |
| Amazon | 0.18 | 0.036 | 0.12 | 0.024 | 0.7 | 0.14 |
| Bentley | 0.03 | 0.006 | 0.32 | 0.064 | 0.65 | 0.13 |
| David Cameron | 0.38 | 0.076 | 0.37 | 0.074 | 0.25 | 0.05 |
| Donald Trump | 0.44 | 0.088 | 0.4 | 0.08 | 0.16 | 0.032 |
| Google | 0.08 | 0.016 | 0.59 | 0.118 | 0.33 | 0.066 |
| Harry Potter | 0.02 | 0.004 | 0.18 | 0.036 | 0.8 | 0.16 |
| i-phone | 0.05 | 0.01 | 0.3 | 0.06 | 0.65 | 0.13 |
| Jurassic World | 0.05 | 0.01 | 0.11 | 0.022 | 0.84 | 0.168 |
| Madonna | 0.02 | 0.004 | 0.21 | 0.042 | 0.77 | 0.154 |

The graphical illustration of the above calculations is made visible using the following graph as shown in Fig. 2.

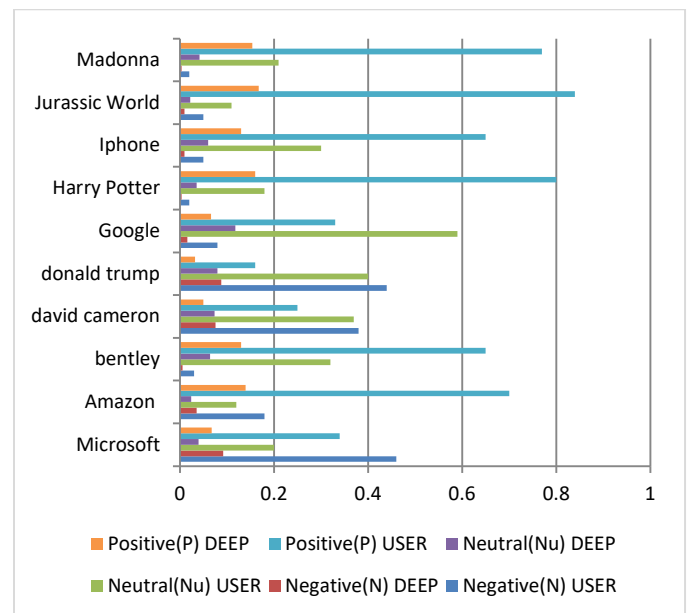

Fig. 2.    Comparison between User and Deep Sentiment Score.

TABLE VII.    COMPOUND SCORE

| Company Name | Compound Score | Final Opinion (Towards) |
|---|---|---|
| Microsoft | 0.552 | Positive |
| Amazon | 0.84 | Positive |
| Bentley | 0.78 | Positive |
| David Cameron | 0.456 | Neutral |
| Donald Trump | 0.528 | Neutral |
| Google | 0.708 | Positive |
| Harry Potter | 0.96 | Positive |
| i-phone | 0.78 | Positive |
| Jurassic World | 1 | Positive |
| Madonna | 0.924 | Positive |

Finally, as discussed in the proposed Fuzzy-Rule Based Deep Sentiment Extraction (FBDSE) Algorithm; the compound score of the sentiments have been calculated as shown in Table VII to understand the sentiment orientation which helps in identification of the polarity of the opinion.

Next, as we discussed in the proposed algorithm extracts the opinion based on the Compound Score (CS). If the CS >= 0.5, neutral if $0 < CS < 0.5$ and negative if $-1 >= CS <= -0$. The graph represents the final compound score is shown in Fig. 3.

The Precision, Recall and F1-Score of the proposed Fuzzy-Rule Based Deep Sentiment Extraction (FBDSE) are compared with the earlier proposed algorithms as shown in Table VIII.

Finally, observed that there is a remarkable enhancement in the performance as shown in Fig. 4.

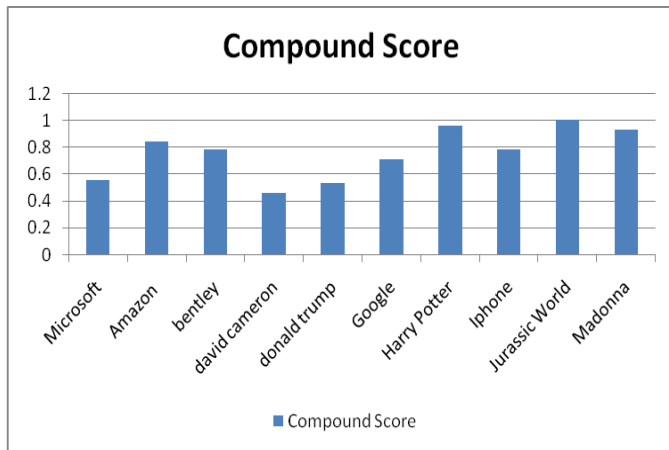

Fig. 3.    Compound Score.

TABLE VIII.    COMPOUND SCORE

| Model Performance | ABC Bi-Gram Model | Proposed RFATO Enabled Deep-RNN | Adaptive RFATO Based Deep Neuro Fuzzy Network | Proposed FBDSE Approach |
|---|---|---|---|---|
| Recall | 0.823 | 0.887 | 0.889 | 0.937 |
| Precision | 0.797 | 0.8 | 0.801 | 0.897 |
| F1-Score | 0.81 | 0.841 | 0.843 | 0.917 |

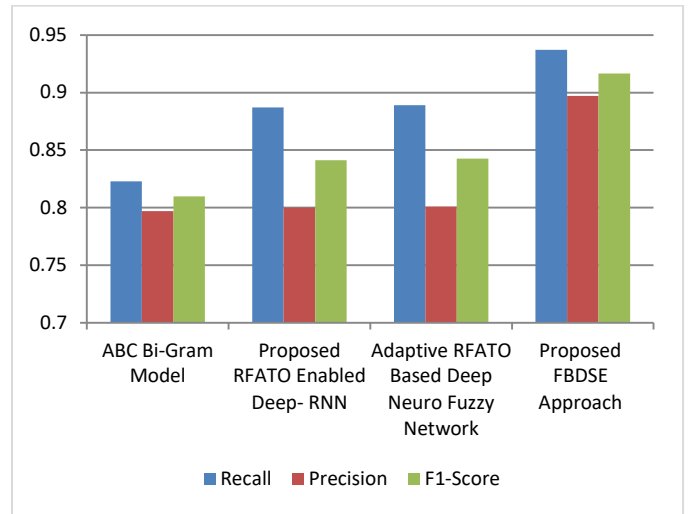

Fig. 4.    Comparison of Performance.

## VI.    CONCLUSION

This research work proposed two approaches for sentiment classification task of SemEval competition. The first approach used machine learning techniques like NB, RF and SVM by using a set of stylistic, syntactic and semantic features. Among these techniques, the SVM obtained good accuracy for sentiment classification. The second approach used deep neural architectures like RNN, LSTM and GRU for sentiment classification. Two word embedding models are used for generating word vectors. The deep learning based approach performance is good compared with machine learning based approach.

A new methodology is proposed to deep sentiment extraction and grading on N-Scale by developing a fuzzy rule based system for sentiment analysis, which can offer more refined outputs through the use of fuzzy membership degrees. The experimental results indicate that our fuzzy-based approach performs marginally better than the other algorithms. In addition, the fuzzy approach allows the definition of different degrees of sentiment without the need to use a larger number of classes and almost 91% of accurate deep sentiments extracted on the given products. Future scope of this work is focused on Multi-Lingual Deep Sentiment Extraction using semantic annotations and AI-based reasons.

# RS Invariant Image Classification and Retrieval with Pretrained Deep Learning Models

D. N. Hire[1]

E&TC Dept, Research Scholar, DYPCOE, Pune, India

Dr. A. V. Patil[2]

E&TC Dept, Principal, DYPIEMR, Pune, India

*Abstract*—CBIR deals with seeking of related images from large dataset, like Internet is a demanding task. Since last two decades scientists are working in this area in various angles. Deep learning provided state-of-the art result for image categorization and recovery. But pre-trained deep learning models are not strong enough to rotation and scale variations. A technique is proposed in this work to improve the precision and recall of image retrieval. This method concentrates on the extraction of high-level features with rotation and scaling invariant from ResNet18 CNN (Convolutional Neural Network) model. These features used for segregation of images using VGG19 deep learning model. Finally, after classification if the class of given query image is correct, we will get the 100% results for both precision and recall as the ideal requirement of image retrieval technique. Our experimental results shows that not only our proposed technique outstrip current techniques for rotated and scaled query images but also it has preferable results for retrieval time requirements. The performance investigation exhibit that the presented method upgrades the average precision value from 76.50% for combined features DCD (Dominant Color Descriptor), wavelet and curvelet to 99.1% and average recall value from 14.21% to 19.82% for rotated and scaled images utilizing Corel dataset. Also, the average retrieval time required is 1.39 sec, which is lower than existing modern techniques.

*Keywords*—*CBIR; CNN; deep learning; ResNet18; rotation; scale; VGG19*

## I. INTRODUCTION

Since last two decades due to usage of mobile phones and easily availability of Internet on likely smart devices the data generated per year is increasing day by day. Usually, the data is in the form of images and figures as it is said that "A picture is worth a thousand words". So, the large amount of image data produced and given for various applications like multimedia, e-commerce, medical, agriculture, etc. Managing of that image dataset, for finding, scanning, describing and diving is the tedious task. Managing that large dataset manually may create difficulties like mishandling and wastage of time. In June 2011, Google included the search by image feature as an application to image retrieval [1]. Before that it was search by text method which includes searching of images by its name but as the annotation of every image is difficult task and it varies from ones to others perspective so, the Content Based Image Retrieval (CBIR) invented in 1990s which make use of the low-level description of images like shape, texture, color [2,3] and now a days with deep learning model high level features [4,5] utilized to improve the retrieval result.

From Fig. 1 and 2, it proved that if the image rotated by 90-degree and given as query image, Google can't retrieve similar correct similar images. Google treating image of building as horizontal cylindrical rods and providing images as per this prediction is incorrect. So, there is a need for geometrically transformed efficient image retrieval method. So, for summarizing, features used for image comparison in these current methods are not robust to rotation and scaling factor.

In this paper, we proposed a technique of image retrieval with deep learning which is robust to rotation and scaling by introducing rotated and scaled images in training dataset. And for extracting high-level features from images ResNet18 model utilized whereas for classification VGG19 used.

The remaining part of paper arranged as mentioned: Section II describes the similar work on this research work. Section III provides information related to VGG19 and ResNet18 models used in proposed technique. The proposed RS invariant image retrieval technique explained in Section IV. The proposed method investigation results and discussion mentioned in Section V. The article concluded with conclusion in Section VI.

## II. SIMILAR WORK

The heart of CBIR is representation of image with its features. In that manner the feature extraction process plays vital role in image retrieval. Low level features were considered at the beginning of CBIR system, viz., color, texture, shape, etc. Out of which color is the most prominent feature which will be considered as invariant to scale and rotation. Many researchers already worked on that feature and came up with different techniques as mentioned in [14]. The combination of features like texture and color provided in paper [18] further improved the performance of image retrieval by developing method called RSHD. In [6][7] author collected color and texture features from images with color histogram and Gabor filter algorithm and selected only prominent features for retrieving similar images to reduce the computational complexity. In [8] color and texture feature called CCM and DBPSP respectively and third feature called based on color histogram called CHKM used for image retrieval. [12][13][14] [17] describes the use DCD features in various means to improve accuracy of image retrieval. Use of curvelet features also provided improvement in accuracy of image retrieval as referenced in [15][16][17]. Wavelet features applied in image retrieval as reflected in [9][10][11][17]. Deep Learning technique evolved in 1943 in the form of computer model developed by Walter Pitts and Warren McCulloch using neural networks derived from the human brain. But the deep learning usage started in real manner after the invention of high-speed computer and GPUs to fulfill the memory requirement of deep learning models. In [4][5] deep learning model provided state-of-the-art result in case of image recognition for large image dataset containing approximately 2.5 million images. So, there is a scope of research in this field of deep learning to further improve image retrieval performance by considering rotation and scale invariant features.

## III. DEEP LEARNING MODELS

There are various deep learning models invented out of which CNN prominently used for image related applications. Using CNN models various algorithms developed out of that we choose ResNet18 and VGG19 by comparing performance related to computational complexity and accuracy.

### A. ResNet18

ResNet-18 is an 18-layer deep convolutional neural community. The community can classify snap shots into 1001 kind of item categories, consisting of keyboards, mice, pencils, and a number of animals. As a result, the community has found out a number of wealthy characteristic representations for a number of images. The community's image enter length is 224 × 224 pixels. We can do the modifications in network by transfer learning as per our requirement.

ResNet18 model is used to create bag of features in our proposed technique due to its advantageous properties.

- Networks with a large number of layers (even thousands) may be easily taught without raising the training error rate.

- ResNets can aid with identity mapping to solve the vanishing gradient problem.

Fig. 3 describes the working of ResNet18 model. The output of a specific layer is linearized and used as a feature vector given the network. We experiment with two alternative layers of the network: the output of the average pooling layer and the linearized output of the fifth convolutional stage (that is conv5x) (that is average pool). The size of the feature vector for the conv5x layer is 25,088 (77512), and for the average pool layer, it is 512. Since the feature vector's size influences computation costs, dimensionality reduction techniques like Principal Component Analysis are used to lower the feature vector's size.

| Layer Name | Output Size | ResNet-18 |
|---|---|---|
| conv1 | $112 \times 112 \times 64$ | $7 \times 7$, 64, stride 2 |
| conv2_x | $56 \times 56 \times 64$ | $3 \times 3$ max pool, stride 2 <br> $\begin{bmatrix} 3 \times 3, 64 \\ 3 \times 3, 64 \end{bmatrix} \times 2$ |
| conv3_x | $28 \times 28 \times 128$ | $\begin{bmatrix} 3 \times 3, 128 \\ 3 \times 3, 128 \end{bmatrix} \times 2$ |
| conv4_x | $14 \times 14 \times 256$ | $\begin{bmatrix} 3 \times 3, 256 \\ 3 \times 3, 256 \end{bmatrix} \times 2$ |
| conv5_x | $7 \times 7 \times 512$ | $\begin{bmatrix} 3 \times 3, 512 \\ 3 \times 3, 512 \end{bmatrix} \times 2$ |
| average pool | $1 \times 1 \times 512$ | $7 \times 7$ average pool |
| fully connected | 1000 | $512 \times 1000$ fully connections |
| softmax | 1000 | |

Fig. 3. ResNet18 Architecture [19].

### B. VGG19

This network shown in Fig. 4, received a fixed size RGB image (224 * 224) as input, indicating that the matrix has shape (224,224,3). The only pre-processing is to subtract the average RGB value of each pixel, which was calculated throughout the training set. They used kernel with size (3*3) and step size of 1 pixel to cover the whole concept of image. To maintain the spatial resolution of the image, spatial padding was applied on 2*2 pixel window. Then, the adjusted linear unit (ReLu) is used to introduce nonlinearity into the model to improve classification and save processing time (previous models used tanh or sigmoid). Three fully connected layers have been implemented, the first two having size 4096, followed by a 1000 channel layer for 1000 line ILSVRC classifier and finally a softmax function.

Fig. 4. VGG19 Architecture [20].

## IV. RS INVARIANT IMAGE RETRIEVAL SYSTEM

To make the system Rotation and scale (RS) invariant we trained the VGG19 model of classification with images containing rotated images with 45-degree and 90-degree and scaled images with scaling factor 0.4 and 0.6. So, the Corel-1k original dataset which consist of 10 classes and in each class 100 images now transformed to 5k dataset as each image in 1k dataset is rotated with 45-degree, 90-degree and scaled with scaling factor 0.4 and 0.6. In that way 1 image in 1k dataset will have another 4 images. Fig. 5 illustrates the detailed working model of proposed system. Firstly, the dataset divided into training and testing parts. Then training dataset trained with ResNet18 model and features of that dataset collected from pooling layer 5 of this model. Then these collected features acts as the input to the VGG19 model and used for classification of query images to find the class of given query image.

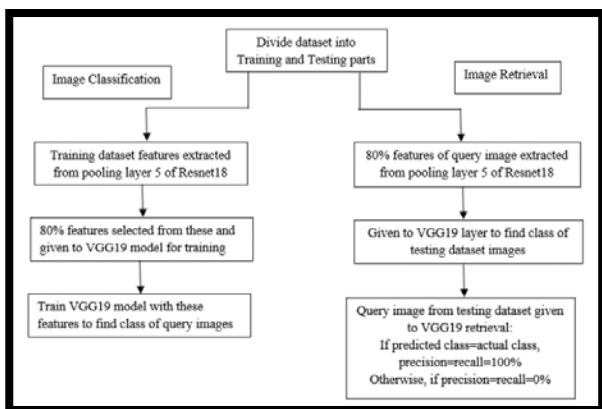

Fig. 5. The Proposed RS Invariant Image Retrieval System.

In the image retrieval part, 80% features of query image extracted from pooling layer 5 of ResNet18 model and given to VGG19 model to find class of query image. Then after classification for output class top 12 images will be retrieved at the output. If predicted class is same as actual class of query image then precision and recall parameter values will be 100% but if predicted class is wrong then precision and recall values goes down to 0%.

## V. EXPERIMENTAL STRUCTURE AND RESULTS

To visualize the practicality of our proposed system analyzed using datasets corel-1k, corel-1k scale and rotate dataset with 45-degree and 90-degree rotated and scaled images including images with scaling factor 0.4 and 0.6, Corel-1k rotated dataset which includes images rotated with angle 0-degree, 90-degree, 180-degree and 270-degree as well as Corel-1k scaled dataset which consists of images scaled with factor 0.5, 0.75, 1, 1.25, and 1.5.

Table I describes the dataset with their categories, classes, total images and total images per class in detail. VGG19 model trained for classification of images in dataset. The dataset divided into training and testing dataset as 70% and 30% respectively. The classification accuracy for every dataset is given in Table II. The classification accuracy is for all dataset is more than 96% which is providing better results for image retrieval.

TABLE I. DETAILS OF DATASET USED

| Name of dataset | Description | Classes | Total images | Images per class |
|---|---|---|---|---|
| Corel-1k | Original dataset | 10 | 1000 | 100 |
| Corel-1k Scale | Scaled by factor 0.5, 0.75, 1, 1.25, 1.5 | 10 | 5000 | 500 |
| Corel-1k rotate | Rotated by degree- 0, 90, 180, 270 | 10 | 4000 | 400 |
| Corel -1k scale & rotate | Scaled by factor 0.4, 0.6 and rotated by angle 45 & 90 | 10 | 5000 | 500 |

TABLE II. CLASSIFICATION ACCURACY OF SELECTED DATASET

| Dataset | No. of Training Images | No. of Testing Images | Classification accuracy (%) |
|---|---|---|---|
| Corel-1k | 700 | 300 | 97 |
| Corel-1k Scale | 3500 | 1500 | 98.3 |
| Corel-1k rotate | 2800 | 1200 | 96.8 |
| Corel -1k scale & rotate | 3500 | 1500 | 96.5 |

Fig. 6 implies the confusion matrix for Corel-1k scale dataset. After analysing this, our model gives 100% classification accuracy for 5 classes bus, dinosaurs, elephant, food and horse whereas minimum accuracy for class building in which out of 150 testing images, 140 classified correctly but 5 classified as African people and 5 as beach due to the features extracted from images.

Correctly classified and retrieved images for query image from Corel-1k rotate dataset and classAfrican People illustrated in Fig. 7. Fig. 8 shows the evidence of wrong classification of query image which actually belongs to African people category classified under elephant category and resulting in 0% precision and recall values.

Fig. 9 and 10 demonstrate the analysis of proposed technique in the form of precision and recall for all query images from dataset Corel-1k, which is highest in all the previous CBIR methods. For the proposed technique the precision values lies between 99% and 100%, whereas recall values lies between 19% and 20% (the maximum value of recall is 20% as retrieving top 20 images).

Fig. 8. Wrongly Classified & Retrieved Image of Category 'African People' from Corel-1k Scale & Rotate Dataset.

Fig. 9. Comparison of Proposed Technique % Precision with Previous Techniques using Corel-1k Dataset.

Fig. 10. Comparison of Proposed Technique % Recall with Previous Techniques using Corel-1k Dataset.

Fig. 11. Comparison of Proposed Technique % Precision with Previous Techniques using Corel-1k scale Dataset.

Fig. 12. Comparison of Proposed Technique % Recall with Previous Techniques using Corel-1k scale Dataset.

In case of Corel-1k scale dataset comparison for parameters precision and recall with previous techniques proves our system as scale invariant image retrieval as illustrated in Fig. 11 and 12. Fig. 13 shows the performance of proposed system for various datasets. The system gives best result for Corel-1k scale dataset which shows robustness of system for scale invariance. Average retrieval time for proposed system calculated by randomly considering 100 query images and averaging their retrieval time and plotted in Fig. 14 which shows that the retrieval time is less for proposed system except retrieval time of system mentioned in [18].

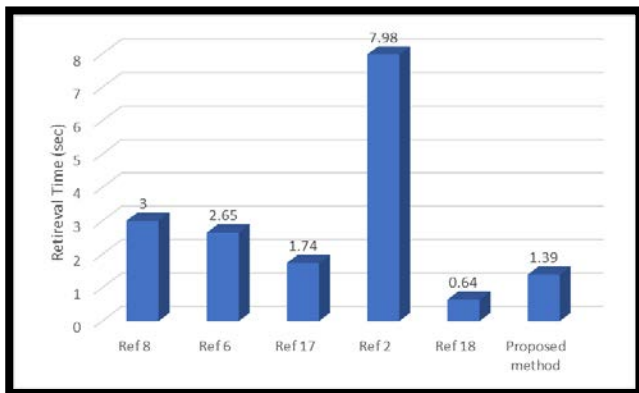

Fig. 14. Average Retrieval Time of Image Retrieval Systems.

## VI. CONCLUSION

We present a deep learning-based feature extraction, classification, and retrieval approach that is resistant to scale and rotation fluctuations in this paper. The most important 80% of collected features are chosen, reducing the computational complexity of the classification and retrieval procedure. In comparison to existing state-of-the-art systems, the experimental findings demonstrated that the suggested CBIR system had the highest precision and recall rate for all datasets, including rotated and scaled images. In addition, compared to previous approaches, there is a lower demand for average retrieval time. Because it has to display the images at output from a selected class rather than the entire database, the classification procedure before retrieval reduces image retrieval time. When the query image is correctly classified, retrieval accuracy is 100 percent.
